TEXTILE TO VASCULAR SYSTEM

TEXTILE PRINTING, the process by which a decorative pattern is applied to a woven or knitted fabric in at least one colour different from the body of the fabric itself. This mode of decoration differs from the formation of a pattern by weaving and knitting processes that employ threads that are already coloured or have different capacities for taking up dyes. The four main methods of textile printing are block printing, copperplate printing, roller printing and screen printing.

EARLY METHODS

Block Printing. — The origin of block printing on textiles is somewhat obscure but it is clear that the printing of textiles by means of blocks was developed from free-hand painting with a brush. Wooden blocks believed to have been used for textile printing have been found in burying grounds at Akhmim, upper Egypt, and are said to date from the 4th century A.D. No textiles printed by means of these blocks have, however, been found. In Europe block printing of fabrics does not appear'to have begun much before the end of the 12th century A.D.; the chief centre appears to have been the Rhineland of Germany.

In blocks used for printing, the spaces between the lines or devices forming the pattern were cut away, leaving the design standing in relief, as in letterpress printing. The colour was then applied to the surface of the block and the coloured block pressed down on the cloth. An interesting description of early block printing on textiles is given in *The Book of the Arts or Treatise on Painting* by Cennino Cennini. a document that dates from the end of the 14th century. According to Cennini, the thickened colour was applied to the block by means of a glove, probably made of leather. The pigments were mixed with starch, gum (tragacanth) or a mixture of these, or even with varnish, so that the colour was in a viscous state and did not run from the raised portions of the block. Cennini describes how the outlines of the patterns were printed by block and additional colours added by means of a brush. Later the colour was applied by a pad, either directly or by pressing the block down on a pad impregnated with colour. Wax resists were also printed by metal or wood blocks for indigo-resist dyeing. This method was used in Egypt in the 9th–10th century A.D. and in Germany in the 17th century. Apart from these indigo-resist dyed textiles. until the end of the 17th century all European block-printed textiles were printed with surface pigments or oil stains that were fugitive (not fast to washing). About 1676, however, more or less simultaneously in England. Holland and France, the European textile printers mastered the secrets of the complex problems of mordant dyeing with madder — the basis of the fast-dyed, hand-painted Indian chintzes that had begun to be imported into Europe during the early 17th century. Thereafter, most European block-printed textiles were produced in what was known as the "madder style."

One of the clearest expositions of block printing in the "madder style" is given in the supplement to John Barrow's *New and Universal Dictionary of Arts and Sciences* (1754). The cotton or linen was printed with chemical substances known as mordants, which on immersion in the vat reacted with the soluble dye to precipitate an insoluble colouring on the cloth fibres so that the colour remained permanently fixed in the mordant-printed areas while the dye taken up by the unmordanted parts could be easily removed by washing. In madder dyeing different mordants can produce various shades of reds, pinks. purples and browns from a single immersion in the dye. The different mordants were printed one by one; the printer moved along the whole length of the cloth printing the first mordant from one wood block, then the second mordant from another block, and so on, until the whole pattern was completed. The mordant-printed cloth was then immersed in the dye. The reds, browns and purples were produced by printing varying strengths of alum and iron mordants, followed by immersion in the madder dye. Yellows and drabs (light brownish colours) uere produced by the printing of similar mordants followed by dyeing with weld, also known as dyer's weed. Blue was produced by "penciling-in" indigo with a brush. This operation was usually carried out by women or girls. All greens were produced by the penciling-in of indigo over yellow. To save expense, the yellows were often blocked or painted in to avoid an additional dyeing but with this method the yellow dye was fugitive and in many extant 18th-century textiles the yellow has almost entirely disappeared.

The standard method of printing madder mordants by wood block involved the use of a "tub" and a "sieve." In England the tub consisted of a sawed-off barrel but on the European continent

a specially constructed square tub was more usual. The tub was filled with a viscous paste, called the "swimmings," made from discarded colour and gum; the paste provided a sort of elastic cushion on which rested the sieve, a wooden drum only fractionally smaller than the tub The bottom of the sieve was a sheepskin the upper surface a tightly stretched fine woolen cloth An assistant. known as "tireur" or "tearer," kept the upper surface of the sieve constantly and evenly supplied with the thickened mordant, which was spread on with a large brush. When the printer pressed his block on the sieve. the swimmings in the tub provided just enough "give" to ensure a satisfactory colouring-up of the block The cloth to be printed was supported on a stone concrete or iron structure covered with a thick blanket; this arrangement provided a firm but resilient surface so that the raised surface of the block contacted the cloth with uniform pressure over the whole area Between the blanket and the cloth was a layer of unbleached calico (the back gray) that absorbed the mordant forced through the cloth When the block was placed on the cloth the printer pave it one or two sharp blows with his mallet or maul to impress the mordant firmly into the cloth Pins known as pitch pins were inserted into each corner of the block as a guide to the printer in matching the repeats. The blocks were generally made of layers of strong durable woods, such as pear wood. arranged so that the grain in each layer ran at right angles to that in the layers above and below: this arrangement prevented warping during the successive wetting and drying. For fine details. such as thin stems and the outlines of flowers or leaves, strips of metal or metal pins were inserted into the wood blocks. Elaborate "pin grounds," also called "picoté" or "sable" grounds, were achieved by inserting metal pins into the block.

A method of mechanical block printing was invented in 1834 by a French mechanic called M. Perrot. This machine, known as the perrotine after its inventor, employed ordinary wood blocks and was widely used in the 19th century. particularly in France, for printing up to four colours. Each block of the design is impressed simultaneously in the cloth at a distance of two repeats apart. The cloth is stepped through the machine, one repeat at a time, to emerge with the full numbers of colours printed upon it. Although the original machine needed five men to tend it, one machine could print as much cloth as 24 printers and 24 assistants using hand methods. By 1836 about 60 perrotines were in operation in Europe; and even in the early 1960s when, in spite of the expense of the process, block printing continued to be used for certain classes of goods. the perrotine was not quite obsolete.

Copperplate Printing.— Copperplate printing on textiles was invented by Francis Nixon at the Drumcondra printworks near Dublin in 1752. Although prior to 1752 maps and embroidery designs had been printed from engraved copperplates with ordinary printer's inks, it was not until Nixon's invention that it was possible to print textile designs in fast colours by printing the cloth with thickened mordants. The designs were printed from a single engraved copperplate. usually with a repeat of about three feet square. in red. purple or sepia. using the madder dye; or in blue, using indigo. by a method known in England and the United States as "china-blue" and on the continent of Europe as "bleu d'Angleterre." This method inv ved p inting th indigo on th cloth in an undissolved stat and arranging f it simultaneous reduction and solution on th cloth after p t This was done by im- g the printed cloth in a bath of lime (to dissolve the indigo) and a bath f ferrous sulfate (t reduce it) as many times as was necessary t achieve t desired strength of blue.

Copperplate printing was eminently suited for the production f large torial designs and a fineness of detail and li acy f drawing not possib with the c ar tively coarse technique of wood-block cutting. It was also d for floral , both for furnishing an ess, ar for the printing of handkerchiefs.

The textile printer's copperplate press was little different f t he y, flat-bed, rolling press used for the ti g of engravings on paper. The plate was first inked up with the th ke d mordant and then was passed through the rollers in contact with the cloth being printed. Various improvements. however. were introduced by the textile printers to make the press more suitable for their purposes. An important innovation was the "D" roller, patented by Robert Kirkwood of Edinburgh in 1803. which overcame the difficulty of getting the plate through the rollers to its original position without winding the cloth back at the same time. Kirkwood's invention consisted of substituting for the lower roller a special roller shaved flat on one side (hence the name "D"). On the forward passage of the plate. the round part of the roller squeezed the plate up against the cloth for printing in the normal way; but on the reverse passage the roller rested with its flattened surface uppermost, thus allowing the plate to go through without touching the cloth.

With the introduction of roller printing copperplate printing began to die out. although it continued in use, particularly for the production of printed handkerchiefs. well into the 19th century.

Roller Printing.— The first commercially successful patent for a roller-printing machine was taken out in 1783 by Thomas Bell, a Scotsman. So fundamental was Bell's invention that the principle of his machine has been retained throughout the numerous improvements and refinements introduced since that date Before 1783 several attempts had been made to replace hand printing by mechanical means but none of them had been commercially successful. As early as 1743 W. Keen and M Platt had taken out a patent for a three-colour roller-printing machine but it does not appear to have been developed. In France a textile printer named J. A. Bonvallet introduced a primitive type of roller-printing machine at his factory in Amiens about 1775. It consisted of two rollers; the upper one was made of wood, the lower one of hollow iron covered with a copper mantle on which the pattern was engraved. The lower roller was filled with red-hot iron or burning coals and revolved in a dye bath. The cloth was passed over the upper, wooden roller and the lower roller pressed up against it by means of weights, levers and a cog wheel. The machine was operated by hand. Bell's original specification (patent no. 1378, 1783) describes his invention as "a new and peculiar art or method of printing with one colour or various colours at the same time, on linnens, lawns, and cambricks, cottons, callicoes, and muslin, woollen cloth, silks, silk and stuffs, and any other species or kind of linnen cloth or manufactured goods whatever."

A second patent taken out by Bell (no. 1443. 1783) contains a similar specification for printing "one, two, three, four or five, or more colours," and by the following year he was able to put the machine into practical operation with the firm of Livesey, Hargreaves and Co near Preston, Lancashire. Strangely enough, however. the indiscriminate use of the new machines contributed to the collapse of the firm in 1788. Bell's machine for rotary printing from engraved metal rollers was fitted with a "doctor," or steel blade, designed to remove the surface colour from the printing rollers while allowing the recessed, engraved parts to retain enough colour to print a continuous length of fabric. The machine was said to be capable of doing the work of about 40 hand printers. Although the machine was theoretically capable of printing five or six colours at a time, mechanical and chemical difficulties that existed as late as 1840 made it difficult to print more than two or three colours simultaneously. At first the new roller-printing machines were used mainly for small-scale dress prints, and it was not until the early 19th century that large-scale furnishing patterns were produced by machine. Many of the furnishing fabrics of the 1820s were produced from a single, stipple-engraved metal roller, with additional colours being printed by wood blocks or surface rollers. With James Burton's and Adam Parkinson's union-machine (1805) it was possible to print simultaneously with engraved metal and wood surface rollers. (See also TEXTILES: Printed Textiles.) (B. J. Mo.)

MODERN INDUSTRIAL PROCESSES

General. — Textile printing on an industrial scale consists of two fundamental operations: (1) the impression, *i.e.*, the mechanical and physical stages in which the colouring matters are distributed on the cloth; and (2) the coloration, *i.e.*, the choice of the appropriate colouring matters (dyes, dye-generating chemicals, pigments and the necessary auxiliary chemicals), the conditions for their application, their preparation in suitable forms for presentation to the cloth and their fixation against removal during use and wear.

Textile printing in some of its aspects differs greatly from the corresponding methods for printing on paper and other materials, although the mechanical methods for bringing the colour to the surface may be similar. Inks and paints used for printing on paper usually contain colouring matter in the form of pigments (*i.e.*, finely divided solid powders insoluble in the medium by which they are applied) ; such pigments are attached by adhesive media to the surface to be coloured; they cannot penetrate between the molecules of the fibres. In much textile printing, however. the various coloured areas that make up the print are, in fact, dyed. The dye is dissolved, usually in water alone or in aqueous solutions containing other reagents, and the molecules thus separated can be induced to enter between the molecules of the fibre in a much more intimate association. In general, a textile print in which the coloured areas are dyed in this way may be found to be faster to washing and similar treatments than a print resulting from the use of pigment in an adhesive. The presence of adhesive may also tend to stiffen the fabric. Improvements in adhesives, though, have made it possible to obtain reasonable fastness and softness and to obtain prints of great brilliance.

Cloth. either woven or knitted, may first be singed to burn off surface fibres, desized to remove weaving sizes. scoured to take away natural impurities and the soils of manufacture, bleached to destroy residual colouring matters, impregnated with solutions of dyes or other necessary chemicals by padding, dried and. occasionally, given extra smoothness by passage through a calender. Drying may be brought about by passing the cloth over steam-heated cylinders or by running it through a stenter. The latter operation fixes the width, ensures that warp and weft are at the correct angle and renders the selvedges straight and parallel. The cloth is wound under even tension on wooden shells to give cylindrical batches.

The pattern is impressed by hand blocks, stencils, silk screens or engraved or relief rollers. Drying is done in a hot flue or by steam-heated plates or cylinders. The cloth is then passed through a chamber (steamer, ager or flash ager) filled with steam. During the passage a limited amount oi water condenses on the print, the dye is redissolved without being spread and the fibre swells The dye molecules are thus enabled to penetrate into the fibre substance so that they can become fixed there. The high temperature of the steam also initiates or speeds up reactions by which some dyes are turned into soluble forms, are actually produced in situ from intermediates or are fixed more firmly within the fibre. Steaming for short periods is called aging or, for very short periods, flash aging. Volatile acids can be introduced into the steam (acid steaming or acid aging) if this is required. Dyes that are themselves volatile can be fixed in man-made fibres—Terylene (Dacron), Orlon, etc.—by dry heat. The adhesive medium in some pigment printing is also set by dry heat. (See also COTTON MANUFACTURE: Converting of Cotton Goods.)

Before and after (and sometimes instead of) steaming. the printed cloth may be passed through certain solutions. *e.g.*, of chromates, to fix the dye. Unfixed colour may be removed by washing or soaping. This minimizes the tendency to bleed off on other cloth during wet treatments and to rub off when dry.

Impression.—This is the essential part of the printing operation. With several exceptions, dyes, dye-generating substances and auxiliary chemicals are dissolved or suspended in water. When applied to a fixed area of a microporous structure like cloth the solutions would spread by capillary attraction (flush) beyond the boundaries of the pattern and so give prints of unsatisfactory definition. The viscosity of the solutions is therefore increased by the addition of thickening agents. These are usually substances of high molecular weight that yield colloid dispersions in water. They include the natural starches, starches that have been altered by regulated depolymerization (for example, by the action of heat or acids to furnish dextrins), chemical derivatives of starch and cellulose, and natural vegetable gums such as gum tragacanth and gum arabic. locust-bean gum, etc. There are other vegetable mucilages, such as sodium alginate (sodium polymannuronate) from seaweed, as well as egg and blood albumin and various synthetic resin products. A more recently developed form of viscous medium is a stabilized emulsion between water and another non-miscible liquid (emulsion thickener). It is possible sometimes to use colloid aqueous dispersions of the mineral bentonite.

The thickening agent for a given printing paste is chosen for its specific thickening power, its compatibility with the dyes to be used, its freedom from interference by the other chemicals that have to be added, its stability and its general flow properties. The flow property of the entire paste is adjusted to the printing method, the shapes of the impressions to be made, the intensity of colour required, the weight and structure of the cloth, the fixation methods to be employed, and the severity of treatment that can be allowed in order to remove the exhausted paste from the print after the dyes on it have been fixed. Many dispersions of thickening agents are thixotropic; *i.e.*, they become more fluid when they are subjected to the stresses that they receive in the printing operation. and this property has an important bearing upon the quality of the impression.

Block Printing. — This, the oldest method of textile printing, is also discussed above under Early Methods. The blocks normally consist of wood with the design carved to stand above the block surface. Alternatively, or in conjunction with these projections (pegs), fine details such as different shaped dots are provided by short lengths of copper wire (pins) of various cross section partly driven into the wood. Lines are provided by shaped copper strip (fillet) driven edgewise into the wood. Large areas of uniform colour known as blotches are produced by filling in an enclosed area with wool felt, which thus gives an extended printing surface. Areas corresponding in size to those produced respectively by pins, pegs or blotches in block printing are given the same name in screen or roller printing. Where the form of the design is suitable, where prolonged use of the block is anticipated or where a number of block sets of the same design are required, the relief printing surface may be cast in type metal. In most cases every distinct colour must be applied as a separate paste from a separate block. Further. since blocks have to be handled during the printing operation, those that are too heavy to be lifted easily are inconvenient; if the repeat of the pattern is large, more than one block may be needed for a single colour, and to print big, detailed and florid patterns the number of separate blocks may exceed 100. Block prints are thus laborious and expensive to produce but they are prized for their full, deep colourings and for the deviation from the exact design, which shows them to be "handmade." Since printing costs per yard are high, expensive cloths (*e.g.*, heavy linens for upholstery and pure silks for dress goods) are generally chosen for block printing. Designs tend to be traditional and may be "kept on the table" for many years.

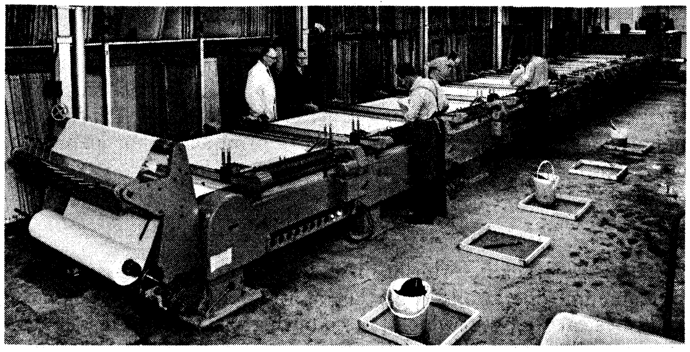
The perrotine is still used occasionally while in some firms the surface, or peg. printing machine, the forerunner of the roller printing machine (see below), is in continuous use. In this machine the circumference of one roller carries an exact number of the repeats of the pattern: a second roller guides the blanket. the back gray (back cloth) and the cloth itself and acts as the printing surface. The pegs of the patterned roller run in contact with the printing roller and are furnished by touching, at another part of the periphery, an endless band spread with paste. As with all cylinder machines, printing is continuous but the length of the repeat that can be printed is limited since the diameter of the printing cylinders cannot be increased indefinitely.

Stencil and Screen Printing.—The stencil printing method uses stencils made from paper impregnated with wax or from thin sheets of ductile metal. The method has been known for centuries but in modern times it has been employed only to a limited extent; some stencil printing is carried out with lacquers on nets and gauzes to give beadlike effects. The stencil may be cut from zinc foil and mounted on a frame that is laid over the fabric; the colour medium is applied through the stencil with air-spray, brush or squeegee.

Silk screen printing (*q.v.*) is the most commonly used form of what is essentially stencil printing. Fine, open-mesh gauges woven from yarns made of silk or nylon, or from fine bronze wires, are stretched with even tension upon rectangular frames of wood or light metal. The printing areas on the gauze are left open, the rest being blocked up with a lacquer. The design can be hand-painted on the screen directly with lacquer but this procedure is slow, especially for large areas, and a photographic method usually is used. The repeat is drawn in black and white on transparent film and this serves as a negative from which a number of positives are made by the ordinary procedures of exposure and development. The positives are pieced together to make up the printing area desired in the final screen, and from the composite a full negative is made on photographic film. The screen itself is coated with a solution of gelatin to which a soluble dichromate (bichromate) has been added and is dried in the dark. It is then exposed to light behind the composite negative, and the part of the gelatin that is exposed to light becomes insoluble in water. When the negative is removed the gelatin on the unexposed areas is washed away with warm water and the deposits are reinforced by coating them with a layer of lacquer. When the lacquer is dry, the screen is ready for use. As in the other printing methods, one screen is prepared for each colour in the pattern.

Screen printing by hand is carried out on tables wide and long enough to accommodate the cloth to be treated. The tables are covered with a resilient blanket on top of which is a smooth impervious fabric. A length of the cloth is rolled off to occupy the full length of the table and is fixed to the impervious cover with starch paste or other adhesive. The screen to be printed is laid on the cloth at one end of the table, gauze side downward, with the frame therefore forming the sides of a shallow trough. Printing paste is poured into the trough and driven through the open areas with a squeegee, which is a stout strip of wood with a firm lip of rubber along the lower edge. The longest side of the screen is usually placed across the cloth (weftwise), and the line in which the squeegee is moved is parallel with the shorter side. Two operatives do the printing, one at either side of the table, passing the squeegee from one to the other in the middle of the stroke. When one impression has been made with the screen, it is lifted and laid down on the next repeat and so on until all the cloth on the table has been printed with one colour. Then the operation is repeated, using another screen and another colour, until the full design is printed. Correct positioning of screens along the length and width of the cloth is obtained by projections on the screen frame that are made to engage with stops correctly adjusted on a metal bar (pitch rail) on one of the long sides of the table. After one table-length of cloth has been fully printed it is pulled from the table and succeeding lengths of the roll are printed by the same procedure.

Screen printing is never as swift as roller printing but the preparation of screens is easier, speedier and cheaper than the engraving of a set of copper rollers. The skill required is not nearly so great as that needed to operate a roller printing machine. While a roller printing machine can best interpret designs in which sharp definition is needed. the screen method may give superior results more easily when full colouring and a full gradation of shading is needed. There are distinctions connected with the nature of the design; *e.g.*, it is easier to get plain longitudinal stripes by roller printing and lateral stripes by the screen method. The screen method is better adapted for the classes of commercial printing in which short runs and quick changes of design are called for.



BY COURTESY OF THE COTTON BOARD

FIG. 2.— TWELVE-COLOUR AUTOMATIC SCREEN-PRINTING MACHINE

Many machines have been introduced to mechanize the screen printing operation. Some imitate mechanically the operations of hand printing. In others, continuous working may be achieved by supporting the screens on rollers whose faces are perforated so that the screens can be furnished from inside; such machines approach the action of the roller printing machine.

Roller Printing.—This is the method by which the greatest percentage of cloth is printed. In general it is faster than other methods and produces a more accurate impression. The printing area is engraved in recess (intaglio) on a smooth copper roller. This is coated with the colour paste and then the unengraved surface is scraped clean with a steel blade (doctor), leaving the engraving filled. The roller then comes into contact with the cloth carried on a supporting roller and transfers the paste in the engraving to it. The number of engraved rollers employed depends upon the number of colours required in the design and may be from one to fourteen. With the exception of a few of continental origin, modern roller printing machines do not differ fundamentally from the one invented by Thomas Bell in 1783 (see fig. 3 and 4).

The engraved copper rollers, or shells, each rotate on a steel mandrel to which they are keyed by a tongue and groove arrangement. The drive is transmitted from one large crown wheel, driven by an electric motor, to a box wheel at the end of each mandrel. Different prints need to be printed at different speeds according to the quality of the engraving and the paste used, and the structure and composition of the cloth itself. The printing machine should be able to run at very slow speeds (inching) at the beginning of a printing in order that final adjustments in the fit of the different coloured impressions can be made before a substantial yardage of cloth has been printed.

The shells themselves are usually made of high-quality copper, but where a long life is called for, and especially where the paste contains hard, solid particles (*e.g.,* pigments and crystals), the surface may be chromium plated. The appropriate part of the total pattern is engraved on each shell by direct manual engraving, by milling or by acid etching, including various adaptations of the photogravure process (see GRAVURE). When another pattern is desired, a new series of shells is fitted on the mandrels.

The central cylinder, or printing roller, is made of cast iron; the larger the number of colours printed, the greater the diameter of the cylinder. It is wrapped with several layers of springy cloth (lapping) to impart resilience. The back gray and the cloth to be printed are carried through the rollers at a steady tension on an endless printer's blanket, which may be made of felt with a smooth resilient surface or made of cloth coated with rubber or a plastic substance. If it is rubberized it will be washed after the impression with water sprays or rotary cylindrical brushes to remove adhering paste, and dried by being passed through hot air or over steam-heated cylinders or by being dusted with talc before being passed forward again to support more cloth. Modern blankets, which are covered with compositions designed to resist wear and chemical attack and are embossed with fine lines, can be used without the back gray for some designs; the depressions hold the small amounts of paste pushed through the cloth and in addition increase the grip between cloth and blanket; such blankets exhibit better springiness than do the older forms.

The cleaning doctor consists of a straight strip of steel fixed in a pivoted clamp or shears, with an edge pressing at an angle against the surface of the shell. It removes the paste from the unengraved portions of the shell surface. The pressure of contact is obtained by weights that act on the shears through a lever. The adjustment of the doctor is one of the most exacting tasks of the printer since the variety of blade and the angle and pressure of contact have to be adjusted to meet the particular quality of the engraving and other conditions of printing. The edge is sharpened so that it is accurately linear, and, although it may receive an initial mechanical grinding. it always has to be finished by hand. Special adjustments (springing) of the steel strip in the shears are required to overcome bowing when wide cloths are printed.

As the shell rotates it is supplied with printing paste by a lapped or coated roller (the furnisher) that rotates in contact with the shell and also runs partly immersed in paste contained in a colour box. As the shell moves round it is cleaned by the doctor and then makes contact with the cloth. Before it completes a revolution. it passes under the edge of a second, or lint, doctor that is similar to the cleaning doctor but is made of a softer metal. Here the smooth portion of the copper is freed from lint and from printing paste of other colours transferred by the cloth from an earlier shell. This operation prevents paste of one colour from passing into the boxes of subsequent colours and falsifying the shade and removes solid impurities that might otherwise wedge between the edge of the cleaning doctor and the copper surface, letting through unwanted colour and giving rise to lines and smears in the print. Furnishing is sometimes effected with a stiff cylindrical brush instead of a roller. The brush is often rotated at a different surface speed from that of the shell; the brushing action prevents permanent clogging of the engraving.

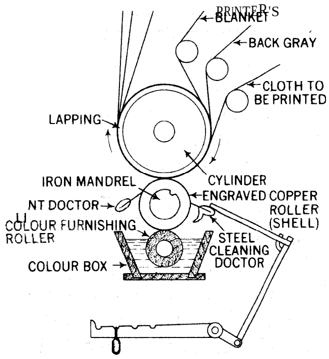


FIG. 3.—WORKING PARTS OF A ONE-COLOUR TEXTILE PRINTING MACHINE

In multicolour printing, the units, each consisting of a shell printing a single colour with its own doctors and furnishing arrangement, are fixed at intervals round the lower part of the periphery of the central cylinder, which is horizontally disposed. As the cloth passes around the cylinder, it is impressed in succession with the different colour components. Careful fitting is needed as each impression must fall accurately upon the appropriate area within the complete pattern; inconspicuous pitch marks are engraved as a guide at the appropriate place on each shell of the set. Adjustments are made after the first few feet of cloth have been inched through the machine: to correct the fit across the width of the cloth the bearings of the mandrel are displaced sideways: adjustments at the box wheel can turn the mandrel slightly relative to the wheel itself and make the impression from one shell fall a little earlier or a little later within the repeat, so ensuring longitudinal fit. Some adjustment of this kind may also be needed while the pattern is being printed. since the cloth may stretch a little unevenly under tension. The diameters of all the shells are the same and all are driven at the same rotational speed. so that the surface printing speed of each shell is therefore also the same. An integral number of repeats of the pattern is engraved around the circumference of each shell so that these repeats are printed without change of spacing regardless of the length of the cloth. With the older box-wheel mechanisms. adjustments in the fit were made manually and the slowing up necessary to effect them sometimes led to changes in the stretch of the cloth. However, more elaborate mechanical and electrical types of box wheels have become available; these allow the shift for fitting to be accomplished while printing at full speed.

Not all the rollers on a machine may be engaged in impression. Sometimes perfectly smooth, unpatterned rollers furnished with a paste containing no dye may be interposed in the sequence of engraved rollers when impressions of greater colour area, or with more intense colours, are printed on the cloth in front of impressions of smaller area or paler colours. This counteracts the danger of contaminating the pastes in the colour boxes toward the end of a series when the action of the lint doctor may not be adequate. The starch roller receives any loose colour from the cloth on its smooth surface, goes around to be coated with plain paste and then has its surface scraped clean by the doctor. When a multicolour machine is used to print a design with fewer colours than its maximum capacity, the engraved rollers may be too few to pull the cloth. blanket and heavy cylinder by frictional contact in the usual way and in this case additional plain rollers are run on the machine for driving purposes.

Three important modifications of the roller printing machine are made to meet special requirements of pattern or quality of impression:

1. Surface printing machines have already been mentioned: they are used to give prints of blocklike quality. Since the printing is from rollers in relief, modifications of the furnishing arrangements are needed.

2. Duplex printing machines are in effect two separate single-sided machines incorporated in the same structure and printing simultaneously on both sides of the cloth with the pattern on the one side in perfect fit with that on the other. Less perfect double-sided effects can be produced with single-sided printing in a push-through operation where the structure of the cloth, the pressure of the roller and the consistency of the paste allow the colour to go right through the cloth and give a reasonable impression on the underside.

3. Jumping machines are used for large repeats that are surrounded by an unprinted border. The machine is provided with gearing that checks the printing operation at the necessary intervals while the cloth moves forward by a distance equal to twice the width of the crosswise border. This obviates shells of inconveniently large diameter.

Transfer of the Repeat to the Shell.—*Milling.*—Patterns with small simple motifs and uncomplicated repeats such as spots, stars. rings, stripes, etc., are engraved by mounting the polished shell in a lathe and rotating it against a hard-steel, wheel-shaped die with a number of the design units in relief; these units indent the copper surface.

Hand Engraving.—To a limited extent, rollers are hand engraved by conventional methods. More frequently, hand engraving is employed to perfect rollers engraved by other methods and to correct defects caused by wear. (See also ENGRAVING, LINE.)

Etching.—This is the method used most frequently for engraving rollers. The original cartoon from the designer is projected optically onto a zinc plate and the repeat is incised on the plate, each detail being then coloured up to match the cartoon. An operator then follows the lines corresponding to one of the component colours on this plate with a stylus that forms part of a machine called a pantograph (or, less correctly, a pentagraph). Mounted in the pantograph is a smooth copper shell, covered with a layer of protective varnish; the movements of the stylus rotate the roller and also actuate a series of diamond points spaced along the length of the roller. As a result. the desired number of repeats are scratched at intervals along and around the shell. The roller is then rotated in a bath of suitable acids that penetrate the scratches and etch the repeats into the copper. If the engraving is a deep one it is not desirable to etch it in one stage, so the roller is revarnished and the scratching and acid treatment are repeated. When one roller of the set has been made. another is inserted in the pantograph, the lines on the zinc corresponding to a different colour are followed, and so on until the whole set has been completed.

Photogravure *Methods.*—A number of acid etching methods have been developed that follow the methods used to produce photogravure rollers for magazine printing. They reduce the time required for engraving and are specially suited for certain pictorial subjects.

Scale.—For all shapes of appreciable area, simple engraving of a depression in the roller will not give satisfactory impressions since the paste that it contains after furnishing is not under adequate control and the printed area consequently will not be uniformly coloured. Such areas are therefore engraved as a series of parallel diagonal grooves. In printing, each line spreads laterally into the impression of its neighbour. The width and depth of the lines must be properly related to each other; these measurements are jointly specified in a number called the scale. In some engravings made by photogravure methods the impression is broken into dots by photographing the original image through a screen (rectangular disposition of lines), and the effect of the screen is the same as that used in photomechanical methods for printing pictures on paper.

Colourings.—A set of engraved rollers, blocks or screens can be used to produce a series of different and distinct decorative effects by (1) changing the combination of colours; (2) using only part of the set; (3) using the set in conjunction with rollers having small "all over" patterns that do not need fitting with the rest of the pattern and modify the ground or the blotches; (4) printing in conjunction with dyeing. Each modification of the use of the set of rollers in this fashion is called a "way."

There are also several more unusual methods for continuous printing. In one group of related methods. the colours are thickened until the printing medium is of the consistency of stiff dough. This is rolled out into sheets and cut into shapes that are mounted in mosaic fashion around the surface of a roller. This roller prints onto cloth damped with water or other solvent; the cloth is supported on another roller with a very resilient surface. The water or other solvent dissolves a small amount of the thickened colour, which is thus transferred to the cloth. Only a limited yardage can be printed with one roller because the roller coating is slowly consumed. The process has been used to produce beautiful and unusual prints that cannot be obtained in any other way; there is no limit to the number of colours that can be printed from the one roller. The usual difficulties of fitting are not present, since these have been dealt with in preparation of the roller itself, but there are restrictions in the kinds of dye that can be used.

In another unusual continuous method the design is first printed on paper with appropriate dyes in special media. It is transferred to the fabric by running the cloth and the paper through a heated calender together. Once the transfer has been obtained, the dyes used are fixed in the normal way.

Colouristic Features.—The choice of dyes and their adaptation for use in a given print depend upon a large variety of conditions, some chemical and some economic: the fibre or fibres from which the cloth is made, the colour requirements of the design to be reproduced and its durability in the expected conditions of use, the relation between the printed effectand later processes of manufacture (*e.g.*, finishing), the cost of production and the length of time before delivery. Most commercial printing is a compromise between the ideal interpretation of the design and the need to produce it at an acceptable price. The choice of dyes for a print, and to some extent the chemical and processing procedures used in their application and fixation, are known as styles.

The relations between the kind of fibre in the material to be printed and the dyes used are in general similar to those that are obtained in dyeing but the physical differences in printing and dyeing systems may greatly modify the conditions of application. Two important differences are: (1) the dye and chemical assistants used in printing have to be applied in a much smaller volume of medium and are therefore concentrated; (2) the stage of diffusion and fixation in printing must be made to occur after the impression and in the relatively short, well-defined period of steaming or chemical aftertreatment. For this reason the formulations of a dye bath and of a printing'paste containing the same dye may be very different.

The following groups of dyes are used in printing:

I. Direct cotton dyes, mainly for cellulose fibres; acid dyes for viscose. wool, silk. and nylon and certain other synthetics; basic dyes for wool, silk, cellulose esters; and disperse dyes for all hydrophobic fibres (those that swell very little in water).

II. Vat dyes. predominantly for cellulosic fibres but also (with special procedures) for other natural and synthetic fibres; insoluble azo dyes, mostly for cellulosic fibres, and often in special chemical forms to meet the special conditions of printing; phthalocyanine dyes, again for cellulosic fibres but again applicable in some chemical forms to other fibres.

III. Mordant dyes, in which the sequence of application of the dye, the mordant and the reagents that control the interaction of the two are specially chosen for printing conditions.

IV. Reactive dyes, which are mostly applicable to cellulosic fibres.

V. Pigment colours applied to the surface of the fibres and fixed with synthetic resin preparations so designed that. when fixed, they are not easily removed in washing and do not stiffen the fabric. They are applicable to a wide range of fibres. are simple to use, give full colorations and are particularly useful in screen printing.

A distinctive feature of much textile printing as compared with dyeing is that it is often necessary to use dyes from different classes to provide the different coloured areas in the same print and, for this reason. great ingenuity is needed in exploiting the chemical properties of individual dyes so that one fixation treatment, *e.g.*, steaming. is appropriate for all of them and so that the reagents used with one colour do not interfere with the other colours.

Two widely used styles that have no exact counterpart in dyeing are: (1) Discharge printing, in which the cloth is first evenly dyed before printing and then is printed with a paste that contains either an oxidizing or a reducing agent. Steaming causes the agent to destroy the dye on which it falls or to convert it to a soluble form so that it can be removed by washing. This therefore gives a white print on a coloured ground. An extension of this method is the use of the illuminated discharge in which a dye indifferent to the discharging agent is incorporated in the paste so that it takes the place of the ground dye that has been destroyed and gives a coloured print on a ground of a different colour. (2) Resist or reserve styles, in which the cloth is printed with a preparation (*e.g.*, wax or a synthetic resin) that protects the fibre from a dye solution, or with a reagent that chemically inhibits the fixation of a particular dye (*e.g.*, an acid for a dye that requires alkali for its fixation). The entire cloth is then dyed and the resisted areas remain undyed. As with discharge styles. the resist may be plain (white on a coloured ground) or coloured. A traditional example is the batik of Java and its analogue in west African styles. (H. A. T.)

TEXTILES are woven fabrics. The term also means all spinnable fibres or materials suitable for weaving, in addition to fabrics produced by knitting and felting, and all laces. The Latin *textilis* meant a woven fabric, but the word *textile* was also used as a transitive verb for plaited, braided, woven or constructed. This article deals largely with decorative textiles. Other articles related to the subject include SPINNING; YARN; WEAVING; and WEAVING, HAND for the making of textiles; DYES, for one process in their finishing; TEXTILE PRINTING for a detailed discussion of commercial aspects of that subject. There are also numerous articles on individual fabrics—*e.g.*, CALICO; CHALLIS; CHIFFON; DAMASK; DIMITY; etc.—which describe these fabrics and deal with them as items of commerce. COTTON MANUFACTURE; SILK MANUFACTURE; and WOOLEN MANUFACTURE similarly are concerned with textiles as industrial products.

This article is outlined as follows:

I HISTORICAL OUTLINE

1. Early History.—Since textiles are easily torn, burned or eaten by insects, the oldest surviving specimens probably date from long after the time when weaving was first practised. Whorls or weights for spinning have been found on Keolithic sites. indicating that thread was spun and therefore that cloth was made. The weaving of textiles for clothing, as a substitute for the skins of wild animals, was a corollary of settled life and the breeding of domestic animals. The four natural fibres, wool, linen, cotton and silk, originated in different parts of the world. Woolen textiles have been found in early Bronze Age sites in Switzerland and Scandinavia. In Egypt plain linen textiles of about 5000 B C. have been found Cotton scraps have been discovered in India on sites of about 3000 B C. and in Peru on sites datable to 2000 B.C. Silk may have been used in China in the 2nd millennium B.C. and was certainly woven by 1000 B.C. Cloaks, tunics and caps from Scandinavian sites show that a high level of skill had already been reached there, even though tools were few and primitive. The preparatory processes of carding and combing raw wool were known, for the threads are well and evenly spun. Felt caps and narrow braids were also made, and sprang, a technique between knitting and netting. was used.

Flax was grown in the Nile valley. The natural colour of flax fibres is brownish. and since whitish linens have been found in very early tombs. methods of bleaching must have been discovered. Spinning was done by hand. using a simple weighted spindle, and cloths were woven on three types of loom: a horizontal loom fixed to the ground, an upright loom with a beam at the top and bottom, and an upright loom with the warp threads bunched in groups and weighted at the foot. Variants of this last loom are seen on ancient Greek vase paintings, and this type was probably used to weave the textiles found in Scandinavia Tablet weaving for making narrow braids, netting, sprang and other techniques were developed. Normally cloth was woven in tabby (plain weave). In Ptolemaic Egypt very fine counts of linen have been found in textiles probably woven for the courts of the Pharaohs. Strangely analogous to the garments found in the north are tunics woven to shape.

The Romans wore both linen and wool, but as the empire extended so did the variety of textiles they imported. Pliny described the Roman toga of wool or linen. and later writers deplored the fashionable clothes made of silk from China. From two sites in Mesopotamia, Doura-Europus (deserted A.D. 256) and Palmyra (sacked A.D. 272), there are textiles showing the weaving repertoire of the ancient world to have comprised chiefly plain wool or linen—though at Palmyra some linens were dyed in true purple and among the wrappings of the dead were some imported cottons. Several of the earliest patterned materials made outside China were also found. These are the tunics and fragments woven in plain linen with tapestry-woven insertions.

The designs of the fragments from Doura-Europus are comparatively simple; on the other hand, for several centuries after the 3rd century A.D. Coptic weavers of Egypt produced an extraordinary variety of decorative textiles, chiefly for clothing. The dry sands of the burying grounds of Akhmim and Antinoe have preserved a profusion of such textiles dating from the 4th to the 10th centuries. The patterns reflect the cultural life of the entire Mediterranean. The bands of decoration, which were narrow on the fronts and shoulders of the tunic fragments at Doura, were larger and more elaborate, with roundels containing mythological and biblical scenes. Naturalistic birds, animals, gods and mortals in fresh, bright colours influenced by Hellenistic art were gradually transformed in subject and in style. Long after the conquest by Islam in the 7th century the Coptic weavers continued to look back to Christian subjects for their inspiration. The influence of other countries and other media can be detected, and the patterns of woven silks were copied in wool. In time, however, whatever their origin, the motifs forming the designs were subordinated to a general decorative effect until they became almost unrecognizable.

Many animal-fibre (vicuña, llama, etc.), agave and cotton textiles have been found in the sands in the narrow coastal strip of South America between the Andes and the Pacific, relics of the pre-Columbian civilization of Peru. The earliest of such relics date from about A.D. 1000, though their chronology is uncertain. Without any further modification of the loom than the weaver's fingers could provide, the inhabitants wove complex patterned textiles in tapestry. double cloth, brocaded gauze and other techniques for belts, blankets, bags and clothing. Anthropomorphic subjects are common.

2. Advances in Weaving.—One of the most important developments in the history of textiles was the invention of a method of making free designs that could be repeated indefinitely once the loom was set up. It is certain that the Chinese had found a means of achieving this early in the Han dynasty (202 B.C.–A.D. 221). The Chinese loom probably had treadles and rotary cloth and warp beams before those in the west, both of which presuppose the weaving of large quantities of fairly complex materials. The invention of a drawloom implies a civilization so advanced that expensive textiles were produced for a wide commercial market—it would not be worthwhile otherwise to set up the pattern. Chinese silks have been found not only on the old silk road from China. at Loulan. Turkestan, and other sites by Sir Aurel Stein but also a group of silk damasks were among the textiles excavated at Palmyra.

On the drawloom it is possible to lift the warp threads required for the pattern irregularly across the textile in each line of the design. In China a drawboy sitting on top of the loom pulled a set of cords attached to all the warp threads necessary for that line of the pattern each time the weaver opened a new shed. The warp threads thus pushed to the back of the textile the weft not required on the surface. The setting up of such a loom was laborious and the work very slow and tiring for the boy or girl helping the weaver. Though several important modifications very much later made the drawloom a more efficient machine — by the 17th century, for instance, the introduction of lashes and simples permitted the boy to work at the side of the loom — fundamentally the drawloom remained unchanged until the late 18th century. In the early Chinese silks the pattern was made either by a form of damask in which a warp-faced weave contrasted with a weft face, or by different-coloured warp threads entered in sequence in the loom and brought to the surface as required by the design. The patterns of the early Han textiles were often similar to the geometric cartouches on the backs of bronze mirrors or were derived from a repertoire of exotic fauna, dragons and birds being especially common.

Farther west the first drawloom patterns appear in woolen textiles found in the Egyptian burying grounds and perhaps dating from the 4th–5th century A.D. A group of these show small birds within compartments, woven in compound tabby. The word compound indicates a two-warp system: the main warp, controlled by the drawboy, is hidden between the front and the back of the textile and the binding warp appears on the surface to bind the wefts in tabby. These textiles were probably woven in the near east but it is not known where.

3. *4th–15th* Centuries. — Middle East. — After the fall of the Roman empire textiles continued to be woven in the traditional centres and exported abroad. Following the Muslim conquests of the 7th century new textile centres appeared in Syria and Arabia. At the western end of the silk route across central Asia from China, silks were woven in Sogdiana and in Sasanian Persia (3rd–7th centuries A.D.). Important patrons of silk weaving were the Seljuks who ruled Persia, Asia Minor and Syria in the 11th and 12th centuries. Apart from a group excavated at Rayy, few Persian textiles can be certainly attributed to an earlier date than this. A number of important silks can be attributed to Egypt in the time of the Mamelukes.

Most of these near-eastern textiles are known only from literary sources but from the 7th–8th century onward woven silks have survived in some quantity in the tombs and reliquaries of saints and other important figures, opened at later dates, and from the 12th century onward as the seal bags of treasuries and as vestments. Such silks often came from far-distant countries; thus silks from central Asia have been found in French and Flemish churches, and Chinese silks have even been found in Viking burial grounds. The designs of near-eastern silks owe little to China but much to the traditions of Sasanian art. In roundels fabulous monsters such as the *senmurv,* half-bird half-dog, are typical. The sculptures of the Sasanian monuments, especially at Taq-e Bostan, prove that such patterns, themselves based on Achaemenid art, originated in Persia. The roundel became the set form of decoration for several centuries, though the motifs it contained and the ornament from which it was composed varied considerably.

A magnificent series of woven silks can be attributed to Byzantium. Silk weaving may not have been very important in the city until the 6th century but very soon afterward imperial workshops were established which controlled the industry. The capture of Ctesiphon, the Sasanian capital of Khosrau II, in 624 and the booty taken by the Byzantine troops may have influenced the development of silks made in Byzantium. Early Byzantine silks were made in compound twill — that is, with the hidden main warp making the pattern and the binding in twill, allowing longer floats of weft than in tabby and thus exploiting the lustrous quality of the silk. Subjects owing much to the inherited tradition of Rome included the Quadriga silk showing a charioteer, and the lion strangler, perhaps Samson. Byzantine silks have been preserved in the tomb of Charlemagne at Aachen. This was opened in 1000 A.D. and new silks added — the elephant silk found there was probably made not long before the opening and is similar in style to lion silks elsewhere with 10th-century inscriptions. These were made in the golden age of Byzantine silk production. A group of silks were woven in the 11th century in which the pattern appeared as a penciled or engraved outline in a self-coloured material, the vestments of Pope Clement II (1046–47) at Bamberg, Ger., are remarkable examples.

While the richest silks fit for kings and emperors have survived, the ordinary wool and linen materials worn every day have perished. The history of textiles between the terminal dates of the Egyptian burying grounds and the 16th century tends to be divided into the history of vanished products based on documentary evidence on the one hand and the history of luxury silks on the other.

Among the rare textiles whose origin is known with certainty are those from the *tiraz* factories. which are inscribed with the names of the place and of the caliph in whose reign they were made. Some of these are tapestry-woven, most have embroidered inscriptions and date from the 8th–11th centuries.

Western *Europe.*—The Low Countries were the centre of a large and politically important cloth industry from the early middle ages. Already in the 8th century England was exporting wool to Flanders, but this trade did not become important till the 11th century. The Cistercians were important sheep farmers. Most districts in northern Europe made cloth of various qualities for local consumption, but by the 12th century the Low Countries were weaving cloth from imported Spanish and English wool and exporting it to other parts of Europe. In the later middle ages English royal policy sought with some success to prevent the export of wool in favour of that of unfinished cloth. Flax was similarly grown and linen woven in a number of European countries, but the only linen textiles to survive in any number are the towels with decorative ends said to have been made in Perugia, It., in the 15th century. Silks and linens were also made in Germany, especially in Cologne and perhaps in Regensburg.

Silk was certainly being woven in Mediterranean countries by the 9th–10th centuries. Although at first raw silk was imported from the near east, the cultivation of the white mulberry tree essential to the silk worm soon followed. Some time after the establishment of the western caliphate in Spain (8th century) silk weaving was established in Córdoba; later it was carried to Almería, Zaragoza, Málaga and elsewhere. In Hispano-Moresque textiles ornament from the near east was combined with a wholly distinctive style of decoration originating in Spain. Emphasis on the purely decorative form of interlacing patterns reached its climax in the last Moorish factories of Andalusia. The Norman conquerors of Sicily established silk-weaving workshops, but it is difficult to distinguish silks from Egypt, Sicily or Asia Minor for all drew on the same cultural sources. The traders of Venice and Genoa imported silks into the mainland whence they were distributed throughout Europe. An accessible source of raw material together with the early growth of compact city-states favoured the establishment of silk weaving in Italy. A treaty between Lucca and Genoa in the mid-12th century gave Lucca access to the Levant and also to the fairs in northern Europe. Merchants of Lucca traveled to the Levant to buy silk and to northern Europe to buy woolen cloths and to sell woven silks. In the 14th century, however, political difficulties displaced the town from its preeminence. Guilds of silk weavers were established in Venice, Florence, Bologna and Genoa.

A comparatively large number of silks can be attributed to northern Italy in the period from the 12th to 15th centuries, though few are known to come from any particular city. Their designs reflect the general style of Gothic art, with animals, rinceaux and heraldic devices of unfailing invention. During the 14th century the route to China was reopened, and many silks woven after that time incorporate decorative details showing Chinese influence—dragons, exotic birds, palmettes and cloud bands. Some of these may be seen in contemporary paintings; *e.g.,* the robes worn by St. Edmund Martyr in the Wilton diptych (*c.* 1395) in the National gallery, London.

The technique with which these silks were woven was advanced; the main warp appeared on the surface of the textile and was combined with a second (or ground) weft to form a texture contrasting with that of the pattern. Damasks were woven, and during the 14th century velvet weaving was established. There were plain-cut pile velvets, cut and uncut pile together, voided velvets in which part of the ground was left without pile but brocaded, often with gold thread, and velvets woven with two heights of pile, sometimes further enriched with gold loops. Many 15th-century velvets probably made in Venice have survived as chasubles and copes.

Velvets with the typical curving pomegranate in silk pile and gold thread may be recognized in paintings both by Italian artists and by those of the northern schools—evidence of the popularity of Italian velvets in Germany and the Low Countries.

4. 15th Century to the Industrial Revolution.—A great variety of textiles have survived from the 16th century. Among woven textiles the silks produced under the Safawid dynasty in Persia are outstanding. The silks of this renascence owed much to the stylistic tradition of Persian illuminated manuscripts in design, colouring and subjects depicted. Hunting scenes, subtle in technique and splendid in effect with lifelike hunters, animals, flowers, trees and birds, were rendered with accuracy and great decorative appeal. Several of the greatest were made in the court factories of Shah Abbas I (1587–1629). Persian treatment of floral design had a profound influence on European art but not on silk design until the period of its greatest inspiration had passed.

The Ottoman Turks also produced a fine series of silks in the 16th and 17th centuries. Brusa (Bursa) was the chief city weaving silks, though others are known. Turkish velvets were especially successful, owing their inspiration to those of Italy, though the designs were often treated on a larger scale.

In Europe Italian silks drew much from those of the 15th century. although by the late 16th century newer forms of ornament can be detected More remarkable is the fine table linen produced in the Spanish Netherlands from the end of the 15th century (and perhdps earlier, though none survives). Special sets were woven to order for such clients as Henry VIII of England. Courtrai was the centre of the linen damask industry, though Haarlem became increasingly important in the 17th century Damask cloths with napkins to match were woven with biblical scenes or coats-of-arms from the 16th century onward. Seventeenth-century damasks include commemorative designs, views of cities and some more original designs such as that of the cloth with a design of plates, knives and forks set for dinner, woven in Haarlem by Paschier Lainertin and now in the Victoria and Albert museum, London.

The War of the Spanish Succession at the beginning of the 18th century provided a rich source of subject matter, particularly beleaguered cities and equestrian portraits to commemorate the victories of Prince Eugene of Savoy and the duke of Marlborough. Such damasks were large, finely woven on a drawloom and expensive. Cheaper diapered or plain linen for napkins, cloths and sheets was also woven in great quantities in the same towns.

From the 17th century there survive some of the textiles made for a wider distribution than the court silks of Persia or the expensiye Italian velvets For those who could not afford the luxury of tapestries or silk hangings, certain northern towns in Italy made strong, coarse, woolen and hempen hangings. In the late 17th century this industry had shifted to Rouen and Elbeuf in France. Moreover during the 17th century the foundation of the English, Dutch and later French East India companies brought an increasing supply of cotton from Bengal into Europe for the making of fustians and other mixed fabrics. ("Cottons" until the 17th century and even later were usually low-grade woolen materials rather than true cottons.) The plantations in the American colonies were growing cotton for export by the second decade of the 18th century but probably little before then.

The establishment of important silk industries north of the Alps was a feature of the 17th century. While the woolen and worsted industries-the latter much developed in the 16th century—continued to produce the most important textiles in northern France, England and the Low Countries, the silk industry began to be significant in southern France. Although some silk had been woven in France in the 16th century and earlier, it could never compete with Italian imports. Under J. B. Colbert, minister of Louis XIV, however, the industries of Tours, Avignon, Nimes and above all Lyons were supported by a rigorous policy of protection and the growth of raw silk was encouraged in southern France. The wars at the end of the reign of Louis XIV diverted French resources for a time from such capital investment, and during this period silk industries were firmly established in Holland and England. In London the industry spread from the City to the district of Spitalfields in the east, which greatly expanded with the industry in the first 60 years of the 18th century. Fine dress silks were woven by a large number of prosperous master weavers, many of them, especially the weavers of patterned silks, being of French Huguenot origin.

The London industry was subject to the general control of its medieval guild, the Weavers' company, but this exercised little influence on the types of silks produced. In France the Grande Fabrique de Lyon had a complex organization of regulations governing the qualities of the silks to be made and officials to enforce them. Wages were low and the economic regulations often in dispute, with an outright rebellion in 1744. It was against a background of almost continuous social unrest and internal dispute that Lyons produced some of its most astonishing dress silks.

During the last years of the 17th century the designs of silks were transformed from the formal pomegranate pattern inherited from the 15th century and the stylized sprigs that persisted throughout the first 70 years of the 17th. Abstract curling forms, often in gold and silver thread on a crimson damask ground, erupted into gigantic bizarre designs with a profusion of motifs of disproportionate scale juxtaposed. Fashions changed with the season, and by the second decade of the 18th century the bizarre forms had given way to luxuriant but formal designs based on the outline of the old pomegranate motif but enriched with lacy diapered fillings. There was an increasing desire in the 1730s to give a three-dimensional form to the designs: a designer named Courtois succeeded in large floral designs by using tones of colour; Jean Revel (1684–1751) introduced ***points** rentrés* by which the tones of colour were dovetailed. A reaction toward naturalistic life-size sprays of flowers came in the 1740s, a period in which some of the most successful English silks were woven. From the middle of the century designs with bunches of flowers and trailing ribbons dominated all others. Neoclassical influence can be detected in the later 18th-century silk designs as in other media, laurel wreaths and plain stripes occurring frequently. A period of very dark colours in the 1790s was succeeded by a fashion for light colours and light materials, especially silk gauzes and cotton muslins.

While such were characteristic dress materials, printed cottons often provided fashionable furnishings. In Lyons, however, Philippe de la Salle (1723–1803), designer and partner in a silk-weaving firm, designed a series of furnishings with lifelike birds, flowers, ears of wheat, etc., on a sumptuous scale.

The continuous change in fashion was perhaps stimulated by intense competition in the market for woven silks Genoa never lost its markets for heavy velvets and damasks, Lucca survived until the middle of the 18th century, but in the general climate of mercantilism every sovereign tried to restrict the import of luxuries and to foster native industries. Silk industries were revived in Spain and founded in Berlin and even in Russia. A large number of Chinese painted silks were also imported into Europe.

It was not, however, until the 19th and 20th centuries that Chinese *k'o-ssu,* silk tapestry-woven textiles, were appreciated in Europe. The dragon robes worn by the highest Chinese officials were not made known in the west,till after the sack of the Summer palace in Peking in 1860. A few fine 18th-century examples survive and can be seen in all major museum collections.

Very high-quality woolen. worsted and mixed textiles were made in the 18th century for everyday clothing, linings and upholstery; they were still very expensive, however, and secondhand clothing was much worn by the poor in all countries. Although all cotton goods were prohibited, substitutes with a linen warp and a cotton weft were made both in England and on the continent of Europe, and in England were virtually indistinguishable from pure cottons. While these goods possibly reached unprecedented technical perfection. far-reaching technical changes began to appear in the cotton districts of Lancashire and the heavy woolen industry of Yorkshire.

5. The Industrial Revolution. — Kay's flying shuttle (invented in 1733) speeded up and therefore cheapened the production of plain textile goods. Quicker weaving increased the pressure upon the spinners to produce more thread than they could by the spinning wheel, virtually unchanged since the 15th century. It was, however, nearly half a century before Richard Arkwright's water frame (1769) and Samuel Crompton's mule (1775) began to replace the hand spinners with machines. These inventions and their perfection gave an incentive to mechanize the preparatory processes of carding and combing. The period from 1780 to 1820 produced a multitude of devices to mechanize each of the processes formerly performed by hand. The first power loom was improved upon soon after the turn of the century. Primarily these inventions made possible the mass production of cheap cottons, but nearly all could be adapted to wool.

The greatest technical problem in silk pattern weaving was the cumbersome and expensive drawloom. The elimination of the drawboy and the automatic weaving of the pattern were finally achieved by Joseph Marie Jacquard (1752–1834), who built upon the ideas of his predecessors. The Jacquard loom was widely used in France by the end of the first decade of the 19th century and elsewhere by 1820. For the first time it was possible to lessen the cost of textiles with a woven pattern. Although Jacquard was a silk weaver his loom was quickly adapted in the cotton and linen industries and by the weavers of shawls, an important new industry in Scotland and at Norwich, Eng.

6. 19th and 20th Centuries. — The break in the normal stylistic evolution of the patterns of woven textiles is not clearly evident before the 1830s. The eclecticism of the taste of the next half-century reflected a total change in outlook. Techniques and new materials were of paramount importance. Using new machinery it was possible for the first time to reclaim rag wool for shoddy, thus lowering the cost of woolen goods and providing good warm clothing for the new poor of the rapidly growing industrial towns.

Except in the extreme luxury trades (in which Lyons silks and St. Étienne ribbons in France led the other nations), the textile centres of Europe and the United States competed with one another to produce large quantities of ever-cheaper power-loom-woven materials. The manufacturers' pride in these goods — each patented variation was acclaimed as a new material — was shown in the great international exhibitions of 1851 and 1862 (London), 1867 (Paris), 1876 (Philadelphia), 1878 (Paris) and others hardly less important. The overloaded Victorian interiors of the newly prosperous made extensive use of every kind of furnishing textile, creating an ever-increasing demand. The multiplicity of uncoordinated patterns was especially marked in textiles and provoked a natural reaction. On the one hand, there were official attempts to found trade schools and schools of design; on the other, William Morris and his associates rebelled against the domination of the machine (see ARTS AND CRAFTS MOVEMENT). Morris himself founded a firm to make high-quality furnishing fabrics using traditional dyes, the best materials and artists' designs. Although its influence was not limited to England, the movement hardly affected the styles of commercially produced textiles until the end of the century. (See also Printed Textiles, below.)

The scientific advances of the 19th century, particularly in chemistry, produced not only new dyes but, toward the end of the century, new fibres. The disease and virtual extinction of the European silkworm left the silk weavers of Europe almost entirely dependent upon the far east for their raw material; hence the incentives to find a substitute were strong. The first textile filaments were made in France from nitrocellulose; in Germany the cuprammonium process developed; in 1892 British scientists invented viscose rayon. But none of these proved wholly satisfactory.

After World War I cellulose acetate was exploited commercially, and in 1938 the first of a new series of fibres no longer based upon the structure of cellulose was developed in the United States. This was nylon, the first of the polyamide fibres, greatly improved after World War II. The polyester fibres were first used in the 1950s. The best of the new man-made fibres produced textiles that were tough, washable, crease-resisting, hard-wearing and less likely than natural fibres to shrink, fade or felt. Drawing on reliable supplies of raw materials they supplemented the four natural fibres very usefully, but the warmth of wool, the coolness of cotton and the elegance of silk were not easy to imitate. (See also SYNTHETIC FIBRES.) From the 1920s textile designs for the higher-quality materials have been once more the work of artists and reflect the general taste of their period.

7. Other Textiles. — Certain textiles fall outside the main historical developments. Japanese silks, though technically similar to Chinese, represent a different idiom in design hardly known in the west until it suddenly became fashionable in the 1870s. The coverlets woven by hand in parts of the United States preserved their traditional patterns throughout the 19th century. In some peasant communities of eastern and northern Europe, in north Africa and among the Indians of North and South America textiles were hand woven until the 20th century. Such textiles retained their intrinsic qualities until the use of aniline dyes destroyed their coherence by introducing alien, harsh and gaudy colour schemes which quickly faded to a lifeless and unpleasant monochrome. II. PRINTED TEXTILES

The term printed textiles covers all textiles patterned by the application of pigments, whether by printing, painting or dyeing or by a combination of these methods. The pattern may be produced by painting on the cloth with a brush, by stenciling, by printing from wood blocks, engraved copperplates or metal rollers, or by screen printing, either with surface pigments or with dyes that penetrate the fibres of the cloth. The pattern may also be produced by "resist" or by mordant dyeing. In resist dyeing, the resist paste or wax, which is impervious to the dye, is painted or printed onto the material, covering the parts that are to remain uncoloured. In mordant dyeing, the parts that are to receive the colour are painted or printed with chemical substances known as mordants; when the fabric is immersed in the dye the colour is fixed on these parts, while washing removes it from the unmordanted areas. (These techniques are described at greater length in TEXTILE PRINTING.)

Printed textiles are believed to have been produced in the Caucasus as early as 2000 B.C. and there is no doubt that the art of ornamenting fabrics by painting or printing is of great antiquity. Painting was among the earliest methods of decorating textiles; among the oldest surviving examples of this are some Greek fabrics, dating from the 4th century B.C., found in tombs in the Crimea, and also the well-known painted Egyptian mummy cloths. In these early painted fabrics surface pigments were used, but at least as early as the 1st century A.D. the process of mordant dyeing was known to the Egyptians and is described by Pliny the Elder (d. 79 A.D.) although no mordant-dyed Egyptian fabrics of this date appear to have survived. Before the Christian era India had a reputation for its resist-dyed and painted cottons. In China the art of resist dyeing was certainly known as early as the 7th or 8th century A.D., while indigo resist-dyed linens, several with elaborate figure patterns of religious subjects, have been found in burial grounds at Akhmim, upper Egypt, and are thought to date from the 9th–10th century A.D.

In Europe, however, the art of textile printing does not appear to have begun much before the 12th century A.D., and the few pieces of printed fabrics of an earlier date that have been found in Europe appear to be of eastern origin. One of these, a piece of linen with a resist-dyed pattern of white circles on a blue ground, was found in the tomb of Caesarius of Arles (c. 470–542) and is preserved in the Nürnberg museum. A fragment of amber silk printed in gold leaf with a design of a falconer on horseback was found in the grave of St. Cuthbert in Durham cathedral (A.D. 1104), but it is assumed also to be of eastern origin.

1. Block-Printed Textiles.— The earliest extant examples of European printed fabrics, dating from the late 12th century, are of Rhenish origin. The fabrics, of silk or linen, were printed from wood blocks with surface pigments, usually in black, gold or silver. A few of the oldest pieces are printed in more than one colour, usually black and red, and occasionally a third colour. The patterns appear to have been copied from the Byzantine and near-eastern woven silks of the period. Although such fabrics seem to have been produced in considerable quantity and extant examples are numerous, there is reason to doubt the authenticity of many of the surviving pieces.

Early Development.—In the 14th century the patterns of Rhenish printed fabrics were based on the woven silks from Venice and Lucca. In one instance printed linen with a design of birds, lions and stylized floral motifs (fragments of which are in the Victoria and Albert museum, London, and at Berlin) survives together with the woven silk from which it was copied, a chasuble in the Stralsund museum in Germany. In the 15th century, patterns copied from Italian velvets, with ogival compartments containing stylized flowers or lobed pomegranate patterns, seem to have predominated.

Italian printed fabrics dating from the 14th century have also been found and examples such as the famous tapestry of Sion, with elaborate scenes of dancers and horsemen (in the Historisches Museum, Basel. Switz.). dating from the middle of the 14th century, show a high standard of technical excellence both in the cutting of the wood blocks and the actual printing.

Records of the Painter-Stainers' company show that painting on cloth was a recognized trade in England as early as the 13th century. but probably the earliest surviving example, dating from the early 15th century, is a burse from the parish church of Hessett, Suffolk, painted with the head of Christ and the symbols of the four evangelists.

By the 16th century simple block-printed fabrics appear to have been produced in most European countries. A number of English examples of the Elizabethan period, copying the popular "black work" embroidery or derived from contemporary lace-pattern books, have survived. Others, printed from engraved copperplates in ordinary printer's ink. were obviously intended as embroidery patterns. The 17th century saw considerable advances: in Germany, for instance, the patterns consisted on the one hand of floral designs not derived from woven sources but characterized by the detailed and elaborate cutting of the wood blocks, and on the other hand indigo resist-dyed linens, often with pictorial and religious subjects, which were copied from the contemporary linen damasks.

2. Origins of the European Calico-Printing Industry.— The chief advances in textile printing were the result of an attempt by European textile printers to imitate the fast-dyed, hand-painted Indian cottons that began to be imported into Europe during the early 17th century. It was not until the 1670s, however, that the European calico printers appear to have been successful (more or less simultaneously in France, Holland and England) in mastering the complex problems of mordant dyeing with madder, the basis of the imported Indian chintzes. Since "calico," the general term for cotton cloth of all kinds imported from the east, was also soon used to describe various cotton fabrics of European manufacture (including those with linen warps), textile printers came to be described as calico printers rather than, as in earlier times, linen or stuff printers. Calico printing was to an extent continued in most European countries during the 18th and 19th centuries but England, France, Holland, Switzerland and Germany were the only countries where the industry achieved any real importance.

The English calico-printing industry appears to have been founded by William Sherwin, an engraver, who in 1676 was granted a patent for a "new way of printing broad callicoe" and set up a printworks at West Ham, east of London on the river Lea. Other printers followed and by the end of the century the industry was well established. Indeed by 1696 the industry had already grown sufficiently strong to arouse the established silk and wool interests against it. A law of 1700 prohibiting the import of Indian chintzes was followed by laws of 1712 and 1714 which placed heavy excise duties on home-printed chintzes. Finally, in 1720, a law was passed that prohibited printing on all cotton cloth, but the calico printers were able to evade the intention of the law by printing on a mixed cloth with a linen warp and cotton weft. It was not until 1774 that the ban on printing was raised from all cotton cloth and not until 1831 that the heavy excise duties were finally removed. In spite of these restrictions the English calico-printing industry continued to expand and flourish.

In France the calico-printing industry was even more hampered by restrictive legislation than in England. An edict of 1686 forbade not only the wearing of imported Indian chintzes but their imitation and, although it was widely evaded, the industry made little real progress until the final removal of all restrictions on textile printing in 1759. Even before the lifting of the ban, however, a number of calico printworks had come into operation, including those of Koechlin Schmaltzer and Dollfuss at Mulhouse (1746), the Danton brothers at Angers (1753) and John Rudolph Wetter at Orange (1758). Wetter, a rich Swiss merchant, had previously established a printworks at the free port of Marseilles in 1744.

Although simple block-printed textiles had been produced earlier in Holland, the first successful attempts at imitating the imported Indian chintzes were made at a printworks at Amersfoort set up in 1678 by two Amsterdam merchants and a Turk living in Holland. Other factories followed and by the middle of the 18th century about 100 printworks were in operation, mainly in Amsterdam and the surrounding districts. The number of printworks, however, gradually declined, largely as a result of increasing French and English competition, and by 1800 only four were in operation. In the following years Belgian printworks supplied most of the exports to the Dutch colonies in the East Indies, but after the separation of Belgium and Holland in 1830, new printworks were established in Holland, forming the nucleus of the modern textile-printing industry in that country.

In Germany during the late 17th and 18th centuries Augsburg was the chief centre of textile printing. Resist-dyed linens and block-printed linens, printed in black or red, are found but, in order to protect the linen industry, printing on cotton was prohibited until about the middle of the 18th century. Among the most important German printworks was that of the brothers Neuhofer at Augsburg, which operated in the early 18th century, and that of Johann Heinrich Schiile, who is said to have introduced copperplate printing into Germany in 1766.

Switzerland was an important textile-printing centre throughout the 18th and 19th centuries. Block printing by the "application" method, which involved the use of watered colours (dye and fixing agent mixed together), had been practised in Switzerland since the 16th century, and although this method continued into the 19th century the resulting prints were not fast to light or soap and water. The *indiennes* industry of Switzerland, however, developed from the processes of indigo and turkey red dyeing rather than from block printing as such, and was introduced by Swiss printers who had worked in Holland and by French Huguenot refugees. The first printworks in Geneva was founded in 1687 by a group of local merchants and a Frenchman named Matthieu Marin. Other printworks followed and by about 1720 Geneva was an important calico-printing centre. During the latter half of the 18th century, however, the industry declined and by 1815 only two printworks remained in operation; by 1830 the Geneva industry was virtually extinct.

The calico-printing industry of Zurich was founded by David Esslinger in 1720, while that of Basel was founded in 1716 by Samuel Ryhiner, who had learned his trade in Holland. The most important centres of calico printing in Switzerland, however, were the cantons of Neuchbtel and Glarus. The first Neuchbtel calico printer was Jean Labran, who opened a printworks at Pré-Royer in 1715. By 1750 several others had come into operation.

One of the largest was that of Du Pasquier and Portales at Cortaillod, established in 1750 and by the beginning of the 19th century the largest in Switzerland, comprising more than 300 printing tables and a considerable number of roller-printing machines. The first calico printworks at Glarus was established in 1740 by Johann Heinrich Streiff, and the Glarus industry reached its peak in the 1840s.

Little is known of the Italian printworks apart from those in the Genoa area which specialized in the production of *mezzari,* large decorative panels copied from Indian models, the so-called "tree of life" being the commonest design. The most important factory was set up at Sampierdarena in 1787 by Michael Speich, a Swiss from Glarus, together with his cousin Luigi Testori, who succeeded to the business about 1830.

The earliest reference to calico printing in America is an advertisement in the Boston Newsletter of April 23, 1712, stating that a certain George Leason from England, together with a Boston clothier named Thomas Webber, had set up a printworks near the bowling green. Although similar advertisements are found with increasing frequency, it was not until the last quarter of the 18th century that textile printing can be said to have become an industry in the United States. One of the most important figures was John Hewson, an Englishman who, encouraged by Benjamin Franklin, set up a calico printworks in Philadelphia in 1774. His work was interrupted by the American Revolution, but he was able to resume his activities in 1789 with the assistance of a loan from the government. Although his output was considerable, and comprised both dress and furnishing fabrics and printed handkerchiefs, practically nothing has survived that can be attributed to him, although he is said to have printed a fine coverlet now in the Philadelphia Museum of Art. His factory lasted until sometime in the 1820s, the business being carried on by his sons. Among other 18th-century American printworks was that set up about 1790 at East Greenwich, R.I., by Herman Vandausan, a textile printer from Mulhouse. Other Rhode Island printworks included that of Schaub, Tissot and Dubosque (1794), and by 1840 there were 17 dyeing and printing establishments in that state.

Calico printing was also carried on in Massachusetts and New York. The first roller-printing machines in America were introduced in 1810 at the factory of Thorp, Siddall and Co. near Philadelphia, Pa.

Designs.—Although certain factories specialized in particular classes of goods, the general development of design in printed textiles was much the same throughout Europe and the United States, with the English and French printers taking the lead. Since surviving English and French textiles are far better documented than those of other countries, the general trend of design can best be studied by those examples.

The earliest surviving European examples were mostly printed in the limited palette of black, reds, purples and brown obtainable from madder dye, and the designs were often free adaptations of Indian floral patterns. Most of the earliest examples survive as linings to late-17th-century leather trunks or as linings to silk coats, stomachers and embroidered bags or purses. An important collection of impressions from early 18th-century textile printers' wood blocks survives in the Berch collection at the Nordiska Museet, Stockholm, which are mostly single- or two-colour prints mainly of floral designs, characterized by fairly elaborate cutting of the wood blocks. Though knowledge of these early European fabrics block printed in the madder style is fragmentary and uncertain, it is clear that by the middle of the 18th century at the latest the European printers were able to add indigo blues and weld yellows to the basic madder colours, either printed by block or painted or "penciled" with a brush, and that by this time the printed fabrics had achieved a status that enabled them to exist in their own right, not merely as cheaper substitutes for woven fabrics.

A folio volume in the library of the Musée des Arts Décoratifs, Paris, contains 13 samples of English chintz, collected by John Holker in Lancashire in 1750 and presented to M. De Montigny of the French Royal Academy of Sciences. These samples, which are quite unfaded and fully annotated, show that by this time the English calico printers were able to produce well-drawn floral designs using the full range of colours obtainable from madder dye, together with indigo and weld yellow. Supplementary evidence of the skill of the English calico printers at this time is found in a series of original designs and impressions from wood blocks (in the Victoria and Albert museum) by John Baptist Jackson, who worked as a calico printer for a few years before he set up as a wallpaper manufacturer in 1752.

3. Copperplate-Printed and Later Block-Printed Textiles.—In the middle of the 18th century, the introduction of copperplate printing radically transformed the appearance of European printed textiles by allowing a fineness of detail and delicacy of drawing that had not been possible with the comparatively coarse technique of wood-block cutting. Copperplate printing on textiles was invented in 1752 at the Drumcondra printworks, near Dublin, by Francis Nixon, who introduced the technique into England within the next four years. For the next two decades—apart from the short-lived factory of Gayet and Montgirod at Sèvres, France, which survived for only 18 months in 1760–61—Ireland and England retained a virtual monopoly of the new technique. From the beginning the technique of copperplate printing was admirably suited to the production of large-scale pictorial designs, with a repeat of about a yard square, covering a wide range of subjects including pastoral, mythological and theatrical scenes, chinoiseries and subjects commemorating important military and political events. It was also widely used for finely engraved floral designs for both dress and furnishing fabrics. Few documented Irish examples have survived but pattern books (in the Musée de l'Impression sur Étoffes, Mulhouse, and the Victoria and Albert museum) containing over 400 different impressions from English calico printers' copperplates, as well as a vast quantity of extant plate-printed textiles, testify to the excellence of the English productions. Although a number of the English pictorial designs have certain affinities with the French toiles de jouy (see below), a particularly striking group of designs with large flowers and birds seems to be especially characteristic of the English printers.

The copperplate designs were almost invariably monochrome, being printed either in blue, red, purple or sepia. One English factory, that of the Wares at Crayford, is known to have printed in copperplate in two colours. In a few instances, such as the textile printed by Robert Jones at Old Ford in 1769 (Victoria and Albert museum) and the "volunteer furniture" printed by Edward Clarke at Palmerstown, Ire., in 1783 (National museum, Dublin) additional colours were added to the basic copperplate design by printing from wood blocks or by hand painting.

Although evidence has shown that generally speaking the English surpassed the French in copperplate printing, the credit for its development previously was given to Christophe Philippe Oberkampf and his factory at Jouy. Oberkampf, the son of a cloth printer and dyer, was born in Germany but moved with his father to Aarau and acquired Swiss nationality. After working first at the Cour de Lorraine factory at Mulhouse and then at the Arsenal at Paris he set up a small factory at Jouy-en-Josas, near Versailles, where his first print was produced on March 1, 1760. Four years later, in 1764, new buildings were begun and, owing to Oberkampf's unrivaled technical skill combined with his flair for singling out the best French designers, Jouy became the foremost printworks in France. The productions ranged from small, block-printed designs for dress fabrics to large-scale pictorial prints for furnishings.

According to the biography of Oberkampf, the secrets of copperplate printing were brought to Jouy in 1770 by his brother Frédéric, who had seen it in use at Morat, near Neuchâtel in Switzerland. However, no surviving Jouy copperplate prints can be positively dated earlier than 1783, the date of the famous Travaux de la Manufacture. This design was the work of Jean Baptiste Huet, who became the factory's chief designer. Most of Huet's early designs were of pastoral scenes, such as "Offrande à l'amour," "La Fête de la fédération" and "Les Plaisirs de la ferme." After the Revolution Huet followed the general trend toward classicism and produced a series of designs in the Directoire style including the "Scènes Pompéiennes" and "Le Loup et l'agneau." Examples of his work can be seen in the Musée des Arts Décoratifs, Paris. Other prominent designers who worked for Oberkampf were Hippolyte le Bas. who specialized in architectural subjects such as "Les Monuments de Paris," and Horace Vernet, who specialized in hunting scenes. Although Oberkampf's reputation was such that the term toile de jouy became a generic description for all copperplate textiles, other French factories produced designs of equal distinction. among them the firm of Favre. Petitpierre et Compagnie (founded 1760) at Nantes and that of J. P. Meillier at Beautiran, near Bordeaux (founded 1792).

The introduction of copperplate printing did not, however. eclipse wood-block printing, and the two techniques developed side by side. The most popular wood-block designs continued to be floral, including designs based on the successive fashions in 18th-century woven silks. There is little basic difference between the wood-block-printed chintzes of the 1760s and 1770s, but in the 1780s several different styles emerge, including coiling floral designs with broken stems based on Indian models and large-scale arborescent designs often incorporating birds. Two parallel styles are especially characteristic of the last decade of the 18th century: first, designs on an almost black madder ground with delicately drawn mossy trails, which in England were popular for both dress and furnishing fabrics though in France they seem to have been limited to dress fabrics; second, designs of alternate vertical stripes, one on a white ground, the other on a dark, which were equally popular. This second type was virtually limited to England, while France favoured designs of detached sprigs of flowers, ears of wheat and insects, characterized by fine and precise cutting of the wood block.

Although finely engraved copperplate prints continued to be produced in France until the early 19th century. copperplate printing was in decline in England by that time. Most of the English factories that had specialized in copperplate prints were in London or the home counties. Among the most important were Robert Jones (c. 1760–80), Old Ford; Nixon and Co. (c. 1752–89), Phippsbridge. near Merton, Surrey; Bromley hall (c. 1740–1823), Middlesex: John Munns (*c.* 1769–84), Crayford, Kent; and Joseph and Mary Ware (c. 1760–81), Crayford.

Calico printing in Lancashire was established about the middle of the 18th century with an important offshoot in Carlisle, and from the onset the Lancashire and Carlisle printers concentrated on the production of wood-block-printed chintzes. By the beginning of the 19th century, most of the London copperplate printworks had closed down and with the shift of emphasis to Lancashire wood-block prints predominated. The leading factory in the production of high-class wood-block "furniture" prints was that at Bannister hall (founded c. 1798). near Preston. Lancashire, which. under successive changes of ownership, remained in operation until 1893.

The Bannister hall records dating from 1799 to 1840 include a continuous series of about 3.800 documented samples of printed cottons supplemented in most cases by the original designs, which provide an invaluable and accurate guide to the prevailing styles throughout those years, particularly since Bannister hall set the fashion for the other factories.

By 1800 the dark-ground style had given way to the so-called drab style, printed in yellow, olive, brown and buff, and the meticulous drawing of the 1790s was replaced by a broader technique with coarser cutting. The French copperplate Directoire prints were paralleled in England by a brief fashion in the years 1804–06 for "classical" and "Egyptian" designs, printed in hot "Pompeian" colours, and for *chinoiserie* designs incorporating figures. buildings and vases; "Indian" designs on bright-red grounds were also popular. Among the other wood-block styles popular in the early 19th century were designs incorporating game birds and architectural features. Panels printed for incorporation into patchwork quilts were produced in considerable quantity in the years around 1815.

4. Roller-Printed Textiles. — Although roller printing was invented by Thomas Bell as early as 1783 and was certainly used in the production of small-scale dress patterns by the beginning of the 19th century, it had little general effect on the design of printed textiles until about 1815. Thereafter in England the technique was used for pictorial prints, often of scenes of hunting and other sports and pastimes, but the designs were generally cruder than those of the 18th-century copperplate prints. In France the technique was widely used for a vast range of pictorial designs, often with diagonally hatched or finely diapered grounds.

From the 1820s onward the development of roller printing led to a vast increase in the output of printed textiles, although high-class furniture prints continued to be printed by wood block in the traditional madder style. In the 1820s the standard of engraving on the metal rollers was often extremely high. The actual engraving of the rollers was generally done not by the printers themselves but by special firms. One of the leading firms of engravers was Joseph Lockett of Manchester (later Lockett, Crossland), which supplied engraved rollers not only to the English calico printers but to printworks throughout Europe. This firm was largely responsible for the "fancy machine grounds" or "cover rollers" in which the whole background of the fabric was covered with elaborately engraved diaper patterns.

These enjoyed a considerable vogue in the 1830s and were often used as a background to the traditional, wood-block-printed floral chintzes.

5. Decline and Revival of Textile Design. — Until about 1810 all printing, with the exception of low-grade fabrics printed in fugitive colours, was based on the use of vegetable dyes, which in practice meant madder, indigo and quercitron. From then on, however, the competitive efforts of the French. German and English chemists resulted in a series of new chemical resists and discharges for transforming the appearance of the old vegetable dyes, and new methods for the use of colours such as prussian blue, cochineal pink and catechu brown. In addition, a completely new range of mineral dyes, including manganese brown, chrome yellow and antimony orange, and a "solid green" were placed at the disposal of the textile printers. These new discharges, resists and mineral dyestuffs had brought about a radical change in the appearance of printed textiles more than 20 years before W. H. Perkin's discovery of the aniline dyestuffs in 1856.

The combination of the indiscriminate use of these new colours, which were eminently suitable for roller printing, and a lower standard of engraving and design led to a gradual deterioration in printed textiles that was increasingly apparent from 1835 onward. A vast amount of cheap, roller-printed fabric was turned out by the English and European printers in a great variety of styles, ranging from floral designs and elaborate pictorial prints of romantic and sentimental subjects to various exotic styles intended for overseas markets. The eclecticism of the designers knew no bounds, and the 19th-century "battle of styles" was reflected in printed textiles that combined rococo, Gothic and classical elements with paisley motifs. tartan ribbons and a host of miscellaneous ornament. Even so, throughout the 1840s and 1850s, both the English and French and particularly the Alsatian printers continued to produce well-drawn floral chintzes, printed by wood block in the madder style, for the high-class furniture trade. Many of these were printed on challet, a fine worsted wool, instead of on cotton, which gave an added richness and depth to the colours Although the Alsatian printers maintained a high standard of technical excellence, little of distinction was produced throughout the 1860s and 1870s.

The revival of textile printing as a fine art and the revival of the decorative arts generally that came about in the later 19th century must largely be credited to William Morris. Morris produced his first design for a printed textile in 1873, the first of 44 different designs for chintz. all of which were printed by hand with wood blocks and, with one or two exceptions, with vegetable dyes. Several of his finest chintzes, including the well-known "Strawberry Thief" (1883), were printed by the laborious and obsolete method of indigo-discharge printing. There is little doubt that the Morris chintzes printed first by Sir Thomas Wardle at Leek, and later at Morris' own workshops at Merton abbey, are among the finest printed textiles of all time.

The 1870s also saw the production of printed textiles influenced by Japanese art, with highly stylized flowers whose flat symmetrical petals were set against fretted backgrounds. In the 1880s a heavily textured cotton known as cretonne and velveteen were much used for printed furnishing fabrics, while some of the finest dress fabrics were printed on silk. From 1880 onward there was an increasing tendency for textile printers to commission designs from leading architects, artists and professional designers, which did much to raise the general standard of production. Throughout the latter part of the 19th century and the 20th century, the styles in printed textiles have closely followed the general development of the decorative arts. In the years around 1900 the influence of Art Nouveau (*q.v.*) was apparent. and outstanding printed textiles in this style were produced by firms such as Liberty of London.

In the 20th century modern movements in painting and the influence of the Ballets Russes and the Bauhaus in Germany led to the development of geometrical and abstract designs, usually printed in strong, vivid colours, often emphasized by black outlines. In England the move toward abstract design was fostered by the Omega workshops. founded by Roger Fry and a group of artists, for whom in 1913 the Maromme printworks of Rouen produced a series of printed textiles. A leading firm that did much to popularize the new styles was that of William Foxton, who from 1917 commissioned designs from leading artists including Charles Rennie Mackintosh and Claude Lovat Fraser. In France outstanding printed textiles were produced by the firm of Bianchini Ferier to the designs of Raoul Dufy and other painters. The later 1920s and early 1930s saw a return to more subdued, pastel colours and floral designs. characterized by overlapping segments and highly stylized flowers. This style achieved widespread currency at the Paris exhibition of 1925.

6. Screen-Printed Textiles.—In the 1930s the development of screen printing finally removed all restrictions from the designer and allowed enterprising manufacturers to try out short runs of experimental designs without incurring the heavy expense of engraved rollers or resorting to the laborious process of hand-block printing. This has resulted in an ever-increasing variety of design in printed textiles and at the same time extended the practice of commissioning designs from artists rather than professional designers.

Between World Wars I and II there was an important revival of hand-block printing in England on the part of a number of artist-craftsmen who produced both dress and furnishing fabrics, designing, cutting and printing the blocks themselves. Most of these fabrics had simple patterns produced in dark low tones, often with vegetable dyes, no doubt as a reaction against the garish colours and elaborate designs of the mass of commercial production.

In most countries there was little advance in the design of printed fabrics during World War II but after the war the development of mechanical screen printing brought an even greater variety of printed textiles. In the postwar years Scandinavia achieved a considerable reputation for printed textiles. Danish manufacturers mere pre-eminent in the development of floral design, while Sweden and Finland tended to concentrate on crisp, geometrical patterns. With modern printing techniques the translation of any type of design onto cloth is possible. In contemporary screen-printed fabrics the designs range from abstract patterns imitating the work of Tachist and Action painters to elaborate florals, often with huge-scale repeats.

7. Oriental Textiles.—Persia.—The block printing of textiles in Persia may be traced back certainly to the 17th century. The journal of Jean de Thévenot (1633–77). *Relation d'un* voyage *au* levant, describes fabrics in which "the flowers and other paints are stamped upon them with a mould besmeared with colours" The French traveler Jean Chardin. in his *Voyages* en Perse (published in 1686), describes not only the painted cloths, similar to those from India. but also taffetas and satin, block printed with gold and silver with calligraphic. floral or pictorial designs Painted and printed textiles produced in Persia were exported to Europe to the East India company in the late 17th and 18th centuries, and although records describe the textiles as "perses" it seems that little distinction was made between those of Indian and Persian origin.

Persian textiles of the 18th and 19th centuries with patterns produced by a combination of block printing and hand painting survive in considerable quantity in the form of wall hangings, prayer mats, curtains for doors or niches, bed coverings and shrouds. Most of the designs are floral but incorporate pine cone and other decorative motifs.

China.—Chinese resist-dyed silks, dating from the 7th or 8th century A.D., are preserved in the Shōsō-in, the imperial treasure house at Nara in Japan, and similar fragments were discovered by Sir Aurel Stein in eastern Turkestan. From the 18th century onward floral patterns painted in body colour on silk were made for export to Europe to be made up as dresses or hangings. A number of ecclesiastical vestments of Chinese painted silk dating from the 18th century also survive.

Japan.—It is probable that the Japanese learned the art of resist dyeing from the Chinese. A fragment of Japanese silk stenciled with the Buddhist sacred wheel is believed to date from the 8th century, and stenciled patterns are generally characteristic of Japanese work. Block printing was also practised in Japan and included a method known as negative block printing in which the hollowed-out parts of the block. not the relief portions, are charged with colour. The form of resist dyeing known as tie-and-dye work was extensively practised in Japan, as well as in India. China and other parts of Asia, and in Africa. In Japan this method was known as the *shibori* process, and in the 18th- and 19th-century examples the process is often combined with embroidery.

Javanese Batik.—Batik is a Javanese word applied to the wax-resist technique of pattern dyeing on cloth, as practised there. Those parts of the cloth not required to take the dye are covered with hot wax, after which the whole fabric is dipped in the dye vat, an operation repeated according to the number of colours in the pattern.

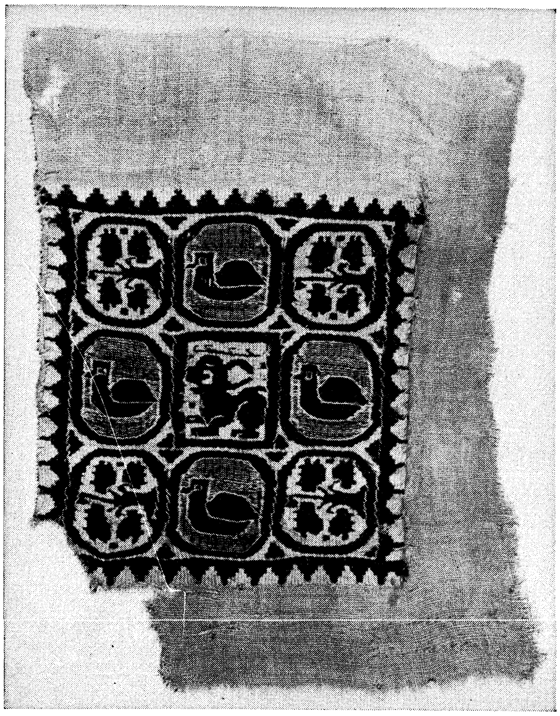
It is doubtful if any batiks preserved in museum collections date from before the 1750s, and therefore little is known about the origins of this technique in Java. However, there is evidence that a simplified batik technique (possibly copied from India) was widely practised independently in southeast Asia: the Toradjas of Celebes (Sulawesi), for instance, until the second half of the 20th century produced simple batiks, applying the hot wax by means of a narrow, flattened strip of bamboo. The decisive advances in Java, probably in the 18th century, seem to have resulted from the invention of the *tjanting*, a small copper crucible with a projecting spout and a bamboo handle. It is filled with wax and the pattern is drawn on the cloth with the molten wax which runs out of the spout. The cloth is elaborately washed and soaked to secure the right texture and surface and is then hung over a frame. the artist, usually a woman. sitting cross-legged before it. The design is sometimes first sketched in charcoal, but the best artists use only their *tjantings*, relying on visual memory. They outline the area that is to be dyed and cover the rest of the surface with wax The cloth is turned over and the operation repeated on the other side.

The cloth is then immersed in cold water till the wax hardens and is afterward dipped in the dye vat. The wax is removed, leaving exposed other parts of the cloth to be dyed different colours by the same process. The traditional colours are indigo blue, madder red and brown; secondary colours are produced by dyeing one colour over another.

In the 19th century copper-mounted wood blocks for applying the wax to the cloth were introduced. This. known as *tjap* printing, has almost entirely superseded the more laborious and highly skilled *tjanting* process. Batik was traditionally used almost entirely for clothing.

III. INDIAN TEXTILES

From early historic times India was famed for its textiles. This is known from literary and archaeological evidence, although very few fabrics of a date earlier than the late 16th century survive.



Near eastern silk with half-bird, half-dog design, thought to have come from a reliquary in the church of St. Leu, Paris; about A.D. 700–900

The decorative techniques traditional from early times are embroidery, resist dyeing, hand painting (with mordants) and brocading. A wide variety of materials have been employed for weaving, but the one most commonly used was cotton. Excavations at Mohenjo-Daro have shown that cotton was woven at least as early as the 3rd millennium B.C. The few minute fragments discovered owed their chance survival to impregnation with silver salts, absorbed from the walls of the silver vase in which they had remained for at least 4,000 years. Traces of purple dye, thought to be madder and therefore suggesting an early knowledge of dye chemistry, add to the significance of the discovery, while the numerous spindle whorls found at the same site—some of crude pottery and others of more expensive faïence—suggest that spinning was practised extensively and by all classes. Contemporary sculptures and terra-cottas show that at least two articles of costume for which India became famous, the girdle and the shawl, were already worn at this period.

Evidence is lacking for the thousand years following the collapse of the ancient city-states of the Indus valley; but the Greek physician Ctesias, writing in the early 5th century B.C., mentions the popularity of brightly coloured Indian textiles among the Persians, an indication that Indian fabrics were being made for export at least as early as this period. It is not known when they first reached Europe, but the use of the oriental word *carbasina* (Sanskrit *karpasa)* for cotton in the *Pausimachus* of Statius Caecilius suggests that it was before 200 B.C. Strabo, on the authority of Megasthenes *(c.* 300 B.C.), recorded the Indian love of finery and ornament, and added, "Their robes are worked in gold, and ornamented with precious stones, and they also wear flowered garments of the finest muslin."

During the 1st century A.D. Indian muslins became famous in Rome under such names as *nebula, gangetika* and *venti* textiles ("woven winds"), the latter exactly translating the technical name of a special type of Dacca muslin still being made in Bengal in the 19th century. Silk was also an important export to Rome, both as yarn and as finished cloth, but the author of the *Periplus (Circumnavigation of the Erythraean Sea),* written sometime between A.D. 50 and 130, makes it clear that the raw material was imported into India from China. Wild silks had been woven in India before this, but there is no proof that the domesticated silkworm was introduced into India from China before the medieval period.

Although there is no specific mention of dyed cottons in the *Periplus,* excavations at the site of the Indo-Roman trading station at Arikamedu, near Pondicherry, have revealed that large-scale dyeing operations were undertaken in the immediate vicinity of the port. Further proof that the Indian dyer was already famous in the Roman world for his skill is indicated by a reference in St. Jerome's 4th-century Latin translation of the Bible, Job being made to say that wisdom is so enduring that it "may not be compared with the dyed colours of India." There is also evidence that by the 8th century A.D. Indian dyed cottons were known in England, for Bede records in his *Life of St. Cuthbert* that the Synod of Clovesho forbade priests to wear clothes *tinctae Indiae coloribus* ("dyed with Indian colours").

Indian textiles of the medieval period can be studied in some detail from the Ajanta wall paintings (particularly those attributed to the 6th century A.D.). Apart from embroidery, at least four distinct techniques can be identified: *bandhana,* or ordinary tie-and-dye work; double tied-resist dyeing *(ikat);* brocading; and fine muslin weaving.

From the 12th century onward Indian dyed cottons were exported in bulk to Egypt, and many such pieces have been recovered from the sites of old urban rubbish dumps, especially at Al Fustat (Misr al Qadimah), the exceptionally dry climate accounting for their preservation. 'These are the oldest Indian patterned fabrics surviving

From earliest times there have been two distinct weaving traditions in India. The first was the domestic one, practised in every village into the 20th century and mainly concerned with meeting local needs. The second was the more specialized tradition of commodity production, mainly concentrated in or near market towns and characterized by guild organization. Whereas in the oldest literary records (such as the Rigveda) the weaver is feminine, the development of commodity production in the 1st millennium B.C. seems to have established professional weaving as an exclusively male occupation. During the 2.000 years between the Roman period and the decline of the handloom industry in the 20th century the main areas of commodity production remained the same. They are described in the *Periplus* in much the same terms as they were described by travelers of the 17th and 18th centuries. These main areas were: the west of the subcontinent with Gujarat, Sind and Rajasthan as the focus; south India, comprising the Coromandel coast as it used to be known, stretching from the Kistna delta to Point Calimere; and the lower Ganges valley, between Varanasi (Benares) and the Delta. The main reason for this disposition of the industry was of course geographical. Each of the three areas could offer ports suitable for foreign shipping, and also comparative ease of inland communication.

From the 16th century onward Indian pattern and design were much influenced by Persia. This influence reached India in the first place through Islamic court fashion; but by the 17th century it had spread to the villages. Many of the sprigged patterns and floral diapers so characteristic of the Indian block printer's art of later centuries were derived from Safawid Persia. The history of mordant printing with blocks (as opposed to the application of mordants by brush) is complicated, and it is not possible to establish with certainty that the former technique was practised in India before the period of Islamic influence. The balance of available evidence suggests that the technique of mordant printing with blocks reached India about the 17th century from Turkey.

One of the oldest traditional techniques of textile decoration and one that has been very widely practised in India is *bandhana.* Portions of a silk or cotton cloth are tied tightly with wax thread before the whole cloth is dipped in a dye vat; the threads are afterward untied. the parts so protected being left uncoloured.

The technique of *ikat* or double-resist dyeing, in which warp and woof are dyed separately by the tie-and-dye process before weaving. was practised in Orissa and the Deccan as well as in Gujarat. At Patan, in Gujarat, which produced the finest work of this kind in silk, such fabrics, known as *patolas,* were used especially as marriage saris. They were also extensively exported to southeast Asia from the 12th century onward. giving rise to many imitations in those countries.

The main centres of brocade weaving were Varanasi, Ahmedabad and the Deccan. The brocades for which India has been especially famed are woven silks in which part of the pattern is distinct from or supplementary to the wefts. Those woven in pure silk are called *amrus,* those with gold or silver thread in addition to silk, *kimkhabs* (Anglo-Indian, kincob).

Another form of brocading for which India was especially famous is the cashmere shawl. In this the technique corresponds to what in Europe would be called the twill-tapestry method. Coloured wefts are inserted by means of floating wooden bobbins on a simple loom. The weft threads alone form the pattern and do not run the full width of the cloth. being woven back and forth round the warp threads only where each particular colour is needed. The finest cashmere shawls were made of *asli tus,* the fleece frorn the underbelly of a particular species of wild mountain goat; the majority of shawls, however, were woven with the fleece of domestic goats, usually mixed with wool. The origins of the cashmere industry are obscure but can be traced back at least to the 15th century. Cashmere shawls were extremely fashionable in Europe between 1780 and 1880, during which period many European imitations were made on both drawlooms and Jacquard looms, especially at Norwich (Eng.) and Paisley (Scot.) and at various centres in France. The European imitation is always distinguishable from a cashmere original by the fact that in the latter the weft threads are inserted in the tapestry method and only for that portion of the required colour. not for the full width of the cloth.

Between 1600 and 1800 silk and cotton textiles were exported in large quantities from India to Europe mainly through the agency of the Dutch, English and French East India companies. The three classes of piece goods most in demand for this trade were plain-woven cottons (sold in competition with European linen), hand-painted cottons or chintzes (much coveted in Europe because of the brightness and permanence of their colours) and silk or mixed silk and cotton fabrics mainly used as dress materials. These goods were usually commissioned according to patterns sent out from Europe in the first place, but in the process of copying or adaptation the Indian craftsmen often infused an exotic spirit into the design's that actually increased their appeal in Europe. The importance of this trade is testified by the number of Indian textile terms assimilated into the English language: chintz, palampore, pajama, seersucker, dungaree, shawl and so on.

TEXTILES, HOUSEHOLD. This article describes the kinds of fibres and fabrics used in table linen. bed linen, tonels and kitchen cloths; offerssuggestions for selecting and buying such articles; and makes recommendations for their care, including laundering. For their manufacture see WEAVING and articles on the different fabrics. such as DAMASK and LINEN AND LINEN MANUFACTURES. See also EMBROIDERY; LACE and TEXTILES.

TABLE LINEN

Types of Fibre. — Linen is traditionally the most desirable of fibres for table coverings. Until the early part of the 20th century, in fact, they were almost invariably made from it. thus giving rise to the generic term table linen. Linen is very hard-wearing and is unaffected by the correct use of reagents for the removal of food stains and normal high-temperature laundering. If fully bleached during manufacture, it retains its whiteness during years of usage without recourse to an oxidizing bleach. and, if stiffened and well ironed. it has a crispness and sheen which contributes much to the attractiveness of a well-appointed table. Linens represent beauty and luxury. and so well do they wear that they are often passed from one generation to the next as cherished heirlooms. Cotton also is suitable for use in table-cloths. as it can be laundered at high temperatures and is not harmed by the correct use of the normal stain-removing agents, but it does not have quite the crispness or sheen of linen. The mercerization process does, however: increase the sheen. Cotton will readily take bright dyes which are fast to washing, so that gay-coloured patterned tablecloths can be manufactured.

Viscose rayon is a versatile fibre that can be finished to simulate linen or cotton and is less expensive than either. It can be treated to withstand normal washing but it is not so resistant to stain-removal agents as linen or cotton. It has a soft handle and therefore drapes easily, and it can be dyed to give lasting. pleasing pastel shades for coloured or patterned cloths. The chief virtues of such man-made fibres as nylon, Orlon and Dacron (Terylene) for table coverings are their ease of laundering and low moisture absorption. Cloths made from them require only washing and drying. without further finishing. and food stains can usually be removed very readily since they are not absorbed. Like rayon, these man-made fibres can be treated during manufacture so that the finished product may have the appearance of either cotton or linen. Oilcloths, pyroxylin covers and those manufactured from plastics of the polyethylene and polyvinyl types offer at low cost table coverings that are resistant to moisture and to soiling (but not to heat) and can be cleaned by wiping. Paper tablecloths are also on the market.

Types of Fabric. — Damasks remain the aristocrat of table linens and are usually made from linen fibres, but cotton, rayon. man-made fibres and blends or mixtures of these with each other or with linen are sometimes used. Damask is a single-structure fabric woven on a Jacquard loom. The designs. which may be geometrical or floral, are obtained by the use of long floats on a satin or twill background. Damask may be single or double. Only high-quality long fibres are used for spinning the thread from which double damask is made and this, together with the long floats, leads to a closely woven fabric with a high sheen, having more yarns per square inch than single damask. In single damask, the proportion of weft to warp threads is roughly equal, but in double there are more weft than warp, often in the proportion of three weft to two warp. Single damask usually has less than 160 threads per square inch whereas double has more than 170 per square inch.

Ginghams are medium- and lightweight cotton fabrics woven with dyed yarns to produce striped or checked effects. Cloths made of seersucker. a crinkled cotton fabric that does not require ironing, are usually in brightly coloured stripes or checks.

Small cloths or cloths for special occasions may be embroidered either by hand or by machine. Hand-embroidered cloths from many countries. including China. Italy. Puerto Rico, Spain and Switzerland, are on the market. The embroidery may be in either cotton or linen thread to match the fibre of the cloth or may be in coloured threads, as is often the case with Chinese embroidered cloths. Special cloths may also be made from lace or have lace insertion. Originally lace was handmade but is now mostly machine-made. The thread used for making it may be either linen or cotton and many of the designs are traditional.

Oilcloths for table use consist of a lightweight cotton material which has a waterproof coating on one side and a backing of a plain loosely woven cotton cloth. This is then coated with several layers of a vegetable oil mixed with colour pigments and fillers. Afterward the surface may be finished to give either a dull or shiny appearance and may be printed or embossed. To give a soft undersurface. the backing is often napped or brushed. Pyroxylin covers are similar to oilcloths, but the cellulose coating produces a more flexible and durable surface and there is little tendency for pyroxylin to become brittle and crack, as does oilcloth.

Plastics are nonwoven materials made without yarns. Sheets are formed by molding, extruding and calendering. Decoration of the surfaces may be accomplished by printing, embossing: embroidery and chemical treatment; these modifications make interesting and attractive textures with patterns that simulate woven fabrics. Additional strength and increased versatility can be obtained by the use of fabric backings bonded to the plastic. Paper fabrics for use as tablecloths are usually made by a bonding process in which a cross-laid web of thermoplastic fibres is laminated on either side with high wet-strength cellulose webbing.

Table napkins are manufactured from the same fibres and woven into fabrics similar to those used for tablecloths. Materials suitable for place mats include, in addition to the fabrics named, terry cloth. cork and straw.

Selection of Table Linen. — Use or purpose is of primary importance in selecting table linen. It is customary to use white linen damask tablecloths for formal dinners and banquets, while pastel-shade damasks are suitable for luncheons, suppers and informal entertaining in the home. Lace. embroidered and other fancy linen cloths are suitable for afternoon tea. Breakfast cloths and those used for informal supper parties are usually bright in colour, often of gingham or seersucker. Oilcloths, pyroxylin and plastic are popular for table covers in kitchens and summer cottages. Clear, lightweight plastic may be placed over plain woven cotton or rayon cloths to serve as a protective cover. Decorated plastic and plastic-coated materials are often used as table covers for informal service.

For most occasions table napkins are chosen to match the cloth, in fibre content. weave and colour. For informal parties, contrasting napkins in gay colours are often used.

In selecting place mats, colours should be chosen to complement the wood of the table surface and the fabric or other material should suit the degree of formality of the occasion.

Size. — The size of the cloth for a particular table is determined by measuring the width and length of the table and adding on 20–36 in. to each figure to allow for an overhang (with an additional allowance if the material is not preshrunk). Tablecloths and napkins are made in a number of standard sizes. Table mats should be of a convenient size and shape to fit the table and. if place mats are chosen, they should be sufficiently large to hold a complete well-spaced place setting.

Quality and Durability. — The staple or average length of the fibres from which yarn has been spun is of fundamental importance, for the longer the staple. the better the wearing qualities of the fabric. The best-quality linen cloths are made from the long flax fibres called line. for the yarns will be uniform throughout their length and have a high lustre. The presence of short flax fibres called tow is indicated by the appearance of thick uneven yarns in the fabric. which will give a fuzzy surface when rubbed. The staple length of different kinds of cotton varies considerably. but for damask cloths only the longest, strongest and finest fibres can be used satisfactorily.

When comparing quality, yarn number or size and fabric count or number of yarns per square inch should be the leading basis for selection. Generally, fabrics containing the larger-sized yarns have a lower count. The relationship of yarn number and fabric count can be readily seen when one visualizes that the finer the yarns the closer they may be woven. All other factors being equal, the greater the number of warp or lengthwise yarns and weft or filling yarns, the stronger the fabric. Compactness of construction is especially important in damasks: the long floats formed as a result of the production of intricate patterns on the Jacquard loom may adversely affect the wearing quality of the fabric, if not closely battened during weaving. A good single damask is more durable than, and therefore preferable to, a medium- or low-grade double damask. A poor-quality cloth is sometimes treated with an excess of size to give the appearance of a compact and closely woven fabric. This may be determined by rubbing two surfaces of the fabric together; if too much filler has been used. a white. powdery substance will be apparent, In good quality fabrics only a minimum amount of sizing need be added to produce a smooth appearance, and therefore little powdery residue should be deposited.

Finishing techniques are also important. The durability of cotton damask is greatly enhanced when the yarns have been treated with a permanent antilint finish which enables the cotton to retain the smooth handle, characteristic of damask, through the many launderings which the cloth must of necessity withstand. If the item is coloured or printed, the kind of dyestuff and its method of application are of major importance. As a class, vat dyestuffs are considered to ha e the highest degree of colour fastness when properly applied. The dyes used on table linen must, of course, be those that are fast to washing. and fastness to light and to dry cleaning are also extremely desirable. Hems should be even and sewn with short, regularly spaced stitches. A plain hem is more serviceable than one hemstitched either by hand or machine.

How well household textiles wear depends to a large extent on how well they launder, and this in turn depends on the fibre, type of construction, colour fastness and presence of special finishes. Linen and cotton are outstanding in this respect: the fibres are stronger wet than dry and tlferefore resist satisfactorily any wearing action in the washing; they can withstand high-temperature washing and are unaffected by the correct use of heavy-duty or built detergents, so that it is possible to thoroughly remove soil from them. The man-made fibres such as rayon have properties similar to the raw materials from which they were manufactured. but. as the fibrous polymers are partly degraded in their reformation during manufacture: the man-made fibres show increased sensitivity to laundering conditions. The synthetic fibres such as nylon are hydrophobic (water-repellent) by nature; therefore soil does not penetrate easily into the fibres and food stains are easily removed by laundering. Construction is also important; in general, the smoother, firmer and closer the weave, the more stable the fabric. Some fabrics in fancy or loose weaves cannot be laundered satisfactorily when made from natural fibres because the material tends to lose its shape, but with the use of man-made fibres this difficulty is overcome. Special finishes, such as those to minimize shrinkage, reduce static effects and increase resilience. may necessitate slight modifications in washing methods.

Cost. — This varies with fibre content, quality of fabric, intricacy of design, special decorations and size. The most expensive cloths are made of linen. In damasks, the more intricate the design, the higher the cost. and damask table napkins and mats with an all-over design are cheaper than those with a central pattern. Hand-made lace and hand-embroidered cloths are often the most expensive; hand work such as appliqué and lace insertions also adds to the price oi the finished item. It may be assumed that cost increases with the size of the cloth. Though the initial cost of linen table coverings and napkins is generally greater than that for other fibres. the service to be expected from such fabrics when properly constructed and woven makes them an economically wise choice. Cotton, rayon and the man-made fibres alone or in blends are attractive and less expensive materials.

Cave *and* Storage. — Table linen well-laundered and carefully stored will have a long life and remain in good condition. If the cloth or napkin becomes stained or spotted during use, it is advisable, when possible, to remove these stains before they have had time to dry into the fabric. The stains normally should be treated with the appropriate reagent but where dealt with immediately water is ofteh all that is necessary. Table linen is laundered by the method suitable for the fabric from which the article is made. White linen damask cloths can be washed at high temperatures up to 160" F. with a fair degree of friction, whereas rayon cloths should not be washed at temperatures exceeding 120° F. with a minimum amount of friction; *i.e.,* shortest washing time. All table linen should be rinsed until the rinsing water is clear, and cotton and linen damasks should be stiffened either by the use of starch or by the use of a synthetic resin. White cloths should be ironed on the right side to give as high a gloss as possible; any appliqué or embroidery should then be raised after ironing by pressing on the wrong side on a padded surface. It is customary to fold table linen in screen folds. large cloths in four and table napkins in three each way, small cloths in whatever way is most suitable for use and storage. It is desirable to have as few folds as is consistent with ease of storage and handling, as the fewer the folds the neater the appearance of the cloth on the table. Table linen should be stored on shelves in cupboards or closets. The storage place should be dark, cool and airy to prevent yellowing and deterioration of the fabric. A place that is warm, such as the top shelf of an airing cupboard, is not suitable for storing linen for any length of time. It is better to have several shelves narrowly spaced rather than few with wide spacings, as shallow piles of linen make for a minimum amount of creasing. Though it is most usual to store table linen in piles folded and flat. fewer creases will occur if cloths are folded only one way and then lightly rolled around cardboard or paper tubes and stored in rolls. Tray and teacart cloths and table runners also can be stored satisfactorily in this way. If linens are to be stored for a long time all starch and sizing should be washed out carefully and the articles thoroughly dried before being put away, to minimize the danger of damage by mildew.

Table Pads. — Used underneath a large cloth. table pads protect the polished wooden surface of the table. help make for quieter serving and often add to the draping qualities of the cloth. The pad may be made of felt alone or of felt with a waterproof top surface. The pad may be of the exact size of the table or. if sufficiently soft to drape, may have an overhang. If the table is large it may be more convenient to have pads that fold in sections, as these are easier both to handle and to store.

BED LINEN AND COVERINGS

Bedspreads or Covers. — These should be chosen to complement the style and colour of the room furnishings. There are two main kinds. (1) those that are merely a rectangular piece of material large enough to cover the bed and hang down to nearly floor level at the sides (and foot, if there is no end board), usually called bedspreads: and (2) those that are tailored, known as fitted bedcovers Spreads and covers should be colour-fast not only to washing and dry cleaning but also to light; lint-free; and crease-resistant.

Spreads may be made from all types of fibres and fabrics and may be woven or tufted. The two major divisions of woven bedspreads are known as Jacquard woven and non-Jacquard woven. Jacquard designs are generally more elaborate as they are produced on the versatile Jacquard loom: patterns include the quilted, raised, stitched and flat types. Plain and crimped constructions are included in the non-Jacquard woven category. All types of fibres and yarns can be used but in every case the weave should be firm and compact.

Tufted fabrics used for spreads, designated by such terms as chenille. candlewick and hobnail. are made by inserting yarn into a plain-woven ground material and slipping the loops to form tufts of short fluffy yarns. Tufts may be spaced intermittently or arranged in uninterrupted rows. A good-quality tufted fabric has a closely woven background and firmly secured pile. In buying a tufted spread it is important to see that the pile is lint-free.

Fitted covers may also be made from all types of fibres and weaves. but they are rarely tufted. The material is usually either plain in colour or bears an allover design which will lend itself to cutting and joining with little waste for pattern matching. These covers can be bought ready-made in standard sizes or made to fit a particular bed.

Blankets. — Made from soft yarns which can be heavily teased or brushed up so that a layer of air is entrapped on either side of the fabric, blankets provide maximum warmth with minimum weight. Wool is the traditional fibre and has many properties that make it highly satisfactory for this use. Though usually the highest in initial cost, a good blanket, *i.e.,* one made with long, strong fibres,. a high tensile strength, a compact weave and a strong nap. will give years of service. A high-quality all-wool blanket is soft to handle. fluffy in texture and light in weight.

Fibres other than wool may be used alone. or in blends with each other. or with wool. each giving special qualities designed for a specific purpose. Cotton is desirable for summer coverings, as it is cooler, easier to wash, less expensive and not attacked by moths. A wool content of 25% or more gives slightly more warmth than an all-cotton blanket. Orlon blanketing is lightweight. insect-resistant, retains heat and is machine-washable (as are wool and Orlon blends). Acrilan produces a very warm material that has exceedingly good shrinkage control and is naturally moth- and mildew-resistant. Proper construction has reduced the shedding problem and with adequate care piling and wrinkling may be kept to a minimum. Dynel received some use in bedding but is not highly satisfactory as it tends to shed and is very heat-sensitive. Rayon may be found alone or in blends in low-priced blankets, but care is necessary in laundering because rayon tends to lose some of its strength when wet. Some luxury blankets contain cashmere, camel's hair and Kashmir or goat hair.

Electric blankets provide uniform. controlled warmth without much weight, a single covering taking the place of two or three conventional blankets. In some, dual controls permit adjustment of temperatures to individual preference in the double-bed size. While performance is not affected by wool content, the presence of wool results in a more luxurious nap, better appearance and increased durability. Safety is assured if the wiring carries Underwriters' Laboratories Inc. approval or other specifications. Electric sheets are lighter and are used over the regular top sheet. Comforters or quilts that are electrically controlled are also available. Instructions as to the care of the electric blanket are given at the time of purchase and should be followed.

Comforters, Eider Downs and Quilts. — These may be chosen for their attractiveness but they are also very practical, adding greatly to warmth with very little weight increase. Often they serve as bedspreads or coverlets by day. They are made in a wide range of fabrics, which should be closely woven to keep in the filling. Coverings of comforters or eider downs may be of cotton, acetate or rayon satin, taffeta, brocade and *matelassé*. Even quilting assures even distribution of the filling, which may be of down, feathers, wool: cotton, acetate or of nylon, Dacron and Acrilan. The beauty of the covers may be enhanced by scroll stitching. A cap end at the foot of fitted satin comforters or eider downs helps to hold them in place, as also do drapes at the side which can be tucked in. Backings of cotton flannelette or other cotton fabrics reduce the tendency for them to slip off during sleep. In the care of these articles the outer covers as well as the inner fillings should be considered. Down. feather and wool fillings are usually dry-cleaned while the man-made fabrics have the advantage of being washable. Washable coverings must be resistant to fading from laundering and light. Quilts are generally of solid colour or printed cotton fabrics and are employed when less warmth than that provided by a comforter or eider down is desired.

Pillowcases and Sheets. — To determine quality when buying cotton or linen sheets, one should hold them up to the light: in a good-quality sheet the light shows through evenly. indicating that the yarn is of even thickness throughout; a poor-quality sheet will show light and dark patches. Sheets should be tested for excess sizing in the same way as table linen. Some sheets are manufactured with more threads to the inch down the centre strip. the area of greatest wear. than at the sides. The selvages should be strong and woven with extra yarns to give a tapelike effect. The size and finish of the hems should also be examined. The sheets should have been torn to size and not cut, so that they are on the straight of the thread and have square corners. (This can be determined by a close look at the hems.) Nylon blended with cotton will give increased wearing qualities as it increases the resistance to abrasion. Fibre and cotton blends. on the other hand. while increasing the comfort value of the sheets, reduce the wearing qualities. Drip-dry finishes applied to cotton sheets reduce the need for ironing but tend to reduce abrasion resistance and to increase both the protein-stain retention and the chlorine retention.

Sheets made entirely of nylon or Dacron (Terylene) are easy to launder. but the slipperiness of these fibres and their low moisture absorption are disadvantages that should be recognized. Some knitted nylon sheets are brushed on one side to give a raised pile and are therefore more comfortable.

The width of the sheet should be equal to the width of the bed plus 30 in.. to give a satisfactory tuck. A standard length is 108 in. before hemming. Fitted styles (with shaped corners'i are easy to launder, and the bottom sheet in particular requires no ironing. To ensure proper fit. the precise mattress measurements are necessary. Pilloncases should be at least one inch wider than the pillow. and are usually chosen to match the sheets in fibre content, colour and weave.

TOWELS

Terry Cloth Towels.—This type of material is most commonly used in bath towels and face cloths because of its softness and high degree of moisture absorption. It is made from a looped warp pile fabric. the loops being formed on one or on both sides by means of a special system of interlacing the yarns. Two sets of warp yarns are used, one of which is held tight and the other loose to form loops which are left uncut. The number of loops varies from 204 to 366 per square inch.

Most terry towels are made from cotton because of its durability and ability to absorb and hold moisture. The grade of cotton fibre and the way the yarn is twisted and spun are basic factors in satisfactory service. The uniformity of the underweave and its compactness determine the resistance of the towel to wear and are an accurate measure of its strength. This property is easily distinguished by holding the towel to the light: small, evenly distributed pinpoints of light are indicative of a regularly woven fabric; a close, tight weave has the ability to hold more of the absorbent loops and to hold them more securely. An indication of the nature of the foundation fabric can be seen from looking at the areas without loops near the hems or borders. Plain or basket weaves are less durable than a twill weave. A compact construction with a balanced count is essential for good wear.

The absorbency depends on the number of loops in the pile. their length and quality. The thicker the pile, the greater the surface; thus the higher the absorption value of the towel. A really good cloth is said to soak up approximately five times its weight of water. For maximum absorbency yarns should be loosely twisted and the loops formed from them of reasonable length. Texture ranges irom soft to hard, but whatever the texture a durable towel will feel firm and resilient to the touch. Selvages should be finished to give a firm edge and the weave should be very close. Hems should be sewn with small, even stitches and on the straight of the thread.

Terry towels are made in a variety of sizes to suit personal taste and purpose. Surfaces may be plain or sculptured, but elaborate designs reduce absorbency by limiting the number of loops in the pile. Embroidered effects in colour, dobby or Jacquard woven borders and the use of metalized yarns give high style characteristics to these articles. Colours in toweling range from pastel to dark shades.

Other Fabrics.—Textured fabrics, which as a group are less absorbent than terry cloth, serve specific purposes as personal and household toweling materials. Huckaback, generally known as huck. is a durable fabric with a rough-textured surface and a pattern produced by long warp yarn floats. Usually made of linen. it is an absorbenf material and is used for hand, face and guest towels. Crash is a coarse fabric with a rough, irregular surface obtained by weaving thick, uneven yarns. It is manufactured in different weights, the heavier type being used for dish towels and the lighter weight for glass, face and guest towels. Glass toweling, a plain weave linen fabric. is similar to crash but of light weight and construction. The fine yarns prevent linting, but the smoothness essential for polishing glassware reduces the rate of moisture absorption. The Jacquard woven or damask fabrics are used in face and guest towels. The quality of the linen yarns is similar to that found in tablecloths and the same qualifications apply. Fibres such as cotton or rayon map also be present. to lower the cost and to increase lustre. Bird's-eye. woven on a dobby loom with a small diamond pattern and a dot or eye in the centre, has heavy, loosely twisted filling yarns to make it more absorbent. It is used for dish towels. Honeycomb. also called waffle cloth, is similar to bird's-eye. the rough surface resembling the cells of a honeycomb, and is highly absorbent.

LAUNDERING OF FABRICS

Most fabrics can be laundered satisfactorily, but in doubtful cases some warm water should be tried on a small area of the material in the least conspicuous place. The material should then be inspected to see if there is any shrinkage, alteration in colour or general appearance. both in the wet state and after complete drying out. before immersing the whole article in water. Washable fabrics should be laundered frequently so that the dirt can be removed from them with the minimum amount of friction. The actual method of laundering an article depends more on the nature of the fibres and fabric construction, and on any finish given to the fabric after weaving, than on the type of article. For example, a blanket and a cardigan both made of wool should receive similar treatment during laundering. whereas the method of laundering a drip-dry cotton sheet should be different from that of a cotton sheet that has not been so finished.

Processes.—*Preliminary Treatment.*—Articles should be shaken or brushed to remove any loose dust or fluff before they are put into water. This is particularly important in the case of such articles as curtains, blankets and bedspreads, which are not washed every week. Double articles such as pillowcases and cushion covers should be turned inside out and the seams and corners brushed, as should pockets, trouser turnups and the inside folds of pleats. Any known stains which are not likely to be removed by washing should be treated and removed at this stage.

Soaking or Steeping.—Articles that are going to be hand-washed are often first steeped for one or two hours. This process does remove some water-soluble dirt and loosens the rest, so that the washing process is less arduous. All white and fast-coloured linens and cottons and some of the man-made fibres such as nylon and Terylene can be put to steep to facilitate dirt removal. If there are no protein stains present in the fabrics. warm water should be used, and the addition of a detergent will increase the amount of dirt removed by soaking. The articles should be opened out and there should be sufficient water to allow free movement. After steeping and before washing. as much water as possible should be removed from the articles.

Washing.—This may be done by hand or by machine. The temperature of the water and the degree of friction employed (the length of time allowed in the machine) depends on the nature of the fabric. For white cottons and linens. high temperatures and maximum wash time can be allowed, for white nylon and Terylene, moderately high temperatures and a fair degree of friction; for woolens the temperature should not exceed 104° F. and the amount of friction should be reduced to a minimum. For fugitive colours salt added to the wash water may reduce bleeding, but a synthetic detergent must then be used since soap is not soluble in salt solutions. Collars and cuffs and other parts of articles where there is a high degree of local soiling should be treated by rubbing or scrubbing with detergent before starting the general wash.

Rinsing.—Efficient rinsing is as important as adequate washing to ensure that there is no dirt left in the fabric. During the rinsing process the water should be changed frequently and the process continued until the water is clear.

Wringing.—Water can be removed from fabrics by hand wringing, hand squeezing. rolling in a dry cloth, passing between rubber rollers or by centrifugal force in a spin dryer. The degree of force used, or the length of time allowed in the spin dryer, depends on the nature of the fabric. Cotton and linen, unless specially finished. can be passed through a wringer most satisfactorily, but knitted woolen goods should be urapped in a cloth before being put through rollers to avoid stretching and undue strain on the wet wool Articles made from many of the man-made fibres are best rolled in a dry terry towel to remove surface water, so that they will not drip when hung up to dry. Passing them through a wringer may cause creases which are difficult to remove. If they are put in a spin dryer only the minimum time should be alloned. Drip-dry articles should not of course be squeezed in any way and neither should articles made from fabrics that retain creases made in the wet state, such as some forms of rayon taffeta.

Boiling.—If articles are boiled, the process should come after washing and rinsing, and best results are obtained if they are put into the boiler when the water is at a low temperature, allowed to come up to boil and held at boiling point for 5–20 minutes.

Stiffening.—Some household linen and personal articles may require stiffening after washing to give satisfaction in use and wear. The most usual stiffening agent used in laundrywork is rice starch. The degree of stiffness obtained after ironing depends on the thickness of the yarn and the closeness of the weave of the fabric, as well as on the strength of the starch solution used. This treatment has to be applied every time the article is washed. There are some commercial preparations on the market based on thermoplastic resins which give a stiffness lasting through several washes and which are usually highly satisfactory. For silk and many types of man-made fibres, starch is not a satisfactory method of stiffening and gum solution should be used.

When using any of the stiffening agents, the article to be stiffened should be damp and should be opened out, completely immersed in the solution and squeezed in it to ensure even distribution. The article should then be wrung to remove as much water as possible before being put to dry.

Drying.—All articles should be dried evenly and in such a way as to give as few creases as possible. If they are to be finished afterward by ironing, they should not be allowed to become completely dry but the process should be stopped when they are at the correct moisture content for finishing for the fabric from which they are made.

Finishing.—When ironing is necessary, the temperature depends on the fabric; for linen the sole plate of the iron should be about 450° F., for nylon 250° F. Dark fabrics are usually ironed on the wrong side to prevent shiny patches on the right side. Embroidery should be raised by firm pressing from the wrong side over a soft pad. For looped or napped surfaces, brushing up against the pile may give the best result, but velvet pile should be raised by steaming.

Airing.—All articles should be thoroughly aired before storing. Household linens are aired folded, but garments are usually placed on hangers.

Garments Not Suitable for Washing.—Some garments that cannot be washed satisfactorily may be sponged and pressed at home in-between commercial dry cleanings. Any loose dust or fluff should be removed by brushing. Grease spots can be removed by the careful application of any of the solvents on the market: care must be taken not to cause ring marks and best results are usually obtained by wiping a large area of the garment with a cloth moistened with the solvent before treating localized spots. When pressing, shiny marks on the right side can be avoided by pressing on the wrong side, using a damp cloth between the sole plate of the iron and the garment or, in some cases, by the use of a steam iron.

TEXTUAL CRITICISM, a general term for the application of logical method to analyzing the relationship between preserved and inferential forms of a text, followed by the application of various techniques, including critical judgment, designed to establish what will ordinarily be the single definitive form of the text.

This article is concerned with general principles of textual criticism, particularly as they apply to the study of literature. For a related discussion, *see* BIBLIOGRAPHY: *Textual Bibliography.* For a detailed consideration of the critical problems posed by variant manuscript texts of the Bible and variant codices of the Old and New Testaments, *see* BIBLE and BIBLE, TRANSLATIONS OF.

CLASSIFICATION OF TEXTS

By "text" is meant a series of word forms inscribed in a language known, more or less, to the inquirer, and assumed to have a meaning that has been or can be ascertained. Thus, decipherment or recovery of meaning from inscriptions in lost tongues is not textual criticism. Texts may be preserved in autograph or in transmitted form. Transmission may be as close as the immediate copy of an autograph, or as distant as copies of copies to any degree; moreover, texts may be transmitted in written or in printed form (each generally defined) or in both. "Transmitted" texts share only one characteristic: their preserved forms are not written out by the author in any manner. When there is mixture, the transmitted and autograph parts are to be distinguished. In some few cases the problem of oral transmission will arise to complicate the usual written or printed line of transmission.

Autograph v. Transmitted Texts.—In its purest sense, "autograph" has traditionally been applied only to a document in the writing of the author. Some critics have argued that whatever has been attested or revised by the author, though in the writing of another, may also be included under autograph; but this position is impractical. If a copy made by an intermediary could be assumed always to be absolutely exact, or the review of the author that of a strict and accurate collator so that his attestation or revision carried the guarantee that in no respect did the whole derived document vary from its original in his own writing, the broader definition might be acceptable. But common experience shows that neither requirement is ordinarily met, and hence appro~ by an author of a nonautograph copy can under no circumstances bestow on that copy the authority inherent in a true autograph original; nor can authorial revision extend specific autograph authority further than the autograph revisions themselves.

In fact, textual criticism is accustomed to treat questions of authority with considerable literalness, and does not confuse what is authoritative with what is necessarily right. Most autograph is likely to contain slips and errors that are wrong by any absolute standard and would be acknowledged as wrong by the author if they were pointed out to him. On the other hand, lacking such specific acknowledgment, a critic has no option but to view autograph errors as authoritative, since no higher authority can be envisaged than the author; but this concept does not prevent their critical correction. Correspondingly, when autograph is not preserved, the form of the text that lies nearest in genetic relationship to the lost original becomes the paramount authority; and its errors must be esteemed as part of the only authority that can be recognized, even though the critic should quite naturally correct them. The act of correction applied to the most authoritative document that is preserved must always in a sense controvert authority. There is no harm in this principle once it is recognized that authority and correctness are not necessarily synonymous. Under these circumstances, correction, but never revision, can be made to a more authoritative from a less authoritative state of the text, or independently by an editor.

Before the invention of the typewriter no difficulty was experienced in demonstrating that a document was autograph, provided that a sufficient number of undoubted specimens of the author's handwriting were preserved for comparison. However, if writing were to be defined narrowly as handwriting, an author composing directly on the typewriter would produce no document that could be admitted as autograph. This situation is anomalous, for whether an author manipulates a stylus of some variety or taps marked keys (or, indeed, records his words electronically on magnetized tape), he has himself produced his original, and no human intermediary has entered until a person other than the writer makes a copy. Autograph, therefore, must be interpreted to include documents produced in the originator's own handwriting, typewriting, engraving or recorded voice—or any of the usual variations of these mechanical processes. The difficulty created in demonstrating actual production by the originator does not affect a case for autograph; indeed, the unevenness with which typewriter keys are struck may offer evidence to the scientific investigator as demonstrable as letter formations in script.

Determination of Original Copy or copies.—For all practical purposes the designation of a text as transmitted defines it as a nonauthorial copy; its degree of distance from the autograph original does not come in question. However, "original" must be taken only as a general term, for a preserved autograph may not represent the originally composed document but a transcript by the author, either as part of an act of further composition (which could include revision) or else as an act of producing a fair copy of the original document. Under few circumstances may a critic assume that the act of revision is absent from the production of an authorial fair copy, although it would be stretching the term to imply major rewriting rather than relatively minor polishing during what is generally a mechanical process. However. until an author has a fair copy (either autograph or transmitted) which satisfies him, the act of composition scarcely can be concluded. Thus several originals of varying form and date may be preserved in autograph, and variant transmitted texts may contain true authorial revisions.

The slippery nature of an original document must be emphasized, for critical writing has vastly oversimplified the problem. For example, a standard definition asserts that the aim of the textual critic is the restoration of a text, as far as possible, to its original form, if by "original form" is understood "the form intended by the author." This ignores the fact that at different times or for different purposes an author may intend a composition to take various forms, each of which will necessarily have its original. Even final intention, supposing it could always be determined when more than revision for literary excellence is present, may be an insufficient criterion. If the version of a play as cut and rewritten during rehearsals is printed, the author will have approved it as printed in its acted form, but if he had had an option he might have preferred to print the initial, more literary form. Revisions may be undertaken for various motives that do not meet with universal approbation. Such authors as William Wordsworth and Walt Whitman may in later years so alter their earliest printed originals as to achieve forms of their poems that call for parallel-text editions rather than the rejection (as the authors intended) of the earlier original in favour of the one that certainly represented their final intentions. All alterations are not necessarily connected with a desire for literary perfection; changes in political beliefs or a desire to moderate too frank autobiographical details may operate. Moreover, it does not necessarily follow that critics will always agree that an author's purely literary revisions are superior to his earlier version.

At any distance authorial intention is usually quite impossible to determine for the details of a text, and cannot be used as part of any scientific definition. If the literary and then the stage versions of an Elizabethan play are both preserved, as with John Fletcher and Philip Massinger's *Bloody Brother,* no later critic in the absence of collateral evidence can estimate the author's intention concerning his relative approval or disapproval of the two different texts. If this is so, it is clear that a critic would be greatly misguided to estimate intention or presumed original form if only one of the two variant forms had been preserved, and the original existence of the other was either not known or merely to be inferred. with no opportunity to reconstruct its forever lost details. Thus a critic must use the term "original" form always with a recognition that the word is loose in substance; and a definition of textual criticism must hedge on its characteristics.

For example, all that can be known, in any strictly authoritative sense, about a lost original must ultimately derive from extant transcripts. As a result. the original can have no recoverable characteristics not found in the preserved transcripts deriving from it. The technical original must be thought of only as the last version of the text produced before the transcription of the extant manuscripts or prints. and their ancestors, began. In a textual-critical sense, therefore, this original may not be, and often is not the author's original, but instead some transmitted copy of that other original which is forever out of reach. Any number of lost versions may have intervened between the textual original and the author's lost original. Thus it is quite false to believe that the critic's purpose in determining the ancestor of the earliest preserved forms of the text is "to recover the author's original." Moreover. it is false thinking if what is called the archetype in Lachmannian textual criticism (see LACHMANN. KARL KONRAD FRIEDRICH WILHELM) is confused with the author's lost original instead of being identified neutrally as the manuscript (or print), inferential or extant, and presumed to be single unless proved otherwise, from which all other extant and inferential copies are derived. In some cases this technical original may be the author's original; in most, however, it will be some intermediate transcript of an author's forever lost autograph.

The aim of the textual critic, then, may be defined (1) as the methodical establishment of a text in its purest and most correct form or forms as limited by the evidence of preserved documents; and (2) as the application of further techniques, including critical judgment. to clear a text insofar as possible of errors still present in the methodically established, or documentary form. The end of this second process is to approximate at least that substantive correctness that would have appeared in an authorial fair copy of a text as represented by preserved documents.

Accidental v. Substantive Variations.—In this definition, the "purest and most correct form or forms" of a text refers not only to an original and its possible revision or modification, but also to a distinction often made in printed texts; *i.e.,* between (1) the significant, or "substantive" readings of a text, namely, those afiecting the author's meaning or the essence of his expression; and (2) others—such as spelling, capitalization, punctuation, word division—affecting mainly its formal presentation, which may be regarded as the accidents and therefore as constituting the "accidentals" of a text. It may be that one form of a text preserves with considerable fidelity the accidentals of an author while at the same time containing substantive readings that he has seen fit to reject on a later occasion. The first edition of John Dryden's *Indian Emperour* (1667) is manifestly closer to his autograph than any other printed edition, since the slightly revised second edition (1668) was set from the first: and the considerably revised third edition (1670) was set from the second. However, this third edition, which on the whole contains the most authoritative range of Dryden's substantive readings, is manifestly inferior to the first in the authority of the accidentals. since in this respect it is a mere copy of a copy of the first edition; and Dryden's general approval of the text of this play for its revised substantives marked in a copy of the second edition can under no circumstances be taken as applying also to the variable compositorial characteristics. which in many cases have altered the third-edition forms of the accidentals from their generally more authoritative versions in the first edition. (It is most unlikely that Dryden ever saw the 1670 accidentals before publication.) In such a case the duty of the textual critic is clear. He must establish the facts that lead to the assignment of the third edition as the last revised substantive form of this text; and then establish the facts as between the rival claims (of the first printed edition and a scribal manuscript of an earlier version of this particular text) to be the most authoritative form of the accidentals on the whole. An editor would then place the most authoritative form of the substantives within the framework of the most authoritative form of the accidentals.

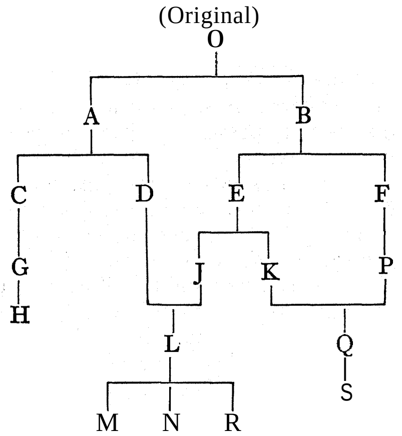
Much confusion has been caused in critical writing by failure to observe the two stages of procedure in the establishment of a text as remarked in the definition finally offered: (1) the fixing from documentary evidence by logical methods of the most authoritative form or forms; and (2) the emendation of this initially established text to approximate as nearly as possible an inferential authorial fair copy, chiefly in respect to its substantives. (In a completely modernized form of any old text, as is customary with the classics, the substantives constitute the sole problem, of course.) This final action achieves on a superior level the establishment of a critically definitive text. At one time only the first operation was called "textual" criticism, the second being known as "higher" criticism; but this distinction lapsed following the recognition that the second stage of purification involves more than simple critical judgment and may include bibliographical, paleographical and linguistic, as well as historical considerations.

The second stage of establishing a text does not differ essentially between manuscripts and printed books. However, the methods of utilizing preserved documents to establish the first, or documentary stage of the text often differ so widely between manuscripts and prints as to call for separate consideration.

THE GENEALOGY OF MANUSCRIPTS

The majority of manuscript texts requiring methodical textual criticism date from ancient or from medieval days before the invention of printing. although the custom of manuscript circulation may lead to problems even in such late Renaissance authors as John Donne.

Types of Genetic Relationship. — The analysis of the relationship of preserved forms of a text. as a whole, ends in the drawing up of a genealogical chart, such as the following, appropriate for a text wholly or chiefly preserved in manuscripts:



The genealogical tree always diverges in its lines of descent from a preserved or inferential original, the strict definition of which has been given above as that latest immediate ancestor, preserved or inferential, to all the manuscripts highest on the family tree; *i.e.,* to the heads of all families. The process of transcription by which the various copies stemming ultimately from this single great ancestor are formed is characterized by variation. If we exclude authorial or editorial alterations, variant readings arise only from the transmission of documents. Such variation, in the words of Sir Walter Greg, is postulated as universal; that is, every act of transcription introduces some variants. Variation is either "spontaneous" or "determined." Spontaneous variation is unconscious variation; it may range from a mere slip of the pen to addition, omission or substitution of readings through misreading or lapse of memory. Determined variation is conscious. and hence usually an attempt at emendation (correct or not) of fancied or of real faults in the copy being transcribed. Spontaneous variation is the more frequent. Of the variants introduced into any transcript, some will persist through subsequent transcription, whereas others will undergo further change and thus illustrate the rule of universal variation. In this way features peculiar to any manuscript are transmitted to its descendants but not in an invariable form. (Variation, one must recognize, is a neutral word and applies only to a difference between two readings, *without* respect to the order of derivation or to correctness.) Variation in a descendant may lead farther and farther away from the original reading; on the other hand, a descendant in varying from its immediate ancestor may actually restore by independent correction the reading of a more remote ancestor.

Variants may be vertical (*i.e.,* within a direct genetic line of descent) as when H, transcribed from G (or more likely from some lost intermediary), varies from G; or variation may be horizontal, as when A differs from B, both being manuscripts transcribed independently from O or from one or more lost intermediaries. (A and B are "collaterals" in that neither is an ancestor nor a descendant of the other.) It is horizontal variation that gives rise among collaterals to "grouping," or the arrangement of the manuscripts into family and subfamily groups according to whether they agree or differ in respect to particular readings.

Unless there is "conflation" (one manuscript affecting the readings of another by contamination), each family group shares an exclusive common ancestor deriving ultimately from the first independent descendants of the inferred or preserved great common ancestor O. In the tree above, the family groups are separated into A and B and their respective descendants, except that L joins both families by conflation and passes on this mixed inheritance to its descendants. A subfamily is a family whose ancestor is derivable from a manuscript which is the ancestor of still other manuscripts. For example, K and P are in separate subfamilies deriving from their ancestors E and F, which are collaterals deriving from B. In reading a genealogical table of texts, no inference can be drawn that a manuscript shown as deriving directly from another manuscript mas in fact copied from the exact manuscript shown on the tree as a parent. Between G and H or between B and F any number of now lost manuscripts very likely existed. Hence all variants in H from G, or in F from B need not have arisen in the act of copying the actual manuscripts of H and F, though for economy of assumption the textual critic must so take it. All that is shown by the table is that the line of descent from G to H and from B to F is a direct ancestor-descendant one. and that H has no other known ancestor than G, or F than B. In other words, no manuscripts deriving from any ancestor other than G were used in the transmission of the text from G to H, whatever the distance between them.

The case is quite different with L. Here the scribe (or a previous editor) had in his possession two exemplars of manuscripts, one in the direct line of descent from D, and the other similarly derived from J. These two manuscripts were conflated when in cases of variation between them the scribe chose readings now from one and then the other (or else merely copied a manuscript that had been editorially revised and annotated by selected readings from another). In this case conflation joined two manuscripts of different genetic, or family relationship, for neither D nor J shared any common ancestor except the ultimate ancestor O. On the other hand, lesser conflation took place in Q, but here the contamination served only to unite the members K and P of two collateral subfamilies. In the first instance, readings may appear together in L that had been used as genetic distinctions to separate the A and B families; *i.e.,* readings in which A and B and their descendants varied from each other. In the second. though variants may be reunited, the conflation, except fortuitously, includes no variant not characteristic of the B family as opposed to the **A** family.

Inferential manuscripts may appear in any family tree, although the recent tendency of textual criticism is to excise them wherever possible, as by Archibald A. Hill's theory of simplicity. An inferential (or hypothetical) manuscript marks a point at which some line of descent branches; it is a manuscript that must be posited to explain similarities between two or more other manuscripts, extant or inferred, when study shows that these are in a collateral and not in an ancestor-descendant relationship. In the sample tree, according to one school of thought, if A did not exist it would need to be posited provided one could show that C did not derive from D. or D from C, or C and D independently from O.

The process of determining the relationship of the manuscripts consists of isolating the major different family groups and then inferring the genetic grouping of the individual texts within these large groups. The process starts with a collation, or comparison of all known texts and a systematic recording of their variants, usually confined to substantive differences. According to Dom Henri Quentin. three major kinds of variants will develop: (1) variants shown by a single manuscript; (2) variants shown simultaneously by a few manuscripts; and (3) variants shown simultaneously by numerous manuscripts. The first are useless and must be disregarded. The second are valuable in determining families and subfamilies, for if the same few manuscripts repeatedly give a common reading different from all other manuscripts. it may be assumed that these few are clearly related and form a family or subfamily of their own. One of the first tasks, therefore, is to delimit the families hy means of such variants as are found repeatedly to be peculiar to certain constant groups of manuscripts. The families thus determined, the groupings within each may be filled in. The precise way in which a textual critic operates to determine the relationship of all forms of his text can scarcely be summarized. because of the complexity of the evidence and the differences in the weight given to various kinds of evidence. In general, the critic aims first at establishing the facts of genetic relationship and then at determining the direction of the relationship between ancestor and descendant.

Distributional **Evidence.**—What Hill calls "distributional" evidence is chiefly of service in determining the basic facts of relationship or nonrelationship. In distributional analysis the arrangement of differences in the texts is utilized as evidence without attention to the nature of the differences. This method rests on the postulate that unity in readings in manuscripts is more probably referable to unity in their source than to coincidence. The facts of variance are enough If the point of difference is, for example. the appearance or nonappearance of a particular word, distributional study does not attempt to inquire whether the nonappearance is an omission, or the appearance is an addition. It merely divides the manuscripts into groups depending upon the appearance or nonappearance of this word.

Distributional evidence may be used to assign the nature of groupings by indicating whether the relationship is direct (as in the vertical ancestor-descendant line) or collateral. For example, direct relationship can be shown in the following illustration. Suppose manuscript L shares readings with all other manuscripts in its family and has no unique readings. Manuscript M shares readings only with L and has no shared readings with other manuscripts not shared with L, but it also has some unique readings. This state of affairs is not compatible with a supposition that L is copied from M, since (because of the unique variants in M) the greater number of times that L agrees with the other manuscripts than does M is unexplained. On the other hand. this state of affairs is compatible with the hypothesis that M was transcribed from L.

One apparent fallacy in this reasoning is usually not of consequence. The larger share of L than of M in readings with other manuscripts could be explained, in isolation, as derivation of L from M if M were the earliest of all manuscripts and all derived from it as the common ancestor. However, a tree branches as it develops, not converges; and no rational genealogical chart can be reversed. Moreover. other evidence, which may be called genetic, provides a check on the direction of change.

The facts of the distribution of variant readings among manuscripts, therefore, may be utilized to show direct relationship. as above. or collateral relationship. For the latter. if in a group of more than two manuscripts having a common ancestor (like M, N and R), all manuscripts have unique readings, and all manuscripts shared readings in no constant arrangement, these facts are compatible only with independent derivation of the type known as radiation. On the other hand if the relationship is always constant, so that the shared readings of M are aluays shared only uith N or aith R the facts can be taken to be incompatible with radiation and hence derivation must be postulated.

Genetic Evidence. — Distributional evidence is frequently enough to settle a case, but it has its limitations when revision is present and especially (as exemplified in the texts of Donne or Robert Herrick) when copies are made from a poem in different stages of reworking. Hence the critic may call on a second order of evidence, which may be called genetic, or the comparison of individual differences with each other in the hope of discovering the direction of change. At its most scientific this inquiry still attempts to emulate distributional study by ignoring the critical considerations of meaning. at least in any strict sense of right and wrong. Instead, genetic study rests on the assumption that certain differences are more likely to have been produced by a given direction of change than by another. For example, if C omitted a passage present in both A and B, the direct sequence CBA, or ACB or any other scheme that set up C ahead of B would be disqualified, for where would A or B secure the passage if they were descended from C, no conflation from another source being proved?

Common errors of other sorts may also profitably be used but always with caution, for the process of correction reverses the direction of change toward error that would be expected from the process of copying. The critic attempts to separate reversible changes from variants that by their nature appear to be nonreversible. Moreover. Greg's postulate that spontaneous variation occurs oftener than directed variation would indicate that in a direct sequence the number of errors will ordinarily exceed the number of corrections, and hence that the most faulty will likely be the descendant, not the ancestor; but this line of argument is to be used with caution.

Similarly, the direction of change may sometimes be postulated by explaining one form as the result of a known type of mechanical error such as eyeskip or haplography. Unless distributional evidence indicates otherwise, an existent word is presumed to be earlier than a nonexistent word created by a familiar type of error. Even when two existent words comprise the variant, a known type of error may best explain the direction of change. Hill points to E. K. Rand's correction of Quentin in the following: *sub umbra culminis mei* (9 manuscripts); *sub umbraculum culminis mei* (2 manuscripts); *sub umbraculum tegminis mei* (5 manuscripts). Quentin had regarded *umbra culminis* as derived from *umbraculum tegminis* by the omission of *-um teg-*, whereas Rand properly derived *umbra culminis* from *umbraculum culminis* by omission of *-um cul-*. Rand's logic rests on true eyeskip fostered by the repetition of *cul-*, whereas Quentin's suggested omission cannot be correlated with such a type of known error.

Suggestive as genetic evidence may be, assumptions from individual readings may often prove to be untrustworthy; and hence the genetic method is usefully employed only when distributional evidence has been completely exhausted.

Physical and Stylistic Evidence. — Physical evidence is ordinarily of little use in dealing with classical or medieval manuscripts, since no correlation need exist between the date of inscription and the state of the text. It is of no pertinence to argue, for example, that because the paper of manuscript Y may be dated in 1640 and that of manuscript Z in 1240, the text of Z must represent an earlier state than that of Y; instead, Y might well have been transcribed from a manuscript that was representative of a form of the text nearer to the common ancestor than the ancestor of Z. However, modern manuscripts (and especially autograph) may yield extraordinary results when external evidence is applied. The manuscripts behind the 1860 edition of Whitman's *Leaves of Grass* neatly divide into groups that can be dated 1857 and 1859 respectively on the basis of the paper and inks. A brilliant recovery of the order of Emily Dickinson's manuscripts resulted from a minute external study of the paper and the handwriting characteristics.

Finally, in this preliminary stage, which consists only of the establishment of one form of a genealogical chart rather than any other, purely literary study based on assumed stylistic respects, superior sense, freedom from mistakes of fact, etc., is almost completely untrust orthy and should not be employed until the preceding three ranges of evidence have been completely exhausted, individually and collectively.

Determining the Most Authoritative Variant. — Once a genealogical chart has been drawn up by the critic's most rigid use of methodical evidence, it is proper to consider the authority of variants in the texts in the light of the facts of derivation as shown by the tree. In the sample chart it is obvious that if O is preserved no other known manuscript can contain a reading that possesses any authority, although some may own readings that are more correct. The textual critic will have arrived at the only preserved manuscript that — as the single common ancestor — is nearest to a lost autograph. Further treatment of this manuscript can involve only emendation.

On the other hand, if O is only inferential, and A and B represent the ultimate heads of only two families, the critic's position is less happy True, no preserved manuscript other than A and B can own authority; true, shared readings between A and B must be presumed to derive from inferential O, and therefore common readings possess the authority they would have if derived from a preserved O. (But notice that in either case O is not necessarily the real archetype or first original, but instead merely the one manuscript it is possible to infer as a common ancestor of A and B, even though through different lost intermediaries.) However, where A and B vary, only critical judgment can decide, on the evidence of each individual variant, which one is superior and therefore — by another assumption not always warranted—authorial.

The school of textual critics stemming from Karl Lachmann favoured the acceptance of one "best" manuscript and the rigid adherence to its readings in all possible circumstances as the only "scientific" attitude for an editor. This school tacitly considered that textual criticism ended with the establishment of the family tree and the consequent decision in favour of some one preserved manuscript as the '(best"; whereas, at least in the above chart, the tree does not favour either **A** or B. The illogic of the Lachmann position, in its abrogation of the critical second stage in preparing a definitive text, was exploded by **A.** E. Housman (Preface, *The Astronomicon of Manilius,* Cambridge University Press) : "To believe that wherever a best MS. gives possible readings it gives true readings, and that only where it gives impossible readings does it give false readings, is to believe that an incompetent editor is the darling of Providence. . . . Chance and the common course of nature will not bring it to pass that the readings of a MS. are right wherever they are possible and impossible wherever they are wrong: that needs divine intervention. . . . In books like Manilius and Lucan, preserved in various copies of equal merit, the editor cloaks his frailty by feigning that their merit is not equal: in books like Juvenal and Ovid's Heroides, where one MS. far excels the rest, h e feigns that it excels them further. and tries hard to treat it not merely as the best but as the sole authority."

Heeding Housman's excoriation, the most advanced textual critic no longer stops short with what the evidence of the genealogical chart may indicate about the authority of the readings; nor, when the chart is indifferent, does he rest content with fidelity to a chosen best manuscript. In every case of nonautograph he will accept only as comparative the authority of the earliest ancestors that can be established; and as the final stage of his establishment of a text he will treat it critically according to bibliographical, paleographical, linguistic or whatever other techniques are pertinent, and over all impose his literary judgment based on his knowledge of the qualities of the author treated. At this point. where methodical techniques largely desert a textual-critic editor, the resulting text will be good or bad depending upon the individual's own capacities. The acceptance of Housman's attitude and its extension, about the middle of the 20th century, to editing from printed texts constitutes one of the most interesting of modern developments in editorial theory. It places the responsibility for a text where it belongs, squarely on the shoulders of the editor. Yet confidence in critical ability to solve all problems may lead to a newer kind of laziness as acute as that Housman found in the "scientific" textual critic, if all the ancillary techniques for examining a text are not exhausted before reliance is placed on judgment rooted in subjectivity and intuition and in the cultural intelligence of an editor.

THE GENEALOGY OF PRINTED BOOKS

Transmission of a text in printed books differs so radically from transmission of an ancient or medieval manuscript text as to call for quite different basic postulates. The chief difference is that a manuscript that is a direct descendant of its most immediate ancestor is ordinarily not copied directly from the ancestor but from some one of a lost series descending from the ancestor. On the other hand, any edition of a book other than the first is ordinarily copied directly from some other known edition. Editions of books, therefore, are assumed to be contiguous in their relationship, and variants between them can be assigned to the agents producing the derived edition, or else to the author, within a given space and time. Secondly, under most circumstances editions of books are dated with reasonably correct dates, which show the relationship between editions. Both assumptions, although sometimes violated, permit the development of physical evidence that is the special province of analytical bibliography, a discipline that studies the effects of the printing process on the transmission of text (*see* BIBLIOGRAPHY).

' For example, the ninth edition (1694) of Dryden's *Indian Emperour* appears to conflate distinctive readings of the seventh edition of 1686 and the eighth of 1692. In manuscript study or in nonbibliographical criticism of printed texts, an editor would inevitably postulate either consultation and contamination or else derivation from a lost edition located between the seventh and eighth. However, the bibliographer trained to observe physical evidence will notice that the distinctive variants of the two editions never appear together on any page of the 1694 print; and starting with this fact he will develop other physical evidence to demonstrate that two different compositors alternated in setting the type for the 1694 edition, one of whom used the 1686 and the other the 1692 edition as printer's copy.

Determining the True First **Edition.**—One of the most difficult problems facing a textual critic of printed books is to determine which is the true first edition, and thus the authoritative text, in case two editions in the same year are issued without external or collateral evidence of priority. Dryden's play *The Wild Gallant* had two editions printed in 1669, the year of publication. On literary grounds Dryden's editor G. Saintsbury rejected what turned out to be the true first edition, and chose for his text the variant readings of the unauthoritative second edition. When the case was scrupulously examined, one piece of physical evidence was enough to demonstrate the true order. In what was proved to be the first edition the word "tells" was printed with a defective type for the second letter "l"; the type inked chiefly at the top and in many copies produced only a short mark that looked like an apostrophe. In the second edition the compositor faithfully copied what he thought he saw and set the corresponding word as "tel's," an impossible form. That this evidence must be accepted may be seen if one tries to reverse it and explain the defective type as deriving irom the apostrophe.

The chiei textual critic oi *Hamlet* between World Wars I and II, J. Dover Wilson, had pronounced the important second edition of 1604–5, the first of the good texts, as set throughout by only one compositor, who was an incompetent novice at the trade. But in 1953–54 one bibliographer showed that, on physical evidence that could be demonstrated from the printing of the sheets of the book, two presses had been employed in an alternation that would require the services of two compositors; Another scholar, J. R. Brown, by an examination of distinctive characteristic spellings, identified the sheets set by each compositor as those indicated by the presswork study and established the fact that these two now identifiable compositors had worked for the printer for several years as his regular men and, indeed, had set the second edition of Titus Andronicus and the first edition of The Merchant *of* Venice, both in 1600. Since these two texts have been much admired for their accuracy, the effect of this inquiry was to establish that deiects in the second edition of Hamlet are chiefly to be derived irom its manuscript rather than from the printer's incompetency. The difference is important for a textual critic.

One of the most brilliant bibliographical discoveries of the 20th century disclosed the false dating of the so-called Pavier Quartos of various Shakespeare plays. It was established that Pavier editions of some plays dated 1619 and editions of others dated a decade or more earlier shared identical standing type in their title pages. This physical impossibility revealed that some texts previously preferred on literary grounds by editors, such as that of ***King*** Lear, were actually unauthoritative second editions of no textual value. Whether Hamlet's flesh was "too too sallied" (*i.e.,* "sullied"), as in the First and Second Quarto editions or "too too solid," as in the Folio, had usually been decided in favour of the Folio. However in 1956 it was pointed out that the unusual form "sallied" in the second edition could not have derived unauthoritatively by contamination from the same reading in the imperfect first edition, since the second appearance in this play of the word "sally" meaning "sully" (Polonius to Reynaldo, Act II, sc. i) came in a section typeset by a different compositor, who would be unaware of the previous occurrence and must have copied his word from the manuscript, the first edition being wanting there. These examples suggest various typical ways in which bibliographical techniques that have been developed in the 20th century have revolutionized the study of printed texts by emphasizing the need to exhaust the physical evidence of analytical bibliography before attempting critical judgment.

The approach to textual criticism made by the analytical bibliographer emphasizes two primary requirements: (1) the careful examination of all preserved forms of a text, not only (a) to assure oneself that the external evidence of printed dates and the like is correct and that one has recovered the earliest edition (that text set from manuscript) but also (b) to guarantee that every other edition in which iresh authority might have entered has been placed in its correct relationship and the authority of its variants analyzed; (2) the careiul examination of the details of any edition possessing authority, whether the first or a revised print, to determine the nature of the copy used by the printer and its authority.

Determining the Nature of Printer's Copy.—The usefulness of this inquiry is by no means limited to early handprinted books but may be applied as profitably to the texts of James Joyce, T. S. Eliot and W. B. Yeats as to the text of Shakespeare. The common practice of dilettante editors to reprint as their text the last edition of a book printed in the author's lifetime is as serious a defect for modern as for older authors. (The theory was that the author might have revised the edition; such editors felt no requirement to look into the evidence for or against this theory.)

To take a small but significant example, the proofreading of F. Scott Fitzgerald's This Side of Paradise was careless in the first printing, and changes in the plates were made partly by the author and partly by the publisher in the fourth and seventh impressions. A few of these alterations, presumably made by the publisher, mistook the sense and created errors from correct readings, An editor would need to reject these in favour of the correct first-printing readings, to accept the corrected and revised readings by the author and publisher from the later printings, and then to make a variety of further corrections himself heiore arriving at a definitive text. In more complex form, no one edition of Joyce's *Ulysses* contains all of his desired readings; on the occasion when he went over the text in correction he unfortunately chose a corrupt edition and did not alter all its unauthoritative changes from the first-edition readings or notice all the first-edition errors that had been perpetuated. Any editor of Eliot or of Yeats would need to disentangle the author's corrections and alterations in revised editions irom errors developed in the course of various printings, which were overlooked. Fidelity to one printing or edition, early or late, cannot serve to establish a modern author's text.

In the 17th century Dryden partly revised the second edition (1668) of *The Indian Emperour* and more rigorously the third edition (1670). The fourth and fifth editions of 1670 derived in order irom the corrected third, but the sixth edition (1681) reverted to the second (1668); thereafter all texts of Dryden followed this family and ignored the corrected third edition, whose line terminated with the fifth edition. Since no Dryden editor beiore the 1950s undertook to collate all the early texts, the authoritative revisions of the third edition remained unknown, and the edited texts, based on the 1701 folio, not only retained most of the corruptions found in this 13th edition but also revealed only the intermediate revised state of the text as transmitted in the second-edition family line.

A typical example of failure to observe the primary rules of textual criticism in the analysis of all editions occurred in the text of Percy Bysshe Shelley's *Posthumous Poems*. In the first edition of 1824, edited by Shelley's wife Mary, an errata leaf containing 24 alterations, including a missing line, was added to the last copies to be bound up. This leaf, being uncommon, was overlooked by all Shelley's editors, although utilized to a greater or lesser extent in the various pirated editions that followed soon after the publication oi the volume. When Mrs. Shelley came to edit the revised collected edition of 1839, by bad luck she chose one of the pirated texts into which various corruptions had entered. Thus, although she collated her proofs against her manuscripts, not only did she overlook three of the errata-leaf corrections omitted in the pirated edition but she also passed some of the piracy's corruptions, notably the reading from "Stanzas Written in Dejection, near Naples," "The breath of the moist air is light" for the errata-leaf version oi this missing line, "The breath of the moist earth is light." The variant "air" appears first in the unauthoritative Galignani text of 1834, to be transmitted thence to Mrs. Shelley's 1839 edition. All Shelley editors, who sheeplike followed the supposedly authoritative 1839 text in the belief that Mrs. Shelley's attestation had been given to it and hence there was no need to inquire into its copy and method of printing, have reproduced as authentic a considerable number of errors that can be demonstrated to have arisen in the pirated texts oi Galignani and of Ascham used by Mrs. Shelley as the basic printer's copy.

The nearer machine printing approaches modern times and routine publishing procedures, the less need is there to inquire into the authority of the manuscript originally used as printer's copy, although the copy for any subsequent revised edition must always be identified and its relation to the earliest authoritative text as well as to the revised edition scrupulously analyzed. For books of the 16th, 17th and 18th centuries, however, when the personal characteristics of the compositor (though with diminishing force as time goes on) are likely to interfere in an important manner with the reproduction in faithful detail oi the underlying manuscript, the distinction of printer's from author's characteristics is of real moment. Two considerations operate. First, in texts dating from the time when authors frequently did not read proof and the printing-house proofreading was casual about variation from the author's wording, a study of the printer may reveal whether difficulties in the text are to be emended in one direction or another in accord with what has been determined about the capabilities of the identified compositor concerned. It is known that Jaggard's compositor A of the Shakespeare First Folio of 1623 was more faithful to his copy, generally speaking, than compositor B. Hence an emendation must pass sterner tests to be accepted in an A section of the Folio than in a B section, or in the pages set by what seems to be a very inaccurate apprentice, compositor E, first identified by C. J. K. Hinman in 1956.

Second, if the veil of print can be pierced, the critic may be able to make various important assumptions about the authority of a text, in whole or in part, according as he can estimate the nature of the lost manuscript underlying the earliest print or any later revision. Once it could be determined that a particular scribe, Ralph Crane, transcribed the manuscript used by the Folio printer for *The Merry Wives of Windsor*, certain very puzzling characteristics of that text were no longer obscure. What texts of Shakespeare were set from his autograph papers, and what irom scribal transcripts, is an inquiry that was scientifically tackled, from the strict bibliographical point of view, only after World War II.

The question of the copy underlying a print is often as acute in the case oi a revision as in the original edition. For example, if the Folio text of *Hamlet* was set from an independent manuscript, common readings between the Second Quarto and the Folio are presumptively authorial, given the collateral theory that the Second Quarto was set irom autograph papers. On the other hand, if, as has been argued, the Folio printer's copy was a Second Quarto that had been annotated by a scribe comparing it with the manuscript in the theatrical company's possession, a shared reading like "pious bonds" (assumed manuscript reading: "bands") for "pious bauds" ("bawds") could have perpetuated in the Folio an error of the Second Quarto, provided the scribe overlooked it. Hence the authority possessed by any Folio reading is much affected by what can be established about the nature of the printer's copy for the Folio text, a subject still in dispute.

Such a determination would not automatically settle in any given case whether the Folio or the Second Quarto variant reading was the authoritative one. But a critic who comes to the final stage in the establishment of a text—the synthesis of readings if there is more than one text possessing authority (as is frequent in manuscript and occasional in printed texts), followed in any case by independent emendation—is in a better position if he has thoroughly worked out the detailed history oi the text as a guide and limitation to the exercise of his critical or literary judgment than if he relies almost exclusively on his sympathetic acquaintance with the characteristics of an author and his period.

(F. T. B.)

THACKERAY, WILLIAM MAKEPEACE (1811–1863), English novelist whose social satires are classics of English literature, was born at Calcutta. India, on July 18, 1811. His father and grandfather had been Indian civil servants. His mother was left a widow in 1816 and married Maj. Henry Carmichael Smyth in 1818. Young Thackeray was brought to England from India as a child and sent to private schools, first in Hampshire and later in Chiswick. In 1822 he was transferred to Charterhouse, at that time still on its ancient site near Smithfield.

Anthony Trollope noted that Thackeray's "change of retrospective feeling about his schooldays was very characteristic. In his earlier books he always spoke of the Charterhouse as Slaughter House and Smithfield. As he became famous and prosperous his memory softened, and Slaughter House was changed into Grey Friars, where Colonel Newcome ended his life."

In "Mr. and Mrs. Frank Berry" *(Men's Wives)*, for example, there is a description of a fight at "Slaughter House" following an incident almost identical with that used in *Vanity Fair* for the fight between Dobbin and Cuff. Although in both cases the brutality of school life, as it then was, is fully described, Thackeray also recognized the chivalry which may go alongside it. In the first chapter of "Mr. and Mrs. Frank Berry," Berry himself and old Hawkins both have a touch of the heroic, and in that story the bully whom Berry gallantly challenges is completely defeated, and one hears no more of him. In *Vanity* Fair Cuff, the swaggerer, is defeated as completely as is Berry's opponent, but he regains his popularity by one well-timed stroke of magnanimity, and afterward shows the truest kindness to his conqueror.

In 1828 Thackeray left Charterhouse to join his mother and her husband at Larkbeare in Devon, near Ottery St. Mary, which is the "Clavering St. Mary." as Exeter and Sidmouth are the "Chatteris" and "Baymouth" of *Pendennis*.

In Feb. 1829 Thackeray went to Trinity college, Cambridge, and contributed lines on "Timbuctoo," the subject for the prize poem (the prize for which was won by Tennyson), to a little paper called *The Snob*. James Spedding, Monckton Milnes (Lord Houghton), Edward FitzGerald and W. H. Thompson (afterward master of Trinity) were among his friends. In 1830 he left Cambridge without taking a degree. A visit to Weimar bore fruit in the sketches of life at a small German court which appear in *FitzBoodle's Confessions* and in *Vanity Fair*. In G. H. Lewes's *Life of Goethe* is a letter containing Thackeray's impressions of the German poet.

On his return to England in 1831 he entered the Middle Temple, and found material for some capital scenes in *Pendennis*. In 1832 he inherited a sum which, according to Trollope, amounted to "about five hundred a year." The money was soon lost—some in an Indian bank, some at play and some in two newspapers. *The National Standard* and *The Constitutional.* In *Lovel the Widower* these two papers are indicated under one name as *The Museum,* in connection with which Honeyman and Sherrick of *The Newcomes* are briefly brought in. Thackeray's adventures at play were utilized on three occasions, in "A Caution to Travellers" *(The Paris Sketch-Bookj.* in the first of the Deuceace narrations *(The Memoirs of Mr. C. J. Yellowplush*), and in *Pendennis,* vol. ii, ch. v, in a story told to Captain Strong by "Colonel Altamont."

About *1834* Thackeray settled in Paris to study art seriously. He had, like Clive in *The Newcomes,* shown early talent as a caricaturist. His pencil was at its best technically in such fantastic work as is found in the initial letters of chapters and in those drawings made for the amusement of child friends which were the origin of *The Rose and the Ring.*

In *1836* Thackeray married Isabella, daughter of Col. Matthew Shawe. There were three daughters barn of the marriage: one dying in infancy. The eldest, Anne Isabella, married in *1877* (Sir) Richmond Ritchie of the India office. She wrote several charming works of fiction: notably *Miss Angel* (1875), and subsequently edited Thackeray's works and published some volumes of criticism and reminiscences. The younger daughter, Harriet Marian, married (Sir) Leslie Stephen in 1867 and died in 1875. Mrs. Thackeray, to quote Trollope, "became ill and her mind failed her," in *1840.* and he "became as it were a widower to the end of his days"; she did not die till 1894.

In 1837 Thackeray went to London, and became a regular contributor to *Fraser's Magazine.* In this in 1841 appeared *The History of Mr. Samuel Titmarsh and the Great Hoggnrty Diamond,* a work filled with the wit, humour, satire and pathos. which found a more ordered if not a fresher expression in his later works. The characters are full of life; the book is crammed with honest fun; and for pure pathos, the death of the child stands in the company of very few such scenes in English fiction; but *The Great Hoggarty Diamond* had to be cut short at the bidding of the editor.

In *1840* came out *The Paris Sketch-Book,* much of which had been written and published at an earlier date. In *1838* Thackeray had begun, in *Fraser, The Yellowplush Papers,* with their strange touches of humour, satire and tragedy and their fantastic spelling; and this was followed by *Catherine,* a strong story, founded closely on the career of a criminal named Catherine Hayes and intended to counteract the then growing practice of making ruffians and harlots prominent characters in fiction. When *Pendennis* was coming out in serial form (1850) another Catherine Hayes, an Irish singer and famous prima donna. was much before the public. Thackeray, thinking of the former and oblivious of the latter Catherine Hayes, caused a great outcry in the Irish press by coupling the name with that of a recently notorious murderer. He afterward suppressed the passage but the incident is of interest because it explains the initial letter drawn by Thackeray for chap. xv, vol. ii, of *Pendennis.* The drawing is in itself highly comic, but must seem quite meaningless without the key. There soon followed *Fitz-Boodle's Confessions and Professions,* and the *Shabby Genteel Story,* a work interrupted by Thackeray's domestic affliction and afterward republished as an introduction to *The Adventures of Philip,* which took up the course of the original story many years after the supposed date of its catastrophe. In *1843* also came out the *Irish Sketch-Book,* and in 1844 the account of the journey *From Cornhill to Grand Cairo,* in which was included the excellent poem of "The White Squall." In 1844 there began in *Fraser* the *Memoirs of Barry Lyndon,* called in the magazine "The Luck of Barry Lyndon, a Romance of the Last Century." "Barry Lyndon" has. with a great difference in treatment, some resemblance to Tobias Smollett's *Ferdinand, Count Fathom* —the hero, that is to say, is or becomes an intolerable scoundrel who is magnificently unconscious of his own iniquity. The form and pressure of the time depicted are caught with striking verisimilitude, and in the boyish career of Barry Lyndon there are fine touches of a wild chivalry, simplicity and generosity. which mingle naturally with those worse qualities that, under the influence of abominable training, afterward corrupt his whole mind and career. The man is so infatuated with and so blind to his own roguery, he has so much dash and daring and is on occasions so infamously treated. that it is not easy to look upon him as an entirely detestable villain until, toward the end of his course, he becomes wholly lost in brutish debauchery and cruelty.

Thackeray became a contributor to *Punch* within the first year of its existence. John Leech, who was one of the earliest contributors, had been at Charterhouse with Thackeray and the two men were friends through life. Thackeray made his first hit with *Jeames's Diary,* begun in Nov. 1845, and may be said to have established his reputation by the *Snob Papers* (1846), now known as *The Book of Snobs.*

"Punch's Prize Novelists," another series which Thackeray contributed to the paper. contains some brilliant parodies of Edward Bulwer-Lytton, Lever. Disraeli and others. Because of differences in political opinion, his connection with *Punch* ended in 1851.

Minor but admirable works of the same period are *Legend of the Rhine* (a burlesque of Dumas's *Othon l'Archer*), in George Cruikshank's *Table Book,* edited by Gilbert À Beckett. *Cox's Diary* (on which was founded a well-known Dutch comedy, *Janus Tulp*), and *The Fatal Boots. Rebecca and Rowena* towers over every other burlesque of the kind. Its taste, its wit, its pathos. its humour, are unmatchable; and it contains some fine songs of a particular sort. In *1846* was published, by Bradbury and Evans. the first of *24* numbers of *Vanity Fair,* the work which placed Thackeray as a novelist of the first rank. It was completed in 1848, in which year it was also published as a book. The charge of cynicism Thackeray has himself met at the end of the eighth chapter, in a passage which is the best commentary on the author's method. He explained how he wished to describe men and women as they actually are. good. bad and indifferent: "Occasionally to step down from the platform. and talk about them; if they are good and kindly, to love and shake them by the hand; if they are silly. to laugh at them confidentially in the reader's sleeve; if they are wicked and heartless, to abuse them in the strongest terms politeness admits of. Otherwise you might fancy it was I who was sneering at the practice of devotion, which Miss Sharp finds so ridiculous: that it was I who laughed good-humouredly at the railing old Silenus of a baronet—whereas the laughter comes from one who has no reverence except for prosperity, and no eye for anything beyond success. Such people there are living and flourishing in the world—Faithless, Hopeless, Charityless: let us have at them, dear friends, with might and main. Some there are, and very successful too, mere quacks and fools; and it was to combat and expose such as those, no doubt, that laughter was made:"

Another accusation brought against the book was that the colours were laid on too thick, in the sense that the villains were too villainous, the good people too goody-goody. The best answer to that can be found by reading the work itself with care. Osborne is meant to be a poor enough creature, and one whose poorness of character is developed as he allows bad influences to tell upon his vanity and folly. The good in him comes out in the beautiful passage describing his farewell to Amelia on the eve of Waterloo, in which passage may be also found a sufficient answer to the statement that Amelia is insipid and uninteresting. So with the companion picture of Rawdon Crawley's farewell to Becky Sharp. Who that reads it can resist sympathy, in spite of Rawdon's vices and shady shifts for a living, with his simple bravery and devotion to his wife? As for Becky. there is certainly not much to be said in her defense. The reader learns that she thought she would have found it easy to be good if she had been rich, and also knows what happened when Rawdon surprised her alone with and singing to Lord Steyne in the house in Mayfair. After a gross insult from Steyne, "Rawdon Crawley, springing out, seized him by the neckcloth, until Steyne, almost strangled. writhed and bent under his arm. 'You lie. you dog,' said Rawdon; 'you lie, you coward and villain!' And he struck the peer twice over the face with his open hand. and flung him bleeding to the ground. It was all done before Rebecca could interpose. She stood there trembling before him. She admired her husband. strong, brave, and victorious." This admiration is the capital touch in a scene as powerful as any Thackeray ever wrote. The supreme art in the treatment of the character of the brilliant adventuress that Becky was makes the reader feel her attractiveness, though he knows her evil qualities.

Vanity Fair was followed by *Pendennis, Esmond* and *The Newcomes,* which appeared respectively in 1850, 1852 and 1854. *Esmond* is perhaps Thackeray's capital work. It is undoubtedly one of the greatest of English historical novels. The romance *Esmond* reproduced with accuracy the figures. manners and phrases of a past time. The character Beatrix is an insolent beauty who captivated men; "Esmond," according to Thackeray. "was a prig."

Beatrix reappears in the *Virginians* as the jaded. worldly and not altogether unkindly Baroness. The reader is left with the impression that it was just what Beatrix must have come to.

In 1851 Thackeray had written *The English Humourists of the Eighteenth Century,* delivered as a series of lectures at Willis' Rooms in the same year, and redelivered in the United States in 1852 and 1853, as was afterward the series called *The Four Georges.*

In 1854 was published that delightful burlesque, *The Rose and the Ring.* In 1857 Thackeray stood unsuccessfully as a parliamentary candidate for Oxford and in the same year appeared the first number of *The Virginians,* a sequel to *Esmond.* The last number came out in 1859, and in the same year Thackeray undertook the editorship of the *Cornhill Magazine.* This was a task which, as readers of his *Roundabout Paper* "Thorns in the Cushion" will remember, the kindliness and sensitiveness of his disposition made irksome to him. and he resigned the editorship in April 1862, though he continued to write for the magazine until he died. In the *Cornhill* appeared *Lovel the Widower,* previously written, with different names for some of the personages, in dramatic form; *The Adventures of Philip* (1861–62); the *Roundabout Papers,* some of his best essays; and (1860–63) the story, unhappily never finished. called *Denis Duval.* Among the *Roundabout Papers* is one differing in form from the rest, called "The Notch on the Axe—a Story a la Mode," an almost perfect specimen of the author's genius for burlesque storytelling. *The Adventures of Philip* is in the nature of a sequel to *A Shabby Genteel Story,* contains scenes which rank with Thackeray's best work; there are fine sketches of journalistic, artistic and diplomatic life, but Philip himself is impossible; the character is not drawn at all. *Denis Duval,* which reached only three numbers, promised to be a first-rate work in the *Esmond* manner. The author died while it was in progress, on Dec. 24, 1863. He was buried in Kensal Green, and a bust by Marochetti was put up to his memory in Westminster abbey.

The grace and the apparent spontaneity of Thackeray's verses are beyond question. Some of the more serious efforts, such as "The Chronicle of the Drum" (1841), are full of power and instinct with true poetic feeling. Both the half-humorous, half-pathetic ballads and the wholly extravagant ones must be classed with the best work of that kind; and the translations from Béranger are as good as verse translations can be, for Thackeray had the true poetic instinct.

THAÏS, a Greek courtesan who lived during the time of Alexander the Great. She accompanied him on his Asiatic campaign, and is chiefly known from the story which represents her as having persuaded the emperor to set fire to the city of Persepolis. This anecdote forms the subject of Dryden's *Ode to Saint Cecilia's Day,* but its authenticity is doubtful, since it is based upon the authority of Cleitarchus, one of the least trustworthy of the historians of Alexander.

Thais subsequently became the wife of Ptolemy Lagus, king of Egypt.

Numerous anecdotes and witticisms attributed to Thai's will be found in Athenaeus.

THALAMUS, a globular congeries of nerve cells and fibres in the middle of the brain, divided into nuclei, and somewhat larger than a walnut. There all sensory impulses except those of smell are relayed on their way to the cerebral cortex.

In submammalian vertebrate animals the thalamus is chiefly olfactory and does not relay specific sensation, for there is no somatic cortex. With the development of the cortex in the mammals, and the projection of the sensations upon it, the sensory relay nuclei of the thalamus expand proportionately. Thus, the thalamus shows a large lateral geniculate body behind and laterally, for relay of visual impulses; a round medial geniculate body adjacent, for hearing; and a large somesthetic nucleus in its lower central part for bodily sensations. These three are the fundamental and best understood of its nuclei.

The thalamus may be divided into about 30 nuclei, each with differing connections and, therefore, differing functions. Most of them project to one or another of the numerous areal units of the cerebral cortex, so their function is indicated by that of the corresponding cortical area, where this is known. A few do not; they are the most ancient and conservative. Ignorance of the incoming connections of most of the nuclei is chiefly responsible for ignorance of their function. It is known, however, that the thalamus is not directly responsible for motor control.

The thalamus is rarely directly injured or the primary seat of disease, but it may be involved in more generalized disturbances. See also BRAIN; HYPOTHALAMUS; FEELING, PSYCHOLOGY OF.

THALES, one of the Seven Wise Men of ancient Greek philosophy who was also universally held to have introduced geometry into Greece, was the son of the Carian Examyas of Miletus and of Cleobuline. The story of his Phoenician descent is unlikely. His date is fixed by the statement of Herodotus that he foretold an eclipse now generally agreed to be that of May 28, 585 B.C. Apollodorus' date for his birth, 624 B.C., was doubtless based on this as a *floruit.* According to Diogenes Laërtius he died in the 58th Olympiad (548–545 B.C.), aged 78.

His inclusion in the canon of the Seven Wise Men gave him an ideal character, and his name attracted many acts and sayings popularly associated with wisdom. Consequently his real achievement is hard to assess, especially since no contemporary sources exist. He was a practical statesman who, according to Herodotus, offered the wise advice that the Ionian cities should federate; and Diogenes states that he dissuaded Miletus from making an alliance with Croesus of Lydia. Practical interests are also indicated by the story told (but not believed) by Herodotus that he diverted the river Halys for Croesus, and by the tradition mentioned by Callimachus that he advised navigators to steer by the Little Bear rather than the Great. He is also said to have used his knowledge of geometry to measure the pyramids (Hieronymus of Rhodes cited by Diogenes) and to calculate the distance from shore of ships at sea (Eudemus cited by Proclus).

Such stories of little historical worth may yet serve to characterize his reputation. They could however be invented or selected according to a writer's predilections. Two in particular provide amusing examples of mutually canceling propaganda. According to Aristotle. Thales, foreseeing by his meteorological skill a glut of olives, hired all the olive presses in advance and, when the season came. was able to charge his own price for reletting them. The moral drawn was that philosophers can be as worldly wise as other men if they so choose. To demonstrate the contrary, that philosophy's chief glory is its abstraction from the world, Plato tells how Thales fell into a well while stargazing and was laughed at for studying the heavens to the neglect of what was at his own feet.

The best attested fact is his prediction of the eclipse which stopped the battle between the Lydian Alyattes and the Mede Cyaxares. The date 585 B.C. suits the chronology now that Herodotus has been shown to have erred slightly in implying that Astyages succeeded Cyaxares in 594. Thales could not have had the knowledge to predict accurately the locality or character of an eclipse. Hence the feat was isolated and apparently only approximate; Herodotus speaks of his foretelling the year only. The use of the Babylonian saros for this purpose has been convincingly denied by O. Neugebauer *(Exact Sciences in Antiquity* [1951]). All that his Babylonian contemporaries could say was that an eclipse was either excluded or possible, and this sufficed for their astrological aims. From their records, Thales could well have said that an eclipse was possible in the year which ended during 585. The coincidence that it occurred during a crucial battle and was nearly total would give him in retrospect an exaggerated reputation as an astronomer.

Thales was specifically credited with five geometric theorems, as follows: (1) that a circle is bisected by its diameter; (2) that angles at the base of an isosceles triangle are equal; (3) that opposite angles of intersecting straight lines are equal; (4) that the angle in a semicircle is a right angle; and (5) that a triangle is determined if base and angles relative to base are given. The real extent of his mathematical achievement is almost impossible to assess in view of the ancient habit of crediting particular discoveries to individuals with a general reputation for wisdom. The fifth theorem is associated with the feat of measuring the distance of ships from shore, for which an empirical rule would have sufficed.

Moreover the requirements of "proof" vary according to period; of the third theorem Eudemus himself said that, although it was discovered by Thales, Euclid provided the scientific proof. Yet we may well believe that the first Greek philosopher improved on Egyptian techniques of land measurement in the way described by Proclus, who after saying that Thales introduced geometry from Egypt adds that "he made many discoveries himself and laid the foundation for his successors, attacking some problems in a more universal way and others more empirically."

The claim that Thales was the founder of European philosophy rests primarily on Aristotle, who says that he was the first to suggest a single material substratum for the universe, namely water, or moisture. The reason, Aristotle suggests, was that moisture is pre-eminently the origin and sustainer of life: vital heat is generated by moisture; semen and all nourishment must contain it. Aristotle frankly admits that he writes from hearsay; whatever Thales may have written had long been lost. Nevertheless both the statement and Aristotle's conjectural reasons are probably true in substance. The origin of all things from water was a commonplace of Babylonian and Egyptian mythology (the tradition of Thales' sojourn in Egypt is strong) and can be traced among the Greeks as far back as Homer's description of Ocean as the genesis of all things. Thales had consciously renounced myth, but its legacy remained.

We need not doubt that he was in method and intention rational. The dualism of matter and life was in the future, and what he seems to have sought was a single principle, both origin of the world and permanent ground of its being, to explain the mutability and multiplicity of phenomena. It must therefore be not only material but also author of change, that is to say, something self-changing; for, as the more mature Aristotle complained, these early Milesians did not distinguish matter from active cause. But. in Greek eyes, what changed or moved itself was alive, had psyche ("soul"). Hence, we may guess, Thales' choice of the substance which seemed to have the closest connection with life, as moisture did in Greek thought both then and later. The whole universe was a living organism, nourished by exhalations from water.

Consonant with this are other statements which Aristotle found traditionally attributed to Thales, that "the magnet has soul because it attracts iron" and that "all things are full of gods." The latter Aristotle connects with the belief that "soul is mingled in the whole." Diogenes Laërtius quotes Aristotle as saying also that Thales attributed life even to the inanimate, arguing from the behaviour of the magnet and of amber.

Of Thales' cosmology nothing is known but the statement quoted by Aristotle that the earth floats on water. To the historian of science, his significance lies not so much in the primacy of water (though some, like Sir Charles Sherrington in *Man on His Nature* [1940], have shown that this is by no means an absurd idea) as in the attempt to explain nature by the simplification of phenomena and the search for causes within nature itself rather than in the caprices of anthropomorphic gods. For cosmic unity as such, mythical precedents may again be quoted. That "all things come from one" was an early belief in Greece as in other lands; the original unity of earth and sky is crudely reflected in Hesiod's *Theogony*. Through the mists of later anecdotal tradition the true stature of Thales emerges only dimly, but as far as can be judged both he and his successors Anaximander and Anaximenes are important as constituting a bridge between the worlds of myth and reason. The ideas of these philosophers appear to some historians as remarkable anticipations of modern science, to others as transparent rationalizations of myth. They could not free themselves entirely from the inherited cosmic framework, but in their approach to it, in their critical spirit and in their determination to produce a simple, rational scheme employing only natural causes, they took a step whose future importance can scarcely be overrated. *See* also references under "Thales" in the Index volume.

THALLIUM, a metallic chemical element, discovered in 1861 by Sir William Crookes. During a spectroscopic examination of the flue dust produced in the roasting of seleniferous pyrites, Crookes observed a green line foreign to all then known spectra. He concluded that the mineral contained a new element, to which he gave the name of thallium, from the Greek for "a green twig."

Crookes presumed that his thallium was something of the order of sulfur, selenium or tellurium; but A. Lamy, who anticipated him in isolating the new element, found it to be a metal. (Symbol Tl, atomic number 81, atomic weight 204.39, stable isotopes 203 and 205.)

Thallium occurs in the rare minerals, crookesite. $(CuTlAg)_2Se$; lorandite, $TlAsS_2$; vrbaite, $TlAs_2SbS_5$; and hutchinsonite, $(TlAgCu)_2S.As_2S_3 + PbS.As_2S_3$. It is also found in minute quantities in various pyrites, some of which are processed for other purposes, as, for example, the manufacture of sulfuric acid. In such cases, thallium is often concentrated, as in the flue dusts which arise in roasting various pyrites and in the chamber muds arising from sulfuric-acid production; these by-product concentrates are the usual raw-material sources of thallium.

For the extraction of the metal from chamber mud, the latter is boiled with water, which extracts thallium as sulfate. From the filtered solution the thallium is precipitated as chloride by addition of hydrochloric acid, along with more or less of lead chloride.

The mixed chlorides are boiled down to dryness with sulfuric acid to convert them into sulfates, ahich are then separated by boiling water, which dissolves only the thallium salt. From the filtered solution the thallium is recovered, as such, by pure metallic zinc, or by electrolysis. The (approximately pure) metallic sponge obtained is mashed, made compact by compression, fused in a porcelain crucible in an atmosphere of hydrogen and then cast into sticks.

Physical Properties.—Thallium is a bluish-white metal that is very soft, malleable and of low tensile strength. Two crystalline forms are known with a transition temperature of 226° C. Some of the common physical properties are given in Table I.

Chemical Character.—The elements gallium, indium and thallium comprise Subgroup III in the periodic table (see PERIODIC LAW). Thallium has the following electron arrangement in the incomplete orbits (O and P): $5s^2$, $5p^6$, $5d^{10}$, $6s^2$, $6p^1$. It readily loses one of its valence electrons to form thallous, the +1 oxidation state, or all three electrons to form thallic, the +3 state. In the chemistry of gallium and indium (*qq.v.*), which have the same outer electron arrangement, the +1 state is of little importance. Thallium metal resembles lead in most of its physical properties. Thallous ion resembles divalent lead in the formation of insoluble chlorides and iodides; it is also quite similar in many of its properties to the alkalies since it is a +1 ion of similar size. Thallic ion resembles aluminum and gold but with less pronounced acid-forming properties since it is a larger +3 ion.

Metallic Thallium.—As shown by the potential in the above table of physical properties thallium is easily oxidized to the thallous state. It tarnishes in air, forming an oxide film which readily dissolves in water; upon prolonged contact with air and water the metal dissolves to form a thallous-hydroxide solution. At red heat, water reacts to liberate hydrogen with the formation of thallous oxide, Tl_2O. Thallium dissolves in nitric acid and sulfuric acid; it dissolves less readily in hydrochloric acid, which precipitates the insoluble chloride. It unites directly with all the halogens.

Salts.—Thallium forms two series of salts: thallous, in which the metal is univalent; and thallic, in which it is trivalent. The thallic salts are, however, much less stable than the thallous.

Thallium salts are used in the manufacture of certain optical glasses because of the high refractive index conferred on the glass. They are all poisonous, having an action somewhat resembling that of lead salts, and are said to have a pronounced depilatory action, but this has also been denied.

Thallous hydroxide, TlOH, is most conveniently prepared by decomposing a solution of the sulfate with barium hydroxide. It crystallizes from its solution in long yellow needles, TlOH or $TlOH + H_2O$, which dissolve readily in water, forming an intensely alkaline solution which acts as a caustic and greedily absorbs carbonic acid from the atmosphere. Unlike the alkalies, it readily loses its water at 100° C. and even at the ordinary temperature to form the oxide Tl_2O, which is black or black-violet. Thallic oxide, Tl_2O_3, is formed when the metal is heated in air or oxygen at 500°–700° C., by the action of hydrogen peroxide upon alkaline solutions of thallous salts, or by heating thallous nitrate. It decomposes into thallous oxide and oxygen above 800°. The corresponding hydroxide, TlO OH, is very unstable. A thallothallic oxide, $Tl_2O.Tl_2O_3$ or TlO, is also known.

Thallous chloride, TlCl, is readily obtained from the solution of any thallous salt, by the addition of hydrochloric acid, as a white precipitate similar in appearance to silver chloride, like which it turns violet in the light and fuses below redness into a (yellow) liquid which freezes into a hornlike flexible mass. It is also formed when the metal is burned in chlorine. One part of the precipitated chloride dissolves at 0° C. in 500 parts of water, and in 40 parts at 100° C. It is less soluble in dilute hydrochloric acid. Thallous iodide, TlI, similarly obtained as a yellow precipitate, requires 16,000 parts of cold water for its solution. The yellow crystals melt at 190°, and when cooled assume a red colour, which changes to the original yellow on standing.

Thallous bromide, TlBr, is a light yellow crystalline powder; it is formed analogously to the chloride. Mixed bromide-iodide crystals have a high infrared transmission; lenses, windows and prisms ground from the crystals are used in instruments for the detection and measurement of infrared radiation.

Thallous perchlorate, $TlClO_4$, and periodate, $TlIO_4$, are interesting inasmuch as they, together with several other thallous salts, are isomorphous with the corresponding potassium salts.

Thallous carbonate, Tl_2CO_3, more nearly resembles the lithium compound than any other ordinary carbonate. It is produced by the exposure of thallous hydrate to carbon dioxide and therefore is obtained when the moist metal is exposed to the air. It forms resplendent monoclinic prisms, soluble in water. The bicarbonate is not known.

Thallous sulfate, Tl_2SO_4, forms rhombic prisms soluble in water, which melt at a red heat with decomposition, sulfur dioxide being evolved. It unites with aluminum, chromium and iron sulfates to form alums (*q.v.*). It also forms double salts of the type $Tl_2SO_4(Mg, Fe \text{ or } Zn)SO_4.6H_2O$. Thallous sulfide, Tl_2S, is obtained as a black precipitate by passing hydrogen sulfide gas into a thallous solution. It is insoluble in water and in the alkalies, but readily dissolves in the mineral acids.

Thallous nitrate, $TlNO_3$, is obtained as white, rhombic prisms by crystallizing a solution of the metal, oxide, carbonate, etc., in nitric acid. Various thallous phosphates are known, *e.g.*, $Tl_2HPO_4.H_2O$, TlH_2PO_4, Tl_3PO_4, $Tl_4P_2O_7$, etc.; they bear a close resemblance to the corresponding phosphates of the alkali metals.

Thallic chloride, $TlCl_3$, is obtained by heating the monochloride with chlorine under pressure, or by saturating a suspension of the monochloride in water with chlorine; when anhydrous it is a crystalline mass which melts at 24°. It forms several double salts; *e.g.*, with hydrochloric acid and the alkaline chlorides. The chlorine is not completely precipitated by silver nitrate in nitric acid solution, the ionization apparently not proceeding to all the chlorine atoms. The mixed chlorides $TlCl.TlCl_3$ and $3TlCl.TlCl_3$ are also produced by the regulated action of chlorine on the monochloride.

Thallic iodide, TlI_3, is interesting because of its isomorphism with rubidium and cesium tri-iodides, a resemblance which suggests the formula $TlI(I_2)$ for the salt, but T. M. Lowry and A. J. Berry (1928) showed that it does not give the reactions of a thallous salt, and when dissolved in methyl alcohol, it behaves as a binary electrolyte; *i.e.*, as $(TlI_2)I$ or as $Tl[TlI_6]$.

Thallic sulfate, $Tl_2(SO_4)_3.7H_2O$, and thallic nitrate, $Tl(NO_3)_3.3H_2O$, are obtained as colourless crystals on the evaporation of a solution of the oxide in the corresponding acid. The sulfate decomposes into sulfuric acid and the trioxide on warming with water, and differs from aluminum sulfate in not forming alums.

Thallous acetylacetone, $C_4H_7O_2Tl$, prepared from an alcoholic solution of acetylacetone and the hydroxide, is of interest.

Analysis.—All thallium compounds volatile or liable to dissociation at the temperature of the flame of a Bunsen lamp impart to such flame an intense green colour. The spectrum contains a bright green of wave length j.351 A. From solutions containing it as thallous salt the metal is easily precipitated as chloride, iodide or chloroplatinate by the corresponding reagents. Hydrogen sulfide, in the presence of free mineral acid, gives no precipitate; ammonium sulfide precipitates Tl_2S from neutral solutions as a dark-brown or black precipitate insoluble in excess of reagent. Thallic salts are easily reduced to thallous by means of solution of sulfurous acid, and thus rendered amenable to the above reactions. Thallous chloride can be titrated by potassium iodate in moderately concentrated hydrochloric acid solution.

THAMES, a river of England, rising in several small streams among the Cotswold hills in Gloucestershire. Its source is generally held to be at Thames Head, in the parish of Coates, 3 mi. W. of Cirencester; but claims have also been advanced on behalf of the Seven Springs, the headwaters of the Churn river, 5 mi. S. of Cheltenham. The length of the river from Thames Head bridge to London bridge is 161¼ mi. and from London bridge to the Nore, 47¾ mi., a total of 209 mi. The width at Oxford is about 150 ft., at Teddington 250 ft., at London bridge 750 ft., at Gravesend 2,100 ft., and between Sheerness and Shoeburyness, immediately above the Nore, $5\frac{1}{2}$ mi. The height of Thames Head above sea level is 356 ft., Seven Springs 700 ft., and Lechlade 237 ft. and the average fall below Lechlade is 20 in, per mile. In the following paragraph the bracketed figures indicate the distance in miles above London bridge.

The upper course lies through a broad valley. The scenery is rural and pleasant; the course of the river winding. Before reaching Oxford the stream swings north, east and south to encircle the wooded hills at Wytham and Cumnor, which overlook the city from the west. The Windrush joins from the north (left) at New Bridge ($126\frac{3}{4}$), the Evenlode near Eynsham (119), and the Cherwell at Oxford (112). Between Lechlade and Oxford the main channel sends off many narrow branches; the waters of the Windrush are similarly distributed. and the branches in the neighbourhood of Oxford form the picturesque "backwaters." The river then passes the woods of Nuneham, and at Abingdon ($103\frac{1}{2}$) receives the Ock from the Vale of White Horse, at Dorchester ($95\frac{1}{4}$) the Thame (left), and it then passes Wallingford ($90\frac{3}{4}$) and Goring (85). The river now bends eastward, and breaches the chalk hills, dividing the Chilterns from the downs of Berkshire. From this point as far as Taplow the southern slopes of the Chilterns descend closely upon the river; they are finely wooded, and the scenery is peculiarly beautiful. At Pangbourne ($80\frac{3}{4}$) the Thames receives the Pang (right), and at Reading (744) the Kennet (right). After passing Reading it bends northward to Henley (65), east ard past Great Marlow (57) to Bourne End (54), and southuard to Taplow and Maidenhead ($49\frac{3}{4}$), receiving the Loddon (right) near Shiplake above Henley. Winding in a southeasterly direction. it passes Eton and Windsor ($43\frac{1}{4}$), Datchet ($41\frac{1}{2}$), Staines (36), Chertsey (32), Shepperton (30) and Sunbury ($26\frac{1}{2}$), receiving the Coln (left) at Staines, and the Wey (right) near Shepperton. Flowing past Hampton Court, opposite to which it receives the Mole (right), and past Kingston ($20\frac{1}{2}$), it reaches Teddington ($18\frac{3}{4}$). Passing Richmond (16) and Kew the river flows through London and its suburbs for a distance of about 25 mi., till it has passed Woolwich. Gravesend, the principal town below Woolwich, is $26\frac{1}{2}$ mi. from London bridge. The estuary may be taken to extend to the North Foreland of Kent. In the tideway the principal affluents of the Thames are the Brent at Brentford, the Wandle at Wandsworth, the Ravensbourne at Deptford, the Lea at Blackwall, the Darent just below Erith, and the Ingrebourne at Rainham, besides the Medway.

The basin of the Thames is of a composite character. Thus, the upper portion of the system, above the gap at Goring, is a basin in itself, defined on the west and south by the Cotswold and White Horse hills and on the east and north by the Chilterns and the uplands of Northamptonshire. But there are several points at which its division from other river basins is only marked by a very low parting. Thus a well-marked depression in the Cotswolds brings the head of the (Gloucestershire) Coln, one of the headstreams of the Thames, very close to that of the Isborne, a tributary of the Warwickshire Avon; the parting between the headstreams of the Thames and the Bristol Avon sinks at one point, near Malmesbury, below 300 ft.; and headstreams of the Great Ouse rise little more than two miles from, and only some 300 ft. above, the middle valley of the Cherwell. The White Horse hills and the Chilterns strike right across the Thames basin, but almost their entire drainage from either flank lies within it, and similarly a great part of the low-lying Weald, though marked off from the rest of the basin by the North Downs, drains into it through these hills. Further, the Kennet continues upward the line of the main valley below the Goring gap, and the Cherwell that of the main valley above it. The basin thus presents interesting problems. Its main features originated on a land surface high above the present level at a time when a thick cover of Mesozoic rocks extended far to the west of their present outcrop. The Thames developed its main stream along the synclinal axis of the London basin, roughly on the line of the present Kennet, at least by mid-Tertiary times. Much of the drainage of the area south of a divide running from Market Harborough through Birmingham to Plynlimon was carried southeastward toward this axis, as is evidenced by the wide valleys of the Cotswold headwaters and by the dry valleys across the Chilterns. When the supposedly Cretaceous cover was removed from the western areas, subsequent streams quickly developed along the outcrops of the clayey Jurassic beds. thus diverting many of these tributary streams to the northeast or southwest. The Goring gap across the chalk escarpment, developed as a deep valley in the ancient surface. was maintained and deepened by the waters collected by the upper Thames from the beheaded Cotsmold streams and by the Cherwell from the north. The lower Thames appears to have followed the Kennet direction northeastward near the line of the present St. Albans vale until the Ice Age when the accumulation of drift deposits blocked that outlet and forced the river south toward its present position. The intricate terraces of the Thames gravels are of great interest to Pleistocene geologists and archaeologists; in the Middle Gravels of the "100-foot" terrace of the Thames, at Swanscombe, Kent, were found fragments of the Swanscombe skull associated with Acheulean hand axes.

Tamesis and Isis.—The Thames about Oxford is often called the Isis, a name recorded in the 14th century. Caesar (De Bell. Gall. v, II) says that at the time of his invasion of Britain it was called Tamesis. E. Ekwall says it is a British river name cognate with the Sanskrit name *Tamasā,* a tributary of the Ganges; the name is taken to mean "dark river." In the first statute passed for improving the navigation of the river near Oxford (21 Jac. I) it is called the river of Thames, while in a statute of George II (1751) the word Isis appears.

River Regulation.— The flow of the Thames varies greatiy, according to the season. In very dry summers the flow at Teddington has been known to fall as low as 200,000,000 gal. per day and as high as 20,000,000,000 gal. in a rainy season. Flooding of the surrounding country is not uncommon, and it becomes a serious menace to the low-lying parts of London, where the river is tidal, when flooding coincides with high spring tides. The importance of storage reservoirs is manifest under such conditions of flow, especially bearing in mind the ever increasing needs of the London district. The water supply of London is considered under that heading; it may be noted here that the Thames forms its chief source of supply, but apart from this the corporation of Oxford and two companies in the Staines district have powers to draw water from the river.

Throughout the whole of the Thames watershed, and especially in the 3,800 sq.mi. above the intakes of the water companies (at Hampton or in the vicinity), the Thames Conservancy has enforced the requirements of parliament that no sewage or other pollution shall be allowed to pass into the Thames, or any water communicating with it.

In 1771 an act of parliament was passed authorizing the construction of pound locks on the Thames above Maidenhead bridge. In pursuance of the powers thus granted, the Thames commissioners of that day caused locks to be built at various points above Maidenhead, and between 1810 and 181j the corporation of London carried out river works on the same lines as far down the river as Teddington. The works as subsequently maintained by the Thames Conservancy board ensure an efficient head of water during the drier seasons of the year, and facilitate the escape of winter floods. The Thames is connected with neighbouring rivers by canals, but nearly all these are now abandoned or used only for pleasure boating or a little local trade. The Grand Union canal carries local London traffic and long distance traffic from London to Birmingham, Nottingham and Leicester. The Lea navigation takes goods to and from the London docks 26 mi. up the Lea valley. The vast traffic on the lower river and the estuary is controlled by the Port of London authority whose administration covers the waterway from Teddington to the Nore. Only pleasure craft and a little barge traffic use the river above Teddington.

In 1857 the Thames Conservancy board was established. Its powers were increased and its constitution varied in 1864, 1866 and 1894, but the creation of the Port of London authority limited its jurisdiction. Fish are fairly abundant, especially coarse fish such as roach, dace and bleak. The salmon was caught as late as 1833, but subsequent pollution killed many fish. The right of the public to take fish freely from the river has been frequently under dispute and fisheries came under the regulation of bylaws made by the Thames Conservancy.

THAMES, BATTLE OF THE, was fought on Oct. 5, 1813, during the War of 1812. During the first year of the war the British captured Detroit and gained control of much of the U.S. northwest. Capt. Oliver H. Perry's naval victory over the British in Lake Erie on Sept. 10, 1813, reversed the course of the northwest campaign. Brig. Gen. Henry A. Procter, the British commander, abandoned Detroit and began a hasty retreat across Upper Canada (Ontario) toward Lake Ontario. He was pursued by about 3,500 U.S. troops under the command of Maj. Gen. William Henry Harrison: who had the aid of Perry's fleet. The battle mas fought at Moraviantown on the Thames river, a few miles east of present-day Thamesville. The British with about 600 regulars and 1,000 Indian allies under Tecumseh were greatly outnumbered and were quickly defeated. Tecumseh was killed and many of the British were captured, but Procter escaped. The United States regained control of the northwest and most of the Indian tribes abandoned their alliance with the British. After the battle the U.S. troops returned to Detroit after destroying Moraviantown. a village of Christian Indians. In Canada the engagement is called the battle of Moraviantown.

THANA, a town and district in India, in the Bombay Konkan division. Bombay state. The town is 21 mi. from Bombay city, of which it is now practically a suburb. Pop. (1961) 101,103.

The DISTRICT OF THANA has an area of 3,683 sq.mi. It extends along the coast and is confined between the. Western Ghats on the east and the sea on the west, while on the north it is bounded by the Portuguese territory of Damaun and by Surat district, and on the south by Bombay suburban district. The district is well watered and wooded, and, except in the northeast, is a low-lying rice tract broken by hills.

Most of the hills were once fortified, but the forts built on them are now dilapidated and useless. The only rivers of any importance are the Vaitarna and the Ulhas. the former being navigable for a distance of about 20 mi. from its mouth. There are no lakes; but the Vehar and the Tulsi, formed artificially, supply Bombay city with water. In 1961 the population was 1,653.327. The staple crop is rice. Fishing supports many of the people. and the forests yield timber and other produce. Salt is manufactured by evaporation along the coast.

The territory comprised in the district of Thana (apart from Salsette island. which was acquired in 1782) formed part of the dominions of the peshwa, and was annexed by the British in 1818 on the overthrow of Baji Rao.

THANESAR, an ancient town of India, in Karnal district of the Punjab, on the Saraswati river. Pop. (1951) 11,273. As the centre of the tract called Kurukshetra in the Mahabharata, it is a holy place. The bathing fair held here on the occasion of a solar eclipse is said to be attended by 500,000 pilgrims.

THANET, ISLE OF, forms the northeast corner of Kent, Eng., and its name is derived either from a Celtic base meaning "bright" or "fire island," referring to beacons, or from the Old English. verb "to protrude." It is composed of a chalk ridge culminating in the North foreland and is separated from the mainland by two branches of the Stour river, one with the ancient name of Wantsum.

This former sea channel was guarded north and south by the Roman forts of Regulbium (Reculver) and Rutupiae (Richborough), and despite medieval reclamation and the silting up of Sandwich harbour! remained open for small boats until the 16th century. Anciently a ferry crossed the Wantsum at Sarre, but in the reign of Henry VII a bridge mas constructed with causeways across the marshes. The southern end of the channel was at Ebbsfleet, the reputed landing place of Hengest c. A.D. 449, and evidence of Jutish settlement has been found at Ozengell near Ramsgate and elsewhere. Thanet suffered later from Danish raids during which Minster abbey was destroyed.

Its location made Thanet of maritime importance and much of the island was associated with Dover or Sandwich and lay within the liberty of the Cinque Ports. During the 18th century Richard "Beau" Nash helped to develop Margate and Ramsgate as watering places. Modern Thanet forms one of the parliamentary divisions of Kent. It contains the municipalities of Margate and Ramsgate and the urban district of Broadstairs, and has a population of (1951) 98,695. (Fx. H.)

THANKSGIVING DAY, a national holiday celebrated throughout the United States, is a day of religious observance, set apart to give thanks for the blessings of the past year, as well as an occasion for family reunions, bountiful dinners and festivities in the home.

Though the origin of the holiday has been attributed to a thanksgiving festival held by Plymouth colony in Dec. 1621, such celebrations date from ancient times (see below). In the United States it became a particularly popular holiday in New England, and native fruits and vegetables, wild turkeys and pumpkin pies became traditional foods for the day.

From early colonial times the various American colonies celebrated thanksgiving days in recognition of such happy events as good harvests and victories over the Indians. Pres. George Washington in 1789 issued the first presidential thanksgiving proclamation in honour of the new constitution. During the 19th century an increasing number of states observed the day annually, each appointing its own date. That Pres. Abraham Lincoln, Oct. 3, 1863, by presidential proclamation appointed the last Thursday of November as Thanksgiving Day was due to the unremitting efforts of Mrs. Sarah J. Hale, editor of Godey's Lady's Book. Each succeeding president made similar proclamations, until Pres. Franklin D. Roosevelt in 1939 appointed the third Thursday of November. In Dec. 1941, however, congress by joint resolution approved by the president set the fourth Thursday of November as Thanksgiving Day, a national public holiday. Though Thanksgiving Day in the United States is rooted in native tradition, the idea of a day set apart to celebrate the completion of the harvest and to render homage to the spirit who caused the fruits and crops to grow is ancient and universal. Similarly, the practice of designating a day of thanksgiving for specific spiritual or secular benefits has been followed in many countries.

In the United States Thanksgiving, despite its religious association, often had a distinctly secular flavour. The Yankee country Thanksgiving in the middle of the 19th century traditionally featured a raffle of fowls on Thanksgiving Eve and a shooting match in the morning. In New York city the day was celebrated by companies of fantastically costumed persons who paraded noisily through the streets. Children dressed in the clothes of their elders went about their neighbourhoods begging for money or for contributions of fruits and vegetables.

Canada has long celebrated a Thanksgiving Day, the date varying from year to year, but finally generally placed on the second Monday in October. Pan-American Thanksgiving Day, observed annually by representatives of the Latin-American countries in Washington, D.C., was first celebrated in 1909.

See F. B Hough, *Proclamations for Thanksgiving (1858)*; W. D. Love, *The Fast and Thanksgiving Days of New England* (1895).

THANT, U (1909–), Burmese educator. writer and UN official who was elected acting secretary-general of the Gnited Nations on Nov 3. 1961, to serve until April 10, 1963. G Thant's election marked the first time that anyone other than a native of Europe had held this position. He filled the unexpired term of his predecessor, Dag Hammarskjold, who was killed in a plane crash in Africa on Sept 18, 1961.

U Thant was born Jan. 22, 1909, in Pantanaw, Maubin district, not far from Rangoon, Burma. (Strictly speaking, "U" is not part of his name but is an honorific title comparable to "Mr." or "Honoured Sir," though the literal meaning is "uncle." The Burmese do not use surnames at all.) He was educated at the National high school, Pantanaw, and at the University of Rangoon, but had to leave the university to help support his family At the university U Thant became acquainted with Thakin Nu (later U Nu), who was to become prime minister when Burma gaintd its independence.

After dropping out of the university, U Thant returned to the National high school in his home town as a senior teacher and later as headmaster. During the Japanese occupation of Burma, in World War II, he was a member of various educational committees, and in Aug. 1943 he returned to Pantanaw to rebuild the high school, which had been damaged during the war.

After World War II, U Thant was persuaded by U Nu and by Gen. Aung San, then leader of Burma, to enter government service. In Sept. 1947 he went to the information department and in 1939 became secretary, ministry of information and broadcasting. He was in 1952–53 a member of the Burmese delegation to the United Nations and, after serving his government in various capacities back in Rangoon, in 1957 he became Burma's permanent representative to the UN. Throughout these years he traveled widely, accompanying Prime Minister U Nu on various good-will missions and to international conferences.

Devoutly Buddhist, U Thant sought to apply the personal disciplines of detachment and concentration to get to the heart of problems at the UN. Neutralist by practice as well as inclination, he castigated the U.S.S.R. for its actions in Hungary, criticized the French over Algeria and rebuked the United States for the situation regarding Cuba. When the U.S. snd the U.S.S.R. could not agree on a secretary-general after Hammarskjold's death. U Thant was the one person on whom they could compromise. The U.S.S.R. had earlier demanded a three-man secretaryship (the so-called "troika"). U Thant continued the Hammarskjold tradition by exercising extreme discretion, keeping himself available to all national representatives and forestalling problems before they became insurmountable. Like his predecessor, he considered the UN to be first and last a world instrument for sustained negotiation.

THAPSUS, a low peninsula, now known as Magnisi, joined by a narrow isthmus to the mainland of Sicily, about 7 mi. N.N.W. of Syracuse. The Athenians used it as a naval station in their attack on Syracuse early in 414 B.C. A number of tombs contained objects helonging to a transitional stage between the second and third Sicel period, attributable roughly to 1000–900 B.C., with a proportion of Mycenaean importations.

See Orsi *in Monumenti dei Lincei* (1897), vi, 89–150.

THAPSUS, BATTLE OF (47 B.C.). After his victor:: at Pharsalus Julius Caesar followed Pompey to Egypt, where the Pompeians accumulated a large army and were joined by Juba, king of Numidia. A battle was fought at Ruspina in which Caesar was almost overwhelmed, after which he moved to Veita and besieged it, withdrew on account of lack of supplies, and, in order to compel Scipio to battle, marched on Thapsus, an ancient city of North Africa in the province of Byzacium (the modern province of Tunis), on the coast more than 100 mi. N. of Carthage. Thapsus contained large military stores, was strongly garrisoned and blockaded by Caesar's fleet. On Feb. 4, 47 B.C., he arrived before the city, and immediately besieged it. This drove Scipio into action, for he at once advanced on Thapsus and threw up two entrenched camps, one for his own men and the other for Juha's eight miles south of the city.

The maneuvers which now followed were controlled by a salt water lake, the modern Sehka di Moknine, which lies to the southwest of Thapsus. Caesar had entirely surrounded the town, but Scipio considered that it was still possible to relieve it from the south. Caesar had foreseen the likelihood of this move, and had built a strong fort in the centre of the strip of land which separates the eastern margin of the lake from the sea. When Scipio advanced he struck this fort, and being unable to take it turned back and decided to march round the lake and force the northern approach to the city. This he did, and constructed two camps north of the lake. Though Caesar would have preferred to defer battle until he had taken Thapsus, he now determined to attack Scipio before he had finished his entrenchments. Leaving Asprenas, the proconsul and two legions to carry on the siege, with the rest of his force he marched against Scipio. One-half of his fleet he left to continue the blockade, and the other he ordered to sail down the coast and make a demonstration against Scipio's rear. Placing his left on the coast, Scipio drew up his army in three lines with his elephants and light troops in front of his right and left wings, his Numidian cavalry on the left, and the rest of his cavalry and light troops on the right. Advancing on him, Caesar also extended his army into three lines with the II. and X. legions on the right, the VIII. and IS. on the left, and five legions in the centre. His flanks he covered by five chosen cohorts supported by archers, slingers and cavalry.

As Scipio's camp was but half dug, Caesar's men wished to advance at once. Caesar, however, was not over anxious to precipitate the battle because he was largely outnumbered by the Numidian cavalry. Whilst he hesitated, the X. legion suddenly sounded the charge which was repeated all down the line. The archers and slingers soon overwhelmed Scipio's elephants with their arrows and stones, driving them back on their own line, where they not only demoralized the infantry but scattered the left wing horse. The infantry lines then clinched, fighting each other until sunset, when Scipio's right wing became demoralized. This affected the centre, and soon the entire line broke and sought refuge in the half-completed camp, which was speedily captured by a double envelopment of Caesar's wings. Scipio's force was annihilated in an awful slaughter of which Mommsen writes. "If the hydra with which they fought always put forth new energies, if the army was hurried from Italy to Spain, from Spain to Macedonia, from Macedonia to Africa, and if the repose ever more eagerly longed for never came, the soldier sought, and not wholly without cause, the reason of this state of things in the unseasonable clemency of Caesar." Fifty thousand corpses were strewn over the battlefield of Thapsus, and among them were several Caesarian officers known as opponents to the new monarchy.

In this battle neither strategy nor tactics are remarkable, but what is so is the insubordination of the men, and their growing sense of mastership in the new order which Caesar was creating. He wished to found an Empire, and aimed at a complete victory, constantly taking tremendous risks and ignoring the units. The soldiers wanted peace, so that they could return to their homes and families. At Thapsus a battle was begun between the will of Caesar and the desires of his men, it was slow and progressive, and did not end until Alaric had sacked Rome. *See* PHARSALUS, BATTLE OF: *Bibliography.* (J. THARGELIA. A Greek festival bearing signs of very high antiquity; in historical times part of the cult of Apollo, but quite possibly, indeed probably, older than its arrival in Greece. The name is derived from θάργηλος, which signifies an offering of some sort (exact nature and etymology quite uncertain) used at the festival. In Attica, it was held on the 6th and 7th of the month Thargelion, to which it gave its name; the latter date (toward the end of May) was supposed to be Apollo's birthday. On the 6th, certainly at Athens and probably elsewhere, two persons known as *pharmakoi* (magical people, "medicine men"), who had been chosen for their ugliness, were beaten with plants of a magically purifying value, including squills; being thus filled with good magic, they were led through the city, presents of food being made to them. In classical times they seem to have been regarded chiefly as scapegoats, and some pretense was made of stoning or burning them to death; it is, however, fairly clear that this was not their only significance. In Attica they were called σύβακχοι; their connection with Apollo is simply that he is the great god of purification. They occur elsewhere in Ionian ritual.

On the 7th, sundry holy things, very likely including an εἰρεσιώνα (see PYANOPSIA), were carried in procession, and an important musical festival, with prizes for the best chorus, was held in honour of Apollo; this is the only rite which definitely can be said is Apolline and not taken from some still earlier ceremony. It is noteworthy that on the 6th an offering of a ram was made to Demeter Chole.

The principal part of the festival was, therefore, agricultural, as already suggested, Apollo perhaps took it over because it was in part purificatory; it certainly had no intimate relation to his worship.

THARPARKAR, a former district of Sind, Pakistan; divided in 1955 into Mirpurkhas and Sanghar districts. Area 13.435 sq.mi. Pop. (1961) 728.300 The western part of the former district. the Pat, is watered by the East Nara canals and the Jamrao canal, and the presence of water created jungle and marsh; the eastern part, called Thar. is a tract of rolling sand hills, running northeast and southwest, composed of a fine but slightly coherent sand and forming part of the much larger Thar, or Indian desert (see INDIAN DESERT).

To the southeast of Thar is Parkar. where there are ranges of rocky hills rising to 350 ft, above the surrounding level and open plains of stiff clay. This area contains the ruins of several old temples. The principal crops are millets, rice, wheat, oilseeds and cotton.

Mirpurkhas (pop., 1961, 60,861) was the administrative headquarters of the district. The town is on the metre-gauge line running from Hyderabad to the India-Pakistan frontier. A metre-gauge feeder line runs north from Mirpurkhas to join, at Nawabshah, the main line from Hyderabad to Lahore, and another goes south to Jhudo.

THARRAWADDY, a town and district in the Pegu division of Burma. The town has a station on the railway, 68 mi. N.W. of Rangoon. Pop. (1953) 8,977. The district has an area of 2.815 sq.mi. The Pegu Yoma range separates it from Toungoo district and forms the water parting between the Irrawaddy and Sittang rivers; there are also many small elevations. The Irrawaddy is the principal navigable river. Teak forests and fuel reserves cover more than a quarter of the whole area. Among the wild animals found in the mountains are elephant, bison and various kinds of feathered game. The rainfal! ranges from about 60 to 90 in. Pop. (1941) 593,909, showing an increase of 15,880 in the decade. The railway runs through the centre of the district. with ten stations.

The chief towns (pop. 1953) of Tharrawaddy are Letpadan (15,896); Gyobingauk (9,922); Zigôn (7,652); Thonzè (14,443); Nattalin (8,927); and Minhla (6,470). The staple crop is rice. The history of the district is identical with that of Henzada (*q.v.*). Tharrawaddy was formed in 1878 out of that portion of Henzada lying east of the Irrawaddy.

THARROS, an ancient town of Sardinia, situated on the west coast, on the narrow sandy isthmus of a peninsula at the north extremity of the Gulf of Oristano, now marked by the tower of S. Giovanni di Sinis.

Tharros was 12 mi. W. of Othoca (Oristano) by the coast road, which went on northward to Cornus and from there to Turris Libisonis. The town was of Phoenician origin but continued to exist in Roman times. It was destroyed by the Saracens in the 11th century.

In the necropolis to the south of Tharros many Phoenician tombs have been excavated; they are rectangular or square chambers cut in the rock, measuring from 6 to 9 ft. each way. About 3 mi. to the north is the church of S. Salvatore, with underground rock-cut chambers below it with walls decorated with pre-Christian paintings.

THASOS, Greek island in the north of the Aegean sea, off the coast of Thrace and the plain of the Nestos river (Turk. *Kara-Su*).

Herodotus (ii, 44; vi, 44–48) tells of an early Phoenician settlement, of gold mines and of a temple of Heracles; Thasus, son of Phoenix, gave his name to the island. In 720 or 708 B.C. Thasos received a Greek colony from Paros. In a war between the Parian colonists and the Saians, a Thracian tribe, the poet Archilochus threw away his shield.

The Greeks also owned gold mines on the mainland. From these sources the Thasians drew annual revenues of from 200 to 300 talents. The Athenians, after a siege of two years, compelled the Thasians in 463 to destroy their walls, surrender their ships, pay an indemnity and an annual contribution (in 449 this was 23 talents, from 445 about 30 talents) and resign their mainland possessions. After the battle of Aegospotami (405 B.C.), Thasos again fell into the hands of the Lacedaemonians under Lysander who formed a decarchy there. In the dispute between Philip V and the Romans, Thasos submitted to Philip, but received its freedom after Cynoscephalae (197 B.C.).

After a period of Latin occupation in the 13th century it was captured by the Turks in 1462. After the close of the first Balkan War it was, by the terms of the treaty of London, May 30, 1913, ceded by Turkey to Greece. The capital stood on the north coast and had two harbours. The highest mountain, Ipsario, is 3,947 ft.

Besides gold, Thasos produces wine, nuts and marble. Germany occupied it in 1941.

The population (1961) 15.916, is distributed in ten villages, mostly at some distance from the sea; for the island suffered from pirates. The people are Greek Christians and do not differ in appearance from the inhabitants of the other Greek islands.

THATÔN, a town and district in the Tenasserim division of Burma. The town is situated below a hill range, ro mi. from the sea.

Thatôn was formerly the capital of the Talaing kingdom and a seaport. Pop. (1953) 38,047. The district has an area of 4,870 sq.mi ; pop. (1941) 592,638.

THAXTER, ROLAND (1858–1932), U.S. botanist and mycologist, was born at Newton, Mass., on Aug. 28, 1858. He received the Ph.D. degree from Harvard in 1888, and in that year was appointed mycologist at the Connecticut agricultural experiment station. Three years later he returned to Harvard as assistant professor of cryptogamic botany. He succeeded William Gilson Farlow (*q.v.*) as professor in 1901, retired in 1919 and died at Cambridge, Mass., on April 22, 1932.

Thaxter's earliest paper on fungi (1887) was on the *Gymnosporangium* rusts and their Roestelia stages. He was among the first to study the slime bacteria (1892). His most famous work was done with the Laboulbeniaceae, a group of fungi that externally and apparently harmlessly parasitize insects. In his monograph (five parts published, 1896–1931) of this previously little-known family he described over roo new genera and 800 new species. In 1909 he served as president of the Botanical Society of America and in 1912 was elected member of the National Academy of Sciences. Farlow and Thaxter were successful in building an outstanding school and herbarium of cryptogamic botany at Harvard.

See account of Thaxter, with a list of his publications, in ***Biogr. Mern. Nat. Acad. Sci.,*** vol. xvii, pp. 55–68 (1937); notice in ***Proc. Linn. Soc. Lond.,*** vol. cxliv, pp. 190–192 (1932). **(J. W. TT.)**

THAYER, ABBOTT HANDERSON (1849–1921), U.S. painter, whose etherealized feminine figures were characteristic of U.S. art in the late 19th century, was born at Boston, Mass., Aug. 12, 1849. He at first specialized in animal painting, but after study in Paris with Jean Léon Gérôme, he returned to the United States (1879) with loftier aims. He was elected president of the Society of American Artists in 1884 and became a member of the National Academy of Design in 1901. He died at Dublin, N.H., on May 29, 1921.

Thayer painted delicate still life, imaginative landscapes and vital portraits. In figure pieces he often idealized young women with the obvious symbolism of wings or halos, but the real quality of these, as also of his youthful male subjects, is in character interpretation. He is best represented in Washington, D.C., at the Freer Gallery of Art and in the Gellatly collection, National Collection of Fine Arts. His long study of wild animals produced a theory of concealing coloration that was useful in developing camouflage in World War I. *See* ANIMAL COLORATION.

THAYER, WILLIAM ROSCOE (1859–1923). U.S. writer, was born in Boston, Mass., on Jan. 16, 1859. After travel abroad with a private tutor. he graduated at Harvard in 1881. In 1918 he was elected president of the American Historical association and was awarded numerous other scholarly honours.

Thayer died at Cambridge, Mass., on Sept. 7, 1923. He was best known for his works on Italian history, especially *The Dawn of Italian Independence* (1893); *A Short History of Venice* (1905); and *The Life and Times of Cavour* (1911). His *Letters* (1926) were edited by C. D. Hazen.

THAYETMYQ, a town and district in the Magwe division of the Union of Burma. The town is situated on the right bank of the Irrawaddy, opposite Allanmyo. Pop. (1953) 11,649. The cantonment is no longer used, and the population and importance of Thayetmyo have tended to decrease with the rise of Allanmyo (15.580 in 1953). There is a special industry of silverwork.

The district has an area of 4,642 sq.mi.; pop. (1941) 297,434. The rainfall ranges between 30 and 50 in. On the west is the Arakan Yoma range, and on the east the Pegu Yomas; and the face of the country, where it does not rise into mountains, is everywhere broken by low ranges of hills, many of which are somewhat barren. The chief river is the Irrawaddy, which traverses Thayetmyo from north to south.

Products are rice, cotton, peanuts, oilseeds, tobacco and cutch; the manufacture of the dyestuff is carried on extensively.

THEACEAE, the tea family, an important group of dicotyledonous shrubs or trees, with 16–18 genera and more than 200 species, chiefly tropical and subtropical, in both hemispheres. An important genus is *Canzellia,* wholly Asiatic, with 50 or more species, among them tea, *C. sinensis;* the cultivated camellia, *C. japonica;* and the Chinese tea oil plant, *C. drzrpifera.*

Stewartia, Franklinia and *Gordonia* species, all native to Asia, are often cultivated for ornamental purposes. The family is represented in the southern U.S. by two species each of *Stewartia* and *Gordonia,* sometimes called camellias, and franklinia *(Franklinia alatamaha),* a beautiful fall-blooming tree. *Ternstroemia,* with 90 or more species. and Eurya, with 100 or more species, occur in both hemispheres. *See* TEA: *Botany;* CAMELLIA.

THEAL, GEORGE McCALL (1837–1919), British historiographer, was born in Canada in 1837 and became a schoolmaster in Cape Colony in 1858.

Theal developed an interest in the natives and in the history of the country and, after settling a dispute with the Gaika Kafirs on behalf of the government (1877), joined the Cape civil service, in the native department. He was also appointed keeper of the archives, and in 1891 was made colonial historiographer, a position which he held until 1905. He died at Wynberg, Cape Province, on April 17, 1919. He published a *History of South Africa (1486–1872)*, 5 vol. (1888–93); official *Records* of *South East Africa,* 9 vol. (1898, etc.); *Records of Cape Colony,* 1793–1827, 36 vol. (1897, etc.); *The Beginning of South African History* (1902); and many other works, some in Dutch.

THEATRE (ARTICLES ON). The article DRAMA discusses the origins of the dramatic arts and gives a historical review of dramatic literature and institutions, from ancient Greece, Rome and India to the Broadway and West End of today. THEATRE is concerned with the dynamics of drama—the evolution of the various forms of stage presentation, and the ideas and methods that animate the modern stage.

The activities involved in bringing a script to life before an audience are treated in ACTING, DIRECTION AKD PRODUCTION. The changing standards by which theatrical values have been judged are discussed in DRAMATIC CRITICISM. The contributions of dramatists to national literatures are evaluated in such articles as AMERICAN LITERATURE; ENGLISH LITERATURE; FRENCH LITERATURE; SPANISH LITERATURE; etc.

Various forms of dramatic art discussed in the surveys mentioned above are represented also by individual articles—for example: BALLET; COMXEDIA DELL'ARTE; KABUKI THEATRE; MASQUE; MUSICAL COXEDY; NŌ DRAMA; OPERA; OPERETTA; PAGEANT; PANTOMIME; SHADOW PLAY.

Additional articles on forms of theatrical presentation include MIKSTREL SHOW; MUSIC HALL AND VARIETY; PUPPETS AND MARIONETTES; VAUDEVILLE.

Articles dealing with technical aspects of the theatre include COSTUME DESIGK, THEATRICAL; MAKE-UP (STAGE. MOTION PICTURE AND TELEVISION); MASK; STAGE LIGHTING; THEATRES (STRUCTURES).

MOTION PICTURES gives a comprehensive survey of motion-picture writing, directing and technology. Sections on animated cartoons and educational films are included, as well as discussions of methods of distribution. Other mechanical media for drama are treated in BROADCASTING and TELEVISION.

A series of articles deals with individual theatrical organizations—for example, COMÉDIE FRANÇAISE; FEDERAL THEATRE PROJECT; FOLIES-BERGERE; GROUP THEATRE; MOSCOW ART THEATRE; OBERAMMERGAU; THEATRE GUILD.

Among the articles on theatrical lore and activities are CONJURING; FOOL (JESTER); FORTUNE TELLING; PUNCH; and VENTRILOQUISM.

Many biographical articles—for example, those on Shakespeare and Garrick—review the work of the great playwrights and actors in the perspective of the societies to which they belonged. The article on Shakespeare outlines his life and work, the sources on which he drew and his place in Elizabethan London. A separate section of this article analyzes the various types of conjecture on which the anti-Shakespearean theories have been based, and balances these against the body of established facts.

The Index. in addition to listing complete articles on theatiical topics, guides the reader to subjects covered in individual sections and passages.

The following articles are suggested as a minimal reading program for an introduction to the history and basic methods of the dramatic arts: ACTING, DIRECTION AND PRODUCTION; DRAMA; DRAMATIC CRITICISM; MOTION PICTURES; TELEVISION: *Television Broadcasting;* and THEATRE.

THEATRE, the place in which dramatic entertainments are presented (from the Greek *theatron)* and, by extension, the activity comprising both the dramatic performances themselves and the work of all who are responsible for presenting them to audiences. This article is arranged as follows:

I. GENERAL

1. Introduction.—When the word theatre is employed in the extended modern sense, descriptive epithets like Greek, Chinese, Elizabethan and Restoration. used in conjunction with it, serve to characterize not only the style of acting, building, costume and setting used in the theatre of the nation or period of history specified but even the style of written texts, together with the complex structure of commercial organization, government regulation and social relations. Theatre is, then, a style of dramatic art individual enough in its theory and practice to warrant description by a special label; "Indian theatre," "medieval theatre," "theatre in the round" define whole subjects either as homogeneous categories or periods of dramatic history, or as identifiable dramatic styles.

These styles are evolved through the cross-fertilization of national and historical artistic traditions in theatre practice, as exemplified in England or France by the adoption during the 17th century of Italian Renaissance landscape scenery, or in Germany by the 19th-century vogue for Shakespeare or during the present century by W. B. Yeats's interest in the Japanese nō play and the public enthusiasm for the Russian ballet presented by Sergei Diaghilev in Paris and London. The physical shape of stage and auditorium. too, in the course of about 2,000 years, has had a direct influence on the sort of play devised for performance: this is clearly seen when Sophocles' *Antigone, Electra* or *Oedipus Rex* are compared with modern versions of the same stories (*e.g.,* by Jean Anouilh. Hugo von Hofmannsthal. Jean Cocteau) where the large role played in the original by a numerous chorus is adapted or omitted to conform with the physical conditions of modern theatres, which are both smaller in size and more intimate in the actor-audience relationship provided.

2. Actor and Society.—In any concept of the word "theatre" larger than that restricted to timber, bricks and mortar, the centre is the actor. It is on him that the author must depend if his own scenario or text is to reach the audience as a living action. It is on him that the audience must depend as the instrument through nhom the author's ideas are fully manifested in word, gesture and deed. Theatre, in the sense of a building, only acquires a *raison d'être* as a place for actors to perform in front of spectators. This is as true of the inanimate puppet and marionette theatre, and of the filmed drama or of the mechanically projected radio and television play, as it is of the animate theatre where. in opera. ballet or play, human actors encounter their audiences in person at every performance. All dramatic art, therefore, regardless of national or period label, takes its essence from the mimetic talent of the actor and its quality from the use to which this talent is put by the society that develops and rewards it.

The quality of the individual theatre will be particular to the society and mill reflect that society's own level of development and standards of civilization. Great periods of achievement in the theatre have generally tended to coincide with or to follow immediately upon great national achievement, as the theatrical vitality of Periclean Athens, of Elizabethan England. of Louis XIV's France or of Scandinavia in the late 19th century illustrates. By contrast, a civilization with a marked addiction to ostentation and material values is likely to reflect this in a theatre dominated by spectacle and vulgarity, as may be seen in the decadence of Roman drama, of the English theatre during the 19th century or in the implications in the name of Hollywood in the latter half of the 20th century.

This relationship between the actor and the society of which he forms a part is itself responsible for the pattern of birth, growth, climax and decay repeated within every period of the theatre's history distinct enough to be identified by such special designations as "Greek tragedy" or *commedia dell'arte.* The creative initiative is invariably spontaneous and supplied by amateurs either directly as performers or indirectly as patrons. Any degree of popular success is then sought by professionals for reward until a point is reached where technical perfection or virtuosity can be admired in its own right. Exploitation of the commercial possibilities by the actors, their sponsors or both, in such a manner that financial gain outweighs care for art, quickly undermines professional integrity; artistic standards decline until that theatre loses first the respect. then the support of its patrons, and finally, its identity. Outstanding examples of the amateur initiative are the dance dramas of primitive peoples, the essays in perspective scenery and stage machinery of the 16th-century Italian *intermezzi* and of the Stuart masque in England, and the American arena theatre movement that began in Seattle. Wash., at the University of Washington and was later endowed on a professional basis in Washington, D.C.

Another cyclic feature often repeated in the theatre's evolution is the sacrifice of an initial reliance on emblematic conventions of presentation to the gradual but increasing requirements of verisimilitude and spectacle for its own sake. This change is characterized by proportionately mounting production costs and by the sacrifice on the part of the actor of much of his own liberty of action to the whims or exigencies of painters and technicians; and in motion pictures, radio and television to the mechanical restrictions of microphones, cameras and transmitters as well.

The actor's standing with society at large depends upon that of the theatre as a whole. In a primitive community he gained the approbation of his fellow men for contributing his own unusually developed human talent for mimicry to their service: in a more sophisticated society his translation to professional status may make him an object of envy to many and of censure to those others who claim that it is improper to esteem. let alone reward. any form of pretense. Acting and actors. when the activity is self-conscious enough to merit description under these terms. have thus always been a debatable asset to society; Plato thought them worthless hypocrites while in England between 1648 and 1660 they were termed "caterpillars of the Commonwealth." At other times they have been valued highly enough to be thought worth fostering, as Aristotle believed them to be, or to warrant receipt of training, salary and pension at the expense of government! as in Soviet Russia in the 1960s.

3. Origins.—This ambivalence in the actor's status and reputation in society derives directly from the way in which his mimetic talent is first harnessed to the needs of society. This talent is instinctive in every child and brings him from infantile to mature social behaviour. Linked with this instinct to explore by imitation and thus to enlarge experience is an egocentric concept of the individual's relationship to other people. The two in conjunction result in the self-assertion that distinguishes the personality of one individual from that of another. Once pretense by imitation has acquired this degree of self-consciousness. a distinction between "the performer" and "the beholder" becomes possible; each is only satisfied by the presence of the other. Theatre is born when this co-operative act of make-believe extends to cover consecutive imitated action. The attention of the beholder is arrested and held by the nature and accuracy of the imitation, while the ability of the imitator is enlarged by knowledge gained from the experience.

Theatre in this most elementary of forms is inarticulate. depending neither on a formal text nor on improvised speech; known as mime (*q.v.*), imitation through gesture and movement of the face and body is common in this state to all peoples and requires only an open space for its enactment.

Historical study has revealed that theatre in this natural form is quickly harnessed by all primitive peoples in seeking explanations for what is mysterious and unknown in their own environment. Attempts are made to establish contact with the sources of power in nature that appear most destructive and hurtful to a primitive people: excessive heat and accompanying drought. rain and floods, extreme cold and other violent phenomena occasioning acute emotional anxiety to tribe or individual. The form that these attempts take is usually mimetic imitation of the phenomenon feared, or imitation of objects observed to be related to that phenomenon in nature; the consuming power of fire is sought from contact with the ashes or the secret of fertility from contact with evergreens; the rhythms of nature as heard and seen in the movement of the wind or the sea are copied and simulated in dance. With such means as these an appeal is made to the spirits or deities deemed to govern the elements to assist or at least to refrain from harming the supplicants. Disguise of the person in the shapes of nature and projection of the person into dance patterns imitating its movements are thus among the earliest distinctive components of theatre; a third essential is an open space where the disguised dancers may undertake their ritual.

The obstacle between these preparations and direct communication with the hidden god is consciousness of pretense in the whole nature of the action; the disguises adopted, being no more than emblems of the nature of the god, cannot be expected to induce the power required to permit speech with the god. A state of heightened emotional awareness has to be stimulated to obliterate this restrictive consciousness. It is here that the performers are called upon to generate an emotional response of an extraordinary kind in the beholders by accentuating the rhythmic quality of the dance patterns. The union between mortals equipped with nothing better than the crude symbols of the god's nature and behaviour and the controlling mind of the god himself, which in everyday life appears impossible, then becomes possible in the frenzy or ecstasy of the dance rhythms; and in this union of the spirit, involving the submergence of the individual in the whole, fear is overcome and anxiety allayed. Famine and plague may recur, but given the means of further communication the god can always be consulted.

The fear that is common to all individuals is that of death; it is thus to be expected that in their dance rhythms primitive peoples have been most attracted to those aspects of nature in which rebirth noticeably grows out of death; that is, to the solstices and the seasons. These phenomena account for the most persistent of all early theatrical imitations—the slaying of the god and his subsequent resurrection. The ancient rites associated with Osiris in Egypt derived from this assumption, and traces of it may be seen in the sword dances and mummers' play of the folk in northwestern Europe.

These rituals were designed to propitiate the forces of nature for past misdemeanours or to seek their assistance in future struggles. but many rites of a similar kind were evolved to give thanks for assistance received. These expressions of joy, however, were not marked by any such clearly defined narrative pattern as that of the dying god; the most notable characteristic was simply excess as exemplified for the whole western world by the proverbial Saturnalian orgy of Roman times or, in the Christian era, by the licentious Feast of Fools. when what E. K. Chambers described as "the peasant beneath the cassock" revealed his nature.

The transition from these dance rituals (specimens of which may still be observed in New Guinea and in parts of Africa) to a species of pretended action that incorporates a long and formal narrative with accompanying dialogue is difficult to discuss since it was not within the means of persons making this transition to record its details. They could only transmit what they knew, verbally or by example, to those who followed them and who added to and embroidered what they inherited with spontaneous inventions of their own. It is, therefore, to anthropologists and experts in the primitive religions of the world that one must turn for information. Relics survived in regular drama in the continued use of masks; in the relationship between actor and chorus in the earliest Greek tragedy and the earliest liturgical plays of the Christian Church, which reflected that of priest and congregation; in the elaborate emblematic headdresses, costumes and gestures of the Indian and Chinese classical theatre; and in the presence of an altar as the focal centre of the earliest Greek and Christian dramatic action. Above all there may be discerned in the written texts of tragic drama a continuance of earlier efforts to explain the inexorable laws of nature to fearful mankind, and in all early comedy a deliberate release of high spirits, which, in mocking everything artificial, pompous or unnatural, extols the liberty and bounty of nature.

Tragedy and comedy are the two primary types of theatrical experience that dramatic art. however sophisticated the place or time. has continued to provide. The more serious kind has always preserved some affinities with its religious origins, while the more frivolous kind has always been liable to degenerate into forms offensive to a highly developed sense of public decency. It is the exploitation of the latter forms of simulated action by professional actors for commercial reward in return for the social recreation provided (in contrast to the spontaneous amateur theatre of worship) that has caused both actors and the theatre to be attacked from time to time as vicious. immoral and better suppressed.

II. THE EAST

The country with the earliest reliable record of a dramatic tradition more advanced than ritual dancing is India, its history being traceable to about A.D. 100. Java, Bali and Burma all possess a notable dance drama, but it is from China and Japan that the most highly formalized dramas have survived into current use, despite contact with the western world. Indian classical theatre (Sanskrit) was virtually extinguished as a result of the Muslim invasions of the 10th century and after; but enough information, in the form of play texts and treatises about their staging, survived for attempts at revival to be made during the 19th century. Sot enough is yet known in the west about the early history of the oriental theatre to ascertain the degree of interaction between the various dramas of distinct national origin; the Japanese theatre, however, owes as direct a debt to the Chinese theatre as the American theatre does to that of western Europe.

The transition from dance drama to regular plays in India, China and Japan was made in each instance through the Buddhist religion and aristocratic patronage, distinct genres with written texts being in existence in India by the 2nd century A.D., in China by the 6th and in Japan by the 14th. In all three countries actors have had a mixed reputation, some enjoying the friendship of princes and others being regarded as little better than beggars or criminals. In India, actors (nuta, "a dancer") formed an identifiable class or caste in society and female roles were played by men until the 20th century. In all three countries an actor's training started in early youth, and a high degree of skill was required not only in dancing but also in singing, mime and acrobatics.

Where theatre buildings and the stage conventions employed in them are concerned, common practice is again evident. Temples and palaces adapted to suit the actor's needs sufficed initially and, in India, probably continued to do so; at least there is no evidence of buildings constructed to accommodate dramatic representations alone. In China and Japan, however, actors acquired wealth and position enough to become independent of their patrons and to build regular theatres for popular audiences. The typical Chinese theatre is a rectangular building containing a large projecting stage (almost square) backed by a curtained or painted wall containing two doors. The nō stage in Japan (and the kabuki stage, which is adapted from it) also projects into the auditorium and is square (18 × 18 ft.). A penthouse roof (adapted from the Shinto temple of origin) projects over this stage and is supported by pillars. (See NŌ DRAMA: Staging; KABUKI THEATRE.)

Theatres of the east have no scenery in the western sense of the word. Place is identified by emblems, some being permanent fixtures like the four stylized pine trees (one large, three small) of the nō stage, others taking the form of large stage properties like the arched gate or painted flags of the Chinese theatre: change of place is identified by the mime of the actors, by special properties like the Chinese tasseled horsewhip and by the shifting of properties in the audience's view by stage assistants, who sit on the stage throughout the action. These architectural and scenic conventions bear a marked resemblance to those used in European theatres of the middle ages and early Renaissance (see below).

A similar reliance upon an emblematic manner of presentation is seen in the costuming and acting style of oriental plays. Masks are rare. Only the first actor (*shite,* slztay) wears one in nō. The painting of the skin. however, and particularly of the face, was regular in all three theatres and developed to a quite remarkable degree in China. where the hua-lien or painted face denotes character through both the particular lines and colours of the make-up. Many have been standardized, and the actor is trained to be competent in the style, colour and scale of beards, applied jewels, lines and spots appropriate to particular characters.

Headdresses and articles of clothing also serve to demonstrate character and temperament. In Indian drama gods and princes are immediately identifiable by their exceptionally elaborate headdresses, while in China and Japan animal headdresses (especially tiger heads) and plumes worn above the painted face are appropriate to warriors of high rank. Colour symbolism plays as important a part in costume as it does in make-up: robes of rich silks and satins are often 'so elaborate as to require long practice in the wearing of them if they are to be maneuvered with any semblance of agility or grace.

Contact with the west did not at first make any difference to these traditions except in India, where, under British rule, a growing European interest in Sanskrit literature led to a revival of classical plays in Bengali translation (1857 and after). This revival was possible because of the survival of both the play texts and the *Natyasastra* of the Brahman priest Bharata, a detailed treatise on the composition and production of plays written during the 3rd century A.D. and as important a document for the study of Eastern drama as the writings of Aristotle and Vitruvius on Greek and Roman drama have proved to be in the west. Other later commentaries embroidered on Bharata's work but added little that was new. Archaeological research has brought to light a few pictorial representations of early performances.

Music has always formed an important element in the oriental theatre. Instrumental music conjoined with religious ceremonies introduced the leading player, who sang or spoke an explanatory prologue. In Japan, this function is shared between the second actor (who enters first) and the first actor; in China, the protagonist of the drama undertakes this task; in India. it was done by the leader of the company (*Sutradhara*). The orchestra (dominated by flutes, drums. cymbals and gongs) not only accompanies chanted dialogue but also sets a tempo that is carefully followed by the actors in their movements.

Formal differentiation of genres exists in the eastern theatres. Japanese kabuki and nō are the most obviously distinct; but in China wu (the military play) and wen (plays with civilian subject matter) are traditionally as different. Distinctions in the Indian theatre, as between *nataka* ("heroic legend") and *prahasna* ("farcical stories"), are also real. Japanese nō is itself divided into categories. Nowhere, however, is there any close correspondence to western genres (with the possible exception of melodrama). and in India the happy ending was invariable. Act and scene divisions of the kind familiar to the west are normal to all oriental plays, but unity of place has never been a question of consequence in a drama where episodic narrative is the dominant characteristic of structural form and where the technical virtuosity of the actor in a familiar role has always counted for more than novelty of plot or formal compactness. Western motion pictures, when introduced into eastern countries, found substantial popular support because of their episodic treatment of narrative; such techniques were already familiar to audiences.

Photographic realism. however, while easily copied by film makers of eastern nationality, has struck a severe blow at the imaginative emblematic conventions of the oriental stage. which by the 1960s had lost popular support to films and television.

III. THE WEST

The history of theatre in the west differs from that of the east in two important respects. In the west there was the phoenixlike rebirth of organized drama in the middle ages after about 400 years of seeming death, and in the 20th century the quest for verisimilitude in dramatic imitation culminating in the mechanical reproduction of performances on film—a western invention subsequently exported to the east.

The most important single feature distinguishing the drama of the first phase. from the 5th century B.C. to the 6th century A.D., from that of the second phase, from the 10th century A.D. to the 20th. was the intervening influence of Christian philosophy and ritual. The theatre of the first phase was Greek in origin, spread to Italy and from there was transplanted east. west and south to the frontiers of the Roman empire; northward it penetrated into Austria, Germany and even Britain. The decline and fall of the theatre. already sapped from within by a growing dependence upon costly spectacle coinciding with objections to the nature of the spectacle raised by Christians on moral grounds, was one of the results of the barbarian invasions.

Although many theatres of the Hellenistic period are still standing in the 20th century, the new drama of Christian inspiration that began to take life and shape in the 10th century did not make use of these buildings; nor did it imitate the sophisticated forms of Greek and Roman regular drama since the new texts. acting and stage conventions mere supplied by amateurs. Not until the 15th century was any serious concession made to earlier practice. The full-scale revival of Greek and Roman play forms and architectural concepts that followed in the 16th and 17th centuries was consequently distorted from the start; difficulties arose because a Christian society was seeking to emulate a product of non-Christian inspiration and because this society lacked adequate knowledge of stage practice in anything but late Roman theatres. The imitation consciously pursued was thus unconsciously based on a phase of Greco-Roman theatre already decadent in its addiction to spectacle and in its relation to society. The result. in every European country that already possessed a theatre of Christian inspiration. was to create a divorce between the two; *i.e.*, between a religious stage commanding popular support and a *commedia erudita*, or academic theatre, of interest only to the aristocracies of intellect and courtly privilege. This divorce coincided in time with the wars of religion; and, since the popular theatre was religious, the divorce took a form in each European country that followed the pattern of ecclesiastical government. In Italy divorce between the two became total by the end of the 15th century; in Spain—because of close supervision and gradual modification by the Inquisition—it is scarcely discernible; in France, Germany, the Low Countries and England it was erratic. Censorship and suppression. however, are everywhere in evidence, the differences from one country to another being in timing and degree. In France the religious stage was dissolved by the edict of 1548; in England it had become impossible by 1590 for any play devoted to religious subject matter to he performed with impunity. To the revival of Roman theatre, the court amateurs of European countries contributed something of their own—a preoccupation with dance and song, which were developed respectively in succeeding centuries as ballet and opera.

Despite the immediate triumph of the academically inspired neoclassical theatre in the 17th and 18th centuries popular elements returned to it, the way being led by the *commedia dell'arte* (*q.v.*) in Italy and by sentimentalism in English drama of the late 17th century. The romantic revival championed by Diderot in France and Lessing in Germany restored some dignity to the popular theatre of earlier times but it did not recover for a theatre of situation, intrigue. manners and scenes the popular support previously accorded to the theatre of religious and heroic narrative with its emblematic conventions of presentation. The development of melodrama in the 19th century restored to narrative and action their earlier pre-eminence, but the theatre's ability to provide accompanying spectacle of a realistic kind was eclipsed by the potentialities of the motion picture, which came into existence by the beginning of the 20th century.

The commercial potentialities of film theatre were quickly realized. The technique of marrying sound to picture was perfected in the late 1920s, opening a national market for repeated showings of a single performance, which. with the additional accomplishment of providing subtitles and "dubbing" in foreign languages. was extended to include a world-wide market. Further wholesale changes in bringing plays to audiences, instead of obliging audiences to come to theatres, are similarly attributable to advances in scientific knowledge; the most notable being the invention of radio and television transmission and of processes for the recording of such transmissions.

A. Antiquity

1. Greece.—As well as creating great dramatic masterpieces, the classical Greek theatre has left a notable legacy to posterity in the (1) distinctness of the three dramatic genres—tragedy. comedy (old, middle and new) and satyr play; (2) the size and shape of the theatre buildings; (3) the division of function within the drama between actors in the roles of characters and those serving as choric commentators interpreting between the protagonists of the stage action and the audience; and (4) the strongly characterized masks worn by the actors.

A relationship between religious festivals and the three forms of regular drama (particularly in the rites associated with the nature god Dionysus) is generally acknowledged by historians but evidence is lacking with which to define this relationship in any detail. The outstanding survival from the earliest Greek tragedy is the relationship among single actor, chorus and audience (the whole community), which parallels that among priest, initiates and congregation in religious ritual. The parallel is reinforced by the themes and structure of the earliest surviving plays. Tragedy, being concerned with the moral government of the universe, was strictly serious and formal; Aeschylus' Oresteia, for example, concerns crime and its consequences in terms of mortal and divine retribution. Comedy (*i.e.*, old comedy), being contemptuous of all human attempts to behave as if mortals possessed the minds of gods, was joyous, robust and satirical; Aristophanes' Lysistrata, although deeply serious in its concern about war, still appears in the 20th century to be as uproariously funny as it is outspoken in the means suggestedto prevent war's recurrence.

As Greek drama developed, emphasis shifted from divine and cosmic themes to mortal and microcosmic problems. H. D. F. Kitto has written that tragedy was formed, ennobled itself and lost its vigour while Athens was passing through the same processes; during this period, he points out, tragedy moved from communal to individual themes. Comedy underwent a series of equally clear transitions from, broadly political (old comedy) to social satire (middle comedy) and then to a comedy of manners with stereotyped characters in plots dependent on intrigue and situation. Changes in theatre practice kept step with these thematic tendencies. Aeschylus (*q.v.*) called on the services of a second actor (both actors doubling in more than one part) and Sophocles (*q.v.*) on those of a third. Both authors tended to increase the number of characters in their plays, and their successor, Euripides, went farther still in this direction. The chorus lost ground to the actors in number and function. The original dithyrambic chorus of 50 that Aeschylus inherited had been reduced in Euripides' lifetime to less than half the number, with nothing more to do than interpolate decorative lyrical odes as interludes in the action. In comedy, whereas Aristophanes used his chorus as formally as Sophocles, the new comedy of Menander used it for induction or the interpolation of songs for their own sake. The pursuit of realism brought with it a corresponding change in the nature of both stage language and setting. The earliest plays are made up of sequences of choral odes interrupted by "episodes" of speech for actors (*e.g.*, Aeschylus' Agamemnon). Sophocles' plays were distinguished by the perfect balance achieved between choral and dialogue speech; the metrical rhythms are of the utmost importance and probably carry in them some reminder of the original choric movements.

The place of performance, initially a large dancing floor (orchestra), was elaborated first with a dressing room and then by extension and decoration of the skene thus created on a scale great enough to permit the use of revolving panels (periaktoi) bearing pictures designed to identify the place of action and other machines. Nevertheless, the Greek theatre was wholly emblematic, employing men to impersonate women, using masks to conceal the fact that one actor was playing more than one part, and identifying place by symbol. ,Moreover, in attempting any imaginative reappraisal of a Greek play in performance, it must be remembered that the auditorium seated 10.000–20,000 persons, all of whom looked down on the orchestra and thus saw at one time the geometrical patterns of the chorus dances and the magnificence of the landscape beyond the skene.

Aristotle's notes on dramatic composition in the Poetics and a list of prize-winning plays (Didascalia) written in the 4th century B.C. provide much knowledge of the historical development of drama in Greece and a careful appraisal of the theory of tragedy, its function and composition. as practised up till his own day. These notes were translated, summarized and commented upon in Latin in later centuries (see below) but did not circulate widely in the west in the Greek original until late in the 16th century.

2. Rome.—The only plays that survive as a basis of an appreciation of Roman theatrical tastes are the comedies of Plautus and Terence (2nd century B.c.), the tragedies of Seneca (probably written to be read, not acted) and a few fragments of pieces attributed to Ennius, Pacuvius and Accius of the 3rd and 2nd centuries B.C. There is the related evidence of a great many theatre buildings (most now in ruins) ranging from such small intimate edifices as may be seen at Verulamium (St. Albans) in England, at Taormina in Sicily or at Pompeii near Naples to such grandiose monuments as the well-preserved examples at Orange in Provence and Aspendus in Turkey (see THEATRES [STRUCTURES]). As it is Aristotle's writings that furnish most knowledge of the history and theory of drama in Greece, so it is Horace (epistle to the Pisos. better known as *Ars poetica*, or "The Art of Poetry") who gives some picture of what Romans expected of their theatre. Documentation of theatre architecture and machinery, however, is better than that surviving from Greece because of the preservation of Vitruvius' De *architectura* (1st century B.c.) and Pollux's *Onomasticon* (2nd century A.D.).

The affinities between Greek new comedy and that of Plautus, as well as those present in the two styles of theatre building, argue a marked continuity between Greek precedent and Roman practice. On the other hand, the lack of any corpus of tragic texts; the nomadic and comparatively professional quality of the Roman actor's status; the certainty of a raised stage in Roman theatres, which was of more importance than the orchestra; the use in theatres built during and after the 1st century A.D. of a drop curtain with the development of scenic effects that the curtain allowed; and the additional attention given to the comfort of the audience—all indicate a positive Roman attitude to theatre that was both mundane and commercially angled. This picture is reinforced by the knowledge that under imperial rule mime and pantomime based upon actors' improvisations and acrobatics came to dominate a theatre growing steadily more luxurious in its appearance and fittings at the expense of the dramatist. Mere theatricality, exploited for the sake of display and for commercial gain, was substituted for the former religious, moral and artistic concerns of actors and audiences. With this change responsible people came to regard the theatre as something unworthy of their attention.

In republican days. Roman comedy at least still possessed written texts and aimed at exposing vice and ridiculing folly in as amusing a manner as possible. A noisy crowd in holiday mood had to be silenced by the actors and its attention held against the competition of rival sports and festival attractions. The success of Plautus and Terence at least is demonstrated by the way in which their plays have held the stage in revivals, translations and remodelings up to the 20th century. Even radio and television have deemed them worth revival in translation, Plautus' *Mostellaria,* Miles *Gloriosus* and *Menaechmi* being among the most successful.

With the alienation of the writers, however, and the steady increase in purely spectacular extravagance and vulgarity it is easy to understand why early Christians should have been as contemptuous of theatrical performances and as hostile to the profession of acting as their writings and actions show that they were. The closing of the theatres in the 5th century A.D. after the triumph of Christianity within both eastern and western halves of the Roman empire did not result from any particular antipathy to regular drama; the early Christian Fathers within the empire were opposed to a form of dramatic art so debased through commercial exploitation as to have lost any relevance to the general good of society. Outside the empire they had to contend with dramatic rituals as yet too primitive to have acquired regular forms but the closer on that account to the primitive religions that Christianity was seeking to suppress. The theatre of the ancient world thus survived in fragments only like some river that has temporarily split itself into several channels: a selection of texts, a variety of disused buildings (useful as quarries), some theoretical treatises, and groups of itinerant mimics, singers and dancers exercising their talents illicitly wherever a patron or passer-by could be found to look and listen, The barbarian invaders from the north and east. possessing no regular drama of their own and speaking languages other than Greek and Latin, could not supply the initiative required to reunite these isolated components of former dramatic and theatrical traditions.

B. Christian Revival

1. International Drama of the Medieval Church.—The first steps toward reunification were taken spontaneously and unself-consciously in the christian liturgy; the festival of Easter and celebration of Christ's resurrection provided the occasion; the meeting of the three Marys with the angel at the empty tomb and the angel's announcement of the resurrection to them was the theme. This elementary dramatic performance involving mime, dialogue and emblematic representation of person and place was soon adapted and repeated in connection with the miraculous birth celebrated at Christmas at the time of the winter solstice. In the first instance both of these dramatic representations took place within the ritual of the Mass and were enacted by the choir. The initiative appears to have come from the duchy of Swabia in the 10th century, the text taking the form of a chanted Latin introit, *Quem quaeritis in sepulchro, O Christicolae?* The great religious houses of St. Gall (now in Switzerland). Limoges and Fleury quickly elaborated these texts both musically and in the extension of subject matter. though treatment of Christ's Passion is conspicuously absent. Dramatic representation spread to areas as remote from one another as Dublin and Augsburg or Winchester and Florence, and would seem to indicate that it was accepted as part of the church's missionary and instructional activities. It is not until the end of the 13th century that the Passion is treated fully or that the vernacular is preferred to Latin.

During 300 years of slow elaboration in these liturgical music plays, a code of symbols drawn from earlier liturgical practice and chant came to be applied to the performance of these plays; the code served as the basis for subsequent theatre practice in respect of acting. costumes and setting. St. Ethelwold, as bishop of Winchester. in his *Concordia Regularis* (*c.* 978) drew up a set of rules for the acting of the *Quem quaeritis* ceremony in his diocese governing gesture. vestments and means of suggesting locale. (*See* E. K. Chambers. *Mediaeval Stage,* vol. ii.)

Similar information may be gleaned from the rubrics of service books all over Europe, though a great many of these were destroyed in the course of the Reformation. One of the fullest to have survived is the French *Festum Praesentationis Beatae Mariae* of Philippe de Mézières (1372), from which the wholly ritualistic and emblematic nature of these performances may easily be reconstructed. This text along with all others of importance is printed in Karl Young's *The Drama of the Medieval Church.* The gradual extension of the subject matter treated in these religious playlets led to an episodic narrative style with small regard to formality in respect of time, place or action. Thus in every respect this drama performed by priests for the enlightenment of worshipers openly admitted the pretense implicit in the representation.

This very important characteristic, so different from the 20th-century theatre practice which often uses every conceivable scientific device to pass off the pretense as the actual, applied with equal force to the vernacular adaptations of scripture in dramatic form that began during the 14th century. Known in Italy as *sacre rappresentazioni,* in Spain as *autos sacramentales,* in France as *mystères* and in England as miracles or (*post* 1800) as mystery plays (*see* Drama: *Medieval*), these plays were centred on Christ's Passion and were designed to stress the humanity as much as the divinity of Christ. Thus. while preserving in field, market place or town hall the same emblematic quality in performance as the liturgical play of cathedral or church interior. the highly ritualistic style of performance was relaxed to accord better with the secular elements now preponderant in the narrative. Chant gave place to speech church vestments were supplemented by contemporary costume appropriate to peasant or secular official. and scenic elements, specially made for the performance. became more decorative. The high seriousness of purpose remained, but comic elements, particularly in association with devils and peasant characters (*e.g.* Mak of the Wakefield second *Shepherds' Play* or Mrs. Noah of the Chester *Deluge*), obtained a place in the plays, assisted no doubt by the use of vernacular speech. The initiative for these cyclic dramas, which grew long enough to occupy anything from a day's duration (in York) to a week's (in London and Mons), probably must be credited to mendicant friars. Plays of similarly didactic and devotional purpose concerning the lives of Christian saints and martyrs grew up simultaneously throughout Christendom but of a more markedly national character, as determined by the particular story. Additional room for topical and local subject matter was provided by the dramatic adaptation of sermons depicting mankind's struggle to arrive before the judgment seat at doomsday with an army of virtues rather than vices to plead his fate. This kind of play. religious in purpose but secular in virtually all externals, linked parable and symbol in dramatic narrative to the symbolic manner of presentation derived from the liturgical music plays.

Thus the way was opened in every European country for a theatre as secular as that of antiquity but now consistently Christian in its ethos. In France the result mas seen in *entremets* and *soties;* in Germany in the *Fastnachtsspiel* and (farther east) in the *Neidhartspiel;* in Spain the *sainete;* in England in the "disguising" (formerly mumming, latterly masque) and the interlude (*see* Interludes; Masque; Mummers). All of these genres are distinct. national, independent; yet at the same time each of them is only an aspect, coloured by racial temperament, geography and climate, of a spirit common to Christendom. These factors also governed the conditions of performance, common practice being more noticeable than particular variants. Performances were closely linked to festivals of the Christian calendar, themselves adapted from earlier folk festivals of the agricultural year—Christmas (winter solstice): Shrovetide, Easter and May day (advent of spring); Ascension, Whitsun and Corpus Christi (summer solstice); St Michael, and All Saints (harvest thanksgiving and autumn). Choice of a place of performance was governed by the mutual convenience of actors and audience. churches. where large enough; adjacent yards or cloisters where the churches were too small: market places, quarries, even playing fields; town halls, baronial halls. palace halls. The hierarchical stratification of medieval society was strictly observed in the provision of "standings" (and more rarely seats) and arrangements for the privacy and sight lines of spectators. Stages and auditoriums were as occasional as performances. with the notable exception of the "pageant waggon" stages used in the north of England that were carefully stored away for future use. Most religious plays were performed, as in Athens, by the local community for its own members. The actors received wages but were not professionals. Female parts were played by choirboys, though not invariably. The "wives of this town" presented the play of *The Assumption of the Virgin* in Chester. The cost was underwritten by both church and town: surviving expense accounts prove that the biggest single item was the cost of scenic units and winch machinery for flying angels and disappearing devils. Modern observers may be surprised at the endurance of audiences ready to sit or stand all day for several days watching these simple but dignified and profound plays; the plays then had a rarity value augmented by long months of corporate preparation and heightened by a sense of occasion, both of which have been lost.

2. Medieval Minstrelsy and Pageantry.— An equally occasional but more nearly professional theatre that aimed at social recreation rather than religious edification grew up during the late middle ages among minstrel troupes in princely courts and the households of the lords spiritual and temporal. The troupe consisted of *jongleurs* ("tregetoures") who entertained with mime, music and circus acts, and whose social status and way of life were probably descended from those of the nomadic mimes of the Roman theatre, it was led by the *trouvère* ("troubadour"), a probable descendant of the Teutonic *scôp,* who held the rank of esquire and sang or recited *chansons de geste.* This theatre gave expression to song dance and romance literature in mime for the pleasure implicit in these things rather than for any devotional purpose. During the 15th century the troupe split into separate groups of musicians and actors. While employed as household servants and expected to perform for their master at calendar festivals, they were allowed to travel, taking their costumes and stage properties with them, and to perform for reward wherever their leader could obtain entree. Weddings and other private celebrations provided the occasions for such performances. The plays. compared with those of the religious stage, were short and often the work of a poet of reputation. Masks were frequently used and doubling of parts was invariable.

This association with aristocratic traditions and requirements brought the nascent theatre of social recreation into close contact with the codes for identifying person, rank and place developed in heraldry. Royal progresses. coronations, tournaments and battle honours which were usually celebrated by elaborate civic pageantry, provided a meeting point where the emblematic conventions of heraldry and of Christian ritual could be fused to the advantage of the actors and the painters and engineers who embellished their stages. The characters of the pageant theatres of city streets, in their persons and their speeches, contributed to a similar amalgamation of scriptural, mythological and historical figures.

This was the theatre—religious in its inception. recreational in its later development—that in the 16th century joined hands with the theatrical traditions of Greece and Rome; this was the theatre that was destined by its associations with Roman Catholic faith and ritual to become a principal target for Protestant reformers.

3. Renaissance, Reformation and Counter Reformation.—The revival of interest in all things. Greek and Roman, hastened by the fall of Constantinople to the Turks (1453) and the invention of printing, affected every theatre in Europe either directly or indirectly through Italian example. At first there was the novelty of seeing in action plays that had not been performed for more than 1,000 years; then there was the attempt to recreate something of the conditions and atmosphere of the original performances in Roman or Greek times; finally there was the adaptation of both to fit changes in manners. language and technical skills: the appeal of "modern dress" performances. Plautus' *Menaechmi* was performed in Latin before Duke Ercole d'Este in 1486. and Terence's *Phormio* by St. Paul's choirboys before Cardinal Wolsey at Hampton court in 1528. The reliance of Latin comedy upon typed characters (master, parasite, young lovers, braggart-coward, etc.) and upon plots of intrigue and situation made it easy for 16th-century adapters to do much the same in both vernacular speech and contemporary idiom. Cardinal Bernardo da Bibbiena's *La Calandria* in Italy, Rodrigo Cota's *Celestznn* in Spain and Nicholas Udall's *Ralph Roister Doister* (*c*. 1553) in England are examples of this adaptation. In tragedy, a similar reliance upon Latin example (Senecan closet drama) and upon Latin adaptations of Aristotle (rather than the Greek original) provided Renaissance revivalists with a picture of ancient drama in which questions of form assumed a greater importance than those of either content or purpose. Dramatic entertainments of this kind, eagerly championed by pedantic scholars and deemed by their patrons to be a proper adornment of a civilized household, were accepted by the intelligentsia of Europe regardless of whether or not they were likely to enjoy any popular support.

Had the divorce between the religious stage and the theatre of pedagogic archaism been as complete in other European countries as it was in Italy (where the latter was largely pioneered). there would have been no "golden age" of Lope de Vega, Cervantes or Calderón in Spain and no .'Elizabethan theatre" in England, for both English and Spanish theatres depended for their existence on the triumph of popular common sense over academic rationalism and an extravagant addiction to spectacle for its own sake

In Italy, *commedia erudita,* comedy and tragedy imitating Roman example, was played out within 100 years and became subject to violent reactions in wholly unexpected directions: the beginning of *commedia dell'arte* and pastoral-lyric drama, or "opera." The former was a revulsion against a restricting form and a reassertion of the spirit of comedy stemming from that peasant stock whose religious stage had been so rudely spurned in the late 15th century. Some of the outward farcical qualities of the *commedia erudita* were taken over (*e.g.,* scenarios, type characters), but with the *commedia dell'arte* (*i.e.,* of the profession) the change is evident enough; improvisation was substituted for a fully scripted text, the personality and skill of the actor were now highlighted rather than the toil and erudition of the author, and the appeal to a popular audience was restored. Tragedy of the Senecan kind (*e.g.,* Gian Giorgio Trissino's *Sofonisba,* written about 1515 and first performed in 1562) was redeemed from suffocating boredom by the *intermezzi,* or interludes, between the five formal acts; these were devoted to songs and dances with decors designed by architect-painters of outstanding genius; *e.g.,* Mantegna. Baldassare Peruzzi. Raphael. Leonardo da Vinci. These *intermezzi* naturally grew in length and scale to a point where they came to eclipse the more serious episodes of the performance The "satyr" play of Greco-Roman drama provided a classical source for the *intermezzi,* with their songs. dances and scenic experiments, which were deemed. in the absence of evidence. to have developed along pastoral lines from them. Torquato Tasso's *Aminta* (1573) and Battista Guarini's *Pastor Fido* (1598) forged the link. In Italy itself the emphasis on song resulted in what is now called opera; in France, dance took precedence, thus opening the way to what was later known as ballet; in England, words, song, dance and spectacle were developed in the perfect equipoise of the Stuart masque; this genre. however, relied too greatly on the occasion celebrated to survive without an autocratically administered exchequer.

The scenic theatre. based on heavily subsidized study of Vitruvius and later on the commentaries on him (Sebastiano Serlio. Andrea Palladio. Vincenzo Scamozzi, and Lorenzin Sabbatini were the most influential), spread during the 17th century to France, Austria, Germany. Scandinavia and also to Spain at the hands of Italian exponents imported for the purpose. Inigo Jones's reputation in English theatrical history, however, rests on his independent development of ideas picked up during periods of study in Italy (1603–04 and 1611–13). The new Renaissance theatre modified the classical theatre construction; the built-in perspective, though still formal, made an attempt at versimilitude that led to a fundamental disharmony in the elements of presentation. The best seats in the theatre were now determined by their view of the scene. The *frons scaena* was remodeled to form a proscenium arch concealing the elaborate scenic devices behind it, though it was still regarded as part of the scenery backing the actors rather than as a barrier dividing them from their audience. It was symptomatic of this theatre that the architect-painter took precedence. at least in respect of production costs, over both dramatist and actor.

That this prototype of Italian origin was not followed either simultaneously in time or uniformly in pattern elsewhere in Christendom was because of a combination of individual national factors and the varying international pressures of the Reformation and Counter Reformation.

During the Reformation it was inevitable that hostility to Catholic Rome and what it stood for on the one hand and enthusiasm for imperial Rome and what that represented on the other should collide at many points, not least in the theatre. In Germany, England and parts of the Low Countries and of France, Rome was at once the throne of the muses and the seat of Antichrist, the viewpoint depending on religious persuasion and academic background. With religious drama already deeply entrenched in popular esteem the theatre in these countries, however involuntarily, could not avoid becoming a contentious issue in domestic politics. In Germany the stage was set to work early in the 16th century as an active instrument of propaganda for the Reformed church. This initiative passed quickly to England—Thomas Kirchmayer's *Pammachius* (1538) was dedicated to Archbishop Cranmer—while Thomas Cromwell employed John Bale (*q.v.*) and others to write polemical interludes mocking the traditions of the Roman Catholic religious stage: the pope, monks, friars, transubstantiation. The plays were adapted from the traditional miracles and moralities and quickly led to riots. Kett's rebellion of 1549 was deemed to have grown out of a disturbance at a play in the Norfolk village of Wymondham. Tudor governments, Protestant and Roman Catholic, from 1543 onward were forced into taking legislative action against the theatre. Actors were systematically placed under strict supervision and control; an increasingly vigorous censorship was imposed on play texts in manuscript and in print; places of performance were scrutinized and made subject to licence. Under Elizabeth I the amateur religious stage was systematically suppressed. the last miracle play to be performed being that at Coventry in 1584. Under James I all actors, plays and theatres were made subject to royal licence.

In 16th-century England neoclassical drama was not accepted unquestioningly, partly because of its association with Rome and with Latin. partly because topical debate proved far more acceptable than intrigue to audiences, and partly because the nation as a whole was thrown back on its own wits and resources in the face of the mounting threat of foreign invasion. Relaxation of tension followed swiftly upon the execution of Mary, queen of Scois (1587) and the defeat of the Spanish Armada (1588), and with it came a readmission of Italian ideas in art and education. By then, however, a distinctly English style of secular theatre had grown out of the ashes of the religious stage. It was distinguished by its reliance on the symbolism derived from liturgical plays and from heraldry; it owed its narrative to the miracle cycles and saint plays, its emphasis on debate and parable to the morality play and its professional character to the players of interludes. The shape and size of its stages and auditoriums were influenced by the animal-baiting arenas, the circular and rectangular tilting yards. the square or rectangular halls and (probably) yards of inns and by the rectangular town halls and guildhalls of provincial towns. Professionally organized and relying on the financial support of commercial speculators and the protection of sovereign and court officials. the theatre of Marlowe. Kyd, Shakespeare. Jonson. Dekker and Webster remained a popular theatre in touch with its medieval heritage and self-confident enough to draw what it wanted from neoclassical precept and no more. Public theatres (Globe, Swan. Fortune, Hope. Red Bull, etc.). private theatres (Blackfriars, Whitefriars, the Cockpit) and the court theatre of the masque represent accurately enough a box-office dependerice on plays and performances reflecting past traditions, present experiments and a prototype for the future.

Where the court masques mere largely the pride of amateur participants, the public and private theatres, in the hands of such shrewd and wealthy men of business as the Burbages (James 1530–97. Richard 1567–1619, Cuthbert 1566–1636), Philip Henslowe (*c.* 1550–1616) and his actor son-in-law Edward Alleyn (1566–1626), were in all respects professional. This distinction they achieved in the face of tough opposition from the more Calvinistically minded reformers and capitalist merchants who objected to the absenteeism created by the popularity of stage performances. These factions in society grew steadily more powerful in Jacobean and Caroline times. banning actors from one provincial city after another; the actors themselves. in concentrating upon a metropolitan business. position at,court, coterie audiences and extravagant spectacle, aided their enemies in cutting the bonds of popular support. The closing of the theatres in 1642 at the outbreak of the English Civil War represented as much a popular revulsion against actors and plays, considered to be little more than royal slaves and royal toys, as it did an act of puritan retribution against a relic of popery.

In Germany. France and Spain features of this pattern are repeated but with important differences of emphasis. In Germany the initiative that adapted the traditions of the religious stage for purposes of Protestant propaganda was strong enough to retard the development of the neoclassical theatre even longer than in England. Little direct Italiari influence is to be seen in German plays or stagecraft (beyond the arbitrary act and scene divisions) until late in the 16th century. The only outstanding theatrical figure was Hans Sachs (1494–1576), who adapted a disused Catholic church (the Marthakirche) in Niirnberg in 1550 as a theatre for his own and other plays acted by a company of which he was himself the leader. English traveling actors, by importing Elizabethan plays and stage conventions, gave the Germans a taste of theatre that was professionally organized for purposes of social recreation rather than for those of moral improvement and reinforced their native traditions. But this vitality was counterbalanced by the social upheaval of the Thirty Years' War, and the sterility of the polemical *commedia erudita* of the Jesuit Counter Reformation. Of attempts to combine popular Protestant drama with neoclassical precepts only the plays of Andreas Gryphius (1616--64) have attracted attention from posterity. Italian opera with accompanying scenery made heavy inroads in court circles, serving to establish a complete divorce between popular tradition and aristocratic taste by the middle of the 17th century.

In Spain, by marked contrast, the impact of the Reformation and Counter Reformation on the theatre was slight. The reason was that the Inquisition, as reorganized under Torquemada (*c.* 1486), had taken care to purge the religious stage of those elements that in other countries laid it open to ridicule. Neoclassical theatrical ideas thus developed alongside traditional popular plays and stage convention, since authors were able to write for either as inclination and occasion suggested. Since the feast of Corpus Christi continued to be observed (it was abolished in England) plays associated with the feast (*autos sacramentales*) continued to be presented throughout the 16th century and after. Courtly actor-playmakers similarly had opportunities of a far less inhibited kind than in England, although less highly organized than in Italy, to refine their craftsmanship by conscious imitation of Latin authors and to develop subject matter of an avowedly secular kind. The playwrights Juan del Encina (1468–c. 1537) and Gil Vicente (c. 1465–c. 1539) and the critic and theorist Bartolomé de Torres Naharro (c. 1480–*c.* 1530) provided between them the backbone of this alternative to the popular (and largely amateur) religious stage.

From this cult of *entremes*, *comedias* and tragedias the Spanish theatre acquired as recognizably professional an outlook and status as that of the English interludes, while from the popular religious stage it retained as distinctly rhetorical and emblematic techniques of performance and presentation as those of' the Elizabethan theatre. Market places and innyards on provincial circuits provided the actor-playwright Lope de Rueda (1510--65) with his theatre building and it was a member of his company, A. de Rojas, who in El *Viaje entretenido* gave a vivid picture of the actor's life. Under municipal control professional theatres were provided in *corrales* (courtyards) administered by religious and charitable institutions. These buildings slightly precede in date those in England, but whereas in England such buildings were limited to London, in Spain the practice spread quickly from Madrid (c. 1560) to all large provincial cities. As in England. the performers suggested improvements in the buildings they used and these found their way into subsequent designs. Performances took place in the afternoons and were accompanied by items of song and dance corresponding to the Elizabethan jig. 4 roof projected over a raised stage; the wall from which the stage jutted contained doors and windows; costume was contemporary dress adorned with heraldic or other emblems of identification; traps and flying machines were provided. This theatre was nearly akin in national temperament and professional need to that of Elizabethan and Jacobean England, and it produced dramatists of as outstanding a quality in Cervantes. Lope de Vega and Calderón, all of whom exploited the narrative possibilities of their stage to the full. Action, wide-ranging and fast-moving, was the hallmark of this theatre of the siglo de oro (see SPANISH LITERATURE: Castilian *Literature*) just as it was in the English theatre. It differed from English practice, however) in the continuing liberty allowed to plays based on biblical and theological subject matter; in the work of Calderón. for example, there is to be found a perfect blend of religious subject matter and symbolic presentation; the medieval theatrical tradition has been modernized in theology and literary style by the Counter Reformation and in stage convention by the adaptation of neoclassical settings and machinery that was wholly lacking in England. Where England contributed to the German theatre through the repertoire of strolling players, Spain contributed to France the vitality of its drama of character, situation and intrigue.

Spanish influence, however, was particularly marked in the Low Countries. governed by Spanish rulers through the first half of the 16th century and in revolt against them during the second half. The indigenous religious stage. with its notable morality play Elckerlyc (Everyman, c. 1470) and the festivals of the Rederijkers Kamers (chambers of rhetoric; see DCTCH LITERATURE), formed the basis of a theatre that might have been as influential throughout Europe as Flemish painting had not conditions of political and social unrest disrupted its development and made it subject in turn to the dominance of Spanish. Jewish and French influence. The Schouwburg theatre, built in Amsterdam by Jacob van Campen (1637), nevertheless provides the theatre historian with as interesting a building as the Teatro Olimpico at Vicenza (Palladio and Scamozzi. 1580–84).

Both illustrate the transition from medieval to classical styles of theatre architecture; the Olimpico, as markedly advanced toward the new style as was the Schouwburg (although built so much earlier in time), is noticeably dependent on the past. In these two theatres and in Johannes de Witt's drawing of the Swan theatre in London (built c. 1594) may be seen three manifestations of neoclassicism tempered by the pressures of the Reformation and Counter Reformation that conveniently epitomize a whole period of violent controversy and astonishingly varied achievement.

C. Classical, Baroque and Romantic Reaction

The French theatre followed Italian example in divorcing religious and popular drama from secular and recondite drama. Sacred drama was forbidden by decree in 1548 to prevent its being used by the Protestants to try to bring Roman Catholicism ınto contempt. Artists, unfortunately. cannot be created by decree and in consequence the great French heritage of religious plays and popular farces was followed by attempts to ape Italian academic example. but in a manner even more dogmatic than the model. The typical medieval mixture of joyous and sad, tragic and comic found no sequel in the rigid theorizing of the scholar poets, of whom Étienne Jodelle (1532–73), Robert Garnier (c. 1535–c. 1600) and Jacques Grévin (c. 1538–*c.* 1570) enjoyed a limited repute at the time. A taste for dancing and spectacle grew up among court amateurs in France centred on the ballet de cours, of mhich Le Bullet *comique* de la reine of Balthazar de Beaujoyeulx is the best-knonm example. Printed ın 1582 it provides illustrations of the scenic arrangements that were still traditional and include Circe's garden, a grove of trees and a large cloud. Early in the 17th century Pierre Corneille encountered bitter criticism in trying to bridge this gap between the unity of place demanded by the theorists and the *décor simultané* of theatre practice. a gap only made the wider by the conspicuous absence until 1595 of any professional acting company other than the crippled Confrérie de la Passion, who owned the Hôtel de Bourgogne.

Not until political stability returned to France under Cardinal Richelieu could a theatre as genuinely professional as that of Spain or England return to Paris. Two theatres. the Hôtel de Bourgogne and the Marais, then began to develop on professional lines and in keen competition, with tragedy, comedy and pastoral in the Italian manner established as the only recognized dramatic genres It was not until 1650, however, that Italian stage machinery was coupled to performances in public theatres' the occasion was Corneille's *Andromède* with settings by Giacamo Torelli It was left to Molikre and Racine to bring the French theatre, one in comedy the other in tragedy, to a pre-eminence sufficient to eclipse that of both England and Spain. and this despite perhaps the most vicious sequence of literary intrigues and personal attacks the theatre has ever known, or at any rate recorded Molière (1622–73), himself an actor. and Racine (1639–99), acquainted from youth with theatre practice and assisted by Molière. enjoyed that same protection of the sovereign and those near to him that had distinguished the careers of Shakespeare, Ben Jonson, Philip Massinger and others in England; together they brought to the theatre a degree of observation both of human foibles and of human passion and suffering that sufficed to give a genuine vitality to the revived classical forms not attained before or since. Aided by two remarkable musicians, Jean Baptiste Lully and Jean Philippe Rameau, the pastoral form was also vigorously developed in France in the directions both of opera and of ballet.

The influence of Molikre and Racine, together with that of Corneille. was felt everywhere in Europe and was synthesized for Europe in Boileau's Art *poétique* (1660). Nowhere else. however, was their genius matched; only in England, and there only in comedy, was anything written or staged that has maintained a hold on posterity in terms of frequent adaptation and revival. English tragedy modeled on the French, of which Sir William Davenant and John Dryden were the twin advocates, degenerated, as Italian tragedy had done, into operatic fantasy. Everywhere, however, from Sweden in the north to Austria in the east the real victor was the theatricality of the baroque spirit expressed in stage settings and their illumination. Classicism triumphed momentarily in France, but it was the spectacular rather than the literary quality of the revival that held Europe entranced throughout the 18th century. Everywhere it was the designers and the actors whose names counted with audiences rather than those of the writers. The costume designs of Lodovico Burnacini (1636–1707). the perspective settings of the Bibbiena family, which between 1680 and 1780 were unchallenged for originality and activity, and theatres like the opera house in Bayreuth define the baroque spirit and its rococo sequel that spread outward from dramatic representations to enhance the whole of aristocratic life. Theatre worthy of the name became a courtly or at least a metropolitan toy designed to kill time in a manner as costly as befitted its aristocratic patrons. Popular theatre dwindled into fairground improvisations and the meagre, eviscerated repertoires of strolling players At both levels there were extensive exchanges, Gustavus III of Sweden enjoying at Drottningholm in 1780 what Louis XIV had initiated at Versailles a century earlier. Pierre de Chamblaine de Marivaux in Paris enjoying closer affinities with Carlo Goldoni in Venice or Richard Brinsley Sheridan in London than with Molière, and booth theatres in provincial streets holding audiences with debased relics of Jonsonian "humour," German farce and Spanish intrigue grafted onto the improvised scenarios of *commedia dell'arte.*

Reaction and revolution came not from left or right but from the centre; *i.e.*, from the bourgeois public denied a theatre for so long by Puritan sentiment in England, by aristocratic privilege in France, by war and social unrest in the Low Countries and middle Europe. by stagnation in Spain and by feudalism in Russia and Scandinavia. A spirit of satire and sentimentality, long smoldering beneath the surface, began to make itself felt in England, particularly in the work of Henry Fielding and George Lillo; similar romantic yearnings in Germany mere made vocal by Lessing and, in the following century. these tendencies were further advanced by the nationalistic and democratic fervour of Italians, Norwegians and Russians. culminating in the work of Verdi, Ibsen and Chekhov. Moreover, the political revolution that, country by country. shattered the aristocratic façade of European theatre was accompanied by an industrial revolution of equal consequence to stage architecture and convention.

The pastoral fantasies, countertenors, literary controversies about the unities and restricted admission by privilege of birth were of little or no interest to the merchant *bourgeoisie* of Europe returning slowly to theatre or demanding theatres of their own. They wished for action and narrative of a kind not seen on the stage (outside Spain) for generations; an unwitting return was made to the genuine beginnings of theatre in ancient Athens or during the middle ages rather than to those beginnings mistakenly judged to be represented by the Roman stage on which the whole edifice of neoclassicism had been built. These yearnings, however, were not supported by any particular erudition and were in any case quickly coloured with political vested interest and spectacular possibilities of the new stage devices. Aristocratic opera and ballet were thus subjected in the early 19th century to popular sentimentalizing. comedy of character, manners and wit; to a taste for farce and tragedy; to an eagerness for violence and horror.

The cult of spectacle. however, so long a luxury for the few and the corrupter of their theatre. did not disappear; it increased and corrupted in turn the taste of the newcomers. The apotheosis of the changed theatrical style was melodrama. Melodrama is a difficult term to define since it embraced among writers such distinguished men as Goethe. Victor Hugo and Pushkin, reached its zenith in Germany and its nadir in England and the United States and, having quitted the animate theatre via grand opera and classical ballet, has perpetuated itself in motion picture and in television serial. In one sense it represents the last despairing heroic fling of the theatrical rhetoric inherited irom a pre-Christian past; in another sense it has come to stand for all that is most sentimentalized and hypocritical in a Christian-rooted theatre. What is clear is that melodrama represents a watershed in the history of European theatre; it was at once the last genuinely theatrical form with an appeal strong enough to dram its support from all ranks of society and the jumping-off point for that division between the actor and his stage that characterized the subsequent development of dramatic art in the west. Some actors, singers and dancers chose to exploit the more hedonistic and less educated element of the popular audience. With methods and organization resembling that of the medieval minstrel troupes or Roman mimes, they made what capital they could from their own personality and special "acts!' but with the important difference that on the financial success of performances in public houses it became possible to erect theatres for the purpose, thus giving a degree of urban regularity to what had hitherto been the largely rural and nomadic occupations of the fairground. From the "music room" annex to public bars sprang not only the professional circus but also the great provincial and metropolitan chains of theatres known in Britain as music hall and in the United States and parts of Europe as vaudeville and epitomized in England by the twice-nightly variety shows managed by Sir Edward Moss and Sir Oswald Stoll (see below).

Where stage plays were concerned, the popular section of the audience derived amusement from parodies of classical theatre forms ('burlesque [*q.v.*]; extravaganza; burletta) and from the spectacular sensations of shipwreck. forest fire and earthquake intermingled with violence and idealism supplied in the more elaborate melodramas, of which R. C. A. de Pixérécourt in France (1773–1844) was the pioneer and prime exponent. A similar cult of individual personality developed within the more orthodox dramatic genres of the traditional theatre, finding its prime expression in productions of Shakespeare's plays in England, in opera under German and Italian leadership and in Russian ballet. Shakespearean title roles gave the "star" actor his pre-eminence in his profession. while vocal virtuosity and powers of mimetic expression were similarly emphasized in opera and ballet respectively. Paradoxically, the narrative and spectacular elements of libretto and setting were also exploited for their own sake in a manner that made all actors other than the star the virtual prisoners of an army of technicians. The invention of gas lighting with the possibility of blacking out the auditorium (c. 1823). subsequently improved in both safety and flexibility by electric lighting. forced even the star actor off his commanding "forestage" and incorporated him within the stage picture as an adjustable item in the pictorial design. Because of the technical problems involved in manipulating these animated landscapes with narrative coherence. the star actor was gradually obliged to hand over his control of his fellow actors and the scenery; both actors and scenery were now subject to control by financial speculators and a neutral observer who. from the humble status of stage manager, came thus to be elevated to the dignity of producer, *régisseur* or director. Further dignity and power were added to his status as techniques of mechanical reproduction in motion pictures, radio and television increased the ratio of engineers and technicians to actors in any single dramatic performance, and as the star actors lost financial control to their managerial partners, (See ACTING. DIRECTION AND PRODUCTION : *Direction.*)

With the retirement of the actor off his forestage and into the scenic picture, realism of an almost photographic kind became a mnin object of production. Assisted by a developing interest in historical and archaeological accuracy that was initiated by the actor David Garrick (*q.v.*) in his costuming of Shakespeare's plays and brought to its highest point by Sir Henry Irving (1838–1905) (see IRVING) and Sir Herbert Beerbohm Tree (*q.v.*) in the costumes and settings used in their productions, this realism in externals demanded concessions from both dramatists and actors in the written and spoken text. Both had to be scaled down if the dichotomy between realistic sets and costumes and a rhetorical text and delivery were not to appear ludicrous. The language of poetry and a large measure of the virtuosity that had earlier distinguished the professional from the amateur actor were both victims of this sacrifice. Dramatists were forthcoming in France in Victorien Sardou and Eugène Scribe, in England in Thomas Robertson. in Germany in Gerhart Hauptmann. in Scandinavia in Bjørnstjerne Bjørnson, Strindberg and Ibsen and above all in Russia in Chekhov, capable of making stage action and dialogue look and sound as natural as everyday life. It was in Russia at the Moscow Art Theatre that the first serious steps were taken by the actor-producer Konstantin Stanislavski (*q.v.*) to codify a style of acting as appropriate or "natural" as the verisimilitude of the new plots. settings and dialogue demanded. The imitations that followed, under George Bernard Shaw and Harley Granville-Barker in England. under André Antoine and Jacques Copeau in France and under Eugene O'Neill (*q.v.*), Lee Simonson and others in the United States, together with the reaction against them, belong to the 20th century and to modern drama and theatre.

D. SUPPLEMENTARY ARTS

1. Opera. — Opera (*q.v.*) deserves consideration as a form of theatre in which song and instrumental accompaniment are predominant. Much eastern theatre is operatic in that the dialogue is musical; so too was the liturgical drama of the medieval church, as the recording of the Plays of *Daniel* made by the New York Pro Musica quickly demonstrates.

Opera of the sort. however, that is generally accepted under that name was introduced into Europe by the group of Florentine patricians known as the *Camerata* (*c.* 1597), whose object was to intone the dialogue of tragedy in the manner they imagined it had been recited in the theatres of ancient Greece. The result was what is known as recitative, which, when linked to aria (song), provided a text or libretto sung throughout to musical accompaniment. The story of *Orpheus and* Eurydice was provided with such settings by J. Peri. G. Caccini and C. Monteverdi in quick succession between 1600 and 1607. The latter did for music-tragedy what the painters of equal genius had done 50 years earlier for the tragic scene. Opera, thus firmly based on scenery, song and tragic or pastoral themes. swept northward through Venice, where the first public opera house was opened in 1637, to Vienna and Germany. Then it swung in two great arcs northeast to Warsaw, Stockholm and St. Petersburg and northwest to Copenhagen, Amsterdam. Brussels and London at the turn of the 17th century into the 18th century. Paris and London enjoyed a brief creative period of indigenous opera in the Italian manner between 1650 and 1700 dominated respectively by Jean Baptiste Lully and Henry Purcell.

Comic themes were introduced from Naples early in the 18th century, being developed irom between-the-acts of serious opera in the same way that tragic and pastoral opera had itself developed out of the *intermezzi* to neoclassical tragedy. While Handel arid Gluck dominated the serious operatic scene during the early and middle parts of the 18th century respectively. these developments reached their peak in Mozart's compositions for the theatre toward the close of the century.

The coincidence of political and industrial revolutions with the bourgeois sentimentalism evident in melodrama brought about a reaction toward romantic and historical plots; together with the development of the orchestra these factors led directly to the romantic opera of Verdi (1813–1901) and Wagner (1813–83). The outstanding theatrical features of all 19th-century operas are the emphasis placed on melodic line and the reliance upon the vocal range and power of the principal singers. These characteristics were quite out of line with development in the regular theatre. as signalized in the plays of Ibsen. who abandoned verse for prose. and in the acting style of the Moscow Art Theatre under Stanislavski.

Reaction to the primarily tragic and serious effusions of Verdi and Wagner (grand opera) found its outlet in light, or comic, opera. In England the light opera of W. S. Gilbert and Arthur Sullivan. in Austria the waltz opera of Johann Strauss and Franz Lehar and in France the *opéra-bouffe* of J. Offenbach (where recitative was reduced to the barest minimum and unaccompanied prose dialogue restored) opened the way to the operetta and musical comedy of the 20th century and perhaps the first distinctively transatlantic form. the American "musical."

2. Ballet. — A ballad, or ballet, in the 15th century formed an item in the repertoire of the minstrel troupe that came to be enacted in mime; to this were added the embellishments of songs and dances, the whole making up an evening's revels. During the 16th century the poem became little more than a prologue to establish the nature of the dances in masquerade. These developed as a series of "entries" of disguised courtiers who. after dancing with one another. took partners from among the spectators. Known in Italy as *maschera,* in England as masque and in France as *mascarade,* the element of dance became predominant in France during the 17th century. These ballets danced by amateurs reached their climax at Versailles at the hands of Lully and Molière. After being taken over by professional dancers they were integrated with Italian opera but could not develop further until fashion in dancers' costume allowed both greater freedom and precision of movement. This change. initiated by Marie Anne de Camargo (1710–70), was followed by attempts to link formal dances mith musically accompanied mime in the same way that one aria was linked to another by recitative in opera. The innovator was J. G. Soverre (*q.v.*), whose treatise *Lettres sur la dunse et sur les bullets* stimulated public interest and discussion of ballet as an art form all over Europe.

The objective was a re-creation of the sort of dancing deemed to have graced the classical theatre of antiquity; but, being pursued at a time when romantic forms were beginning to find public favour at the expense of classical ones, ballet derived little more from pseudoclassicism than the conventional ballerina's costume of skintights surmounted by a short skirt of tiered muslin and the so-called "classical" dance figures before being enveloped in the mystical miasmas of fantasy and spectacle derived from Gothic melodrama. Severtheless the combination of costume and dance figures sufficed to re-establish the bodily skill. grace and expressiveness of the actor with force enough to attract to it the unsophisticated folk dances of peasant communities who as yet had no other theatre. The imperial ballet of the Russian court was in the most advantageous position for this assimilation: for in Russia. as a comparatively undeveloped country of great geographical and climatic variety, a wider range of peasant dances existed for exploitation than anywhere else in Europe. A rapidly developing and strongly nationalistic school of music. itself largely indebted to the melodies and rhythms of folk music. provided Russian ballet with creative impetus enough not only to surmount any danger of the new art's dying as a result of suffocation from repetition and stereotyped convention but also to revivify dancing in the west (*see* BALLET).

3. Mime, Pantomime, Vaudeville and Music **Hall.**—Any concept of a theatre other than that restricted to timber, bricks and mortar depends for its existence on and develops around the person of the actor. Moreover. any society that has once advanced far enough to recognize the pleasure latent within the performer-beholder relationship has never been able to dispense with it. Thus although the peoples of the world have, from time to time and from place to place, and for various reasons, either refused to permit or failed to sustain an organized theatre, they have never lost touch mith the rnimer who is able to entertain with no properties other than his own voice and person. Recognizing the tenuous nature of his hold over his audience. the mimer has inevitably and invariably relied upon the easiest means of provoking laughter—verbal mockery and physical indignity.

Whatever society has prescribed to he sacred or illicit has tempted comment from him by virtue of the power that any shock possesses to attruct and hold attention. The barbed satire of social criticism and the appeal of pathos. both demanding a high degree of awareness and intelligence in their portrayal: augment the equipment of the more skilful and experienced mimer.

Throughout recorded history therefore the mimer, whether known under Greek, Latin or vernacular names, has enjoyed the abiding favour of the more oppressed sections of society and the constant disapproval of those in authority, except at rare times when that authority was too secure for any challenge to be regarded as a threat. hlarkets, fairgrounds, city streets at festival times. village green and taverns have provided their perennial auditoriums. At times they have organized membership, their finances and their patrons well enough to originate a distinctive style of theatrical performance warranting a label. The Xttelan fairs of Roman Italy, the medieval minstrel troupe. the Feast af Fools, the *commedia dell'arte* of Renaissance Europe, harlequinades. English pantomime and music hall, extravaganza, burlesque. revue, cabaret. American vaudeville and American burlesque (including strip tease) are among the most notable forms. All have been characterized by the lack of any regular script; the liberty permitted to the actors to improvise their actions and extemporize their dialogue as prompted by audience response; by the occasional interpolation of song and dance; by solo performances from individual artists; and by the exploitation of spectacle for its own sake in conjuring tricks. sexual allure. scenic machinery and. in the case of pantomime, music hall and vaudeville. in luxury and glitter of the auditorium. Blasphemy, obscenity and sensationalism, if not invariable characteristics. have been near enough neighbours to provoke constant reproof from councilors of church and state of actors engaged in these activities. Bourgeois opinion has generally aligned itself behind these dignitaries when faced with a choice between advancing its own status in society and forsaking the entertainments of the peasant, serf or manual labourer. While therefore it is on these entertainers that the theatre always relies in times of crisis for its very survival and the renewal of its energy (and must accordingly award them a place of honour and esteem), it is upon them too that responsibility must be laid for the theatre's reputation as a disreputable. frivolous, naughty. wicked or otherwise undesirable element in society. (G. W. G. W.)

IV. 20TH CENTURY

1. Asian Theatre. — The most flourishing theatre in Asia in the early 1960s was the Chinese. Every town of size had several theatres, and there were many hundreds of touring troupes. The traditional theatre prospered alongside the modern theatre. since the Communist government, although it suppressed much that was traditional in other forms of Chinese culture. allowed the immensely popular classical opera to survive: forbidding performance of only a few operas on political and moral grounds. The history of the modern theatre in China dates from 1907, when the first western plays were performed. "The talking drama," so called to distinguish it from the classical opera, was at first attacked by the universities opposed to the translation of plays into the vernacular. *paihua,* instead of the formal antique language of literature. In 1919 the "literary revolution" of the students won official recognition for *paihua* as the language for the translation of modern works, As western plays became more numerous. a number of theatres adopted western methods of staging and Chinese playwrights began to write plays in the realistic manner dealing with contemporary problems. Actresses. banned from the theatre in the 18th century, were allowed to return in 1912 after the establishment of the republic. but only in all-women troupes, in which the actresses played the male parts. In the 1920s they were admitted to the ordinary companies. By this time the status of the actor was very different from what it had been at the beginning of the century when he was regarded as belonging to the very lowest social class. The change was largely because of Mei Lan-fang, 20th-century China's greatest actor. and also a considerable scholar and a man of infinite grace and charm. The Chinese theatre in the early 1960s relied mainly on its own playwrights though a number of Russian plays were performed. Western plays were comparatively few as they were only allowed when they completely accorded with the views of the government.

In Japan the modern theatre movement began in 1924. when the Tsukiji Little theatre opened in Tokyo. This was the first Japanese theatre modeled on the realistic theatre of the west. Its founder, Hijikata Yoshi, had studied with the Moscow Art Theatre and had also become a convert to Communism. Four years later a kabuki actor, Ichiawa Chojuro, who had been playing in the U.S.S.R. with his troupe, left the kabuki to form the Progressive theatre, a community theatre on the Russian model. It included both kabuki and modern plays in its repertoire. In the middle 1930s the government decided that it could no longer tolerate the political propaganda of these two theatres. so the Little theatre was closed; Hijikata settled in Russia and the Progressive theatre confined itself to classical kabuki. But under the post-World War II occupation the Progressive theatre returned to its original policy, producing a number of Russian plays, and Hijikata came back to work in Japan. By the 1960s the Japanese theatre had long outgrown its Communist beginnings, but as a result of its origins a great many of its plays dealt with social problems. The variety of western plays given in the Japanese theatre was proof of its tolerance and interest in many conflicting ideas. Playwriting was increasing in the early 1960s, and with it Japan's theatrical importance in world drama.

The immense diversity of the 20th-century Indian theatre was exemplified by the annual drama festival in New Delhi, started in 1954, at which some 15 different languages and cultures were represented. The most influential theatre in India was the Prithvi because it played in Hindi, the national language of India. and thus reached a far larger audience than, for instance, the Bengal and Maharashtra theatres, which could be understood only in their own provinces. The Prithvi theatre was founded in 1943 by Prithviraj, famous throughout India as a film star. Its tours extended from Calcutta in the east to Saurashtra in the west, from Kashmir in the north to Dhanushkhuti Raneshwaram in the south. The plays in the repertoire mostly dealt with contemporary life and reflected Prithviraj's political and religious views. Most of the comparatively small amount of professional acting in India was concentrated in Calcutta. which had a number of modern theatre buildings as well as a prosperous motion-picture industry; as a consequence, actors were able to work in both mediums, In Bombay was India's most modern-minded theatre, called Theatre Cnit, founded in the middle 1940s by Alkazi, a young actor and director trained in London at the Royal Academy of Dramatic Art. The company performed in English but nevertheless was essentially an Indian theatre catering for an Indian public. An instance of the combining of the traditional folk and dance drama with modern theatre was Sundari's Gujerati theatre, which had its headquarters in Bombay. The plays dealt with political and social themes and particularly with the emancipation of women. In south India the first modern theatre was founded in the early 1930s by Rajamanickam. The choice of play was strongly influenced by the founder's deep religious convictions. Besides playing in its own theatre in Madras the company, more than a hundred strong in the 1960s. toured extensively, visiting other provinces to play to the Tamil communities. The Indian National theatre in Bombay. founded as a worker's theatre to take the drama to the farms and the factories, by the 1960s had branches in all the big Indian cities. The actors were mostly amateur! but more and more amateurs turned professional and it seemed likely that India would have a considerable number of professional companies when Hindi. compulsory in every school in India, became the common language.

Outside India. Japan and China, there was hardly any modern theatre in Asia. In countries such as Ceylon, Burma, Malaya and Indonesia, the highly developed forms of dance drama were so popular that there was little urge to found a modern theatre. Only in the Philippine Islands were there signs of a modern theatre developing from the efforts of enthusiastic amateur groups such as the Philippine National theatre and the Manila Theatre guild.

2. Great Britain: Direction *and* Development.—During the 19th century the English theatre was ruled by the actor-managers who directed their own productions with their permanent companies, invariably playing the leading parts themselves. At the beginning of the 20th century their authority began to be challenged by the new independent directors who rarely acted in their own productions. The first of these to establish himself firmly in the theatre was Dion Boucicault, who from 1901 to 1915, under the management of Charles Frohman, directed all the plays presented at the Duke of Tork's theatre. An autocratic director, he acted all the parts himself to the cast, who had to copy him down to the minutest detail. A director with an entirely different method was Harley Granville-Barker (*q.v.*), who from 1904 to 1907. in partnership with John E. Vedrenne, directed a series of plays for short runs at the Royal Court theatre. The venture was founded as a protest against the stagey artificial style of acting in the English theatre at that time. At first he was accused of teaching his actors "not to act" because he trained them to avoid over-exaggeration, to behave as normal human beings. He taught his actors to create a part by identifying themselves so completely with the character that gesture, movement and facial expression were the natural expression of the character's thoughts and feelings. At a time when actors had no hesitation in sacrificing character for the sake of a flamboyant theatrical effect. Granville-Barker laboured with endless patience to make the characters in a play "seem to live and move by the laws of their own being." He soon gathered round him a group of new writers hitherto uninterested in writing for the theatre because of its artificiality. Bernard Shaw alone among the authors whose plays Granville-Barker directed disliked his methods. Shaw disliked naturalism; he wanted the actors in his plays "to pull out all their stops and declaim"—which was precisely what Granville-Barker was teaching his actors to avoid. He was at his best as a director with the plays of Gerhart Hauptmann, Ibsen and John Galsworthy.

Granville-Barker did not limit himself to the direction of naturalistic plays; his three Shakespearean productions given at the Savoy (1912–14) revolutionized the Shakespearean theatre in England. As a young man he had acted in William Poel's productions for the Elizabethan Stage society. From Poel he had learned how much the full effect of a Shakespeare play depends on unbroken continuity from scene to scene, though contemporary actor-managers with their elaborately spectacular productions kept halting the play to give time for elaborate changes of scenery. Instead of realistic scenery Granville-Barker used stylized, decorative backgrounds. He speeded up the plays not only by avoiding waits for scene changes but also by teaching his actors to speak the verse swiftly though without gabbling. To audiences and critics accustomed to the slow and ponderous declamation of the Shakespearean actors at that time it seemed a breakneck speed.

In 1920 Granville-Barker retired from the theatre but the subtle and exact kind of realistic production, purged of all theatrical clichés, was continued and developed by both Gerald Du Maurier and Basil Dean. Before World War I Dean had worked under Annie Horniman at the Gaiety theatre. Manchester. where she had been insisting on the same sort of naturalism that was practised first at the Royal Court theatre; like Granville-Barker she too had gathered around her a new school of playwrights including St. John Ervine, Stanley Houghton and Harold Brighouse. At the St. Martin's theatre Dean trained a young company to give an exact interpretation of the external characteristics of their parts instead of encouraging them to use their imaginations as Granville-Barker did, but the result was acting that had extraordinary clarity, sharpness and precision. In his method of directing Dean continued the dictatorial methods of Boucicault. Du Maurier, on the other hand, directed with a deceptive casualness, which, like his own acting, concealed a very highly developed naturalistic technique. Both as an actor and as a director he had a bad influence on English acting because his imitators, lacking his technical skill, achieved only underplaying and inaudibility in their attempts to emulate the extraordinary quiet ease of Du Maurier's naturalness.

A foreign director who refreshed English acting and direction was Theodore Komisarjevsky. uho in 1919 went to England from Russia, where he had been director of the Imperial and State Theatres. Under his direction of a series of plays by Chekhov and other Russian authors the acting achieved a sensitiveness and an inner realism that set a new standard in the English theatre. His Shakespearean productions at Stratford-upon-Avon startled and often infuriated audiences accustomed to seeing there the conventional presentation of the plays. His productions were full of invention. sometimes brilliant. amusing and illuminating, sometimes merely wayward. He must be blamed for starting the "let's-be-different-at-all-costs" style of Shakespearean production that is still all too prevalent in the English theatre.

In the same tradition. Sir Tyrone Guthrie, a great director with a superb theatrical imagination, beginning in the 1930s. enforced the point of a line with a revealing stroke of "business" or brought small parts vividly to life by imaginative touches of detail, heightening the effect of everything that happened on the stage by his gift of pictorial composition and swirling movement. But sometimes his inventiveness was used merely to surprise and shock the audience or to satisfy his own sense of humour. Another fine Shakespearean producer in the English theatre at mid-20th century was Peter Brook with his superb productions of *Measure* for *Measure, Timon* of Athens and *The* Winter's Tale. His work also included brilliant interpretations of a number of French authors.

In the late 1950s the director who most powerfully influenced the English theatre was Joan Littlewood. For many years she had worked with her own company at Stratford East, on the outskirts of London, without causing any particular stir. When her productions were transferred to the West End, however. audiences responded immediately to her tremendously vigorous productions of "low-life" plays directed in the style that owed a great deal to Bertolt Brecht (*q v.*) and the traditions of the English music hall. The actors often addressed the audience direct, freeing themselves from the confines of the play. The productions were fast, noisy. broadly humorous and brimful of vitality and often. at the same time. managed to convey a considerable subtlety of characterization.

In the late 1950s and early 1960s the most experimental theatre was the Royal Court under George Devine. It gave opportunities to an extraordinary number of new writers, new directors and new designers. Rut lacking a permanent company, at the beginning of the 1960s, the young directors were not able to evolve a style of production sufficiently individual to influence the theatre as a whole In London there was no permanent company apart from the opera and ballet companies; even the Old Vic engaged its actors on comparatively short contracts. It was to remedy the lack of a permanent company with a recognizable style that Peter Hall, the director of the Royal Shakespeare theatre at Stratford-upon-Avon, in 1960 engaged a company on long-term contracts to play both at Stratford-upon-Avon and in London at the Aldwych theatre, presenting modern plays as well as plays by Shakespeare and other classics. In the provinces there were many repertory companies where the players remained comparatively unchanged for two or three years, but as most of them did a new play every week they had no time to experiment From the very few repertory companies that ran their plays longer and had longer to rehearse. an occasional production came to London; but probably the most experimental and influential was the Birmingham Repertory. which. under the direction of Sir Barry Jackson, between World Wars I and II brought many of its productions to London, including the first modern-dress *Hamlet* and the first production of Shaw's Back to *Methuselah* in its entirety.

Provincial and Repertory Theatre.—In the English provinces, the theatre divides into touring theatres and repertory theatres The touring theatres are visited by London companies either before or after they have played in London. and also by companies specially engaged to tour a London success in the provinces A play on tour seldom remains at any of these theatres for more than a week, but in the larger cities a big musical production sometimes stays up to six weeks. At Christmas nearly all these theatres stage an elaborate Christmas pantomime, a form of entertainment peculiar to England and so popular that the run often extends far past Christmas, sometimes lasting for three or four months In the early 1920s there were more than 250 touring theatres in England and Scotland. Many towns had several such theatres, besides at least one music hall. By 1960 the number of touring theatres housing straight plays had dwindled to less than 30. Many had been unable to survive the competition of motion pictures; others were destroyed during World War II; and after the war television proved the deadliest rival of all.

The provincial repertory theatres have withstood the competition of other forms of entertainment more successfully than the touring theatres. These so-called repertory theatres have no real right to the title, because they are not repertory theatres in the true sense of the word. Although they maintain permanent companies they do not keep a repertoire of plays ready for production as is the practice in the continental repertoire theatres, which give performances of several plays from their repertoire in the course of a week. The English repertory theatres put on a play for a short continuous run and then the production is scrapped. Most of these theatres run each production for only a week, some for a fortnight, while a few in the big cities perform their plays for three weeks or a month. Producing a play a week for the greater part of the year obviously means that these weekly repertory companies are always working against time; nevertheless the standard is often surprisingly good, especially when the company is so organized that the leading players can appear in minor roles for a week or two when they have a major part ahead of them.

Most of the players in the London theatre gained their early experience in the provincial repertory theatres, starting in "weekly rep" and graduating to the repertories that are able to give two or three weeks to rehearsals because their productions run for more than a week. The London theatre owes much to the repertory theatres not only because they supply it with actors who have been accustomed to playing a wide variety of roles but also because many London successes were first produced by the repertory theatres.

The first repertory theatre in Great Britain was founded by Annie Horniman (*q.v.*) at the Gaiety theatre, Manchester, in 1907. It introduced to England the work of a number of important continental dramatists and also gave opportunities to a number of promising local playwrights who became known as "the Manchester school." In 1921 it closed through lack of support and became a cinema. The oldest existing repertory theatre is the Playhouse at Liverpool, which opened in 1911. The one with the most distinguished record is the Birmingham Repertory, founded by Sir Barry Jackson in 1913. Among many other leading repertory theatres are those at Nottingham. Bristol, Sheffield, Glasgow, Windsor, Worthing, Salisbury, Oxford, Leatherhead, Coventry, Colchester and Richmond.

There are approximately 50 repertory theatres in Britain that play all the year round (except for a summer vacation of a few weeks), but there are nearly 30 more at the holiday resorts that open only during the summer months.

The *National* Theatre.—In 1949 the British parliament passed the National Theatre act empowering the treasury to make a grant of £1,000,000 to build a National theatre. Two years later the queen mother laid the foundation stone on a site on the south bank of the Thames overlooking the river, donated by the London County council. Successive governments continued to put off the building of the theatre on the grounds that there were many other buildings more urgently required. It was not until 1962 that the treasury at last agreed to release the £1,000,000.

3. U.S.S.R.—The history of modern theatre in Russia began with the founding of the Moscow Art Theatre (*q.v.*) in 1898 by Konstantin Stanislavski and Vladimir Nemirovich-Danchenko. For the previous 12 years Stanislavski had worked with a company of amateurs and it was the best of these, turned professional, who formed the nucleus of the Moscow Art Theatre company. When Stanislavski began his work the Russian theatre mas one of the most backward in Europe; acting consisted mainly in selecting from a stock of theatrical clichés whatever seemed most appropriate to the moment; little time was spent in rehearsal. The plays. mostly French comedies and farces, or Russian imitations of them, were so stereotyped that the same performances and the same sets could. with a few slight variations, be used time after time. The first three productions at the Moscow Art Theatre, which opened in 1898. caused no particular stir. It was the production of Chekhov's *The Seagull* that established the theatre and Stanislavski's reputation. The quietness, intimacy and complete naturalness of the playing was something entirely ne .

While Stanislavski continued in production after production to develop his infinitely detailed method of direction. the antirealist movement initiated by the Symbolists and Surrealists spread to Russia. where the Art Theatre was an obvious target. These criticisms came at a time when Stanislavski himself was beginning to feel that having perfected his realistic method of production he must seek new paths. In 1905 he founded a small studio theatre for experiment and research, appointing Vsevolod Meyerhold (*q.v.*) as its director. Meyerhold had been a member of the Moscow Art Theatre company but had left it three years previously when he became a convert to the Symbolist movement. When, after many months of preparation. Meyerhold staged two productions. Stanislavski disliked them so intensely that he closed the studio. He felt that the actors had been used merely as puppets to illustrate Meyerhold's theories. Yet these two productions had an important effect on him as a demonstration of the abject and slavish obedience to which the dictatorial producer could reduce his actors. He determined that henceforth the actor should be his collaborator instead of his subordinate and he began to develop the method of "inner realism" that came to be knomn as the Stanislavski method and was still the basis of the training of all the actors in the Russian theatre in the early 1960s.

After the 1917 Revolution Stanislavski refused to allow his theatre to become a platform for spreading propaganda. He believed that the mission of the Art Theatre was to maintain a standard of acting that actors in the other theatres might attempt to emulate when the first excesses of the Revolution had abated. The official edict decreed that everything—characterization. ideas. emotions—should be reduced to the simplest possible terms for the sake of the new audiences, many of them completely illiterate. This amounted to a command to the actors to overact, to abandon all subtleties of characterization and feeling. to return to the old, crude. melodramatic style of acting. 4s some of Stanislavski's own company were being influenced by the enthusiasm with which the new audience in the Soviet theatre acclaimed overacting, he decided to take his company out of Russia: so in 1922 he left on a tour of Europe and America that lasted for two years. On his return he decided that the Moscow Art Theatre must to some extent adapt itself to suit the mentality of the new audiences. He began to produce in bold, sweeping strokes, stressing whatever was dramatic in the play and enlivening the comic scenes with tricks borrowed from vaudeville. There were no half tones, no subtleties. but none of the crudities and exaggerations of the Soviet theatre of that time.

Meanwhile. hfeyerhold had become one of the most powerful influences in the Russian theatre. He declared that the principles of the propagandist theatre conform with those of Marxism because they attempt to underline "the elements which make prominent what is common to all men, the unindividual." The detailed and subtle portrayal of emotions was described as "worthless soul junk" and the actor was ordered to "forget his little rickety ego" and become "an instrument for social manifestos." There were many other producers who. educated to despise an individualistic society, exercised every kind of ingenuity to deprive the actors of their individuality. Aleksander Tairov made his actors wear fantastically exaggerated make-ups to ensure that they would not resemble anyone in real life and thus become individuals in the eyes of the audience. It was Tairov who invented the "constructivist" setting, a gaunt scaffolding supporting a few bare platforms on different levels, with every strut and bolt ostentatiously exposed to view. The aggressive functionalism of this kind of setting was regarded as having considerable propaganda value at a time when the Russians mere being taught to revere the machine as part of their training to become one of the great industrial nations of the world.

A more moderate director in the postrevolutionary theatre was Evgheny Vakhtangov, a pupil of Stanislavski. In 1914 he had been put in charge of one of the studios attached to the theatre and in 1920 he was appointed director of this subsidiary of the Art Theatre. renamed the Third Studio. But Yakhtangov was not altogether in accord with the quiet, everyday naturalness of the Art Theatre. His natural exuberance impelled him toward a style of production that. while avoiding the extreme stylization and unrealism of Meyerhold and Tairov. would. nevertheless. enlarge, heighten and sharpen character. emotion and gesture. He wanted to work in vivid colours instead of the half tones of the Art Theatre. In place of Stanislavski's inner realism he wanted what he called "outer-technique." He found the ideal actors for his purpose when Stanislavski put him in charge of a group of Jewish players who in 1917 had formed themselves into a company for the production of plays in Hebrew. Calling themselves the Habima Players they later became affiliated with the Art Theatre. Vakhtangov's masterpiece was his production of *The Dybbuk* in 1922. It was his last production; he died a few months later at the age of 39. but for many years afterward the Habima Players included his production of The *Dybbuk* in their tours of Europe and America so that it became, outside Russia, the best knomn of Soviet productions. In 1931 the Habima permanently settled in Palestine and in 1945 opened their own theatre in Tel Aviv (see HABIMA THEATRE).

The youngest of the postrevolutionary directors was Nikolai Okhlopkov, born in 1900. His earliest productions were entertainments given in World War I on an improvised platform set up in the middle of the square of his home town to entertain the troops, who encircled the stage on all sides. As a result of his experience of the open stage he found the proscenium theatre cramping and in Moscow experimented with ways of breaking down the barrier between actor and audience. In 1932 he became director of the Realistic theatre. where for his production of *The* Iron Flood he converted the whole auditorium into a rocky. mountainous terrain. seating the audience among the rocks so that the actors, playing scenes in every part of the auditorium, were mingled with the audience. He made many other experiments in other kinds of staging but in 1938 the Realistic theatre was closed on the grounds that his work appealed too exclusively to specialists and intellectuals. By this time, under Stalinism, the experimentalism that in the 1920s had made the Russian theatre the most exciting in the world had come to an end. Four years previously Meyerhold, officially censured for his "obsession with the vague abstractions of decadent art" and for being "the father of formalism," had been deprived of his position. Tairov. rebuked for being out of touch with his audiences. had been relieved of the direction of the Kamerny theatre. In the cases of Meyerhold and Tairov it is certainly true that their work was too cold and abstract to please audiences who wanted warmth and humanity and reality. But under Stalinism the theatre virtually ceased to progress since any sign of originality, any deviation from the normal, was at once condemned as decadent. The scenery became more and more laboriously realistic as any setting that was in any way impressionistic was apt to be condemned as belonging to abstract art. Only the magnificent standard of acting in the Russian theatres remained unchanged.

After Stalin's death the theatre was relieved of many of its shackles and there was a cautious return to experiment, particularly at the Satire theatre. Okhlopkov, the only survivor of the group of experimentalist producers who dominated the theatre in the 1920s. remained the most original and stimulating director, though there were times under the Stalinist regime when his originality displeased the authorities and he was criticized for having too unruly an imagination.

In the early 1960s the Russian theatre was perhaps seen at its best in its productions of the classic Russian authors, directed with meticulous care and exactitude and reproducing. with extraordinary verisimilitude and no longer with any satiric intention. the manners and customs and ways of life of the tsarist days. The unique feature of the Russian theatre was its gigantic scale—the vast number of theatres. the fact that there were companies playing in more than 50 different languages. the size of the companies (100 actors was not unusual). the size of the repertoire of every theatre. the huge and superbly equipped stages showing a succession of elaborate scenes. the size of the theatregoing audience and the vast sums of money spent on the theatres by the government so that they need make no attempt to pay their way and could keep their prices reasonably low. The professional theatre could not wholly satisfy the demand for dramatic entertainment and every encouragement was given to the amateur to supplement the work of the professional. Most theatres accepted responsibility for at least one amateur group, the members of the company giving much of their spare time to training and advising the group. Amateur companies of outstanding merit were given the title of "people's theatre." Most of these companies were based on the palaces of culture and toured the neighbouring towns as well as playing in the factories and the collective farms. The close relations between the professional and the amateur were mutually beneficial because the professionals found that contact with the everyday people who were the personnel of the amateur groups infused freshness and reality into their own performances.

4. Germany.— The character of the German theatre was entirely changed during the early years of the 20th century by the work of Max Reinhardt (*q.v.*). When in 1903 he gave up acting to concentrate upon direction, the German theatre was an educational institution rather than a place of entertainment; producers of the classics had to be scrupulously faithful to long-cherished traditions and conventions. The slightest deviation aroused the wrath of the critics. most of them university professors. Reinhardt, who lived his early life not in Germany but in Vienna, had a love of colour and gaiety, richness and display, and it was these qualities that he brought to his productions. He was fiercely attacked not only by the traditionalists but also by the new school of German realists. What they particularly disliked about his work was its unashamed theatricality, a quality that they scrupulously avoided in their own low-toned productions. One of Reinhardt's greatest services to the German theatre was that he restored to it its theatricality — but a theatricality purged of staginess. In doing so he revolutionized German acting. In his productions of modern plays he taught his actors a style that was realistic in feeling but avoided the drab, painstaking exactness of the realist school; it was warm, vivid and colourful. always a little larger than life. In his productions of the classics he demanded lively, supple speaking in place of the slow, ponderous delivery of the traditionalists. He made his actors think afresh about the characters instead of dutifully assuming ready-made characterizations. When in 1906 Reinhardt opened his Kleines Theater in Berlin. he initiated a movement that grew steadily throughout the 20th century. Its aim was to break down the separation of stage and auditorium and to restore the old intimacy between actor and audience Reinhardt. in his endeavours to rescue the players from their isolation behind the proscenium arch. often took them out of the theatre to play in places that in those days seemed odd and eccentric settings for a theatrical entertainment — a square in Venice. a palace ballroom in Vienna, the Boboli gardens in Florence and the Domplatz and inside the cathedral itself in Salzburg. He produced *Oedipus Rex* in a circus arena with one end used for gigantic architectural settings unframed by any kind of proscenium. For his production of *The* Miracle in London in 1911 he transformed the huge Olympia exhibition building into a cathedral so that the audience became part of the congregation. But although Reinhardt was a master of spectacle, his versatility was such that with equal skill he directed subtle and intimate plays in small theatres. From the early years of the century up to the outbreak of World War I his personality completely dominated the German stage; nearly all the young directors and actors had either worked in one of his companies or had been trained in one of his schools.

Immediately after World War I two of his disciples, Leopold Jessner and Erwin Piscator, became the dominant figures of the German theatre. Their Expressionist style of direction was partly evolved because of the desperate shortage in postwar Germany of material for building scenery. In their antirealistic productions. actors on the bare, darkened stage were picked out by shafts of light against a black background; if there was any scenery at ail, it mas limited to one or two small pieces, symbolic rather than realistic. Stylization in staging inevitably led to a stylized method of acting. which in turn demanded stylized writing, and it was thus that the short-lived German school of Expressionist drama was created. Characters in the plays became symbols instead of people. Their lines were stripped of all but the key words and phrases, so that the dialogue resembled the staccato wording of a telegram. Later, in the 1920s, when steel. timber and other material became more plentiful in Germany. Piscator directed a series of Expressionist productions in which he used elaborate and expensive machinery. The front of his stage was constructed on the principle of the conveyor belt; in the centre of the stage a cantilever bridge moved up and down; lantern slides and motion-picture films were projected onto the back wall; above the proscenium Communist slogans blazed in lights; the gigantic shadows of pulsating machines were thrown onto gauzes. Jessner, too. made exuberant use of the lifting of the restrictions on the use of building materials in theatres. His favourite form of setting was a vast flight of steps extending the entire width of the stage, rising steeply to a high platform at its back. He was greatly influenced by the work of the Russian directors of the immediate postrevolutionary period and copied them in oversimplifying characters and their motives, abandoning subtlety for elementary forms of symbolism. The Expressionist movement failed because when an actor is reduced to the level of a puppet he can only express a few emotions, and those only in the simplest form.

The postrevolutionary phase was followed by a period in which the German theatre reverted to conventional realism. When the Nazi party assumed power, their passion for vast meetings and immense processions was reflected in the theatre — or rather, in vast propaganda dramas presented in the open air in sports stadiums. parade grounds and huge natural sites. World War II destroyed most of the theatres in Germany but the desire for theatre and opera among the people was so intense that rebuilding started immediately after the war. A great opportunity presented itself for building theatres of new and revolutionary design but many were still based on the picture-frame stage, often elaborately mechanized for the handling of huge. realistic settings.

The most important influence in the post-World War II German theatre was Bertolt Brecht. When, in the early 1930s, Reinhardt and many other leading players and directors were driven into exile. the acting on the German stage lapsed into exhibitionism and splurgy emotionalism. Brecht was a disciple of Meyerhold and made constant use of the anti-illusionist devices that Meyerhold invented to enforce his dictum that "the actual world exists and is our subject; but this play and this stage are not it." For instance, as a means of destroying the illusion of actuality Brecht flooded his stage with white light throughout the performance, irrespective of whether the action took place at daybreak or sunset, at midnight or noon. In between the scenes, captions, slogans and comments were projected onto a gauze curtain. Points were emphasized by songs that had nothing to do with the action of the play but were what Brecht called "musical addresses to the audience" in which the actor stepped out of the story and commented on the play. Brecht's theory of acting was a reversal of Stanislavski's doctrine that the actor: must identify himself completely with the part he was playing. Brecht demanded an objective style of acting. It was to free the audience "from the spell cast upon them by the witchcraft of realistic producers who make a dream world of reality" that Brecht evolved what he called "the alienation effect." After Brecht's death in 1956, his company, the Berliner ensemble, continued to train actors according to his principles and toured in many countries with a repertoire of his plays.

In spite of the number of German theatres and the huge sums lavished upon them in the form of government and municipal grants, there were few signs in the early 1960s of any strongly progressive movement and no directors were dominant enough to impose any distinctive style. Much of the best creative work was done in the opera houses. The extreme shortage of contemporary playwrights was the main reason for the lack of any essentially Germanic style of acting and direction. As the majority of plays were imported from other countries the actors and directors were forced to compromise in their methods. leaving themselves too little time and opportunity to develop an indigenous style.

5. France. — The reaction against realism. which during the early years of the 20th century was a powerful influence in the

German and Russian theatres, was slower to reach France. It was the founding of the Théâtre du Vieux Colombier by Jacques Copeau (*q.v.*) in 1913 that initiated the reaction in that country. Copeau came from outside the theatre. He was a literary critic and editor of *La Nouvelle revue française.* Profoundly dissatisfied with contemporary plays, which were shallow because obsessed with photographic detail and classics "so tightly swathed in the trappings of tradition that they were unable to breathe," he became a producer and set up his own company. Like Reinhardt, Copeau sought to break down the barrier between actor and audience; at the Vieux Colombier the stage was left unframed. There were no wings and no definite line of demarcation between stage and auditorium (the actors simply made their entrances through doors from the adjoining rooms). Decor was used rarely and sparingly, seldom consisting of more than one or two painted screens, or a balustrade or a draped curtain. Only the barest minimum of furniture and properties was used. and nothing was put on the stage merely as an aid to realistic illusion. The atmosphere for each play was created almost entirely by lighting.

Before opening the Vieux Colombier Copeau took his little company of 11 actors away from Paris to his home at Le Limon. There they improvised scenes and practised exercises designed to make their bodies and voices flexible instruments. In their improvisations they learned much from Charles Dullin, who had been a reciter in the cafés of Montmartre and was an exponent of the traditional *comédie improvisée,* which was still popular in the cabarets of Paris and the fairs of provincial France. The acting at the Vieux Colombier was, in a modern play, at first sight completely realistic. although the detailed business of the ordinary realistic production was reduced to a minimum. But closer watching showed that gesture was being used sparingly and selectively, so that each gesture was given unusual significance. Copeau's productions of Molikre and Shakespeare were notable for their lightness, grace and gaiety. In 1923, he took a group of young actors to Burgundy. where, besides studying acting, they worked in the fields and in a carpenter's shop. They took part in the local wine festival, performing what they described as "diversions." The peasants called the group "Les Copiaux," and it was under this name that they first appeared before a town audience at Basel, Switz., in 1926. The most characteristic of their productions was *La Danse de la ville et des champs,* described as a *spectacle Bourgzcignon, joué, dansé, chanté, mimé par Les Copiaux.* It was written and produced by Michel Saint-Denis. In 1930 he took over the direction of the company. which was renamed the Compagnie des Quinze. It was disbanded in 1936 but during these few years it became internationally famous for its fine speaking and expressive miming, the imaginative simplicity of the settings and the pictorial beauty of the groupings. The company had its own author, André Obey, who wrote his plays to suit the methods and talents of the group.

Copeau's influence on the French theatre was greatly strengthened and extended through the productions of Louis Jouvet (*q.v.*) and Charles Dullin, who left his company in 1922 to start theatres of their own. Jouvet's productions of Molikre were his most important contribution to the French theatre. He freed the plays from the weight of tradition built up from literary criticism that was stifling them on the stage. His famous production of *L'École des Femmes* was hailed by the French critics as *le retour à l'art classique—le retour au véritable esprit de Molière et son sidcle.* While Jouvet was always scrupulously careful to subjugate himself to his author, Dullin's productions were strongly coloured by his own personality and tastes. He hated what he called *l'horrible naturel.* He loved brightness—bright colours. bright music, bright movements. Copeau's influence on him was apparent in his elaborate use of expressive gesture and mime. His productions of Aristophanes' *The Birds* was a good example of the mingling of the elements of carnival and social satire that he sought to find in nearly every play he produced. In complete contrast to the colourfulness of Dullin's productions was the asceticism of Georges Pitoeff, who believed that the primary aim of the director should be to focus attention on the central idea of the play and eliminate all external details of decor and acting that might tend to obscure it from view. His greatest contribution to the French theatre was the number of foreign dramatists whom he introduced to the Parisian public. These three directors, together with Gaston Baty, were known as "Les Quatre."

Baty served his apprenticeship in Germany under Reinhardt, from whom he learned how to handle crowds brilliantly and to use elaborate stage mechanism and lighting equipment with skill and showmanship. His pictorial sense was superb and his groupings and movement were beautifully composed, but they existed for themselves rather than for their contribution to the play. He was often accused by critics of overelaborating the classics in order to display his inventiveness, but on the other hand he directed the delicate plays of Jean Jacques Bernard with infinite subtlety. Dullin's use of mime was continued and elaborated in the productions of one of his pupils. Jean Louis Barrault. who left the Comédie Française in 1946 to form his own company at the Marigny theatre. Much of his work was symbolistic, both in decor and acting, a combination of pantomime, rhythmic movement and shadowgraphs. He has been accused, rather unfairly: of being "an enemy of speech," of regarding words simply as an accessory to visual means of expression. Another pupil of Dullin was Jean Vilar, who in 1951 became the head of the Théâtre Nationale Populaire (T.N.P.). His style of production was governed by the size of the Palais de Chaillot, the headquarters of the T.N.P., a theatre seating nearly 3,000 with a stage 70 ft. deep and a proscenium opening 80 ft. wide. Vilar made no attempt to fill the stage with scenery. He did no more than suggest the background of the play by the simplest possible means. Instead he filled his huge stage with big, swirling movement and because the size of the auditorium made subtlety impossible he trained his actors to use bold, simplified gestures and to delineate their characters in powerful outline rather than in detail. It is a style that is well suited to the great open-air theatre at Avignon, where the company appeared every summer. Until the 1950s theatrical activity in France was almost entirely concentrated in Paris, but with the help of the French government theatrical centres mere established at Strasbourg, Aix-en-Provence, St. Étienne, Toulouse and Reims, from where the companies go out to play in the surrounding districts.

6. British Commonwealth.— The arrival of the talking pictures practically annihilated the theatre in the countries of the British commonwealth but after World War II there were signs of a rebirth. Interest in the theatre was stimulated by visits to Canada and Australia by companies from England, including the company from the Shakespeare Memorial theatre (in 1961 renamed the Royal Shakespeare theatre) at Stratford-upon-Avon and the Old Vic headed by Sir Laurence Olivier and Vivien Leigh. In Australia in 1954, it was decided to commemorate the queen's visit by establishing an Elizabethan Theatre trust to encourage Australian drama and opera. Two-thirds of the sum raised was contributed by the public. the remaining third by the government; The Majestic theatre in Sydney. renamed the Elizabethan theatre, became the headquarters of the trust and Hugh Hunt, previously director of the Old Vic in London, became its first director. The company from Sydney had a considerable success in London in 1957. when it appeared in Ray Lawler's *The Summer of the Seventeenth Doll.*

In Canada the Festival theatre at Stratford, Ont., was opened in 1953 to give summer seasons of Shakespeare. At first it mas housed in a huge tent; in 1957 a permanent theatre was built. Sir Tyrone Guthrie frequently produced at thc theatre and a number of British stage stars: including Sir Alec Guinness, appeared with the company but the theatre became increasingly able to rely upon Canadian actors. A National Theatre school was founded in Montreal. Que., teaching in French as well as in English so that it could train players for the French-speaking companies. In Toronto, Ont.. the Davies theatre, directed by the two Davies brothers. gave a wide variety of plays; but it was symptomatic of the shortage of good Canadian playwrights that when the company appeared in London it was in a play by an English author. In Oct. 1960 the O'Keefe centre, a large well-equipped modern theatre, was opened in Toronto.

New Zealand is a difficult country for the professional because even in the largest cities the population is too small to support a permanent professional company and the distances between towns make touring expensive. In 1960 the only professional company, the New Zealand Players, who once toured the country, were forced to abandon their work through lack of sufficient financial support. However, in 1961 Richard Campion, who had formed the Players, helped to organize the New Zealand Theatre company; this new group planned to tour one production a year and was given a grant by the government arts advisory council.

Kenya has a National theatre in Nairobi, opened in 1956. At the beginning of the 1960s there was no professional company attached to the theatre, which was largely devoted to amateur companies, European, African and Asian, including some that drew their members from all three groups. Nairobi had also had for many years the only professional company in east Africa, the Donovan Maule Players, recruited mainly from the English theatre. In 1959 they moved into a finely designed new theatre. In Kampala, the capital of Uganda, a National theatre was opened in 1960 and was run much the same way as the Kenya National theatre. In both Uganda and Nairobi the annual drama festivals showed a continual rise in the quality and quantity of the plays by African authors dealing with life among their own people.

7. South Africa. — The theatre in South Africa relied mainly upon touring companies from other countries, but during the 1950s it became largely self-supporting. The National Theatre organization, founded in 1948 with a government subsidy, had permanent centres in Johannesburg and Pretoria and gave regular performances all over the country by the 1960s. Johannesburg continued to be the main theatrical centre with a number of permanent companies, such as the Brian Brooke Company and the Johannesburg Repertory Players. Cape Town had the Cockpit Players run by Leonard Shachs and the Hofmeyr Theatre with its own company, and throughout the country there were flourishing amateur organizations.

In the early 1960s Negro theatre in South Africa was as yet unorganized, depending for its strength on the vitality of township jazz concerts. Late in the 1950s the African Drama trust was founded to try to give it coherence. In 1961 an all-Negro cast scored a notable London success with *King Kong*. (N. M.)

8. United States. — The first theatre — actors, scenery and repertory — was imported to the American colonies from England about 1750. Early performances were given in existing halls or in hastily built quarters resembling the small English provincial theatres of the day. These provided a small stage with little wing or fly space, framed by a proscenium arch, in front of which extended a shallow apron with a proscenium door on either side. The first scenery consisted of the minimum of traditionally painted drops, wings and borders necessary to suggest the many settings required by a large repertory. When the first permanent theatres were erected, shutters running in grooves replaced drops to close in most settings at the rear. Illumination was provided by candles in chandeliers hanging from the ceiling of the auditorium, in a row of reflector holders placed as footlights and in holders fastened to the backs of the wings.

The first American plays were modeled on English drama. A native type, the shrewd, rural Yankee, first appeared in Royall Tyler's *The Contrast* (1787), which introduced also a favourite theme of early American drama: the triumph of native honesty and worth over foreign sham and affectation. In 1798. William Dunlap, America's first professional playwright, dramatized recent American history in his blank verse tragedy *André,* in which George Washington is a principal character. The heroic Indian was added in John Augustus Stone's *Metamora* (1829), the tough city lad in Benjamin Baker's *A Glance at New York* (1848) and the stout-hearted frontiersman in Frank Murdoch's *Davy Crockett* (1872). Native-born actors early performed in minor roles. and the native star, able to hold his own with the best on the London stage, appeared with Edwin Forrest in the 1820s and Charlotte Cushman in the 1830s. Forrest's "American" style was characterized by muscular strength and vocal power. Theatre, first confined to the eastern seaboard, in 1815 expanded into the Ohio and then to the Mississippi valleys. In 1850 it made the leap to San Francisco and the Pacific coast.

To begin with, settings, including all except a few pieces of furniture actually used by the actors, were painted on wings and shutters. The use of real instead of painted rugs and draperies and a full complement of furniture appeared in the production of Dion Boucicault's *London Assurance* (1841). Detailed historical accuracy in setting and costume first attracted attention in Charles Kean's production of *King John* (1846). In Edwin Booth's theatre in 1869, wings and shutters in grooves were abandoned, scenery was supported by stage braces and the box setting began to be used. In the next 30 years, the detailed realistic setting was perfected by such producer-directors as Augustin Daly, Steele MacKaye and David Belasco. Realistic production was stimulated by the introduction of gas lighting about 1825 and of electricity about 1885.

Realism in acting appeared in some of the characterizations of Yankee specialists like George H. Hill in the 1830s and '40s; in Francis F. Chanfrau's tough city lad in the '40s: in Matilda Heron's unconventional *Camille* in the '50s; in Edwin Booth's quieter acting of Shakespeare and Joseph Jefferson's "natural" Rip Van Winkle in the '60s; and was fully developed by William Gillette and Mr. and Mrs. James A. Herne in the '80s. James A. Herne's *Margaret Fleming* (1890) was the first realistic problem play in the manner of Ibsen. Herne could not secure production of this "new" drama in a regular theatre because of a radical change in theatre organization.

At the beginning of the 19th century, each major city had a resident repertory company. As population grew and spread westward, so did the number of resident companies, and a leading actor found it profitable to set himself up as a star. playing brief guest engagements with one resident company after another. The proliferation of such stars and the rise of the long run, which was necessitated by increasingly expensive staging, eventually destroyed the resident company. It was replaced in the 1860s and '70s, except in a few of the largest cities, by the traveling "combination." Originating usually in New York city, which since 1825 had been the leading theatre centre, hundreds of these combination companies, presenting either a small repertory or a single play, were providing entertainment the length and breadth of the land. Booking agencies were formed as liaison between companies and theatres. Several theatre owners; producers and agents, of whom Charles Frohrnan was the best known, formed the Theatrical Syndicate in 1896, which by controlling booking in key cities gained a virtual monopoly of theatre throughout the country. The Syndicate was not interested in the play with limited audience appeal. The theatre on all levels, from serious drama to burlesque, was the country's chief medium of entertainment. It was a big and prosperous business, and it was beginning to be attacked for "commercialism." The change from repertory to the single play and the rise of realistic production also shifted artistic control from the actor to the manager. who became the producer-director, or *régisseur*. In the last decades of the 19th century, Daly. MacKaye and Belasco not only selected and cast their plays, and directed the rehearsals, but also personally supervised all other aspects of production.

In the first decade of the 20th century, realism dominated: in the plays of Clyde Fitch, William Vaughn Moody and Edward Sheldon; in the acting of Mrs. Fiske, Richard Mansfield and Ethel Barrymore; and in the productions of Belasco and Harrison Grey Fiske. The pretty operettas of Victor Herbert and the brash musical comedies of George M. Cohan were popular. The first *Ziegfeld Follies* appeared in 1907. The New Theatre in New York city, with a resident company dedicated to art rather than business, was established in 1909 but collapsed after two seasons. Visits of the Abbey Theatre in 1911, Reinhardt's *Sumurun* in 1912. Granville-Barker's company in 1915 and Copeau's group from the Vieux Colombier in Paris in 1917 provided exciting glimpses of the work of Europe's art theatres and of the "new stagecraft.," thus adding to the growing dissatisfaction with the U.S. theatre.

The modern period on Broadway may be said to have begun in 1919 with the establishment of the Theatre Guild, the first commercially successful U.S. art theatre, for in the next decade occurred a flowering that placed U.S. theatre for the first time on a par nith the best theatre of Europe. Eugene O'Neill emerged from the Provincetown Players (*q.v.*) in 1920 with *Beyond* the *Horizon* to win world-wide fame. He was quickly followed by Sidney Howard, Robert Sherwood. Maxwell Anderson, George Kelly, Elmer Rice, S. N. Behrman, Philip Barry and others; their plays provided an expression of American life that was unprecedented in its richness and variety. Besides the Theatre Guild, such producers as Arthur Hopkins, Gilbert Miller. Winthrop Ames, George C Tyler and Kenneth Macgowan staged the new American drama, interesting new plays from abroad and some classics in the new style. Designers Robert Edmond Jones, Joseph Urban, Lee Simonson. Cleon Throckmorton. Norman Bel Geddes and Jo hlielziner provided distinguished settings that were realistic, symbolistic or expressionistic as required by the new drama The Moscow Art Theatre company visited New York in 1923 and impressed with the quality of its ensemble acting. which only a permanent organization could achieve. Some of its members remained in New York to practise and teach the Stanislavski system for actors (see also MOSCOW ART THEATRE). In 1926 Eva Le Gallienne established a permanent repertory company that presented classics old and new. Show Boat appeared in 1928 and became a classic of the musical stage. Outside New York city, competition from motion pictures reduced the number of theatres open to traveling companies from 1,500 in the early 1900s to 500 but on Broadway the number of productions grew from 150 in 1920–21 to 280 in 1927–28.

The stock market crash of 1929 heralded the end of unparalleled prosperity in the theatre and in the nation. The nation recovered from the ensuing economic depression, but the theatre, under increasing competition from motion pictures, radio and television, did not In the next 30 years traveling companies all but disappeared. and productions on Broadway shrank to 60 in 1949–50 and expanded only to an average of 70 in the following ten years. No new theatres were constructed. The Civic Repertory theatre succumbed in 1933.

Nevertheless, live theatre continued to attract talented writers: Clifford Odets. Sidney Kingsley, Lillian Hellman, Thornton Wilder and William Saroyan beginning in the 1930s; Tennessee Williams, Arthur Miller and William Inge starting in the 1940s. Rising costs encouraged simplification of setting and by 1950 the box setting mas seldom seen. Rising costs and shrinking audiences necessitated longer and longer runs. Enterprises outside the standard pattern, however, enjoyed some success. The Group Theatre (*q.v.*) for six years maintained a permanent company, developed new playwrights and evolved a new acting style based on the Stanislavski system. From 1935 to 1939 the Federal Theatre project (*q.v.*) presented hundreds of productions of all sorts and showed that a large untapped audience existed for live theatre at low prices. From 1937 to 1939 Orson Welles and John Houseman maintained a permanent company and limited runs in the Mercury theatre. From 1947 the Actors Studio cultivated the "method," derived from Stanislavski's system and practised by such actors as Marlon Brando, Geraldine Page and Julie Harris. In 1955 the first U.S. Shakespeare festival was held at Stratford. Conn.. and it became more popular each summer. The American National Theatre and Academy (ANTA), chartered by congress in 1935 and activated in 1946, encouraged theatre, professional and nonprofessional, throughout the country. As theatre activity decreased, the producer declined in importance and the stage director rose. Among the important directors in the 1940–60 period were Elia Kazan. Robert Lewis. Harold Clurman, Joshua Logan and Jose Quintero. The musical show after 1930 gained in polish and sophistication. Examples were: *The* Band *Wagon* and Of Thee I *Sing* (1931), Pal Joey (1940). Lady in *the* Dark (1941), *Oklahoma!* (1943). South *Pacific* (1949) and *My* Fair Lady (1956). In 1935 George and Ira Gershwin turned the play Porgy by DuBose and Dorothy Heyward into America's first successful folk opera. Porgy and Bess.

Off-Broadway Theatre.—Plays have always been produced in small theatres outside as well as in the main theatrical district in New York. In 1915–18 the Washington Square Players, in the 1920s the Provincetown Players and in the 1930s the New Playwrights drew audiences and critics off Broadway. A new era began in 1952 with the successful revival of Tennessee Williams' *Summer and Smoke* at the Circle in the Square and gained momentum with productions at the Phoenix. the Theatre de Lys and the Fourth Street theatre. In 1961–62, the *New* York *Times* counted 100 off-Broadway productions. 34 more than on Broadway. Revivals of classics and of recent plays that had failed on Broadway predominated at first, but the proportion of new plays increased, With a few exceptions, such as at the Phoenix, the single play and the long run predominated. Since production often took place in improvised quarters under makeshift conditions, it showed styles and forms seldom seen on Broadway. Many productions were staged without a proscenium arch and with the audience on two or three sides of the playing area. Actors, directors, designers and producers who achieved success off Broadway were soon active on Broadway. And those who had made their mark on Broadway began to appear in off-Broadway theatre, attracted by the greater freedom it offered. Some notable productions off-Broadway were Threepenny Opera at the Theatre de Lys, the revivals of Chekhov at the Fourth Street theatre and The *Iceman Cometh* at the Circle in the Square.

Summer Theatre.—Declining production on Broadway was accompanied by a growth of theatre in resort areas during the vacation season. In 1940, 80 summer theatres were open for a ten-week season, performing a different play or musical each week in tents. barns and sometimes in regular theatre buildings. More than 200 such "straw-hat" theatres were in operation in the early 1960s. Resident companies, frequently augmented by visiting stars: usually performed recent Broadway successes, and occasionally they tested a new play for possible Broadway production.

The *Negro* in the *U.S.* Theatre.—In native plays, the Negro appeared first as a plantation hand. a minor comic character, Later he was frequently seen as a comic domestic servant. In the 1830s Thomas Dartmouth Rice was extremely popular singing and dancing as the eccentric "Jim Crow" in an entertainment he called "Ethiopian Opera." Out of such white performances of Negro song and dance came Negro minstrelsy (see MINSTREL SHOW). Edward Harrigan introduced the city Negro in his comic Mulligan plays of the 1880s. The slavery plays like Uncle Tom's *Cabin* (1852) and the Civil War plays like The Reverend *Griffith Davenport* (1899) first treated the Negro seriously. Edward Sheldon's The *Nigger* (1910) was the first play to deal with Negro problems in modern society. After the Civil War, Negroes became popular performers in minstrel shows and later in all-Negro musicals. From 1910 on. individuals like Bert Williams were featured in musicals like the Ziegjeld Follies; the integrated musical appeared in the 1940s. Negroes gained recognition in serious drama somewhat later: Charles Gilpin in The *Emperor* Jones (1920), Richard Harrison in The *Green Pastures* (1930), Canada Lee in Native Son (1941) and Paul Robeson in *Othello* (1943). Playwrights who contributed to the drama of Negro life include Ridgely Torrence, DuBose and Dorothy Heyward and Paul Green. Negro playwrights had little success on Broadway until Lorraine Hansberry's *A* Raisin *in the* Sun became a hit in 1959.

Community Theatre.—Community theatre grew out of the little theatre movement and its art theatres that sprang up (c. 1900–25) in protest against the commercial theatre and under the inspiration of the free theatres of Europe. Among the leaders were Gilmor Brown in Pasadena. Calif.. Frederic McConnell in Cleveland, O., Samuel J. Hume in Detroit, Mich., and Maurice Browne in Chicago. The little theatres presented noncommercial plays, European and American, with the "new stagecraft." in small theatres for small audiences. As road companies disappeared, most of these organizations lost their "art" theatre aims and became substitutes for professional theatre, presenting popular plays in larger theatres to larger audiences with more paid personnel. By the early 1960s three types of community theatres existed: (1) a few with paid actors and staff. like the Arena theatre. Washington, D.C.; (2) a few more with paid staff and a few paid actors, like the Cleveland Playhouse; and (3) the great majority with some paid staff only.

University Theatre. — Dramatic performances by students go back to the colonial period, but instruction in theatre subjects did not enter the curriculum until about 1900, largely in colleges of liberal arts and as part of the reaction against commercial theatre. Early leaders in this movement included George Pierce Baker at Harvard. Thomas H. Dickinson and Gertrude Johnson at Wisconsin, and Frederick H. Koch first at North Dakota and later at North Carolina. In 1914 the first department offering training for the professional theatre was established at Carnegie Institute of Technology under Thomas Wood Stevens. After World War I, under the leadership of such men as A. M. Drummond at Cornell, E. C. Mabie at Iowa and Glenn Hughes at Washington, there was a tremendous expansion of courses, departments and degrees. The National Theatre Conference of leading university and community theatres was organized in 1932. The American Educational Theatre association was established in 1936 and after 1949 published the Educational Theatre Journal. By 1958–59 more than 500 college theatres were producing annually more than 1,000 plays for audiences of about 3,000,000. Much of this growth was because of the disappearance of professional theatre outside New York city. Although the aims of university theatre have been primarily cultural, it has affected the professional theatre, especially off-Broadway. Its unique contributions have been the development of theatre for children and the popularization of arena and other forms of open staging. (B. HT.)

9. Latin America. — The theatre in Latin America varies greatly from country to country. Its development is highest in Argentina, Mexico, Brazil, Uruguay and Cuba in that order, with the other countries trailing considerably behind. The advent of motion pictures around 1900 brought about a decline in the theatre throughout Latin America but a theatrical revival became noticeable after the 1930s when playwrights abandoned the late 19th-century Spanish dramatists as models and introduced techniques and styles from the best European and New York theatres.

Early in the 20th century a nationalistic theatre arose in Argentina depicting the conflicts between the *criollo* population (descendants of settlers from the old world) and the immigrants. This movement produced a legion of playwrights, the best known of whom was an Uruguayan, Florencio Sanchez. His plays, written between 1903 and 1909, were mostly dramatic but others cultivated a more festive theatre, such as the Argentine *sainete* ("farce"). Modern Buenos Aires, Arg., boasts scores of professional theatres, numerous experimental and art theatres and the Teatro Colón with its own opera company, symphony orchestra and ballet. The Argentine motion-picture industry developed steadily until it ranked second in America only to that of the United States.

Although the Mexican theatre is not comparable to that of Argentina, it grew through the efforts of enthusiastic art groups and many exceptional dramatists, such as Rodolfo Usigli (Corona de sombra, 1947) and Xavier Villaurrutia (Juego peligroso, 1950). Beginning in the 1950s numerous theatres were built or halls adapted as teatros de *bolsillo* ("pocket theatres"). Mexico's motion-picture industry was almost on a par with Argentina's. Mario Moreno (Cantinflas) became a world-famous motion-picture star.

In Brazil the theatre enjoyed generous official protection and a high level of theatrical culture resulted. The quality of Brazilian theatrical production was comparable to that of any country. Among the best-known modern Brazilian authors were Joracy Camargo (Deus *lhe pague,* 1932) and Guilherme Figueiredo (*A rapôsa* e as uvas, 1935). Procópio Ferreira came to be considered one of the world's greatest contemporary actors. The modern Brazilian motion-picture industry, though commercially smaller than those of Argentina and Mexico, was technically and artistically excellent.

Cuba, with a glorious theatrical past, witnessed a sharp decline at the beginning of the 20th century. The peculiar political satire known as the bufos *cubanos* flourished for a while but dwindled away in the 1920s. In that decade and in the 1930s composers and playwrights developed the *zarzuela* cubana, a type of musical comedy that was successful at home, in Spain and in Latin America. Among the composers of the *zarzuelas* were Ernesto Lecuona, Moisés Simons and Gonzalo Roig. Cuba also made important contributions to the theatre in the field of the ballet; the Cuban ballerina Alicia Alonso became internationally known.

Chile produced at least one outstanding playwright; Armando Moock (Rigoberto, 1935). (Lu. A. B.)

10. Drama Festivals. — During the height of the season there are so many drama festivals in Europe that it is difficult to keep count of them. The most comprehensive is the annual "Theatre of the Nations" festival in Paris. The festivals in the Netherlands, Stockholm, Berlin, Zürich, Munich and Vienna are, like the Paris festival, international in character. The Dublin festival is essentially national, although one or two companies are invited from other countries. The festival at Pitlochry in Scotland, which lasts throughout the summer months, always includes a proportion of Scottish plays in its program but is by no means exclusively national. At Epidaurus, Greece, the festival is devoted to the Greek classics. This is one of the many open-air festivals, among which the most important are those at Baalbek, Lebanon, Avignon, France, and Dubrovnik, Yugos. Besides these there are many smaller open-air festivals in France and Italy, most of which use surviving Roman theatres. The festivals at Salzburg and Edinburgh combine music and drama. The Edinburgh festival has given the first performances of a number of distinguished plays, including two by T. S. Eliot, but much of the most interesting drama at this festival is to be found among the "fringe," the name given to the small pioneering companies, mostly very youthful, that are not officially part of the festival. (N. M.)

Some of the best-known summer drama festivals in the United States are devoted to Shakespeare. At Ashland, Ore., Shakespeare's plays are presented outdoors in what resembles an Elizabethan public theatre. A similar repertory is presented in a reconstruction of the Globe theatre at San Diego, Calif. At Stratford, Conn., Shakespeare's plays are produced in a modern theatre. The New York Shakespeare festival is staged in the city's Central park. Opera has replaced the spoken drama in the 19th-century opera house at Central city, Colo. The Arts festival in the Public Garden, Boston, Mass., includes opera and ballet, as well as drama; so does the Richmond, Va., Festival of Arts.

Although Stratford, Ont., is best known for its productions of Shakespeare, its program includes new plays, operetta, films and music. Vancouver, B.C., stages an international festival of drama, opera and ballet. (B. HT.)

THEATRES (STRUCTURES). A theatre is a building or place furnished with seats and provided with a stage upon which plays or dramatic spectacles are performed; a playhouse. The present article deals only with the physical aspects of the building and its equipment. For articles dealing with the theatre in the larger meaning of the term, see DRAMA; THEATRE; also ACTING, DIRECTION AND PRODUCTION; COSTUME DESIGN, THEATRICAL; STAGE DESIGN. (X.)

HISTORICAL DEVELOPMENT

In considering the form of the modern theatre building and its physical aspect, and in tracing the origins and development of that form from the earliest known theatres of Europe, it is well to keep in mind the basic meaning of the word "theatre." From the Greek θεασθαι, it means roughly "a place for seeing." In a short survey of the subject it is not necessary to mention pre-Greek theatres, beyond saying that there is no known connection between those of earlier civilizations and the theatre of Dionysus at Athens, with which the histories of drama in the western world traditionally start. In Egypt nothing approaching a constructed theatre in the place-for-seeing sense has been uncovered, although accounts and fragmentary texts of passion plays, resurrection plays and coronation plays are known, some of a date earlier than 3000 B.C. Egyptologists identify the performances as ritualistic and pageant-like, involving processional movement, so that it is likely that temple courts and terraces rather than planned auditoriums accommodated the devotional audiences.

Greek Theatre.—The first Greek theatres were little more than marked-out dancing circles, each around an altar, at the foot of hillsides on which spectators stood or sat. From this natural form the first built theatres took their main outlines: a circle or orchestra (ὀρχήστρα) for the chorus and actor or actors, and rising tiers of wooden seats, built against a hillside for the spectators. These seats extended usually around two-thirds or more of the orchestra, since at this time dancing or movement was more important than acting, and there was no stage for the spectators to face. The type of the first built theatres is shown in fig. 1. The one actual example that has survived (partly restored) is the magnificent theatre at Epidaurus, although archaeologists have uncovered foundations of theatres of this stageless type under several Greek-Roman or Roman theatres surviving in partial ruin. It should be kept in mind that in no period were any two Greek theatres exactly alike.

Returning to the theatre of Dionysus at Athens, one notes that the temple of Dionysus Eleuthereus appeared in relation to the theatre approximately as indicated in the diagram (all within the precinct sacred to Dionysus on the southeastern slope of the Acropolis). One conjecture is that the architectural form of this 6th-century temple helped determine the shape of the stage building, which was later to be added at the edge of the circle opposite the seats. But the more widely accepted theory is that out of necessity a hut or tent (σκήνη) was added at the edge of the orchestra as a retiring room for the actors, for changes of masks or costume, etc.; and that the stage building was in all later ages an elaboration of this shelter—dressed, in the later Greek period, with those beautiful architectural forms with which the Athenians adorned all their important structures.

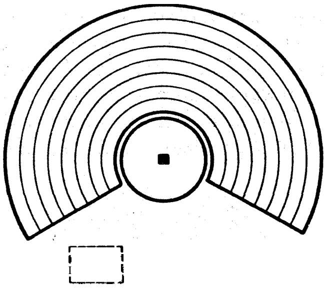

FIG. 1.—PLAN OF GREEK THEATRE OF EARLIEST TYPE

Just when the *skene* became truly a stage building with studied relationship to orchestra and auditorium is a matter of conjecture. As a step in the development of the larger theatre form, the three parts of the theatre may be thought of as developing gradually into a set arrangement as shown in fig. 2.

Here one sees the accretion of the three features that characterize theatre building through many succeeding centuries: (1) θέατρον or auditorium; (2) orchestra; and (3) scene; names which persist even today. But at this time players and chorus appeared only in the orchestra, the scene remaining an architectural background to the action and a practical retiring house for the actors, structurally separated from the auditorium by entrances or runways called παραδοί (Lat. parodi).

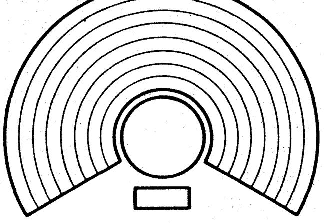

FIG. 2.—THE THREE-PART THEATRE ARRANGEMENT OF SEATS, ORCHESTRA AND SKENE

Such was the theatre form when the 5th century B.C. dawned, and such it remained, with only slight changes, in all probability, during the period of Aeschylus, Sophocles and Euripides. The architectural features and the height of the *skene* are still only to be conjectured, though excavated foundations at Athens indicate clearly the plan and limits of an early stage building, wider than the dancing circle and with ends projecting forward toward the auditorium.

Archaeologists have waged one of their bitterest battles over the question as to when the raised stage made its first appearance, but it is now almost unanimously agreed that in the "high" period of Greek drama there was no platform stage. The theatre at Athens had taken this general form, with possibly a portico at the front of the scene building, between the paraskenia or projecting skene ends (fig. 3); but the acting space in front of the skene was level with the orchestra floor. A platform would imply a separation of actors from chorus belied by the only evidence, the play texts.

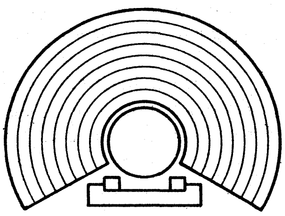

FIG. 3.—SKENE ENLARGED AND PROBABLY ADORNED WITH ARCHITECTURAL ORNAMENTS OR POSSIBLY A PORTICO

In Greece the theatres were regularly built in hillside hollows, thus avoiding any need to build supporting framework for the tiers of seats, xcept perhaps at the ends of the rings. The auditorium was broken by up-and-down aisles with steps into a number of wedge-shaped segments of seats, and sometimes by one or more lateral aisles (as in the theatre at Epidaurus).

The student of later forms may profitably transfer his attention to a point beyond the controversy about the introduction of the raised stage to that time when there was, without doubt. an auxiliary platform for acting. The next well-differentiated type of theatre is that in which the stage building is characterized by a high narrow platform on the audience side, called at times the proskenion (from which "proscenium" is derived), and at others the *logeion* or "place for speaking." As acting became more and more important, the skene developed into a combined architectural background and platform for lifting the actor into clearer view (fig. 4). It is to be noted here that the typical Greek separation of auditorium and scene building still exists, although acting now is divided between the orchestra and a stage in the later sense. Through the late Greek and the so-called Greek-Roman periods, the narrow *logeion* doubtless went through a gradual widening process. Also the stage building was soon a two-storied affair. When the actor appeared on a raised stage, the acoustics (generally excellent in open-air theatres) were improved. As acting on platforms became standard, the rings of seats doubtless came to be planned as less than the old two-thirds of a circle, moving toward the standard half-circle plan of the Romans. The Greek tragic drama retained a certain processional element, and the separation of the stage building by means of the παραδοι was then retained. There came to be three doorways in the stage wall for actors' entrances; the παραδοι afforded fourth and fifth entrances to the orchestra, especially for the chorus and, by a convention adopted at some unknown time, for actors understood to have arrived from a distant place. (Later the two side entrances became symbols for arrival from the country on the one hand and from the forum or the city on the other.)

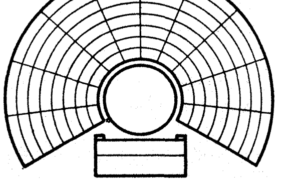

FIG. 4.—A PLATFORM ADDED AS PART OF THE SKENE

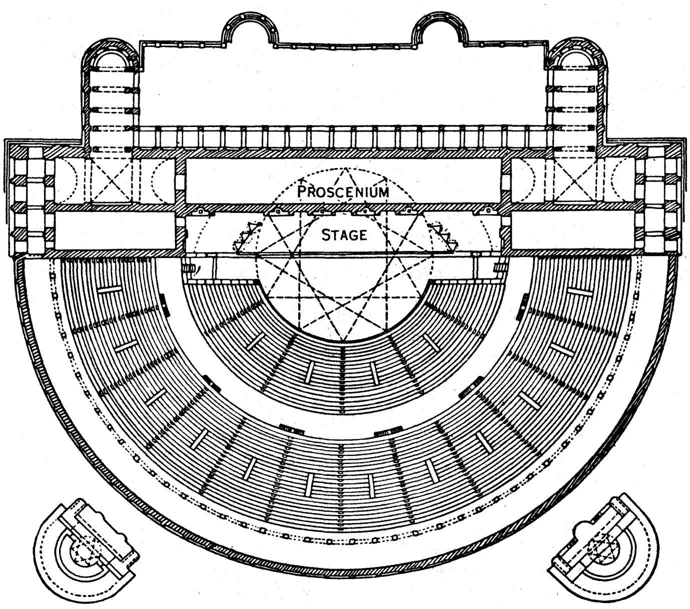
Roman Theatre.—Ruins of Roman theatres afford absolute evidence regarding the arrangement of the Roman stage and auditorium. The two heretofore separate buildings had now been pushed together to form one structure, not placed, as in Greek times: against a hillside hollow, but erected as a free-standing building supported'by arch construction. The orchestra had been contracted to a half circle and added to the seating space; and all the acting was done on a platform stage, behind which the greatly enlarged skene and paraskenia rose, with rich architectural ornamentation, to a considerable height. (See fig. 5.) There is shown in fig. 6 a drawing after A. N. Caristie's restoration of the stage of the Roman theatre at Orange, Fr., of which the stage wall still exists, though stripped of its ornamental features. In many Roman theatres, including this one, a colonnade above the highest tier of seats ended in junction with the left and right top extremities of the stage wall. This provided in the Roman theatres a sense of enclosure unknown to the Greek playhouses or to the transitional structures.



FROM A. STREIT, "DAS THEATER"

FIG. 5.—PLAN OF A TYPICAL ROMAN THEATRE AS SEEN IN THE RECONSTRUCTION OF THE THEATRE OF MARCELLUS, ROME

A special sort of theatre with wooden platform stage, for comedies, as shown in many extant vase paintings, is disregarded here as having little or no influence on the traditional or persisting form of theatre. These' simple stages existed in both Greece and Rome. Left aside too are such classic structures as the Odeum of Atticus Herodes on the Acropolis in Athens, built in the 2nd century A.D. as a recital hall; and similar odea and senate chambers and the like, characterized often by graceful auditoriums but lacking stages.

In the Roman theatres there were no built-in facilities for scene changing, and it may be assumed that in general there was no painted scenery, though elaborate stage machinery for trick effects, apparitions, etc., is described by contemporary writers. The *ekkyklema* seems to have been a sort of wagon stage, so pivoted beside the "palace doorway" of the skene that it could be wheeled onto the stage to disclose a set tableau. Efforts to localize the play scene visually may have been tried on lesser stages than those of the great surviving stone theatres. And there is a description (in Vitruvius) of a device, originally Greek, for indicating to the audience a change in the play's locale: a three-sided standard or signboard, on a pivot, with painted indications of a severe architectural scene for tragedy, a less monumental street scene for comedy and a forest scene for satyr plays. These boards or *periaktoi* were revolved at the interval for change of plays and possibly at some entrances (as of a god character) within a play performance. Nevertheless it must be inferred that, in general, the architecture of the stage wall *was* the "scene." This wall was regularly pierced by five doorways, three at the back and one in each of the *paraskenia*. The large centre door was the "palace entrance."

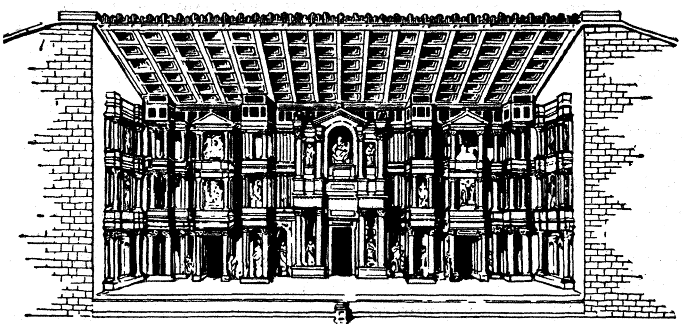


FIG. 6.— BACKGROUND OF ROMAN STAGE SHOWING NARROW CENTRAL "PALACE DOORWAY WHICH WAS MODIFIED IN THE RENAISSANCE THEATRE. AS SHOWN IN FIG. 11, TO PROVIDE A MORE EXTENDED VISTA

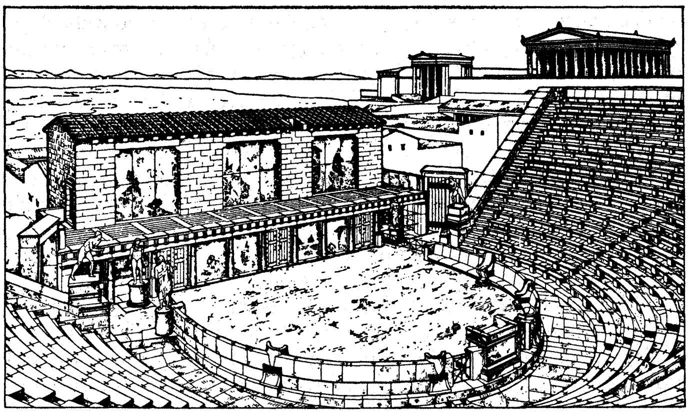
The main thesis (of a gradual evolution from dance circle to monumental late Roman playhouse) has here been baldly set down, with diagrams, in order that the reader may visualize a continual process of adaptation of the theatre to the needs of a changing drama and—in the case of degenerate Rome—of spectacular "shows." Without attempting a census of all surviving classic theatres, one may pause over the especially instructive examples.

Existing Classic Theatres and Restorations.—The pure type of Greek playhouse, with full-round orchestra, is to be seen only in the beautiful structure at Epidaurus. Otherwise there are the restorations on paper and museum models of such areas as the Acropolis at Athens or the sacred precincts of Delphi and Olympia. The early wooden playhouses would in any case have disappeared; but the savagery with which wars were conducted by the conquering Romans accounted for the ruination of the stone structures that adorned not only the cities of Greece proper but the provincial Greek cities of the Asian and African coasts and of Sicily and the Italian mainland.



FROM A. VON GERKAN, "DAS THEATER VON PRIENE"

FIG. 7.— THE THEATRE AS PART OF THE TEMPLE GROUP. A RECONSTRUCTION OF THE GREEK-ROMAN THEATRE AT PRIENE

After destruction came generally rebuilding, but on the transitional Greek-Roman or the straight Roman model. Thus the Greek theatre at Syracuse disappeared when the city was devastated and the inhabitants were massacred in 212 B.C. But later one of the largest of Roman theatres was constructed on the site. Considerable portions of the auditorium and of the foundations of the stage building remain.

Of the transitional type buildings, when a raised stage has been added and the orchestra has been cut down from the full round but the stage building has not yet been consolidated with the auditorium, sufficient ruins survive for archaeologists to present fairly accurate restorations. Fig. 7 shows the probable aspect of the Greek-Roman theatre at Priene in Ionia, as pictured by A. von Gerkan. The ground plan and arrangement of parts can be relied upon; though the windowlike spaces in the upper stage building have been criticized as wholly conjectural, as perpetuating the 19th-century belief that provision was commonly made for painted scenery.

A further step toward consolidation of the building's once separate parts is illustrated in the theatre of Dionysus at Athens, as the structure appears in its latest, partial restoration. Indeed there is evidence that the Greeks under their Roman masters remade this most holy of ancient theatres so that gladiatorial fights could be staged there. The orchestra, moreover, was sealed up in such a way as to improvise the playhouse into a naumachia or lake-theatre for the staging of mimic sea fights.

Of the large stone or concrete Roman theatres the one at Aspendus, in Asia Minor, is best preserved. The entire auditorium with its crowning colonnade may be seen (since Count Lanckoronski's restoration in 1884), together with the stage wall, including parts of the impressive ornamentation. The stage floor, being of wood, has disappeared. This magnificent structure, built in the reign of Marcus Aurelius, is estimated to have seated 7,500 spectators. It may be considered typical of the scores of playhouses erected in the far-flung cities of the Roman empire. A sketch, fig. 8, illustrates perfectly the relationship of parts. Examples more accessible to the ordinary traveller include the impressive ruins at Orange in France, the theatre at Taormina in Sicily, in which some of the columns adorning the stage are still intact, and the two theatres at Pompeii. The larger theatre at Pompeii, dating probably from the 1st century B.C., is said by Plutarch to have been modelled after that at Mytilene in Lesbos—which at so late a date would be a Greek-Roman type structure. The smaller theatre at Pompeii, aside from a certain feeling of grace and intimacy that pervades it, is of special interest as bolstering the theory that in Roman times small, roofed theatres were commonly built adjacent to the larger open-air playhouse for use in case of rain. It is a theory not easily proved; certainly the roofed Odeum in Athens, built during Hadrian's reign (A.D. 117–138), was not well suited for a typical Roman extravaganza, and the rare covered theatre-like structures elsewhere seem to have been designed as chambers for musical recitals, senate houses, etc.

In Rome itself the theatres wholly crumbled, except for parts of the theatre of Marcellus, after the stone facings had been stripped away by pillagers during the dark ages. But contemporary writers supply a record of some unusual, not to say amazing, examples of ingenuity in raising bigger and ever bigger playhouses. It is said that the first stone theatre in Rome was torn down before completion, in 154 B.C., as part of the republican campaign to halt the march of "Greek luxury" among the stern and practical Romans. This seems to have been one of the few times that morals had anything to do with the Roman theatre or drama. Roman drama had begun in humble and obscure types of ritual procession and farcical interlude, mostly Etruscan; but later there were Roman playwrights copying Greek plays. Nevertheless, the theatre was already divorced from religion—a basic difference between the two nations and an important factor in shaping the Roman playhouse form.

It was Pompey who erected the next celebrated stone theatre in Rome (begun in 55 B.C.). As a ruse he placed a shrine to Venus Venetrix at the top of the auditorium. Thus it could be said that the rows of stone seats served as steps to a temple; but the stage lacked nothing for the showing of such spectacles as the populace now demanded. Pliny wrote that Pompey's theatre accommodated 40,000 spectators—doubtless a gross exaggeration, though the stage wall was 300 ft. long. The place had architectural grandeur, and certainly it was big enough to permit gladiatorial contests. At its opening, it is said, 500 lions and 20 elephants were killed.

After the change-over to rule by emperors, Augustus Caesar boasted that he had rebuilt the "magnificent" Pompey's theatre, had erected the theatre of Marcellus and had been instrumental in getting Cornelius Balbus to build a third playhouse. In view of the known magnificence of adornment in the theatres of Roman provincial cities, one can only believe that the capital city of the empire would decorate its playhouses sumptuously, and every attempted restoration on paper has shown the stage wall as architecturally rich and showy. This is the very peak of palatial adorning of the stage wall with story on story of columns, pilasters and niches, with an abundance of statues and of gilding—the very elements destined to turn up in the stage-wall ornamentation of the academy theatres of the Italian Renaissance and to persist as standard ornamental features of the proscenium arch in theatres built in the 18th and 19th centuries throughout Europe and the Americas.

As a last word about the theatres in Rome it should be said that even greater claims of bigness and munificence were made for wooden theatres temporarily erected. Pliny writes that the aedile M. Aemilius Scaurus constructed in 58 B.C. a theatre seating 80,-

000 people and adorned with 3,000 statues among 360 columns; and that a few years later one G. Curio built two theatres so arranged that after use as separate playhouses in the morning one of the auditoriums could be swung around to face the other, thus forming an amphitheatre for performances in the afternoon—an architectural curiosity that taxes piesent-day credulity. Nevertheless the Romans accomplished well-nigh incredible feats of engineering in other types of building. And the final impression to be carried away from an examination of the surviving ruins should be one of wonder that so many small Roman cities should have owned theatres almost incredibly grand.

Mediaeval and Elizabethan Theatres.—In the history of theatre architecture there is, strictly speaking, no mediaeval chapter. The latest ancient mention of activity in a Roman theatre is dated A.D. 533; but it can be assumed that most of the classic playhouses had long before gone "dark" under the stress of the barbarian invasions. The drama was then, and for many centuries after, a tenant in castle halls, courtyards and town squares. Toward the end, important new sorts of stages and staging came in—the beginnings of modern illusory scene design. But no type theatre developed out of the acting of plays in the altar area of the Christian church, the first place in which a new tradition of playwriting and acting took form.

When the plays were pushed out onto the church porch, and then driven away to public squares, there still was no crystallization of a structure combining stage and "place for seeing." The strolling players of another sort, inheritors possibly from the suppressed miming tradition of fading Rome, from minstrels and from Teutonic *scop* and gleeman, no more had theatres. Indoors a castle hall would do. Outdoors a platform with simple curtains served the actors; the audiences stood.

One exception alone is sometimes claimed: the school theatres. But colleges, then universities, appeared (on the foundations of student guilds or student-scholar guilds, under church protection) only in the late 12th and the 13th centuries, and there is no record of their dramatic activities. There is an edition of Terence's plays, printed in 1493, illustrated with puzzling diagrammatic sketches of an "opened" auditorium and of scenes on a platform stage before curtains; and these illustrations teased some scholars into inferring a type theatre specially suited for revivals of classic comedy or for native plays after Roman models. This is in any case a revival activity, typically of the Renaissance in both substance and date.

The Jesuit theatres, moreover, overshadowed all other manifestations of the school theatre. They would be expected to have picked up and carried on any tendency toward crystallization of a type playhouse. As a matter of fact the instructional school plays of the Jesuit colleges—colleges numbering possibly 300 in Europe within 50 years of St. Ignatius of Loyola's death in 1556—were staged in every imaginable sort of improvised theatre: school hall, college courtyard, public square and, in exceptional cases, theatres especially constructed in imitation of contemporary models, from the classic theatre as reconstructed for the learned academies to the ballroom theatre with provision for the new changeable scenery. Bridging thus from the mediaeval era's incomplete theatre to the Renaissance time when two types of playhouse were being standardized, the Jesuit activity emphasized all tendencies toward a new playhouse without providing a lasting structure of its own. One sort of stage used by the Jesuits in Holland, that of the *Rederijker* societies, who had utilized it for the unveiling of *tableaux-vivants* in the then novel "scenery," is of interest historically as suggestive of the change from the stage of the Italian academy theatre to the typically modern proscenium-framed stage.

The theatre in Shakespeare's time, in England, is technically of the Renaissance era. But its utter difference of design from the types of Italian Renaissance theatres already developed, which were destined to determine the form of practically all the playhouses of Europe (including England) within the 18th century, mark it as unique. It was of immense importance for a few years, then thrown away.

The sources go back to wide English activity in church plays (from the early 13th century); then mystery plays in town squares or market places, produced by the mediaeval guilds, most notably on wagon stages; and, as the guild productions began to lapse, secular drama offered by strolling players. Productions by the strolling bands of actors at town house or country castle had, eventually, a revolutionary effect upon the history of scene design, and that was destined to determine the form of the English theatre after the Restoration. But it was the production of plays in the inn courtyard that determined the general form of the Elizabethan playhouse.

The first theatre built in London was put up in 1576 by the actor James Burbage. After use by many of the court-protected acting companies, and for exhibitions of fencing, swordplay and other sorts of "sport," it was demolished and its timbers utilized in the construction of the Globe theatre. This is Shakespeare's playhouse, built in 1599, and its structure is known to modern students in practically every detail.

The auditorium is the old innyard; though yard and balcony rings have been rounded—or, like the exterior, made hexagonal. In any case, the whole is doughnut-shaped; or, as Shakespeare described it, a "woodden O." The shilling patrons sat on the stage, three-penny patrons had stools in the balconies, which were in three tiers, while the groundlings stood in the yard, at one penny. The stage platform jutted out into this yard and placed the actors amid an audience pressing round three sides of them. Some of the declamatory element in the verse drama of the time can be ascribed to this actors' intimacy with the audience and to a certain disorder that would be inevitable among standees. It is not to be missed that this was still a daylight theatre. Its capacity, at a stretch, was 2,000.

The stage is a jutting platform with a low railing, and it is roofed. It is of the architectural type—that is, without provision for change of scenery. But at the back are curtained recesses, in three stories, and angled at the sides are two permanent stage-level doorways.

There is a considerable amount of machinery, including trap doors and a cannon that can be fired from a window at the top of the tiring house. In general this is a very large stage for acting in

FIG. 9.— THE GLOBE THEATRE

the round, yet fitted at the back for diversified effects of grouping and with curtained openings for revealments, balcony scenes and the like.

The Globe theatre is typical and most popularly known (fig. 9); and all the others, the Theatre, the Swan, the Curtain, the Rose, the Fortune and a small number more, approximated its architectural features. The one contemporary picture of an Elizabethan theatre is a sketch by a Dutch visitor to London, one Johann de Witt, of about the date 1596. Allowing for possible inaccuracies in the rough drawing, one may note the general accordance with the Globe theatre plan, yet a considerable difference in the tiring house features (fig. 10).

In Spain there developed at this time a somewhat similar courtyardlike theatre. Where strolling players had earlier found sufficient a hastily erected platform, backed by a blanket hanging between poles, there now appeared the *corral* theatre. The "auditorium" provided galleries and balconied windows for important spectators, while the unroofed but sometimes canopied pit accommodated standees and some seated patrons.

The stage never approached the elaboration of the English Globe or Fortune type. It seems to have been merely a platform, unrailed. jutting well into the pit. Behind was the tiring room, at first no more than a curtained space, later developed for varied "reveal" effects—and finally making concessions to the vogue for illusory scenery.

The English theatres were closed immediately upon the Puritan triumph of 1642. When others opened, 20 years later, they were modelled, at least piecemeal, upon the Italian type. (And indeed London had known, before the closing, one indoor candlelit playhouse, the Blackfriars, where Shakespeare played in James Burbage's company in winter; and at some undetermined date the new foreign scenery was tried out there, as well as frequently in court masques.) The Spanish *corral* theatres lasted longer.

Renaissance Theatre.—At almost exactly the time when Shakespeare was entering the London theatre and Lope de Vega was writing for the Spanish *corral* stage, Italian scholars and patrons were coming to fullest activity in the revival of every aspect of classic culture. The Renaissance spirit demanded construction of theatres on the classic model. The earliest, that of the Este family at Ferrara. no longer exists; but the second, a perfect example, survives in the Teatro Olimpico at Vicenza. This was built by the Olympian academy between 1579 and 1584, and was designed by the famous architect Andrea Palladio. It is, in effect, a small Roman theatre roofed over and rendered more compact. Palladio, acting upon his knowledge of the laws of classic architecture as set down by Vitruvius (of the 1st century B.C.), saw to it that the stage was commodious, that the five stage doorways were in orthodox position and that the stage wall was covered with a rich architectural show of pilasters, niches, statues and assorted bric-a-brac (fig. 11). It was this decorated and encrusted stage wall that was to survive in later theatres even up to the 20th century, at first as partial background to the action (as in the plan of Inigo Jones, fig. 14), then solely as the ornamental proscenium frame when the stage for changeable scenery had gone behind a curtain.

While Italy had developed no type theatre to house the diverse elements surviving from mediaeval religious plays and the activities of strolling comedians, the ruling families had cultivated two tastes that influenced the next move in theatre architecture. The one was for strictly classical plays, the other for pageantlike settings and general scenic display.

Palladio had enlarged (beyond any known Roman model) the central or palace doorway in the Olimpico stage wall. In 1585 his pupil Vincenzo Scamozzi, yielding to the demand for scenic novelty, built within this doorway a street in diminishing perspective, and in each of the other four doorways lesser "perspectives." Thus unwittingly he, more than any other, ended the era of classic, permanent architectural backgrounds for acting and opened the way to the stage with illusory setting, a type which was destined to become universal. There would be no more serious talk of architectural stages and acting in the round until the early 20th century.

As a matter of fact Scamozzi had not provided a changeable make-believe setting. He had not even provided acting space within the perspective. But a glance at the plan of a theatre built by Scamozzi at Sabbioneta in 1588 (fig. 15), and at the plan by Inigo Jones for a theatre never constructed (fig. 14), shows the process by which the vista became the stage, the architectural stage wall being reduced in importance until it was finally no more than a proscenium frame. From one make-believe background (usually a street, as specified by Vitruvius for his *periaktos* machine, for tragedy and comedy, back in Roman times) the producers raced on to movable backgrounds and to changes of setting within a single play session or a session combining a classic play with the spectacular intermezzi, or introduced masquelike episodes between acts.

Localized stage setting had a long history behind it at this time, albeit mostly on temporary stages. (See STAGE DESIGN.) There had been the station stages of the mystery and miracle plays, with realistic scenes such as the famous "Hell mouth"; and picture scenes in the masques at courts or in classic play revivals there, including those perspectives based nominally upon Sebastiano Serlio's interpretations of Vitruvius; even localized place roughly painted on the curtain of platforms used by the popular outdoor comedians. But for the first time the architecture of the theatre is radically changed to accommodate scenery.

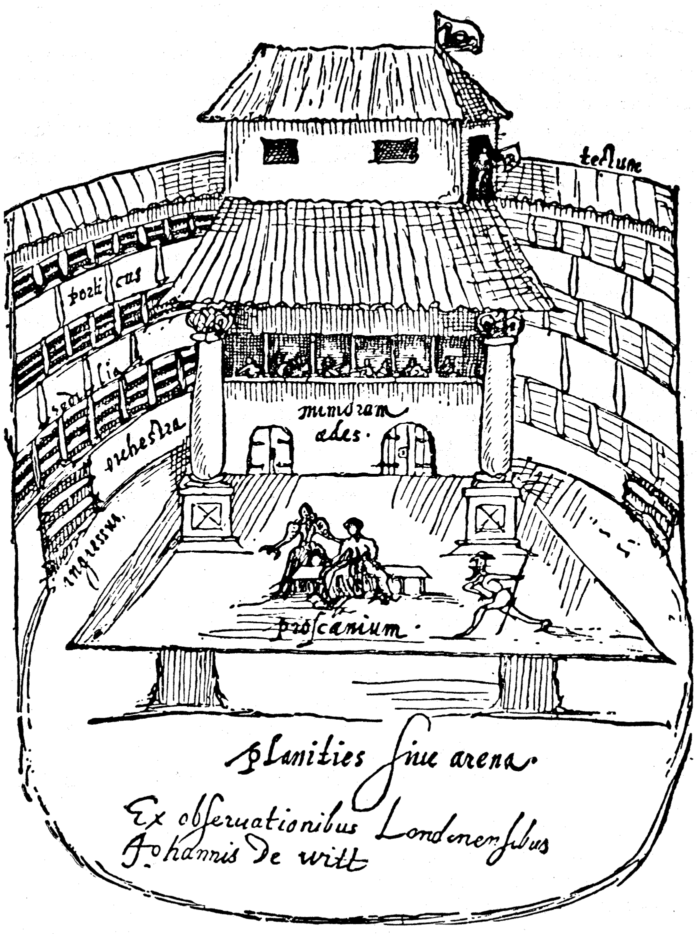

FIG. 10.—A DRAWING OF THE SWAN THEATRE BY JOHANN DE WITT ABOUT 1596, ONE OF THE FEW CONTEMPORARY SKETCHES OF THE ELIZABETHAN THEATRE

The final step is illustrated in the playhouse that is usually called the first modern theatre, the Teatro Farnese at Parma (1618 or 1619), shown in fig. 16. Here the entire stage may be said to have been pushed through the central doorway of the old stage wall, the ornamentation of the Roman skene remaining only as decoration of what is now the proscenium arch—and a very impressive display this residual element makes. The stage within is curtained from the auditorium and is thus adapted to changing pictorial settings. From this time on the curtained stage and proscenium arch are unfailing features of the theatre. The plan of the Farnese theatre is particularly interesting, too, as showing the entry of another influence into the shaping of the auditorium. Instead of a semicircular bank of seats, as illustrated in all the Roman and Renaissance diagrams so far, the auditorium is U-shaped. This influence entered because the masques and court plays had been produced largely in ballrooms or banquet halls, where one end of the hall had been reconstructed for an auxiliary stage and the main floor left free for dancing or as an arena for pageantry, etc. The spectators were ranged around the three sides away from the stage, perhaps in chairs on temporary platforms, perhaps in balconies. Architects combining this U-shaped auditorium with the curtained proscenium-frame stage, pushing the bank of seats forward, soon determined the theatre form that was basic thereafter—the horseshoe auditorium.

The Horseshoe House—17th to 19th Centuries.—It was this Italian plan that became the standard of theatre building throughout the western world, conquering successively the French courts, the courts of Austria, Bavaria and other countries to which the Italian and French Renaissance influence extended, then England and indirectly America. Scenery was soon standardized so that the wings and backdrop restricted the playing space to a wedge-shaped section of the stage floor; and the auditorium sidelines followed the lines formed by the edges of the wings. The picture scene persisted through two and a half centuries, with ever greater elaboration, demanding larger and larger stages; and the auditorium half of the building kept its many-galleried horseshoe plan. With variations toward rounder or squarer auditorium, the general form persisted until late in the 19th century, from smaller court playhouses to immense opera houses.

At first the arena portion of the auditorium was merely a flat floor and consequently the best seats were not there but at the front of the first balcony; and almost throughout the period of the horseshoe theatre the main floor sloped but slightly, thus allowing three, four or five superimposed balconies or galleries.

In the late decades of the 17th century there had occurred an amazing spread of "the Italian idea," and the public theatres everywhere came into line as soon as circumstances permitted. In some countries, nevertheless, especially those in which private theatres, *i.e.*, those of the court or nobles, constituted all the theatre there was, the new buildings incorporating the stage fitted for wing settings and the auditorium shaped like a horseshoe arrived laggingly.

In France there had been, in small number, tennis-court theatres, a sort of feeble analogue to the English Elizabethan stage and the Spanish *corral* theatre. France retained even after 1600 a type of multiple-station setting inherited from the outdoor religious plays. Its stage was hardly more than a "shelf for acting." But as far back as the mid-16th century there had been court occasions when Italian artists? stage machinists and settings had been imported by the French; and in the early 17th century the Italians were putting in full-rigged stages for the French kings, in palace-ballroom theatres.

A painting of King Louis XIII at a performance in Richelieu's ballroom theatre (later the Théâtre du Palais Royal) is typical of this sort of transitional playhouse. In France the Italian proscenium and the Italian operatic setting thereafter remained standard, and as the ballroom auditorium was given up, the horseshoe auditorium was to appear in both private court theatres and in the larger public houses.

The English theatres of the Restoration period were of similar kind. Inigo Jones, who had studied classic ruins in Italy, who had made copious notes on everything Palladian and especially the Teatro Olimpico, designed adaptations of the vista stage and the architectural proscenium, and he staged masques at court. The next step is illustrated in a famous set of engravings (dated 1673) of the stage and its "very elegant frontispiece" in the Duke's theatre in Lincoln's Inn fields (the second house of the name). It shows the typical "elegant" proscenium and a full set of Italian-style in-

door and outdoor settings. In the transition to the horseshoe auditorium, however, the English were sloner to give up certain advantages of the pre-Restoration playhouses. An apron stage or forestage in front of the curtain, with a doorway or dooraays (up to three) for actors' entrances on either side, remained a feature until the late 19th century. The pit for standees or with benches remained too, the quality seats being all in boxes and galleries above.

Christopher Wren (1632–1723) drew what seems to be the earliest plan of an English theatre with a true horseshoe audito-

rium. This may have been a study for the Drury Lane theatre of 1674. With the opening of the equally famous Covent Garden theatre in 1732, the French-Italian type of theatre may be said to have become wholly acclimated in London. Pictures of the interior of Drury 'Lane in 1795 and again in 1842 (rebuilt) show how the progress ended. 4 well-known painting of the Park theatre in New York city in 1822 reveals how closely America followed the English type; though there the builders omitted an auditorium feature that had become standard in most European houses: a tier or tiers of boxes adjoining the proscenium frame at the ends of the balconies or galleries. In the English theatres these boxes looked down on the forestage or apron (as they had in one of the earliest Venetian opera houses in the early part of the 18th century; as they did occasionally in France when the stage jutted before the curtain line); but more often the boxes gave but an awkward and incomplete view of the action.

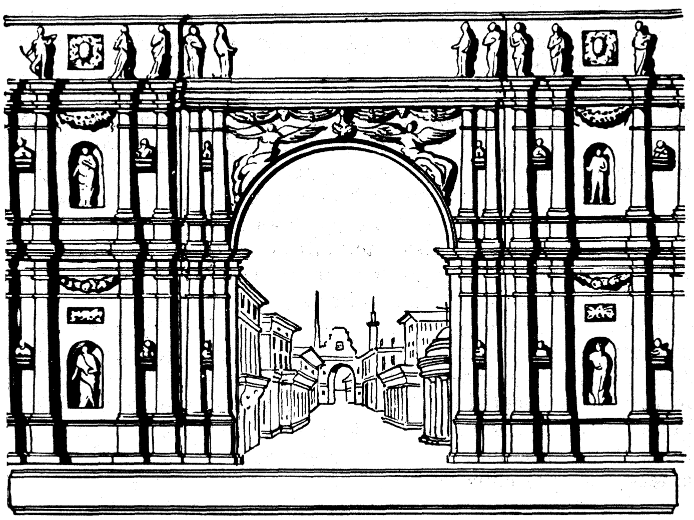

FIG. 13 — ELEVATION BY INIGO JONES OF A WIDENED CENTRAL VISTA. DESIGNED TO GIVE A PICTORIAL BACKGROUND AND PROVIDE ACTING SPACE WITHIN THE VISTA

One other transitional building must be mentioned: the famous Schouburgh in Amsterdam as shonn in an engraving dated 1638. In a rough semicircle backing the acting platform are apparently some relics of the simultaneous or station stage of the mediaeval mystery plays. centring in a construction not unlike the outdoor *Rederijker* stages, but with openings for vistas and, well forward, provision for a curtain to veil changes. But Holland was soon moving into the international current and the history of its theatres after 1750 is little different, architecturally, from that of other European countries.

These and many lesser exceptions aside, the horseshoe playhouse, arriving as a type in the late 17th century, dominated theatre building through the 18th century and the 19th. It is easy to visualize it in terms of the great and regally decorated monuments such as the San Carlo Opera house in Naples, La Scala in Milan, Drury Lane, the Théâtre Français, the Burgtheater (originally the Hofburgtheater) and the Opera in Vienna, the Paris Opéra and New York's Metropolitan Opera house.

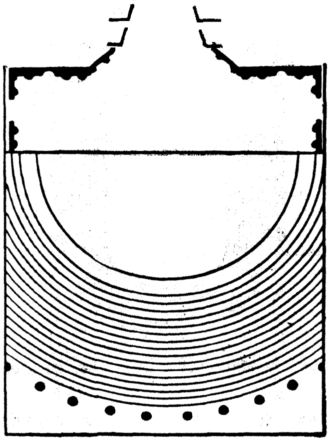

FIG. 14.— PLAN OF FIG. 13

With the great multiplication of commercial theatres in the 19th century, effort was sometimes made to equal the architectural showiness of these monuments, but more often to duplicate their plan on a smaller scale.

Practically all descriptions of Renaissance and later theatres begin with accounts of the stage arrangements and the plan and appointments of the auditorium interior. The exterior architecture is seldom mentioned. So many post-Roman theatres at first were constructed inside existing buildings that there was seldom a concern for façades. If at court, a ballroom or a courtyard was assigned. "Public" theatres were squeezed into. among other buildings, tennis courts (which were roofed in those days), innyards, even bear-baiting "gardens" and riding schools and warehouses. The grander continental theatres of the 18th and 19th centuries were, however, erected as independent entities, often dominating a small park or city square.

Palladio. Inigo Jones, Christopher Wren, Gottfried Semper and Karl Friedrich Schinkel were architects who came to be associated with theatre projects. But there emerged no theatre style, unless it was a species of Baroque as brought in by the scene designers and architects of the Galli da Bibiena family in the late 17th and the 18th centuries. They practised internationally. The style, debased into French Rococo, found new release in the Paris Opéra built about 1870 by (Jean Louis) Charles Garnier. Between 1700 and 1870 more sober architects had fitted their theatres with casings designed in whatever derivative style was in vogue at the moment. Italian Renaissance had come first, then Baroque, followed by the softer French Renaissance and Rococo, and through the cycles of Greek Revival and Roman Revival.

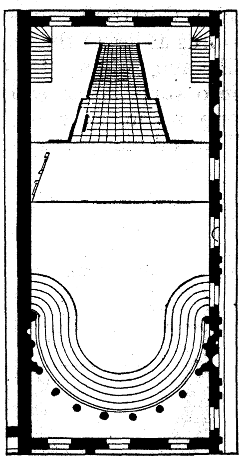

FIG. 15.— PLAN OF NARROWING VISTA. THEATRE AT SABBIONETA, IT., BUILT BY SCAMOZZI IN 1588

Unfortunately the capital cities of the world. and especially those of the royal and ducal courts in Europe, felt that the Garnier monument, the Paris Opéra, chef-d'oeuvre of lavish Rococo or showy Exposition architecture, was a model perfectly suited to house the art of the theatre and a regal achievement to be jealously copied. Official theatres from the Royal theatre at Wiesbaden (1894) and the National theatre in Prague (1883) to the National theatre in Mexico City (20th century) emulated this "style," at least so far as the sumptuous air and overdecoration a ere concerned.

It is a melancholy truth that pictures of theatres seldom appear in books illustrating the history of the art of architecture, so nondescript are the outward appointments. A few monuments consistently stylized are exceptions to the rule: Schinkel's Schauspielhaus in Berlin, severely classic; the somewhat stodgier Opera in Vienna, in controlled French Renaissance; and some would say the Haymarket theatre in London.

Theatres of 1900–30.—The main changes in the construction of early 20th-century theatres, when the builders of commercial houses became leaders, were the exclusion of all but one balcony and the steeper tilting of the main floor, thus throwing the best seats into the orchestra. It had been noted that the horseshoe form provided a considerable number of bad seats, in the proscenium boxes, at the gallery ends and even at the ends of the orchestra rows. The proscenium boxes were therefore generally abolished, then all the side galleries; and the auditorium, in relation to the proscenium frame, was narrowed and eventually was made fanlike.

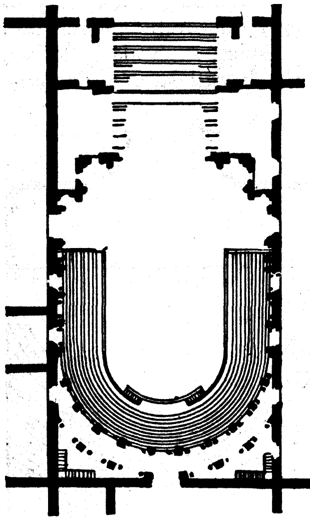

FIG. 16.—PLAN OF THE TEATRO FARNESE, PARMA, IT. (1618–19), CALLED THE FIRST MODERN THEATRE

With the coming of more realistic standards in stage setting, with the disappearance of the old-style painted wing settings and the appearance of the box set (for interiors at least), the old vista lines, marking the edges of the wings or flats, no longer needed to determine the auditorium sight lines.

The Germans were the first to reform the horseshoe auditorium, and the finer monuments of the simplified style are in Germany; but the American theatres built after 1900 were generally in the new idiom. In France and Italy the 18th–19th century tradition persisted more stubbornly. The contracted orchestra remained and the best seats (for seeing the play) were in slightly raised rings of loges and in the front of the first balcony just above.

A remarkable example of advanced thinking about theatre design had occurred in 1876, when the Wagnerian Festspielhaus at Bayreuth in Germany was constructed. The architect was ostensibly Gottfried Semper, but it was Wagner who sketched out (in words at least) the requirements that led to the revolutionary fanlike auditorium. He demanded that every spectator face directly into stage space and have sight into full stage depth—so that only a bank of seats, the rows slightly curved, could be utilized. The full plan of the revolutionary building is shown in fig. 18.

In Germany the impulse was taken up by Max Littmann and he became the outstanding theatre architect of the early 20th century. His Prince Regent theatre in Munich, his Schiller theatre in Charlottenburg, Berlin, and his Kiinstlertheater in Munich, all with simplified banks of seats, had influence throughout Europe and the United States. The Kiinstlertheater especially delighted the generation of young theatre artists who became disciples of Adolphe Appia and Edward Gordon Craig in the decade after 1915. Its chaste exterior in modern style and its simple interior, with the single, rather steeply sloping bank of seats, as seen in fig. 19, seemed perfectly fitted to the ideals of the new stagecraft. Littmann experimented also with adaptable proscenium frames in an effort to take advantage of the enlarged possibilities in the field of stage lighting, One of the most impressive of 20th-century theatre façades, this marking a return to classic motifs, is that of Littmann's State theatre in Stuttgart, a building group actually housing two theatres. In the hands of other German architects the simple bank of seats was modified to a form less severely wedgelike. Oskar Kaufmann adapted the Wagner-Semper idea to a large theatre (with an immense "space stage") in the Volksbiihne or People's theatre, a socially advanced co-operative theatre in Berlin (fig. 20B). His Kroll Oper in Berlin added to the wedge of orchestra seats some useful remnants of balcony boxes and gallery, for greater seating capacity, without impairing the atmosphere of spacious modern decoration or the utilitarian sight lines, and in the Volksbuhne he only modified the old-time three galleries. At Stratford-on-Avon in England the new Shakespeare Memorial theatre built in 1932 followed closelv the German reform models, especially those of Littmann.

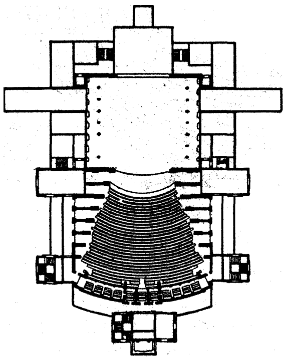

FIG. 18.—PLAN OF THE BAYREUTH FESTSPIELHAUS, GOTTFRIED SEMPER, ARCHITECT. THE FAN SHAPE WITH STRAIGHT SIDES AND A WIDE SPLAY WAS USED

In America the squeezing out of balcony, gallery and boxes was a slower process; at any rate there were fewer examples than in Germany of the total reform of the horseshoe-and-hencoop auditorium. But soon after 1900 the American commercial theatres had got well along toward a standard fan-shape plan. The orchestra, enlarged and scientifically tilted, contained the best seats. Above this at the back there was one balcony. Metal construction and modern engineering made it possible to dispense with the troublesome pillars and posts that had been all too conspicuous in many earlier examples.

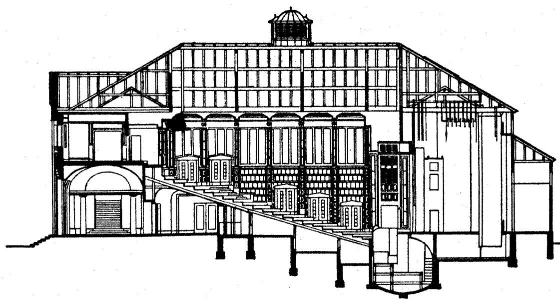
In large cities, especially New York, where ground value was an overwhelmingly important consideration, the commercial theatres were commonly built with shallow stages, wider proscenium openings and wider auditoriums. Ingenious solutions were found to the problem of fitting such a house to small and sometimes irregularly shaped sites. Standard fire laws imposing the necessity for a certain number of aisles and adjacent doorways and certain types of fire escape, laws not kept up to date in view of progress abroad, hampered American architects.

There were, however, theatres in New York early in the new century which approached the German "modern" standard. Three may be briefly described as typical. The Little theatre, opened in 1912, circumvented the laws that hampered neighbouring playhouses because its seating capacity (originally) was only 299. In basic plan and outline it approximated the most advanced houses abroad, as indicated in fig. 20A.

In 1927 there opened the Ziegfeld theatre, which was intended to be a model American theatre for large musical productions. One of its two architects, Joseph Urban, had been intimately connected with reform theatre and art movements in Austria and Germany before settling in America in 1911. He planned the Ziegfeld theatre technically on the latest continental models and decorated it gaily because it was particularly designed for musical shows of the "Follies" type. Joseph Urban also designed theatres for moving pictures—but these, with their different requirements, are part of another story.

The builders of the Guild theatre in New York, after assembling advice from a great number of modern stage designers and architects, provided a house undistinguished in its decorative features but logically adapted to modern methods of staging and affording a fair view from every seat. The longitudinal section and plan of the orchestra floor, fig. 21, indicate that at this time the last vestiges of the 19th-century horseshoe auditorium with boxes had been exorcised.

The one feature at first glance apparent in these three American theatres, as distinguished from the same type as developed in Germany, is the breaking-up of the orchestra with two aisles. In Europe theatre architects traditionally have allowed more space between rows of seats, and entry to each row is from the ends. Thus the modern orchestra was one solid bank of seats (fig. 20B). The less generous allowance of space to each seat in America, added to the very strict laws about access and exit (after disastrous fires), brought about the specifying of a certain number of aisles per length of seat row.



FROM LITTMANN, "DAS MÜNCHENER KÜNSTLER THEATER"

FIG. IS.— SECTION OF MUNICH KÜNSTLERTHEATER, SHOWING THE STEEPLY SLANTING FLOOR

Except for the breaking-up of the banks of seats, the American theatre of the early 20th century seemed simpler in plan than the German. There were smaller lobbies, fewer vestibules and social rooms and the dressing rooms for actors were relegated to positions above or below the orchestra level. This again was due to excessive ground cost in the large cities.

The great accumulation of machinery for changing scenery, which had grown and grown since the days of the Italian and French Renaissance ballroom theatres, reached a peak about 1900; and machinery for electric lighting had then become complicated and cumbrous. A building such as the Paris Opéra might have as many as eight floors (or the equivalent space) above and below stage to facilitate handling of scenery; and as late as 1901 Littmann built the Prince Regent theatre in Munich with extraordinary over-stage and under-stage space—contrasting strangely with the simplified single-bank auditorium. But when the ideals of Gordon Craig and Adolphe Appia found wide support, especially as to the de-emphasizing of scenery and the need for an artist-director as co-ordinator of all the elements of production, a new simplification of stage equipment was initiated. There was considerable experimenting with turntable or revolving stages, with wagon and elevator stages and with other devices calculated to effect changes of scene quickly and so to do away with the stage house in which painted flats were "flied" or hung (from, technically, the gridiron). This house above stage had been a bother to architects who wanted to afford a consistent period look to the exteriors of their theatres. But it must be said that the reform movement of 1910–30 failed to relieve the theatre of the high storage building for hanging flats and curtains, though it did bring in a great deal of simplification of stage machinery. In the same years lighting engineers developed equipment of almost miraculous variability, flexibility and delicacy, the whole controlled from a single switchboard.

The latest of the historic type theatres was, then, this house that took shape especially in Germany, a little later by reflection in America. In the end, hardly a country in the western world escaped the influence. France, England (where the new stagecraft was very slow in gaining converts), Scandinavia, Czechoslovakia and many another country might yield pictures of similar, if generally later houses. Most would show an exterior indicating the basic nature of the division of space within: auditorium lower than of old, with towering stage house at back; within, a bank of seats, on a floor uniformly sloping or slightly saucer-shaped, more tilted than during the horseshoe period, restricted at the sides along lines determined by the edges of the proscenium portal (which, of course, had lost most of its ornamentation). And there was one balcony—generally. This might be called the conformist theatre of, say, 1930.

***Nonconformist Theatres*, 1915–35.**—Between **1915** and 1935 there was an unprecedented ferment of ideas about "new" ways of staging plays. Revolutionary opinions, especially about bringing the actor clear of the old clutter of painted scenery, clear even of any contrived setting, were heard in many countries. Individualistic plans for new theatres, mostly starting from the premise that the proscenium-frame playhouse was due to be scrapped, were committed to paper—and sometimes became the basis of actual buildings. Since no type theatre was widely established, all this effort must be summarized very briefly.

First of all, there was agitation for a return to the architectural stage. The Elizabethan or Shakespearean theatre was most often thrust forward as a model, though this must be put down as far more than a revivalist activity. Probably the first attempt to recapture the intimacy and vividness of forestage acting before an unchanging architectural structure was that of Karl Immermann, who built his "Shakespeare Stage" at Diisseldorf in 1840. Similar projects were under discussion during the decades following; but only after 1910 were theatres with architectural stages built in any number—and then only by the little theatre groups. The most professional and by far the most fruitful artistically of the permanent-stage theatres was the Théâtre du Vieux Colombier in Paris. The animating genius there was Jacques Copeau, the wisest and most lovable of all the members of the group of idealists and reformers in Paris. Associated with him was Louis Jouvet. The Vieux Colombier stage was a very free adaptation of Elizabethan models. A number of interchangeable elements or units were added, in the nature of screens, sections of stairs, curtains, etc. Yet with all its possibilities of change of mood in setting, it had no provision for the picture scene. For a few years it was the world's foremost progressive stage.

Adolphe Appia never had a theatre of his own, but his drawings of simplified and mood-creating stages cannot be overlooked as influences. So too, in America. Norman Bel Geddes published a considerable number of plans for "theatres of the future." He, too, failed to see any planned playhouse built, but his drawings of scenes as they would be in circular or circuslike theatres—that

is, theatres in the round—encouraged the longest-lasting impetus carrying on from the 1915–35 period; *i.e.*, production in the round.

What is generally termed the space stage does not necessarily demand abolition of the proscenium arch. It is only that the space within which the actors appear is darkened and the figures are picked out by localized light. The settings, if any, are fragments of wall or possibly a hummock or a small platform with steps—never a full stage picture. Perhaps the finest staging of the sort was accomplished at the Volksbiihne in Berlin during the 1920s, on a proscenium-framed stage.

For production in the round, in the full sense, there were and are innumerable improvised theatres. In these the audience surrounds the acting platform on at least three sides, if not full circle. As a matter of fact, the one great exemplar of this type of theatre failed considerably of closing the circle; but in the Grosses Schauspielhaus in Berlin (constructed in a circus building) Max Reinhardt presented many extraordinarily vivid productions. He dramatically utilized the immense forestage to keep his actors in intimate contact with the spectators, but he took advantage of an inner regular stage too.

In the United States the testing of new ways of staging, in the face of a great decline in production at the commercial theatres, fell to the university and little theatres, or to the few community theatres. But the best of the community theatre houses, notably those at Pasadena, Calif., and Cleveland, O., were built within the proscenium-stage type. Certain of the university playhouses are perhaps the finest theatres in America—say those at the University of Iowa, Iowa City, the University of Wisconsin, Madison, and, a little older in type, Yale university. But these too have the proscenium frame.

Nowhere in America, indeed, has experimental staging led to the building of nonconformist houses as important as the Théâtre du Vieux Colombier or the Grosses Schauspielhaus. The Russian producers, who were the world's foremost adventurers in new ways of staging between 1920 and 1935, fitted some of their improvised theatres with forestages and some with banks of seats not unlike Greek theatre auditoriums; but there is no report of a standardized new type of house.

Most heralded was the Theatre of the Young Spectator, or more simply the Children's theatre, in Leningrad, which seated 600 spectators in a semicircular Roman-type auditorium, with an enlarged orchestra pit arena, a forestage and small inner stage. The constructivist type of setting, which is considered especially an invention of the Russians, demands no more than a stage with a decently wide proscenium portal, though it can be fitted upon a forestage or in an arena as well.

All these individualistic theatres, and the theories behind them—theories looking forward to the elimination of the proscenium-frame house (and the "peephole stage" that especially represented late 19th-century realism)—all these developed before 1935. They represent historic advanced thought about theatre architecture as it existed before World War II.

BIBLIOGRAPHY.—In English one book is outstanding as regards physical changes in the theatre's form: Allardyce Nicoll, *The Development of the Theatre*, 3rd ed. rev. and enl. (New York. London, 1948). It is profusely illustrated, particularly in the areas of Roman, Greek and English playhouses. *See* also George Altman, Ralph Freud, Kenneth Macgowan and William Melnitz, *Theater Pictorial: a History of World Theater as Recorded in Drawings, Paintings, Engravings, and Photographs* (Berkeley, Calif., 1953; Cambridge, 1954). This is primarily a collection of scenes and settings, but includes views of stages and auditoriums, with historical notes. Notable as offering, in a monumental work, views and plans of the theatre of one era is Edwin O. Sachs, *Modern Opera Houses and Theatres*, 3 vol. (London, 1896–98); it memorializes the regal-display, horseshoe houses and the beginnings of the German reform movement. Succinct and useful still is Martin Hammitzsch, *Der moderne Theaterbau* (Berlin, 1906). For further guidance the researcher should consult Nicoll's book, which includes extensive bibliographies. (S. DESIGN AND CONSTRUCTION OF MODERN THEATRES

Since the Renaissance the design and construction of theatres, their auditoriums and their stages, have been determined by three factors: (1) the relation of the actors to the stage and the stage setting; (2) the relation of the actors to their audience, as influenced by methods of acting and stage setting; and (3) the size and social status of audiences which patronize theatres and make them popular and potentially profitable.

As these factors change, the essential parts of a theatre change with them. namely the stage itself, including its apron or forestage, the dimensions of the stage house or backstage, the plan and seating arrangements of the auditorium. It is therefore necessary to summarize briefly the development of theatre architecture by way of understanding how the basic elements of theatre design function.

No innovation, modern in its own day, has ever been wholly original. Each in turn has revived and modified theatre structures of earlier epochs. The first Renaissance theatre, the Teatro Olim-

pico at Vicenza (1584), used the steeply pitched, semicircular arena seating of the Roman theatre and simplified its elaborate architectural facade back of the platform on which the actors played, piercing it with three portals through which vistas of streets in perspective could be seen. In the Teatro Farnese at Parma (c. 1618)) the stage had a single wide curtain in an ornamental frame, the proscenium, which became a permanent part of theatre design for three centuries in every royal, state or commercial theatre in Europe and the United States and remains one prevalent type of stage familiar to every theatregoer.

The auditorium of Wagner's Festspielhaus at Bayreuth, a revolutionary innovation in 1876, reproduced almost exactly the seating arrangements of the Teatro Olimpico. Max Reinhardt, for his Grosses Schauspielhaus, Berlin, 1919, remodelled an existing circus arena, using it for much of the action of his spectacular pro-

ductions, and added a bare platform stage at one end—a combination of a Roman gladiatorial arena and a Roman theatre. The Volksbühne in Berlin adopted the same general scheme. Entrance doors or portals at either side of the proscenium opening, a standard feature of London theatres throughout the 18th century, were revived at the Provincetown playhouse, New York city (1923), Smith college, Northhampton, Mass. (1928), the University of Wisconsin theatre (1939) and at numerous other college theatres. Reproductions of the Shakespearean stage, either replicas or modifications of the basic structure of the Globe theatre or the Curtain theatre, were built at the Folger library, Washington, D.C., the Shakespeare Memorial theatre at Stratford-on-Avon, Eng., and at Stratford, Conn. The theatre designed for the Cologne exhibit of modern architecture, 1914, was permanently divided in three parts that could be used simultaneously or closed off by curtains in alternation; it revived the simultaneous settings of the Hôtel de Bourgogne, Paris, 1609, and the arrangement of the wagon stages on which allegorical tableaus were performed in the streets of Flemish and French cities during the 16th and 17th centuries for the festivities that greeted visiting royalty. The semicircular extended forestage of the Civic theatre, Malmo, Swed., 1944, is similar to forestages used for ballet interludes at the Drury Lane and the London Opera house, *c.* 1809. Modern directors who deride the proscenium stage as a mere peep show and have established theatres in the round, where actors are encircled by the audience, in turn revive the actor-audience relationship of the primitive ritualistic performances of Africa and Asia.

Influence of Popular and Literary Taste.—The popularity of the proscenium was originally due to another Renaissance innovation—architectural and landscape vistas, receding to a vanishing point within a picture frame, established by the masters of Renaissance painting. The first perspective stage settings were three di-

mensional, but the illusion of vast distance in a limited space was soon heightened by painted perspectives of soaring vaults and colonnades, as in the designs of a great family of Baroque artists, the Calla da Bibienas.

At the same time, directors, playwrights and audience were eager to witness spectacular productions with many changes of scene. Molière, who supposedly declared that all he needed to stage a play was three boards and a passion, as a theatrical manager reconstructed the Palais Royal theatre, occupied by his company, in order to accommodate elaborate scene-shifting machinery. The royal theatre was known as the Hall of the Machines and a favourite effect was the gloire or apotheosis, in which as many as 30 or 40 actors, costumed as Olympian deities, were seated on platforms masked with tinsel rays and silhouettes of clouds; these were lowered and suspended in mid-air above the stage as a spectacular finale to a performance.

Where scene shifts were originally made by sliding flats on and off stage in a series of grooves or slots, the increasing weight and elaboration of stage settings required machinery for lowering scenery and hauling it out of sight. Before the middle of the 19th century the grooves became obsolete. Backdrops, platforms or flats were suspended overhead from beams, the flies. counterweighted with sandbags and lowered into place on hemp lines, tied off to a pinrail or fly gallery, similar to the system used for handling the rigging of sailing ships. With the substitution of a metal gridiron and a pinrail at stage level, this counterweight system remains a permanent part of stage equipment. For efficient use it requires a sufficiently high stage house and thus determines one important building cube in theatre construction.

The spectacle of a performance was not confined to the stage. The auditorium plan adopted was U-shaped with shallow tiers of balconies or boxes where, during the intermissions, the socially élite, plutocrats or the nobility, could display themselves and be seen by the commoners or bourgeoisie seated on the orchestra floor. This remained the prevalent plan for theatres and opera houses throughout the 19th century; the first tier of boxes at the Metropolitan Opera house in New York city was known as the "diamond horseshoe."

This basic plan was modified by three trends: the decline of the aristocratic or titled classes as a political and social influence; the rise of democracy; and the introduction of iron and steel in building construction. Deep cantilevered balconies increased the number of theatre seats and improved their sight lines. These, with a realignment of orchestra seats in a fan-shaped or flattened arc, became the basic elements of a theatre plan.

Two other developments, one technical and one literary, also modified theatre design. The first was the introduction of gas-lighting in the 1850s and of electricity in the late 1870s. Until then the principal source of illumination consisted of huge candle chandeliers, usually three, hung directly in front of the proscenium arch; by comparison the stage itself was dim. Actors came forward in order to be seen, and the prevalent rhetorical style of acting in classic and romantic drama reinforced this tendency, tirades and soliloquies being delivered directly to the audience as verbal arias. The second development was the growth of realistic play-writing. With this and the introduction of the box set, the proscenium opening became an invisible fourth wall; behind it the actors moved in factual reproductions of palace halls, living rooms, cafés, kitchens or hovels. The illusions of painted perspective seemed artificial, destroying the new illusion of reality which, both in theory and practice, became the artistic goal of directors and playwrights. As a result, stage settings became increasingly architectural with built columns: cornices, doorways, stairways and balconies and even mythical sites monumental in scale.

In consequence theatre technicians and architects of German and Austrian state and municipal theatres enlarged the stage house and equipped it with elaborate machinery for handling and shifting stage settings.

In the Dresden Royal theatre Max Littmann divided the entire acting area with three elevator stages that sank to cellar level where wagon stages (on rolling platforms), each containing an entire setting, were speedily slid into place and raised to stage level. Similar shifts could be made at stage level. Another technician, Karl Lautenschlager, introduced the revolving stage, used in the popular theatre of Japan, a turntable at stage level, and enlarged it to hold several settings which could be rotated into view. The depth of the stage was increased to house plaster domes that, under diffused lighting, replaced sky drops and heightened the illusion of atmospheric depth.

The Declining Professional Theatre.—No important contribution to theatre design was made in the theatres built in New York city between 1903 (the Lyceum) and 1927 (the Ethel Barrymore). The total number of such legitimate theatres in operation (*i.e.*, for the production of plays or musical comedies) dwindled steadily in and after the 1930s, many having been demolished or converted into motion-picture houses or television studios. These "Broadway" theatres, crowded into an area roughly half a mile square, with capacities ranging from 500 to slightly more than 1,700 seats, were built on expensive, centrally located real estate with costs of construction running from $500,000 to $1,000,000. As a result, plottage was reduced to a minimum, and with the exception of the Guild theatre and the Ziegfeld the stages were constricted in width, depth and height and lobby and promenade space was inadequate. Façades were a pastiche of some historic style such as Georgian or Hispano-Moresque or a hybrid combination of several.

In order to encourage theatre building, the New York city code was revised so that a theatre could be made part of a larger office or business building, thereby enabling it to carry only a portion of the real estate: maintenance and construction costs of any site.

The Resurgent Amateur Theatre.—The total number of professional theatres throughout the United States, housing either local stock companies or Broadway plays on tour. also dwindled during the same period to scarcely more than 200 by the 1960s.

During approximately the same period, the number of college and university theatres increased to almost 2,000. It was in this field, including the allied one of civic centres, that modern theatre architecture had progressed by mid-century. Notable examples were the Pasadena Community playhouse (1925), the Yale University theatre (1926), the Cleveland playhouse (1927), the Kalamazoo (Mich.) Civic auditorium. Such theatres give an opportunity for integrated planning and functional design. The commercial theatre, crowded into a constricted plot between business buildings, was and is nothing more or less than a boarding house, rented to temporary tenants who have either to provide the excess profits of a "smash hit" or vacate the premises.

On the other hand, college and civic playhouses. like the municipal and state theatres of Europe, are considered of enough cultural importance to be endowed. Exterior design becomes not a mat-

Minimums and Alternatives.— Function determines form, and planning in turn determines the effective functioning of a building. In designing these theatres, the architect is faced with the necessity for basic minimums in regard to the stage and various alternative solutions in organizing the related units of the entire building.

Backstage dimensions are determined by the balance of scenic units and sight lines. The minimum width of the stage should be at least twice the width of the proscenium opening; allowing half at each side for circulation and stacking space, *i.e.*, for a 25-ft. proscenium, 50 ft.; for a 30-ft. opening, 60 ft. But these are minimums.

A properly planned stage should be three times the average proscenium width. *i.e.*, 80 to 90 ft., and the height of the stage house should be 65 to 85 ft. For a stage is a space where large amounts of scenery not in use have to be stacked out of sight during or between the performances of a single play, as well as props such as furniture ranging from thrones to living room tables and chairs. However stylized a production may be. no abstract substitute for tables and chairs has been discovered. A simplified unit setting for the revival of a Greek tragedy may involve a large chorus. and the most expressionistic interpretation of a classic, Elizabethan or modern script may call for arcades, pylons, ramps, stairways and playing areas at several levels. as well as crowds of extras. Smaller groups of actors may have to exit from stage right and re-enter from stage left a few minutes later. They cannot be exoected to clamber over stacked furniture or sets to be used in the next act.

The elaborate mechanism of a series of elevator stages can be dispensed with, but a combination of a revolving stage and one or more wagon stages at stage level in off-stage wings provides an efficient way of meeting the most varied demands of a repertory program. However, an elevator forestage remains a valuable adjunct. It can form the forestage apron or be sunk to hold an orchestra or additional seats; lowered to cellar level it provides the best means of handling heavy props or scenic units and routing them to storage space.

An adequate stage house, ample in height, width and off-stage space, is the core of a theatre. Any attempt to dwarf or constrict it results in handicapping the theatre's program. A recurrent and excellent plan (which has been used for the Mannheim, Ger., Malmo, University of Wisconsin and other theatres) provides two auditoriums. a smaller one for more intimate productions, recitals and lectures. and a large one for major dramatic productions, operas and orchestral concerts. This plan has been effectively used wherever it has been adopted.

Several technical requirements remain to be considered, such as stage traps, fire precautions. lighting control and acoustics. Almost every 19th-century theatre provided a "Hamlet trap" for the burial of Ophelia. It is advisable to provide for a group of 12 or 16, each approximately 3 ft. × 3 it. 6 in., which can be lifted out to form larger openings and then replaced. However formal the stage, an asbestos curtain. connected to the skylight over the stage house on a counterweighted rope line. is an essential. In case of fire. the rope is cut and the skylight automatically opened, creating a back draft and keeping smoke out of the auditorium. For the immediate hazard of fire is primarily from smoke, injuries or asphyxiation during panic and stampede. The New York city fire code sets an excellent standard of safety in regard to the minimum width of aisles. number and size of emergency exits.

height of risers between rows of seats and the width between each row, fireproof doors backstage between the stage and workshop and storage areas! fire escapes for auditorium balconies and dressing rooms not at ground level. Where the more steeply pitched "continental" seating is adopted (so-called because it was first used in European theatres) the aisles are widened at exits provided at both ends of each aisle.

'The distribution of spot- and floodlighting also affects the design of the auditorium. In addition to the light troughs extending across the auditorium ceiling for general lighting, an additional trough is essential for spotlights that cover the forestage and the forward portion of the acting area. The fluctuations of light, the "light plot," which are an integral part of any production, require a hundred or more sources of light—spotlights and floodlights ranging in capacity from 250 to 1,500 w. each.

Lighting control has been greatly aided and simplified by the development of remote electronic control—particularly the C-I board. This board is operated from a console approximately 36 in. wide and 30 in. long and requires only a single operator for a total of 45 dimmer circuits and a maximum capacity of 300,000 w. Small master handles interlock and synchronize simultaneous lighting changes.

The dimming element, consisting of a series of thyratron tubes, can be placed below stage, thus freeing the stage area from bulky assemblages of manually controlled or motor-operated dimmer banks. Being compact, this type of control board can be placed either in a lighting booth at the rear of the auditorium or on stage at either side of the proscenium opening.

Acoustics present a special problem. The elaborate "gingerbread" ornament of the 17th- and 18th-century theatres with Baroque and Rococo ornament covering the proscenium and the entire interior, including the auditorium ceiling, the fronts of the tiers of boxes and the galleries. together with the natural resonance of wood walls and numerous draperies, provided an excellent balance of sound reflection and absorption.

Modern design with its emphasis on diffused auditorium lighting over plane surfaces of hard plaster tends to upset this balance. In general, concave surfaces whether in plane or section are to be avoided; the fan-shaped plan of the auditorium is likely to give to large surfaces of the rear wall a curve that is acoustically bad, particularly one that is struck on a centre near the stage. In general the principle to be followed is the proper balance and distribution of sound absorbing and reflecting surfaces and contours. But as their determination is a highly technical problem, unless an architect is particularly qualified, the services of an acoustic consultant are indispensable in the design of an auditorium.

Various alternative solutions can be studied in connection with the theatres at Oberlin, Sarah Lawrence and the University of Arkansas, which at the same time enable the architect to achieve fluent and simplified interior contours.

Multipurpose Theatre.—Two recently completed playhouses, at Sarah Lawrence (1951) by Marcel Breuer and at Oberlin by Harrison, Abramowitz and E. Snyder (1953), are outstanding examples of functional theatre design.

At Sarah Lawrence the various levels provide a theatre foyer that can double as an exhibition hall, a common room with a snack bar opening onto a terrace and, at a lower level, a spacious common room and dance studio. The 500-seat theatre is so flexibly arranged that it can be used for an arena style performance or for

plays within a proscenium, as a night club for student entertainments and as a lecture or concert hall. When the sliding doors at the rear of the stage are opened it can be used for open-air performances with the audience seated on the tennis-court area. The forestage is a hydraulic elevator that can provide an orchestra pit or 33 additional portable seats at floor level. A pioneer designer of metal-frame furniture. Breuer devised a new type of orchestra chair, a light seat on a tubular frame. All seats swivel, permitting spectators to turn 12° to right or left. The rows are set 42 in. apart (10 in. wider than standard), permitting exceptional ease of ingress and egress. A U-shaped balcony directly below the ceiling provides space for spotlighting the stage from any angle; at the rear there is a booth for the light control board and a motion-picture projector.

One of Breuer's tenets is that architecture tends to he too often concerned with inconsequential detail and should return to the unaffected beauty of simpler materials. Here the exterior facing of wall and terrace surfaces present the contrasted textures of rough stone, flagstone and painted brick; in the auditorium concrete block masonry contrasts with alternating brick-shaped projections. These serve to break up the surface sufficiently to secure an excellent acoustic balance together with the broken planes of the side walls, painted in contrasting tones of red and blue.

In commenting on the Oberlin theatre, the Architectural Forum said: "Few buildings in recent years have faced up to the major problems as boldly as Oberlin has faced up to them. The little auditorium, with its sway-backed roof, its strangely cubist forms and its wavy interior surfaces, tries, creatively, to answer a lot of challenging questions that most architects like to dodge . . . . Can he (the architect) 1. Design an auditorium to fit snugly around an acoustic engineer's 'optimum shape' and still get good architecture? 2. Resolve the glaring conflict . . . .between a low slung auditorium and towering stage house without making the former too high or the latter too low for good appearance? 3. Can modern architects keep on designing 'anonymous' buildings . . . or do we need a new vocabulary of expressive, modern forms that suggest clearly the purpose of the building before us?"

The problem is successfully resolved with an architectural balance of dramatic forms almost monolithic in their simplicity, further emphasized by the varying shadows cast during the course of the day. The space between the concave roof and the broken surface of the auditorium ceiling is utilized for indirect lighting troughs and troughs for spotlighting the stage, with a catwalk to service them. The convoluted screen at the entrance portico provides a dramatic background for open-air performances or open-air concerts and dances.

The Theatre as an Art Centre.—The program of the University of Arkansas called for a building that would be "a workshop, a place where painting, sculpture, architecture, music and dance live and grow and from which their civilizing influence spreads into our daily lives."

The building is another example of effective functional design in the general composition of its component parts, in the treatment of its various façades, in its flexible but well-integrated ground plan and general circulation among interrelated activities—painting, sculpture and architectural studios, exhibition gallery, library, sculpture court and concert hall. The stage is completely trapped and has a total width of 104 ft.; its lighting equipment is so arranged that with the curtain down and temporary seats in place it can be used as a theatre in the round; one wing connects with an open-air theatre.

The acoustic concrete blocks used for the auditorium walls have given completely satisfactory results. A scenic workshop, two stories high, 26 ft. × 56 ft. in area, connects with the stage at stage level and is overlooked by the scenic design studio, which in turn connects with a costume workshop. The building as a whole is a centre where students can develop in stimulating contact with all the arts.

Where appropriations, as in many colleges, limit the size of a playhouse to a comparatively small building, a great degree of flexibility may nevertheless be achieved, as in the theatre at Baylor university, Waco, Tex., designed by Paul Baker and completed in 1954. The main studio theatre consists of three connecting platform stages, one of which has a stage house and a proscenium opening. The acting area can be centred there, or cover all three simultaneously or in succession.

The audience, seated on swivel chairs, can turn in any direction to follow the action of a play. For an arena-type production the seats are moved to the stage level and the action takes place on the

orchestra floor. A lighting booth suspended from the ceiling can light any or all of the stages.

Other Experimental Forms.—Mies van der Rohe's project for a National theatre at Mannheim, Ger., is unique in that it applies to theatre architecture the continuous glass and steel shell, a form which he was one of the first to develop and which later became widely used in factories, office buildings. apartment houses and country residences. The building is approximately 520 ft. long and 240 ft. wide, with a marble-faced lower story 15 ft. and an upper story 40 ft. in height. Its steel and glass walls are carried by exposed steel truss construction. Flexibility is achieved by two auditoriums placed back to back: one with 1,200 seats for operas, ballets. orchestral concerts and pageants; the other with 500 seats for intimate drama, recitals and chamber music.

The entrance foyer to the main theatre rises to the full height of the building. Two wide corridors at the theatre level, which can also be used for exhibition purposes, extend along both sides of the building and lead to a restaurant at the farther end. The continuous tinted glass walls are screened with translucent curtains that can, on occasion, be drawn to command a view of two adjacent parks, and the combination of large spaces with the curtain material used will, in the architect's judgment, give sufficient absorption to solve any acoustical problems.

Flexibility is again emphasized in Walter Gropius' project (1927) for a "total theatre." Here the entire floor of the theatre revolves so that it can be used in any one of three ways—as a circus arena, an amphitheatre with a circular stage at floor level or in conjunction with a platform stage placed above it.

Another experimental method of play production, originally known as "central staging" when first used in 1914 at Teachers college, Columbia university, has provided a simplified type of theatre construction. Glenn Hughes of the University of Washington, an early adherent, completed his Penthouse theatre in 1940. The theatre in the round, as it came to be generally called, consists of a central, circular acting area, the stage floor, where the locale of the play is suggested only by stage properties. This is surrounded by a circular tier of seats, cut by aisles for the actors' entrances and exits. This type of playhouse has proved increasingly popular for smaller audiences in civic and college groups where funds for a more elaborate modern theatre are not available.

THEBES, an ancient Greek city in Boeotia (ancient Θῆβαι, Thebae), is situated on low hilly ground north of the Asopus valley, overlooking the Ismenian plain, about 44 mi. from Athens, whence it is reached by roads and by railway. It has about 4,800 inhabitants, and is the seat of a bishop. The present town occupies the site of the ancient citadel,.the Cadmea; two fragments of ancient wall are visible on the north and another, belonging either to the citadel or the outer wall, on the south. There are remains of a Minoan "palace" and chamber tombs. The church of St. Luke, southeast of the Cadmea, is believed to contain his tomb. Two streams, rising a little to the south, flow on the two sides, the ancient Ismenus on the east and Dirce, Δ(ηί)κρ, on the west. The "waters" of Thebes are celebrated by Pindar and the Athenian poets, and the site is still, as described by Dicaearchus (3rd century B.C.), "all springs," κάθυδρος πᾶσα. From the abundance of water the neighbouring plain is fertile, but the population is scanty, and the town unimportant.

History.—The record of the earliest days of Thebes was preserved in a mass of legends. Five main cycles of story may be distinguished: (1) the foundation of the citadel Cadmea by Cadmus; (2) the building of a "seven-gated" wall by Amphion, and the cognate stories; (3) the tale of the "house of Laius," culminating in the adventures of Oedipus and the wars of the "Seven" and the Epigoni; (4) the advent of Dionysus; and (5) the exploits of Heracles. It is difficult to extract any historical fact out of this maze of myths; at most it seems safe to infer that it was one of the first Greek fortified cities.

In the period of great invasions from the north Thebes received settlers of that stock which spread over Boeotia. The military security of the city tended to raise it to a commanding position and its inhabitants endeavoured to establish a complete supremacy over the outlying towns. In the late 6th century the Thebans were brought into hostile contact with the Athenians, who helped the small fortress of Plataea to maintain its independence against them. The aversion to Athens explains the attitude of Thebes during the great Persian invasion, though it should be remembered that Herodotus, the chief authority for the period, wrote this part of his history in all probability at a period when feeling between Athens and Thebes was bitter in the extreme. Though a contingent of 400 was sent to Thermopylae (480 B.C.) and remained there with Leonidas to the end, the governing aristocracy soon after joined the enemy and fought zealously on his behalf at the battle of Plataea (479 B.C.). The victorious Greeks punished Thebes by depriving it of the presidency of the Boeotian league. In 457 B.C. Sparta, needing a counterpoise against Athens in central Greece, reinstated Thebes as the dominant power in Boeotia. The great fortress served this purpose well by holding out when the Athenians overran and occupied the rest of the country (457–447 B.C.). In the Peloponnesian War (*q.v.*) the Thebans, embittered by the support which Athens gave to the smaller Boeotian towns, and especially to Plataea, were firm allies of Sparta, which helped them to besiege Plataea and allowed them to destroy the town after capture (427 B.C.). In 424 B.C., at the head of the Boeotian levy, they inflicted a severe defeat upon an invading force of Athenians at Delium. After the downfall of Athens at the end of the Peloponnesian War the Thebans, finding that Sparta intended to protect the states which they desired to annex, broke off the alliance. In 404 B.C. they had urged the complete destruction of Athens, in 403 B.C. they secretly supported the restoration of its democracy in order to find in it a counterpoise against Sparta. A few years later, they forced on the so-called Corinthian War and formed the nucleus of the league against Sparta. The result of the war was disastrous to Thebes as the settlement of 387 B.C. stipulated the autonomy of all Greek towns and so withdrew the other Boeotians from its political control. Its power was further curtailed in 382 B.C., when a Spartan force occupied the citadel by a treacherous coup-de-main. Three years later the Spartan garrison was expelled; in the consequent wars with Sparta the Theban army, trained and led by Epaminondas and Pelopidas (*qq.v.*), proved itself the best in Greece. Some years of desultory fighting culminated in 371 B.C. in a victory over the Spartans at Leuctra (*q.v.*). The winners carried their arms into Peloponnesus and at the head of a large coalition permanently crippled the power of Sparta. But the predominance of Thebes was short-lived. The states which she protected were indisposed to commit themselves permanently to her tutelage, and the renewed rivalry of Athens prevented the formation of a Theban empire. With the death of Epaminondas in 362 B.C. the city sank again to the position of a secondary power. In a war with Phocis (356–346 B.C.) it could not even maintain its predominance in central Greece, and by inviting Philip II. of Macedon to crush the Phocians it extended that monarch's power within dangerous proximity to its frontiers. In 338 B.C. the orator Demosthenes persuaded Thebes to join Athens in a final attempt to bar Philip's advance upon Attica. The Theban contingent fought bravely in the decisive battle of Chaeronea (*q.v.*). Philip was content to deprive Thebes of her dominion over Boeotia; but a revolt against Alexander was punished by the complete destruction of the city. Thebes never again played a prominent part in history. It suffered from the establishment of Chalcis as the chief fortress of central Greece, and was severely handled by the Roman conquerors Mummius and

Sulla. In Pausanias's time (A.D. 170) its citadel alone was inhabited. During the Byzantine period it served as a place of refuge against foreign invaders, and from the 10th century became a centre of the new silk trade. In 1311 it was destroyed by the Catalans and passed out of history.

The most famous monument of ancient Thebes was the outer wall with its seven gates, which even as late as the 6th century B.C. was probably the largest of artificial Greek fortresses. Two of the springs have been identified with some probability—that of St. Theodore with the Oedipodeia, in which Oedipus is said to have purged himself from the pollution of homicide, and the Paraporti with the dragon-guarded fountain of Ares (see CADMUS). From the interest of the site in history and still more in literature, as the scene of so many dramas, the temptation to fix details has been specially strong. There are two main difficulties to contend with. The description of Pausanias was written at a time when the lower city was deserted, and only the temples and the gates left; and the references to Thebes in the Attic dramatists are, like those to Mycenae and Argos, of no topographical value.

THEBES (Θῆβαι), the Greek name of the ancient capital of Upper Egypt. It occurs in Homer (Il. ix. 381–4) where it has the epithet **ἑκατόμπυλος,** "hundred-gated," probably derived in the first place from the gateways of its endless temples, for Thebes was never a walled city with gates, though its vast temple enclosures in different quarters would form as many fortresses in case of siege or tumult. Its Egyptian name was Wesi (or Wis?), later Ne, "the city" (sometimes Ne-Amun, hence No-Amon in Nahum iii. 8). Ammon, Amen-Ra, or Amenrasonther ("Ammon-Ra king of the gods") was its deity, with his consort Mūt and their child Rhons. Mont also was a local deity and Hathor presided over the western cliffs of Thebes. In very ancient times the city lay on the east bank, the necropolis on the west. The chief nucleus of the ancient Wēsi was a town about the temple of Karnak: it probably reaches back to the prehistoric period. At Drah abu'l nagga, opposite to it, are tombs of its princes under the VIth Dynasty. The temple of Karnak is no doubt of immemorial antiquity. In it Senusret I. dedicated statues to his predecessors of the Vth Dynasty who had probably showed their devotion to Ammon in a substantial manner, and Cheops of the IVth Dynasty is named in it. After the end of the Old Kingdom Thebes grew from an obscure provincial town to be the seat of a strong line of princes who contended for supremacy with Heracleopolis and eventually triumphed in the XIth Dynasty. The most important monument of the Middle Kingdom now extant at Thebes is the funerary temple of Mentuhotep III at Deir el Bahri. The name Amenemhet, so common in the XIIth Dynasty, shows the importance of the Theban god at this time. It was, however, the early rulers of the XVIIIth Dynasty down to Tethmosis III. who developed Karnak, and on the west bank built the great funerary temple of Deir el Bahri and smaller temples as far south as Medinet Habu, and began the long series of royal tombs in the lonely Valley of the Kings far back in the desert. Amenophis III. continuing, transformed western Thebes monumentally: built three great temples in addition, that of Mont on the north of Karnak, the temple of Mut on the south and the temple of Ammon at Luxor, and connected the last two with the state temple of Karnak by avenues of sphinxes. The city and its monuments now covered an area about three miles square. After this Thebes experienced a serious set-back with the heresy of Ikhnaton, the son of Amenophis III. He moved his capital northward to Akhetaton (El Amarna) and strove to suppress the worship of Ammon, doing infinite damage to the monuments of Thebes by defacing his name and figure. After about twenty years, however, the reaction came, Thebes was again the capital, and a little later under Seti (Sethos) I. and Rameses II. of the XXth Dynasty it was raised to greater architectural magnificence than ever. These two kings built the great columnar hall of Karnak, added a large court with pylons to Luxor, and on the west bank built the funerary temple of Seti at Kurna, and the Ramesseum with its gigantic colossus, besides other edifices of which only traces remain. Under the XVIIIth and XIXth Dynasties Thebes was at the height of its greatness. Conquering Pharaohs brought home trains of prisoners and spoil, embassies came thither of strange people in every variety of costume and of every hue of skin, from Ethiopia, Puoni (Punt), Mesopotamia, Asia Minor, Libya, and the islands of the Mediterranean, bringing precious stones, rare animals, beautiful slaves, costly garments and vessels of gold and silver. The tombs of the XVIIIth Dynasty on the west bank and the sculptures in the temples reflect the brilliancy of these days, but with Rameses II. came the turning-point of its glories, and the efforts of all his successors combined could add little to the wonders of Thebes. The temple and tower of Rameses III. (XXth Dynasty) at Medinet Habu, his tomb in the Biban el Moluk, the temple of Khons (Rameses III. and later) and the court of Sheshonk I. (XXIInd Dynasty) at Karnak are the only great achievements.

The tide of prosperity was now flowing northward and such monumental energy as remained was expended more widely. For several centuries after the fall of the New Empire Thebes was but one of several alternating or contemporaneous capitals. Memphis, Tanis, Bubastis, Sais, Heracleopolis had at one time or another at least equal claims. The Ethiopian conquerors of Egypt made Thebes their Egyptian capital, but in 668 Assur-bani-pal sacked the city. Psammetichus did not neglect it, but Ptolemy I. gave a new capital to the upper country in the Greek foundation of Ptolemais, and thus struck a fresh blow at the prosperity of Thebes. For a short period in the reign of Epiphanes, when Upper Egypt was in rebellion against the Ptolemaic rule, Thebes was the capital of independent native dynasts. In a later rebellion, Thebes was captured after a three years' siege and severely punished by Lathyrus (Ptolemy X., Soter II.). In the reign of Augustus, having joined in the insurrection against the tax-gatherers, it was destroyed by Cornelius Gallus and became a collection of villages. Though its vast buildings have since served as quarries for mill-stones and for the lime-burner, Thebes still offers the greatest assemblage of monumental ruins in the world.

We will now briefly enumerate the principal groups of monuments. On the east bank at Karnak stand the great state temple of Amen-Ra with its obelisks of Hatshepsut and Tethmosis I. and the vast columnar hall of Rameses II.; the temple of Mūt and the well-preserved temple of Khons; the temple of Luxor and avenues of rams and sphinxes connecting all these. On the west bank, in front of the necropolis, on the edge of the desert or projecting into the cultivation, was a low row of temples: the northernmost, placed far in front of the others, is the well-preserved temple of Seti I. at Kurna; then follow the Ramesseum and Medinet Habu; and the foundations of many others can be traced. The temple of Amenophis III., to which the colossi of "Memnon" were attached, was again far forward of the line. The Ramesseum contains the remains of a stupendous seated colossus, in black granite, of its builder Rameses II., thrown on its face. When perfect it was probably 57 ft. high and weighed about 1,000 tons, surpassing the "Memnon" statues of Amenophis III. in size and weight. The temple of Rameses III. at Medinet Habu, sculptured with very interesting scenes from his Syrian, Libyan and other wars and from religious festivals, is remarkable also for the unique entrance-tower which probably formed part of the royal palace. Northward and far back in the foot-hills is the Ptolemaic temple of Deir el Medina, and beyond under the cliffs of Deir el Bahri the terrace temple of Queen Hatshepsut, the walls of which are adorned with scenes from her expedition to Puoni (Somaliland) in search of incense trees, and many other subjects. Far behind Medinet Habu are the Tombs of the Queens, where royal relatives of the XXth Dynasty are buried; and immediately behind the lofty cliffs of Deir el Bahri, but accessible only by a very circuitous route from Kurna, are the Tombs of the Kings (from Tethmosis I. onward to the end of the XXth Dynasty) in the Biban el Moluk and the Western Valley. Those of Seti I. and

Rameses III. are the most remarkable. These royal sepulchres are long galleries excavated in the rock with chambers at intervals: in one of the innermost chambers was laid the body in its sarcophagus. In the XXIst Dynasty, when tomb robberies were rife and most of their valuables had been stolen, the royal mummies were removed from place to place and at last deposited for safety in the tomb of Amenophis II. and in the burial-place of the priest-kings at Deir el Bahri. The finding of the two *cachettes* nearly intact was one of the greatest marvels of archaeological discovery. The systematic exploration of the Valley of the Tombs of the Kings was rewarded with results of the highest interest. The greatest as well as the most recent of these was the discovery in Oct. 1922 of the tomb of Tutankhamun (reigned 1360–1350 B.C.) with its magnificent equipment almost intact.

THECLA, ST., one of the most celebrated saints in the Greek Church (where she is commemorated on Sept. 24) and in the Latin Church (where her festival is Sept. 23). She is honoured with the title of "protomartyr." The centre of her cult was Seleucia, in Isauria. Her basilica, south of Seleucia, on the mountain, long a popular place of pilgrimage, is mentioned in the two books of St. Basil of Seleucia. According to her *Acta,* Thecla came under the personal teaching of the apostle Paul at Iconium. In spite of their highly fabulous character (Thecla escaped from burning, from wild beasts, bulls and serpents), which caused them to be more than once condemned by the Church, the *Acta* of Paul and Thecla, which date back to the 2nd century, are interesting monuments of ancient Christian literature.

THEGN or **THANE,** an Anglo-Saxon word meaning an attendant, servant, retainer or official. From the first, however, it had a military significance, and its usual Latin translation was *miles,* although *minister* was often used. The word is used only once in the laws before the time of Aethelstan (*c.* 895–940), but more frequently in the charters.

The thegn became a member of a territorial nobility, and the dignity of thegnhood was attainable by those who fulfilled certain conditions. In like manner a successful thegn might hope to become an earl. There were others who were thegns on account of their birth, and thus thegnhood was partly inherited and partly acquired. The thegn was inferior to the aethel, the member of a kingly family, but he was superior to the ceorl. The status of the thegn is shown by his wergild. Over a large part of England the amount of this was fixed at 1,200 shillings, or six times that of the ceorl. He was the twelfhynde man of the laws.

The increase in the number of thegns produced in time a subdivision of the order. There arose a class of king's thegns, corresponding to the earlier thegns, and a larger class of inferior thegns, some of them the thegns of bishops or of other thegns. **A** king's thegn was a person of great importance, the contemporary idea being shown by the Latin translation of the word as *comes.* He had certain special privileges. No one save the king had the right of jurisdiction over him, while by a law of Canute we learn that he paid a larger heriot than an ordinary thegn.

The 12 senior thegns of the hundred play a part, the nature of which is rather doubtful, in the development of the English system of justice. By a law of Aethelred they "seem to have acted as the judicial committee of the court for the purposes of accusation" (Holdsworth, *Hist.* Eng. ***Law,*** vol. i., 1921), and thus they have some connection with the grand jury of modern times.

The word thane was used in Scotland until the 15th century to describe an hereditary non-military tenant of the Crown.

THEILER, MAX (1899–), South African microbiologist, won the Nobel prize for medicine and physiology in 1951. He was born Jan. 30, 1899 in Pretoria, U. of S. Af., the son of Sir Arnold and Emma (Jegge) Theiler. He received his early education in South Africa and completed his medical training at St. Thomas' hospital, London, and the London School of Tropical Medicine in 1922. From 1922 to 1930 he worked in the department of tropical medicine at the Harvard Medical school in Boston. There he carried out important studies on amoebic dysentery, rat-bite fever and leptospira.

Shortly after the discovery by A. Stokes, J. H. Bauer and N. P. Hudson that yellow fever was caused by a virus transmissible to monkeys, Theiler made his first important contribution to the conquest of this disease by demonstrating that the common albino mouse was susceptible to the virus. In addition to facilitating the work on the natural history of yellow fever, Theiler's discovery led to the development of the first attenuated strain of this virus, which is still in use for human vaccination. In 1930 he joined the laboratories of the Rockefeller foundation in New York and together with E. Haagen, W. Lloyd, N. Ricci and H. Smith carried out further fundamental studies on the yellow fever virus which led to the development of the improved 17 D strain widely used for human immunization. He also discovered a natural virus disease of mice which closely simulates that of human poliomyelitis. (A. B. SN.)

THEISM, in the broadest sense, means belief in God. The word, however, is used generally with the implication that the belief is held in a conscious and rational manner, and hence Theism is usually applied only to a system of beliefs which has some claim to be regarded as a philosophy. According to the Oxford Dictionary the first occurrence of the word is in Cudworth's *Intellectual System of the Universe* (1678). The etymology of the word (θεός) would suggest that it might cover any conception of the universe which admitted the existence of Deity; but in practice Theism has come to mean a belief in one God, and the word is not easily distinguished from Monotheism, save that Theism has a more theoretical implication.

Theism as a philosophical and theological position may be distinguished from other theories. It is, of course, the direct antithesis to Atheism (*q.v.*), which, strictly speaking, is the denial that God exists. It is to be distinguished, again, from Agnosticism (*q.v.*), the view that there is no sufficient grdund for either an affirmative or negative answer to the question: Does God exist? and that the only rational attitude is absolute suspense of judgment. It should be observed, however, that there is a sense of the word Agnosticism which is not wholly incompatible with Theistic belief. The theory of Herbert Spencer, that we can know that an Ultimate Reality exists but can also know that that Reality is unknowable, is sometimes described as agnosticism. Herbert Spencer's theory, as it stands, is plainly absurd, because in order to know that the Ultimate Reality is unknowable we must know enough of the nature of the Unknowable to be justified in making this assertion about it. All reflective Theists would acknowledge, however, that there is an element of truth in the Agnostic position — the human mind is incapable of grasping completely the nature of the Divine, and though there is a genuine knowledge of God, for finite mind that knowledge must always be incomplete. It is customary to distinguish Theism from Deism (*q.v.*).

The Deists were writers on natural religion in the 18th century who shared the desire to set religion on a purely rational basis and tended, in a greater or less degree, to exclude the ideas of revelation and mystery, reducing Christianity to those truths which, it was alleged, could be attained by the unaided reason. Though some of these authors had pantheistic tendencies, the name Deism has been given to that type of theology which considers God and the world to be absolutely distinct from one another, thus conceiving the Deity as an external Creator and Governor. In the language of modern philosophy Deism is the view which emphasises the transcendence of God but denies His immanence. In contrast to Deism, Theism affirms the presence of God in the world, holding both immanence and transcendence. Pantheism (*q.v.*) presents a contrast to Theism of the opposite kind to that which we have found in Deism. Pantheistic systems, though widely different from one another in spirit and presentation, agree in making an identification between God and the Universe. It is sometimes said that Pantheism maintains divine immanence while eliminating from its creed every vestige of divine transcendeqce. This manner of expression, though open to criticism, has the merit of making clear the main difference between Pantheism and both Deism and Theism. Certain philosophical systems may be classified for this purpose under the head of Pantheism. Spinoza's philosophy of God as the Infinite Substance and some forms of Absolute Idealism, as for example, that represented in England by the late F. H. Bradley cannot be described as theistic in the narrow sense of that word and are, theologically considered, pantheistic in tendency. Dualism is to be regarded as another theory which, in some of its forms, has affinities with Theism but is in essence different. Properly, Dualism means a view of the world which attributes its existence to two different or possibly antagonistic principles both equally ultimate, whether those principles be conceived as two deities, as in some forms of Zoroastrianism, or God and matter as in Manichaeism. A modified Dualism enters into most Theistic theories, but no theory could be called fully Theistic which was satisfied with a final Dualism.

We may now proceed to state in a positive manner the general tenets of Theism. It must be remembered that pure Theism has never been a widely influential religious belief. In the historical religions Theism is mixed with other elements, or rather perhaps is the basis of them. Thus Christianity is a Theistic religion, but its distinctive characteristic is the doctrine of the Incarnation. In the same way, Mohammedanism is Theism modified by special beliefs about the revelation of Allah through Mohammed. The fundamental conception of Theism in all its developed forms is that of a Being who is at once the supreme Value and the Source of all finite existence. Theism has usually thought of the Supreme Being as in some sense personal, or at least as One with whom personal relations were possible. This Supreme Being, in Anselm's phrase, *id quo majus cogitari non potest,* is, in the Theistic view, neither identical with the Universe nor wholly aloof and separate from it. The relation of God as Cause with the world has been conceived in various ways, the most common being creation, which itself may be capable of more than one interpretation. The idea of emanation, however, has also been employed, as in the Neo-Platonic philosophy (chief exponent Plotinus, A.D. 204–270) which exercised a considerable influence upon Christian theology. The peculiarly Theistic doctrine of the relation of God with the world is often expressed by the phrase, "God is both transcendent and immanent."

ARGUMENTS FOR THEISM

Theism, being a reflective theory and not simply a religious faith, has sought to defend its position by rational arguments. Historically, three arguments have been supremely important and are sometimes known as the "traditional proofs." They are the Cosmological, the Teleological, and the Ontological arguments.

The first philosopher, at least in the West, to state an argument which he held to be demonstrative of the existence of God is Plato. The proof which he gives (in the *Laws* X.) is the starting point of the rational theology or "natural" theology which claims to establish the being of God on the ground of reason. The Laws is universally admitted to be the work of Plato's old age. In his earlier writings Plato had made use of the idea of God and indeed the conception was central in his thought. He had constantly protested against unworthy ideas of the divine and asserts both in the *Republic* and *Theaefetus* that God is perfectly good and cannot be the cause of evil. The proof in the *Laws* may be regarded as the fruit of long reflection on the problem and contains the germ of much subsequent development. The proof turns upon the existence of motion and change. Motions and changes may be divided into several classes, but there is one fundamental distinction, that between spontaneous and communicated motion. It can be shown that spontaneous motion must be prior to communicated motion, since if there is motion at all it cannot all be communicated. Now the soul is the source of spontaneous motion, as distinguished from matter which can only receive communicated motion. Hence the soul is prior to the body. The motions in the Universe which have no human origin must likewise be referred to a soul. We are thus led to the conception of a Soul of the world. But the motions of the Universe, and in particular of the heavenly bodies, are orderly and thus indicate that the World Soul is rational and good, the "mind which ordered the universe." In Plato's argument two of the "rational" proofs are joined—the Cosmological (from the existence of a universe in which motion exists to a Source of motion), and the Teleological (from the existence of order to the Divine Mind as its ground). It will be convenient to consider these arguments in their subsequent formulations separately.

The **Cosmological** Argument. — The philosophy of Aristotle is not, like that of Plato, profoundly religious in spirit, and the concept of God in Aristotle's thought has little religious significance, being mainly a metaphysical conclusion; but the formulation of the cosmological argument by Aristotle has been of primary importance for Christian philosophy. Like his master Plato, Aristotle rises to the thought of God from the fact of change and motion (κίνησις) which means for him much more than change of place. Motion is conceived by Aristotle as the passage from potentiality to actuality (δύναμις and ἐνεργεία). Every change which actually occurs is the realization of a potentiality which was hitherto latent. Associated with this conception is Aristotle's doctrine of "form" and "matter." Every concrete and finite existence is composed of matter and form and it is the latter which gives to it a specific nature. In "sublunary" existences the expression of form is always imperfect, the matter never being absorbed in the form completely. The motion and change of the world are therefore explained as the striving of the potential to become actual, of the forms to become fully realised. The universe which is in constant motion is not, however, self-explanatory; the change must have some source beyond itself. This source is God, who must be conceived as at once the First Mover and the Unmoved. There can be nothing higher than God, otherwise He himself would be moved towards that higher being. God must exist or there would be no movement. God is therefore pure form and pure actuality, in Him there is no "matter" and no potentiality. He is the realization of all form and of all potentiality. Thus God moves the world ὡς 'ερώμενον, as an object of desire; but it is an essential part of Aristotle's view that God does not desire or need the world. The world is not even known to Him as it exists in actuality. He contemplates the pure forms which are the content of His own intellect. The outcome of Aristotle's reflection is then a Deity who is completely transcendent and pure thought. All personal relations with the world, every trace of emotion and even moral goodness is excluded from his nature which is described as a thinking of thought (νόησις νοήσεως) (Aristotle, *Physics*, Bk. VIII., *Metaphysics*, Bk. XII.).

It is one of the curiosities of history that a theology so "intellectualist" should have profoundly influenced the thought of Christianity which is in spirit widely different from that of Aristotle. Yet the Aristotelian logic and metaphysics formed the basis of the great constructive systems of the middle ages, the scholastic theology, of which the greatest representative is St. Thomas Aquinas (1227–1274). The cosmological argument forms the basis of St. Thomas's rational theology. It was a fundamental conviction with him that the *preambula fidei,* the foundation truths of religion, were demonstrable by the human reason without the aid of Revelation. In his greatest, though unfinished work, the *Summa Theologica* (Pt. I., Quaest. ii., art. 3), he gives five proofs of the existence of God, of which four are versions of the cosmological argument. (1) The argument from *motion:* "Any thing which is moved is moved by some other thing . . . one thing moves another in so far as the former is in actualitv, for to move is nothing else than to draw anything from potentiality to actuality. But nothing can be brought from potentiality into actuality except by means of something which is already in actuality. . . . It is impossible that in the same respect and the same manner anything should be both moving and unmoved, or be self-moved." We cannot go on to infinity in the series of "movers" which are themselves moved, for in that case there would be no first source of movement and consequently no movement at all. We must then conclude that there is a first source of movement which is moved by nothing else—*i.e.,* God. (2) The argument from *Efficient* Causes: Experience shows that there is an order of efficient causes. Nothing can be the cause of itself, for that would imply that it was prior to itself. We cannot rest content with an indefinite series of causes and effects, because if there is no First Cause there can be no last effect. Hence we conclude that there is a First and Uncaused Cause—*i.e.,* God. (3) Argument from possible and necessary existence: Some existences are possible and not necessary, *i.e.,* they may exist or not exist, being generated and corrupted. But all existence cannot be of this nature, for unless there were necessary existence there would be no ground for possible existence. If there are necessary existences there must be an existence which is necessary in itself and does not derive the necessity of its existence from some other necessary existence. An indefinite regress is as impossible here as in the case of efficient causes. There must therefore be Something which is necessary per *se*—*i.e.,* God. (4) Argument from degree of quality or value: We find things more or less "good," "true" and "excellent." "More" or "less" is predicated according to degree of approach to a "greatest." There is therefore something which is most true, good and excellent—*i.e.,* God.

It should be observed that the first two forms of Aquinas' cosmological argument lead to the conception of a purely Transcendent Deity while the latter two suggest immanence.

The cosmological argument, very much in the form which was given to it by Aristotle and Aquinas, appears as a fundamental element in many philosophies. Mention must be made of Leibniz who supplemented it by laying down a new law of thought—the law of "sufficient reason"—according to which "for everything there must be a sufficient reason why it is so and not otherwise," thus making it clear that, for him, the basis of the cosmological argument was not empirical observation but a rational and self-evident principle—that of universal causation.

The objections to the traditional cosmological argument have been formulated by Hume and Kant. The former struck a blow at the simplest and most obvious version of the argument—that to a First Cause—by his sceptical analysis of the ideas of cause and necessary connection, though it should be noticed that he himself appears to have retained the conviction that the conception of a First Cause could not wholly be abandoned. In Hume's view, however, there is no universal principle of causation. The idea of necessary connection between phenomena is derived from habit breeding expectation, and the so-called "principle of causation" is due to nothing more than "the mind's propensity to feign," *i.e.,* it is a convenient fiction. Obviously this view, which was but the logical conclusion of the empirical movement in English philosophy, undermines the whole of our knowledge of the natural order and physical science, but it has also a direct bearing on the cosmological argument, for if causation is a principle on which we cannot rely when dealing with phenomena, we cannot use it to take us beyond phenomena to God. Kant attempted to save our knowledge of Nature from Hume's sceptical objections. He did so in a somewhat equivocal fashion. He held that the "categories" which the mind employs in synthesizing perception (cause, substance, etc.) are a *priori* in the sense that the mind does not derive them from experience but necessarily uses them in ordering experience—in short that Nature apart from Mind has no existence, but in some sense "Mind makes Nature." Kant is emphatic, however, in his limitation of this principle. The categories of the understanding are confined to dealing with phenomena. The use of such a category as causation to carry us beyond phenomena to a super-phenomenal Reality is an illegitimate—a "transcendent"—use. This is the real ground of Kant's objection; it is based upon his rigid limitation of the understanding to phenomena. Some special criticisms are also of permanent interest. Kant points out that the argument, in the only form which he discusses (that of efficient causation), does not, even if sound, lead to the conclusion that God exists, but only that a First Cause of some kind exists, and in order to attain the conception of God we need another argument—the Ontological. With reference to the alleged impossibility of conceiving an infinite series of causes, Kant remarks that the inconceivability attaches also to the idea of an uncaused cause, and there is therefore no reason why the mind should embrace one alternative rather than the other.

In spite of the objections to which the traditional form is open, the cosmological argument in a wider application has kept its power. In modern philosophy all those systems which employ the idea of an Absolute Reality arrive at the Absolute by some kind of cosmological argument. An important example of this is found in the Theistic philosophy of Hermann Lotze. The impossibility of rendering intelligible the fact of "transeunt" causation (*i.e.,* that change in one thing is the occasion of change in another thing), so long as we conceive the ultimate reality to consist of a collection of independent "reals" leads to the conception of an all embracing Absolute of which the particular things and their changes are modifications. Arguments of this type lead rather to an immanent Deity than to the transcendent God of Aristotle and Aquinas.

The cosmological argument has permanent value, though it has not the demonstrative force which was formerly attributed to it. It serves to substantiate the conclusion that "nature," whatever we may mean by that term, is not a self-explanatory system, and therefore to support the Theistic view as preferable on rational grounds to rival hypotheses. The form of the cosmological argument which begins with the apprehension of values, such as goodness and truth, has received little attention in the history of thought, but is one which has most positive weight for modern philosophy. Modern Theism would lay great stress on the contention that the existence of goodness, beauty and truth in finite experience compels us to postulate an absolute Goodness, Beauty and Truth.

The Teleological Argument.—This argument, sometimes called "the argument from design," is rightly described by Kant as the most impressive, the most easily comprehended of the traditional "proofs." Like the cosmological argument it is a posteriori in character, since it starts with the observed facts of adaptation to ends in the natural world. As we have seen, however, when referring to Plato, the teleological argument may be based upon the more general consideration of the order of the universe. The purposive character of the events of the world was a common topic of Stoic philosophers in connection with their doctrine of Providence. Here again we may turn to Thomas Aquinas for a succinct statement of the argument in its common form. It is the fifth proof of the existence of God given by that philosopher—the proof from the *gubernatio* of things. "Some things which have no power of knowing, such as natural bodies, work for ends, as is manifest from their constantly, or at least frequently, working in the same way for the attainment of that which is best. . . . Now such things as have no power of knowing do not tend towards an end unless they are directed by some being which has knowledge and intelligence." (Summa Theologica, Pt. I. Quaest. ii. art. 3.) It will be noticed that there are two elements in this argument (a) the observation of "working for ends"; (b) the inference from this to a directing Intelligence.

The evidence for working for ends or the adaptation to purposes on which stress is laid has varied; at times the main emphasis has been on general adaptation of the Universe to the existence and well-being of men or, more abstractly, to the production of values; at other times the argument has turned chiefly upon special instances of apparent design as, *e.g.,* the human eye. The latter type of reasoning was prominent among the rationalist Theologians of the 18th and 19th centuries. Paley's Natural Theology, with its famous analogy between the eye and a watch, is a familiar example of this kind of presentation.

Before proceeding to a discussion of the present position of the teleological argument it will be well to note the objections and limitations which arise on a consideration of the argument itself. These again have been clearly stated by Kant. It is obvious that the argument by itself is not sufficient to demonstrate the existence of God. Even if it be admitted that there are evidences of design, it does not follow that they are due to one Mind. The facts might be explained on the hypothesis of several intelligences. It is only when we have reached the conclusion on other grounds that the Source of Being is one, that the teleological argument may tend to show that Source to be intelligent. The argument again, tends to suggest an analogy with the carpenter or sculptor who makes the best of his material and thus to lead to the conception of God as the Architect of the Universe working upon alien material. It may be alleged further, that the argument is based upon purely subjective estimates, and implies an absurdly anthropocentric conception of the universe. It cannot be denied that the teleological conception has frequently been carried to ridiculous extremes, and attempts have been made to show that this is the "best of all possible worlds" in the sense that all its features minister to human convenience; but these extremes are no necessary part of the argument, and it may be observed that Kant himself, in the *Critique of Judgement,* allowed that the teleological judgment is necessary and inevitable in dealing with living beings and the appreciation of the beautiful.

A permanent difficulty for the teleological argument is the existence of evil, particularly of pain, waste, and the missing of apparent ends. If stress is laid on the "working towards ends" which are good, stress should equally be laid upon the working towards ends which to us appear to be bad. Additional weight has been given to this objection by the evolutionary theory of the origin of species through the struggle for existence and the survival of the fittest. The Darwinian theory of evolution seems to make death, defeat, and their concomitant pain, a necessary part of the evolutionary process. On these and other grounds it has been held, by Guyau, Bertrand Russell and many others, that there is neither beneficent nor maleficent purpose in the world, but that Nature is indifferent to the hopes, aspirations and needs of man. Some answer to these objections may be attempted. It is argued, for example, that the amount of pain in the lower orders of creation has been greatly exaggerated by the tendency to interpret the experience of the lower animals in terms of our own, and by the neglect of the consideration that the pains of anticipation are absent in sub-human creatures. Suffering in human beings again may be supposed to serve spiritual ends *(see* James Martineau, *A Study of Religion).* The most conclusive answer attempted to the problem of evil as an objection to a teleologically ordered universe is that of Leibniz, who maintained that this is the "best of all possible worlds." Any other world would have contained more evil and less good than the actually existing one. This view depends upon Leibniz's conception of the nature of possibility which, according to him, is determined, not by the arbitrary will of God, but by "eternal verities" which are absolutely valid for the Eternal Mind. Thus out of an infinite number of possible worlds the Creator chose that which included the greatest sum of good, and the evils in it exist as necessary conditions for the greater sum of good. This theory has been somewhat unfairly summed up by F. H. Bradley in the epigram, "The world is the best of all possible worlds, and everything in it is a necessary evil."

We may remark here that our view of the teleological argument will be profoundly affected by our view of the meaning of "good" and "value." If we are "hedonists," believing that good means pleasure and the absence of pain, the teleological argument will have little weight. The Universe is plainly not designed to afford the greatest possible degree of pleasurable feeling. If on the other hand, we conceive that value means the development of spiritual and moral persons the argument will appear in a different and more favourable light.

The rise of the evolutionary concept has had another and even more important effect on the teleological argument. The principle of the adaptation of species to their environment by survival of those best adapted has removed the favourite examples of teleology, such as the eye, from the sphere of directly created things and offered a "natural" explanation of their delicate adjustment. The Darwinian and post-Darwinian theories of biological evolution seemed to destroy the basis of the most popular argument for Theism. It was evident that if the argument was valid at all it needed complete restatement. Post-evolutionary exponents of the teleological argument have consequently laid stress, not on particular instances of apparent design, but on the general trend of evolution which, it is maintained, can only be explained by the hypothesis of Divine Providence. A subtle statement of this line of thought is to be found in Lord Balfour's writings, the *Foundations* of *Belief* and *Humanism and Theism,* in which he urges that, unless there is some intelligent guidance of evolution, the values of truth and beauty cannot be maintained.

The philosophical analysis of the idea of evolution in the present century has led many thinkers to abandon a purely mechanical conception of its method. The problem of newness and the development of values has engaged attention. M. Bergson has completely abandoned the mechanical view and substituted the idea of "creative evolution," new types of existence being in his theory the result of the effort of the *Élan Vital* to achieve freedom. Somewhat analogous is the conception of "emergent evolution" which was worked out by Professor S. Alexander and Professor C. Lloyd Morgan and adopted by several other English authorities. The "emergent" theory of evolution distinguishes between two types of effect, "resultants" which are the predictable outcome of previously existing conditions, and "emergents" which are specifically new and not completely predictable. New species, and in particular new types of being, such as life, consciousness and self-consciousness, would thus belong to the "emergent" type of effect. None of these writers would describe his view of evolution as definitely teleological, and Bergson is as much opposed to teleology as to mechanism; but it is obvious that such conceptions of evolution are leading in the direction of at least "immanent teleology"; and it may be argued that a purely immanent teleology is not by itself an intelligible conception. On the whole then, it may be said that the movement of thought is in favour of a restatement of the teleological argument.

The inherent tendency of the human mind to think in the teleological mode suggests that there is really an *a priori* element in the argument. The mind is irresistibly impelled to regard the Universe as rational, *i.e.,* as pervious to its categories and methods of thought. On this irresistible assumption or "act of faith" the whole structure of science is built. It is one further step in the same process to regard the Universe as rational in the fullest sense, *i.e.,* as a teleological system which exists for an end which we can accept as reason for its existence—the production of values or of good.

The Ontological Argument.—This is the only one among the traditional "proofs" which is explicitly a *priori.* It is the inference from the idea of God to the existence of God, and does not employ any data derived from observation. The argument, though adumbrated by S. Augustine, was first clearly presented by S. Anselm (1033–1109) in his work the *Proslogium.* Even the fool "who says in his heart, there is no God" has the idea of God, otherwise he would not be able to deny His existence. The idea of God is the idea of "that than which no greater can be conceived" *(id quo nihil majus cogitari potest).* Now this idea cannot be in the understanding alone, because if it were, it would not be the idea of that than which there can be nothing greater, for a Being who existed would be greater than a being who did not exist. (It should be noticed that *majus* does not mean simply magnitude but includes value.) In other words, the idea of the greatest conceivable implies the existence of that Greatest. The obvious objection to this line of reasoning was raised by Gaunilo during Anselm's lifetime in his *Liher pro Insipiente.* Gaunilo dissented from the passage from idea to existence, and adduced the famous illustration of the "perfect island," which he argued, on Anselm's principle, must exist. The essence of Anselm's reply to this objection is to draw a distinction between that which is the greatest conceivable absolutely and that which is the greatest only relatively as the member of a class. The idea of God is the idea of "that than which nothing greater can be conceived" absolutely, and to this idea alone the ontological argument applies.

The subsequent history of the ontological argument has been curious. It has been rejected by many considerable thinkers as a patent fallacy and by others regarded as the'foundation of constructive thought. Descartes. who is sometimes held to be the father of modern philosophy, adopted it in two forms as the corner stone of his system, the bridge by which he passed from universal doubt to confidence in the possibility of knowledge. Descartes places in the forefront the consideration of the possession by the mind of the idea of an infinite and perfect being, and the question how this idea can originate. I cannot derive it from myself, because I am certainly neither infinite nor perfect. The idea then implies a really existent infinite and perfect Being as its source. Descartes adds an important element to the argument by distinguishing between the positively infinite and the merely "indefinite." The latter is a negative idea implying simply the absence of limits, the former is concrete, and is the idea of God. Unless I were in possession of the positive idea of infinity and perfection I should not know myself to be finite and imperfect. Descartes also states the ontological argument very much in the form given to it by Anselm. Though in all other instances it is possible to distinguish between essence and existence and to conceive of a being as not existing, this is not possible in the single case of the idea of God. "The existence can no more be separated from the essence of God than the idea of a mountain from that of a valley. . . . It is not less impossible to conceive a God, that is, a being supremely perfect to whom existence is wanting, or who is devoid of a certain perfection than to conceive a mountain without a valley." *(Meditations* III. and *V.)* The ontological argument was also adopted by Leibniz, who made the addition to it that we need first to demonstrate that the idea of God is the idea of a possible existence.

The great flaw in the argument in its traditional form was clearly shown by Kant, who pointed out that it implies existence to be an attribute of the same nature as other attributes the absence of which would constitute imperfection, whereas this is not the case, since every concept we form is of a being as existing in some sense. Kant's illustration however, of the "hundred thalers," which are the same in properties in the imagination as in the pocket though not the same in usefulness, seems to miss the point even more obviously than Gaunilo's perfect island. The permanent value in the ontological argument has been emphasised by Hegel. It is the necessary attempt to bridge the gulf between thought and things, between concept and reality. In this sense it is really at the root of all thought. However we may express it, we are compelled to hold that what the mind necessarily thinks *qua* mind is real, that there is no impassable chasm between the *"ordo idearum"* and the *"ordo rerum."* All philosophies which distinguish between appearance and Reality on the ground that the irrational cannot be the real, rest upon something akin to the ontological argument. Probably it would be better to say, "upon an ontological assumption." The ontological argument is, in truth, an attempt to put into the form of a train of reasoning a postulate without which the mind is helpless. It may be questioned therefore whether the ontological argument or postulate leads us directly to the God of religious experience. It leads rather to the conception of an absolute or rationally coherent system of being.

Before leaving the famous "three proofs" a remark must be made on their value for modern Theism. Before Kant's drastic criticism they were taken to be demonstrative proofs of the existence of God at least by the rational theologians It is clear that as demonstrations they are unsafisfactory. This does not mean, however, that they are devoid of value. The post-Kantian Theist would, in most cases, adopt a different approach to his problem. The central question of constructive philosophy does not present itself to him in the form: given the idea of God as a belief, to find some rational proof of His existence. Rather the problem presents itself as analogous to the scientific problem: given the universe as disclosed in experience, to find the most reasonable account of it. Several hypotheses present themselves for consideration, among them Theism. The question before the mind of the philosopher, therefore, is to decide which of the possible hypotheses squares most adequately with the whole experience of the universe which is open to us. The Theist maintains that his hypothesis is the most rational in this sense. The traditional arguments, on this view, call attention to various aspects, of the universe which, when taken up into reflective thought, go to support the Theistic view. Thus in spite of their failure as demonstrative arguments they have great value as indicating lines of thought, suggested by experience, which tend to substantiate the Theistic theory. (For a fuller statement of this *see* W. R. Sorley, *Moral Values and the Idea of God,* and *W. R.* Matthews, *Studies in Christian Philosophy.)*

The change in the method of approach to which we have referred in the preceding paragraph is reflected in the type of argument on which modern Theism has laid greatest stress. Though not putting on one side the "rational" proofs, the main appeal in the philosophy of Theism has been to considerations drawn more directly from experience, and particularly from moral and religious experience.

The Moral Argument. — Kant is the historical turning-point in the philosophy of religion. His criticism of the Theistic proofs was not made in the interest of Atheism, and he was an agnostic only in the technical sense that he denied the possibility of arriving at a knowledge of God by the pure or speculative reason. Religion belongs to the sphere of moral faith, of the "practical reason." There are three postulates of the moral reason, God, Freedom and Immortality; these cannot indeed be proved in any scientific manner, but the consideration of the limits of theoretical knowledge leads us to see that the pure reason cannot disprove their validity. It remains neutral. We are therefore free to affirm the three ideas without which our moral experience of the authority of the moral law and the inexhaustible ideal of holiness could not be conceived as rational. This is Kant's fundamental position. The train of reasoning by which he seeks to establish the necessity of the postulate of God is less important, being complicated by his peculiar views of the nature of the moral experience. The argument turns on the alleged moral demand that the highest holiness should ultimately coincide with the highest happiness.

The moral argument has been presented in various forms by important writers of the 19th and 20th centuries. Theories of ethics naturally fall into two classes, (1) those which take the fundamental concept in morals to be duty and the moral law; (2) those which take the idea of the Good to be fundamental. From both of these standpoints Theistic conclusions have been defended. James Martineau in his *Types of Ethical Theory* and *A Study of Religion* adopts on the whole the first, T. H. Green's *Prolegomena to Ethics* and *W.* R. Sorley's *Moral Values and the Idea of God* are salient representatives of the second, while Dr. Hastings Rashdall's *Theory of Good and Evil* combines to some extent both points of view.

There are three elements in the moral consciousness on which stress is laid in Theistic arguments. (a) The authority which the conscience attributes to the moral ideal. This unique authority cannot, it is urged, be explained on any view which does not allow us to find the moral law in some way built into the structure of the world, grounded in Reality. Other possible accounts of the source of the sense of obligation really issue in an explaining away of the moral "ought," and hence in the consequence that the fully moral life is irrational. Further, it is urged, the Theistic view is the view which most clearly enables us to hold that the moral law is not simply imposed externally but is the expression of the deepest self and also that it is no mere individual product, but of universal validity. (b) The "objectivity" of the moral ideal. The conscience cannot be satisfied with the belief that the moral ideal is dependent upon opinion, whether of the individual or of groups. In spite of the obvious fact that moral ideas change, the moral life depends upon the conviction that the moral ideal itself is absolute. Though men's apprehension of it may grow, their apprehension does not create it. It may be argued that Theism gives us the most rational account of this aspect of the moral consciousness, since it suggests that the moral ideal may exist in the thought of God. (c) The content of the moral ideal, particularly when viewed in its social aspect. Though we know what we mean by progress, we cannot conceive any temporal condition which would be the final goal of social progress. Unless therefore we are prepared to allow that progress is towards an end which is inherently unattainable, we are led to the thought of an End which is beyond the temporal order Here again the theistic hypothesis appears to offer the most reasonable view, since it would hold that perfect communion with God and herein with all rational beings, is the nature of the highest Good. The central thought of the moral argument in all its forms is this: given man's moral experience at its highest we have the choice of regarding it as rational and significant, or of explaining it away as partially founded on a mistake with the probable consequence of weakening its effectiveness. If we choose to regard it as rational and significant Theism is the view of the world which will most adequately fulfil our demands.

The Argument from 'Values in General. — Strictly speaking the moral argument is a special case of the line of reasoning which sets out from the existence of values. The world manifests the character of having value, or of being the occasion of our apprehension of value. Truth, goodness and beauty are real in our experience. In every case however, we are led to the conception of an absolute value, a complete Truth, a perfect Good and Beauty. The very fact that we recognise degrets of truth, goodness and beauty, implies that we tacitly presuppose an absolute standard towards which the partial values which we enjoy are approximations. Nor again, can we suppose that in the end these values are opposed to one another, though in finite experience they may sometimes seem to conflict. On the contrary, the Ultimate values must form a Unity, or rather perhaps, be aspects or attributes of one Supreme Value, which is what we mean by God. This is the line of thought which carries on the Platonist tradition in Christian philosophy and is impressively stated by Dr. W. R. Inge in his *Philosophy* of *Plotinus* and other writings.

Religious Experience. — Among the ancient arguments for Theism should be enumerated the argument *e consensu Gentium*, from the agreement of the nations. The evidence to be derived from the fact that all men everywhere believed in the Divine was insisted on by the Stoics and has been held to show that the idea of God is "innate" in the human mind. Precisely in this form the reasoning is open to objection. Locke, in his polemic against "innate ideas" in general, pointed out that the argument collapsed when we asked, what idea of God is innate? for the conceptions of the divine held by savages differ profoundly from those of civilized nations. The study of Comparative Religions since the time of Locke has served to support in detail his contention; but on the other hand it has shown that religion is practically a universal phenomenon wherever the human race is found. A new and more profound approach to Theism, which has some affinity with the old argument *e consensu Gentium*, has been opened by this enlarged knowledge. It is now possible to study the religious experience of mankind as a whole. When this is done we can discern an upward movement of the experience and of the concepts of the Divine in which it finds expression. This upward movement does not take place over the whole field, but certain principles of development may be noticed which are fully exemplified only where the religious impulse has free course. The primitive ideas of animism and polydaemonism, give place to polytheism, which in turn is displaced by monotheism either in the form of pantheism or ethical monotheism. It is always open to the critic to dismiss the whole religious experience of humanity as based on illusion and mistake; but such a drastic rejection of a universal type of consciousness is hard to justify. If we base our knowledge of the Universe on experience, religious experience has a claim to be included. If further, we find that the religious experience tends to pass from obviously inadequate forms to forms which lend themselves to rational presentation, we shall be justified in regarding the later and higher as the nearest approximations so far to adequate discriminations of the Object with which all religious experience is concerned.

Parallel to this consideration of the general development of religious experience runs the evidence to be derived from a study of the great religious personalities. and particularly of the mystics. The mystical type of religious "genius" seems to enjoy an immediate contact with the Divine, and the statements made by such persons have some general agreement. Too much stress should not be laid on their testimony to the truth of Theism, since some of the evidence would support Pantheism rather than Theism, and there is a tendency among mystics to interpret their experience in terms of the religious imagery in which they have been brought up. The witness of the mystics to the supernatural is impressive, and they may be linked with the general argument from religious experience as salient instances of its power at every level. It is urged by several Christian writers that the definitely Theistic mysticism of the Christian mystics is a higher and more complete type of mysticism than any other. *(See*, for example, W. R. Inge, *Christian Mysticism,* E. Underhill, *Mysticism,* and *R.* Otto, *West Östliche Mystik.)*

In concluding this summary of grounds of Theistic belief we must remark again that few philosophical Theists would rest their case on a direc. demonstration or claim that they were in possession of an "apodeictic" argument; they would urge that the full force of the reasons in favour of Theism can only be appreciated when it is compared with other possible views of the Universe, and that several converging lines of thought form a cumulative argument which is difficult to resist.

SOME PROBLEMS OF THEISM

The Theistic view of the world is naturally impelled to articulate itself by considering the problems of the nature of God and His relations with the world. Some of the more important of these problems must now be briefly indicated.

Divine Personality. — Most Theists, if not all, would agree that God is, in some sense, personal, or at least not of a nature inferior to personality. The latter tenet seems to be implied in the Theistic hypothesis, for othenvise God could not be thought of as the Supreme Value. It is important however, to distinguish between the two propositions, "God is personal" and "God is a person." Though the second of these propositions has been held by many Theists, it is not an essential point. Orthodox Christianity cannot be cited on behalf of the belief that God is a person, for the doctrine of the Trinity would suggest that the Godhead is a Unity of Persons. No one, of course, would maintain that God is a person in precisely the same sense as human beings are persons, and in view of this some would prefer to speak of the Divine Nature as Supra-Personal, others, on the conlrary, as for example Lotze, would hold that God alone is the perfect person and that finite selves are "pale shadows" of His personality. No very vital principle is involved in this difference, so long as those who prefer the term "supra-personal" are clear that it is not a polite phrase ior "impersonal." Theistic religion is profoundly concerned to maintain that God is a being with whom personal relations are possible; if that be abandoned we shall be compelled to dismiss that religious experience, which Theists take to be the highest and most significant, as illusion. The main theoretical ground for accepting Divine Personality is the contention that personality is the highest type of existence known to us, the "bearer," the discerner, and the creator of values, and also that personal life is the most conspicuous instance of multiplicity in unity, it is, as Plotinus called it, a πλῆθος ἕν : the category of personality would appear, in its ideal form, to suggest an ultimate solution of the problem of the One and the Many. A difficulty has been raised concerning the attribution of personality to God on account of the alleged necessity of a "not-self" distinguishable from the self in all cases of self-consciousness. The discussion of this problem by Lotze in his *Microcosmus* (Bk. IX , Chap. IV.), remains the classical authority. It is noteworthy however, that this special difficulty does not press with such force upon the Trinitarian form of Theism. On any Theistic view it would appear that the created order must be in some sense a "not-self" with respect to God, since the identification of the created order with the Being of God would be Pantheism.

Divine Attributes. — The Theistic doctrine of God has usually included an account of the Divine Nature under the title of "attributes," but the error must be carefully guarded against of conceiving the Divine Nature as the sum of the Divine Attributes. They are rather different aspects from which the Divine Being may be viewed by us. The traditional division is into Metaphysical and Moral. The Scholastic Theology considered the Metaphysical Attributes to be those which refer to God as He is in

Himself and the Moral Attributes those which refer to Him in relation with the world. It may be questioned however, whether the human mind is capable of having knowledge of God of that absolute character suggested by this definition of the Metaphysical Attributes. If the division be retained it is perhaps better to say simply that by Metaphysical Attributes we mean those which have a primarily intellectual importance, such as Unity and Infinity, while by Moral we mean those which have a directly practical bearing, such as Righteousness and Love. The classification, however, is of doubtful value, since even the attributes which are most evidently "metaphysical" have profound religious results, and those which are "moral" have metaphysical import.

Reflection upon the Being of God has followed along two paths—the *via negativa,* and the *via eminentiae.* The first of these methods turns on the conception of God as the Infinite and works with a negative conception of infinity. God, being infinite, cannot be described by any predicates which would imply limitation. All positive assertions, however, imply such a limitation. It follows therefore that no positive quality can be affirmed of God, not even goodness or indeed even being, so that if we say that God is τὸ ὄν we must also say that He is equally τὸ μὴ ὄν. Clearly this method leads to a position which is hardly distinguishable from Agnosticism. The *via eminentiae* starts with the conception of God as the Ground and Source of all existence and with the postulate that the Ground must be adequate to the consequences. All positive qualities, therefore, which occur in created existence must be ascribed to God; but plainly not *"simpliciter";* they are, so to speak, raised to infinity. Knowledge is in God Omniscience, Will Omnipotence, Beauty perfect Loveliness. We must observe here that the via *eminentiae* really implies the view that evil is not positive being but privation or defect of being, a view which was held by Augustine and Aquinas; for if evil were a positive existence or quality of existence the argument of the *via eminentiae* would lead us to predicate evil of God.

The Divine Attributes have been the subject of much subtle and intricate speculation into which it is impossible to enter here. Brief remarks on two must be made, since they are of great importance in Theistic theory. Omniscience is the perfection of that quality of knowledge which is found imperfectly in some created beings. Evidently the Divine knowledge cannot suffer from the imperfections of human knowing. It is scarcely appropriate to imagine the Divine Intelligence engaged in "discursive" thought and pursuing trains of reasoning. The most adequate human knowledge is that described by Spinoza as *scientia intuitiva,* intuitive knowledge in which grounds and conclusion are apprehended in one intellectual act. Of this kind, it would seem, the Divine knowledge must be. We are brought here to the recognition of one aspect of the Divine Infinity and Eternity. Human knowing is a part of a temporal experience and therefore itself a temporal process. The Divine experience and knowledge cannot be temporal, or at least cannot be "in time." A recognition of this truth has important bearing on some of the puzzles of Christian and other Theologies connected with the Divine Foreknowledge. If the Divine Experience is not successive but simultaneous, the expression "foreknowledge" is evidently misleading and indicates that in presenting to ourselves the Divine Nature and Experience we are compelled to make use of inadequate concepts derived from our own experience, and hence to encounter problems which are insoluble because we have not the terms in which to state them accurately.

The same remarks apply to the attribute of Omnipotence in which we attempt to indicate the nature of the Divine Will. Clearly a supra-temporal will is beyond our powers of adequate conception This does not prove, as Spinoza held, that will is absent from God's experience, but it certainly shows that we cannot transfer ideas derived from our experience of finite acts of will directly to the Divine Will. The conception of Omnipotence gives rise to problems which are, in their nature, not completely soluble by human reason. Two possible meanings of the word have been suggested. It has been held, on the one hand, that omnipotence implies not only the power to do all that is possible but also that the determination of the possible is due to the will of God, so that the fundamental laws of thought and of morality are fiats of the Divine Will and not limitations upon it. On the other hand, it is held that the will of God is determined by the principles of reason and goodness which are inherent in His Nature and that omnipotence means the power to do all that is possible. Of these two views the latter is to be preferred, since the former asks us to conceive of the Divine Will as arbitrary and not in any intelligible sense either rational or good. Even so, however, it cannot be pretended that all difficulty has been removed from the conception of omnipotence, and we may perhaps be content to say, with Schleiermacher, that both omnipotence and omniscience are ways of expressing the fundamental conviction of Theism that all things ultimately depend upon God.

Creation and Self-limitation.—Theism does not identify God and the world. It maintains indeed that God is immanent in creation but also transcendent, and it holds therefore that there is a real distinction between God and the world. This distinction is expressed in the idea of Creation. Theism on the whole has preferred the idea of creation to that of emanation, which is the idea adopted by systems which lead to Pantheism. Emanation implies that the world proceeds from the Divine Being by a kind of necessary process, a common figure being that of the sun and its rays. Creation, on the other hand, emphasizes the factor of will and implies that the world exists as a result of an act of choice. Creation does not necessarily involve a belief that the world began at a definite moment of time or that the creative act of God is single; it is perfectly compatible with the belief in a continuous creation which would be in harmony with modem theories of evolution.

Any belief in creation, and indeed any belief in the reality of freedom, seems clearly to necessitate some limitation of the omnipotence and perhaps of the omniscience of God. At the same time, Theism cannot admit that any portion of existence is absolutely independent of God. To meet this dilemma the thought of a divine "self-limitation" has been employed. Admittedly this is a thought which cannot be articulated in any detail. We cannot know the conditions of such self-limitation. But the conception itself is required by the facts as they appear in religious and moral experience. We may urge that the idea is not really contradictory of omnipotence, for an omnipotence which could not limit itself would not be omnipotent. And there is no inherent difficulty in the moral attributes of God, for it may be argued that the development of free moral persons who can enter into communion with God is the ultimate purpose of creation, and that this end could not be attained apart from a limitation of the divine power which makes freedom possible and with it both moral good and moral disaster

A difference of opinion among Theists exists on the question whether creation is in any sense necessary to God. On this point traditional Christian theology and some modem idealistic interpretations of Christianity (*e.g.,* Hegel's) are at variance. Christian theology on the whole has laid down that the world is in no way necessary to God and that its creation does not add to His perfection or satisfaction. The opposite view, which emphasises the Divine immanence, holds that the world is as necessary to God as God to the world. A distinction should be made between the active and passive sense of "creation." Thus it might be conceived that creation is an essential attribute of God and at the same time that the present universe is not necessary to God, that to create is an eternal activity of God but no product of that activity is eternal. A theory of this kind would avoid the difficulties which arise when we attempt to conceive a beginning of creation. (On this point *see* further, *Studies in Christian Philosophy* by *W.* R. Matthews.)

A problem in Theistic philosophy closely connected with the foregoing is that of the place of suffering in the Divine Experience. Here again the weight of Christian thought is against the admission of anything which would seem to qualify the absolute self-sufficiency and perfection of the Divine Nature. Suffering arises through frustration and limitation, conditions which are hardly to be thocght of in connection with the Supreme Being Against this may be set some considerations arising from the problem of evil and the moral perfection which we believe God to possess. It would seem difficult to think of Divine Sympathy with suffering if suffering could not enter into the Divine Experience; and it would seem strange to ascribe moral perfection to God if self-sacrifice, which involves voluntary pain, were excluded. On these grounds many writers on Theism and Christian Theologians in the present century have argued that suffering must enter into the Divine Consciousness, and some have urged that this is really an essential element in the Christian view of the world. (For a survey of opinion on this subject see J. K. Mozley, The *Impassibility* of God.) It must be observed, however, that Theism could not admit that suffering is the dominant note of the Divine Experience. To do so would be to fall back upon the conception of a "God" so limited and struggling that He may be ultimately defeated. Our experience, however, offers us an analogy which throws light upon the problem. At the highest level of spiritual life a condition of "blessedness" has sometimes been attained which is far different from a condition of mere pleasure and absence of pain. Pain enters into it as an essential element, but the condition itself is not one of pain, rather it is one in which the self finds its truest satisfaction and which it would not exchange for any maximum of pleasant feeling. Of this kind, though in an infinitely higher degree, we may imagine the life of God to be.

THEISS: see TISA.

THELEPTE, an ancient Roman city in western Tunisia, 35 m. S.W. of Sufetula (Sbeitla), 2,650 ft. above sea-level. The ruins are extensive, but most of the buildings are almost entirely destroyed, and only their ground plan can be recognized. To the south-west are some massive remains of baths.

THEMIS. (1) An ancient goddess, often identified with Ge, said to have been the occupier of Delphi in days before Apollo (see ORACLES). She is the mother of Prometheus (*q.v.*). (2) A goddess of justice (cf. NEMESIS). In Homer θέμις is used both as a common noun (doom, decree; cf. GREEK LAW) and as a proper name; Themis is the servant or companion of Zeus, her chief function being to summon the assemblies of both gods and men (Odyssey, ii. 68). In the Hesiodic theogony, she is the daughter of Uranus and Ge, and according to Pindar the wife of Zeus, by whose side she sits, assisting him with her advice, which is even better than that of any of the gods. She is the mother of the Horae and of the Fates (*q.v.*). Her opposite is Hybris (ὕβρις), insolent encroachment upon the rights of others. The exact relation between (1) and (2), save that they have in common the idea of stability (Θέμις, root θε, place) is obscure. Orphic poetry makes her a daughter of Helios.

See R. Hirzel, *Themis, Dike,* und *Verwandtes* (1907).

THEMISTIUS (317–?390), named *euphrades* ("eloquent"), statesman, rhetorician and philosopher. who proclaimed himself a follower of Aristotle, but also drew freely upon Plato, holding that there is no real opposition between the two. He was born in Paphlagonia and educated in philosophy by his father Eugenius. He taught at Constantinople, where, apart from a short sojourn in Rome, he resided during the rest of his life. Though a pagan, he was admitted to the senate by Constantius in 355. He was prefect of Constantinople in 384 on the nomination of Theodosius. There are extant some paraphrases of the treatises of Aristotle, which belong to the earlier years of his life, and 34 orations. The former are valuable; but the orations in which he panegyrizes successive emperors, comparing them to Plato's "true philosopher." are servile. It is the practical application of Plato's doctrine that interests him; and for him the other branches of philosophy are subordinate to ethics.

THEMISTOCLES (c. 514–449 B.C.), Athenian soldier and statesman in some respects probably the ablest and most far-sighted whom Greece produced in the first half of the 5th century. He was the son of Neocles, an Athenian of no distinction and moderate means, his mother being a Carian or a Thracian Hence according to the Periclean law ἐξ ἀμφοῖν ἀστοῖν he would not have been a free Athenian at all (see PERICLES). Thucydides observes that, though he lacked the culture typical of the Periclean age, he displayed a marvellous power of analysing a complex situation together with a genius for rapid action. Plutarch similarly enlarges on his consuming ambition for power both personal and national, and the unscrupulous ability with which he pursued his ends. Of his early years little is known. He may have been strategus of his tribe at Marathon.

At all events the death of Miltiades left the stage to Aristeides and Themistocles. It is sufficiently clear that their rivalry turned largely on the fact that Themistocles was the advocate of a policy of naval expansion. This policy was unquestionably of the highest importance to Athens and indeed to Greece. Athens was faced by the equal if not superior power of Aegina, while the danger of a renewed Persian invasion loomed large. Themistocles persuaded his countrymen to put in hand the building of 200 triremes, and to fortify the three natural harbours of Peiraeeus (see E. Gardner, Ancient Athens, 562 f.) in place of the open roadstead of Phalerum. For the building of the ships Themistocles persuaded the Athenians to allocate 100 talents obtained from the new silver mines at Laureium (*Ath.* Pol. 22) which were about to be distributed to the citizens (10 drachmae each). One hundred of the proposed 200 mere built.

He may or may not have been archon in 483, according to the Ath. *Pol.,* when this programme began. Dionysius of Halicarnassus places his archonship in 493–92, in favour of which are several considerations. In 487 the office lost much of its importance owing to the substitution of the lot for the election; the chance that the lot would at the particular crisis of 483 fall on Themistocles was obviously remote. In any case, the chief men of the other side disappear one by one — culminating in the ostracism of Aristeides in 482, and the year prior to the invasion of Xerxes found Themistocles the chief man in Athens if not in Greece. Though the Greek fleet was nominally under the control of the Spartan Eurybiades, it was Themistocles who forced the indecisive battle of Artemisium, and by his threat that he would lead the Athenian army to found a new home in the West, and by his treacherous message to Xerxes, precipitated the engagement at Salamis (see P. W. Dodd in Class *Rev.* 27, p. 117). The retirement of the Persians left the Athenians free to restore their ruined city (see ATHENS). Sparta opposed the rebuilding of the walls, but Themistocles by a subterfuge got the walls built high enough to be defensible. He also carried out his original plan of making Peiraeeus a harbour and fortress for Athens. Athens thus became the finest trade centre in Greece, and this fact, coupled with Themistocles' remission of the alien's tax (μετοίκιον) induced many foreign business men to settle in Athens.

After the crisis of the Persian invasion Themistocles and Aristeides appear to have composed their differences. But Themistocles soon began to lose the confidence of the people, partly owing to his boastfulness (it is said that he built near his own house a sanctuary to Artemis Aristoboulē "of good counsel") and partly to his alleged readiness to take bribes. Diodorus (xi. 54) and Plutarch (Themist. 23) both refer to some accusation levelled against him. There is, however, much difficulty regarding this accusation; it may be simply a misunderstanding of his ostracism. Some time between 476 and 471 he was ostracized. He took refuge eventually in Asia Minor, and was proclaimed a traitor in Athens. He was well received by the Persians and was allowed to settle in Magnesia on the Maeander. He died at Magnesia at the age of 65, and a splendid memorial was raised by the people of the town, though it is said that his bones were secretly transferred to Attica. He was worshipped by the Magnesians as a god, as we find from a coin on which he is shown with a patera in his hand and a slain bull at his feet (hence perhaps the legend that he died from drinking bull's blood: cf. Aristoph. *eq.* 83;

Diod. xi. 58; Plut. *Them.* 31).

Though his end was discreditable, though his great wealth can hardly have been obtained by loyal public service, there is no doubt that his services to Athens and to Greece were great. He created the Athenian fleet and with it the possibility of the Delian League (*q.v.*) which became the Athenian empire, and there are many indications (*e.g.,* his well-attested plan of expansion in the west) that the later imperialist ideal originated in his fertile brain.

THÉNARD, LOUIS JACQUES (1777–1857), French chemist, author of a standard textbook on elementary chemistry and discoverer of hydrogen peroxide, was born on May 4, 1777, at La Louptière, Aube. the son of a poor peasant, who made great sacrifices for his son's education. He worked in a humble capacity in the laboratory of Louis N. Vauquelin, who procured for him various teaching posts. In 1802 when Vauquelin left the College de France, he used his influence to secure Thénard's succession to the chair of chemistry. Later, ThCnard held the chair of chemistry at the École Polytechnique and at the Sorbonne. Made a baron by Charles X in 1825, he was a peer of France (1832), deputy for Yonne (1827–30), chancellor of the university and a member of the council of education.

Thénard died in Paris on June 21, 1857, and the name of his native village was changed (1865) to Louptière-Thénard in his honour.

ThCnard was a great teacher, and his *Traité élémentaire de chimie théorique et pratique* (4 vol., 1813–16) did more, perhaps, than even his many important original discoveries to advance the cause of science. With his lifelong friend, J. L. Gay-Lussac (*q.v.*), he carried out many researches. His researches on esters (1807), sebacic acid (1802) and on bile (1807), his discovery of peroxide of hydrogen (1818) and his work on organic phosphorus compounds (1846) deserve mention. The substance known as ThCnard's blue he prepared in 1799 in response to a peremptory demand by J. A. Chaptal for a cheap colouring matter, as bright as ultramarine and capable of standing the heat of the porcelain furnace.

A list of Thénard's memoirs may be found in the Royal Society's *Catalogue of Scientific Papers.*

THEOBALD (d. 1161), archbishop of Canterbury, was of Norman parentage, but the date of his birth is unknown. Early in life he entered the abbey of Bec, of which he became prior in 1127 and abbot ten years later. In 1138 he was elected to the see of Canterbury, and as archbishop he behaved with a moderation which is in striking contrast to the conduct of his rival, Henry of Blois, bishop of Winchester. During the struggle between Stephen and Matilda it was Bishop Henry who fought for the privileges of the Church; Theobald, while showing a preference for Stephen's title, made it his rule to support the *de facto* sovereign. But as Stephen's cause gained ground the archbishop showed greater independence. He refused to consecrate the king's nephew to the see of York, and in 1148 attended the papal council of Reims in defiance of a royal prohibition. This quarrel was ended by the intercession of the queen, Matilda of Boulogne, but another, of a more serious character, was provoked by Theobald's refusal to crown Count Eustace, the eldest son of Stephen, the archbishop pleading the pope's orders as the excuse for this contumacy. In 1153 Theobald succeeded in reconciling Stephen with Henry of Anjou, and in securing for the latter the succession to the throne. He placed the interests of the Church in the hands of Thomas Becket, his archdeacon. Theobald died on April 18, 1161.

In history Theobald lives chiefly as the patron of three eminent men: Becket, who began life as a clerk in his household; Master Vacarius, the Italian jurist. who was the first to teach Roman law in England; and John of Salisbury, the learned scholar. Theobald's household was a university in little; and in it were trained many leading prelates of the next generation.

THEOBALD, LEWIS (1688–1744), English man of letters, playwright and Shakespearian commentator, the son of an attorney. was born at Sittingbourne, Kent. He was baptized on April 2, 1688, and was educated for the law. He translated the *Phaedo* of Plato in 1713, in 1714–15 the plays of Sophocles and of Aristophanes, and in 1716 the first book of the *Odyssey.* Meanwhile he had got into trouble in 1716 on a charge of plagiarism in his play *The Perfidious Brother.* But Theobald is remembered neither as translator, nor as original author, but for his work on the text of the Shakespeare plays.

In 1726 he produced *Shakespeare Restored, or a Specimen of the many Errors as well Committed as Unamended by Mr. Pope in his late edition of this Poet; designed not only to correct the said Edition, but to restore the true Reading of Shakespeare in all the Editions ever published* (1726). Some of his happiest emendations are to be found in this work, which conclusively proved Pope's incompetence as a Shakespearian editor.

In 1731 Theobald undertook to edit Shakespeare for Tonson the publisher. The work appeared in seven volumes in 1734, and completely superseded Pope's edition. Subsequent editors reaped, in many cases without acknowledgment or with actual scorn, the fruit of Theobald's painstaking labour, his wide learning and his critical genius.

His correspondence with Matthew Concanen, Styan Thirlby and William Warburton is to be found in Nichols's *Illustrations of Literature* (ii. 204–654), which also gives the fullest account of his life. *See* also R. F Jones, *Lewis Theobald; his contribution to English Scholarship* (1919).

THEOBALD, SAMUEL (1846–1930), U.S. ophthalmologist, was born at Baltimore, Md., on Nov. 12, 1846. After receiving his medical degree from the University of Maryland in 1867, he specialized in ophthalmology and otology, studying in Vienna and at the Royal London Ophthalmic hospital, 1870–71. Returning to Baltimore in 1871, he helped found the Baltimore Eye and Ear dispensary in 1874 and in 1882, with a few colleagues, set up the Baltimore Eye, Ear and Throat Charity hospital. He was ophthalmic surgeon at Johns Hopkins hospital (1889–1925), clinical professor of ophthalmology and otology at the Johns Hopkins School of Medicine (1896–1912) and professor of ophthalmology at the same school (1912–25).

During his career he published more than 100 articles dealing with his specialty. Among them were descriptions of new instruments, surgical procedures, case reports, etc. He also prepared reports on the relationship between general diseases and diseases of the eye and on the prevention of blindness. Among the new techniques he developed were the use of boric acid in the eye and the use of electromagnets for removing metallic particles from the eye. He also pioneered in the use of cocaine as an anesthetic.

In addition to many articles, Theobald published *Prevalent Diseases of the Eye* (1906). He was president of the American Ophthalmological society (1910) and of the Medical and Chirurgical Faculty of Maryland (1900). He died at Baltimore on Dec. 20, 1930.

THEOCRITUS (*c.* 310–250 B.C.), Greek poet born in Syracuse, was the creator of pastoral poetry. His poems were termed idylls (*eidyllia*) by the grammarians. The word is a diminutive of *eidos* and may mean "little poems." Some, however, interpret it as meaning "forms"; *i.e.,* the bucolic, epic or lyric forms, and apply it to Theocritus' poems because they are of many different types.

There are no sure facts as to Theocritus' life beyond those supplied by idylls xv, xvi, and xvii. One view is that after composing xvi and perhaps iv and v Theocritus left Sicily and joined the circle of Philetas in Cos, but soon found his way to Alexandria. Later, on this view, he left Egypt and went either to Cos again or to some other place; *e.g.,* Rhodes, in the eastern Aegean. Idyll vii was almost certainly written in Cos, but probably after the visit to Egypt. The rest of the poems, except xv and xvii, which were no doubt composed in Egypt, may belong to either of the visits to Cos or to that to Alexandria.

The writings of Theocritus must be handled with caution as some of the poems commonly attributed to him have little claim to authenticity. It is possible that at an early date two collections were made, one of which included a number of doubtful poems and formed a corpus of bucolic poetry, while the other was confined to those works which were considered to be by Theocritus himself. The record of these recensions is perhaps preserved by two epigrams in the Palatine anthology, one of which (9:205) proceeds from Artemidorus, the grammarian, who lived in the time of Sulla and is thought by some to have been the first editor of the bucolic poets. He says "Bucolic muses, once were ye scattered, but now one byre, one herd is yours." The second epigram (Anth. *Pal.* 9:434) is anonymous, and is translated as follows: "The Chian is another. I, Theocritus, who wrote these songs, am one of the many Syracusans, the son of Praxagoras and famed Philinna. I never sought after a strange muse." The last line may mean he wrote nothing but bucolic poems, or that he wrote only in Doric. The statement that he was a Syracusan is confirmed by allusions in the idylls.

The *Suda* lexicon states that besides the bucolic poems some persons also attribute to Theocritus the following: Daughters *of* Proetus, Hopes, Hymns, Heroines, Dirges, Lyrics, Elegies, Iambics, *Epigrams.* Except for the Hymns, Lyrics and Epigrams these works are lost.

Authentic Poems.—The poems which are generally held to be authentic comprise bucolics and mimes, epics, lyrics and epigrams.

Bucolics and Mimes.—The distinction between these is that the scenes of the former are laid in the country and those of the latter in a town. The most famous of the bucolics are i, vii, xi and vi. In i Thyrsis sings to a goatherd how Daphnis, the mythical herdsman, having defied the power of Aphrodite, dies rather than yield to a passion with which the goddess had inspired him. In xi Polyphemus is depicted as in love with the sea nymph Galatea and finding solace in song; in vi he is cured of his passion and naïvely relates how he repulses the overtures now made to him by Galatea. The monster of the Odyssey has been "written up to date" after the Alexandrian manner and has become a gentle simpleton. Idyll vii, the Harvest Home, is the most important of the bucolic poems. The scene is laid in the isle of Cos. The poet speaks in the first person and is styled Simichidas by his friends. Other poets are possibly introduced under feigned names, but the only certain identification is that of Sicelidas (line 40) as Asclepiades of Samos. Theocritus declares that he is not yet superior to the latter nor to Philetas of Cos, said to have been his teacher, but boasts that his lays have been brought by report even unto the throne of Zeus, meaning apparently that they have secured the approval of Ptolemy Philadelphus. In lines 47–48 he criticizes "the fledgelings of the Muses, who cackle against the Chian bard and find their labour lost," thus taking the side of Callimachus in his controversy with Apollonius Rhodius over the merits of epic poetry.

The other bucolic poems are less interesting. Several consist of a singing match, conducted according to the rules of amoebaean poetry, in which the second singer takes the subject chosen by the first and contributes a variation in the same air. The peasants of Theocritus differ greatly in refinement. Those in v are low fellows who indulge in coarse abuse. This idyll and iv are laid in the neighbourhood of Croton in southern Italy, and it seems that Theocritus was personally acquainted with Magna Graecia. Suspicion has been cast on viii and ix for various reasons. It is clear that they were in Virgil's Theocritus and that they passed the scrutiny of the editor who formed the short collection of Theocritean Bucolics. Nevertheless, ix at any rate is not by Theocritus.

The mimes are three in number, viz., ii, xiv, xv. In ii Simaetha, deserted by Delphis, tells the story of her love to the moon; in xiv Aeschines narrates his quarrel with his sweetheart, and is advised to go to Egypt and enlist in the army of Philadelphus; in xv Gorgo and Praxinoa go to the festival of Adonis at Alexandria. These three mimes are wonderfully natural and lifelike.

It is convenient to add to the bucolics and mimes three poems which cannot be brought into any other class: xii, a poem to a beautiful youth; xviii, the marriage song of Helen; and xxvi, the murder of Pentheus. The genuineness of the last has been attacked on account of certain crudities, but the evidence of the manuscripts and papyri is in favour of the poem. Eustathius quotes from it as the work of Theocritus.

Epics.—Two of these are encomia. In xvi the poet praises Hiero II of Syracuse, in xvii Ptolemy Philadelphus. Two are hymns, xxii to the Dioscuri and xxiv to Heracles; xiii is an epyllion, or short epic, the story of Hylas and the nymphs. It cannot be said that Theocritus exhibits signal merit in his epics. In xiii he shows some skill in word painting, in xvi a passage at the end, where he foretells the joys of peace after the enemy has been driven out of Sicily, has the true bucolic ring. The most that can be said of xxii and xxiv is that they are very dramatic. Three poems in this group can be dated, though only approximately. In xvii Theocritus celebrates the marriage of Ptolemy Philadelphus with his sister Arsinoe. This marriage is held to have taken place in 277 B.C., and Arsinoe died in June 270. This poem, therefore, together with xv, which mentions (lines 23–24) the queen as alive, must fall within this period. So probably does a lost poem called Berenice.

The encomium of Hiero seems prior to that of Philadelphus, since in it Theocritus is a hungry poet seeking for a patron, while in the other he is well satisfied with the world. Hiero first came to the front in 276–275 B.C., when he was made "general"; Theocritus speaks of his achievements as still to come (line 73), and the silence of the poet would show that Hiero's marriage to Philistis, his victory over the Mamertines at the Longanus river and his election as "king," events which are ascribed to 270–269 B.C., had not yet taken place.

Lyrics.—These number four, xxviii–xxxi. The first is a very graceful poem presented together with a distaff to. Theugenis, wife of Nicias, a doctor of Miletus, on the occasion of a voyage thither undertaken by the poet. The three other lyrics are all pederastic.

Epigrams.—These, numbering 24, are without special merit, and their authenticity is often doubtful.

Doubtful Poems.—There remain the poems which are generally considered spurious. They are as follows: xix, Love Stealing Honey, which is anonymous in the manuscripts and has a conception of love that is not Theocritean.

Of the next group—xx, The Herdsman, xxi, The Fishermen, xxiii, *The* Lover—only xxi possesses any merit. A more interesting poem is xxv, Heracles the Lion-Slayer. This is a long poem consisting of three episodes, the interview of Heracles with Augeas' bailiff, the review of the king's cattle and Heracles' recital to Phyleus, the son of Augeas, of the story of the Nemean lion. The composition is not unworthy of Theocritus. The Wooing, xxvii, contains imitations of Theocritus, but the tone and the language betray a later writer.

Language and Metre.—Theocritus wrote in various dialects according to the subject. The lyrics are in Aeolic, that being the traditional dialect for such poems. xii and xxii were written in Ionic, as is stated in titles prefixed to them, but a number of Doric forms have been inserted by the scribes. The epics in general show a mixture of Homeric, Ionic and Doric forms. The bucolics, mimes and the marriage song of Helen are in Doric, with occasional forms from other dialects.

The metre used by Theocritus in the bucolics and mimes, as well as in the epics, is the dactylic hexameter. A feature in his verse which has attracted much attention is the so-called bucolic caesura. The rule is that, if there is a pause at the end of the fourth foot, this foot must be a dactyl. This pause is common in Homer, but Theocritus uses it so frequently in the bucolics that it has become a mannerism. In the epics his practice agrees with that of Homer.

Like all the Alexandrians Theocritus had no scruples about borrowing with a variation from earlier Greek writers. Homeric phrases, adapted to a new setting, crop up everywhere in his verse, but he was no slavish imitator, and despite the scholiast it seems very improbable that in ii and xv he owed any considerable debt to Sophron, the Sicilian writer of mimes. The latter idyll has resemblances to the fourth mime of Herodas, but which preceded the other it is impossible to determine.

Theocritus' Place in Poetry.—Like his contemporary Callimachus, Theocritus was an accomplished literary artist and modern scholarship has thrown much light on the details of his craftsmanship, but, whereas the poems of Callimachus (admittedly most survive only in fragments) must remain "caviare to the general," Theocritus makes a universal appeal to the modern reader for the reason that his bucolics and mimes, however elegantly and at times eruditely expressed, reflect human nature, which Callimachus' poetry never does. This truth needs no demonstration as regards the mimes. Cynisca and her lover (in xiv) and Gorgo and Praxinoa (in xv) are manifestly real; so too, on a higher level of art, is Simaetha (in ii), as she recounts her betrayal.

The bucolics, however, have sometimes been criticized as attributing to peasants sentiments and language beyond their capacity. There is something in the criticism, but comparison with modern Greek folk songs, which owe little to literary influences, reveals many striking resemblances between them and Theocritus' bucolics and there can be little doubt that both derive from real life. That life, set in a Mediterranean scenery of flowers, sun, sea and mountainside and described by a master of style, will never lose its charm.

THEODECTES (*c.* 380–340 B.C.), Greek rhetorician and tragic poet, of Phaselis in Lycia, pupil of Isocrates and Plato, and an intimate friend of Aristotle. He at first wrote speeches for the law courts, but subsequently composed tragedies with success. He spent most of his life at Athens, and was buried on the sacred road to Eleusis. The inhabitants of Phaselis honoured him with a statue, which was decorated with garlands by Alexander the Great on his way to the east. In the contests arranged by Artemisia, queen of Caria, at the funeral of Mausolus, Theodectes gained the prize with his tragedy *Mausolus* (extant in the 2nd century A.D.), but was defeated by Theopompus in oratory. According to the inscription on his tomb, he was eight times victorious in 13 dramatic contests. Of his tragedies (50 in number) 13 titles and some fragments remain. His treatise on the art of rhetoric (according to the *Suda* written in verse) and his speeches are lost. The names of two of the latter—*Socrates* and *Nomos* (referring to a law proposed by Theodectes for the reform of the mercenary service)—are preserved by Aristotle in his *Rhetoric.*

The *Theodectea* was probably not by Theodectes, but an earlier work of Aristotle, which was superseded by the extant *Rhetorica.*

THEODOLITE, a surveying instrument consisting of two graduated circles placed at right angles to each other, for the measurement of horizontal and vertical angles, a telescope, which turns on axes mounted centrically to the circles, and an alidade for each circle, which carries two or more verniers. The whole is supported by a pedestal resting on footscrews, which are also employed to level the instrument.

Theodolites are designed to measure horizontal angles with greater accuracy than vertical, because it is on the former that the most important work of a survey depends; measures of vertical angles are liable to be much impaired by atmospheric refraction, more particularly on long lines, so that when heights have to be determined with much accuracy the theodolite must be discarded for a levelling instrument. When truly adjusted the theodolite measures the horizontal angle between any two objects, however much they may differ in altitude, as the pole star and any terrestrial object. The instrument is made in many forms and modern surveying has introduced a great degree of accuracy. For the uses of the theodolite and other details *see* SURVEYING. The name has been a puzzle to etymologists. Various ingenious explanations have been given, all based on the apparent Greek form of the word; thus it has been derived from *θεᾶσθαι,* to see, *ὁδός,* way, and *λιτός,* smooth, plain; from *θεῖν,* to run, and *δολιχός,* long, and in other ways equally fanciful. Another imaginary origin has been suggested in a corruption of "the O deleted," *i.e.,* crossed out, the circle being crossed by diameters to show the degrees; others have found in it a corruption of "the alidade." It would appear, however, to be taken from the O. Fr. *theodolet* or *theodelet,* the name of a treatise by one Theodulus, probably a mathematician (see *Notes and Queries,* 3rd series, vii. 337, 428, etc. Skeat, *Etym. Dict.,* 1910).

THEODORA, the wife of the emperor Justinian (*see* JUSTINIAN I), was born probably in Constantinople, though according to some in Cyprus, in the early years of the 6th century, and died in 547. According to Procopius, our chief but by no means a trustworthy authority for her life, she was the daughter of Acacius, a bear-feeder of the amphitheatre at Constantinople, and while still a child appeared on the stage. Becoming a noted courtesan, she accompanied a certain Hecebolus to Pentapolis (in North Africa), of which he had been appointed governor, and, having quarrelled with him, betook herself first to Alexandria, and then back to Constantinople through the cities of Asia Minor. In Constantinople she attracted the notice of Justinian. He desired to marry her, but could not overcome the opposition of his aunt, the empress Euphemia. After her death (usually assigned to the year 523) the emperor yielded, and as a law forbade the marriage of senators with women who had followed the stage, this law was repealed. Thereupon Justinian married Theodora. They were some time after (527) admitted by Justin to a share in the sovereignty; and, on his death four months later, Justinian and Theodora became sole rulers of the Roman world. He was then about forty-four years of age, and she some twenty years younger. Procopius relates in his unpublished history (Ἀνέκδοτα) many repulsive tales regarding Theodora's early life, but his evident hatred of her, though she had been more than ten years dead when the *Anecdota* were written, and the extravagances which the book contains, oblige us to regard him as a very doubtful witness. James Bryce discovered in Rome what is believed to be the only ms. of this so-called life of Justinian; he considered it worthless as an authority.

Theodora speedily acquired unbounded influence over her husband. She had a right to interfere, for she was not merely his consort, but empress regnant. In the most terrible crisis of Justinian's reign, the great Nika insurrection of 532, her courage and firmness in refusing to fly when the rebels were attacking the palace saved her husband's crown, and no doubt strengthened her command over his mind. Officials took an oath of allegiance to her as well as to the emperor (*Nov.,* viii.). Procopius describes her as acting with the greatest cruelties. The city was full of her spies, who reported to her everything said against herself or the administration. She surrounded herself with ceremonious pomp, and required all who approached to abase themselves in a manner new even to that half-Oriental court. She constituted herself the protectress of faithless wives against outraged husbands, yet professed great zeal for the moral reformation of the city, enforcing severely the laws against vice, and immuring in a "house of repentance" on the Asiatic side of the Bosphorus five hundred courtesans whom she had swept out of the streets of the capital. How much of all this is true we have no means of determining, for it rests on the sole word of Procopius.

But there are slight indications in other writers that she had a reputation for severity.

In the religious strife which distracted the empire Theodora took part with the Monophysites. As Justinian was a warm upholder of the decrees of Chalcedon, this difference of the royal pair excited much remark and indeed much suspicion, and if it should be true that Theodora disapproved of Justinian's western conquests, her judgment must be acknowledged to have been correct.

In other matters also the wife spoke and acted very differently from the husband; but their differences do not seem to have disturbed either his affection or his confidence.

According to Procopius, Theodora had before her marriage become the mother of a son, who when grown up returned from Arabia, revealed himself to her, and forthwith disappeared forever; but this is a story to be received with distrust. That her behaviour as a wife was irreproachable may be gathered from the fact that Procopius mentions only one scandal affecting it, and that with some hesitation, the case of Areobindus. Her health was delicate, and, though she took all possible care of it, frequently quitting the capital for the seclusion of her villas on the Asiatic shore, she died comparatively young. Theodora was small in stature and rather pale, but with a graceful figure, beautiful features, and a piercing glance.

There remains in the apse of the famous church of S. Vitale at Ravenna a contemporaneous mosaic portrait of her, to which the artist, notwithstanding the stiffness of the material, has succeeded in giving some character.

Nearly all the evidence against Theodora is derived from the violently written *Anecdota* of Procopius, and has therefore been suspected. *(See* especially Débidour's *L'Impératrice The'odora.)* Modern researches, particularly those of Panchenko, the Russian scholar, have vindicated the general credibility of Procopius. Of course, he can frequently be convicted of unfairness; he always attributes the worst motives. His description of the profligacy of Theodora only proves his familiarity with the pornography of Constantinople. But it rests on the solid witness of John of Ephesus that Theodora's youth was disreputable. We gather too from other writers that she was harsh and tyrannical, as, for instance, from the references to her in the lives of the popes in the *Liber Pontificalis* (which used to pass under the name of Anastasius, the papal librarian). Her threat to the person whom she commanded to bring Vigilius to her was "nisi hoc feceris, per Viventem in saecula excoriari te faciam." Much of what we find in these lives is legendary, but they provide some evidence of Theodora's reputation. Again, (3) the statute (Cod., v, 4, 23) which repeals the older law so far as relates to *scenicae mulieres* is now generally attributed to Justin, and agrees with the statement of Procopius that an alteration of the law was made to legalize her marriage. There is therefore reason for holding that she was an actress. About the beauty, the intellectual gifts, and the imperious will of Theodora there can be no doubt. She was evidently an extraordinary person, born to shine in any station of life.

Her fortunes have employed many pens. Among the later serious works dealing with them may be mentioned M. Antonin Débidour's *L'Impératrice The'odora: Etude Critique* (1885), which endeavours to vindicate her from the aspersions of Procopius; and among more imaginative writings are Sir Henry Pottinger's interesting romance *Blue and Green* (1879), *M.* Rhangabé's tragedy Θεοδώρα (Leipzig, 1884), and M. Sardou's play *Théodora,* produced in Paris in 1884. *See* also F. Dahn's *Prokopios von Casarea* (1865) and *B.* Panchenko in "Vizant Vremennik" vol. ii, iii and, in addition, the works cited under JUSTINIAN I.

THEODORE, the name of two popes.

THEODORE I, pope from Nov. 642 to May 649, was a Greek, born in Jerusalem. Noted for his generosity to the poor, he had to devote most of his attention to the struggle against Monothelitism *(see* MONOTHELITES).

Theodore I refused to recognize the uncanonically installed patriarch of Constantinople, Paul. In 648 he excommunicated Paul's predecessor, Pyrrhus, who had relapsed into Monothelitism, and the next year he declared Paul's deposition for the same heresy.

THEODORE II, pope for 20 days in Dec. 897, recognized the validity of the acts of the deceased Pope Formosus (*q.v.*), whose outraged corpse he reburied. (A. G. Bi.)

THEODORE I (1557–1598), tsar of Russia, the son of Ivan the Terrible and Anastasia Romanova, nominally succeeded his father in 1584, but being of weak intellect was governed throughout his reign by the boyar, Boris Godunov, whose sister Irene he married in 1580. On his death-bed he is said to have left the throne to his consort, with the Patriarch Job, Boris Godunov, and Theodore Romanov, afterwards the Patriarch Philaret, as her chief counsellors. Irene, however, retired into a monastery and her brother Boris stepped into her place.

THEODORE II. (1589–1605), tsar of Russia, was the son of Tsar Boris Godunov and one of the daughters of Malyuta-Skuratov, the infamous favourite of Ivan the Terrible. Passionately beloved by his father, he received the best available education for those days, and from childhood was initiated into all the *minutiae* of government, besides sitting regularly in the council and receiving the foreign envoys. He seems to have been precociously intelligent, and the first map of Russia by a native, still preserved, is by his hand. On the sudden death of Boris he was proclaimed tsar (April 13, 1605). On July 10, he was murdered in his apartments in the Kreml.

THEODORE III. (1661–1682), tsar of Russia, was the eldest surviving son of Tsar Alexius and Maria Miloslavskaya. In 1676 he succeeded his father. He had received an excellent education at the hands of Simeon Polotsky, the most learned Slavonic monk of the day, knew Polish, and even possessed the unusual accomplishment of Latin; but, disfigured and half paralyzed by disease, he had been an invalid from his birth. In 1679 he married his first cousin Agatha and assumed the sceptre. His native energy was not crushed by his disabilities; and he soon proved as thorough a reformer as a man incompetent to lead armies and obliged to issue his orders from his litter, or his bed-chamber, could be. His consort, Agatha, shared his progressive views. On her death (July 4, 1681) Theodore married Martha Apraksina. He died on April 27, 1682, without issue.

THEODORE (602–690), seventh archbishop of Canterbury, was born at Tarsus in Cilicia in 602. On the death of Wighard, who had been sent to Pope Vitalian by Ecgberht of Kent and Oswio of Northumbria in 667, apparently for consecration as archbishop, Theodore, who had become prominent in the Eastern work of the church, was recommended by Hadrian of Niridanum to fill the vacant see. Vitalian consecrated Theodore in April 668 on condition that Hadrian, afterwards abbot of St. Peter's, Canterbury, should go with him. Hadrian was detained for some time by Ebroin, the Neustrian mayor of the palace, but Theodore reached England in May 669. According to Bede's account he made a tour of the whole of Anglo-Saxon England, reforming abuses and giving instruction as to the monastic rule and the canonical Easter. Bede also declares that he was the first archbishop to whom all the "church of the Angles" submitted.

In 673 Theodore presided at the first synod of the clergy in England which was held at Hertford. Various disciplinary regulations were emphasized, and an annual meeting arranged at a place called Cloveshoe. After this council Theodore revived the East Saxon bishopric, to which he appointed Earconwald. Soon after the first expulsion of Wilfrid in 678 he divided the Northumbrian diocese, appointing Trumwine bishop to the Picts. This led to a quarrel with Wilfrid which was not finally settled until 686–687. In 679 Theodore intervened to make peace between Ecgfrith of Northumbria and Aethelred of Mercia. He presided at other synods held in 680 at Hatfield and in 684 at Twyford, and died in 690. A penitential composed under Theodore's direction is still extant.

THEODORE LASCARIS (d. 1222), emperor of Nicaea, was born of a noble Byzantine family. He became the son-in-law of the Emperor Alexius III. and distinguished himself during the sieges of Constantinople by the Latins (1203–04). After the capture of the city he gathered a band of fugitives in Bithynia and established himself in the town of Nicaea. Relieved of the danger of invasion, owing to an incursion of Bulgarians into the Latin empire, he set to work to form a new Byzantine state in

Asia Minor, and in 1206 assumed the title of emperor. He defended himself stubbornly against the Latin emperor Henry, defeated his rival Alexius Comnenus of Trebizond, and carried out a successful counter-attack upon Gayath-ed-din, the sultan of Koniah. His crowning victory was gained in 1210, when in a battle near Pisidian Antioch he captured the deposed emperor Alexius III. and wrested the town itself from the Turks.

See A. Meliarakes,'*Ἱστορία τοῦ Βασιλέιου τῆς Νικάιας καὶ τοῦ Δεσποτάτου τῆς Ἠπέιρου* (Athens, 1898).

Theodore's grandson, THEODORE II. (Lascaris), emperor from 1254 to 1258, is chiefly noticeable for two brilliant campaigns by which he recovered Thrace from the Bulgarians (1255–56). His ill-health and early death prevented his making full use of his ability as a ruler.

THEODORE OF MOPSUESTIA (c. 350–428/9), early Christian theologian, the most eminent representative of the so-called school of Antioch, was born at Antioch about the middle of the 4th century and was a friend of John Chrysostom; in rhetoric the celebrated Libanius was his teacher. Soon, however, he attached himself to the school of the great exegete and ascetic, Diodorus, a presbyter in Antioch, and with only a transitory period of vacillation, from which he was won back by Chrysostom, he remained faithful to the theology and ascetic discipline of this master. Under Diodorus he became a skilful exegete, and ultimately outstripped his master in biblical learning. About 383 Theodore became a presbyter in Antioch, and began to write against Eunomius the Arian and against the christology of Apollinaris. Soon after 392 he became bishop of Mopsuestia in Cilicia (the modern Missis near Adana). As such he was held in great respect, and took part in several synods, with a reputation for orthodoxy that was never questioned. It was greatly to his advantage that in the Eastern Church the period between the years 390 and 428 was one of comparative repose. He was on friendly terms even with Cyril of Alexandria. He died in 428 or 429.

Theodore wrote commentaries on almost every book of the Old and New Testaments, of which, however, only a small proportion is now extant, as at a later period he lost credit in the church. We still possess in Greek his commentary on the Minor Prophets, in a Syriac version his commentary on St. John[1], and, in Latin translations, commentaries on the shorter Pauline epistles, besides very many fragments, especially on the epistle to the Romans. Theodore's importance as an exegete lies in two characteristics: (1) in opposition to the allegorical method he insists on getting at the literal meaning, and adheres to it when found; (2) in his interpretation of the Scriptures he takes into account the historical circumstances in which they were produced, and substitutes the historical-typological for the pneumatico-christological interpretation of prophecy; in other words, he interprets all Old Testament passages historically in the first instance, and sees the fulfilment of Old Testament prophecy in the history of Christ and His church only in so far as the entire Old Testament is a "shadow of things to come."

Theodore also was the author of a special dissertation against the allegorists, *i.e.,* against Origen and his followers, which, however, has unfortunately perished. The comparative freedom of Theodore's view of inspiration is also noteworthy. He discriminates between historical, prophetical and didactic writings, and in accordance with this distinction assumes varying degrees of inspiration. Finally, he entertained very bold opinions about the canon and several of the books included in it. He esteemed very lightly the Solomonic writings and the book of Job; Canticles he explained as a nuptial poem of Solomon's; the book of Job appeared to him in many places hardly worthy of its subject, and he censures the writer sharply; Chronicles, Ezra and Nehemiah he entirely rejected; he denied the accuracy of the titles of the Psalms, anticipated the hypothesis that many of them belong to the Maccabean age, and referred the so-called Messianic element almost invariably to the kings of Israel; he even criticized the Catholic epistles and rejected the epistle of James. Characteristics such as these bring Theodore, of all patristic writers, nearest to the modern spirit.

LITERATURE.—Migne, *Patrol.,* ser. Gr., lxvi. The Greek fragments of Theodore's New Testament commentaries have been collected by O. Fr. Fritzsche *(Theod. Mops. in N.T. Comm.,* Turin, 1847). The commentaries on the Pauline epistles (Pitra, *Spicilegium Sotesmense,* Paris, 1852, i. 49 *seq.)* have been edited by H. B. Swete *(Theod. Mops. in Epp. B. Pauli Comm.,* i., ii., Cambridge, 1880–82), along with the Greek fragments and the fragments of the dogmatical writings; on this edition, *see* E. Schiirer, *Theol. Lit. Ztg.,* 1880–82. The commentary on the Minor Prophets will be found in Mai's *Nov. Patr. Biblioth.,* vii. 1854 (Berlin, 1834; Mai, *Script. Vet. Nov. Coll.,* vi., 1832). *See* also E. Sachau, *Theod. Mops. Fragm. Lietzmann in *Sitzungsberichte der Kgl preuss. Akad. der Wissensch., zu Berlin,* 1902, pp. 334 *seq.* Extracts from the writings of Theodore occur in the *Catenae* of Marius Mercator, in the *Acta* of the third and fifth oecumenical councils in Facundus, Liberatus, and Theodore's chief adversary Leontius Byzantinus. E. von Dobschiitz, in *Amer. Journ. of Theol.,* ii. 353–387, published the Greek prologue of a commentary on *Acts* that is probably the work of Theodore.

The principal monograph on Theodore, apart from the prolegomena of Swete, and the same writer's article in *Dict. Christian Biog.,* iv. (1887), is that of H. Kihn *(Th. v. Mops. u. Junilius Afric. als Exegeten,* Freiburg, 1880). On his importance for the history of dogma *see* the works of Baur, Dorner, Harnack, Loofs and Seeberg. THEODORET, bishop of Cyrrhus, an important writer in the domains of exegesis, dogmatic theology, church history and ascetic theology, was born in Antioch, Syria, about 386. At an early age he entered the cloister; and in 423 he became bishop of Cyrrhus, a small city in a wild district between Antioch and the Euphrates, where, except for a short period of exile, he spent the remainder of his life. The date of his death is uncertain, but it must have been not earlier than 457.

Commentaries.—As an exegete Theodoret belongs to the Antiochene school, of which Diodorus of Tarsus and Theodore of Mopsuestia were the heads. He was not actually the personal disciple of either, but he adopted their methods, though without the consistency and boldness of the first-named. His extant commentaries (those on Canticles, on the Prophets, on the book of Psalms and on the Pauline epistles) are brief.

Dogmatic **Works.**—Theodoret's chief importance is as a dogmatic theologian, as the most considerable opponent of the views of Cyril and Dioscurus of Alexandria. For more than twenty years he maintained the struggle against the Alexandrian dogmatic and its formulae (*θεοτόκος, ἕνωσις καθ' ὑπόστασιν, μία ὑπόστασις ἕνωσις φυσική,* and the like), and taught that in the person of Christ we must strictly distinguish two natures (*hypostases*), which are united indeed in one person (prosopon), but are not amalgamated in essence. For these years his history coincides with that of the Eastern Church from 430 to 451, and for this very reason it is impossible to sketch it even briefly here. (See Hefele, *Conc.-gesch.,* vol. ii.) The issue was not unfavourable to Theodoret's cause, but melancholy enough for Theodoret himself: the council of Chalcedon condemned monophysitism, but he unhappily yielded to pressure so far as also to take part in pronouncing "anathema upon Nestorius, and upon all who call not the Holy Virgin Mother of God, and who divide the one Son into two."

Some of Theodoret's dogmatic works are no longer extant: of his five books On The *Incarnation,* for example, directed against Cyril after the council of Ephesus, we now possess fragments merely. A good deal of what passes under his name has been wrongly attributed to him. Certainly genuine are the refutation (*Ἀνατροπή*) of Cyril's twelve *ἀναθεματισμοί* of Nestorius, and The Mendicant, or *Πολύμορφος* (written about 446), consisting of three dialogues, entitled respectively Immutability, *Inconfusibility* and Apathy, in which the monophysitism of Cyril is opposed, and its Apollinarian character insisted on. Among the apologeticodogmatic works of Theodoret must be reckoned his ten discourses *On Providence.*

Other Works.—The 30 ascetic biographies of his *Religious History,* which has been widely read, form a pendant to the *Historia Lausiaca* of Palladius and the monkish tales of Sozomen. For the East it has had the same importance as the similar writings of Jerome, Sulpicius Severus and Cassian for the West.

BIBLIOGRAPHY.—The edition of Sirmond (Paris, 1642) was afterwards completed by Garnier (1684), who has also written dissertations on the author's works. Schulze and Nösselt published a new edition (6 vols., Halle, 1769–74) based on that of their predecessors; a glossary was afterwards added by Bauer. The reprint will be found in vols. lxxx.–lxxxiv. of Migne, and considerable portions occur in Mansi. The church history has been published frequently in connection with the histories of Socrates, Sazomen and others, *e.g.,* by Valesius (1693) and Reading (1720). There is an English translation of the history by Bloomfield Jackson in the *Nicene and Post-Nicene Fathers,* series ii., vol. iii.; the translation including also the dialogues and letters.

THEODORIC, king of the Ostrogoths (*c.* 454–526). Referring to the article GOTHS for a general statement of the position of this, the greatest ruler that the Gothic nation produced, we add here some details of a more personal kind. Theodoric was born about the year 454, and was the son of Theudemir, one of three brothers who reigned over the East Goths, at that time settled in Pannonia. The name of Theodoric's mother was Erelieva, and she is called the concubine of Theudemir. The Byzantine historians generally call him son of Walamir, apparently because the latter was the best known member of the royal fraternity. At the age of seven he was sent as a hostage to the court of Constantinople, and there spent ten years of his life. Soon after his return to his father he secretly attacked the king of the Sarmatians, and wrested from him the important city of Singidunum (Belgrade). Theodoric took the chief part in an expedition into Moesia and Macedonia, the result of which was to settle the Ostrogoths as *foederati* in the heart of the empire. About 474 Theudemir died, and for the fourteen following years Theodoric was chiefly engaged in a series of profitless wars, partly against the emperor Zeno, but partly against a rival Gothic chieftain, another Theodoric, son of Triarius. In 488 he set out, with the sanction of the emperor, to win Italy from Odoacer. The invasion and conquest of Italy occupied more than four years (488–493). Theodoric, who marched round the head of the Venetian Gulf, had to fight a fierce battle with the Gepidae, probably in the valley of the Save. At the Sontius (Isonzo) he found his passage barred by Odoacer, over whom he gained a complete victory (28th of August 489). A yet more decisive victory followed on the 30th September at Verona. Odoacer fled to Ravenna, and it sccmcd as if the conquest of Italy was complete. At length (26th of February 493) the long and severe blockade of Ravenna was ended by a capitulation, the terms of which Theodoric disgracefully violated by slaying Odaacer with his own hand (1jth of March 493). (*See* ODOACER.)

The thirty-three years' reign of Theodoric was a time of unexampled happiness for Italy. Unbroken peace reigned within her borders (with the exception of a trifling raid made by Byzantine corsairs in 508). The venality of the Roman officials and the turbulence of the Gothic nobles were sternly repressed. Marshes were drained, harbours formed, the burden of the taxes lightened, and the state of agriculture so much improved that Italy, from a corn-importing, became a corn-exporting country. Moreover Theodoric, though adhering to the Arian creed of his forefathers, was during the greater part of his reign conspicuously impartial in religious matters. At the time of the contested papal election between Symmachus and Laurentius (496–502), Theodoric's mediation was welcomed by both contending parties. At the close of his reign (524), the emperor Justin's persecution of the Arians led him into a policy of reprisals. He forced Pope John to undertake a mission to Constantinople to plead for toleration, and on his return threw him into prison, where he died. Above all, he sullied his fame by the execution of Boethius and Symmachus. (*See* BOETHIUS, ANECIUS MANLIUS SEVERINUS.) Theodoric's death, which is said to have been hastened by remorse for the execution of Symmachus, occurred Aug. 30, 526. He was buried in the mausoleum which is one of the marvels of Ravenna (*q.v.*), and his grandson Athalaric, a boy of ten years, succeeded him, under the regency of his mother Amalasuntha.

AUTHORITIES.—The most important source for Theodoric's life reign (ed. in *Monumenta Germaniae Historica,* vol. xii.) is the *Variae* (state-papers) of Cassiodorus, chief minister of Theodoric. The most modern work is Hartmann's *Geschichte Italiens im Mittelalter,* vol. i. (Stuttgart, 1923). The English reader may consult Gibbon's *Decline and Fall,* chap. xxxix., and Hodgkin's *Italy and her Invaders,* vol. iii. (1885), his introduction to *Letters of Cassiodorus* (1886) and *Theodoric the Goth* (London and New York, 1891).

THEODORUS STUDĪTA [Theodore of the Studion] (A.D. 759–826), abbot of the monastery of the Studion, Constantinople, succeeded his uncle Plato, as head of the monastery of Saccudium in Bithynia in 794. He was banished to Thessalonica in connection with the marriage of Constantine VI. After the emperor's death in 797 he was recalled and removed with his monks to the monastery of the Studion in Constantinople, where he carried on a vigorous campaign in favour of asceticism and monastic reform. In 809 he was again banished in consequence of his refusal to hold communion with the patriarch Nicephorus, who had pardoned the priest Joseph for his part in the marriage of Constantine and Theodotē. In 811 he was recalled by Michael Rhangabes, and again banished in 814 for his opposition to Leo the Iconoclast. He was liberated in 821 by the Emperor Michael the Stammerer (Balbus). In 824 he violently attacked Michael for iconoclasm and was forced to leave Constantinople. He lived at various monasteries until his death on Nov. 11, 826. He was buried at Chalcitis, but his body was afterwards (Jan. 26, 844) removed to the Studion. He subsequently received the honours of canonization. Of his extant works the following are the most important:—The three λόγοι ἀντιρρητικοί and other works in defence of images and his *Letters.* He was also the composer of hymns; many of which are still extant. Like all the monks of the Studion, Theodore was famous for his calligraphy and industry in copying mss.

THEODOSIA, formerly Kaffa, a seaport and watering-place of South Russia, on the east coast of the Crimea, in 45° 3′ N., 35° 22′ E., and on the railway. It has an excellent modern harbour, which is never frozen and has a floating crane lifting 40 to 50 tons. Pop. (1939) 28,200.

The ancient Theodosia, the native name of which was Ardabda, was a colony founded from Miletus. Archaic terra-cottas show it to have been inhabited in the 6th century B.C., but it is first heard of in history as resisting the attacks of Satyrus, ruler of the Cimmerian Bosporus, *c.* 390 B.C. His successor Leucon took it and made it a great port for shipping wheat to Greece, especially to Athens. This export of wheat continued until the days of Mithradates VI. of Pontus, against whom the city revolted. Later it became a special part of the Bosporan kingdom with its own governor. In the 3rd century A.D. it was still inhabited, but seems to have been deserted not long afterwards. Besides the terra-cottas and pottery, very beautiful Greek jewellery has been found near Theodosia. It coined silver and copper during the 5th and 4th centuries B.C. The name Kaffa (Genoese *Capha,* Turk. *Kefe)* is first mentioned in the 9th century. The Genoese established themselves on the site shortly after 1266, and the settlement flourished exceedingly, being the depôt of a trade route reaching to China. It became the head of the Genoese establishments in Gazaria, the see of a bishop, and the chief port on the northern shore of the Black sea, surpassing the Venetian Tana. When the Turks took Constantinople the colony was almost cut off from the mother city, which handed it over to the enterprising bank of St. George; but it could not be saved and fell in 1475 to the Turks, who sometimes called it Kuchuk-Stambul (Little Stambul) or Constantinople, or Krym-Stambul (Stambul of Crimea). In 1771 it was taken by the Russians, and in 1783 annexed by them, whereupon the greater part of its population deserted it.

THEODOSIUS, the name of three Roman emperors of the East.

THEODOSIUS I., "the Great," son of Theodosius, Valentinian's great general, who in 368–69 saved Britain from the Picts, and suppressed the revolt of Firmus in Mauretania (372). Shortly after (376), the elder Theodosius was put to death, perhaps by order of Valens. The younger Theodosius was born about the year 346. He was a native of Spain, but the exact place of his birth is uncertain. He accompanied his father into Britain (368), and a little later defeated the Sarmatians who had invaded Moesia (374). On his father's death he retired to his native place, where he lived quietly till after the great battle of Adrianople (Aug. 9, 378), when Gratian summoned him to share the empire. After gaining some fresh victories over the Sarmatians, Theodosius was made Augustus at Sirmium on Jan. 19, 379, and was assigned all the eastern provinces, including part of Illyricum. In 379 Theodosius, after reorganizing the army at Thessalonica, carried on a successful campaign of skirmishes along the Danube and induced numerous Gothic bands to give in their allegiance; his lieutenant Modares, a Gothic refugee, defeated the invaders severely in Thrace. In 381 he was called upon to meet two armies of invaders. He conducted in person the war against the Visigoths under Fritigern, this campaign, being only ended by Fritigern's death. The defence of the Danube against the Ostrogoths under Alatheus and Safrax was entrusted to the general Promotus, who severely defeated the enemy in an attempt to cross the river. Theodosius attained even greater successes by his diplomacy. He persuaded the fugitive Visigoth king Athanaric to enter his service, and enlisted 40,000 of his former enemies as *foederati*, providing them with settlements in various parts of the realm.

In 383 Theodosius created his eldest son Arcadius Augustus. The same year saw the revolt of Maximus in Britain and the murder of Gratian. For five years Theodosius consented to accept the usurper as his colleague; but when Maximus attempted a few years later to make himself master of Italy Theodosius advanced against the invader and overthrew him near Aquileia (July 28, 388). This victory was followed by the murder of Maximus and his son Victor, after whose death Theodosius conferred upon Valentinian II. all that part of the empire which his father had held. After celebrating a triumph in Rome (389) he stayed to arrange the government of Italy for another two years. If we may trust the evidence of Zosimus, from the end of the year 388 Theodosius resigned himself to gluttony and voluptuous living, from which he was only roused by the news that in the Western empire Arbogast had slain the young Emperor Valentinian and set up the grammarian Eugenius in his stead (May 15, 392).

Theodosius at once marched out against Eugenius. The armies met near the river Frigidus, some thirty-six miles distant from Aquileia. On the first day Theodosius' barbarians, engaging with those of the hostile army, were almost destroyed, and the victory seemed to be with Eugenius. After a night of prayer, towards cockcrow the emperor was cheered by a vision of St. Philip and St. John, who, mounted on white steeds, promised him success. On the second day the issue was doubtful till, if we may trust the concurrent testimony of all the contemporary church historians, a sudden gust of wind blew back the enemy's arrows on themselves. This was the turning-point of the battle: Eugenius was slain by the soldiers; and two days later Arbogast committed suicide (Sept. 5–9, 394). From the north-eastem parts of Italy Theodosius passed to Rome, where he had his son Honorius proclaimed emperor under the guardianship of Stilicho. Thence he retired to Milan, where he died of dropsy (Jan. 17, 395), leaving the empire to be divided between his two sons Honorius and Arcadius.

The chief authorities for the age of Theodosius are Ammianus Marcellinus, Zosimus, Eunapius and the ecclesiastical historians (Socrates, Sozomen, Theodoret). Much information may also be gleaned from the writings of St. Ambrose, St. Gregory of Nazianzus, Isidore of Seville, and the orators Pacatus, Libanius, Themistius. Among modern authorities see: E. Gibbon, *The Decline and Fall of the Roman Empire* (ed. Bury, 1909), chaps. 25 and 27; T. Hodgkin, *Italy and her Invaders* (Oxford, 1892), chaps. 5, 6, 8–11; A. Güldenpenning and J. Ifland, *Der Kaiser Theodosius der Grosse* (Halle, 1878); G. R. Sievers, *Studien zur Geschichte der romischen Kaiser* (Berlin, 1870), pp. 283–333, and Van Ortroy, *St. Ambroise et l'Empereur Théoduse,* Analecta Bollandiana (1904).

THEODOSIUS II. (401–450) succeeded his father Arcadius as emperor of the East in 408. During his minority the empire was ably ruled by the praetorian prefect Anthemius and Pulcheria, who became her brother's guardian in 414. Under his sister's care the young emperor grew up into a weak though amiable character. Through his generals Ardoburius and Aspar he waged two fairly successful wars against the Persians (421 and 441), and after the failure of one expedition (431) by means of a gigantic fleet put an end to the piracies of the Vandal Genseric. A Hunnish invasion in 408 was skilfully repelled, but from 441 the Balkan country was repeatedly overrun by the armies of Attila, whose incursions Theodosius feebly attempted to buy off with ever-increasing payments of tribute. His internal administration was upright and thoughtful. Among its chief events may be mentioned the council of Ephesus (434) and the publication of the *Codex Theodosianus* (438), a collection of imperial constitutions 'for the benefit of public officials. Theodosius died in 450.

THEODOSIUS III., emperor of the East (716–717), was a financial officer whom a Byzantine army rebelling against Anastasius III. unexpectedly proclaimed monarch in his stead. He captured Constantinople after a six months' siege and deposed Anastasius, but in the following year was himself forced to resign by a new usurper, Leo III (*see* LEO III, THE ISAURIAN). Theodosius ended his life in a monastery.

See G. Finlay, *History* of *Greece* (ed. 1877, Oxford), i. p. 396).

THEODOSIUS, Greek geometer and astronomer, was the author of three works included in the collection of treatises known as the "Little Astronomy" or "Astronomer" (ὁ μικρὸς ἀστρονούμενος or ἀστρονόμος). He was not "of Tripolis," but came from Bithynia, as we gather from Strabo, who mentions, among natives of Bithynia famous for their learning, "Hipparchus, Theodosius and his sons, mathematicians"; he is also evidently the Theodosius mentioned by Vitruvius as the inventor of a universal sun-dial (*horologium* πρὸς πᾶν κλίμα). He lived, therefore, not later than the 1st century B.C.

His chief work, the *Sphaerica,* in three books, is a tolerably complete treatise on the pure geometry of the sphere, and was still the classical book on the subject in Pappus's time. It does not contain (except for a faint suggestion in iii. 11–12) any trace of spherical trigonometry, which, on the other hand, was the special subject of the work with the same title by Menelaus of Alexandria, who lived at the end of the 1st century.

From the fact that both Autolycus of Pitane in his *Moving Sphere* and Euclid in his *Phaenomena* assume without proof various propositions given by Theodosius, we conclude that already in the 4th century B.C. there existed a textbook on *Sphaerica* scarcely differing, in its essential contents, from Theodosius's work; the rôle of Theodosius was therefore mainly that of editor and elaborator of previously existing material. The *Sphaerica* was translated into Arabic in the 9th century, in part by Qusṭa b. Lūqā, and in part by Thābit b. Qurra. (T. L. H.; X.)

THEODULF, bishop of Orléans, was born about the middle of the 8th century of a noble family of Gothic extraction. probably in Spain. He was made abbot of Fleury and of St. Aignan, and in 781 became bishop of Orléans. He supported Charlemagne's principles of government and educational reforms; he established schools, and was a member of the learned circle which graced the Carolingian court. In 798 he was appointed *missus dominicus,* and two years later performed such great services for Leo III as judge in the cause between the pope and his enemies that he returned from Rome with the pallium. After the death of Alcuin he became the king's principal theological adviser; it was he who made, on Charlemagne's request, a collection of the opinions of the fathers on the much disputed point of the procession of the Holy Ghost. After the death of Charlemagne he was accused, probably quite unjustly, of having taken part in the conspiracy of Bernard of Italy, and in 818 was deposed and imprisoned in a monastery at Angers.

Theodulf died in prison, probably from poison, in 821.

The complete works of Theodulf are in J. P. Migne, *Patrol. Lat.,* vol. 105 (1851). An edition of his poetry was published by E. Diimmler in the *Mon. Gernz. Hist. Poetae latini aevi carolini,* vol. i (1881).

THEOGNIS OF MEGARA (6th century B.C.), Greek poet. More than half the elegiac poetry of Greece before the Alexandrian period is included in the 1,400 lines ascribed to Theognis. This collection contains several poems acknowledged to have been composed by Tyrtaeus, Mimnermus and Solon; with two notable exceptions (T. W. Allen in *Classical Review,* Nov. 1905, and E. Harrison) modern critics unanimously regarded these elegies as intruders, that is, not admitted into his works by Theognis himself; for this and other reasons they assumed the existence of further interpolations which can no longer be detected.

The best-attested elegies are those addressed to Cyrnus, the young friend to whom Theognis imparts instruction in the ways of life. bidding him be true to the "good" cause, eschew the company of "evil" men (democrats), be loyal to his comrades and wreak cruel vengeance on his foes. Theognis lived at Megara on the isthmus of Corinth during the democratic revolution in the 6th century B.c.; some critics hold that he witnessed the "Persian terror" of 590 and 580; others, including the present writer, place his *floruit* in 545 B.C.

There is neither profound thought nor sublime poetry in the work of Theognis. but it is full of sound common sense embodied in exquisitely simple, concise and well-balanced verse. In his day verse was the recognized vehicle for political and ethical discussion, and the gnomic poets were in many ways the precursors of the philosophers and the sophists. who indeed often made their discourse turn on points raised by Theognis and his fellow moralists. For many generations Theognis was to the Greeks the moralist par excellence; Isocrates says that Hesiod, Theognis and Phocylides mere admitted to be the best teachers of practical morality; and the emperor Julian in his defense of paganism asks whether "the most wise Solomon is equal to Phocylides or Theognis or Isocrates."

Besides the elegies to Cyrnus the Theognidea comprise much miscellaneous verse that may well have come from Theognis.

THEOLOGICAL ARTICLES: *see* RELIGION AND *THEOLOGY,* ARTICLES ON.

THEOLOGICAL EDUCATION. The Christian church has always been a teaching church. for it began with the life and work of a teacher. Christian theological education, therefore, owes its origins to his remembered command: "You shall love the Lord your God . . . with all your mind."

By the 3rd century Christian schools not only maintained the learning of Greece—dialectics, physics, geometry, astronomy, philosophy, ethics—but added to these the study of the Scriptures, of God himself (or theology) and of piety. Such were the subjects taught in Origen's schools, first at Alexandria, then (A.D. 232) at Caesarea. The school of Lucian at Xntioch became known for its historical emphases, that at Edessa for its concern for the Bible. The Nestorian school at Nisibis anticipated the medieval universities in holding its own property, enforcing its own disciplines under its own rules of behaviour and showing other signs of independence, including the exacting of a promise from students to reside at the school and to study. At Constantinople, although theological education in the east always kept itself free from state control, the patriarchal school maintained a friendly, reciprocal relation with the state university which had no faculty of theology.

Following the collapse of Rome and its culture in the 5th century, monastic and episcopal (later cathedral) schools, providing for education from childhood to priesthood, not only preserved the heritage of the ancient world through the dark ages but also led to the establishment of over 50 universities in slightly more than three centuries prior to 1400, among them Bologna (the oldest, 1088). Paris, Oxford and Cambridge.

The Reformation and After.—Education in medieval times included grammar, rhetoric and dialectic (the trivium) and mathematics, music, geometry and astronomy (the quadrivium). In the 16th century Philipp Melanchthon enlarged the trivium with Hebrew, Greek and Latin; the inclusion of theology followed. For the Reformers, as earlier for St. Thomas Aquinas, learning was of great importance. The Scriptures were their source of doctrine. The "priesthood of believers" opened the way to individual judgment which needed to be informed and the faithful required instruction to fulfill their new sense of obligation to preach to those outside the church.

Meanwhile the Church of Rome recognized that the Reformation had been caused partly by ignorance, superstition and lack of education among the clergy. At the Council of Trent, therefore, in 1546, legislation was enacted which provided for a liberal education plus professional priestly training for each diocese, permitting poor dioceses to combine, large dioceses to establish more than one seminary, but taxing the church to ensure a sound preparation for the clerical calling.

"Among the greatest achievements of the Council of Trent," writes Stephen Neill, "was its creation of the seminary. When the Protestants spoke bitterly of the returning emissaries of the Roman Church as 'Seminary priests,' the name hit the mark; these young men, trained at Douai or elsewhere, had learned discipline and devotion; they had been trained in the methods of controversy. The training might be narrow and scholastic, but it was calculated to make them more than a match for anything that they were likely to meet in England." (Stephen Neill. *Anglicanism,* p. 110, Penguin Books, Harmondsworth, 1958.)

On the North American continent Harvard college, founded in 1636, was designed to provide training for responsible service in both church and state but especially in the former. Modeled after Cambridge university, its course of study reflected medieval and Renaissance practices and continued the Reformation stress on biblical teaching and preaching. Thus, the high level of Reformation education was maintained in the new world.

Changing Patterns.—During the 18th century a candidate for the Protestant ministry in the British Isles or Korth America received little education beyond the arts degree to prepare him for his calling. If he did not attend college he mould study privately in the home of a parish minister. Or he might pursue theological training in the Protestant universities on the continent of Europe. In 1721 Harvard began in America the differentiation of theological training from general education by the establishment of the Hollis chair of divinity. Yale followed with a similar step in 1756. However. a theological student usually took his "divinity" after completion of his X.B.; the A.B., intended for all, remained the most important part of his training. To the 20th century, both in Protestantism and Catholicism, a sound education in the liberal arts remained a proper foundation for ministerial and priestly studies. "We urge," said Pius XII in the encyclical *Menti Nostrae,* "that the literary and scientific education of future priests be at least not inferior to that of laymen who take similar courses of study."

Toward the close of the 18th century, however, various forces operated strongly further to separate education for the ministry from education for other callings. One of these was the differentiation of occupations in a more highly organized society, leading to the organization of medical schools (King's college [Columbia university], Sew Tork, 1767) and schools of law (Litchfield, Conn., 1784) which did not require a previous A.B. The age of reason had run its course and some theological schools were founded in reaction against the influences of 18th-century rationalism upon the universities. Revivalism, the expansion of frontiers, the growth of denominational consciousness accompanying rapid immigration and social stratification and lively theological controversies all combined to produce a new movement, the creation of independent or separately organized theological schools.

In England. also, medical and legal studies were separated from the undergraduate universities and centred in London. For a time, academies designed for the preparation of Dissenting ministers who were barred from schools of the established church flourished. By the middle of the 19th century, however, these academies had declined and ministerial training became concentrated in theological colleges, many affiliated with universities. It was this pattern that prevailed in the British Isles after 1850. On the continent theological studies, almost entirely pursued in universities, tended to become more concerned with the scientific study of religion and, in Protestant circles. less involved in the equipment of the students for their special ministries.

To return to North America, although a school of the Dutch Reformed Church, begun in New Tork city in 1784, subsequently became the New Brunswick Theological seminary, the reasons for this important departure in theological education were most clearly stated in 1805 by John Mitchell Mason, founder of a less permanent seminary of the Associate Reformed (Presbyterianj Church. Anticipating emphases of a much later day, Mason insisted that the Scriptures be studied in their original languages; that students be encouraged to form independent judgments (a professor is "never to forget that his business is not so much to think for the students as to assist them in thinking for themselves"); that the whole person—body, mind and spirit—be simultaneously strengthened; and that the highest standards of comprehensive thoroughness and intellectual creativity be maintained against all hardened dogmatisms and considerations of expediency. In the subsequent three and a half decades about 50 Protestant seminaries were established in the United States. Because of the financial panic of 1837, there was a lull. but between 1850 and 1890 over 120 others appeared. all to some extent indebted to Mason's ideas about the role of the professor, the nature of the subject matter and the life of the student. Many of these insisted on at least a measure of administrative independence. a college course leading to a B.A. or its equivalent as a requirement for admission and attendance at the seminary for three academic years of approximately 40 weeks each.

Meanwhile, beginning in 1791 when Archbishop John Carroll established St. Mary's seminary in Baltimore, Roman Catholicism developed new seminaries n·ith the formation of new dioceses. By 1833 there were 7, by 1866 approximately 20 more and by 1943 over 250, some conducting studies at the high school and junior college level (six years), some at the senior college and specifically theological level (another six years), some working in both divisions. Some were under diocesan control, others were under religious orders, but all prepared young men exclusively for the priesthood.

The similarities between Roman Catholic and Protestant seminaries in the early 19th century are striking. Many, both Roman Catholic and Protestant, began as house schools in the home of the teacher or teachers. Gradually separate buildings and increased faculties appeared. Many were connected with a college or school. Plagued by inadequate financial resources. scarcity of students, lack of books and generally low intellectual standards and achievement, many were closed.

After 1860.—Although theological education tends to cling to the past more tenaciously than other disciplines, it could not escape the influence of vast changes in the modern world. The enormous increase in the study of the physical sciences! the historical-critical method of investigating ancient documents, the economic interpretation of history, the new psychology, the growth of secularization. the exploding population, the enlarged possibilities of communication, the practical interests of the western world. the threat to the very codtinuation of life on earth—all these and many more had their effect on seminaries and schools of theology that once were isolated from such concerns.

There are two main purposes that characterize these schools, summarized in the distinction Edward Pusey made in 1832 when he said that the British educational system was best calculated to form ministers of the church while the German system could best impart knowledge. The priest or minister is taught to be a "parson" or person worthy to represent his calling and to be respected as an ambassador of Christ, a father to a family with which he has close touch. At the same time he is a "cleric" or one who can write—one who possesses the general and special professional knowledge that enables him to maintain and advance understanding of God's ways with man.

Partly, therefore, the problem of theological education is to meet the needs of the churches and of the "coming great church." In response to the expansion of the Christian movement. the increase of population and the interests ci great ecclesiastical organizations, seminaries sprang up all over the world in great profusion. In Europe. where theology has been traditionally connected with a university faculty, the number of seminaries remained relatively constant, but in Asia, Africa and Latin America more than 200 Protestant and over 350 Roman Catholic seminaries, plus about a dozen Eastern Orthodox, had emerged by the mid-20th century. In the United States the 15 years after 1945 saw an increase in the number of Roman Catholic seminaries of more than 50% and in the United States and Canada the number of Protestant theological students more than doubled in the second quarter of the 20th century.

Problems posed by this rapid expansion were manifold: the maintenance of high standards of admission; provision for the adequate preparation of theological teachers and their lifelong growth; the preservation of the seminary's community life at a time when Protestant students tended to marry at an early age; financial support; the development of theological libraries; the employment .of modern techniques that have proved their value in other disciplines. In the non-English-speaking world, difficulties were intensified. Indigenous leadership was often scarce; the paternalism of teachers, ministers and boards from mother countries was maintained too long; schools tended to conform to patterns imposed from outside which were unsuited to a new time and place; books in many of the languages of the far-flung Christian movement were in short supply; and the rival forces of nationalism, secularism and Communism were keenly felt. Except for that of language, most of these difficulties were also apparent in certain areas of the western world, such as those with predominantly Segro populations.

On the other hand, the problem of theological education is the maintenance of theological learning. For Protestant theological schools, more than for Roman Catholic or Eastern Orthodox, there was in the 20th century, as in the 16th. a considerable expansion of the curriculum, which was generally divided into four main fields: biblical, theological or doctrinal, historical and practical. Although in Europe relatively few new courses were introduced, in Sorth America the wide diversity characteristic of the universities' offerings affected the seminary, especially in the fourth or practical field. Frequently courses were offered in the interpretation of culture and the arts, in the nature of the modern world in which the Christian church is set, in rival philosophies and in the understanding of human behaviour. Attempts were made to bring Christian insights of Scripture, theology and history to bear upon the pressing ethical problems of the modern era. Men were trained in the conduct of public worship, in the use of modern methods of communication, in the art of teaching and in the preparation and delivery of various forms of public address. Field work, internships, clinical pastoral training and practice teaching all reflected current methods of learning by doing.

To encourage the maintenance of high standards of theological education, Protestant seminaries in the United States and Canada began to meet in biennial conferences in 1918, and in 1936 formally organized the American Association of Theological Schools.

In reaction to the secularization of modern society, numerous Bible colleges or Bible schools appeared, only a few of which maintained studies at a predominantly postgraduate level. While Bible schools generally do not provide the general education that the seminaries require and thus sometimes offer a short cut to the ministry, it is to be remembered that not a few seminaries began as Bible schools.

Where theological education was under the control of the state or of a state church, as in Germany, Greece, Scandinavia, the Netherlands and England, the curriculum tended to be more traditional, with a heavy emphasis upon Scripture, its languages and the classical formulations of Christian theology. In Greece and in Sweden the majority of those enrolled in the theological faculties of the universities tended to become lay teachers rather than ordained ministers. Consequently Greek Orthodoxy, for example, finds most of its theologians among its laity.

The government of theological schools or colleges varied widely from complete independence to direct control by a university, church or department of the state. Roman Catholic schools might be under the direction of diocesan authorities or of religious orders. In the United States and the countries of the "younger churches," there were a few Protestant interdenominational seminaries and numerous schools which in one way or another co-operated with each other. The pattern of a yoked college and seminary was receding in favour of an institution with its own board of trustees and a faculty which determined academic policy. Efforts were being made in many churches to acquaint the membership with the acute problems of the seminaries, their importance as intellectual centres of the church's life and the necessity of their vastly increased support. Despite denominational rivalries, there were signs of increasing care in the location of new and the removal of older seminaries to ensure co-operation with other seminaries and universities.

Although the dual responsibility of theological schools to provide ministers for rapidly expanding churches and to maintain high standards of theological learning often caused tensions, on the whole this concern for both life and thought, both peoples and principles, both practice and knowledge was healthy. When the demands of the church were uppermost, seminaries tended to be located in places where a strong community life could be fostered and individuals nurtured in prayer, personal discipline, the church's lore and ritual and the denominational program. When the intellectual standards for the ministry were uppermost, preparation for the ministry was likely to be concentrated in university centres and in some way connected with the acquisition of an academic degree. Even in the schools with the strongest denominational ties, however, isolation was diminishing. The importance of these schools as centres of intellectual culture was being recognized. On the continent, where theology long insisted on its position as queen of the sciences and theologians were entrenched in university faculties, there was a movement, reminding the queen of her biblical role of handmaid, to establish church high schools. preacher seminars and other forms of auxiliary institutions designed to equip the ministry for its task. Throughout the world increasing stress was being put upon the theological education of the laity, reflected in the German *Kirchentag* and the establishment of over a score of lay academies, the majority in Germany.

"The lessons of history clearly demonstrate," says Yorke Allen, Jr., "that the training of the clergy is at the core of the process of maintaining any ecclesiastical organization." From the Vatican comes this word, "The Church fears neither persecutions . . . nor heresies . . . , but this one thing she does fear, ignorance of the truth."

THEOLOGY, in the comprehensive sense of the name, embraces so much of philosophy as is concerned with explanation of the world in terms of a supreme mind or spirit, with the being and attributes of the Deity and His relation to nature and man and with the grounds and the limits of knowledge or belief as to such matters. It also includes the comparative study of religions and the psychology of religious experience. Specifically Christian theology, which is often what is denoted by the word "theology," sets forth the contents and implications of the revelation in Christ. It consists of a systematic exposition of doctrine and of the course of its development (dogmatic theology or dogmatics), the historical, critical and exegetical study of the Bible and the history of the church, its institutions, etc. Thus theology is a science, or a group of connected sciences, that, on the one hand, is in touch with general philosophy—as is indicated by the name of the department called "philosophy of religion," or "philosophical theology"—and, on the other hand, is more or less isolable in that it deals with the deliverances of distinctively religious experience and its pre-eminent manifestations.

The Relation of Theology to Religious Experience.—It is commonly held that religious experience contains data other than those of natural knowledge, enabling it to possess insight into reality otherwise unattainable. And we may first note the implications of this belief in their bearing on the position of theology among other departments of thought such as natural science and philosophy.

All natural knowledge, *i.e.,* knowledge of the physical world and mankind, is generally believed by philosophers to be derived originally from the impressions of sense, between which the understanding establishes relations. Out of these relations are constructed the body of common-sense knowledge, the sciences and metaphysics. Sensory perception in the first instance, and then ideas distilled from percepts evoke the feelings. desires and valuations of which aesthetic and ethical sentiments and principles are the outcome. According to this science or theory of knowledge, then, religious beliefs and theological doctrines can only be mediated by reflection on the sensible world, the mind of man and human history. On the other hand it is often claimed by theologians that religious experience is founded on apprehension of another species of the objective than the sensory or the sense derived, and on feelings, etc., induced thereby. This objective datum, evocative of unique emotional states and dispositions, is asserted to be apprehended with the same immediateness as is the sensory and so to afford a basis of knowledge about ultimate reality, independent of that on which the natural sciences are built.

If this view were beyond criticism. it would suffice to explain the uniqueness of religious experience and consequently the special characteristics of theology. And one ingredient in it certainly seems to be beyond reasonable doubt. This is that whatever there is, on the affective or emotional side of religious experience, that renders it an experience *sui generis,* or distinct from cognate kinds of experience, that peculiarity must be accounted for by the distinctiveness of the object or objects eliciting the subjective response. Religious experience, on its affective side, comprises sentiments such as loyalty and love, awe and adoration, none of which is peculiar to religion, but each of which differs somewhat from other instances of love, reverence, etc., solely in virtue of the object—deity—toward which the religious emotion is a response. Even those who incline to the opinion that there is one kind of valuation, viz., appreciation of sacredness, that is peculiar to religion throughout all the stages of its development, ascribe its peculiarity and its forthcomingness to the unique object that evokes it. But doubtfulness attaches to the further representations that this sacred, numinous or supernatural object is immediately apprehended as such; that it is irreducibly different in psychological nature from. the sensory, or rather from the image or the idea which are derived from the sensory, and that its apprehension involves a special faculty, not included among those known to ordinary psychology. In the primitive stages of religion the supernatural object seems always to be lodged in some natural object or phenomenon, which inspired emotion such as awe, as is evinced in the notions of clean and unclean, worship of animals, the dead, etc. Thus the numinous, or divine, reality, devoid of the concrete particularity that characterizes an immediate sensation or percept, and capable of entering into diverse mythologies and religions, seems rather to be of the nature of the vague generic image, derived by human imagination and idealization from impressive phenomena. And it is not enough to point to the indubitable objectivity (in the psychological sense) of this alleged numinous reality. For images and ideas, as well as percepts, are also objective; and they are as potent as actualities or real things in eliciting valuation and emotional response, provided that belief in their reality is entertained. Immediacy is a conception which plays important parts in connection with religion and theology; and attention may here be called to the ambiguity which lurks in it and is wont to be overlooked. At the moment when a particular experience, such as perceiving a familiar thing, takes place, we are not aware of performing any synthetic activities; the percept has the unity and the instantaneousness of a flash-photograph, and the whole act of perceiving seems as if unanalysable and unconditioned by previous experiences. From the standpoint of such an experience, the perception is immediate. But from the standpoint of subsequent reflection on that experience, especially if we happen to be versed in the science of psychology, the perception in question was not immediate. It was not a simple, unanalysable, unity nor unconditioned by previous mental processes and present interpretation. Its immediacy thus resolves into our unawareness, at the moment, of real mediation. Now in order to maintain that religious experience, as illustrated by the primitive instance that has been mentioned consists in immediate apprehension of a spiritual environment or a supernatural beyond, that is real or actual and not imaginal or ideal, it is essential that the immediacy involved be accounted such from the latter of the two points of view that have just been distinguished. Yet it is from the former of them alone that it can be vouched for by the religious experient, appealing only to his religious experience. Thus it is doubtful, on more than one ground, whether apprehension of the sacred and supernatural is essentially different from sensory knowledge, eked out with interpretative notions derived from human analogy, constructive imagination and idealization. It may be that the primitive notion of a god, precursor of the later conception of God, was derived by such processes from current knowledge of man, and read into some impressive natural object, constituting it numinous and capable of eliciting religious emotion.

If this view be adopted, religious experience, on its first emergence in mankind, will, mutatatis *mutandis,* have been grounded in a way similar to that in which theistic belief is grounded by the philosopher. It was the outcome of what may be called primitive philosophizing on Nature and man, and not of the exercise of an alleged transcendent faculty of intuition. Indeed it would seem that such direct touch of God upon the human soul as religion and theology imply does not admit of being discerned with real immediacy: it is a case of causal activity, which admittedly is never perceptible. And as for the rest that has been said above, its gist is contained in the generally endorsed dictum, "no man hath seen God at any time." The mystic, it is true, claims to be an exception. But it is not necessary here to weigh his testimony, partly because he can only assert, on the strength of his peculiar experiences, the specious kind of immediacy which has already been shown to be irrelevant, and partly because mystical experience seems never to have issued in theological insight and doctrine that was unknown before and otherwise. Knowledge of God would seem to be in the same case with knowledge of our own souls and of other selves, as distinct from their material bodies. In each of these instances the object is not apprehended with directness, but read in analogically; and the reading or interpretation is justified or verified (qever logically certified) by cumulative practical success. There well may have been, from the infancy of our race, a touching of man by God, even before man arrived at belief in the daemonic or the divine; but such rapport would not be religion until man had come to believe in such beings as gods. "He who cometh to God must believe that He is." That is to say, religion or religious experience presupposes, and is constituted distinctive, by a theological notion or concept. This concept cannot be in the first instance derived from religious experience, because religious experience cannot exist till the idea is forthcoming.

It is very generally taught that theology presupposes religious experience and is but the explication of it. But it is all a matter of where, in a long chain of development, we fix our starting point for consideration. In the series of natural numbers, every odd number precedes an even number and every odd number also succeeds an even number until we work back to I. Similarly, the "Athanasian" creed presupposes much Christian experience while the religious experience of Paul the Apostle differed from that of Paul the Rabbi in virtue of his acquired doctrinal belief as to the Person of Christ. But if we go back to the beginning of the series in which theology determines religious experience and in turn is determined by such experience, pursuing psychological beginnings since historical origins are beyond our ken, it would seem that, originally, some crude equivalent to natural theology must have preceded and caused the emergence of distinctively religious experience. But religious experience once having arisen in this way, it will determine theological thought; and the new thought will render possible a further advance in religious experience, and so on. Thus there is as much truth in the statement that theological doctrine determines the quality of religious experience as in the statement that religious experience and faith are presupposed by theological dogmas. When, *e.g.,* the Christian asserts that he has experience of the indwelling Christ, he is obviously interpreting his really immediate experiences, which consist in consolations, joy, peace, uplifting of the will, etc. He would not so interpret such mental happenings had not Christ been preached to him, and had he not received doctrine as to the Person of Christ which he did not make out of his individual experience. Nevertheless, it is a fact that the idea of God, both in dogmatic theology and in philosophy, was moulded by religious experience, guided both by morality and intellect, after the initial stage of the long course of religious development.

The Relation of Theology to Philosophy. — From the earliest times philosophy has had a theological side. Since the dawn of Greek science and metaphysic, philosophy, Greek and other than Greek, has produced copious speculation concerning the existence and nature of God, as well as a vast volume of thought bearing more or less direct relevance to theological problems, such as the origin, destiny and meaning of the world and human life. The greatest of philosophers have dealt with these problems and it has often been from the side of religion that great thinkers have received their chief impulse towards philosophy. Moreover theology and philosophy are largely identical in that theology is essentially metaphysics. No doubt the majority of those who profess theological beliefs hold their beliefs in complete absence of metaphysical reasoning; in that sense their belief—*i.e.,* believing—is non-metaphysical. But their beliefs—*i.e.,* their credenda —are all metaphysical dogmas or assertions about ultimate reality. They are religious beliefs in so far as they are metaphysical. For instance, that Jesus "suffered under Pontius Pilate" is, as a bare historical fact, of no religious import; but when it is intended to imply further that He suffered for us—*i.e.,* for our salvation— it is a metaphysical statement concerning the relation of God to human souls and, in virtue of that metaphysical content, is a religious doctrine.

Besides being concerned with the same metaphysical subject-matter, philosophy is involved in theology and can aid its work in various ways. Firstly, in respect of the systematization and unification of knowledge. Christian theology needs must connect its more or less separate and independently elaborated doctrines into a coherent whole. Thus Origen, one of the first Fathers to present an ordered system of Christian dogma, tells us that while the Apostles delivered themselves clearly on certain points necessary for all to understand, they left the grounds of their utterances and the more precise determination and demonstration of many doctrines to the more zealous of their successors who should be "lovers of wisdom"; and he expresses his desire to form a connected series of truths or one body of doctrine. That is the goal of dogmatic theology which would relate, *e.g.*, the doctrine of the Atonement with that of the Incarnation or the doctrine of Sin with that of Creation, and obviously such connection involves resort to philosophy. Again, the exposition of any single doctrine involves the use of interpretative ideas, such as can only be supplied by the science and philosophy current in a given age. Several doctrines that purport to be deduced from scripture alone are less the result of strict exegesis than the result of speculation applied to such material as secular knowledge was believed to have established. To give one example: the doctrine of Original Sin is not contained in the Old Testament and the only unmistakable presentation of it that can be found in the New does not appear to have been the starting-point for the first framers of the ecclesiastical doctrine. Tertullian set out from stoic psychology, Origen from the institution of infant-baptism and also from the myth of Plato concerning the fall of the soul from the celestial sphere into earthly life. But of greater importance than cases of this kind is the fact that the very terms and conceptions, requisite as a mould into which the relatively undefined traditional beliefs of the early Church must be cast in order to yield explicit and definite doctrine and, appropriated for that purpose, were supplied by Greek philosophy.

The office of philosophy within the sphere of theology, with which we have thus far been concerned, may be described as that of interpreting to the reason the contents of religious experience. The philosophy of religion seeks to show that the fundamental ideas of religion, so far from being contrary to reason or from being ideas begotten of faith indifferent to knowledge, are capable of receiving a rational, or at least a reasonable, justification in terms of philosophical principles. Philosophy, or even theology, is no substitute for religion, and, of course, does not profess to be. It professes, rather, to show the compatibility of faith with reason and knowledge and to interpret the contents of faith to the reason.

Another function of philosophy is the undertaking of a critical examination of the processes involved in what we call knowing and of the various conceptions that enter into the knowledge claimed either by common sense or the sciences, with a view to disclosing the nature, validity and limits of human knowledge. And this function has a necessary place also in the sphere of theology. There we require to understand the precise relations between what are respectively called knowledge and faith; and it is necessary to pursue the "critical regress" within the field of dogmatic theology because, as history shows, the legitimate desire for completeness of system and knowledge and for definiteness of dogmatic expression is apt to become the wish to know more than, perhaps, can be known and to know too definitely. In the middle ages, when theology was more ambitious than critical, fulness and precision were claimed in so inordinate a degree that, as a sympathetic historian has observed, an agnostic reaction was necessary in the interests of reverence. And it is always natural for theologians to betake themselves too exclusively to the drawing of inferences when more attention might profitably be devoted to the sifting of premisses. Thus it is that the word "dogmatic," which technically indicates one province of theology, has come sometimes to bear a less noble signification; and dogmatic theology has been distrusted as requiring assent to doctrines that are not self-evident and for which no proof can be supplied.

But while philosophy, as a critical method, is a corrective of dogmatism in the foregoing sense, philosophical theology is not necessarily hostile to dogma. Individual philosophers have doubtless tended to set up empty abstractions, as will presently be seen, in place of positive facts and concrete existents; but that is no necessity inherent in philosophy itself, as a pursuit.

Hegel observes in his Philosophy of Religion that in his day an anti-dogmatic spirit was abroad among dogmatic theologians, who at the same time charged philosophy with merely negative or destructive tendencies. These, he said, have thrust dogmas into the background, pronouncing them unimportant and extraneous definitions or mere phenomena of past history. Christ's work of redemption had received a very prosaic and merely psychological significance and the doctrines of the Trinity, etc., were neglected as matters of indifference, even by pious theologians. This spirit was by no means confined to Hegel's day. It might be called the temper of indefiniteness. It is met with in the supposed antitheses between kernel and husk—as if kernels ever grew without husks—and between the life and the creed—as if Christianity were not a life based on a creed, and Christian ethic did not owe its distinctiveness to its dependence on Christian doctrines. In recoiling from dogmatism such as would be over-precise, it distrusts precision of expression as such.

The necessary and intimate connection of theology, even dogmatic theology, with philosophy now having been illustrated from several sides, the two main types of method that have been employed in philosophical theology may in turn be described: they are respectively called the a priori and the empirical.

The a priori Method and Rational Theology.—Of the phrase **a** priori we can distinguish two meanings that are apt to be confounded. It may have a psychological sense, when the phrase means "contributed by the mind itself," and so is generally equivalent to "innate." It may also bear a logical sense, as when a priori truth is described as truth characterized by universality such as, in contrast with mere generality, bespeaks intrinsic or unmediated necessity. In the former case, contrast with the empirical and sense-given is pointed, in the latter case, contrast with the contingent—*i.e.,* with what is, but conceivably might have been otherwise.

It may be said, with accuracy sufficient for the present purpose, that the a priori method was introduced into philosophy and theology by Plato. He took the ideal or pure science of mathematics, which deals with the non-actual, to be the paradigm of knowledge of the actual—science and philosophy. Despising the sensory, and empirical investigation, he valued only the relations and the universal qualities manifested in facts, so that these came to be considered, not as entering into the constitution of actuality, but as existing wholly independently, and this rational or intelligible world, as contrasted with the sensorily perceived, was accounted the truly existent or the "real." Thus arose the a priori method, in the logical sense of that phrase, and the rationalistic theory of knowledge, which, without much qualification, may be said to have dominated philosophy for centuries. So long as it did not and could not—till analytical psychology was born—be suspected that sense and understanding may have a common root and that between understanding and reason there is continuity rather than disparateness, the rationalist's belief in a faculty called reason, capable of functioning in independence of sensation and sensory data, was possible and natural. This faculty was regarded by the ancient philosophers as the sole source of real, *i.e.,* higher, knowledge; as independent of body and "animal soul," and even as a participation in the Divine Reason, a "spark of Deity." Christian theologians, who found much in Plato's system that they could assimilate, also appropriated this ancient doctrine as to reason. Augustine applied it to explain the reception of supernatural truth and the divine illumination of the mind of man, and it coalesced with the Logos-doctrine of the Church. From Augustine and neoplatonism it was accepted by Descartes and so became entrenched in early modern philosophy. The existence of a lumen naturale, a faculty innate as instinct, but mediating necessary and eternal truths, was one of the tenets of rationalism and one that theologians were naturally inclined to adopt. Hence a *priori* theology, in the psychological as well as the logical sense of the phrase, flourished long. Another feature of the rationalistic and a priori theory of knowledge is its tendency to identify knowledge and thought. Knowledge (of actuality) is pre-eminently thought, but since the 18th century we have been compelled to recognize that it is also more. Further, the consistency of thought with itself was often confounded with validity—*i.e.*, with "holding of" actual things. But fiction can be consistent while not being truth about actual persons, and metageometries may be as consistent as Euclid without having any applicability to our world. Moreover, what were deemed to have been self-evident axioms, forming the basal principles of various sciences from mathematics to theology and purporting to be read off as necessary truths by pure reason, have in these latter days been accused of being either conventions, like the rules of a game, or disguised empirical inductions. These modern discoveries and the emergence of a genetic science of common or universal, as distinct from private or individual, experience have rendered tenet after tenet of the a priori school obsolete for many minds.

Turning now to the application of this method and type of philosophy to the sphere of theology, we may note that to it is due a large part of the content of the traditional conception of God and His attributes. From the patristic age to the modern period of philosophy philosophical theologians took over the concept of God as largely fashioned during the long development of religious thought, including the Hebrew thought in which Christianity has its roots. And in Hebrew religion, the transcendent attribute of Jehovah is His holiness. God is personal, not a cosmic force, interested in individuals, immanent in Nature and man. But the Greek philosophers, who founded philosophical theology, had relatively little concern with such qualifications of Deity. Greek philosophy began as cosmology and ethics was an after-development. And Greek theology was rather an academic product than born of personal experience and life. Hence, save for Plato's identification of God with the Good, it endowed God with what may roughly be called "the physical" attributes in a predominant degree. The Greek mind, not the Hebrew, is responsible for the attribute of infinity, perhaps for those of omnipotence and omniscience in their absolute and rigorous senses, and for the qualities of immutability and impassibility, the taking over of which by Fathers of the Church involved them in the difficult task of reconciling such attributes with the nature of a living Spirit. Some of the Greek theological ideas, a priori in character rather than derived from life and experience, proved to be a mould somewhat incongruous with the Hebrew-Christian content which philosophically-minded Christian doctors thrust into it. It was at once too large and too small. If immutability means more than self-consistency, and impassibility more than freedom from human anger and corporeal passions, they cannot be predicates of a God of love and a Father of spirits. Like infinity, until that concept passes over into the idea of ethical perfection, they are derived from inert matter rather than active spirit and are quasimaterialistic or mathematical rather than spiritual and ethical conceptions. "Infinity" has borne several distinct meanings, both in Greek and in later philosophy. Originally its sense seems to have been that of indeterminateness or being devoid of any particular characters, formless, indefinite and indefinable: in which case it is, of course, not predicable of any actual being. Then it came to mean the endless or limitless, what cannot be reached by successive acts of addition or division. Infinity, in this sense of the endless in time, space or number, is only relevant in mathematics; it can have no application to God, who is without parts or magnitude. Lastly, "infinity" acquired the meaning of completeness, ethical perfection and immutability. Then, however, it became a redundant word; as properly used it can be dispensed with by theology.

Even more inapt to Christian or theistic theology than some of the Greek a priori concepts is the abstractive method of arriving at a conception of God, which passed, through Philo especially, from Greek thought to some of the Fathers of the Church. The rationalistic propensity to regard the most abstract conception as the ultimately real being, coupled with the formally intellectual tendency to oust from philosophy and theology not only the anthropomorphisms of vulgar thought but also the inalienable anthropic functions of human mentality, led to usage of "the negative way." That consists in repudiating all positive characterizations of God supplied by human analogies. It has aptly been described as a deification of the word "not." Everything, it is represented, that can be affirmed of the finite must be denied of the Infinite One. Thus God becomes conceived as an indeterminate absolute, ineffable and unknowable; the living Spirit is replaced by a pure idea. The Fathers favourable to this method, who even when abstract philosophers were also pastors and curators of Christian tradition, were saved from propounding these extravagances by a wholesome inconsistency. But Philo, gnostics, and neoplatonists, who took the negative way more seriously, found it necessary, in order to bridge the impassable gulf which they set between the Infinite One and the finite world, to invent powers, aeons and emanations.

The Empirical Method and Natural Theology.—The phrase "natural theology" has usually been a synonym for "rational theology"; *e.g.,* the natural theology of the English deists, who may aptly be described as rational theists, consisted of doctrines supposed to have been discerned by human reason, its first principles being self-evident, and its secondary doctrines being deduced from them, in accordance with the a *priori* principle, that so and so is because it must be. But it is convenient to give to "natural theology" a distinctive meaning. As a synonym for "rational theology" it is superfluous; while there is a theology derivable empirically from the study of Nature, man and human history, and consequently not "rational" and a priori, for which the title "natural" is the most appropriate. It will therefore be so used in the present context.

The possibility of a theology of this kind was recognized at least as early as the time of St. Paul, who wrote that "the invisible things of [God] from the creation of the world are clearly seen, being understood by *the things that are made."* But though theology is thus derivable, it must be added that it has not as yet been derived, at least not with anything like the completeness and system possessed by some of the rational theologies that have been forthcoming between the times of, say, Aristotle and Hegel. Empiricism, in a nobler than its historical sense which degrades it to sensationism, yet awaits its master-mind comparable to a Plato or a Spinoza; hitherto, both in philosophy and theology, it has been represented but fragmentarily, and, if by able thinkers, scarcely by genius of the highest order. Some of the threads which await weaving into the texture of an empirically grounded philosophical theology by a future master-weaver are already within the common ken and may be briefly indicated.

It is admitted that theology rests on faith. Faith, in the first instance, creates ideas, such as that of God, and believes in real or actual counterparts to them. It claims to be knowledge, but is not knowledge or cannot be known to be knowledge, in the same sense that natural science is knowledge. Faith may issue in knowledge or it may not. The individual believer, whether a mystic or a non-mystic, may adopt, for the ordering of his own life, the attitude "I am certain." Therein he is invulnerable; but his faith will be a matter of personal biography and his certainty will be but subjective certitude or convincedness until reasons be forthcoming for taking the objects of his belief to be actual (as is the king of England) and not merely imaginal (as the mermaid) or purely ideal (as the line without breadth). Theology and philosophy are concerned with the knowability and the actuality of God and with the validity of statements about Him. Rational theology maintained that God's existence, etc., could be proved as coercively as a theorem in Euclid. Empirical theology denies that this is so, and empiricism asserts that knowledge, in that sense, is not forthcoming even as to the existence of other subjects or souls than one's own. Empiricism can also assert that what is called scientific knowledge and what are our most assured convictions as to the physical world rest ultimately on indemonstrable postulates or an act of faith, and observes that there is no more a rational cosmology than there is a rational theology. In both spheres verification is pragmatic and is very different from logical certification, which would only be forthcoming if science were composed of deductions from axioms, instead of inductions from facts. Thus, in the entire realm of actuality, as distinguished from that of the pure or ideal sciences, what, of courtesy, we call knowledge is after all but probable belief. We can only be reasonable, not rational.

Such is the empirical account of the relation of faith to reason, theology to science and philosophy. It follows that no proof, in the most rigid sense, of the primary dogma of theism is possible. Such proof as may be had will consist in showing that theism is the most reasonable interpretation of the world and man, and in displaying the cumulative evidence for the assertion that the cosmos is due to the conspiration of innumerable causes and adaptations, by their united and reciprocal action, to issue in a general order of Nature, such as cannot reasonably be ascribed to fortuitousness but only to design by a supreme mind that must be intelligent and moral, the ground of the Good, the Beautiful and the True. Philosophical theology will thenceforward consist in the reinterpretation of the world and human history in terms of that metaphysical conclusion.

Theology Based on Other Grounds. — After rational theology received the classic criticism of Hume and Kant, attempts were made to establish theology on a new basis. The old proofs having been shown to be either fallacious or insufficient, the theoretical knowledge-methods by which they had been mediated were renounced, as not the proper foundation of theology. But the empirical procedure, seeking for grounds of reasonable belief wherewith intellectually to justify faith, did not commend itself to the generations which succeeded Kant. In the 19th century the discovery of the deists that revealed religion presupposes natural religion was ignored; and Butler's suggestion, that what he vaguely called probability constituted our guide, was deemed inadequate. The latter line of thought was indeed pursued, without explicit awareness of the fact, by the numerous English writers who, from S. T. Coleridge onward, developed the doctrine that religious truth can only be judged and accepted by "the whole man," and not by man as merely intelligent. Recoil from discredited 18th-century rationalism, however, did not direct itself to the empiricism represented by Locke, and perhaps more faithfully, in the theological sphere, by Butler. Confusing probability, as something pertaining to common or public beliefs and "knowledge," with acceptance as merely probable on the part of the individual believer, objectors generally submitted that ardent faith is not a weighing of probabilities, nor can faith be content to stake its vital convictions on what it merely deems probable.

Of course the faithful man is certain, in the sense of being privately convinced; but what he is confident about may not have logical or scientific demonstrability from the point of view of objective or common knowledge. And it is the latter issue, not the mentality of this or that individual, with which theology is concerned. But inasmuch as this confusion of standpoints was prevalent, it is not surprising that efforts were forthcoming to find a new basis for theology such as should constitute it a science, yet vindicate subjective certitude. Schleiermacher appealed to immediate experience. But it may perhaps be said that the immediacy of which he treated is but mediateness unrecognized. When he proceeded to draw out what was implicit in his fundamental immediate truths, he reveals the presupposing of a whole system of philosophy and science. Another such attempt was that of Ritschl, who sought to make theology independent of the sciences of Nature and historical criticism, of metaphysics or theoretical (by which he seems to have meant rational) knowledge, grounding it on judgments of worth. That theology derives its arguments largely from considerations as to values is of course true. But these valuations must be appreciations of the actual, and so presuppose knowledge of the world and man, in order to yield any theistic argument. The existence of a real object, such as God or heaven, cannot be inferred from the worth of an ideal object or from doctrines about such objects. An existential science, then, cannot be extracted from considerations as to worth alone. There is room, moreover, for nothing but private faith or blind hope in the realization and conservation of the valuable, until the universe has been found, by theoretical knowledge, at least not to be of such a nature as to involve extinction of the valuable. That the good *ought* to be conserved is irrelevant to whether it *will* be conserved, until we have established a reasonable belief in a good God. Thus it would again seem that theology can only claim to be reasonable belief and that it can only provide itself with reasonable belief by interpreting the actual world. Once severed from the kind of "knowledge" on which it is dependent, it is unable to find any criterion whereby to distinguish reasoned and reasonable belief from superstition, theology from rules for pious behaviour or for pious feeling towards objects that may be but fond imaginations

Biblical and Dogmatic Theology. — Only a few words can be added here to what has been already said as to dogmatic and biblical theology, subjects on which the special headings should be consulted. There is, of course, no one theology of the Old Testament. That collection of books, belonging to different times, is constituted a unity by its record of how Hebrew monotheism gradually developed during several centuries. It describes man's groping after God, which, from the theistic point of view, is but the converse side of God's progressive revelation of Himself to man, imparting knowledge of Himself or inspiring the pursuit of religious discovery, not by overriding human faculties but by adaptation or condescension to them. God, as a Christian father expresses it, ever took man as he was, in order to make him what he was not. Thus was gradually reached the lofty and ethical conception of God and His relation to humanity which was presented by the great prophets. The Old Testament contains the history of God's preparation for the reception by humanity of the highest and fullest revelation of Himself in a human personality. The New Testament, again, contains the account of the impression produced by the life and teaching of Christ and the earliest extant interpretations of His Person. The relation of Christ to God came to be formulated in terms of the conception of incarnation; but though incarnation involves an event in "the fulness of time," the Incarnation has been by no means exclusively regarded by Christian doctors as a complete discontinuity or as but contingent on man's need of redemption. From antiquity there have been those who regard the Incarnation, on the one hand, as the last of many stages and, on the other, as part of the eternal counsel of God. The doctrine of the Incarnation and that of the Trinity which is intimately bound up with it are the two dogmas that are most distinctive of the Christian type of theism; and they are the two which for the first five centuries figure most prominently in the development of the church's doctrine. In this connection it is interesting and important to observe that during this constructive period there was a considerable approach, within the church, to that divergence as to philosophical method that has received notice in earlier sections of this article. The school of Alexandria was largely Platonist in its theological conceptions; and, setting forth from the divinity of Christ as—in a sense—a *priori* datum or prior certainty, sought as best it could to account for Christ's human nature and to explain its union with the divine nature in one person. The school of Antioch, on the other hand, was more empirical. It pursued the scientific or historical, rather than the allegorical, method of exegesis of Scripture and, in Christology, it set out from the observed facts about Christ as man, seeking how to conceive of His deity compatibly with them. The Alexandrines cherished the metaphysical concepts of substance, etc., and spoke of the union of the two natures in Christ as "hypostatic"; the Antiochenes preferred to think in terms of the ethical and spoke of a "moral harmony." For better or for worse, the former school exerted the dominating influence in the final and ecumenical formulation of orthodoxy. It transmitted doctrines expressed in terms of philosophical conceptions which the modern mind sometimes evinces a desire to discard or supersede, on the ground that they do not take account of distinctions which, once emergent, cannot be ignored, and otherwise present difficulties which, unsuspected in the past, to-day are felt to be acute.

Returning to the particular dogmas of the Trinity and the Person of Christ, we may observe that in the case of the elaboration of the former of them the search was made for a conception of the Persons of the Triune God such as should avoid the implication that God is a divine society of several individuals and also the implication that the Persons are merely temporal roles or modes of God. In other words, the great doctors from Tertullian to Aquinas who have expounded Trinitarian doctrine were feeling for a mode of being intermediate between what can be denoted by a noun and what can be denoted by an adjective, such as an attribute or a relation. Since human experience knows of no such mode of being and the conception of it cannot be elucidated by any analogy, these teachers have recognized that, in the last resort, they were dealing with mystery or with what transcends the limits of the human mind to comprehend or to conceive. And, shrinking more from tritheism than from modalism, they gave to the orthodox formulation of the doctrine of the Trinity a meaning which it is not easy to distinguish in essence from the rigidly monotheistic or monarchian conception of God as undifferentiated, save in respect of possessing a plurality of attributes or relations that are eternal and intrinsic and not merely temporary, as heresiarchs had asserted. On the other hand the doctrine of the Person of Christ which received the consent of the universal church implies that in Christ, as incarnate, there was but one subject—if this term of modern psychology accurately represents what was meant, viz., the Logos or pre-existent Son, and that our Lord's human nature was "impersonal." This would seem to involve a conception of the Trinity somewhat different from that contained in the dogma as just expounded, inasmuch as the Logos is now treated as an agent or subject and yet as distinct from God or the Father. Perhaps it is because of a sense of discrepancy in this connection that recent thought has sometimes manifested a tendency to interpret the Incarnation of the Logos in terms of the notion of divine immanence in a human personality. From this point of view, "God was in Christ . . ." would better express the Incarnation doctrine than "The Word became flesh." But the translation of these two fundamental Christian doctrines into terms of conceptions such as are serviceable in psychology and theology at the present day has not yet been accomplished.

THEON, AELIUS, Alexandrian sophist of uncertain date, was author of a collection of *progymnasmata* (preliminary exercises) for the training of orators. The work, which probably formed an appendix to a manual of rhetoric, shows learning and taste, and contains valuable notices on the style and speeches of the masters of Attic oratory.

Theon also wrote commentaries on Xenophon, Isocrates and Demosthenes and a treatise on syntax. He is to be distinguished from the grammarian Theon, who lived in the time of Augustus and also wrote on rhetoric.

THEOPHANES, surnamed "the Confessor" (c. A.D. 758–818), Greek ascetic, chronicler and'saint, belonged to a noble and wealthy family and held several offices under Constantine V. Copronymus (741–775). He subsequently founded a monastery (τοῦ Μεγάλου 'Αγροῦ) near Sigriane. He took a strong position against the iconoclastic policy of Leo V and was imprisoned in Samothraee, where he died (818). He subsequently received the honours of canonization. He continued the Chronicle of George the Syncellus from the accession of Diocletian to the downfall of Michael I, Rhangabes (284–813). The work, although wanting in chronological accuracy, is of great value as supplying the accounts of lost authorities.

There is also extant a further continuation, ,in six books, of the *Chronicle* down to the year 961 by a number of mostly anonymous writers (called Oi μετὰ Θεοφάνην, *Scriptores post Theophanem*), who worked by the instructions of Constantine Porphyrogenitus.

THEOPHANO (d. 991), Holy Roman empress. That Theophano w s a Byzantine princess is accepted, but there is no agreement about her parentage. Some historians make her the daughter of the emperor Romanus II and Theophano, who had been an innkeeper's daughter. Others maintain that it is only certain that she was the niece of John Tzimisces, who assassinated the emperor Nicephorus II in 969 and became emperor himself.

Whatever her parentage, the princess Theophano rose to the position of imperator if one document so signed by her is proof positive. After the death of Romanus II, whom Theophano the elder was suspected of poisoning, the Holy Roman emperor Otto I, who had attacked the Byzantine possessions in Italy, proposed a marriage between the young princess and his heir, Otto. But this alliance was not favoured by the new Byzantine emperor Nicephorus Phocas, who had married the elder Theophano. It was only after the accession of John Tzimisces that the young princess's wedding was finally arranged, and the ceremony took place with much pomp in Rome in 972. Rich estates were assigned to Theophano.

In 973 she was present at the last diet presided over by Otto I before his sudden death. In the first years of Otto II's reign, Theophano's influence was overshadowed by that of her mother-in-law, the powerful Adelaide (Adelheid), but as Adelaide became estranged from her son, Theophano rose in power. She had four children: three daughters and one son, Otto, born in 980. Shortly after the birth of Otto, Theophano accompanied her husband during his campaign in Italy, which ended in a severe defeat caused by an alliance between the Arabs and the emperor of Byzantium, Basil II. While preparing a fresh campaign in Italy, and after he had arranged the election of his three-year-old son as German king, the emperor suddenly died in Rome (983). A rebellion broke out in Germany, led by Otto's cousin, Henry the Quarrelsome, duke of Bavaria. In 984 the child king was handed over to the two empresses and to his aunt, Mathilde, abbess of Quedlinburg.

Theophano ruled as empress with great success and wisdom. The education of her gifted young son she entrusted to Saxons. Her daughters were educated in the great imperial abbeys, and two, Adelaide and Sophie, became abbesses, of Quedlinburg and of Gandersheim respectively. At Easter in 991 Theophano held a diet at Quedlinburg, but, while traveling in the interests of the imperial government, died suddenly at Nijmegen on the following June 15. She was buried at Cologne, in the church of St. Pantaleon, whose relics had been the most precious part of her dowry. She was succeeded by her mother-in-law, yet only as regent, without the full authority exercised by Theophano.

In her short reign Theophano was an energetic ruler under incomparable difficulties. The manuscripts she donated to those churches and cloisters she especially favoured testify to her culture and piety.

THÉOPHILE, the name by which Théophile de Viau (or Viaud), French poet (1591–1626), is more commonly called. He was born in 1591, at Clairac, near Agen, and was educated at the Protestant college of Saumur. In 1612 he met Balzac, with whom he made an expedition to the Netherlands, which ended in a serious quarrel. On his return he seems to have been for two years a regular playwright to the actors at the Hôtel de Bourgogne.

In 1615 he attached himself to Henry, duke of Montmorency (1595–1632), under whose protection he produced the tragedy of *Pyrame et Thisbé*, acted probably about 1617. This piece, written in the extravagant Spanish-Italian manner, was ridiculed by Boileau (preface to his *Œuvres,* 1701). Théophile was a Huguenot and a freethinker, and had made unsparing use of his sharp wit in epigrams on the church and on the government. In 1619 he was banished from Paris, but was allowed to return in the next year. He then served in that year in the campaign against the Huguenots, but in the autumn was an exile in England. He was recalled in 1621, and abjured Protestantism in 1622. In 1622 he had contributed four pieces to the *Nouveau Parnasse Satirique,* a miscellany of verse by many hands. In the next year a new edition appeared, with the addition of some licentious verse, and the inscription *par le siew Théophile* on the title page. Contemporary opinion justified Théophile's denial of this ascription, but the Jesuit father, François Garasse. published a tract against him entitled La *Doctrine curieuse* (1623). Théophile was again prosecuted. This time he fled from Paris, to the court of Montmorency, and was condemned in his absence (Aug. 19, 1623) to death. On his flight to the border he was arrested, and imprisoned in the conciergerie in Paris.

Théophile defended himself in an *Apologie au roi* (1625), and was liberated in September, his sentence being commuted to banishment for life. Under Montmorency's protection he hid in Paris for some time, and subsequently accompanied his friend and patron to the south.

He died in Paris on Sept. 25, 1626.

Forty-two pamphlets on the prosecution of Théophile, written between the dates 1622 and 1626, are preserved in the Bibliothèque Nationale in Paris. The standard modern edition of the works of Théophile is that of Alleaume in the *Bibliothèque Elzévirienne* (2 vol., 1856). Besides *Pyrame et Thisbé,* his works include a paraphrase. half verse, half prose. of the *Phaedo.* There are numerous French and Latin letters, his *Apologie,* a promising fragment of comic prose narrative and a large collection of occasional verses, odes, elegies, stanzas, etc.

THEOPHILUS, SAINT, bishop of Antioch about A.D. 180 (his chronological sketch of the history of the world ends with the death of Marcus Aurelius in that year), is known from his three apologetic treatises *To Autolycus*, preserved in a single 11th-century Greek manuscript. The first deals with Christian faith in God and in the resurrection of the dead: it may be based on catechetical instructions. The second contains theological criticism of Greek religion, philosophy and poetry, followed by a "typological" commentary on Gen. i. 1–iii, 19. The third attacks pagan writers and "proves" that Christian teaching is both better and older than that of all other peoples.

Theophilus tried to create a theology by interpreting the Bible (especially the Old Testament) in relation to contemporary rhetoric and eclectic philosophy. He gives extensive quotations from Hellenistic anthologies of poetry and philosophy, as well as from the Jewish *Sibylline Oracles.* Theophilus is the first Christian known who defined faith as necessary in any human activity (i. 8; *cf.* Cicero. *Lucull.* 109); the first to use Skeptical "modes" in attacking pagan religion; and the first to speak of the dignity of man (ii, 1) He is the earliest writer who mentions the inspiration of New Testament writings (iii, 12; *cf.* ii, 22), the triad of God, his Word and his Wisdom (though with man they form a tetrad; ii, 15). and the (Stoic-Philonic) immanent and expressed Word of God (ii, 10, 22; *see* LOGOS).

Theophilus emphasizes man's free will and his duty to keep God's law; thus he stands between the older Jewish Christianity and Greek patristic thought. Theophilus influenced Irenaeus, Tertullian and Novatian, but was later forgotten.

Nothing is known of his life. though in the 4th century he was mentioned by Lactantius and by Eusebius. His work was first published by Johannes Frisius in 1546. The best edition is that of J. C. T. Otto (1861). (R. McQ. G.)

THEOPHILUS, East Roman emperor (829–842), the second of the Phrygian dynasty, a pronounced iconoclast. In 832 he issued an edict strictly forbidding the worship of images. His whole reign was occupied in war against the caliphs of Baghdad. *(See* CALIPHATE. *The Abbasid Caliphs.)* This war mas caused by Theophilus, who afforded an asylum to a number of Persian refugees. The Roman arms were at first successful; in 837 Samosata and Zibatra (Zapetra, Sozopetra). the birthplace of al-hlu'tasim, were taken and destroyed. Eager for revenge. al-Mu'tasim assembled a vast army, one division of which defeated Theophilus, who commanded in person, at Dasymon, while the other advanced against Amorium, the cradle of the Phrygian dynasty. After a brave resistance the city fell into al-Mu'tasim's hands through treachery. Thirty thousand of the inhabitants mere slain, and the city razed to the ground.

Theophilus never recovered from the blow, and he died at the beginning of 842.

THEOPHILUS (THEODORE NICHOLAS PASHKOVSKY) (1874–1950), primate of the Russian Orthodox Greek Catholic Church of America from 1934 to 1950, was born in Kiev province. Russia, on Feb. 19, 1874, and received his early theological training there.

Moving to the United States in 1897, he was ordained to the priesthood in San Francisco the same year. While in San Francisco, he founded that city's Russian Orthodox cathedral in 1909, replacing an older church destroyed in the great earthquake of 1906.

In 1913 Pashkovsky was transferred to Warsaw, Poland, and when World War I broke out he served with the imperial Russian army as a chaplain. Caught in the Russian Communist revolution, he had difficulty leaving the Soviet Union; but in 1922. upon being named bishop of Chicago, he returned to the United States to take up his new duties. Transferred to San Francisco in 1931, he was made presiding bishop of the Pacific coast in 1934. Later that year he was elected metropolitan archbishop of the United States and Canada.

One of the problems which faced Theophilus during his primacy was the question of whether the North American Russian Orthodox Church should reunite with the mother church in Moscow. In 1945 the American bishops voted for such a reunion, but three years of negotiations led nowhere. In 1948 the bishops reversed their stand and declared their independent status. The soviet news agency then reported that Theophilus was to be tried by the Russian Orthodox Church in the U.S.S.R. for "attempts to split the church." The trial was held *in absentia,* when the American metropolitan refused to attend.

Theophilus died in San Francisco on June 27, 1950.

THEOPHILUS (THEOPHILUS PRESBYTER, sometimes identified with ROGERUS VON HELMERSHAUSEN) *(c.* 1100), author of the *Schedula diversarum artium,* an important treatise on medieval arts, particularly that of the goldsmith. He assumed the name "Rugerus" and may have been a Greek monk who after traveling extensively in Europe settled in a Benedictine monastery at Helmershausen, near Paderborn. The *Schedula* includes a prologue treating the fall of man and the beginning of labour. The text is in three parts: book i, painting; book ii, glass windows; and book iii, metalwork from furnaces to liturgical objects. Also included are directions for niello *(q v.),* the use of precious stones, bell casting, ivory working and organ making. Many of the techniques described in the *Schedula* may be found on such 12th-century works as the portable altars of Baderborn cathedral. In spite of occasional details of alchemy and superstition, the explicitness and accuracy of the instructions suggest that Theophilus, if not a practising craftsman, was a shrewd observer.

His own Latin manuscript of the *Schedula* disappeared but numerous copies survived, such as the Codex Vidobonensis no. 2527 (Nationalbibliothek, Vienna), the Codex Gudianus no. 69 (Herzog-August Bibliothek, Wolfenbüttel) and the Codex Harleianus no. 3915 (British museum). Various translations exist in French, German and English (R. Hendrie, 1847).

THEOPHRASTUS (371/370–288/287 B.C.), Greek Peripatetic philosopher, was born at Eresus on the island of Lesbos and went to Athens to study under Aristotle. The latter designated him as head of his school, the Peripatos, when he himself retired to Chalcis (322/21). It was under Theophrastus that the Peripatetic school was frequented by the highest number of pupils and auditors.

Apart from Eudemos of Rhodes, Theophrastus was the only Peripatetic who embraced Aristotle's philosophy to its full extent—metaphysics, physics, physiology, zoology, botany, ethics, politics, the history of culture, etc. His general tendency was to strengthen the systematic unity of those subjects and to reduce the transcendental or Platonic elements of the whole doctrine.

Little has been preserved of Theophrastus' works. The principal remains are nine books *On the History of Plants* and six *On the Causes of Plants.* Smaller treatises extant under his name deal with fire, winds, signs of weather, scents, sensations and other subjects; but their authenticity is in part contestable. The famous *Characters* consists of brief and vigorous delineations of moral types developed from studies that Aristotle had made for ethical and rhetorical purposes: this is the work on which La Bruyère's masterpiece was based. In his *Ethics,* known from the assaults of the Stoics, Theophrastus distinguished, as Aristotle had done, a plurality of virtues with their relative vices and acknowledged a certain importance to external goods.

Theophrastus' *Doctrines of the Natural Scientists,* as reconstructed by H. Diels in *Doxographi Graeci* (1879; reprinted 1929) provides the foundation of all history of ancient philosophy.

The works of Theophrastus were edited by F. Wimmer (1854–62); the *Characteres,* were edited by H. Diels (1909). There is an English translation of the *Characters* by Sir R. Jebb, with introduction and notes (1870; new ed. by J. E. Sandys, 1909). For the extant fragments of the *Metaphysica* of Theophrastus *see* the edition by W. D. Ross and F. H. Fobes (1929). *See* also references under "Theophrastus" in the Index volume. (F. Wi.)

THEOPHYLACT (d. *c.* 1110), biblical commentator, was born most probably at Euripus, in Euboea, about the middle of the 11th century. He became a deacon at Constantinople, attained a high reputation as a scholar, and became the tutor of Constantine Porphyrogenitus, son of the emperor Michael VII, for whom he wrote *The Education of Princes.* About 1078 he went into Bulgaria as archbishop of Achrida. In his letters he complains much of the rude manners of the Bulgarians, and he sought to be relieved of his office, but apparently without success.

Theophylact's death took place after 1107.

His commentaries on the Gospels, Acts, the Pauline epistles and the Minor Prophets are founded on those of Chrysostom, but deserve the considerable place they hold in exegetical literature for their appositeness, sobriety, accuracy and judiciousness. His other works included 130 letters and various homilies, orations and other minor pieces.

THEOPHYLLINE: *see* PURINES.

THEOPOMPUS OF CHIOS (b. *c.* 380 B.C.), Greek historian and rhetorician, whose *Philippica,* though lost in original, has survived through the work of later writers to form one element in the tradition concerning the reign of Philip II of Macedonia. He was born at Chios and in early youth seems to have spent some time at Athens, along with his father, who had been exiled because of his sympathies with Sparta. There he became a pupil of Isocrates, and rapidly made great progress in rhetoric. According to Cicero, Isocrates used to say that Ephorus required the spur but Theopompus the bridle: he once won a prize for oratory in a contest in which Isocrates himself was taking part. It is said to have been the advice of his teacher that finally determined his career as a historian—a career for which he was peculiarly qualified by his inherited wealth and his wide knowledge of men and places.

Through the influence of Alexander the Great, he was restored to Chios about 333, and figures for some time as one of the leaders of the aristocratic party in his native town. After Alexander's death he was again expelled and took refuge with Ptolemy in Egypt, where he appears to have met with a somewhat cold reception. The date of his death is unknown.

The works of Theopompus were chiefly historical. They included an epitome of Herodotus' *History* (the genuineness of which is doubted), the *Hellenica,* the *Philippica* (history of Philip of Macedon) and several panegyrics and hortatory addresses, the chief of which was the letter to Alexander. The *Hellenica* treated of the history of Greece, in 12 books, from 411 (where Thucydides breaks off) to 394—the date of the battle of Cnidus. Of this work only a few fragments survive: the attribution to it of the important historical fragment known as *Hellenica Oxyrhynchia* or "the Oxyrhynchus historian" (first published by B. P. Grenfell and A. S. Hunt, *The Oxyrhynchus Papyri,* vol. v, no. 842, 1908) did not win acceptance. A far more elaborate work was the *Philippica* in 58 books. In this Theopompus narrated the history of Philip's reign (359–336). His narrative included not only moral and political discussions but also digressions on the names and customs of the various races and countries of which he had occasion to speak, which were so numerous that Philip V of Macedon reduced the bulk of the history from 58 to 16 books by cutting out those parts which had no connection with Macedonia. It was from this history that Pompeius Trogus (of whose *Historiae Philippicae* the epitome by Justin is extant) derived much of his material.

In spite of some extravagance both of style and judgment, examples of which can be seen in the extant fragments, it seems likely that Theopompus was the most interesting and considerable of all the Greek historians who are "lost."

THEORBO, the large double-necked bass lute much used during the 16th and 17th centuries as general bass in the orchestra. The body of the theorbo was constructed on the same principles as that of the lute. The theorbo was made in two sizes, the ordinary instrument measuring about three feet, six inches, and the Paduan, also known as archlute, about five feet.

The chitarrone, or Roman theorbo, was the largest of all, a contrabass lute in fact, and frequently stood more than 6 ft. high. *See* LUTE.

THEORELL, AXEL HUGO TEODOR (1903–), Swedish biochemist and Nobel prize winner, noted for his research on enzymes, was born at Linköping, Swed., on July 6, 1903. After taking his M.D. degree at Stockholm in 1930, he began general practice but an attack of poliomyelitis left him crippled and he decided to devote himself to research. He worked at Uppsala university, 1932–36, and also studied in Germany while holding a Rockefeller fellowship.

In 1934 Theorell produced for the first time in pure form the yellow enzyme which influences combustion in living cells. He later divided the enzyme into two parts, the coenzyme, which acts as a catalyst, and the apoenzyme, which is pure protein, and worked out the chemical chain reaction by which enzymes enable living cells to burn oxygen; that is, to breathe. He also was the first to produce pure myoglobin, the red colouring substance of muscle. He devised a method of blood examination which came to be widely used in Sweden as a test for drunkenness and also discovered an antibiotic called proaptin. These discoveries, however, were overshadowed by his work on enzyme chemistry, and he was awarded the 1955 Nobel prize for medicine for his discoveries concerning the nature and mode of action of oxidation enzymes.

Theorell was appointed director of the biochemical department of the Nobel institute at Stockholm in 1937 and became a member of the Swedish Society for Medical Research and the Swedish Academy of Science in 1942. (W. J. Bp.)

THEOREM, a term used in mathematics to represent a proposition (*q.v.*) which is to be demonstrated. In geometry, a proposition is commonly considered as a problem (a construction to be effected) or a theorem (a statement to be proved). For example, the statement: "If two lines intersect, each pair of vertical angles are equal" is a theorem. The so-called "fundamental theorem" of algebra asserts that every rational integral equation has at least one root. The Greeks also recognized a proposition lying between a theorem and a problem, the porism (*q.v.*).

See BINOMIAL THEOREM, FERMAT'S LAST THEOREM; REMAINDER THEOREM. For related terms see also AXIOM, HYPOTHESIS; POSTULATE.

THEORY has various meanings in ordinary speech and in science. It may be contrasted with practice as unverified speculation. It may be used so as to signify any hypothesis, whether confirmed or not. It may be restricted to hypotheses which have been so strongly confirmed as to become part of the accepted doctrine of a particular science. In its best use, it signifies a systematic account of some field of study, derived from a set of general propositions.

These propositions may be taken as postulates, as in pure mathematics (theory of functions, etc.), or they may be principles more or less strongly confirmed by experience, as in natural science (theory of heat, electromagnetic theory). There may be rival theories in a particular field (*e.g.,* in psychology) differing in their selection of principles, or in the emphasis laid on particular principles. 4s a science develops the part played by deductive theory in it tends to become more and more important. (See HYPOTHESIS.) (L. J. R.)

THEOSOPHY, a term used to denote those forms of philosophic and religious thought which claim a special insight into the Divine nature and its constitutive moments or processes (from Gr. theos, "god," and sophia, "wisdom"). Sometimes this insight is claimed as the result of the operation of some higher faculty or some supernatural revelation to the individual; in other instances the theosophical theory is not based upon any special illumination, but is simply put forward as the deepest speculative wisdom of its author.

In any case it is characteristic of theosophy that it starts with an explication of the Divine essence, and endeavours to deduce the phenomenal universe from the play of forces within the Divine nature itself.

General Theory. — Theosophy is thus differentiated at once from all philosophic systems which attempt to rise from an analysis of phenomena to a knowledge, more or less adequate, of the existence and nature of God. In all such systems, God is the *terminus* ad *quem,* a direct knowledge of whom is not claimed, but who is, as it were, the hypothesis adopted, with varying degrees of certainty in different thinkers, for the explanation of the facts before them. The theosophist, on the other hand, is most at his ease when moving within the circle of the Divine essence, into which he seems to claim absolute insight. This, however, would be insufficient to distinguish theosophy from those systems of philosophy which are sometimes called "speculative" and "absolute," and which also in many cases proceed deductively from the idea of God. In a wide sense the system of Hegel or the system of Spinoza may be cited as examples of what is meant. Both thinkers claim to exhibit the universe as the evolution of the Divine nature; so much is involved, indeed, in the construction of an absolute system But in such systems the known universe — the world of experience — is nowhere transcended; God is really no more than the principle of unity immanent in the whole. Hence, while the accusation of pantheism is frequently brought against these thinkers, the term theosophical is never used in their regard. A theosophical system may also be pantheistic, in tendency if not in intention; but the transcendent character of its Godhead definitely distinguishes it from the speculative philosophies which might otherwise seem to fall under the same definition. An historical survey shows, indeed, that theosophy generally arises in connection with religious needs, and is the expression of religious convictions or aspirations.

Accepting the testimony of religion that the present world lies in wickedness and imperfection, theosophy faces the problem of speculatively accounting for this state of things from the nature of the Godhead itself. It is thus in some sort a mystical philosophy of the existence of evil; or at least it assumes this form in some of its most typical representatives. The term Mysticism (*q.v.*) has properly a practical rather than a speculative reference; hut it is currently applied so as to include the systems of thought on which practical mysticism was based. Thus. to take only one prominent example, the profound speculations of Meister Eckhart (see ECRHART) are always treated under the head of Mysticism, but they might with equal right appear under the rubric Theosophy. In other words. while an emotional and practical mysticism may exist without attempting philosophically to explain itself, speculative mysticism is in current usage almost another name for theosophy.

In the above acceptation of the term, the neoplatonic doctrine of emanations from the supra-essential One, the fanciful emanation-doctrine of some of the gnostics (the aeons of the Valentinian system, for example), and the elaborate esoteric system of the Kabbalah, to which the two former in all probability largely contributed, are generally included under the head of theosophy. In the two latter instances there may be noted the allegorical interpretation of traditional doctrines and sacred writings which is a common characteristic of theosophical writers. Still more typical examples of theosophy are furnished by the mystical system of Meister Eckhart and the doctrine of Jakob Boehme (see BOHME. JAKOB), who is known as "the theosophist" *par excellence.* Eckhart's doctrine asserts behind God a predicateless Godhead. which, though unknowable not only to man hut also to itself. is. as it were, the essence or potentiality of all things. From it proceed. and in it exist, the three persons of the Trinity, conceived as stadia of an external self-revealing process. The eternal generation of the Son is for Eckhart equivalent to the eternal creation of the world. But the sensuous and phenomenal, as such, so far as they seem to imply independence of God, are mere privation and nothingness; things exist only through the presence of God in them, and the goal of creation, like its outset, is the repose of the Godhead. The soul of man, which as a microcosmos resumes the nature of things, strives by self-abnegation or self-annihilation to attain this unspeakable reunion (which Eckhart calls being "buried" in God). Regarding evil simply as privation, Eckhart does not make it the pivot of his thought as was afterward done by Boehme; but his notion of the Godhead as a dark and formless essence is a favourite thesis of theosophy.

Boehme was indebted not only to mystical theology but also to the writings of Paracelsus. This circumstance is not accidental, but points to an affinity in thought. The nature-philosophers of the Renaissance, such as Nicolaus Cusanus, Paracelsus, Cardan and others, curiously blend scientific ideas with speculative notions derived from scholastic theology, from neoplatonism and even from the Kabbalah. Hence it is customary to speak of their theories as a mixture of theosophy and physics, or theosophy and chemistry, as the case may be. Boehme offers us a natural philosophy of the same sort. As modern theosophy has nourished itself almost in every case upon the study of his works, his dominating conceptions supply us with the best illustration of the general trend of this mode of thought. His speculation turns, as has been said, upon the necessity of reconciling the existence and the might of evil with the existence of an all-embracing and all-powerful God, without falling into Manichaeism on the one hand, or, on the other, into a naturalistic pantheism that denies the reality of the distinction between good and evil. He faces the difficulty boldly, and the eternal conflict between the two may be said to furnish him with the ground-principle of his philosophy. It is in this connection that he insists on the necessity of the Nay to the Yea, of the negative to the positive. Eckhart's Godhead appears in Boehme as the abyss, the eternal nothing, the essenceless quiet (*Ungrund* and *Stille ohne Wesen* are two of Boehme's phrases). But, if this were all, the Divine Being would remain an abyss dark even to itself. In God, however, as the condition of His manifestation, lies, according to

Boehme, the "eternal nature" or the *mysterium magnum*, which is as anger to love, as darkness to light, and. in general, as the negative to the positive. This principle (which Boehme often calls the evil in God) illuminates both sides of the antithesis, and thus contains the possibility of their real existence. By the "Qual" or torture, as it were, of this diremption, the universe has qualitative existence, and is knowable. Even the three persons of the Trinity, though existing *idealiter* beforehand, attain reality only through this principle of nature in God, which is hence spoken of as their *matrix*. It forms also the matter, as it were, out of which the world is created; without the dark and fiery principle, we are told, there would be no creature. Hence God is sometimes spoken of as the father, and the eternal nature as the mother, of things. Creation (which is conceived as an eternal process) begins with the creation of the angels. The subsequent fall of Lucifer is explained as his surrender of himself to the principle of nature, instead of dwelling in the heart of God. He sought to make anger predominate over love; and he had his will, becoming prince of hell, the kingdom of God's anger, which still remains, however, an integral part of the Divine universe.

Schelling's *Philosophical Inquiries Into the Nature of Human Freedom (1809)* is almost entirely a reproduction of Boehme's ideas, and forms, along with Baader's writings, the best modern example of theosophical speculation. In his philosophy of identity Schelling (*q.v.*) had already defined the Absolute as pure indifference, or the identity of subject and object, but without advancing further into theogony. He now proceeded to distinguish three moments in God, the first of which is the pure indifference which, in a sense, precedes all existence—the primal basis or abyss, as he calls it, in agreement with Boehme. But, as there is nothing before or besides God, God must have the ground or cause of His existence in Himself. This is the second moment, called nature in God, distinguishable from God, but inseparable from Him. It is that in God which is not God Himself, it is the yearning of the eternal One to give birth to itself. This yearning is a dumb unintelligent longing, which moves like a heaving sea in obedience to some dark and indefinite law, and is powerless to fashion anything in permanence. But in correspondence to the first stirring of the Divine existence there awakes in God Himself an inner reflective perception, by means of which—since no object is possible for it but God—God beholds Himself in His own image. In this, God is for the first time as it were realized, although as yet only within Himself. This perception combines, as understanding, with the primal yearning, which becomes thereby free creative will, and works formatively in the originally lawless nature or ground. In this wise is created the world as we know it. In every natural existence there are, therefore, two principles to be distinguished: first, the dark principle, through which the being in question is separated from God, and exists, as it were, in the mere ground; and, second, the Divine principle of understanding. The first is the particular will of the creature, the second is the universal will. In irrational creatures the particular will or greed of the individual is controlled by external forces, and thus used as an instrument of the universal. But in man the two principles are consciously present together, not, however, in inseparable union, as they are in God, but with the possibility of separation. This possibility of separation is the possibility of good and evil. In Boehme's spirit, Schelling defended his idea of God as the only way of vindicating for God the consciousness which naturalism denies, and which ordinary theism emptily asserts. Among thinkers on the same lines, but more or less independent, Molitor is perhaps the most important. Swedenborg (*q.v.*) is usually reckoned among the theosophists.

THE THEOSOPHICAL SOCIETY

The term theosophy in later years obtained a wide currency in certain circles as denominating the beliefs and teachings of the Theosophical society. This society was founded in the United States in 1875 by Madame H. P. Blavatsky (*q.v.*), in connection with Col. H. S. Olcott and others. Colonel Olcott remained president of the original society till his death in 1907, when he was succeeded by Mrs. Annie Besant. But soon after the death of Madame Blavatsky (1891) a split took place which led to the formation of a separate organization in America under the leadership of William P. Judge.

The main objects of this society, as originally propounded, were:

1. To establish a nucleus of the universal brotherhood of humanity.
2. To promote the study of comparative religion and philosophy.
3. To make a systematic investigation into the mystic potencies of life and matter, or what is usually termed occultism.

Mahatmas.—According to Madame Blavatsky's original statements, this wisdom has been transmitted through the ages as a secret doctrine or esoteric teaching by a brotherhood of adepts or mahatmas scattered through the world but in close relation with one another. With a certain group of these in Tibet she claimed to be in communication. In such adepts the spiritual nature is supposed to have been so developed that the body has become the ductile instrument of the intelligence and they have thus gained a control over natural forces which enables them to bring about results that appear to be miraculous.

Religious Aspect.—The most characteristic feature of this modern "theosophical" teaching is the belief in reincarnation, and here again the close connection with Indian thought is observable. The succession of earthly lives through which the spirit advances to its goal is interpreted in strict accordance with the Brahmanic and Buddhistic doctrine of karma. First introduced in the Upanishads as the great secret which solves the problem of human destiny, karma is in a sense the logical origin of all Indian thought. It expresses the inexorable law of moral causation—whatsoever a man soweth that shall he also reap—and this law is represented as fulfilling itself in the life history of each individual agent. The consequences of a man's actions in his present life are reaped by the agent on earth in a fresh incarnation. Hence the saying, "A man is born into the world he has made." The theory of karma is thus primarily an explanation of a man's lot in the present life as determined by his own actions in a series of previous lives. If it is true that whatsoever a man soweth that shall he also reap, it must be equally true that whatsoever a man reaps that he must also have sown.

The doctrine is thus in its essence a vindication of cosmic justice in face of the perplexities caused by the apparent disregard of moral considerations in the distribution of happiness and misery in the present life. and it is in this sense that it is accepted and applied, by theosophists. (A. S. P.-P.)

THEOT, CATHERINE (d. 1794), French visionary, was born at Barenton, Manche. She was from her youth a victim of hallucinations, and after a long course of religious asceticism in the convent of the hliramiones in Paris she was placed under restraint. After she was liberated in *1782*, her early delusions concerning a Messiah became accentuated; she was assured that she was destined to be the mother of the new Messiah, and pictured to her followers the fantastic features of the coming paradise on earth.

From the idea of the advent of a Messiah to its realization was but a step, and in Robespierre the Théotists saw the redeemer of mankind. The enemies of Robespierre, resenting his theocratic aims, seized upon his relations with the Théotists. Catherine, with others, was arrested and imprisoned, and a letter to Robespierre was discovered in her house.

In the Convention M. G. A. Vadier trumped up the conspiracy of Théot, asserting that Catherine was a tool of Pitt, that the mummeries of the Théotists were but a cloak for clerical and reactionary intrigue, and hinting that Robespierre favoured their designs. The case was adjourned to the revolutionary tribunal, and figured in the proceedings of the 9th Thermidor. The accused were ultimately acquitted, but Catherine herself died in prison on Sept. 1, 1794.

THEOTOCOPULI, DOMENICO: *see* GRECO, EL.

THERA, the southernmost island of the Sporades. After the fourth crusade, when it became part of the duchy of the Archipelago, and until recent times, it was known as Santorin (*q.v.*).

THERALITE, in petrology, a group of plutonic rocks built up of basic plagioclase (labradorite), nepheline and a titaniferous augite. The name is derived from the Greek *theran*, "to pursue," since it was believed that its discovery would complete the series of basic rocks containing nepheline as an essential constituent They are classified in the nephelite-tephrite group in this series (see NEPHELINITE.)

Olivine, an alkali-amphibole, biotite and orthoclase may be present as subordinate constituents. With the exception of nepheline and orthoclase, the minerals of theralites are usually in well-shaped crystals. Nepheline itself may be largely represented by secondary zeolites.

Theralites are of comparatively rare occurrence. They are found in Bohemia in association with shonkinite, in Odenwald (Mt. Katzenbuckel) Ger.. together with pulaskite and foyaite in the Serra de Monchique, Port., in the Kola peninsula, U.S S.R. and among the Carboniferous intrusions of Ayrshire. Scot.

Closely related to the theralites are the teschenites (from Teschen, Czech.). In place of nepheline these rocks contain primary analcime, but types containing both nepheline and analcime are known. In central Scotland, around Edinburgh and Glasgow, teschenites are abundant, forming thick sills intrusive into the Carboniferous rocks. Teschenites are sometimes ophitic, *i.e.*, with augite enclosing crystals of plagioclase, and show transitions to olivine-dolerite on the one hand and to picrite on the other.

The rock known as lugarite (from Lugar, Ayrshire) is a related type containing small amounts of plagioclase but abundant analcime; nepheline is present in subordinate amounts.

Other rocks related to the theralites are the essexites and shonkinites. The former are characterized by dominant plagioclase, subordinate orthoclase, and green augite, hornblende, biotite and olivine. Nepheline also occurs commonly. By an increase in the proportion of nepheline the essexites pass into theralites. Essexites occur, together with nepheline-syenite, in Essex county, Mass., at Mt. Royal near Montreal, in southern Norway (Oslo district), at Rongstock, Czech., and among the Carboniferous teschenites of Scotland near Edinburgh and in the Campsie fells (hills), Stirlingshire. The shonkinites are dark-coloured, igneous rocks of much rarer occurrence. Augite and orthoclase are the prime constituents, but plagioclase, barkevikite, olivine, biotite and variable amounts of nepheline are present.

At Shonkin sag, in the Highwood mountains of Montana, shonkinite forms the greater part of a stratified laccolith passing at the border into a peculiar basic rock described as a leucite-basalt porphyry.

Shonkinites are also found in Ontario, British Columbia and Indonesia (Celebes. Timor). (C. E. T.; X.)

THERAMENES (d. 403 B.C.), Athenian statesman, was the adopted son of Hagnon, a prominent conservative who in 430 impeached Pericles, and after the Sicilian expedition became one of the ten pro*buli* (πρόβουλοι, commissioners) appointed to devise economies in the administration. As a pupil of the sophist Prodicus he acquired facility in public speaking. Under his father's patronage he joined in the conservative reaction which came to a head in 411, when hopes of a Persian alliance or peace with Sparta strengthened the existing dissatisfaction with the democratic rule. Theramenes specially studied the constitutional side of this movement and formulated a new party cry, "the constitution of our fathers."

It was no doubt largely due to his advocacy that the *probuli*, strengthened by additional members, were commissioned to draft new measures on behalf of the public safety and to examine the "ancestral code" of the noted Athenian statesman Cleisthenes. In their report the following measures were recommended: annulment of the act against promulgating illegal measures; abolition of pay, excepting the troops in the field and the archons (chief magistrates of Athens); restriction of the franchise to 5,000 able to serve "with person and purse"; and the appointment of a special board to choose the specified 5,000. When these proposals were passed (apparently in a packed assembly outside the walls), a constituent assembly of 100 was elected—nominally by the 5,000, who as yet were a mere phantom body, but in point of fact by the leading conspirators.

The new constitution provided for a boule whose members were to be recruited by lot from all citizens over 30; the functions of this body were to be exercised by four sections succeeding one another by yearly rotation and serving without pay; and all high officials were to be chosen by the boule out of its own members. This scheme embodied the chief reforms desired by Theramenes, and marked the triumph of his policy. Before it could be carried into effect, however, it was superseded by a "provisional constitution," which gave unlimited power to a boule of 400 (chosen by a roundabout system which favoured intrigue) and its nominees, the ten "absolute" generals. This extreme reaction displeased Theramenes, who in retaliation began to agitate for the calling of the 5,000 into real existence. Furthermore, he warned Athens against the treason of the extreme oligarchs, and induced the troops to raze a mole erected to facilitate a Spartan descent on Peiraeeus.

After the disaster of Eretrea, which caused the fall of the extremists and the institution of a government of "5,000" (*i.e.*, all citizens who could afford a suit of armour), Theramenes stood in high esteem (*see* PELOPONNESIAN WAR). After assisting in the prosecution of his former colleagues, he received the command of a squadron with which he helped to win the great victory at Cyzicus (410) and to recover the Bosporus.

After the triumph of the radical democrats which followed upon these successes he lost his high command. At Arginusae (406), he fought as a simple ship's captain. Following the battle, however, he was favoured by the generals with a commission to rescue some drowning crews—an order which proved impossible to execute with his ill-trained and exhausted troops in a heavy storm. The generals were severely criticized at Athens for this failure and an inquiry by the boule led to their arrest. While before the ecclesia they weakened their case by pleading the conflicting points that, on the one hand, the storm had made a rescue impossible and that, on the other hand, Theramenes was to blame. Theramenes in reply brought out the implied contradiction in these statements. and he was subsequently reinstated as general while the assembly condemned the accused generals to death.

Late in 40j Theramenes went as plenipotentiary to Lysander (*q.v.*) to obtain peace terms; after long negotiations he proceeded to Sparta and arranged a settlement which the Athenians ratified in April 404. In spite of this peace the disorder in Athens did not abate. The restored fugitives selected five ephors (title of the highest magistrates of Sparta), including Critias, to organize a revolution, while the radicals opposed that return to the "ancestral constitution" for which Theramenes had stipulated. At this point Lysander returned to Athens and had a constituent committee elected, of whom ten members were nominees of each section. In this body Theramenes at first assumed the chief role, and the new measures rescinding the laws against the Areopagus (the supreme tribunal of Athens) and suppressing sycophancy were well received. However, exactly as in 411, a more violent party under Critias, ignoring its real duties, appointed an autocratic boule of its own supporters, and proceeded by judicial murders and confiscations to earn for the new government the name of "the Thirty Tyrants."

Theramenes protested, and managed to have a citizen-body of 3,000 admitted to a share of the government. Critias, however, fearing a renewal of the collapse of 411, disarmed the people and decided to remove Theramenes before he could create a new democratic party. The latter successfully repelled Critias' denunciation of treason, but was later led away by violence and forced to take poison. His well-known gibe, "Here's to the noble Critias," evidenced his strength of mind at the hour of death.

Theramenes demonstrably had a definite policy throughout his career. His ideal was a return to a 6th-century constitution, which his contemporaries could equally regard as a moderate oligarchy or a restricted democracy. The main features of his plan included property qualifications for franchise, abolition of pay and transference of some judicial powers from the popular courts to a restored Areopagus.

At times he seemed likely to succeed, but amid the violent oscillations of parties he could not definitely join with any one faction, and so earned the nickname Κόθορνος (a stage-boot fitting either foot). Aristotle, however, discerned Theramenes' real policy and, like Cicero and Caesar, in later years ranked him among the greatest Athenian statesmen.

THERAPEUTAE, an ancient sect of ascetics believed to have lived in the vicinity of Alexandria and near Lake Mareotis. They are mentioned in *De Vita Contemplativa,* attributed to the Jewish philosopher Philo (*q.v.*), which is the sole original account of the community, and they are characterized as being unusually severe in their discipline and mode of life.

According to *De Vita Contemplativa,* on joining the order a man died to the world, and so voluntarily resigned his property to his heirs. How the order itself was supported is not reported. So far as the reader is informed, prayer and study were the sole occupations of the Therapeutae. The community at Alexandria lived in mean and scattered houses, near enough to afford protection, without depriving the members of the solitude which they so valued. Each of these houses contained a chamber which was devoted to prayer and study, and into which the inmate brought nothing but the Law and the Prophets, together with the Psalms and other works which tended to the promotion of piety. At sunrise the Therapeutae prayed and again at sunset. The whole interval was devoted to a study of the internal sense of the Scriptures.

In addition to the Old Testament, the Therapeutae had books by the founders of their sect on the allegorical method of interpreting Scripture. They also contributed to sacred literature themselves in the composition of new psalms. Attendance to the ordinary needs of nature was entirely relegated to the hours of darkness. Some of these recluses ate only every second day, while others succeeded in confining the necessity for food to a single weekday. But the Sabbath was a feast on which, after attending to their souls, they indulged their bodies. But their indulgence even then did not exceed coarse bread, flavoured with salt and sometimes hyssop, and a drink of spring water. Thus during the six days of the week the Therapeutae "philosophized," each in his own cell, but on the Sabbath they met in a common assembly, where women also had places screened off from the men. and listened to a discourse from one who was the eldest and most skilled in their doctrines.

The sober celebrations of the Therapeutae on the eve of the feast of Pentecost are described. They assembled together with glad faces and in white garments, and the proceedings were begun with prayers; they stood with eyes lifted and hands stretched to heaven. After taking seats according to the order of their admission, all listened devoutly to a discourse by the president, followed by the singing of ancient and modern hymns. Then came a meal of the simple type already described. And after this a pervigilium, celebrated with antiphonal and joint singing by the men and women and with choral dancing in imitation of Moses and Miriam at the Red sea. At sunrise. turning to the east, they prayed that the light of truth might illumine their minds, and then returned to their studies. Such is the account of the Therapeutae given in De *Vita Contemplativa.*

As the result of *De Vita Contemplativa* being the only authority regarding the life and existence of the Therapeutae, a number of controversial questions concerning the sect arose. Some authorities regard the Therapeutae as a Christian order because of the similarity between their asceticism and that of Christian monasticism, but the consensus among modern scholars is that they were a radical offshoot of pre-Christian Judaism. The supposition that the Therapeutae were a branch of the Essenes was contested by A. von Harnack. While these two ascetic sects resembled each other in many instances and especially in discipline, the Therapeutae regulations were more severe.

To the modern reader the importance of the Therapeutae, as of the Essenes, lies in the evidence they afford of the existence of the monastic system long before the Christian era. No clue is given to the origin of the Therapeutae, but it is plain that they were already ancient when described in *De Vita Contemplativa.* Eusebius was so much struck by the likeness of the Therapeutae to the Christian monks of his own day as to claim that they were Christians converted by the preaching of St. Mark. He goes so far as to say that "the writings of ancient men. who were the founders of the sect" referred to by *De Vita Contemplativa,* may very well have been the Gospels and Epistles (which were not yet written). Eusebius having gone wrong on this point, others of the Fathers followed suit, so that Philo was reckoned by Jerome among the ecclesiastical writers of the Christians.

It is likely that Christianity gained adherents among the Therapeutae, and that their institutions were adapted to the new religion, just as they seem to have been borrowed by the Jews from the Egyptians.

THERAPEUTICS is the science and art of healing. The term also includes the use of drugs and other measures to prevent disease. Thus therapeutics is related to both therapy and treatment.

Types.—The scope of therapeutics is evident when the types of therapy are considered. Included are biologic therapy, which involves the use of biologic products such as serums. vaccines and antitoxins; chemotherapy, the use of specific pure chemicals to attack specific diseases; cold therapy, the use of cold objects such as ice; collapse therapy, the collapsing of an organ such as of the lung to combat tuberculosis; diathermic therapy, the use of diathermy equipment; electroshock therapy, the treatment of a patient with mental disease by passing an electrical current through the brain; endocrine or glandular therapy, the use of hormones or endocrines or secretions from glands (these may be extracted from glands or made synthetically); fever therapy, the treatment of disease by inducing a high fever in the body; heat therapy; insulin shock therapy; oxygen therapy; and radium and X-ray therapy. There are other forms of therapy but their names are usually self-explanatory and they are more or less specific in their approach, for example, gold therapy, vaccine therapy, musical therapy and physical therapy.

Practically any drug or treatment measure can be introduced and a name applied to it to describe it. Or, from another approach, practically any part of the body can be treated and the procedure called a form of therapeutics, *e.g.,* dental therapeutics or alimentary therapeutics (pertaining to the digestive tract, the stomach and intestines or bowel). Also, therapeutics may be specific or nonspecific, and it may be rational and irrational (the latter form usually employed by quacks).

Development.—At the turn of the 20th century there were only a few drugs and other measures of outstanding importance, and some of these were improperly understood. Most doctors knew the value of sun, fresh air, fresh fruit and some pain-relieving substances. but little was known of the precise way in which they served man. Furthermore, while surgery was a useful part of medical practice it was formerly fraught with danger because of the lack of satisfactory antiseptic measures. satisfactory anaesthetics and specific aids to combat shock, loss of blood and infections. It is probably safe to say that modern therapeutics really followed World War I although the foundation for its development was laid in earlier years by the work of such men as Paul Ehrlich, Robert Koch and others.

The application of measures to prevent disease and to cure those suffering from it goes back to the early history of man when someone tried to apply leaves, mud and splints and invoked blessings from the gods. Primitive man feared the unknown and attributed sickness to the displeasure of his gods or to some other factor. As he learned by trial and error the value of a few simple remedies he began the practice of medicine, although this in time fell into the hands of tribal medicine men, many of whom mere crafty and also influential because of their self-claimed mystic powers. Since many of early man's actions were based on superstitious beliefs, strange and fascinating influences were attributed to rocks, trees. clouds, rivers and other objects which man could see but could not understand. Then in time he recognized the unusual properties of animals and bushes and flowers and attributed to them life-saying value. For example, because the lion is brave, man believed that eating the heart of this animal would make him brave; because the fox can run for a long time he believed eating the lungs of a fox would make him long-winded; and because the bear is strong he thought this animal could impart to him unusual strength.

Such beliefs were largely based on ignorance, on which of course much superstition is founded. From time to time an element of truth was discovered in these practices but it took countless years to determine that fact. Man had to pass to civilized ages before he found much of therapeutic value in plants, animals and minerals. In later centuries accidental discoveries, keen observations and careful study resulted in some useful findings. For example, the value of quinine for malaria was discovered by an explorer from the old world observing the actions of Indians; the value of digitalis for heart diseases was learned by a physician in England investigating a brew made from foxglove by an elderly housewife; and the usefulness of Epsom salts was demonstrated when a farmer became curious as to why his cattle would not drink from a certain well.

Value.—Following basic chemical and physical findings in the 19th century modern chemotherapy and therapeutics were born. Drugs were purified, specific measures against disease were developed, diseases were identified and techniques for diagnosis, treatment and prevention of disease were unearthed. Some of these discoveries were based on studies seemingly unrelated to medicine. Thus, Gerhard Domagk while searching for better dyes for woollen goods found the precursor to the sulfa drugs, and Sir Alexander Fleming found penicillin by observing the growth of mould on bacteria-growing media in his bacteriologic laboratory. Regardless of the origin of therapeutic measures, however, their usefulness changed the welfare of mankind, influenced the winning of wars and was responsible for the development of huge industries. They also changed educational patterns, permitted the growth of primitive and underdeveloped areas, caused nations to work together more closely than might otherwise be possible and resulted in the creation of many laws that might not be required otherwise. They also brought medical quacks into focus more clearly.

Some idea of the value of modern therapeutics can be obtained by comparing statistics for given periods of time. During the Crimean War the French lost eight men from diseases for every one killed in battle and the Russians lost 20 to one. The common causes of death were cholera, typhus, dysentery and infections, all diseases which could later be controlled. In the Spanish-American War seven soldiers were lost for every one who died in battle. In the Civil War in the United States 50% of the wounded died, whereas in World War I 6% to 12% died, and in World War II no more than 3%. In World War I the annual death for American soldiers away from America was 12.8 for each 1,000 men abroad, and in World War II it was 0.5 per 1,000 men. In World War I 20% to 30% of soldiers who contracted pneumonia died; in World War II only 1%. In the first 40 years of the 20th century 25,000 lives in the United States were saved through better control over just five diseases, pneumonia, diphtheria, typhoid, meningitis and smallpox. In 1900 a newborn child had a life expectancy of 49.2 years but in 1940 it was 63.3 years and in 1948, 68 years.

Much of this improvement was due to better hygiene, health education, improved hospital facilities, better food, sanitary measures, better surgical techniques, improved transportation facilities and other factors. The introduction of more and purer drugs, the development of physical devices (*e.g.,* X-ray machines) and the creation of foods for special health purposes (*e.g.,* baby foods and foods for the sick) have also been important factors. The production records for a few well-known compounds show that in an average year in the middle 1940s in the United States alone there were produced 750,000 lb. of aspirin, 23,000 lb. of a vitamin, 22.000 lb. of phenobarbital and 650,000 lb. of sulfonamides. Penicillin grew in production from 400,000,000 units for January through May in 1943, to 200,000,000,000 units in December in 1944 to billions of units daily in 1955. A similar story exists for the other antibiotics.

General Problems.—There are some problems common to many diseases which must be considered when treatment is practical, particularly if drugs are involved. Thus specific orders must be given to the patient, his family or his nurse; there may be need for limiting or increasing exercise; diet may have to be controlled; and laboratory procedures may be necessary.

If a prescription is ordered the prescriber considers the age and weight of the patient, any history of allergy and the way and time of administration. In addition, there may be need for special bathing and skin, nose, eye or mouth care consideration. Many people fail to realize the importance of some of these measures that are ancillary to drug therapy. Diets alone may pose problems since there are liquid diets, soft diets, regular diets and special diets as peptic ulcer diet, bland diet, nonresidue diet, low residue diet, high residue diet, high calory diet, diets for patients with diabetes and with nephritis, high protein diet, low salt diet and others. But diets, like vitamins, can be very important in therapeutics.

Standardization of Therapeutic Agents.—In most countries throughout the world an attempt is made to ensure the marketing of satisfactory foods and drugs but in only a few countries is this carried to a degree that provides assurance for user and prescriber. Many countries use pharmacopoeias, which are books for the standardization of drugs, as a guide for quality but do not have laws to enforce them or to prevent the marketing of harmful or useless substances. There are exceptions, of course (notably Canada, Great Britain, the United States, the Netherlands and the Scandinavian countries). In the United States drugs, foods and to some extent devices which are in interstate commerce are subject to control in several ways: manufacturers, because of keen competition and the fear of adverse publicity and lawsuits as well as a growing sense of moral obligation, try to develop effective and pure drugs and foods. In addition, there is a Federal Food, Drug and Cosmetic act which governs quality, labelling and to some extent promotional claims. Acting as an agent for this and other acts is the Food and Drug administration, which can seize and examine products and inspect factories. To govern the sale of serums and vaccines there is another law and another federal agency. Some states have their own laws and agencies and one or two of the larger cities have organizations that function similarly. The medical profession is, of course, always doing its own examining through experience and even supports through the American Medical association several councils who examine drugs, foods and devices to determine their usefulness.

Drugs and foods may be tested chemically, by assay on animals and through other measures. The purer chemicals obviously pose fewer problems as a rule than the impure mixtures, many of which are of botanical or animal origin. While most drugs can be examined by chemical tests there are some that defy such an approach, an outstanding example in the 1950s being liver extract, used for treating pernicious anaemia.

Mode of Action.—The method of approach to a disease and the remedy to be used depends on several factors such as the disease involved, the depth of illness of the patient, its hazards as a public health menace and the kind of remedy available. Thus a drug may be given by mouth, injected into the skin or under the skin, or into a muscle, vein or even artery, or into other tissues of the body, or it may be applied to the skin. It may be available as a tablet, or powder, or in solution, or in a capsule or ointment.

A drug or other remedy may be given to specifically combat a disease; it may be given to help the body mobilize its own natural defense forces, as the sulfa drugs hold in check the growth of bacteria while the body overcomes those already present; it may be used to provide symptomatic relief, such as aspirin for headache; or it may be used to directly attack disease, such as X-rays for cancer. The choice of treatment depends on the cause of the disease, complications and specificity of available therapeutic measures. In addition, there is the always to be remembered adjunct to treatment, peace of mind. This is why sympathetic understanding of a health problem sometimes is more effective than the use of drugs or surgery. Kind words, a change in scenery and association with new friends often have effected miraculous improvement.

Prevention of Disease.—The prevention of disease is founded on good living, adequate sanitation and the use of specific measures against specific diseases. Some have referred to this as preventive therapeutics. School clinics, venereal disease clinics, public health laboratories, vaccination, balanced meals, extra milk for children, the addition of iodine to salt to prevent goitre, the addition of fluorine to water to prevent dental decay and the addition of vitamin D to milk and vitamin C to other foods are part of current preventive practices.

Among the diseases that can be prevented by vaccination or similar measures are smallpox, diphtheria, yellow fever, and typhoid and paratyphoid fever. Even tuberculosis and poliomyelitis may soon be controlled by vaccination as promising vaccines are now available.

Other important preventive measures supplementary to actual therapy are proper disposal of sewage, eradication of disease-carrying mosquitoes, avoidance of polluted water and isolation of people sick with infectious diseases. Since animals and birds carry many diseases to which man is susceptible, they too must be subjected to certain control measures such as testing for tuberculosis and vaccination against rabies.

Specificity of Drug Action.—One of the encouraging aspects of modern therapeutics is the specificity of drug action. Formerly drugs were not particularly specific; in fact, "shotgun therapy" was often the order of the day. Today, however, one can choose a drug for many diseases and health problems. Thus, one can choose the type of anaesthetic agent indicated for an operation; the type of drug indicated for sleeplessness and pain; the type of drug best suited to muscle spasm, or high blood pressure, or allergy, or infection. Such a direct approach was made possible by the development of more precise diagnostic techniques, by a better understanding of the functions of the body and by the combined efforts of chemists, physicians and other specially trained people who can jointly develop first in theory and then in practice the chemicals needed to combat a certain health problem.

THERESA, ST. (1515–1582), or Teresa de Cepeda, Spanish nun, was born at Avila, in Old Castile, on March 28, 1515, and was educated in an Augustinian convent in the town. As a child she was interested in the stories of martyrs, and at the age of eighteen left home one morning, and applied for admission at the Carmelite convent of the Incarnation. She was disappointed at first at the slackness of discipline, but she appears afterward to have accommodated herself with tolerable success to the worldliness of her environment, though not without intervals of religious misgivings.

It was in the year 1554, when she was nearly 40, that the event known as her conversion took place, and the second part of her life began. The death of her father roused her to serious reflection, and one day, as she entered the oratory, she was struck by the image of the wounded Christ, placed there for an approaching festival. She fell in tears at the feet of the figure, and felt every worldly emotion die within her. The shock threw her into a trance, and these trances, accompanied by visions, recurred frequently in the subsequent part of her life. They have since been adduced as Divine attestations of her saintship, but the sisterhood in the convent set them down to possession by a devil; her new departure was caused in their eyes by no worthier motive than the desire to be peculiar and to be reputed better than other people. Theresa herself was very humble, and thought their explanation might be true; she took her case to her confessor and to the provincial-general of the Jesuits, who put her under a course of discipline. One day, while thus occupied, her trance came upon her, and she heard a voice say, "Thou shalt have no more converse with men, but with angels." After this the trance or fit always returned when she was at prayers, and she felt that Christ was close to her. Presently she was able to see Him, "exactly as He was painted rising from the sepulchre." Her confessor directed her to exorcise the figure, and she obeyed with pain, but, it is needless to say, in vain. The visions grew more and more vivid. The cross of her rosary was snatched from her hand one day, and when returned it was made of jewels more brilliant than diamonds, visible, however, to her alone. She often had an acute pain in her side, and fancied that an angel came to her with a lance tipped with fire, which he struck into her heart. August 27 is kept sacred in Spain to this mystery, which has also formed a favourite subject of Spanish painters. She also had visions of another description: she was shown hell with its horrors, and the devil would sit upon her breviary, belabour her with blows, and fill her cell with imps. For several years these experiences continued, and the verdict as to their source still remained far from unanimous.

Foundation of the Descalzos.—Meanwhile, the spread of the Reformation became the subject of much searching of hearts to pious Catholics. Theresa reflected like the rest, and her experience led her to find the real cause of the catastrophe in the relaxation of discipline within the religious orders. She formed the project of founding a house in which all the original rules of the Carmelite order would be observed. In spite of great opposition from the authorities of the order, and in particular from the prioress and sisters of the Incarnation, she persevered with her scheme, being encouraged to appeal to the pope by certain priests who saw the benefit which would accrue to the Church from her zeal.

A private house in Avila was secretly got ready to serve as a small convent, and, when the bull arrived from Rome, Theresa went out on leave from the Incarnation and installed four poor women in the new house dedicated to her patron St. Joseph. It was on Aug. 24, 1562 that Mass was said in the little chapel and the new order constituted. It was to be an order of Descalzos or Barefoots, in opposition to the relaxed parent body, the Calzados. The sisters were not to be literally shoeless, but to wear sandals of rope; they were to sleep on straw, to eat no meat, to be strictly confined to the cloister, and to live on alms without regular endowment. After lodging her four sisters, Theresa returned to the Incarnation; but, when the secret was discovered, Carmelites and townspeople were alike furious. Violence, however, was prevented, and the matter was referred to the council of state at Madrid. Philip II referred it again to the pope, and after six months a fresh bull arrived from Pius V. The provincial of her order now gave her leave to remove and take charge of her sisterhood. The number of 13, to which on grounds of discipline she had limited the foundation, was soon filled up, and Theresa spent here the five happiest years of her life. Her visions continued, and, by command of her ecclesiastical superiors, she wrote her autobiography containing a full account of these experiences though she was far from basing any claim to holiness upon them.

The general of the order visited her at Avila, and gave her powers to found other houses of Descalzos, for men as well as women. The last 15 years of her life were spent mainly in hard journeys with this end and in the continually growing labour of organization. Convents were founded at Medina, Malaga, Valladolid, Toledo, Segovia and Salamanca, and two at Alva under the patronage of the famous duke. Then she had three years of rest, as prioress of her old convent of the Incarnation. She next went to Seville to found a house, thus overstepping for the first time the boundaries of the Castiles, to which her authorization limited her. The latent hostility of the old order was aroused; the general ordered the immediate suppression of the house at Seville, and procured a bull from Gregory XIII prohibiting the further extension of the reformed houses (1575). But the movement against her came from Italy, and was resented by Philip and the Spanish authorities as undue interference; and after a fierce struggle, during which Theresa was two years under arrest at Toledo, the Carmelites were divided into two bodies in 1580, and the Descalzos obtained the right to elect their own provincial-generals. (See CARMELITES.) The few remaining years of Theresa's life were spent in the old way, organizing the order she had founded, and travelling about to open new convents. Sixteen convents and 14 monasteries were founded by her efforts; she wrote a history of her foundations, which forms a supplement to her autobiography. Her last journey of inspection was cut short at Alva, where she died on Sept 29, 1582.

Canonization. — A violet odour and a fragrant oil were said to distil from her tomb; and when it was opened nine months afterward the flesh was found uncorrupted. A hand cut off by a fervent brother was found to work miracles, and the order became convinced that their founder had been a saint. It was resolved in 1585 to remove her remains to Avila, where she was born, the sisters at Alva being consoled by permission to retain the mutilated arm.

But the family of the duke of Alva procured an order from the pope enjoining that the body should be restored to Alva, and she was accordingly laid there once more in a splendid tomb. But even then she was not allowed to rest: she was again disentombed, to be laid in a more magnificent coffin, and the greed of reverential relic-seekers made unseemly havoc of her bones.

Theresa was canonized by Gregory XV in 1622. The honour was doubtless largely due to her asceticism and mystic visions. She called herself Theresa de Jesus, to signify the closeness of her relation to the heavenly Bridegroom, who directed all her actions. Though she deprecated excess of ascetic severity in others, she scourged herself habitually, and wore a peculiarly painful haircloth. But her life shows her to have been, besides, a woman of strong practicality and good sense, full of natural shrewdness, and with unusual powers of organization. "You deceived me in saying she was a woman," writes one of her confessors; "she is a bearded man." She was brave in the face of difficulties and dangers, pure in her motives, and her utterances, some of which have been quoted, have the true ethical ring about them. Her mss. were collected by Philip II and placed in a rich case in the Escorial, the key of which the king carried about with him. Besides her autobiography and the history of her foundations, her works (all written in Spanish) contain a great number of letters and various treatises of mystical religion, the chief of which are *The Way of Perfection* and *The Castle of the Soul*. Both describe the progress of the soul toward perfect union with God.

Her works, edited by two Dominicans were first published in 1587, and have since appeared in various editions. They were afterward translated into Italian, French (4 vols., Paris, 1840–46) and Latin; an English translation of the *Life* and works (except the letters) by A. Woodhead appeared in 1669. Other translations of the *Life* are those by John Dalton (1851), who also translated *The Way of Perfection* and the *Letters* (1902), and by David Lewis (1870), who in 1871 also translated the *Foundations*. A. R. Waller repnnted Woodhead's translation of *The Way of Perfection* in "The Cloister Library" (1901). Biographies appeared soon after her death by the Jesuit Ribera, who had been her confessor (1602), and by Diego de Yepez, confessor to Philip II (1599). Details are also given in Ribadeneyra's *Flos Sanctorum* and in Alban Butler's *Lives of the Saints* (rev. 1926). A separate biography, with preface by Cardinal Manning, appeared in 1865; a full and critical edition of the *Life* is that by Mrs. G. C. Graham, 2 vols. (1894). See also H. Prinz v. THERM. A name originally employed in elementary textbooks for any thermal unit but now generally restricted to the statutory unit of heat adopted for the sale of lighting gas in terms of its calorific value. The therm is defined as being equal to 100,000 British Thermal Units (B.Th.U.), the unit of heat most commonly used for measuring the calorific value of gas or other fuels throughout the British empire and (B.T.U.) in the U.S.

THERMAE, in architecture, is a term referring to the baths of a large bathing establishment, particularly those of ancient Rome. *See* BATHS.

THERMIDOR, the name given during the French Revolution to the 11th month of the year in the republican calendar. The month fell in the hottest season of the year, beginning on July 19 or 20 and ending on Aug. 18 or 19. according to the year. The most important event that took place in this month was the revolution of 9 Thermidor year II (July 27, 1794), the so-called revolution of Thermidor, which resulted in the fall of Robespierre and the collapse of the Terror. The name Thermidorian (*Thermidorien*) was given to the authors of this revolution and to the supporters of the reactionary movement of which it was the signal. The name Thermidor is derived from the two Greek words for heat and gift.

THERMIONICS. Thermionics deals with the production of charged particles, electrons or ions, at a heated surface. Useful examples of hot surfaces are electrically heated filamentary wires or ribbons of refractory metals such as tungsten or nickel. By far the most extensive application of thermionic electron emission is in the radio receiving tube. (*See* ELECTRON *TUBE.*)

An atom may be thought of as a structure that has a specific number of electrons in constant motion around a positively charged, massive nucleus. The number of electrons characterizes the particular chemical element and is known as the atomic number. Since the positive charge on the nucleus of an atom is exactly equal in magnitude to the sum of the negative charges on the electrons that surround the nucleus. a normal atom has no net charge. In the broadest sense of the word, a thermion is produced from an atom if an electron is either added to or subtracted from a normal atom at a heated surface. The production of atomic thermions depends on physical principles that have little or no relation to the thermal production of free electrons. Therefore, since the latter phenomenon has found such extensive and valuable applications, this article will deal exclusively with electron emission from heated surfaces.

Discovery of Thermionic Emission of Electrons. — Thomas A. Edison (*1883*) discovered that electrical conduction could be maintained between a hot filament and a nearby cool metallic plate if the plate was made positive with respect to the filament. No appreciable current was observed with a negative plate. Edison concluded that negative charges of electricity (now known to be electrons) were given off the hot filament and that these charges conducted electricity across the evacuated space. W. H. Preece (188j) studied the effectin more detail and gave it the name Edison effect. J. J. Thomson (1899) established the electronic nature of the charge carrier and found that the magnitude of the charge was the same as that discovered in previous experiments with ionized particles but that its mass was less than $\frac{1}{1,800}$ that of the hydrogen ion.

Early investigators included O. W. Richardson, Max von Laue, W. Schottky (1914), I. Langmuir (*1913*) and others, who by *1920* had established many of the principles of the new field. The most advanced and widespread application of thermionic emission to electronics depends on the very high efficiency and reliability of the oxide cathode discovered by A. Wehnelt (*1903*). (*See* ELECTRICITY: *The Particles of Electricity.*)

Applications of Electronic Thermionics.—The importance of the thermionic emission of electrons can best be established by mentioning some of the applications that depend on the utilization of this phenomenon. The high-voltage hot-cathode rectifier depends on the emission of electrons into an evacuated space and in this way supplies the means of electrical conduction from the cathode to the anode of the tube structure. The latter receives electrons while it is positive with respect to the cathode. The anode structure operates at such a low temperature that its thermionic emission is exceedingly small, and therefore the tube operating as a rectifier conducts well only with the one polarity of applied voltage.

The arrival at the anode of free electrons with high energy produces X-rays as the electrons are stopped, and therefore most X-ray tubes depend upon thermionic emission for their operation. The emitted free electrons may be accelerated through certain gases and upon collision with the atoms produce atomic excitation and ionization. These are steps in the operation of fluorescent lamps, gas-filled rectifiers, grid-controlled rectifiers or thyratrons and many other devices of everyday usefulness that depend on the thermionic emission of electrons for their very existence.

The vacuum tube also depends on thermionic emission. Amplification of modulated power for telephone, radio and television communication depends on the controllability of the free electrons that have been emitted thermionically from the cathode of the structure.

Theory of Thermionic Emission.—To understand the theory of thermionic emission one must first have some knowledge of the electronic properties of atoms, molecules and solids. The fact that atoms have a "structure" that includes a positively charged heavy nucleus surrounded by a system of electrons equal in number to the atomic number of the chemical element has been mentioned above. Experiments have shown that the electrons are grouped together in electronic energy levels. In every complex atom there are two electrons very close to the nucleus which serve to fill the "K" shell.

The next one is the "L" shell with a maximum of eight electrons. Depending on the total number of electrons that are associated with each atomic nucleus to make it electrically neutral, additional shells may be filled. The outermost electrons are known as the valence electrons. The metals that are good conductors are nearly all to be found among those elements that have only one or two of these valence electrons in the outermost structural shell. The details are well understood as a result of the application of wave mechanics to the problem. (See QUANTUM MECHANICS: *Wave Mechanics.*)

The common metallic elements upon crystallization yield their valence electrons to quantum states, described best in the language of wave mechanics, that extend throughout the crystal as a whole and in that way are no longer the property of the individual atoms. The transfer of an electron from one quantum state to another always is accompanied by a change in energy of the system as a whole, and therefore the general concept that the most stable state of the system tends to be that of "least energy" implies that the electrons will occupy all of the low-energy quantum states first and that the high-energy ones will be empty.

Quantum mechanics serves as the means of determining the number of quantum states easily available to the valence electrons of a crystal. A comparison may be made between the number of states needed and those available. If the two are exactly equal then the substance is a very poor conductor, as is the case for diamond. If the available states far exceed the demand then the substance is a good conductor (for example, copper). Since at some specified temperature practically all of the low-energy quantum states in the crystal are filled and most of the high-energy states are empty, there must be some energy state (or level, as these states are often called) that will have exactly a 50% probability of being filled. This quantum state and its corresponding energy are identified by the term Fermi level, in honour of Enrico Fermi, who was one of the first to develop the quantum statistics of electrons.

It is difficult to establish a universally acceptable way of giving a numerical value to the Fermi level since the energy of an electron depends both on its location and on its momentum. In thermionic emission theory the primary interest is in the transport of electrons through the substance used as the emitter of electrons and the transport of electrons across the boundary between the metal and the surrounding space. Statistical theory tells us that no matter what the substance is on each side of any boundary established in a region in which there is thermodynamic equilibrium, the Fermi level is continuous across that boundary and the net flow of heat and electricity across the boundary will be exactly zero. As a consequence of this fact, theory provides a means of computing the "random" flow of electrons that occupy any set of quantum states of known energy relative to the Fermi level. By random flow is meant the number of electrons that cross a unit area per second in one direction. For the net current to be zero, the random flow in opposite directions must be equal in magnitude.

This discussion of statistical theory is best illustrated by the diagram of fig. 1. The vertical direction in this diagram represents relative energies of electrons and the horizontal direction represents distance. The left of the dotted vertical line is inside the conductor and the right is outside the last layer of atoms of which the crystal is made. If the potential energy of an electron is zero at a large distance away from the surface, then the potential energy inside is lower by the amount shown as W_a. This difference in potential energy is known as the elec-

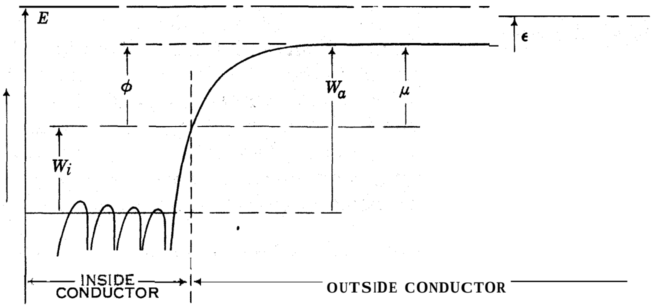

FIG. 1.— RELATIVE ENERGIES OF ELECTRONS PLOTTED AGAINST DISTANCE FROM SURFACE

W_i is the Fermi level relative to the conduction band; ϕ is the true work function in electron volts: E is the kinetic energy inside the conductor of an electron in motion perpendicular to a surface; W_a is the electron affinity; μ is the Fermi level for a low density of electrons outside; and ϵ is the kinetic energy of an electron in motion perpendicular to a surface and outside it

tron affinity of the surface. There is no single value of W_a that characterizes the particular metal of which the crystal is made, since its value depends not only on the metal but also on the particular crystallographic surface that is exposed. The usual way of defining a crystallographic direction is by the Miller indices of a line perpendicular to the surface. If reference is made to the experimental determination of the differences in W_a for the [110] direction of tungsten in comparison with the [111] direction, A. R. Hutson (1955) showed it to be at least 0.8 ev (electron volt) higher in the [110] direction. An electron volt is the energy gained or lost by an electron in moving across a region in which there is a difference in potential of one volt. Since the charge on an electron is 1.602×10^{-19} coulomb, the electron volt is 1.602×10^{-19} joule. The most convenient energy unit to use in the discussion of thermionic emission is the electron volt, and it will be used in this article.

To help orient the reader in his understanding of fig. 1, other values of the symbols will be given as they refer to tungsten. The value of W_i, which is the Fermi level with respect to the bottom of the conduction band of electrons, is 5.8 ev when it is assumed that there is one conduction electron for each tungsten atom. This number is computed by the following formula, which comes directly from the application of Fermi statistics to an assembly of free electrons of concentration n:

$$W_i = \frac{h^2}{2m}\left(\frac{3n}{8\pi}\right)^{2/3}\left\{1 - \frac{\pi^2}{12}\left[\frac{kT}{\frac{h^2}{2m}\left(\frac{3n}{8\pi}\right)^{2/3}}\right]^2\right\} \text{ in electron volts} \quad (1)$$

In this equation h is Planck's constant (6.6238×10^{-34} joule-sec.); m is the electron mass (9.107×10^{-31} kg.); q is the charge on an electron (1.602×10^{-19} coulomb); k is Boltzmann's constant (1.38042×10^{-23} joule/° K.); and T is the absolute temperature on the Kelvin scale. An evaluation of W_i as it applies to tungsten, in which there are 6.4×10^{28} atoms per cubic metre, shows that the second term which depends on the temperature T is so very small compared to unity that W_i of 5.8 ev may be used without correction over the useful range in temperature of 1,800° K. to 2,500° K. Very careful experimentation by M. H. Nichols (1940), G. F. Smith (1954) and A. R. Hutson (1955) established the value of ϕ as $4.3 + (3 \times 10^{-5})$ T for the [111] surface. It follows that W_a is close to 10.1 ev for this surface and at least 10.9 ev for the [110] surface.

The diagram shows that the Fermi level in the outside space is the negative of ϕ; that is, $\mu = -\phi$. For this statement to be exact the space must be in thermodynamic equilibrium with the metal.

The value of μ (Fermi level for a low density of electrons) may be calculated from the equilibrium density of electrons in the space by the following equation:

$$\mu = -\frac{kT}{q}\, 1n \frac{2(2\pi mkT)^{3/2}}{nh^3} \qquad (2)$$

This equation is generally applicable for electron densities less than 10^{25} electrons per cubic metre.

The quantity ϕ is the true work function. It is defined as the difference in the energy of an electron at the Fermi level and one at rest just outside the surface.

In terms of the energy diagram of fig. 1 it is possible to explain thermionic emission from a metallic conductor. With the metal at a very low temperature, the electrons fill all the quantum states from the bottom of the conduction band right up to the Fermi level and very few electrons will be found above this level. There will be some high-energy electrons, however, and the Fermi level will mark that quantum state that has a 50% probability of being occupied. As the temperature is raised, more and more electrons will occupy the high-energy states, even as high as W_a, and there will be vacancies in the states below W_i exactly equal to the number occupied above W_i.

In their random motion in the interior of the metal, many of the very high-energy electrons will approach the surface of the metal. Assume that an electron is moving at high speed in the metal and that the kinetic energy associated nith the motion toward the boundary is E. As it crosses the boundary at the surface of the metal, it gives up kinetic energy in order to do work against the electrical forces that attract the electron to this surface of the crystal. The total work is the change in potential energy W_a. The kinetic energy with which the electron escapes into the surrounding space is shown on the diagram as ϵ.

By direct calculation, quantum statistics gives equation *(3)* for all of the electron current that impinges on the boundary surface with internal kinetic energy greater than W_a. It is this value of current density (I) that is the maximum that could be observed from the surface at the specified temperature:

$$I = \left[\frac{4\pi mk^2 q}{h^3}\right] T^2 e^{-\frac{\phi q}{kT}} \qquad (3)$$

In this equation e is the base of natural logarithms *(2.71828)*. Richardson *(1912)* was one of the first to develop this equation form based on general thermodynamic reasoning. S. Dushman *(1923)* worked out the value of the universal constant, the bracketed quantity in equation (3), while R. *H.* Fowler *(1928)* and L. Nordheim (1929) developed the theoretical basis for equation *(3)* by the application of Fermi statistics.

Empirical Equations and Thermionic Constants.—The superficial approach to the experimental testing of the validity of equation *(3)* is to observe an average current density I as a function of the temperature and plot the data according to the following relation:

$$1n\left(\frac{I}{T^2}\right) = 1n\, A_R - \frac{q}{kT}\,\phi_R \qquad (4)$$

where A, is the Richardson constant as an empirical constant and ϕ_R is the Richardson work function as an empirical constant.

The observable quantity on the left of equation (4) is plotted as a function of T^{-1}, or better yet, as a function of $(1/V_T) = (q/kT)$ V, is the electron volt equivalent of temperature. Generally a straight-line relation is found and values of A, and ϕ_R are determined this way. Comparisons are often made between A_R and the theoretical value of the universal constant *(A)* of equation (3), which is defined as follows and has the value shonn:

$$A = \frac{4\pi mk^2 q}{h^3} = 120 \times 10^4 \text{ amp./metre}^2 \text{ deg}^2 \qquad (5)$$

More often than not A, is less than A, but many examples are found in which A, is much greater than A. There are a number of reasons for the shortcomings of this method:

1. A given sample generally does not exhibit a single crystallographic surface for emission and therefore the average current density I will not equal the density needed for the test of equation *(3)*. It will be less than the maximum density and greater than the minimum of the various exposed surfaces of a test sample.

2. Nothing in the theory from which equation (3) was obtained limited its use to the condition that ϕ is a constant. The fact that a straight line may be obtained as indicated above only means that the effective average work function (ϕ_{eff}) may be represented by the equation shown as

$$\phi_{\text{eff}} = \phi_R + \alpha\frac{kT}{q} = \phi_R + \alpha V_T \qquad (6)$$

where a is the temperature coefficient. Note that the energy corresponding to kT can be expressed equally well as qV_T, and the electron volt equivalent of temperature is obtained as follows:

$$V_T = \frac{kT}{q} = \frac{T}{11{,}606} \qquad (7)$$

It is not necessary to add more detail to see that the observed value of the constant A, would be altered by the factor $e^{-\alpha}$ from the theoretical A. Thus if a is negative. as it may well be when absorbed atoms of the electronegative type are present as surface impurities, A, can be very large. If a is positive then A, will be small.

3. There is still another influence that may or may not be important. This is reflection at the boundary. The theory outlined above gave the maximum current that could be observed, but if not all of the available electrons actually left the metal the current would be less.

It follows that most experiments that have been reported in the literature give values of A, and ϕ_R. These constants must be considered to have very little theoretical importance, even though they do yield numbers of engineering usefulness. These numbers may be used to predict the electron emission that will be available from similar samples, but the work function ϕ will very seldom be the true work function ϕ of equation *(3)*. The basic Richardson thermionic equation is equation (3), and there the true work function ϕ is the only correct one to use. The empirical values of constants A, and ϕ_R are referred to as the Richardson constants and carry the subscript R because they are to be used with the Richardson form of the equation given as follows:

$$I = A_R T^2 e^{-\frac{\phi_R q}{kT}} = A_R T^2 e^{-\frac{\phi_R}{V_T}} \qquad (8)$$

The Richardson work function is ϕ_R and is a constant since it was determined by the slope of the best straight line that represented experimental observations according to the linear approximation of equation (4). The Richardson thermionic constant is A,. It is also a constant since its choice is made so that at some specified temperature the value of the calculated emission is in agreement with the experimental value.

The first equation put forward by Richardson did not make use of quantum principles and was expressed as:

$$I = A_R' T^{1/2} e^{-\frac{\phi_R' q}{kT}} \qquad (9)$$

As an empirical equation this one is no better nor worse than equation (8). since in nearly every example the experimental data are equally well represented by equation (9).

Since both equations (8) and *(9)* are empirical, having engineering usefulness only, it should be clear that the following equation is more useful for this purpose:

$$I = ae^{-\frac{\Phi}{V_T}} \qquad (10)$$

The two empirical constants for this form may be determined by a direct examination of data, or they may be related to A, and ϕ_R as will be shown below. The work factor Φ in electron volts is the slope of the line given by:

$$1n\, I = ln\, a - \frac{\Phi}{V_T} \qquad (11)$$

The constant a is chosen to give correct values as was done for

A_r. The relations used to convert one set of constants to the other are:

$$\Phi = \phi_R + V_m + V_n \tag{12}$$

$$a = 10\, A_R\, T_0^2 \tag{13}$$

$$T_0 = \frac{T_m + T_n}{\ln 10} = \frac{T_m + T_n}{2.3} \tag{14}$$

In these equations T_m is the minimum temperature of the range chosen for equation (10) to be the equivalent of equation (8). The maximum temperature of the range is T_n and the corresponding electron volt values are V_m and V_n computed by equation (7). T_0 is close to the mean temperature.

A useful set of thermionic constants is given in the table. The following empirical equations may be used with the tabulated constants to calculate approximate current densities in amp./cm.^{2} from the sources listed (the information on the constants for the sources shown was obtained from various articles in scientific literature):

$$I = A_R T^2 e^{-\frac{e\varphi_R}{kT}} \qquad I = A_R T^2 e^{-\frac{b}{T}} \qquad I = A_R T^2\, 10^{-\frac{b'}{T}}$$

$$I = a e^{-\frac{e\Phi}{kT}} \qquad I = a e^{-\frac{\beta}{T}} \qquad I = a\, 10^{-\frac{\beta'}{T}}$$

Reduction in Electron Affinity.— It is only the refractory or high-melting-point pure metals that serve as practical electron emission sources, and the best is tungsten. It is used in most high-voltage rectifiers and X-ray tubes.

The great objective is to obtain more electrons for less input power to heat the source. Although heat shields can be used to reduce the total power radiated, a considerable gain may be made by surface alterations that reduce the electron affinity. Fig. 1 shows that the methods that reduce W_a will generally reduce ϕ, since

$$\phi = W_a - W_i \tag{15}$$

I. Langmuir and W. Rogers (1914) discovered that thoria (ThO_2), occluded within a tungsten wire at the time of its manufacture, could be made to yield thorium by suitable heat treatment. The thorium atoms diffuse out of particularly active regions along crystal boundaries and finally over the external surface of the tungsten wire to form a coverage less than one atom layer thick. The thorium adheres very strongly to the underlying tungsten surface and becomes polarized. The direction of the dipole corresponds to a displacement of the outermost valence electrons of the thorium toward the tungsten. This displacement or polarization of the negative charge with respect to the positive charge on the thorium nucleus creates a dipole of strength μ_t at each thorium atom. If there are n_t thorium atoms per unit area, the dipole moment per unit area will be $n_t\ \mu_t$. A dipole moment has units of (charge $\times$ length) and therefore $(n_t\ \mu_t)/\epsilon_0$ has units which are potential difference or "volts." Analysis shows that W_a is changed due to an adsorbed layer of polarized atoms according to the relation

$$W'_a = W_a - \frac{n_t \mu_t}{\epsilon_0} \tag{16}$$

In this equation ϵ_0 is the permittivity of free space (8.85×10^{-12} faradimetre). Since oxygen polarizes in the opposite direction to thorium, W'_a (reduced electron affinity) is greater than W, if a fraction of a monolayer is adsorbed. Generally the adsorption of electronegative atoms increases the electron affinity, and a decrease comes with adsorbed electropositive elements. Although the alkali metals polarize strongly, as for example cesium, it is more difficult to maintain the optimum coverage in comparison aith thorium. The approximate reduction in W, by a 0.7 coverage (10^{19} thorium atoms per square metre) may be seen from the table to be about 1.4 ev.

This reduction in electron affinity realized with thoriated filaments is sufficient to make its use of practical value in many medium-capacity power amplifier tubes. Often perfectly good tubes of this type are discarded as worthless merely because they have lost their efficiency due to some temporary overload condition. Many such tubes may be reactivated and restored to useful service.

The greatest step in the reduction of the electron affinity came with the discovery by A. Wehnelt that a coating of alkaline-earth oxides would greatly enhance the electron emission obtained from a surface at a very low temperature. This discovery led to the modern technology of the oxide cathode.

Theory of the Oxide Cathode.— The oxide cathode is generally constructed as an internally heated nickel sleeve upon which a suitably prepared barium-strontium carbonate is sprayed. The fine particles are held in a binder, which is later removed by heating. The conversion of the carbonate into the oxide takes place within the final assembly during the early stages of evacuation. The conversion is completed by maintaining the cathode at about' 1,300° K. for about one minute (G. M. Herrmann and J. S. Wagener, 1951).

Important factors that govern the procedure include: (1) the need for nickel alloys that contain reducing agents such as silicon, titanium, magnesium, etc. (E. S. Rittner, 1953); (2) development of required particle size of about two or three microns; (3) porosity after sintering of about 50% with pores of about two microns' linear dimensions; (4) cleaning of all other parts of the tube is important for maintenance of cathode emission life; (5) coating adherence is dependent on vacuum conditions, cleaning of parts and other factors.

The electron emission from this structure depends upon the transfer of electrons from the nickel base metal to the coating, the conduction through the coating and finally the emission from the coating. Barium oxide in the absence of imperfections is an insulator and therefore a very poor conductor of electrons. The electron affinity is very low for practically all insulators. The probable value of W_a for the crystals of an oxide cathode is 0.8 ev.

This great reduction in W, from the metallic value of about ten electron volts does not automatically result in the high-efficiency cathode desired because both the coating conductivity and the electron emission depend on the location of the Fermi level. Semiconductor theory shows that the presence of an amount of excess barium in the oxide of only 1 part per 1,000,000 is enough to raise the Fermi level to within 0.4 ev of the conduction band if the temperature is about 500° K. This combination gives a true work function at low temperature of

$$\phi = W_a - W_i = 0.8 - (-0.4) = 1.2 \text{ ev} \tag{17}$$

A difficulty arises with such a low concentration of excess barium because as the temperature is raised the concentration of electrons in the conduction band soon equals the number of barium

atoms and the Fermi level becomes more and more negative as shown by equation (2). It follows therefore that in order to stabilize the Fermi level, a barium concentration of 10 to 20 parts per 1,000,000 is needed.

During the life of a cathode, barium is evaporated, and it also may be lost effectively if electronegative gas such as oxygen is evolved from other parts of the tube and goes to the cathode. It is the function of the reducing agent put into the nickel alloy to maintain the required concentration of barium to compensate for these losses. The migration of the excess barium atoms is influenced by the concentration gradient and by internal electric fields. Since the flow of electrons through the coating produces a drop in potential across the coating which is positive near the exterior surface and negative at the nickel, the excess barium ions in the crystals tend to flow away from the surface. This flow reduces the concentration there and increases the resistance.

This discussion of problems of the oxide cathode serves to illustrate the complexity of the phenomena associated with its electronic properties. More detailed and quantitative studies were made by W. B. Nottingham (193'6).

Field Effects Including Space Charge.—An understanding of thermionic emission requires some knowledge of the means of its observation. The diode structure, which includes a thermionic emitter and a collector, is all that is needed.

For the purpose of cathode temperature measurement the application of a moderately strong magnetic field with its B vector perpendicular to the emitting surface is desirable. If the emitter is cylindrical and possibly surrounded by an elliptical collector as in a practical vacuum tube, then the B vector should be perpendicular to the axis of the emitter and parallel to the short axis of the collector. The purpose of this magnetic field is to cause the emitted electrons to follow spirally along the lines of magnetic field so that their trajectories will be independent of the retarding potential which is used to analyze the energy distribution associated with the electron velocity vector parallel to the magnetic field. This method of temperature determination is subject to considerable error if the magnetic field is not used.

The applied potential on the collector may be made negative with respect to the emitter, and if the tube construction is designed for low leakage between its elements the measured current will indicate the number of high-energy electrons that are emitted. An equation based on a statistical analysis relates changes in the observed current to changes in applied voltage. It is the following:

$$2.3\,(\log_{10} i - \log_{10} i_1) = \frac{q}{kT}\,(V - V_1) \qquad (18)$$

In this form of the equation, V_1 and i_1 are a reference voltage and current relative to which V is referred in that if V is more positive than V_1, the current i is greater than i_1. This equation applies over the range for which the electron flow to the collector is not influenced by space charge. Important practical purposes are served by a set of measurements of current and voltage as related by equation (18). The data points may be co-ordinated by the semilogarithmic plot suggested by this equation, and the slope of the line gives an accurate measure of the temperature T of the emitter.

Fig. 2 is the circuit diagram applicable to the measurement of the current voltage characteristic of a diode. A plot of typical data is given in fig. 3. For applied voltages more negative than the critical one, V_R, the points lie on a straight line that is accurately represented by equation (18). An applied potential more positive than V_R results in an increase in current which follows the curve shown. This departure from the straight line shows that a space-charge minimum has developed close to the collector.

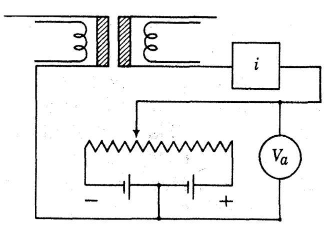

FIG. 2.—CIRCUIT DIAGRAM FOR THE MEASUREMENT OF A DIODE CHARACTERISTIC. OBSERVED CURRENT IS i; APPLIED POTENTIAL IS V_a

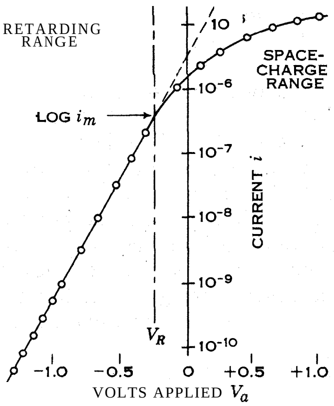

FIG 3 —SEMILOGARITHMIC PLOT OF DIODE CHARACTERISTIC

Applied voltage in retarding range more negative than V_1. Space-charge range positive with respect to V_R. Critical voltage for space-charge minimum at collector surface V_R. Diode current at critical voltage is i_m

Further changes in potential in the positive direction cause the current to increase while at the same time the space-charge minimum moves across the space between the collector and the emitter until it finally coincides with the emitter. Only under this condition is the true emission capability of the cathode determined. It is often difficult to achieve this condition with practical oxide cathodes operating at normal temperature because the Dower dissiaated at the collector may be many kilowatts. It is therefore found necessary to make the cathode evaluation over a range of lower temperature and determine suitable values of a and Φ of equation (10). Equipment has been designed which applies the high collector potential for a microsecond and repeats this application of voltage perhaps 60 times per second. The instantaneous power capacity of the collector is thus increased 16,000-fold.

Many writers evaluate ϕ_R rather than Φ and consider that the lowering of ϕ_R is the best direct indication of cathode quality. A more detailed consideration of the problem shows that ϕ_R or Φ changes very little with the activation of the cathode since the values depend only on the materials used. The true evaluation of the cathode quality depends on the determination of the α of equation (6). It is this temperature coefficient that indicates the concentration of excess barium. The higher the barium excess the lower the value of α and the higher the emission capability. Observationally the α is closely related to the a constant, which is large when α is small.

This outline showing the influences of space-charge on the observation of thermionic emission is all too brief. The details were worked out and reported by Nottingham (1956).

Under the condition of "zero field" at the emitter, the applied voltage on the collector supplies exactly that surface charge of positive electricity needed to balance the negative charge on all the electrons in transit between the emitter and the collector. Additional positive applied voltage can increase the current only at such a slow rate that the emission current is said to be saturated. For pure metals and simple composite surfaces such as thorium on tungsten, which have a high value of W_a, the most important force acting on an electron as it leaves the metal is the "mirror image" force. This fact was first pointed out by Schottky (1914), nho explained that since the total value of W_a is largely made up by the integration of the mirror image function, the application of the accelerating external field reduces the net force acting to hold the electron to the surface. This reduction permits an increase in current according to the Schottky equation as follows:

$$i = I_0\, e^{\left(\frac{q}{4\pi\epsilon_0}\right)^{1/2} \frac{q}{kT} (GV_c)^{1/2}} \qquad (19)$$

In this equation I_0 is an empirical constant (often incorrectly called the zero-field emission) and GV, is the electric field at the surface of the emitter. For high values of collector potential V_c the factor G depends only on the geometry of the diode structure, but at lower values of V_c space-charge becomes important and G becomes zero at that particular value of V_c for which the space-charge minimum coincides with the emission surface.

The problem is far more complex as the accelerating field is applied to the oxide cathode. Image forces are weaker because the oxide is more like an insulator than a conductor. The surface is generally rough enough so that the G factor is not constant and may exceed the one calculated by geometry. Space-charge effects are still important within the pores of the surface structure even though space-charge outside the surface may not be of much importance. These factors all combine to give a more rapid increase in current with applied potential than would be expected according to equation (19).

Direct Conversion of Heat to Electricity.—The diode characteristic shown in fig. 3 serves to demonstrate that thermionics may be used to convert heat to electrical power. The product $i_m V_R$ represents available power derived directly from the heated emitter. The efficiency of a vacuum diode will be very small unless the spacing is 10 microns or less. The presence of ionized cesium permits high efficiency with larger spacing. This use of thermionics is becoming more and more important for the generation of power in space vehicles.

THERMIONIC VALVE (THERMIONIC TUBE): *see* ELECTRON TUBE.

THERMIT, the trade name for a mixture of aluminum powder and iron oxide used in welding, in foundry work as a source of heat, and in the reduction of metal oxides. Thermit was widely used in incendiary bombs in the European theatre during World War II.

On ignition the reaction ($8Al + 3Fe_3O_4 = 9Fe + 4Al_2O_3$) gives a temperature estimated to be about 2,400° C. The reaction, stated in weight, means that 216 parts of aluminum plus 695 parts magnetite (iron oxide) equals 503 parts iron plus 408 parts slag, or approximately three parts of aluminum plus ten parts of magnetite will produce, on combustion, seven parts of iron. The iron thus produced represents about one-half the original thermit by weight and about one-third by volume.

Although the above reaction is the one commonly termed the thermit reaction, a generalized thermit reaction may be defined as an exothermic, self-propagating process in which finely divided aluminum powder is used to reduce metal oxides; the metal is liberated by direct oxidation of aluminum to aluminum oxide, with accompanying reduction of the less stable metal oxide.

Thermit was discovered by Hans Goldschmidt of Essen, Ger., in 1895, while trying to reduce chromium and manganese oxides. Goldschmidt's principal discovery related to a simple and safe method of ignition, as the action of aluminum when mixed with various oxides, sulfides and chlorides was well known. Fine aluminum powder will not react with pure iron oxide below a temperature of about 1,100° C. Previous experimenters had resorted to heating mixtures in a crucible, making the initial temperature so high that at the moment of ignition the mixture reacted with explosive violence. Goldschmidt obtained ignition of a cold mixture by means of a barium-peroxide fuse, which was set off by a storm match. Later, magnesium powder or ribbon was used, set off either in the manner described above or by a red-hot iron rod. The thermit reaction, once initiated locally in a cold mixture, then spreads through the mixture since the heat generated by the reaction will ignite adjacent regions. Goldschmidt's original U.S. patent was granted March 16, 1897, and related principally to the use of aluminum as a reducing agent for the production of carbon-free metals such as cobalt, chromium, magnesium, tungsten, etc., by what is known as an aluminothermic process.

Uses.—The thermit reaction is of importance for its use as a heat and metal source in welding, as a heat source in foundry work to supply heat to one region of a mold, and as a source of carbon-free metal. Two methods of thermit welding are used. The first method, known as the plastic method, can be used for welding pipe. In this method, the thermit is simply used as a heat source. The ends of two pieces of pipe are carefully butted together, and after being heated to forging temperature by the thermit, are forced together, completing the weld. The second method, known as the fusion method, is used to weld large metal sections, such as ship rudder frames. Here the molten iron formed by the thermit is used to join two or more large metal members. (For a detailed description of thermit fusion welding, *see* WELDING: *Aluminothermic Welding.*) Thermit welding does not compare favourably with other methods of welding and is consequently relegated to special cases such as welding very large sections and welding in areas to which equipment cannot be easily transported. The thermit reaction is used in foundry work to provide heat to the metal reservoir called the riser. Since the riser is the last to freeze, it is consequently able to feed metal to the casting as solidification proceeds. The thermit reaction is used for the manufacture of carbon-free metals either by direct ignition in a separate magnesia-lined steel crucible or by reaction in a ladle of molten metal to which the carbon-free metal is to be added. Since it is difficult to control the reaction so that it proceeds stoichiometrically, the resultant carbon-free metal usually contains small quantities of aluminum.

One of the greatest hazards in the thermit reaction results from contamination with moisture. During the reaction water is reduced and hydrogen evolved, which can produce an explosive mixture with the surrounding air. This hazard necessitates careful packaging and handling to exclude moisture from the mixture.

THERMOCHEMISTRY is the name given to that branch of theoretical chemistry which seeks to trace the connection between the heat evolved or absorbed during a chemical reaction and the nature and course of the reaction. Chemical reactions which are accompanied by a great evolution of heat are familiar; the combustion of coal or gas, the reduction of iron ores by coke in the blast furnace, and the slaking of lime are common examples. All explosives are unstable compounds or mixtures of compounds, the gaseous reaction products of which are raised to a very high temperature by the great heat evolved by the explosion; the propulsive force is due to the great pressure exerted by the gaseous products, owing to the high temperature and to the small volume they occupy before expansion. Such reactions are familiar because their effects are so obvious. They take place so rapidly that the heat evolved cannot be dissipated without raising the products of the reaction to a high temperature. It is the effects of the high temperature that are noticed, rather than the fact that large amounts of heat are evolved. In the rusting of iron we have an example of a chemical reaction which is also accompanied by the evolution of much heat; but this fact escapes ordinary notice since the rusting usually takes place so slowly that the heat has time to dissipate without perceptibly raising the temperature of the metal.

If, however, finely divided iron filings are dropped into pure oxygen, the reaction takes place so suddenly that there is no time for the heat to get away before the particles get white hot.

Confronted with so many every-day examples of chemical reactions accompanied by evolution of heat, it is natural to assume a close connection between the energy changes and the material changes. For a long time, however, the interest of chemists was mainly occupied by material changes only. Following the general recognition of the law of conservation of matter and the gradual acceptance of Dalton's atomic theory in the early part of the 19th century, there was a great development of knowledge of the properties and composition of different chemical substances and of their action on each other. The real development of modern thermochemistry may be said to start from the recognition of the law of conservation of energy in the middle of the century. Somewhat earlier Thomas Andrews and Hess had systematically studied the thermal effects of chemical reactions taking place in solution, and Hess, as a result of his work, had formulated a law which is one of the consequences of the conservation of energy, namely, that the thermal effect of a chemical reaction is the same however it takes place.

Law of Conservation of Energy.—According to the law of conservation of energy, energy, though it can exist in many forms, is indestructible. No method is known by which it is possible to create energy out of nothing. No system is known from which it is possible to obtain useful work without an exactly correspond; ing diminution in the total energy of the system. If the system is restored to its original condition by the addition of heat, then the heat absorbed is found always to be exactly proportional to the amount of work performed by the system. A few specific examples will illustrate the application of the law to chemical processes.

(a) Heat is necessary to convert water at its boiling point into steam at the same temperature. A small part of this heat goes to perform work through expansion against atmospheric pressure; the major part is transferred into internal energy of steam molecules. The internal energy of unit mass, of water vapour is therefore considerably greater than that of unit mass of liquid water at the same temperature. When steam is condensed again to water, exactly the same amount of heat is evolved as was absorbed when it was formed.

(b) A chemical reaction, such as the combustion of petrol, can be made to take place without performance of useful work, *e.g.,* by allowing it to take place in a closed vessel. The heat evolved by the combustion of unit weight to carbon dioxide and water vapour under these conditions can be accurately measured. When petrol is burnt in an internal combustion engine, the power output (and therefore the useful work performed by combustion of unit weight), the loss of heat to the cylinder walls and the residual heat in the exhaust gases can all be measured. The sum of the heat loss to the cylinder walls, and the residual heat in the exhaust gas is always less than the total heat of combustion by an amount which is the equivalent of the work done.

(c) **A** solution of copper sulphate will react with zinc, dissolving it and depositing copper. The heat evolved by the solution of an "equivalent" of zinc can be measured. In the Daniell cell, which consists of a zinc electrode dipping into zinc sulphate solution in a porous pot, surrounded by another container where a copper electrode dips into copper sulphate solution, this chemical reaction takes place in such a way that it can yield an electric current. We can obtain work from such a cell, *e.g.,* by using it to drive a small electromotor. The work can be measured accurately. If E is the electromotive force (volts) and C the current (ampères), then work done is EC units per second. While the current is passing we can measure the heat changes in the cell itself. These are found to be small, but not zero. If we express in heat units the electrical work done by the solution of unit mass, and add (or subtract) the simultaneous evolution (or absorption) of heat in the cell, we obtain a result which is the same as that obtained when the simple reaction was allowed to take place without the production of electrical energy. Alternatively, we could join the two electrodes with a wire and measure the heat produced in the wire by the passage of the electric current and the heat produced in the cell itself at the same time. The sum of these two would be the same as the heat produced by dissolving the same weight of zinc in a similar solution of copper sulphate, but by arranging the experiment in this way, most of the heat appears outside the solution instead of inside 'it.

It will be observed that the applications of the principle of conservation of energy depend on the assumption that a unit of one kind of energy always bears a constant relation to a unit of any other kind of energy. This is a necessary deduction from the law. If a mass of m grams is held h centimetres above the earth's surface, its *potential energy* is measured by the product *mgh,* where g is the constant of gravity and mg the force (in dynes) with which the earth attracts it. If it is allowed to fall freely, and we neglect the resistance of the air, it will have a velocity of v centimetres per second just before hitting the earth. Its potential energy has then been entirely converted into *kinetic energy* which is measured by the product $\frac{1}{2}mv^2$. As no energy is lost, $\frac{1}{2}mv^2=mgh$ and $v=\sqrt{2gh}$. When it hits the earth its kinetic energy is entirely converted into heat, and the amount of heat produced is exactly proportional to $\frac{1}{2}mv^2$, or to mgh. The potential energy is so called because, if the restraining force is removed, the mass acquires kinetic energy if left to itself. The energy is originally latent and only becomes apparent when the restraining force is removed; we can speak similarly of *latent* chemical energy.

Every element and every chemical compound has a definite content of energy which varies with the temperature. We know it varies with the temperature, because if we want to raise the temperature of anything we have to put heat into it. We do not know, however, what is the total energy content of any chemical substance, nor how it is divided up within the molecules; what we can determine is the *change in total energy* content which takes place during chemical reactions, and we can express the law of conservation of energy, in its application to chemistry, in the form

$$U=A-Q,$$

where U is the*diminution in total energy content accompanying a chemical reaction, A is the work done during or by means of the reaction, and Q is the actual measured absorption of heat during the reaction. In applying this equation it is necessary to express all quantities in the same units. A, the work done by a chemical reaction, is usually either mechanical work, as in the internal combustion engine, or electrical work, as in the accumulator. The unit of mechanical work in the C.G.S. system is the *erg,* the unit of heat is the *calorie,* which is the amount of heat necessary to raise the temperature of 1 gram of water from 15° to 16° C. The expenditure of $4{\cdot}18\times10^7$ ergs, or 4.18 *joules* will produce *1* calorie of heat.

Determination of Total Energy Changes.—The realization that the total energy content of a chemical substance was a property of the substance as important as any other property, and that the changes in energy accompanying chemical reactions were closely connected with the nature of the reaction, led to a very large number of experimental determinations of heats of reaction by J. Thomsen and M. Berthelot. Heats of reaction are determined in principle by causing the reaction to take place rapidly under such conditions that its heat is transferred to a large and well stirred volume of water, which is thereby raised a few degrees in temperature. As the specific heat of water is by definition unity at 15° C, the heat evolved can be calculated if the mass of water and its rise in temperature are accurately known. Allowance must be made for the actual heating of the containing vessels and the reacting substances, and also for the loss of heat during the time the reaction takes place. This loss of heat is kept down by keeping the rise in temperature small, which necessitates the use of very sensitive thermometers. Accurate calorimetry depends essentially on making proper allowances for this loss of heat, or alternatively on methods employed to counterbalance it. In general the data given in chemical literature cannot be relied upon to within $\frac{1}{2}\%$, and in many cases the error of determination is much greater. An experimental error of this order may be serious in certain cases, as we shall see later.

It is necessary to distinguish between heats evolved when reactions take place at constant pressure and at constant volume. Only the latter accurately correspond in all instances to the change in total energy due to the reaction. If the reaction is allowed to take place at constant (atmospheric) pressure and there is a change in volume due to the reaction, then work is done, and the measured heat of reaction will not be the same as the change in total energy. In the case of reactions taking place between solids or liquids the difference is usually negligible; in cases of gases the necessary correction can be easily applied. For instance, in the combustion of methane to carbon dioxide and liquid water, $CH_4+2O_2=CO_2+2H_2O$, three volumes of mixture react to form one volume of carbon dioxide and a negligible volume of liquid water. This diminution of volume means that at constant pressure work is performed by the atmosphere. This work reappears as additional heat in the calorimeter. If we take the volume of one mol. of gas (22.4 litres) as the unit volume, the work done, $2P\times V$, according to the gas laws $=2$ RT, where R, the gas constant, is approximately 2 when the work is expressed in heat units, and T is the absolute temperature. Thus the heat of combustion of methane, measured at 18° C (or 291° absolute), should be approximately 1 200 calories higher when the combustion takes place at constant pressure. *e.g.,* when the gas is burnt in a jet, than when the mixture is burnt in a completely closed vessel. If, however, the combustion takes place above 100° C so that no water vapour condenses, there is no change of volume, and no difference between the heats evolved at constant volume and constant pressure.

Indirect *Determination.*—Many heats of reaction are difficult if not impossible to measure directly. This is true of most reactions in organic chemistry which either do not take place rapidly enough to allow of accurate measurement, or yield other products besides those under investigation. But if the heats of combustion of organic compounds are known, the heat of any conceivable reaction between such compounds can be estimated by means of the first law. Take, for example, the technically important formation of methyl alcohol from carbon monoxide and hydrogen which proceeds according to the equation, $CO+2H_2=CH_3OH$. The heat of combustion of 1 mol. of carbon monoxide to carbon dioxide at constant pressure is 68,300 calories. The heat of combustion of 2 mols. of hydrogen to *liquid* water at constant pressure is $2\times68,400$ calories$=136,800$ calories. The heat of combustion of 1 mol. of methyl alcohol in the form of vapour to carbon dioxide and liquid water is 182,000 calories. Now the total change in energy must be the same whether the carbon monoxide and hydrogen are burnt directly to carbon dioxide and water, or whether they are first transformed into methyl alcohol and then burnt. Hence the heat evolved when carbon monoxide and hydrogen unite at constant pressure to give methyl alcohol in the form of vapour is:

$$68,300+136,800-182,000=23,100 \text{ calories.}$$

This example will serve to show the importance of accuracy in calorimeter measurements. For suppose Thomsen, whose figures have been taken, underestimated the heats of combustion of carbon monoxide and hydrogen by 1%, and overestimated that of methyl alcohol by 1%, the corrected figure for the heat of reaction to methyl alcohol would then be $69,000+138,200-180,200=27,000$ calories, which is nearly 20% higher than the estimate made on the basis of Thomsen's recorded results.

Variations Due to Physical Conditions.—Since the intrinsic (total) energy of a substance varies with the conditions under which the substance exists, it is necessary in recording the mechanical data to specify the conditions of the initial and final systems. Besides change of volume, the following conditions have to be considered: (1) Dilution of solutions. (2) Physical state. (3) Temperature.

(1) *Dilution of Solutions.*—Generally speaking, there is a considerable thermal effect when a substance is dissolved in water, and this effect varies in magnitude according to the amount of water employed. It is only, however, when we deal with comparatively concentrated solutions that the heat-effect of diluting the solutions is at all great, the heat-change on diluting an already dilute solution being for most practical purposes negligible. In dealing, therefore, with dilute solutions, it is only necessary to state that the solutions are dilute, the exact degree of dilution being unimportant. It occasionally happens that a change in dilution affects the chemical action that occurs. Thus, if concentrated instead of dilute sulphuric acid acts upon zinc, the action takes place to a great extent not according to the equation $Zn+H_2SO_4=ZnSO_4+H_2$, but according to the equation $Zn+2H_2SO_4=ZnSO_4+SO_2+2H_2O$, sulphur dioxide and water being produced instead of hydrogen. Here we have a different final system with a different amount of intrinsic energy, so that the thermal effect of the action is altogether different.

(2) *Physical* State.—The physical state of the reacting substances must be considered, since comparatively large amounts of heat are absorbed on fusion and vaporization. Thus the heat of fusion of ice (for 18 grams of H_2O) is 1,440 cal, and the heat of vaporization of water at 100° for the same quantity is 9,670 cal. When a substance, *e* g., carbon, phosphorus, sulphur, exists in allotropic forms, the particular variety employed should always be stated, as the conversion of one modification into another is frequently attended by a considerable thermal effect. Thus the conversion of white into red phosphorus evolves about one-sixth of the heat of combustion of the latter in oxygen, and so the knowledge of which variety of phosphorus has been employed is of essential importance in the thermochemistry of that element (*See* POLYMORPHISM)

(3) *Influence* of Temperature.—The influence of temperature on the thermal effects of a chemical reaction is sometimes considerable. If we know the change in total energy associated with any reaction at one temperature, the first law enables us to calculate it for any other temperature. If, for example, the total energy content at temperature T_1 is U_{H_2} for 1 mol. of hydrogen, U_{O_2} for 1 mol. of oxygen, and U_{H_2O} for 1 mol. of water vapour, the change in total energy due to the combination of hydrogen and oxygen to form 2 mols. of water vapour is, say,

$$2U_{H_2}+U_{O_2}-2U_{H_2O}=U_{T_1}.$$

If we raise the temperature of 1 mol. of hydrogen (etc.) from T_1 to T_2, its total energy is increased by $(C_v)_{H_2}(T_2-T_1)$, where $(C_v)_{H_2}$ is the mean capacity for heat of 1 mol. of hydrogen at constant volume between the temperatures T_2 and T_1. This is simply a definition of what we mean by *molecular specific heats*. Hence the total energy change at the higher temperature T_2 is:

$$2\{U_{H_2}+(C_v)_{H_2}(T_2-T_1)\}+U_{O_2}+(C_v)_{O_2}(T_2-T_1)$$
$$-2\{U_{H_2O}+(C_v)_{H_2O}(T_2-T_1)\}=U_{T_2}$$

$$\therefore \quad U_{T_2}-U_{T_1}=(T_2-T_1)\{2(C_v)_{H_2}+(C_v)_{O_2}-2(C_v)_{H_2O}\}$$

We can express this most simply by saying that the rate of change of U with the temperature (dU/dT) is equal to the sum of the heat capacities of the reacting compounds minus the sum of the heat capacities of the products of the reaction.

Thermochemical Measurements.—Some general results of thermochemical measurements applied to heats of combustion, neutralization and solution may now be considered.

(a) Heats of *Combustion.*—Experiment has shown that the heat of combustion of organic substances of various kinds varies regularly with the molecular weight. The difference between the heats of combustion of two neighbouring members in a series of homologous compounds is practically constant, and the value of the constant shows very little variation as we pass from one series to another. Thus the heat of combustion of methane, CH_4, to carbon dioxide and liquid water at constant pressure is 212,000 calories; of ethane, C_2H_6, is 370,500 calories, a difference of 158,500 calories; of propane, C_3H_8, is 529,200 calories, which is 158,700 above that of ethane; and the heat of combustion of all paraffin hydrocarbons (C_nH_{2n+2}) can be expressed by the formula $212,000+158,500\ (n-1)$ or $158,500\ n+53,500$ calories, where n is the number of carbon atoms in the molecule, and the mass to which the heat of combustion refers is the molecular weight in grams of the compound

Similarly the heat of combustion of alcohols $C_nH_{2n+1}OH$, can be expressed by the formula:

$$183,000+158,800\ (n-1)$$

or

$$158,000n+34,200 \text{ calories.}$$

As a rule the addition of a CH_2 group to any organic molecule will increase the molecular heat of combustion by about 158 800 calories, but the rule is not exact, and the actual figure varies somewhat from series to series. In particular the heat of combustion of two isomeric substances, i e, substances with the same number of carbon, hydrogen, oxygen, etc., atoms in the molecule, but differently arranged are very nearly but not exactly the same. It follows that there are similar regularities in the *heats* of *formation* of organic compounds, for the heat of formation is the difference between the heat of combustion of a compound and the total heats of combustion of the carbon, hydrogen, etc., it contains.

(b) *Heats* of *Neutralization.*—The heats of neutralization of acids and bases in aqueous solution are additively composed of two terms, one being constant for a given base, the other constant for a given acid. In addition to this the further regularity has been observed that, when the powerful monobasic acids are neutralized by the powerful monacid bases in dilute solution, the heat of neutralization is in all cases the same. The following table gives the heats of neutralization of the commoner strong monobasic acids with soda:

	Formula	Cal.
Hydrochloric acid . .	HCl	137,400
Hydrobromic acid . .	HBr	137,500
Hydriodic acid . . .	HI	136,800
Nitric acid	HNO_3	136,800
Chloric acid . . .	$HClO_3$	137,600
Bromic acid . . .	$HBrO_3$	137,800

Within the error of experiment these numbers are identical.

It was at one time thought that the greater the heat of neutralization of an acid with a given base, the greater was the strength of the acid. It is now known, however, that when weak acids or bases are used, the heat of neutralization may be either greater or less than the normal value for powerful acids and bases, so that there is no proportionality, or even parallelism, between the strengths of acids and their heats of neutralization (see REACTION KINETICS).

(c) Heats of Solution.—When substances readily combine with water to form hydrates, the heat of solution in water is usually positive; when, on the other hand, they do not readily form hydrates, or when they are already hydrated, the heat of solution is usually negative. The following examples show the effect of hydration on heat of solution in a large quantity of water:

I. *Sodium Carbonate*

	Heat of solution	Heat of hydration
	cal.	cal.
Na_2CO_3 . . .	+ 5,640	. .
Na_2CO_3,H_2O . .	+ 2,250	+ 3,390
$Na_2CO_3,2H_2O$ . .	+ 20	+ 5,620
$Na_2CO_3,10H_2O$ . .	−16,160	+21,800

II. *Sodium Sulphate*

	Heat of solution	Heat of hydration
	cal.	cal.
Na_2SO_4 . . .	+ 460	. .
Na_2SO_4,H_2O . .	− 1,900	+ 2,360
$Na_2SO_4,10H_2O$ . .	−18,760	+19,200

First and Second Laws of Thermodynamics.— It should be clearly realized that the law of conservation of energy, like the law of conservation of mass, is a statement of experimental observations and in chemistry admits of no exception. All recorded observations support the law within the unavoidable errors of experiment; all deductions from the law have been amply verified. Apparent limitations of the law have been brought to light by recent physical research, and in particular through Einstein's famous theory of relativity (*q.v.*), but in ordinary chemistry we do not deal with atomic or ultra-atomic changes, but with molecular rearrangements, and the laws of conservation of energy and mass, as originally conceived, still hold good.

Reversible Chemical Reactions.—As the result of the large number of experiments made by them, Thomsen and, later, Berthelot expressed the opinion that heat of reaction must be regarded as a measure of chemical affinity, and that every chemical change tended to take a course which evolved the maximum amount of heat. Berthelot in particular regarded this as a general guiding principle in chemistry, and impressed its importance so much on others that it continued to be upheld long after Berthelot himself had recognized its error. It is not easy now to realize why this "principle" commanded such universal acceptance; simple physical transformations which took place spontaneously either with absorption or evolution of heat, according to the circumstances, must have been familiar. For instance, water will freeze spontaneously and in doing so will liberate thermal energy if the temperature is below 0°. Above 0° ice melts spontaneously and in doing so absorbs heat from its surroundings. Further, even at the time Berthelot put forward his theory, there was a growing recognition of the fact that many chemical reactions are reversible, *i.e.*, that they take place either in one direction (with evolution of heat) or in the opposite direction (with absorption of heat), according to the conditions of temperature and pressure and the relative masses of the reacting substances. So long ago as 1801, the great French chemist Berthollet had introduced the idea of "chemical equilibrium," and in the same year that Berthelot put forward his erroneous theory (1867) Guldberg and Waage published their famous book on chemical affinity, which dealt with reversible chemical reactions and in which they put forward the law of chemical mass action.

Chemical Equilibrium.—This law, in so far as chemical equilibrium is concerned, may be formulated as follows. Suppose chemical substances, A_1, A_2, etc., react to form B_1, B_2, etc. The reaction tends to proceed until a condition of equilibrium is set up, governed by the equation

$$\frac{[A_1]\times[A_2]\times \text{etc.}}{[B_1]\times[B_2]\times \text{etc.}} = K.$$

where $[A_1]$, etc., represents the concentration of the compound A_1, etc., in the equilibrium mixture. On the other hand, if the compounds B_1 and B_2 are originally brought together, then the reaction will proceed in the reverse direction with production of A_1 and A_2 until the same condition of equilibrium is set up. The value of the equilibrium constant K is itself independent of concentration—for example, in the case of gaseous reactions it is independent of pressure—but it varies with the temperature. Clearly such constants are of great significance in the study of chemical affinities. If K is very small, then the affinity of A_1 for A_2, etc., may be said to be very great, and the affinity of B_1 for B_2, etc., small, although not zero.

The important thing to notice is that every single instance of a reversible chemical reaction really disproves the Berthelot principle. Nevertheless, the principle has this much to be said for it, that most chemical reactions which take place spontaneously at low temperatures do so with evolution of heat, and that it is only when the effects of high temperatures are studied that one becomes really familiar with important reactions that take place spontaneously nith absorption of heat. There is one such reaction that is made use of daily on an enormous scale for the production of heat, namely, the reaction between steam and coke at a bright red heat to yield "water gas," a mixture of approximately equal volumes of hydrogen and carbon monoxide. As the reaction proceeds the coke cools, and at regular intervals it is necessary to shut off the supply of steam and to pass air over the coke in order to raise it again by combustion to a temperature sufficiently high to allow the reaction with steam to continue rapidly It is true that the cooling of the eoke during the passage of steam does not entirely result from the chemical reaction, for it is partly accounted for by the cooling effect of the steam itself, which is introduced to the retort at a lower temperature than the coke. But even if the steam were initially at the same temperature as the coke, it would be found that the mass gradually cooled. The spontaneous formation of nitric oxide by the passage of air through an electric arc, a process by which nitric acid is manufactured on a large scale, is also accompanied by absorption of heat. Pure nitric oxide, on the other hand. decomposes into its elements, nitrogen and oxygen. at a somewhat lower temperature with evolution of heat. Hydrogen and oxygen will combine explosively and completely at low temperatures; but steam is found to decompose spontaneously though not completely into hydrogen and oxygen if it is heated to a temperature above 2,000° C., and heat is absorbed during the decomposition. Clearly, therefore, the heat evolved during a chemical reaction cannot give a direct measure of the affinity of the reacting substances.

The first big practical advance that was made in the knowledge of the relations between thermal changes and chemical affinity was due to van't Hoff's demonstration that the law of mass action was a necessary consequence of the second law of thermodynamics and of the quantitative connection between the value of the "equilibrium constant" and the change in total energy due to the reaction. The second law of thermodynamics, like the first, is a statement of experience, perhaps one might say a collection of interrelated statements of experience. The first law states that it is impossible to create energy; the second law states that it is impossible to convert the heat energy of our surroundings continuously into useful work. The second law deals with a question which the first law does not answer, namely, under what conditions can heat energy be converted into useful work (that is to say, mechanical energy). If heat energy passes spontaneously from one body to another, the first body is said to be at a higher temperature. It is a matter of universal experience that the reverse change, *i.e.,* the passage of heat from one body to another of higher temperature never takes place spontaneously. It is also a matter of experience that any spontaneous process can be made to yield a definite amount of useful work. For instance, the cooling of a furnace is a spontaneous process. By the use of steam and suitably designed engines, it is possible to obtain useful work from this process.

Carnot's Definition.—The question how much useful work can be obtained by the spontaneous passage of heat from one temperature to another is of fundamental importance both in mechanical engineering and in chemistry. Sadi Carnot, a young French engineer, actually solved this problem in *1824* before the law of conservation of energy was universally accepted He showed that the maximum amount of work which can possibly be obtained from the "spontaneous" transference of a quantity of heat Q from a reservoir at temperature T_1 to another of the lower temperature T_2 was $Q(T_1-T_2)/T_1$. It will be noted that Carnot's result involves a quantitative definition of "absolute" temperature. The so-called "thermodynamic scale of temperatures" which is implicit in his result, is based on the behaviour of a perfect gas, the energy content of which is independent of its volume and dependent only on the temperature. The absolute temperature of a perfect gas is defined by the fundamental gas law $T=PV/R$, where P is the gas pressure, V its volume, and R a constant. The value of R depends on the units in which the pressure and volume are expressed. Many gases approach very nearly the properties of the imaginary "perfect" gas, particularly at low densities.

The next point of interest is that Carnot in deriving his result imagined a perfectly frictionless engine, with a perfect gas as a working fluid, taking heat from the high temperature reservoir (as steam takes heat from a furnace), converting part of the heat into work, and rejecting the rest to the low-temperature reservoir. The argument is that such an engine will always yield the maximum amount of work, because if it is reversed, the expenditure of work, only infinitesimally greater in amount than the engine yields on the direct operation, will suffice to restore the heat from the low temperature to the high temperature reservoir. For suppose it was possible to make another reversible and frictionless engine which was capable of converting a greater proportion of the transferred heat into work. Then it would be possible to use part of the work yielded by this change to reverse the first engine, and to restore the whole system to its original condition, leaving a definite amount of work over which has been created out of nothing. This is contrary to the first law. Hence we say that the work that can be done by a perfectly efficient reversible engine or process is independent of the nature of the process.

The Gibbs-Helmholtz Equation.— This conclusion leads to a mathematical expression of the first and second laws of thermodynhmics in a form which can be applied to all chemical as well as other phenomena. For if, instead of having a perfect engine to transfer heat from the reservoir at $T+dT$ to another at T, we allow a chemical process to take place in the first reservoir, yielding a maximum amount of work A and absorbing heat from the reservoir equal to Q, and we then reverse this chemical process in the second reservoir by the expenditure of $A-dA$ of work, we have gained an amount of work$=dA$, and if the process is conducted reversibly this work must be equal to that gained by any other perfect process; in other words, $dA=Q{\cdot}dT/T$. But Q, the heat absorbed, is equal (by the law of conservation of energy) to the maximum work A, less the diminution in total energy U, *i.e.,*

$$dA=(A-U)dT/T,$$
$$\text{or } A-U=T{\cdot}dA/dT$$

This is the relation which was deduced independently by Helmholtz and Willard Gibbs. The quantity A is the maximum amount of work that can be obtained from a (reversible) chemical process taking place spontaneously and at constant volume at the temperature T; $A+dA$ is the work that would be obtained by allowing it to take place at the same volume at the higher temperature $T+dT$; and U is the diminution of total energy which corresponds to the heat evolved when the reaction takes place without the performance of any work, *e.g.,* in a closed vessel. A is often known as the *decrease* in free energy, to distinguish it from U, the decrease in total energy.

The most direct use of this equation is found in its application to the electric cell or battery. For the electric cell is a contrivance for converting chemical energy into useful work. If the cell is reversible, the work will be the maximym obtainable from the chemical reaction which is the source of the electric current What we mean by a reversible cell is that, if a potential infinitesimally greater than that yielded by the cell is applied to the electrodes, the current will travel in the reverse direction in the cell and the chemical reaction will be reversed. The lead accumulator is nearly reversible in this sense; so is the Daniell cell. The electromotive force of the Daniell cell is found to be 1·1 volts. For every gram-equivalent of copper deposited and zinc dissolved in the cell, an amount of work is done$=EF$, where F is the quantity of electricity *(96,540* coulombs) associated with one gram-equivalent. These units can be expressed in calories; calculation shows that if E is the potential, the work done by the reaction is $23{,}050E$ calories. Hence the work done by the Daniell cell is *25,260* calories per gram-equivalent of copper deposited, The heat of the reaction, when it takes place without performance of work, is found to be *25,060* calories. Hence in this case A=U nearly. We should find therefore that dA/dT, or dE/dT, which is the change of electromotive force with the temperature, is very small. Measurement shows that it is only 0·000034 volt per degree.

Lord Kelvin put forward the view in 1851 that the electromotive force of a cell could always be calculated from the heat of the chemical reaction, that is to say from the decrease in total energy. This "law" involves the assumption that no chemical reaction can be made to yield electrical energy unless it is accompanied by a decrease in total energy. It holds approximately for the Daniell cell. and for others such as the standard Weston cell. The Helmholtz equation shows that it can only be true when the electromotive force does not change with the temperature. We are familiar now with cells which yield an electric current even if the chemical reaction is associated with an absorption of heat; we know of cells the voltage of which increases with temperature, and others in which it decreases. None of these cells obeys Kelvin's law, but the behaviour of all of them can be shown to be in exact accordance with the Helmholtz equation. The study of electric cells provides the most interesting and exact confirmation of the fundamental laws of thermodynamics.

The Van't Hoff Equation.— Apart from the combustion of coal and oil, most chemical reactions interest us more from the point of view of the nature of their products than from that of the work obtainable from them. As all chemical reactions are in principle reversible, and as many of the more important from a practical point of view can be made to proceed in one or the other direction according to conditions of temperature and pressure, it is not only of theoretical interest but of great technical importance to get an accurate picture of the relations between chemical equilibrium and thermal changes. Van't Hoff succeeded in doing this by calculating the maximum work that could be obtained from a chemical reaction taking place between gases, by the use of an imaginary "ideal" process. By the application of the second law two important results emerged:

(1) The law of mass action, first deduced from consideration of molecular theory, was shown to be a necessary consequence of the thermodynamical laws, that is to say, if a state of equilibrium exists between gases according to the chemical equation

$$n_1\mathrm{A}+n_2\mathrm{B}+\text{ etc.}=n'_1\mathrm{A}'+n'_2\mathrm{B}'+\text{ etc.}+U\text{ calories,}$$

then
$$\frac{[\mathrm{A}]^{n_1}\times[\mathrm{B}]^{n_2}\times\cdots}{[\mathrm{A}']^{n'_1}\times[\mathrm{B}']^{n'_2}\times\cdots}=K.$$

(2) *The equilibrium* constant K was shown to be connected with the temperature and the decrease in total energy through the equation

$$d \log_e K/dT = U/RT^2.$$

In practical applications it is usually more convenient to express the quantities of gases present in an equilibrium mixture in terms of their partial pressures instead of their concentrations. If there are N molecules of gas present altogether in a mixture which contains n_1 molecules of one kind, n_2 of another, and so on, the partial pressures are n_1P/N, n_2P/N, etc. where P is the total pressure. It is simple to show that

$$\frac{P_A^{n_1} \times P_B^{n_2} \times \cdots}{P_{A'}^{n'_1} \times P_{B'}^{n'_2} \times \cdots} = K_p$$

where P_A^n represents the partial pressure of A, and the new constant $K_p = K(RT)\ \Sigma_n$, Σ_n being the difference between the number of the reacting molecules and the total number formed by the reaction: $d \log_e K_p/dT = Q_p/RT^2$. It can also be easily shown that where Q_p is now not necessarily the diminution in total energy but corresponds to the heat evolved when the reaction takes place at constant pressure, nithout the performance of any work other than that caused by the change of volume, if any, associated with the reaction. This equation is similar to that found to hold good for the change of vapour pressures of liquids (and solids) with the temperature, *viz.*, $d \log_e p/dT = \lambda/RT^2$, where λ is the latent heat of evaporation of one gram molecule of the liquid or solid.

Some Thermochemical Reactions.—The application of these equations to chemistry inaugurated a new era, and led not only to a rapid extension of knowledge of chemical reaction, but also to the recognition of the connection between many apparently diverse phenomena. Some illustrations of the use of the equations will now be given.

Hydrogen and oxygen combine to form steam with evolution of heat according to the equation

$$2H_2 + O_2 = 2H_2O + 116{,}000 \text{ calories.}$$

If we start with 2 mols. of hydrogen and 1 mol. of oxygen, then according to the law of mass action an equilibrium will be reached when $2(1-x)$ mols. of water vapour are formed, and $2x$ mols. of H_2 and x mols. of O_2 are left uncombined. Supposing the volume occupied is v, then the law states that at equilibrium

$$\frac{(\text{Concn. of } H_2)^2 \times (\text{Concn. of } O_2)}{(\text{Concn. of water vapour})^2} = K$$

or

$$\frac{\frac{(2x)^2}{v} \times \frac{x}{v}}{\left\{\frac{2(1-x)}{v}\right\}^2} = K \text{ or } \frac{x^3}{(1-x)^2} \times \frac{1}{v} = K.$$

Now at ordinary temperatures, the amount of hydrogen and oxygen left uncombined is very small and escapes direct measurement. As x is small, K is also small. But van't Hoff's equation shows that, as U is large and positive, log K, and therefore K, increases with the temperature. Hence x increases with the temperature. In other words, water vapour will dissociate when the temperature is raised.

This result may be generalized. All compounds which are formed with evolution of heat tend to decompose when the temperature is raised. The same applies to molecules such as H_2, O_2, N_2, Cl_2, I_2, etc., which are formed from their atoms with evolution of heat. Conversely, compounds which are formed with absorption of heat become more stable at high temperatures. Nitric oxide cannot be made from nitrogen and oxygen at low temperatures, but is formed when air is blown through an electric arc. Hydrogen peroxide may be detected in an oxy-hydrogen flame. Calcium carbide is formed in an electric furnace at a very high temperature. If v in the equation given above is made smaller, then x must also diminish, because K is constant. High pressure tends, therefore, to assist combination or to prevent dissociation. This is the case whenever the reaction is accompanied by a decrease in the number of molecules. The synthesis of ammonia is an important technical example. Here one molecule of nitrogen combines with three molecules of hydrogen to form two of ammonia, $N_2 + 3H_2 = 2NH_3$. The mass action equation is

$$27x^4/4(1-x)^2v^2 = K,$$

where x is the fraction of nitrogen left over. If the value of v is diminished, x must also be diminished, and the amount of ammonia formed increases. As is well known, the commercial success of the process depends on very high pressure being used. If no change in the number of molecules is caused by a reaction, v cancels out, and therefore an alteration in the pressure has no effect on the equilibrium. If the number of molecules is increased, v appears in the numerator instead of the denominator, and an increase of pressure will then have the opposite effect.

The effects of pressure and temperatures on equilibrium can be generalized in the statement that the equilibrium will always adjust itself in such a way as to oppose a change in physical conditions. If the pressure is increased, the equilibrium will shift in the direction of smaller volume. When heat is added that reaction will take place which results in an absorption of heat, thus tending to stop a rise of temperature. The same applies to physical processes. Water expands when it freezes; if we compress ice at the freezing point it will do its best to diminish its volume by melting. Liquids always absorb heat when they evaporate; if heat is added to water which is boiling at atmospheric pressure, its temperature is not increased. All that happens is that it boils faster.

If a reaction between gases is studied experimentally at any one temperature and pressure, so that the equilibrium conditions are known, then the effect of a variation in pressure at that temperature can be accurately calculated provided the mixture obeys the "perfect gas" laws. If the heat of reaction is also known at that temperature, then the equilibrium for any other temperature not too far removed can be calculated from van't Hoff's equation. For integration of the equation gives

$$\log_e K = -U/RT + \text{constant},$$

if U does not change much with the temperature. Hence if K_1 and K_2 are the equilibrium constants at temperatures T_1 and T_2

$$\log_e K_1/K_2 = U(1/T_2 - 1/T_1)/R.$$

Gases and Solids.—Chemical reactions in which gases and solids take part present features of special interest. To take a simple example, carbon dioxide combines with lime to form calcium carbonate with evolution of heat:

$$\underset{\text{solid}}{CaO} + \underset{\text{gas}}{CO_2} = \underset{\text{solid}}{CaCO_3} + 42{,}500 \text{ calories.}$$

Now the pressure of saturated vapour above any solid or liquid is independent of the amount of solid or liquid present, unless the amount is very minute. If a closed space contains carbon dioxide gas, in the presence of solid calcium oxide and carbonate, there will be an equilibrium in the gaseous phase governed by the relation

$$\frac{(\text{Concn. of CaO vapour}) \times (\text{Concn. of } CO_2)}{(\text{Concn. of } CaCO_3 \text{ vapour})} = K.$$

As the concentrations of the vapours of the two solids are constant (though extremely small) at any given temperature, it follows that the concentration of carbon dioxide must also be constant. In other words its pressure is constant. Above a mixture of calcium oxide and carbonate we have, therefore, our apparent "vapour" pressure of carbon dioxide, which varies with the temperature.

The heat of the reaction is analogous to the heat of evaporation of any solid or liquid, and if P is the "vapour" pressure, which is called the dissociation pressure in this and similar cases,

$$d \log_e P/dT = Q/RT^2,$$

where Q is the heat of reaction, *i.e.*, the heat absorbed on dissociation of 1 gram-molecule, and includes the work done against atmospheric pressure by the evolution of 1 gram-molecule of carbon dioxide. The dissociation pressure, like the vapour pressure of liquids, increases with the temperature. At a high temperature, about 900° C, the dissociation pressure is equal to ordinary atmospheric pressure. If the carbonate is heated above this temperature it is converted into lime and carbon dioxide is rapidly evolved.

If other carbonates are examined it is found that the temperature at which they are converted into their oxides varies directly with their heat of dissociation as the following table shows:

Substance	Heat of dissociation	Temperature
	cals.	°C.
Silver carbonate . .	20,100	225
Lead carbonate . .	22,600	302
Manganese carbonate .	23,500	ca. 330
Calcium carbonate . .	42,500	900
Strontium carbonate .	55,800	1,150

On similar reasoning, it may be shown generally that in all reactions in which gases and solids take part, the equilibrium conditions only take account of the gases. For instance, when carbon dioxide is passed over red-hot coke it is converted into carbon monoxide with absorption of heat, $C+CO_2=2CO-38{,}500$ calories. The equilibrium condition is

$$P_{co}/P_{co2}=K \text{ or } d\log_e K_p/dT=38{,}500\ RT^2$$

from which it can be deduced (a) that the ratio CO/CO_2 in the gas mixture at equilibrium is constant if the temperature and pressure are constant; (b) that if the temperature is kept constant, and the pressure is increased, the proportion of carbon monoxide in the mixture goes down; (c) that if the temperature is increased, the proportion of carbon monoxide goes up.

In the blast furnace, air is blown through a white-hot mixture of oxides of iron and coke, and the carbon monoxide formed by the combustion of coke reduces the oxides to metallic iron. The exit gases must contain a large proportion of carbon monoxide to carbon dioxide, corresponding to the equilibrium conditions which obtain near the cooler top of the furnace. It was at one time thought that by building furnaces higher, the period of contact between the gases and the ore would result in a greater measure of reduction, a diminished proportion of carbon monoxide in the exit gases, and consequently a smaller consumption of coke per ton of ore reduced. Attempts to achieve these results, by building furnaces as high as 100 ft., failed. As Le Chatelier pointed out, if there had been a better acquaintance with the laws of chemical equilibrium, these experiments would have been unnecessary. It was an expensive, although no doubt an instructive, method of proving the correctness of one of the deductions from the second law.

Heat and Velocity of Reaction.—These examples will suffice to indicate how the quantitative application of simple fundamental thermodynamic principles has been successful in reducing to order an enormous range of observations on chemical reactions apparently very diverse in character. It has also given the chemical engineer the power to calculate the conditions for achieving the maximum technical success in the conduct of any chemical manufacture on the large scale. Unfortunately, though the application of thermodynamics has been so successful in the study of chemical equilibrium, it has as yet taught us nothing about the rate at which equilibrium is attained, or, in other words, about the rate of chemical reaction. There seems to be no direct connection between the rate of a reaction and either the heat evolved (change in total energy), or the maximum work of the reaction (change in free energy). Hydrogen has a great affinity for oxygen, and much heat is evolved when they combine; yet a mixture of them can be kept for an indefinite period of time at the ordinary temperature without a trace of combination. Nitric oxide is an extremely unstable substance at low temperature; on thermodynamical grounds we should expect that only an infinitesimal amount of it would be in equilibrium with nitrogen and oxygen at the ordinary temperature; yet it is so difficult to decompose by heat that even at 900° C it only decomposes slowly. Ammonia becomes progressively less stable as the temperature is raised. Thermodynamics indicates that in order to obtain high yields, its synthesis from nitrogen and hydrogen should be conducted at as low a temperature as possible. The reaction is, however, so slow that technical manufacture only becomes possible at temperatures so high that the yield of ammonia at atmospheric pressure is extremely small. The ill effects of the high temperature have to be counterbalanced by the use of high pressures. Nearly all gas reactions take place extremely slowly unless the temperature is very high. Nearly all, too, take place more quickly in the presence of certain solids called catalysts. The nature of the catalyst to produce the best results varies with the nature of the reaction, and though many theories have been put forward to account for their action, there is no general theory which has been successful in predicting anything—which is the ultimate test of the real value of a theory.

Free Energy.—The second law of thermodynamics deals with changes in the free energy of a system. A system only possesses "free energy" when it is capable of doing work. It is only capable of doing work if it will change spontaneously into another system of greater stability. Only an unstable system has free energy. A stable system can be changed into an unstable system by the performance of work, or by the transference of free energy from another system. The whole of life, and of civilization as we know it, depends on thermodynamic instability; as Boltzmann (1886) put it, the struggle for-existence is a struggle for free energy available for work. Nearly all manufacturing processes depend essentially on using the free energy stored in coal to convert a useless stable system into a useful unstable system. For instance, the synthetic manufacture of fertilizers depends essentially on the use of a small part of the free energy available when coal is burnt, to convert the stable system nitrogen+water, into the unstable system ammonia+oxygen. The ammonia in various forms can be made use of to fertilize plants, *i.e.,* to increase the free energy in the plant world which the animal world can convert again into useful work. The enormous amount of energy which the earth continuously receives from the sun is theoretically almost completely available for useful work, for the energy leaves the sun at a temperature over 8,000° and is finally dissipated into space at a temperature of about 300° Absolute. Calculation shows that the energy so received is at least a million times greater than the energy given by the world's power plants. But unfortunately we know of no means for making use of anything more than a minute fraction of the sun's energy. A very small part of it is converted into mechanical energy by water power plants; another very small part is used by the plant world to build up "unstable" organic compounds, and thus to supply the free energy available in food. One of the chief tasks of the scientist of the future will be to devise means for converting into useful work, or storing, a greater part of the energy received from the sun. The second law shows that this should be possible. If he does not succeed the advance, and even the maintenance, of civilization may be impossible when the energy stored in coal through the agency of the plant world in past ages is exhausted.

The Third Law of Thermodynamics.—It has already been pointed out that although the Gibbs–Helmholtz equation enables us to calculate from purely thermal data the change in any equilibrium with the temperature, it does not give any information on the actual value of the equilibrium constant unless this is already known from experimental observations under one set of conditions. To obtain the actual value from purely thermal data, it is necessary to integrate the fundamental equation $d\log_e K/dT=U/RT^2$, and integration introduces an unknown integration constant.

In 1901 Nernst advanced a method of evaluating this constant, and his theorem is often referred to as the "third law" of thermodynamics, although its universal applicability is still open to some doubt.

In Condensed Systems.—Nernst postulates that in the case of chemical reactions in condensed systems, *i.e.,* reactions in solids or between solids and liquids, not only does A become $=U$ at absolute zero $(T=0)$, as is required by the Gibbs-Helmholtz equation, but that they both reach their final (equal) value at temperatures not far removed from the absolute zero. In mathematical language, $dA/dT=dU/dT=0$ when $T=0$. Now dU/dT is equal to the difference between the sum of the molecular heat capacities (C_v) of the reacting substances and of the products. Since it is found by experiment that the specific heats of substances can be expressed with sufficient accuracy by equations of the form $C_v=a+bT+cT^2+$ etc. it follows that U can also be expressed in the form

$$U=U_0+\alpha T+\beta T^2+\gamma T^3+\ \dots$$

But if $dU/dT=0$ when $T=0$, it follows that $\alpha=0$, or

$$U=U_0+\beta T^2+\gamma T^3.$$

If this expression for U is substituted in the fundamental equation $A-U=T.\ dA/dT$, it follows that

$$A=U_0+aT-\beta T^2-\frac{\gamma}{2}T^3-\text{etc.}$$

where a is an unknown constant. But if $dA/dT=0$ when $T=0$, as Nernst postulates, a must also be equal to zero, and therefore

$$A=U_0-\beta T^2-\frac{\gamma}{2}T^3-\text{etc.}$$

Hence if the heat of reaction, and the specific heats of the substances taking part in the reaction are known, it should be possible to calculate A for any temperature.

Consider such a change as the melting point of a solid, or a transition from one modification to another such as the change from rhombic to monoclinic sulphur. Then at the temperature when the solid and liquid, or the two forms of solid, co-exist in equilibrium, A, the work obtainable from the change, is zero. If we know the heat of the reaction at this temperature (latent heat), and if we know the difference between the specific heats of the two forms over a wide range of temperature, we can express U in the form

$$U=U_0+\beta T^2+\gamma T^3+\dots$$

and therefore T, the temperature where $A=0$ (melting point, or transition point), is given by

$$U_0=\beta T^2+\frac{\gamma}{2}T^3+\cdots$$

Nernst has shown how the transition point of sulphur can be calculated in this way from purely thermal data.

The difficulty of applying the theory to a wide range of such reactions is due to the fact that the all-important knowledge of the variation of specific heats with temperature is still lacking in the majority of cases; only in the case of regularly crystallizing elements do we now know the relation accurately. Theory is insufficiently advanced to guide us in the other cases, and accurate experimental work over a great range of temperature is extremely difficult as well as laborious. Nevertheless the application of the Nernst theorem to many different types of condensed systems has been so successful, and the theorem itself is supported in so many other indirect ways, that there is little doubt as to its essential truth.

In **Gas** Reactions.—It is, however, in its extension to gas reactions that the Nernst theorem has won its most significant successes. If we substitute for U in the van't Hoff equation, the expression

$$U=U_0+\alpha T+\beta T^2+$$

we get
$$\frac{d\log_e K}{dT}=\frac{U_0}{RT^2}+\frac{\alpha}{RT}+\frac{\beta}{R}+\cdots$$

Integration gives

$$\log_e K=-\frac{U_0}{RT}+\frac{\alpha}{R}\log_e T+\frac{\beta}{R}T\cdots+\mathrm{I},$$

where I is an unknown integration constant. Since the vapour pressure (p) of a liquid is similarly connected with the latent heat (λ) by the equation $d\log_e p/dT=\lambda/RT^2$, we can also write

$$\log_e p=-\frac{\lambda_0}{RT}+\frac{\alpha_0}{R}\log_e T+\frac{\beta_0}{R}T+\text{etc.}+i,$$

where i is the unknown integration constant of the vapour Pressure curve.

Nernst shows that a consequence of his fundamental theorem is that $I=\Sigma ni$, where n is the number of molecular species taking part in the reaction; that is to say, if the reaction is

$$A+B+C+\text{ etc.}=D+E+F+\text{ etc.}$$

then
$$I=i_A+i_B+i_C+\ \dots\ -i_D-i_E-i_F\ \dots\ \text{etc.}$$

This is a most important advance, for it means that it is possible to calculate any equilibrium between gases, provided the heat of the reaction is known, and the vapour pressure curves of the molecular species taking part in the reaction.

In the absence of sufficiently accurate data to make the strict application of the Nernst theorem possible, except in a very small number of cases, Nernst has also developed an approximation formula which is of great practical use. It depends on the fact that the vapour pressure of most substances can be represented sufficiently accurately by the equation

$$\log_{10}p=-\frac{\lambda_0}{4{\cdot}57T}+1{\cdot}75\log_{10}T-\frac{\beta T}{4{\cdot}57}+C.$$

C, the so-called *conventional* chemical *constant*, is itself found to be approximately $0{\cdot}14\ \lambda/T_0$, where λ is the latent heat at the boiling point T_0. For most substances which are liquid at the ordinary temperature, $\lambda/T_0=22$ approximately, and therefore $C=3{\cdot}1$. Only a few substances give values for C under 3; mainly they vary between 3 and 3.5.

On the basis of this semi-empirical vapour-pressure equation the corresponding formula for gaseous equilibria becomes:

$$\log_{10}K_p=-\frac{Q_p}{4{\cdot}57T}+\Sigma n{\cdot}1{\cdot}75\log_{10}T+\frac{\beta}{4.57}T+\Sigma nC$$

which may as a rule be further simplified by omitting the term $\frac{\beta}{4{\cdot}57}T$, thus giving:

$$\log_{10}K_p=-\frac{Q_p}{4{\cdot}57T}+\Sigma n{\cdot}1{\cdot}75\log_{10}T+\Sigma nC.$$

Now it is not pretended that an equation of this form represents actual results with accuracy. Its claim of utility is that it is based generally on correct principles, and that in actual practice it represents with considerable success the effect of temperature on chemical equilibria. A few examples will show how this claim is borne out.

(a) Consider the reaction:

$$2CO+O_2=2CO_2+136{,}000\text{ calories.}$$

K_p, the equilibrium constant, is $P^2_{CO}\times P_{O_2}/P^2_{CO_2}$, where P_{CO}, etc., represents the partial pressure of CO, etc., in the equilibrium mixture. Q_p, the heat of reaction at constant pressure and room temperature, is 136,000 calories. Σn is the difference between the number of molecules on the left and right hand sides of the chemical equation, *i.e.*, $\Sigma n=1$; ΣnC is twice the chemical constant of CO plus the chemical constant of O_2 minus twice the chemical constant of CO_2, *i.e.*,

$$\Sigma nC=2\times 3{\cdot}5+2{\cdot}8-2\times 3{\cdot}2=3{\cdot}4.$$

$$\therefore\ \log K_p=-\frac{136{,}000}{4{\cdot}57T}+1{\cdot}75\log T+3{\cdot}4.$$

At 2,000° Abs. K_p calculated from this equation is 2×10^{-6} whereas the most recent results indicate that this value is reached at 2,020° Absolute. When CO_2 is half dissociated, there are 0·5 molecules of CO_2, 0·5 of CO, and 0·25 of O_2 present at equilibrium. If the total pressure is 1 atmosphere, the partial pressures of

CO and CO_2 are $\frac{0.5}{1.25}$ atmos., and of O_2, $\frac{0.25}{1.25}$ atmos.; therefore, $K_p=0.2$. The corresponding temperature is calculated from the above equation to be 2,930° Abs., whilst the temperature actually observed is 3,100°.

(b) If the reaction brings about no change in the number of molecules, the second term of the equation vanishes, and the third usually becomes very small. For instance

$$2NO=N_2+O_2+43,200 \text{ cals.}$$

and
$$\log K_p=\log\frac{P^2_{NO}}{P_{N_2}\times P_{O_2}}=-\frac{43,200}{4.57T}+1.6=-\frac{9,450}{T}+1.6.$$

This shows, in accordance with observation, that only at very high temperatures are appreciable quantities of nitric oxide formed from nitrogen and oxygen.

(c) If on the other hand, the change in the number of molecules is big, then the first term of the equation may be of little influence. For instance, the probability of a high-boiling paraffin hydrocarbon being formed from hydrogen and carbon can be calculated:

$$nC+(n+1)H_2=C_nH_{2n+2}+Q \text{ calories.}$$

Thomsen's experiments have shown that the heat of formation of such a hydrocarbon from its elements is given approximately by $Q_p=(7n+15)1{,}000$. As the chemical constant of H_2 is 1.6, and of C_nH_{2n+2} about 3.0 we have

$$\log K_p=\log\frac{P^{n+1}_{H_2}}{P_{C_nH_{2n+2}}}=-\frac{1000(7n+15)}{4.57T}+n\times1.75\log T+1.6n-1.4.$$

Suppose $T=773°$, *i.e.*, 500° C. Then

$$\log\frac{P^{n+1}_{H_2}}{P_{C_nH_{2n+2}}}=-1.98n-4.24+5.06n+1.6n-1.4=4.68n-5.64.$$

If $n=1$, *i.e.*, if the hydrocarbon formed is methane, CH_4, then

$$\log\frac{P^2_{H_2}}{P_{CH_4}}=-0.96 \text{ or } \frac{P^2_{H_2}}{P_{CH_4}}=0.11$$

from which it can be calculated that if hydrogen is passed over carbon at 500° C., the issuing gas should contain about 70% of methane if equilibrium is reached. Experimental results agree quite well with this. If, however, $n=7$, *i.e.*, if the hydrocarbon is heptane, C_7H_{16}, which boils at about 100° C., $\log\frac{P^8_{H_2}}{P_{C_7H_{16}}}$ is over 27, or $\frac{P^8_{H_2}}{P_{C_7H_{16}}}$ is over 10^{27}, which means that the amount of heptane formed at atmospheric pressure will be quite negligible. All the higher liquid hydrocarbons, such as occur in natural petroleum oil, are thermodynamically unstable at ordinary temperatures. They tend to pass into carbon and methane, but the velocity of this reaction at ordinary temperatures is very slow. If they are heated, however, they are "cracked"; hydrocarbons of lower boiling point, such as occur in petrol, are formed, and coke and gas are formed at the same time. If the cracking is continued for a long time at atmospheric pressure, the whole liquid forms into coke and gas (mainly methane). But high pressure tends to prevent the formation of gas and coke, and to give therefore a higher yield of "petrol." This is in complete general agreement with the Nernst equation, which enables us to predict approximately the conditions for the best technical success.

The further development of the third law, and its quantitative application to chemical problems depends on the provision of accurate data on the specific heats of substances over a wide range of temperature. The increase in the specific heat of gases as the temperature is raised lacks at present any sound theoretical explanation. The classical kinetic theory of gases does not account for it, and the more recent developments of the quantum theory have hitherto failed to be of assistance. But there can be little doubt that the third law provides in principle a complete explanation of the connection between chemical equilibria and the thermal changes associated with chemical reactions.

THERMODYNAMICS. The name thermodynamics (from Gr. θερμός, hot, δύναμις, power), was originally given to the branch of science dealing with the motive power of heat, or the transformations of heat into mechanical work, or vice versa. A summary of the historical development of thermodynamics from this point of view is included in the article HEAT. Further illustrations relating to heat-engines will be found in the articles INTERNAL COMBUSTION ENGINES and STEAM: *Steam Engine.* The subject was soon extended to include other applications of the same general principles: (1) the conservation of energy, and (2) Carnot's principle of the reversible cycle, which are commonly known as the first and second laws of thermodynamics. The present article is intended to deal mainly with applications of these principles to the relations between the physical properties of a simple substance. Further applications to physical chemistry, dealing with the conditions of equilibrium between different substances, are dealt with in a separate section.

THERMODYNAMICS AND HEAT ENGINES

Definitions of Symbols.—The principal physical properties of the working fluid with which we are concerned in the case of heat-engines are the specific volume V, the intrinsic energy E, the total heat H and the entropy Φ, all of which are measured per unit mass of the substance considered. The laws of thermodynamics require certain general relations between these properties and their derivatives, as affected by additions of heat Q per unit mass, or by variations in the imposed conditions of temperature T and pressure P. It should be observed that in all these relations P is the absolute pressure and not the gauge-pressure; and that T is measured on the absolute scale, as defined by Carnot's principle which differs very little from absolute temperature on the scale of a gas thermometer. Temperature measured on the same scale from 0° C. is denoted by t, so that $T=t+273.1°$. The total heat H is defined as $E+aPV$ in thermal units, including the equivalent aPV of the work PV done by the pressure P on the volume V of unit mass. The entropy Φ of a quantity of heat Q supplied at a temperature T is defined as Q/T. The entropy of a substance per unit mass is the property which remains constant in adiabatic expansion, when no heat is supplied by friction or otherwise, as will be more fully explained in a later section, in connection with the second law of thermodynamics.

Applications of the First Law.—The intrinsic energy E denotes the quantity of energy existing in unit mass of the substance in any given state, which may in general be specified by its volume V and temperature T. We have no means of measuring the total quantity of energy contained in any body in a given state, but it suffices to be able to measure changes of E from any convenient state E_o selected as the zero. Any such change from E_o to E may be measured by observing the quantity of heat Q required to produce the change and the work W done by the substance per unit mass in the process. Assuming that no energy is lost, the application of the first law to this case gives the obvious relation

$$Q=E-E_o+W/J. \qquad (1)$$

In any equation of this kind it is tacitly understood that all the terms are reckoned per unit mass of the substance, and are expressed in terms of the same units, either units of work or units of heat as desired. The general practice in dealing with heat-engines is to measure Q, E, and H in thermal units per unit mass, and to reduce W to thermal units by dividing by the appropriate value of the mechanical equivalent J. In nearly all cases W represents work done by expansion $V-V_o$ against a uniform pressure P, in which case $W=P(V-V_o)$, if P remains constant during the expansion, and equation (1) takes the form

$$Q=E-E_o+aP(V-V_o)=H-H_o, \text{ at const. } P, \qquad (2)$$

where the total heat H is defined as $E+aPV$, and a is the factor required for reducing PV to heat units per unit mass. The factor required for this purpose in practice is seldom $1/J$, because pressure-gauges are never graduated in lb./sq.ft. or kg./sq mi., but often in arbitrary units such as inches of mercury.

Specific Heats.—If the heat Q is added at constant volume, $V=V_o$, and $W=o$, so that $Q=E-E_o$. If $T-T_o$ is the rise of temperature, we observe that the increase of E per degree at constant volume V_o is equal to $Q/(T-T_o)$, which is by definition the specific heat s at constant volume. Similarly $(H-H_o)/(T-T_o)$ from (2) is equal to the specific heat S at constant pressure. Thus the values of E along a line of constant volume on any diagram may be found from observations of the specific heat s at constant volume. Similarly values of H along a line of constant pressure may be deduced from observations of the specific heat S at constant P.

Thus $H-H_o=S(T-T_o)$ at const. P,

and $E-E_o=s(T-T_o)$ at const. V. (3)

These simple relations between H and S, and E and s, are exact for all substances at all temperatures in consequence of the definition of H, and are often very useful. But the specific heats S and s may vary widely with temperature and pressure, in which case it is usually better to measure H or E directly, in place of trying to deduce them from empirical formulae for S or s. In the case of solids or liquids, since V is small and varies little with T, the variation of E at constant pressure, such as atmospheric, does not differ appreciably from that of H. But the variation of H at *constant* volume may greatly exceed that of E under the same condition on account of the high pressures developed. In practice it is usually preferable to measure the value of H and deduce that of E, if required, by subtracting aPV.

Application to Gases.--In the case of ideal gases obeying the law $aPV=RT$, it follows directly from the general relations (3) that the difference $S-s$ is constant and equal to R. It will be shown later that the specific heats of such gases cannot vary with pressure, though they may vary considerably with temperature, while the difference S — s remains constant, as in the case of hydrogen. (See HEAT.) On the other hand, vapours, like steam, though they usually approximate closely to the law $aPV=RT$ at low pressures, show large deviations from the gas-laws at high pressures near saturation, and the value of S shows a wide range of variation with *pressure,* especially near the critical point. Fortunately these variations can be deduced from the thermodynamical relations given in a later section of this article.

Cycle or Cyclical Process.--The application of the first law, as expressed in (1), to the cycle of a steam-engine, in which the working fluid is restored to its initial state of water at each repetition of the cycle, is fully considered in the articles already referred to. Briefly stated, if $E=E_o$ at the conclusion of the cycle Σ_o, it follows from (1) that the algebraic sum ΣQ of all the quantities of heat Q received and rejected by the working substance during the cycle must be equal to the net balance of work done by the engine per cycle, work done by the fluid in expansion being reckoned positive, and work done on the fluid in compression being reckoned negative. With this understanding the formula for the cycle may be expressed as follows,

$$\Sigma Q=\Sigma W=\int PdV. \qquad (4)$$

In an ideal reversible engine, in which no heat is lost and no work is wasted in friction, the area of the cycle on the PV diagram, expressed by the integral of PdV taken round the cycle, will represent the maximum work obtainable from the cycle considered. In any actual engine some of the heat received by the working fluid is lost before it has contributed its full quota of work, and some of the work done is reconverted into heat by internal friction and is rejected in the form of heat. If the properties of the working fluid are known, such losses may be estimated in the reciprocating engine by comparing the ideal diagram, as calculated, with the actual diagram as observed with the indicator. (See STEAM: Steam Engine.) In the case of a turbine, to which the indicator method is inapplicable, it is necessary to use a different kind of diagram, or the ideal output may be calculated from the properties of the working fluid, and compared with that actually realised.

Frictionless Adiabatic Expansion.—The term "adiabatic" implies that there is no gain or loss of heat by the working fluid. Putting Q=O in (1) we see that in this case E — E, must be equal to $-W/J$, or the intrinsic energy of the working fluid is diminished by an amount equivalent to the work done. If no work is wasted in friction, this represents the most efficient method of conversion of heat into work, which is the ultimate aim of every heat-engine. To calculate the work done from the integral of PdV under this condition, it is necessary to know the form of the expansion curve on the PV diagram, or the adiabatic equation representing the relation between P and V for the working fluid employed, which requires an appeal to experiment. Watt made the first experiments of this kind with his indicator, but found the expansion curve for a slow speed engine using wet steam to be approximately PV=constant, the same as Boyle's law for the expansion of a gas at constant temperature, whereas the fall of pressure in adiabatic expansion should have been more rapid than that given by Boyle's law owing to the fall of temperature. Watt was well aware that this anomaly was due to partial condensation of the steam on admission by the cool walls of the cylinder, followed by re-evaporation towards the end of the stroke, which made the conditions far from adiabatic. Laplace subsequently showed (see HEAT) that the rate of drop of pressure dP/dV in the adiabatic expansion of a gas must exceed that for the same state at constant temperature, in the ratio, $S/s=\gamma$, of the specific heats. Assuming Boyle's law for a gas at constant temperature, and y =constant in adiabatic expansion, it followed that the adiabatic equation must be of the form, $PV^\gamma=$constant for a gas.

The adiabatic equation of Laplace and Poisson for a gas, was established long before the first law of thermodynamics was formulated, and has proved to be the most convenient type of equation for the purpose. But with the assistance of the laws of thermodynamics, the scope of the adiabatic equation in this form may be considerably extended. Thus with the assistance of the first law, in the form in which it is usually employed for mathematical purposes, namely

$$dQ=dE+aPdV=dH-aVdP \qquad (5)$$

the adiabatic equation, $PV^\gamma=$constant, may be shown to apply generally to any kind of substance, not necessarily a perfect gas, for which the change of intrinsic energy in any transformation is proportional to that of aPV; or more generally that it will be of the form $P(V-b)^\gamma=$constant, provided that the expression for the intrinsic energy E satisfies the condition,

$$E-B=naP(V-b) \qquad (6)$$

in which B, b, and n are constants depending on the substance, and $\gamma=1+1/n$.

To prove this relation, we put $dQ=o$ in (5) as the general condition for the adiabatic, and equate dE as obtained from (6) to $-aPdV$, which gives,

$$an(V-b)dP+a(n+1)PdV=o. \qquad (7)$$

Dividing by $aP(V-b)$ and integrating we obtain

$$n\log P+(n+1)\log(V-b)=\text{constant} \qquad (8)$$

which when put in the exponential form becomes

$$P(V-b)^{n+1/n}=\text{constant}. \qquad (9)$$

It will be observed that the value of the index y is *constant*, and is not necessarily equal to the ratio of the specific heats, which may vary widely with pressure. This is fortunate, because an equation of this type is of little practical use if the index is variable.

With the assistance of the second law of thermodynamics in addition to (5) and (6), it will be shown in a later section that the same adiabatic, (9) may be put in either of the equivalent forms

$$P/T^{n+1}=\text{constant}=k_1 \text{ or } (V-b)T^n=\text{constant}=k_2 \qquad (10)$$

and that $P(V-b)/T=k_1k_2=$constant, along an adiabatic, though it is not necessarily constant under other conditions.

Experimental Verification of the Adiabatic.—The most direct way of testing the adiabatic equation is to use a cylinder containing a constant charge of gas or vapour which is alternately compressed and expanded by a reciprocating piston. Indicator cards give fairly accurate values of the actual volume and pressure, if the clearance is carefully measured, the pressure scale calibrated, and everything in perfect adjustment. But in working

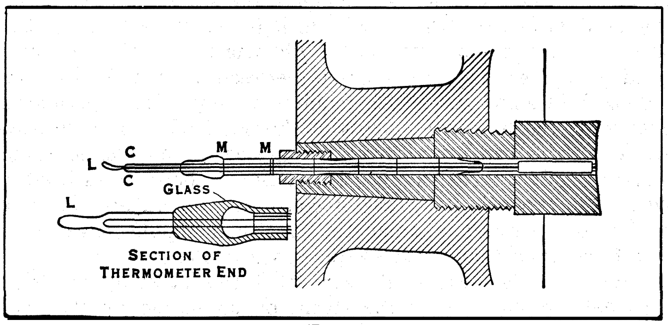

FIG. 1

over large ranges of pressure, as is necessary for a satisfactory verification, there are formidable difficulties due to the wide variation of heat exchanges between the charge and the walls of the cylinder at different points of the stroke. These effects are further complicated by accidental leakage past the piston, and, in the case of steam, by the risk of condensation, both of which affect V indirectly by reducing the apparent mass of the charge. The most complete method of eliminating these uncertain sources of error, which profoundly affect the uniformity of V throughout the cylinder, is to observe, instead of the relation between P and V, the relation between T and P, as given by the adiabatic equation in the form (10), deduced from the second law. In this case the temperature observed in the middle of the cylinder will be practically unaffected by the action of the walls, and is determined solely by the actual pressure as observed with the indicator. We are no longer concerned with the *theoretical* pressure, corresponding to the compression ratio by volume, which might be realized in the absence of condensation or leakage or heat-loss to the walls. These effects will still reduce the observed pressure below the theoretical value, but will not affect the relation between pressure and temperature. The success of the thermometric method depends on the construction of a thermometer sufficiently sensitive to follow the rapid variations of temperature without appreciable lag, and on obtaining simultaneous readings of the relative values of the pressure with the same order of accuracy at the maximum and minimum points of the cycle. It is easy to cover the range of temperature with a single thermometer, but, the pressure range being upwards of 10/1, it is necessary to use a separate indicator with a light spring for the low pressures. Applied in this manner the method is particularly suited to give the best average value of the index over large ranges of pressure and temperature. The procedure may be varied when it is desired to obtain the value of the index at some particular point of the scale, *e.g.*, at high or low temperatures.

The annexed figure 1 shows one of the thermometers employed for this purpose, mounted on the piston of a steam-engine for observing the adiabatic relation between P and T for dry steam. The sensitive portion of the thermometer consisted of a differential loop L of fine platinum wire a thousandth of an inch in diameter and 1 inch in length. The fine wire was connected to thick platinum leads, insulated by being fused through a glass tube MM held in a gland in the centre of the piston. The platinum leads in the glass tube were connected to insulated copper leads, which were carried out to the measuring apparatus through a hole 2 ft. long bored through the piston rod. Since the ends of the fine wire, where it is attached to the thick platinum leads, cannot follow the rapid variations of temperature of the steam, it is necessary with this type of thermometer to compensate these end-effects by connecting a short loop of the same fine wire to the ends of the compensating leads CC. The quantity measured being the difference of resistance of the long and short loops, all such end-effects are automatically eliminated. Readings of temperature were taken with the aid of a periodic contact (mounted on the revolving shaft) which could be adjusted, while the engine was running, in such a way as to close the circuit of the galvanometer at any desired point of the stroke. It was found possible to read the temperature to one or two tenths of 1° C at the maximum and minimum points, with the engine running at 100 rev./min. and a range of temperature of about 300° C between maximum and minimum. Readings taken at intermediate points, where the temperature was changing at the rate of more than 500° C per second, showed very good agreement, but could not be utilised in the calculation because the simultaneous values of the pressure could not be located with sufficient accuracy on the steep part of the indicator curve, whereas the maxima and minima could be measured with the greatest precision. The ports of the cylinder used in these experiments were caulked with lead to prevent leakage, and the cylinder was heated by steam in the jackets and steam-chest to minimize condensation. The flywheel was belted to an electric motor and driven at a steady speed by a large storage battery. The observations covered a range of temperature from 100° to 420° C, but could not be extended beyond 150 lb. pressure by this method, owing to deficient strength of the engine and driving gear. The results obtained with several different thermometers and indicators, showed that the adiabatic index for steam must be very nearly constant over this range of pressure and temperature with a value given by $n+1=13/3$ in (10), or $\gamma=1{\cdot}300$ in the relation (9) between P and V. Recent observations on the total heat H up to 4,000 lb. pressure, have shown that the same relation holds for dry steam with remarkable accuracy in the critical region, in spite of enormous variations in the ratio of the specific heats. The importance of this result in practice lies in the fact that it gives a very simple expression (6) for E or H in terms of P and V, or for V in terms of H and P, in addition to giving the simplest possible expressions for the work done in adiabatic expansion, or for the discharge through a nozzle, the utility of which can hardly be exaggerated in practical thermodynamics. Similar relations, but with $\gamma=1{\cdot}40$ or $n=2.5$, have long been applied to the case of atmospheric air, which forms the chief constituent of the working fluid in the internal combustion engine. But in the case of air the application is much more simple and obvious, because air obeys the gas equation $aPV=RT$ very closely, and its specific heats vary very little with pressure under ordinary conditions.

The Energy Equation in Steady Flow.—The flow of a fluid through a pipe or any closed apparatus, is said to be "steady" when the mass M per second passing any cross-section X is the same at every point, and remains constant during the flow. This implies that the fluid is supplied at a steady rate by some external agent (*e.g.*, a pump or boiler) at a constant pressure and temperature, in which case the whole apparatus traversed by the fluid will soon settle down into a steady state in which the values of P, V, and T remain constant at each point, though they will not be the same at different points, if the section X varies from point to point, or if the fluid receives heat or does work at a steady rate during its passage. It follows from the law of conservation of mass that, when the mass-flow M is constant at every point, the velocity U of the fluid at any section X is given in terms of V by the relation

$$U=kMV/X \qquad (11)$$

where k is a constant depending on the units employed.

A second relation follows from the law of conservation of energy, since the energy existing in any section must remain constant when the conditions are steady. The total energy carried into any section by the fluid per unit mass in thermal units will consist of its intrinsic energy E', together with the equivalent $aP'V'$ of the work done by the pump, and with the kinetic energy of flow, $K'=U^2/2Jg$, reduced to thermal units by the factor $1/Jg$. Thus the total energy carried in by the fluid may be represented briefly by $H'+K'$. Similarly the total energy carried out of the same section by the fluid may be represented by

$H''+K''$. But with the energy carried out we must include the equivalent W/J of any work done by the apparatus, and any heat Q lost by radiation or convection, both measured per unit mass of the fluid passing through. Collecting the terms, the general equation may be written

$$H'-H''=K''-K'+W/J+Q. \qquad (12)$$

The steam-turbine may be taken as a typical example. $H'-H''$ represents the drop of total heat of the fluid, or more briefly

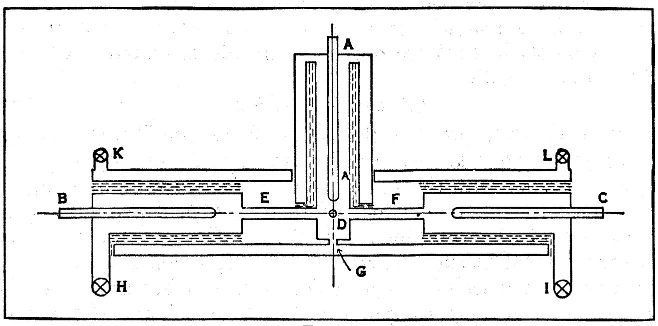

FIG. 2

the 'Heat-drop,' between the inflow and outflow of any section. In an efficient machine, this heat-drop is very nearly equivalent to the external work W done by the steam on the revolving blades. The external heat-loss Q is a small percentage of the whole. The kinetic energy K'' of the steam leaving the section usually exceeds K', that of the steam entering and $K''-K'$ represents a similar percentage loss. The greater part of the loss in a turbine is that due to internal friction, by which part of the available kinetic energy is reconverted into heat. This part of the loss is included in the total heat H'' carried out by the steam. If there were no friction or heat-loss, the drop of total heat, representing heat converted into kinetic energy or work, would be that obtainable in frictionless adiabatic expansion between the same limits of pressure, which may be found from the tables and compared with the actual performance to estimate the efficiency. The method of doing this will be explained later, when some of the simpler applications of equation *(12)* have been illustrated.

The Throttling Method.—The function of a throttle, or reducing-valve, is to regulate the flow, or change the state of the fluid, by lowering the pressure without altering the total heat. The throttle, having no moving parts, cannot do any external work, so that $W=0$ in equation *(12)*. In this case, most of the kinetic energy is reconverted into heat by friction, so that K'' can be made nearly equal to K' under favourable conditions. The equation then reduces to the form

$$H'=H''+Q \qquad (13)$$

The chief use of the equation in this form is to find the value of the total heat H' at a high pressure by throttling to a lower pressure, such as atmospheric, and observing the temperature T''. The total heat H'' at the lower temperature and pressure may be regarded as known by equation *(3)*-*in* terms of the specific heat S. Thus the required value of H at T and P is given by *(13)* if the heat-loss Q can be determined. The best way of doing this is to employ a differential calorimeter as shown in fig. 2. The high pressure steam enters the centre pocket at the back and circulates round the thermometer tube *(A)* for measuring the initial temperature. The initial pressure is measured at the same point through the connection (D) to the high pressure gauge. The main current then divides right and left through the throttle tubes (E) and (F) to the side pockets (B) and (*C*) where the temperature of the throttled steam is measured. These pockets are precisely similar, and are lagged and jacketed with throttled steam in order to reduce heat-loss, which would otherwise be rather large at high temperatures. The throttle tubes are fitted with a progressive series of throttles and baffles, designed to give maximum friction and reduce the kinetic energy to a negligible quantity. Using single and double dashes to distinguish the two sides, the flows M' and M'' on either side, as defined above can be adjusted in any desired ratio. The rate of heat-loss $M'Q'$ per second will evidently be nearly equal to the rate of heat-loss $M''Q''$ from the other side. Hence Q and Q'' (per unit mass) will be inversely as the flows, which are condensed and measured separately. For instance, if $M'=2M''$, we have $Q''=2Q'$, and $Q'=H'-H''$, by taking the difference between the two equations

$$H'+Q'=H_0=H''+Q'' \qquad (14)$$

where H_0 represents the total heat in the centre pocket. Whence $H_0=2H'-H''$, both of which are known from the observed temperatures t' and t''. Since S is nearly constant for steam at atmospheric pressure, it usually suffices to correct the observed temperature t' for heat-loss by adding $(t'-t'')\ M''/(M'-M'')$, as in the following example. Starting with steam at *3,805* lb. pressure and 426·6° C, the observed temperatures on either side after throttling to *16* lb. were $t'=120{\cdot}3°$ C and $t''=114{\cdot}1°$ C, the ratio $M''/(M'-M'')$ being 0·97. The correction to t' for heat-loss is $0{\cdot}97\times6{\cdot}2°=6{\cdot}0°$, giving 126·3° C for the corrected temperature, at which $H_0=652{\cdot}4$ cal. C, as given in the tables at *16* lb. This method is one of the simplest for measuring H at high pressures and temperatures, but cannot be applied if H is less than *640* cal., because the throttled steam would be wet. Thus in measuring H at the critical point, 374° C, and 3,222 lb , where its value is only *554.4* cal. it is necessary to use the jacketed condenser method as described in the article CALORIMETRY. This method is rather more difficult. but has the advantage of applying equally to the case of water.

Discharge Through a Nozzle.—The function of a nozzle in a turbine is to convert as much as possible of the total heat of the steam into kinetic energy for turning the wheels. For this reason the nozzle is formed with a bell-mouth on the high pressure side tapering smoothly to a nearly parallel throat, so as to produce a uniform jet of high velocity with the least possible friction or turbulence. In this respect the nozzle is the opposite of the throttle which reconverts as much as possible of the kinetic energy into heat, leaving the total heat practically unaltered. In one respect it is like the throttle, in that it has no moving parts and does no external work in itself, so that $W=0$ in equation (12), when applied to either nozzle or throttle. The heat-loss Q in the case of a nozzle is also very small compared with the heat-flow, which is usually large owing to the high velocity of flow. Neglecting W and Q on this account, the heat-drop is the exact equivalent of the kinetic energy generated, thus equation *(12)* becomes

$$H_1-H_2=K_2-K_1=(U_2^2-U_1^2)/2Jg, \qquad (15)$$

in which the constant Jg is required for reducing $U^2/2$ to heat units. It may be observed that equation (15) remains true if any proportion of the kinetic energy generated is reconverted into heat by friction, since this has the effect of increasing H_2 exactly as much as it reduces K_2. As a rule the initial velocity is small and K_1 is almost negligible in comparison with K_2. The velocity generated may then be calculated from the heat-drop by the formula

$$U_2=(2Jg)^{\frac{1}{2}}\ (H_1-H_2)^{\frac{1}{2}} \qquad (16)$$

If H is taken in calories C and U in feet per sec., the value of the constant is *300.2*, or a heat-drop of 1 cal. C will correspond to a velocity of *300* ft./sec.; or 100 cal. to 3,002 ft./sec. A velocity of 100 ft./sec., or *70* miles per hour, though not unimportant in meteorology, may often be neglected in dealing with turbines, as it corresponds to only $\frac{1}{9}$th of a calorie C. Other conditions being equal, the heat-drop and velocity will evidently be greatest in the absence of friction, or in frictionless adiabatic expansion as defined by putting $dQ=0$ in equation *(5)*. This gives the condition $dH=aVdP$ for finding the heat-drop by integrating $aVdP$ along the adiabatic (9) between the given limits of pressure P_1 to P_2. Neglecting b, this reduces to the simple form,

$$H_1-H_2=(H_1-B)(1-T_2/T_1) \qquad (17)$$

where $T_2/T_1=(P_2/P_1)^{\frac{3}{13}}$, for steam *by* equation (10) with $n+1=13/3$.

Having found the heat-drop, which is preferably obtained from the Tables, the velocity U_2 follows from (15), or from (16) if U_1 is small. The discharge M is easily obtained from (11) in terms of the area of the throat X, and the volume V_2 at the same point. The latter is most easily obtained from H and P by the general relation (6), which may be put in the form,

$$V=(H-B)/a(n+1)P=2\cdot2436(H-B)/P. \qquad (18)$$

Maximum Discharge.—It results from the form of these equations that for any given nozzle or throat area X, for a given initial state of the steam as defined by P_o and V_o, the discharge M will at first increase as the final pressure P is lowered, but will ultimately reach a very definite maximum, when $P/P_o=0\cdot546$ in the case of steam. Differentiating (11) to find the condition under which M is a maximum, we have $d(U/V)=0$, or $dU/dV=U/V$. Putting (15) in the form $U^2-U_o^2=2Jg(H_o-H_o)$, differentiating with regard to V, and remembering that U_o and H_o are constant, we obtain

$$-Jg(dH/dV)=U(dU/dV)=U^2/V. \qquad (19)$$

Since by (5) $dH/dV=aV(dP/dV)$ in adiabatic expansion, this may be written,

$$-aJg(dP/dV)=(U/V)^2=(kM/X)^2 \qquad (20)$$

giving the discharge M/X per unit area of throat in terms of dP/dV in the throat. Since equation (20) for $(U/V)^2$ in terms of dP/dV is the general expression for the velocity of sound U in any fluid, we infer that, when M/X is a maximum, the exit velocity of the fluid relative to the throat must be equal to the velocity of sound in the same fluid under the same conditions. Thus no drop of pressure beyond the throat could travel back fast enough through the fluid to affect its state in the throat or increase the discharge. In the case of any fluid like steam, having the adiabatic equation (g), $dP/dV=-\gamma P/(V-b)$, which when substituted in (20) gives the discharge in terms of P and V in the throat. To find a numerical formula for the maximum discharge in the case of steam (for which $\gamma=1\cdot3$) in terms of the initial conditions, P_o, V_o, we have the approximate relations (omitting b, which is very small), which follow from (20),

$$(H_o-H)/(H_o-B)=(\gamma-1)/(\gamma+1)=3/23 \qquad (21)$$

$$P/P_o=0\cdot5457,\ V/V_o=1\cdot5934 \qquad (22)$$

which give for the discharge M/X in lb. per sec. per sq.in. of throat (k = 144),

$$M/X=U/144V=0\cdot3155\ (P_o/V_o)^{1/2} \qquad (23)$$

when P is in lb. per sq.in., U in ft./sec. and V in cu.ft. per lb. The correction for b is less than $\frac{1}{20}$ of 1 per cent when $P_o=300$ lb.

Applications of **Carnot's** Principle.—The whole science of thermodynamics may be said to date from the establishment by Sadi Carnot (1824) of the principle limiting the amount of work obtainable from heat under given conditions. The reasoning by which Carnot established his principle is outlined in the article HEAT, and is justly regarded as one of the most remarkable triumphs of the deductive method, but the experimental data available at the time were far too scanty and inaccurate to supply conclusive proof. With the advance of experimental methods Carnot's predictions have been abundantly verified in every conceivable instance, and have formed the basis of the development of all kinds of heat-engines in theory and practice. The important applications to heat-engines are discussed elsewhere in their proper place. We are here concerned chiefly with the applications of the principle to the thermodynamical relations between the various properties of any substance, and to the conditions which determine the possible states of equilibrium. Carnot in applying his principle to such cases put it in the following form as being most convenient for the purpose. If a quantity of heat Q is supplied to any substance at a constant temperature t, the work dW obtainable from Q by an ideal reversible engine working in a cycle of range dt must be proportional to Qdt multiplied by some function of the temperature, F't, which must be the same for all substances. Putting this statement in the form of an equation, we find

$$dW/dt=QF't, \qquad (24)$$

as given by Carnot, and applied by him to the following simple cases:

Clapeyron's Equation.—In the vaporisation of unit mass of steam in a boiler, the whole work of expansion W along the isothermal at constant pressure and temperature, would evidently be equal to $p(V-v)$, the product of the vapour-pressure p by the increase of volume from that of water v to that of steam V. Thus the work dW/dt obtainable in a cycle of range dt would be $(V-v)dp/dt$, where dp/dt is the rate of increase of the steam-pressure per degree rise of temperature. The heat Q absorbed in the vaporisation of unit mass is the latent heat L. Substituting these symbols in (24) we obtain the result commonly known as Clapeyron's equation,

$$(V-v)dp/dt=LF't, \qquad (25)$$

which evidently represents the condition of equilibrium between liquid and vapour at any temperature, and is applicable to any other substance with the same value of F't at the same temperature, but with different values of L, V, and p, depending on the properties of the substance considered. Carnot employed this relation for calculating the value of his function F't at 100° C from the properties of steam, which were roughly known at this temperature. Taking L = 540 cal. $dp/dt=27.2$ mm. of mercury, or 370 kg./sq. metre, and $V-v=1\cdot670$ cb.m./kg., we find F't = 1·135 kilogram metres per kilocalorie for the work obtainable in a cycle of 1° range at 100° C. We may remark in passing that the value found is equal to 427/373, being the mechanical equivalent of the kilocalorie in kgm. divided by the absolute temperature. This implies that the whole of the heat could be converted into work if the range of the cycle were extended to the absolute zero with the same rate of production of work per degree fall. But Carnot, who had at that time no knowledge of the value of the mechanical equivalent, naturally failed to notice this remarkable coincidence, though the result he obtained for *F't* was correct.

Lowering of *the* Freezing Point of *Ice* by Pressure.—The application of Carnot's equation (25) to the rate of increase of vapour-pressure dp/dt with temperature, or to the rise of the boiling-point dt/dp with pressure (which are merely different ways of expressing the same property of the substance) is easily made in any case in which the latent heat L and volume V of the vapour are known, and affords in fact one of the most direct methods of verifying Carnot's principle by experiment. A more dramatic verification was that made by James Thomson (1851), who observed that equation (25) must apply just as exactly to the equilibrium between liquid and solid at the freezing-point, as to that between liquid and vapour at the boiling-point. In the case of solid and liquid, L is the latent heat of fusion, and V–v is the increase of volume in melting, which is positive for a substance like wax which expands in melting, but negative for a substance like water which expands on freezing. Thus in the case of wax, the sign of dt/dp should be positive, or the melting point should be raised by pressure (as is always the case for the boiling-point), whereas in the case of water the sign should be negative, or the freezing-point should be lowered by pressure. Taking the known values of L and V–v for water and ice, he predicted that the freezing-point of water should be lowered 0·0075° C per atmosphere of pressure, a result which was immediately verified by his brother, Lord Kelvin, and materially assisted in the final establishment of the second law of thermodynamics.

Application to Gases, Absolute Scale of T.—The application of Carnot's equation (24) to the case of a gas obeying the law PV = RT, is equally simple. The whole work W done in isothermal expansion, is represented by the analytical expression RT $\ln$ r, where $\ln r$ denotes the natural logarithm of the ratio of expansion. It immediately follows, as Carnot remarks, that $dW/dt=R\ln r$, or is simply equal to W/T. Thus equation (24) reduces to the form,

$$W/T=Q\,F't. \qquad (26)$$

Carnot deduced from this relation that the ratio W/Q of the work done to the heat absorbed in isothermal expansion must be the same for all gases at the same temperature, and that if equal volumes of different gases were taken at the same temperature and pressure (or masses proportional to the molecular weights) the heat Q absorbed in isothermal expansion must be the same for all gases under similar conditions since the work W was the same for all. It followed as a special case that the *difference* of the specific heats at constant pressure and volume, being the heat absorbed in an isothermal expansion equal to V/T, must be the same for equal volumes of all gases. His endeavours to extract a value of $F't$ from this relation gave results similar to those obtained from steam and other vapours, but failed to give a decisive conclusion owing to the uncertainty of the ratios of the specific heats as deduced from the velocity of sound. At a date when Joule *(1845)* proved by direct experiment that the heat absorbed by a gas in isothermal expansion was approximately *equivalent* to the work done, it became evident, by substituting $W=JQ$ in equation *(26)* that the value of $F't$ must be nearly equal to J/T for all substances. But since according to Regnault's experiments *(1847)* the temperature scales of actual gases differed quite appreciably different gases would give different values of T at the same temperature, and it was impossible to say which should be selected. The essential point of Carnot's principle being that the value of $F't$ was *the same* for all substances at the same temperature, the most logical method was that proposed by Kelvin, to define absolute temperature T as being proportional to the reciprocal of Carnot's function. Exact consistency with Carnot's principle and with the law of conservation of energy could thus be secured, while leaving the deviation of the scale of any particular gas from the absolute scale thus defined to be determined by experiment in each case.

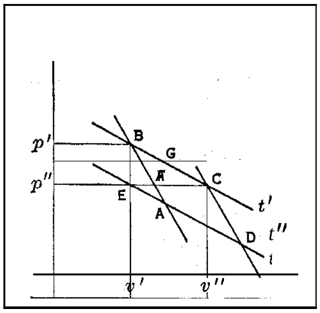

FIG. 3

Carnot Cycle of Finite Range —If we substitute J/T for $F't$ in Carnot's equation (24) in accordance with the definition of absolute temperature T, and also write $W=JQ$ as required by the first law, the equation reduces to the form $dQ/dT=Q/T$, which tacitly involves the law of conservation of energy in addition to the adoption of Carnot's principle for the definition of the scale of temperature The relation in this form implies that, if the range of the cycle is extended to any lower temperature, the ratio Q/T will remain constant, and the heat converted into work will increase in direct proportion to the range of temperature, since the constant ratio Q/T is equal to dQ/dT representing the heat converted into work per degree fall. Thus the formula for a Carnot cycle of finite range, in which a quantity of heat Q is supplied to the working substance at T', and a quantity Q'' is rejected at T'', with the conversion of heat $Q'-Q''$ into work W, reduces to the simplest possible form, namely,

$$W/(T'-T'')=J(Q'-Q'')/(T'-T'')=JQ'/T'=JQ''/T'', \quad (27)$$

in which the reduction factor J may be omitted if Q is expressed in work units.

Entropy.--The quantity Q/T which remains constant in a Carnot cycle of any range bounded by two adiabatics, is called the entropy of the heat Q supplied at a temperature T. According to *(27)* the entropy of the heat supplied at T', is equal to the entropy of the heat rejected at T''. The entropy difference between any two adiabatics is constant, or the adiabatics are lines of constant entropy, and are often called isentropics. The thermal equivalent of the work done in any Carnot cycle is the product of the entropy supplied, namely Q'/T', by the range of temperature $T'-T''$. This relation is frequently the most convenient for calculating the work obtainable, not only in a Carnot cycle, but also in a cycle of any form.

Clapeyron's Relations.—Clapeyron *(1834)* observed that Carnot's principle, as represented by equation (24), implied the existence of certain general relations between the quantity of heat absorbed in isothermal expansion and the pressure and expansion coefficients of the working substance. He employed the indicator diagram, as illustrated in fig. 3, for the deduction of these relations by a method equivalent to that employed by Maxwell, *Theory of Heat (1870)*. The coordinates of the point B are the pressure p', and the volume v' of unit mass of the substance at a temperature t'. Let the substance expand from B to C along the isothermal at t' absorbing a small quantity of heat dQ, while its volume increases from v' to v'', and its pressure diminishes from p' to p''. Draw the line of constant volume v' through B intersecting the line of constant pressure p'' through C in the point E. Through E draw the isothermal EAD at the temperature t''. Complete the Carnot cycle by drawing the adiabatics BA and CD through B and C. In the limit, when the difference of temperature $t'-t''$ is small, it may be represented by dt as in Carnot's equation (24), and the form of the cycle $ABCD$ will become a parallelogram as indicated in the figure. The area $ABCD$ represents the work dW done in the elementary cycle, and is equal to that of the rectangle $BE \times EC$, or to $(p'-p'')(v''-v')$. Making these substitutions in Carnot's equation (24), we obtain the general relation,

$$(p'-p'')(v''-v')/(t'-t'')=F't \times dQ. \quad (28)$$

In order to interpret this relation in terms of the pressure coefficient at constant volume, or the expansion coefficient at constant pressure, as may be desired, we may in the first place transfer $v''-v'$ to the right hand side of the equation. We then dbserve that $p'-p''$ is the increase of pressure BE at constant volume corresponding to the increase of temperature $t'-t''$, so that the ratio represents the familiar pressure-coefficient at constant volume, denoted by $(dp/dt)_v$ in the usual notation of partial differential coefficients. Similarly $dQ/(v''-v')$, being the ratio of the heat absorbed at constant temperature to the corresponding increase of volume, may be denoted by $(dQ/dv)_t$ in the same notation. If we also substitute J/T for $F't$ in accordance with the definition of absolute temperature, we obtain,

$$T(dp/dt)_v=J(dQ/dv)_t \quad (29)$$

which is often called the first thermodynamical relation, and was in fact employed by Kelvin as a general expression for Carnot's principle in his first exposition of the equations of thermodynamics (1851), except that he retained the symbol μ for $F't$, following Clapeyron, in place of substituting J/T, as in (29), according to modern practice.

Pressure and Expansion Coefficients.—The utility of a relation of this kind lies in the fact that small quantities of heat absorbed in expansion are very difficult to measure, but can usually be calculated with the aid of relations like *(29)* in terms of other coefficients, such as the pressure coefficient. Many examples of this will be given later. If the relation *(29)* itself is not directly applicable, it can usually be transformed by purely mathematical relations between the various coefficients into a different shape which is more convenient for the purpose required For instance the pressure coefficient $(dp/dt)_v$ is seldom directly measurable in the case of a solid or a liquid, owing to the difficulty of keeping the volume constant while the temperature is being raised. The difficulty of measuring the pressure-coefficient may be avoided by using the familiar relation,

$$(dp/dt)_v=-(dp/dv)_t(dv/dt)_p \quad (30)$$

giving the required value in terms of the isothermal elasticity and the coefficient of expansion at constant pressure, both of which can be measured. Relation *(30)* is one of the commonest examples in practice of the general relation between the partial differential coefficients of any three quantities, such as x, y, z, connected by a single equation, such that any one of the three may be regarded as a function of the other two. It is most easily remembered in the cyclical form,

$$(dx/dy)_z(dy/dz)_x(dz/dx)_y=-1. \quad (31)$$

from which any required relation of this type such as (30) may be written down by replacing p, v, t, by $x. y, z$, or *vice versa.* But as relations of this type are usually required in the form (30), it may be as well to explain how they are deduced from first principles. The volume v of unit mass of any substance depends on the temperature t and the pressure p either of which may vary independently of the other. Any expansion due to change of temperature alone, is found by multiplying the rise of temperature dt by the expansion per degree at constant pressure, represented by the coefficient $(dv/dt)_p$. Similarly any change of volume due to increase of pressure alone, is given by the product of the increase of pressure dp by the isothermal compressibility $(dv/dp)_t$. In the general case, when both p and t change, the whole expansion dv is the sum of the two independent effects,

$$dv=(dv/dt)_p dt+(dv/dp)_t dp. \tag{32}$$

Similar formulae apply to all other properties of the substance depending on p and t and are frequently required in thermodynamics. In the case of the volume v, it is immediately obvious from *(32)* that, if the compression due to increase of pressure dp is equal to the expansion due to increase of temperature dt, the volume will remain constant, or $dv=0$. The ratio of dp to dt at constant volume, or the required coefficient $(dp/dt)_v$, is obtained in terms of the other two by putting $dv=0$ in (32), dividing by dt and transposing, which gives the required relation in the form *(30)* if we observe that the isothermal elasticity $(dp/dv)_t$ is the reciprocal of the isothermal compressibility $(dv/dp)_t$.

Second Relation.—From the first thermodynamical relation, as given in equation (29), Clapeyron deduced his second relation, for the heat evolved in isothermal compression, by substituting for $(dp/dt)_v$ the expression given in (30), which leads immediately to the corresponding expression for $(dQ/dp)_t$,

$$T(dv/dt)_p=-J(dQ/dp)_t \tag{33}$$

in terms of the coefficient of expansion at constant pressure. The negative sign in this relation indicates that heat is *evolved* by an increase of pressure, whereas heat is absorbed when the volume increases. There are several other thermodynamical relations, which are in effect equivalent to Carnot's equation (24), but the two originally given by Clapeyron are the most useful, and suffice for the majority of practical requirements. It will be observed that they are not independent relations, since one can be deduced from the other by a purely mathematical transformation, but either may be employed as required with the certainty of obtaining results consistent with the laws of thermodynamics.

Specific Heats.—The specific heats are among the most familiar and useful coefficients in practice since they are commonly required for calculating quantities of heat. They are usually measured by observing the quantity of heat given up by a body in cooling through a large range of temperature, and are often treated as constants. But in addition to the variation with temperature, as illustrated in the articles HEAT and CALORIMETRY, the results found may depend to a great extent on other conditions, such as pressure, in a manner subject to the laws of thermodynamics and amenable to calculation. In dealing with variable specific heats, the general expression for the specific heat of any substance at a temperature T is the ratio dQ/dT of the small quantity of heat dQ supplied per unit mass to the corresponding rise of temperature dT produced; but it is also necessary to specify the conditions under which the measurement is made, as these may affect the result. The two simplest cases are those in which the specific heat is measured, (a) at constant pressure, (b) at constant volume, though the latter condition can seldom be realised satisfactorily in the case of a solid or liquid. For this reason it is useful to have a relation giving the specific heat at constant volume in terms of that at constant pressure. The required relation may be obtained most directly by the aid of Clapeyron's relation *(33)* in the following manner, which also gives incidentally the expression for any other variety of specific heat.

Difference of *Specific* Heats.—To find a general expression for the specific heat dQ/dT under any condition, write down the general expression for dQ in terms of dt and dp, exactly as for v in (32), by simply replacing the letter v in *(32)* by the letter Q, and divide each term in the expression by dt, thus we obtain,

$$dQ/dt=(dQ/dt)_p+(dQ/dp)_t dp/dt. \tag{34}$$

The first term on the right, namely $(dQ/dt)_p$, representing the heat absorbed per unit mass per degree rise of temperature at constant pressure, is obviously the specific heat as ordinarily measured at constant pressure, which may be denoted by S_p. The next coefficient, $(dQ/dp)_t$, represents the heat evolved per unit mass per unit increase of p in isothermal compression. The value of this is given by Clapeyron's second relation *(33)* in terms of the coefficient $(dv/dt)_p$. Since the specific heat is usually required in thermal units, it is best to retain the reduction factor $1/J$, explicitly in equations expressed in thermal units, in which it is usually represented by the single letter a for convenience in writing or printing. The last factor dp/dt must be taken to correspond with the condition under which the specific heat dQ/dt is desired. Thus if we require the specific heat at constant volume $(dQ/dt)_v$, or S_v, we must also append the suffix v to dp/dt implying that it must be taken at constant volume. Making these substitutions in *(34)* we obtain the required expression for S_v,

$$S_v=(dQ/dt)_v=S_p-aT(dv/dt)_p(dp/dt)_v \tag{35}$$

Saturation Specific Heat.—As a further illustration of the same method, if we require the specific heat S_s of a wet vapour maintained in the state of saturation, implied by the suffix s, we have merely to replace the suffix v in (35) by the suffix s, thus,

$$S_s=(dQ/dt)_s=S_p-aT(dv/dt)_p(dp/dt)_s \tag{36}$$

in which $(dp/dt)_s$ represents the rate of increase of saturation pressure p with temperature, which is usually much larger than $(dp/dt)_v$ for the *dry* vapour. For this reason S_s is often negative, whereas S_v though smaller than S_p, is always positive. Thus, in the case of wet steam at 100° C, $S_s=-1{\cdot}04$.

By means of these and similar relations the variation of any specific heat can be calculated if one specific heat, such as S_p or S_v is known by experiment at the required temperature. In some cases these variations may be considerable, especially near the critical point of any substance. In general, if the path on the indicator diagram along which the specific heat is to be measured approaches the isothermal, the specific heat will become very large. If the path coincides with the isothermal, the specific heat becomes infinite, because there is finite absorption of heat while $dt=0$. When the path on the diagram is a little steeper than the isothermal the specific heat becomes *negative,* changing from positive to negative infinity in crossing the line. For any path between the isothermal and the adiabatic the specific heat is negative, falling to zero when the path coincides with the adiabatic $(dQ=0)$, and changing to positive again on the other side. Such changes would be very troublesome to deal with in experimental work, if the thermodynamic relations did not afford a complete method of taking them into account.

Cooling Effect in Adiabatic Expansion.—The efficiency of any heat engine depends primarily on the range of temperature through which the working fluid can be cooled while converting its heat energy into work done in adiabatic expansion. It is important for this reason to be able to observe and calculate the cooling effect, which is most conveniently defined as the ratio of the drop of temperature dt to the drop of pressure dp under the condition that no heat is supplied to the working fluid, and that the expansion is frictionless and reversible. The heating effect in compression is the same coefficient with the signs of both dp and dt reversed, so that its value is the same as that of the cooling effect in expansion. To find a thermodynamic expression for the cooling effect under the condition $dQ=0$, we may put $dQ/dt=0$ in the general expression *(34)* for the specific heat; in which case we must also take dp/dt in *(34)* under the same condition at constant Q, *i.e.*, we must write $(dp/dt)_Q$, which is the reciprocal of the required cooling effect $(dt/dp)_Q$. Substituting as before from Clapeyron's relation (33), we obtain immediately,

$$S_p(dt/dp)_Q=+aT(dv/dt)_p \tag{37}$$

which gives a general expression for the cooling effect, in terms of the specific heat and the coefficient of expansion, both at constant pressure, and comparatively easy to determine by experiment.

Thus if the specific heat of a *liquid* and its coefficient of expansion are known, as is the case for most liquids, it is easy to calculate the heating effect of a sudden compression. The effect is zero for water at its point of maximum density, but increases rapidly with the coefficient of expansion, since S is nearly constant.

In the case of a gas or vapour, which approximates to the equation $aPV=RT$ at low pressures, since (dV/dt) approaches the limit R/aP, the expression for the cooling effect becomes RT/SP, corresponding to the adiabatic equation in the form (10), with $SIR=n+1$. This shows that. if a vapour, like steam, obeys an adiabatic equation of this type with n constant, the limiting value S_o of its specific heat at zero pressure must be constant; *i.e.*, independent of the temperature. Conversely in the case of a gas, such as hydrogen, which follows the law $aPV=RT$ very accurately, there will be no variation of S with pressure, but any variation of S with temperature requires a corresponding variation in the index n+ 1, and in the cooling effect, which is equal to $T/(n+1)P$. In such a case, it is often much easier to measure the cooling effect directly with a thermometer of a well-adapted type than it is to measure the specific heat itself at high or low temperatures. The variation of the specific heat with temperature may then be deduced from observations of the cooling effect. This method was applied by Makower (*Phil. Mag.*, Feb. 1903) to verify the constancy of S in the case of steam by observing the cooling effect in a jacketed vessel at 110° C. By allowing the steam to expand suddenly from a pressure of 81 cm. to atmospheric and observing the corresponding drop of temperature, he found a value of the index $\gamma=1.304$, agreeing closely with that deduced from the engine experiments at much higher temperatures and pressures, as previously described. Brinkworth (Proc. Roy. *Soc.*, 1925) employed a similar method for verifying the variation of the specific heat of hydrogen at low temperatures. It will readily be understood that it is most important in all such cases to have an exact thermodynamical relation such as (37) between the coefficients to be measured. Otherwise the interpretation of the results is apt to be uncertain Thus it is usually possible to allow for the small variations of dv/dt in reducing the results, and similarly for the variations of S with pressure.

The **Joule-Thomson** Cooling Effect.—This is the most important coefficient of its type, and is most easily measured in steady flow. It was first measured by Joule and Thomson (1852), and was defined by them as the ratio of the drop of temperature to the drop of pressure in a pure throttling process, in which the kinetic energy generated by the pressure drop is completely reconverted into heat without any external heat loss. Under these conditions. as explained previously. the value of H is the same after passing the throttle as in the initial state, except that in any actual experiment at high temperatures it is necessary to make a small correction for heat loss. Since H remains constant in a pure throttling process, the cooling effect in throttling may be defined as the ratio of dT to dP at constant H and may be denoted by $(dT/dP)_H$ provided that small changes of temperature are being dealt with. In the example previously cited concern was only with the fact that the value of H at the high initial pressure and temperature must be the same as that observed at atmospheric pressure after throttling when corrected for heat loss. The drop of temperature amounted to more than 300° C., but the cooling effect represented by the ratio 300.3°/3789 lb., or 0.07925° per pound, does not enter explicitly into the calculation. though it might be described as the mean cooling effect over the given range. To find the limiting value of the cooling effect at a particular temperature and pressure, it is of course necessary to make measurements over much smaller ranges of temperature.

Variation of H *With* P.—The cooling effect C at constant H as thus defined is the ratio of the two partial differential coefficients of H with respect to P and T, thus,

$$C=(dT/dP)_H=-(dH/dP)_T/(dH/dT)_P \qquad (38)$$

This does not involve thermodynamics, but is merely a special case of the formal relation (30), as is easily verified by writing H in place of V in (30). Putting S for $(dH/dT)_P$, the specific heat at constant pressure, the useful relation $(dH/dP)_T=-SC$, giving the variation of H with P at constant T in terms of the specific heat S and the cooling effect C, which are the most easily measured of all coefficients, is given. Another expression for the same coefficient may be obtained by applying the two laws of thermodynamics. From the first law in the form $dH=dQ+aVdP$, as given in (5), dividing by dP at constant T,

$$(dH/dP)=(dQ/dP)_T+aV=-aT(dV/dT)_P+aV \qquad (39)$$

in which the second law is involved in the substitution for (dQ/dP) from Clapeyron's second thermodynamical relation (33), is found.

Joule-Thomson Equation.—The utility of relation (39) lies in the fact that it supplies the necessary and sufficient condition which must be satisfied by any expressions selected to represent H and V (the two most important thermodynamical properties of any substance) in order to render such expressions consistent with the laws of thermodynamics. Joule and Thomson made use of (39) in the form

$$SC=aT^2(d(V/T)/dT)_p \qquad (40)$$

in order to deduce an expression for V consistent with their observations on the cooling effect. Their experiments showed that C was approximately independent of the pressure, but varied as $1/T^2$ with temperature for air and CO_2 over the range 0° to 100° C. Integrating (40) at constant P, with S constant, and $C=K/T^2$, they obtained the solution:

$$-SK/3T^3=aV/T-R/P \qquad (41)$$

in which the constant of integration R/P was determined by the condition that the equation must approximate to the form $aPV=RT$ when T is very large. The small term $SK/3T^3$, which may be written $SC/3T$, represents the deviations of the actual gas, air or CO,, from the ideal state, in terms of the observed values of S and C for the gas employed. Thus equation (41) makes it possible to deduce the absolute temperature T from the observed temperature by air thermometer as defined in terms of P and V, but the process of reduction is far from being as simple as it might appear to be at first sight.

Moreover the original Joule-Thomson equation as given in (41), though it showed that the deviations of air from the ideal state must be very small, was somewhat unsatisfactory in other respects. It failed to explain the heating effect observed in the case of hydrogen, and made no allowance for the known variation of specific heat in the case of CO,. These difficulties may be avoided in practice by reversing the procedure. Assume a convenient type of equation for V, differentiate to find the expression for SC as in (39), and determine the constants by comparison with experimental results for S and C.

Modified Equation.—A suitable equation of a type similar to (41) is the following,

$$V-b=RT/aP-c, \text{ where } c=c_1(T/T)^n \qquad (42)$$

The small constant b, called the covolume, may be regarded as representing the limiting volume of the molecules at high temperatures and pressures. The small correction term c, called the coaggregation volume, represents the defect from the ideal volume caused by coaggregation or pairing of molecules. This is assumed to vary inversely as the nth power of T, and c_1 is the value of c at any convenient temperature T such as 0_o C. On this assumption c is a function of the temperature only, and $dc/dt=-nc/T$. Differentiating equation (42) in order to find SC as given by (39) or (40),

$$SC=aT(dV/dT)_P-aV=a(n+1)c-ab \qquad (43)$$

from which the values of the constants c, n, and b, may be deduced, when the values of S and C are known by observations taken over a sufficient range, is obtained. It is easy in this way to take account of any variations of S with temperature or pressure. The slope of the isothermals on the Amagat diagram, in which PV is plotted against P, is represented by $d(PV)/dP=-c+b$, and is positive in the case of hydrogen (for which PV increases with P) because b is so much larger than c at ordinary temperatures. For the same reason the cooling effect G is negative, as found by Joule and Thomson, who observed a rise of temperature with drop of pressure in throttling. This result is explained by (42), if b exceeds $(n+1)c$, as is actually the case with hydrogen.

Expression for the Total Heat **H.**—The same equation (42) may be employed as a simple illustration of the general method of deducing consistent expressions for the total heat and the entropy of a substance when an equation for V in terms of P and T has been obtained by the above method. To find an expression for H we start with the general formula for dH in terms of S and C, thus,

$$dH = SdT - SCdP. \qquad (44)$$

Since the value of H depends only on the state, we may perform the integration along any convenient path, starting from any convenient zero. The simplest method is to integrate the first term from o to T at zero pressure, since the value of S at zero pressure, denoted by S_o, is a function of the temperature only. We may denote this integral by S_mT where S_m is the mean value of S_o from o to T. We then have to add the integral of the second term at constant T from $P=o$ to P. In the present case, since SC is a function of T only, as given by (43), the integral of $SCdP$ is simply SCP. Adding the two terms, we obtain the general expression for H at T and P,

$$H - B = S_mT - SCP \qquad (45)$$

in which the constant of integration B is determined by reference to any known value of H at some definite point, such as 100° C and atmospheric pressure. In the case of steam, S_m may be taken as constant and equal to S_o.

Variation of the Specific Heat *S with Pressure.*—According to (45) the specific heat S at constant pressure will be a function of both temperature and pressure. The required expression for S is easily obtained by differentiating (45) at constant pressure, thus,

$$S = (dH/dT)_p = S_o + an(n+1)cP/T. \qquad (46)$$

This shows that, with an equation of the type (41) or (42), S cannot be constant, as assumed by Joule and Thomson in the integration of (40), and invalidates their method of deducing (41), but the same objection does not apply to the reverse procedure employed in deducing (42). The variation of S with pressure at constant temperature for any equation of this type can also be obtained from the consideration that H is a definite function of P and T depending only on the state, so that if we differentiate S as found in (46) with regard to P at constant T, we must obtain identically the same result, namely $d^2H/dPdT$, as by differentiating $(dH/dP)_T$ (or $-SC$) with regard to T at constant P. Using the general expression for SC given in (39), we obtain,

$$(dS/dP)_T = -(dSC/dT)_P = -aT(d^2V/dT^2)_P \qquad (47)$$

which shows that S cannot be independent of the pressure, if SC is a function of the temperature. From another point of view (47) represents the condition that dH as given in (44) should be the exact differential of a definite function of P and T, as must be the case if H is a property of the substance depending only on the state as defined by P and T. On the other hand if we apply the same condition to the general expression for dQ, namely,

$$dQ = SdT - aT(dV/dT)_P dP \qquad (48)$$

we observe that (47) cannot be satisfied in the case of dQ consistently with the second law of thermodynamics, because the heat added in any transformation is not simply a property of the substance depending on the initial and final states, but depends essentially on the process by which the transformation is effected. In other words, dQ is not the exact differential of any function of P and T, and cannot be integrated without knowing the relation between P and T defining the process. But if the path is given, Q can always be found from (48). Thus if the path on the indicator diagram is a straight line defined by $dP = kdT$, $dQ/dT = S - akT(dV/dT)_P$, and the required value of Q can be found for any substance for which the specific heat and the coefficient of expansion are known. The heat required for any transformation is often required in practice, and may always be obtained in this way, if the path is given.

Expression for the Entropy Φ.—If a small quantity of heat dQ per unit mass is supplied to any substance at a temperature T, the corresponding increase of entropy $d\Phi$ is dQ/T. Thus we obtain immediately from (48),

$$d\Phi = dQ/T = (S/T)dT - a(dV/dT)_P dP. \qquad (49)$$

If we apply the mathematical test for an exact differential, as in (47), we find,

$$(d[S/T]/dP)_T = (1/T)(dS/dP)_T = -a(d^2V/dT^2)_P \qquad (50)$$

which, it will be observed, is precisely the same as that found for dH. We conclude that 4, like H may be regarded as a property of the substance depending only on the state, and capable of tabulation in terms of P and T.

Since Φ itself cannot be measured in practice in any convenient manner, it is usually deduced for any substance from the expression found by experiment for H. Since $dQ = dH - aVdP$, by (5), taking dH from (44), we obtain,

$$d\Phi = dQ/T = (S/T)dT - (SC/T + aV/T)dP \qquad (51)$$

which is seen to be identical with (49) if we substitute for SC from (39). This may be integrated, as in the case of H, from o to T at zero pressure, with $S = S_o$, and from o to P at constant T. Taking as an example the simple equation (42) for V, with SC from (43), we find the expression,

$$\Phi - A = \int (S_o/T)dT - \int (R/P + anc/T)dP$$
$$= S_o \ln T - R\ln P - ancP/T \qquad (\ln = \text{rat. log.}) \qquad (52)$$

in which A is the constant of integration determined in the usual manner.

Use of the Entropy.—It should be observed that the entropy is not an independent property of the substance, since it can be deduced from H and V, but it is most useful in practice for defining the process of frictionless adiabatic expansion, and for deducing the maximum work obtainable from a quantity of heat supplied to the working substance under specified conditions. As a simple example we may take the case of the steam-turbine. Any part of the heat received (*e.g.*, in the superheater) at the constant initial pressure P' is represented in virtue of relation (3) by the increase DR of the total heat of the steam over the range considered. Let $D\Phi$ represent the increase of entropy taken from the tables over the same range of temperature. In the ideal cycle after adiabatic expansion the corresponding part of the heat rejected at the constant temperature T'' of the condenser will be $T''D\Phi$. The difference $DH - T''D\Phi$ represents the work obtainable from this part DH of the heat supplied, and the ideal efficiency is given by $1 - T''D\Phi/DH$. Thus it becomes possible to estimate the thermal efficiencies of different stages of the heating system, as depending on the temperature T' of heat reception by the working fluid.

The equivalent of the work theoretically obtainable in any part of an ideal cycle included between two adiabatics may also be found by subtracting the heat-drop along the lower adiabatic from that along the higher adiabatic. This gives the same result as subtracting the heat rejected from the heat received, but saves trouble in calculation if tables of adiabatic heat-drop are available.

If the "mean effective temperature" T_m of heat reception DH at constant pressure P is defined as being equal to $DH/D\Phi$, the expression for the ideal efficiency of the cycle between the two adiabatics differing in entropy by D4, reduces to the form $1 - T''/T_m$, the same as that of a Carnot cycle in which all the heat is received at one temperature T_m. As G. M. Clarke has pointed out, the mean effective temperature thus defined affords a convenient method of expression for the ideal efficiency of any cycle as compared with the Carnot cycle. But it does not supersede the use of the entropy, which is required in order to be able to calculate T_m.

Efficiency of Expansion in a Turbine.—The foregoing method of finding the efficiency of an ideal cycle, or part of a cycle, between two adiabatics, depends on assuming that the useful work done is equal to the excess of the heat received over that rejected by the working fluid, and is restricted to the case in which no losses are incurred in expansion, and all the heat is rejected at one temperature T'', as in the condenser of a steam-engine or turbine. The method gives the fraction of the heat received in any part of the heating system which could be converted into work by a perfect engine under the conditions imposed. On the other hand, in analysing the performance of an actual engine or turbine, it is necessary to take account of losses incurred in the engine during the expansion, and to compare the actual performance with that obtainable in adiabatic expansion under ideal conditions over the same range. The general principle of the method by which this may be accomplished in the case of a turbine is as follows:

The Case of Dry Steam.—As explained previously, and implied by equation (12), the drop of H in expansion through a turbine, when corrected for the minor losses Q and K, is the equivalent of the useful work done by the steam. So long as the steam is dry, the value of H at any point of the expansion can be determined by observing the pressure and temperature, and the actual drop of H, denoted by DH, between any two points can be deduced. The work theoretically obtainable in frictionless expansion can also be found from the adiabatic equation as shown in (17). The ratio of the actual hcat-drop DH, as corrected, to the adiabatic heat-drop for the same drop of pressure, gives the efficiency of any stage or section of the turbine. This simple method fails when the steam is wet, as usually happens towards the end of the expansion, because there is no satisfactory means of measuring the degree of wetness under these conditions at low pressures. But if the initial value Φ of the entropy is known, the adiabatic heat drop can still be found from the final temperature T'', with the aid of the tables giving H_s'' and Φ_s'' for dry saturated steam, since for wet steam in the state H'', Φ'', at any temperature T'' we have the simple relation,

$$H_s''-H''=T''(\Phi_s''-\Phi''). \tag{53}$$

Heat-Drop for *Wet Steam.*—Putting $\Phi''=\Phi'$ in (53) the final H'' for wet steam at T'', in adiabatic expansion, is obtained in terms of the tabulated values H_s and Φ_s. Thus we obtain for the adiabatic heat-drop from the initial state H', Φ'.

$$H'-H''=H'-H_s''+T''(\Phi_s''-\Phi'). \tag{54}$$

Equation (54) is also the appropriate equation to employ for finding the adiabatic heat-drop over the whole range of expansion in the turbine, from admission to exhaust, when the final state of the steam is wet, as is usually the case with a condensing engine. It is equally applicable to the case of a reciprocating engine, since the discontinuities involved in the operation of this type of engine are supposed to be absent from the ideal cycle. The heat-drop thus found may be compared with the work actually done per lb. of steam, as deduced from measurements of the feed and the power, for which see STEAM: Steam Engine.

Equation (53), with Φ'' constant and equal to Φ' may be regarded as the simplest and most useful form of the adiabatic giving the final value H'' of the total heat for a wet vapour, when tables of Φ and H are available. It may be expressed if desired in terms of H and T only, but cannot be put in the usual form (9) or (10) (as is often attempted), because the value of the index γ varies so much with temperature and wetness as to make the equation difficult to use and less accurate in practice than measurements on a diagram.

Types of Characteristic Equation.—The general relation between P, V, and T, which exists for any substance in various states is commonly called the characteristic equation, or equation of state, of the substance. It has often been thought possible to include both liquid and vapour states in a single equation, such as that of van der Waals, since the properties of the two states a p proximate to each other in the critical region, and show a continuous transition above the critical pressure. This will be further discussed in the article VAPORIZATION dealing with the relations between the two states. For the present purpose we may confine our attention to a few simple types of equation for the gas or vapour state, which is of primary importance in practice in relation to heat engines. It appears that all simple substances with stable molecules tend to approximate in the vapour state at low pressures to the ideal gas equation PV= RT, in which the value of the constant R varies inversely as the molecular weight (if V is the volume of unit mass) and is equal to the difference of the specific heats in work units. An equation of this type receives a satisfactory physical explanation on the kinetic theory of gases, but it is the province of thermodynamics to indicate how the simple gas equation must be modified to take account of deviations from the ideal state, and to interpret the results of various experimental methods as applied to the problem.

One of the commonest methods of measuring these deviations is to observe the variation of the volume with pressure at constant temperature. The values of the product PV should then be constant if Boyle's law is obeyed, and should give a horizontal line on the PV—P diagram. As a rule the isothermal lines thus plotted from observations at various constant temperatures, are nearly straight for a moderate range of pressure at each temperature, but have a downward slope, represented by $d(PV)/dP=-c$, where c diminishes with rise of temperature as the vapour approximates more closely to the ideal state. Observations of this kind could be represented by an equation of the type (42) by assuming PV to be proportional to T at low pressures, and choosing c, or $c-b$, to be a suitable function of the temperature. But even if all the isothermals were found to be horizontal, this method by itself would not prove that PV was proportional to the absolute temperature, as in $PV=RT$, since Boyle's law would be perfectly satisfied by an equation of the type, $PV=F(T)$, with $F(T)$ any arbitrary function of the temperature.

Fortunately the Joule-Thomson method, as described on page 98, affords an independent means of verifying the form of the characteristic equation. It has the additional advantages of being easy to apply and of measuring the small deviation itself, without requiring any absolute measurements of volume, which are essential to the Boyle's law method, and very exacting. As shown by the thermodynamic expression (40) for the cooling effect, any substance for which $C=0$ must have a characteristic equation of the general type $V/T=F(P)$, in which $F(P)$ represents any arbitrary function of the pressure. The ideal gas, $PV=RT$ is a special case for which $F(P)=R/P$. The condition $C=0$ by itself leaves the form of $F(P)$ indeterminate. But when the same gas also satisfies Boyle's law, which requires a characteristic equation of the form $PV=F(T)$, the two conditions can be simultaneously satisfied only by the ideal gas equation PV=RT. Joule and Thomson were therefore justified in their choice of the constant of integration R/P in equation (41), since the gases they employed also satisfied Boyle's law at low pressures.

Type of Equation Required by *Condition* (6).—Another case of practical interest is to find the general form of characteristic equation compatible with condition (6), and with the simple form of adiabatic equation (9), which follows by the first law of thermodynamics from the assumption that the change of intrinsic energy is proportional to that of aPV as expressed in (6). Equations (6) and (9) make no mention of temperature, and it is obvious that the deduction of the relation between PV and T must essentially involve an appeal to the second law with its implicit definition of T. The most direct way of doing this is to find the two specific heats, S_p and S_v, from H and E as given by (6), and to equate the difference, S_p-S_v, thus found to the expression (3j) for the difference of the specific heats as given by the second law. Thus by differentiating (6) at constant volume we obtain for the specific heat S_v,

$$S_v=(dE/dT)_v=an(V-b)(dP/dT)_v. \tag{55}$$

Similarly by adding aPV to (6) to give H— Binstead of $E-B$, and differentiating H at constant pressure, we obtain for the specific heat S_p,

$$S_p=(dH/T)_p=a(n+1)P(dV/dT)_p. \tag{56}$$

Substituting the difference of these two expressions for S_p-S_v in (35), and dividing by $a(dP/dT)_v(dV/dT)_p$, we obtain the required expression for T in terms of P and V in the form of a differential equation, namely,

$$T=(n+1)P(dT/dP)_v-n(V-b)(dT/dV)_p \tag{57}$$

which is a special case of Lagrange's linear equation, and is easily solved as follows.

(a) Write down the corresponding subsidiary equations of Lagrange, namely,

$$dT/T=dP/(n+1)P=-dV/n(V-b) \tag{58}$$

(b) Find any two independent solutions of these equations. The two simplest and most obvious solutions of (58) are those given in (10) above, which are alternative forms of the adiabatic equation, and are also solutions of (57). (c) To find the most general solution. including all other possible solutions, make one of these expressions an arbitrary function of the other. This will be the most general form of characteristic equation consistent with (6) and (9). The most convenient form for most practical purposes, giving V explicitly as a function of P and T, is as follows,

$$P(V-b)/T=F(P/T^{n+1}) \qquad (59)$$

which is expressed in words by stating that $P(V-b)/T$ must be constant along any adiabatic represented by $P/T^{n+1}=\text{constant}$. Thus (59) includes all possible forms of characteristic equation consistent with the adiabatic found experimentally for steam, and with the expression (6) for the intrinsic energy, which was assumed as the basis of the equations first proposed for steam by the writer (Proc. R.S. 1900, p. 269). At that time none of the experimental evidence available, except that for the adiabatic, extended much beyond 200 lb. pressure and 200° C, and the state of knowledge did not justify going further than the first approximation represented by equation (42), in which the arbitrary function F was assumed to be of the simple form $R/a-cP/T$. This proved to be a very good approximation and amply sufficient at moderate pressures or high superheats, but it appeared that higher powers of cP/T would be required at higher pressures. and that no equation of this type could represent the accepted theory of the critical state, as represented by the van der Waals equation.

While retaining the fundamental assumption (6) it would evidently be possible to construct an equation of the van der Waals type, giving P as a cubic function of $1/(V-b)$, by replacing P/T^{n+1} in (59) by $1/(V-b)T^n$, as follows,

$$aP(V-b)/RT=1-c/(V-b)+c^2/3(V-b)^2 \qquad (60)$$

which would give a critical point of the usual type defined by the conditions,

$$V-b=c=RT/3aP, \qquad (61)$$

but in the absence of accurate experimental data it was impossible to predict that this would be more satisfactory than (59) in terms of P, whereas it would certainly be much less convenient for practical calculations.

It has recently been found possible (Proc. R.S. Sept. 1928), to extend the experimental range for water and steam to 400° C and 4,000 lb. pressure, including the whole of the critical region. Results obtained for water, by the steady flow method described in the article CALORIMETRY, verify the thermodynamic equation there given for the total heat with extreme accuracy up to the critical point. Those for steam disagree materially on several fundamental points with the accepted theory of the critical state, and appear to show that an equation of the type (59) is capable of representing the critical phenomena with much greater accuracy than any equation of the van der Waals type. Since the points in question are of primary importance with respect to the relations between the liquid and vapour states, they are further discussed in the article VAPORIZATION, though they also afford a good illustration of the application of the laws of thermodynamics to experimental research.

As it would be impossible within the limits of this article to illustrate or explain adequately the applications which have been made of the principles of thermodynamics, it has been necessary to select such illustrations only as are required for reference in other articles, or could not be found elsewhere. For fuller details and explanations of the elements of the subject, the reader must refer to general treatises, such as Ewing's *Thermodynamics* for Engineers (Cambridge, 1920), Birtwistle's The Principles of Thermodynamics (2nd ed , Cambridge, 1927) or Preston's Theory *of* Heat (5th ed., 1928). One or two chapters on the subject are also generally included in treatises on the steam engine or other heat engines, such as those of Rankine. Ewing, or Perry. Of greater interest, especially from a historical point of view, are the original papers of Joule, Kelvin and Rankine. A more elaborate treatment of the subject will be found in many foreign treatises, such as those of Clausius, Zeuner, Duhem, Bertrand, Planck and others. (H. L. C.)

THERMODYNAMICS AND PHYSICAL CHEMISTRY

Introductory.— The principles of thermodynamics (introduced in their modern form by Clausius in 1850) are the basis of a method of dealing with mechanical problems in which heat exchanges take place, without the necessity arising of considering the detailed mechanical structure of a system. The system may consist of an assemblage of an enormous number of molecules in agitated movement and exerting attractions and repulsions upon one another. Very little can be found out about the individual motions and positions of these particles. Thermodynamics provides a means of examining certain properties of matter in bulk. The principles that are discovered form the basis of the preceding article and reference must be made to that article for their description and proof. They are applied there mainly to the properties of steam and its applications to steam-engines. In the present article which deals with the application to bodies in general we must be content with summarizing the fundamental facts which will be utilized.

i. The intrinsic or internal energy of a body can change by the entry of heat (by conduction or radiation) and by the performance of external work, i.e., $dE=dQ-dW$ provided the system remains sensibly in equilibrium (*Conservation of energy*).

ii. A body may get hotter even if no heat flows in. The energy depends on the temperature and this is increased if work is done upon the system even when dQ is zero (Adiabatic *changes*).

iii. The energy, E, depends only upon the state; so that, in whatever way the system is changed, if the original state is returned to, the initial value, E, is recovered.

iv. The work done depends in general not only upon the initial and final states but also upon the path of transformation.

This results from the fact that three variables at least are necessary to specify the state, viz., pressure, volume and temperature, and they are connected by only one equation (the equation of state). The work done is in each case $\int pdV$. In a complete cycle the work done is equal to the area enclosed by the cycle on a p, V diagram. For any given value of V, T and therefore p may have different values on the return and forward paths and the cycle encloses an area. It follows that for an *isothermal* reversible cycle the pressure for any given volume is fixed and the work done must be zero for the path then returns on itself.

v. The energy E depends on both the temperature and the volume: for internal work can be done against molecular attractions when the volume changes.

When the system is subjected to a uniform pressure the fundamental equation becomes $dH=CdT+ldv$.

We select unit mass for consideration. In this case C is the specific heat at constant volume and $l\left(=\frac{\Delta H}{\Delta v}\right)$ is the latent heat of expansion. In the case of a perfect gas, for which the characteristic equation is $pv=RT$ and for which no internal attractions exist, so that the internal work is zero

$$dH=C_vdT+pdv$$

which can be put in the alternative forms (by using the characteristic equation)

$$dH=C_pdT-vdp=\frac{1}{R}(C_ppdv+C_vvdp)$$

where C_v and C_p are the specific heats at constant volume and at constant pressure.

From these for adiabatic changes ($dH=0$)

$$C_vdT+\frac{RT}{V}dv=0 \quad \text{or} \quad vT^{C_v/R}=\text{const.}$$

$$C_pdT-\frac{RT}{p}dp=0 \quad \text{or} \quad \frac{T^{C_p/R}}{P}-\text{const.}$$

and $$C_ppdv+C_vvdp=0 \quad \text{or} \quad pv^{C_p/C_v}=\text{const.}$$

The work done is $\int pdv=-C_v\int dT=C_v(T_1-T_2)$.

It is presumed that the changes are reversible throughout. A very quick change is always irreversible owing to the rushes of material that take place. The only way to bring about approximate reversibility is to keep the heat from getting in or out as well as possible by means of non-conducting boundaries.

vi. The second law of thermodynamics enables relations to be found between the several quantities (or their derived quantities). According to this law the work that can be done in a reversible Carnot cycle is the maximum possible for the two extreme temperatures concerned, and, *independently of the working substance*, the work done divided by the heat taken in at the higher temperature is equal to $(T_1-T_2)/T_1$: where T_1 and T_2 are absolute temperatures on the perfect gas scale. This ratio is called the efficiency.

[This law is derived from the fact that heat can only flow *down* a gradient of temperature. Clausius showed that if a more efficient performance were obtainable it would be possible to make a hot body hotter while simultaneously a cold one became colder without any performance of work. This would entail that heat flowed *up* the temperature gradient.]

vii. Since the efficiency is also given by $\frac{W}{Q_1}=\frac{Q_1-Q_2}{Q_1}$ we deduce that $\frac{Q_1}{T_1}=\frac{Q_2}{T_2}$.

Now in a Carnot cycle Q_1 and Q_2 are the only transfers of heat (each at constant temperature); if therefore me define a quantity ϕ such that $Td\phi=dQ$ this quantity ϕ undergoes zero change in any complete reversible cycle. It is called the entropy of the system per unit mass.

For irreversible changes this definition is not complete. In such changes there is kinetic energy of matter in bulk; and friction which is alnays present is continually frittering the motion down into heat. If we regard the system as an assemblage of small elements rubbing against one another the heat produced flows across the boundaries of these elements. In doing so some has entered each element and produces the same changes of p, v, T and entropy as any heat entry would do. When this heat production and corresponding entropy change is summed up for the whole system we have

$$Td\phi=d(Q+q)$$

where q is the heat produced by friction inside the walls of the complete system. Since friction never produces "cold," dq is always positive and consequently for any change

$$Td\phi\geqq dQ.$$

Cases in which the equality sign holds are ideal cases only; but they are approximated to more nearly the nearer a system keeps in equilibrium states throughout.

The quantity T_1 is, as we have said, the absolute temperature according to a perfect gas scale. We could have defined it alternatively in terms of the efficiency equation and it is therefore called the *thermodynamic* temperature. It would have been necessary then to show that it is identical with the ideal gas scale.

The advantage gained by introducing the conception of entropy is that it provides us with a function of Q which depends (unlike Q itself) only upon the state of the system, provided that we measure it for reversible changes only.

viii. When any property of the state of a system (say E) is defined completely by two independent variables (say x and y) so that we can write

$$dl3=adx+bdy$$

where $$a=\left(\frac{\partial E}{\partial x}\right)_y \quad\text{and}\quad b=\left(\frac{\partial E}{\partial y}\right)_x$$

the following mathematical relation must be valid, viz.:

$$\left(\frac{\partial a}{\partial y}\right)_x=\left(\frac{\partial b}{\partial x}\right)_y$$

the suffixes denoting quantities which remain constant during the partial differentiations to which they are appended.

This mathematical relation can be applied in the case of reversible changes to E and + which depend only on the state but it cannot be applied to Q or to W, which depend upon the path taken between the extreme states. In consequence some writers prefer not to use the expressions dQ and dW for small changes in Q and W because, for example, these may each acquire different values whether the "co-ordinates" of the system (e.g., v, T) have changed on *the* whole or not. Small changes in quantities which depend only upon the state are said to be perfect differentials.

When there are more than two independent variables we can apply the same theorem to any two of them in turn. For example, adding a third term cdz, we have the additional relations

$$\left(\frac{\partial a}{\partial z}\right)_{x,y}=\left(\frac{\partial c}{\partial x}\right)_{y,z} \quad\text{and}\quad \left(\frac{\partial b}{\partial z}\right)_{y,x}=\left(\frac{\partial c}{\partial y}\right)_{z,x}$$

where two of the independent variables are kept constant in each differentiation.

The employment of thermodynamics in the study of various systems consists very largely of the application of this important mathematical theorem. We shall apply it first to homogeneous systems in equilibrium.

Homogeneous **Systems.—A** homogeneous system is alike in all its parts. Its state can be defined in terms of its pressure, volume and temperature. Any one of these three may be eliminated by means of the so-called characteristic equation when it is known; so that Q, ϕ, E may be taken as functions of T and v, of T and p, or of p and v. Since each portion is the same as any other we can deal with unit mass. Since equilibrium exists the temperature and pressure will be uniform throughout. No assumption will be made as to the molecular constitution of the system; nor, until applications are considered will any assumption be made as to the form of the characteristic equation.

For such a system we can write:

$$dQ=dE+pdv=C_vdT+ldv$$

also $$d\phi=(dQ)/T.$$

so that $$dE=C_vdT+(l-p)dv$$

and $$d\phi=\frac{C_vdT}{T}+\frac{l}{T}\,dv.$$

It follows that (a) $$\left(\frac{\partial C_v}{\partial v}\right)_T=\frac{\partial}{\partial T}(l-p)_v$$

(b) $$\frac{1}{T}\left(\frac{\partial C_v}{\partial v}\right)_T=\left(\frac{\partial}{\partial T}\frac{l}{T}\right)_v.$$

The latter (b) multiplied by T gives

$$\left(\frac{\partial C_v}{\partial v}\right)_T=\frac{\partial l}{\partial T}-\frac{l}{T}$$

which, comparing with (a), giver $l=\mathrm{T}\left(\frac{\partial p}{\partial T}\right)_v$

and $$\left(\frac{\partial C_v}{\partial v}\right)_T=T\left(\frac{\partial^2 p}{\partial T^2}\right)_v.$$

For a perfect gas $pv=\mathrm{RT}$, whence $\mathrm{T}\left(\frac{\partial p}{\partial T}\right)_v=p$ and $\left(\frac{\partial C_v}{\partial v}\right)_T=0.$

For a van der Waals gas 3+ – $(v-b)=\mathrm{RT}$, so that

$$T\left(\frac{\partial p}{\partial T}\right)_v=p+\frac{a}{v^2} \quad\text{and}\quad \left(\frac{\partial C_v}{\partial v}\right)_T=0;$$

whence $dQ=C_vdT+\frac{adv}{v^2}+pdv$; the term $\frac{a}{v^2}dv$ shows how the energy depends upon the volume.

It will be noticed that these are all cross-relations between different terms. There is no thermodynamical relation giving $\frac{\partial C_v}{\partial T}$ because C_v and T both refer to the same term. We know nothing about C_v as a function of T except from experiment and from tentative mechanical theory.

In a similar way if $dQ=C_pdT+l'dp$ (T and p being taken as independent variables) me have

(a) $$dE=C_pdT+l'dp-pdv$$

and (b) $$d\phi=\frac{C_pdT}{T}+\frac{l'dp}{T}.$$

Now $d(pv)=pdv+vdp$; and if this be added to both sides of (a) we have $d(E+pv)=C_pdT+(l'+v)dp$. Since, the product pv

returns to a fixed value whenever p and v do therefore $E+pv$ also depends on the state alone and its change is defined here in terms of dT and dp. Hence

$$\left(\frac{\partial C_p}{\partial p}\right)_T = \left[\frac{\partial}{\partial T}(l'+v)\right]_p$$

and
$$\left[\frac{\partial}{\partial p}\left(\frac{C_p}{T}\right)\right]_T = \left[\frac{\partial}{\partial T}\left(\frac{l'}{T}\right)\right]_p$$

which yield finally $l' = -T\left(\frac{\partial v}{\partial T}\right)_p$ and $\left(\frac{\partial C_p}{\partial p}\right)_T = -T\left(\frac{\partial^2 v}{\partial T^2}\right)_p$

It is to be noted that these equations in reality express the connections that must e s b e e n e properties of a substance in order to bring about the universality of the value of the efficiency if the substances were employed as the working substances in reversible engines working between two given temperatures. A high vapour pressure or a low boiling point does not lead to higher efficiency, the variables being so interconnected that this is impossible.

The above equations hold for any homogeneous systems. The equation

$$dQ = C_v dT + T\left(\frac{\partial p}{\partial T}\right)_v dv$$

is exceedingly important, embodying all that can be learned from the two thermodynamical principles, and serving as a secondary starting point from which other relations may be obtained without further reference to the two principles. For example if x is any other variable we can write

$$\left(\frac{dQ}{dT}\right)_x = C_v + T\left(\frac{\partial p}{\partial T}\right)_v \left(\frac{dv}{dT}\right)_x$$

the suffix x indicating that x is to be kept constant during the differentiation. For example, if $x=p$ (the pressure), $\left(\frac{dQ}{dT}\right)_x = C_p$ (the specific heat at constant pressure) and we have

$$C_p = C_v + T\left(\frac{\partial p}{\partial T}\right)_v \left(\frac{\partial v}{\partial T}\right)_p$$

which is an expression for the difference between the two principal specific heats. For a perfect gas the right hand side equals R, the gas constant. For a van der Waals fluid it equals

$$R \Big/ \left(1 - \frac{2a}{v^3}\cdot\frac{(v-b)^2}{RT}\right).$$

Berthelot's equation of state is very widely used in calculating the difference of the specific heats. The equation is

$$\left(\alpha + \frac{16}{3\gamma\beta^2}\right)\left(\beta - \frac{1}{4}\right) = \frac{32}{9}\gamma.$$

It is given here in its "reduced" form; *i.e.*, the actual pressures, volumes and temperatures are given as the fractions α, β, γ of their respective critical values. Calculating in the same way, this equation leads to

$$C_p - C_v = \frac{32}{9}\frac{p_c v_c}{T_c}\left(1 + \frac{6}{\gamma^2\beta}\right) \text{ approximately}$$

when β is large compared with unity. This can be written

$$C_p - C_v = R\left(1 + \frac{6}{\gamma^2\beta}\right) \doteqdot R\left(1 + \frac{27}{16}\frac{\alpha}{\gamma^3}\right)$$

where R is the characteristic constant of the gas.

Callendar's simplified equation, $v-b = RT/p - c/T^n$ leads to

$$C_p - C_v = R\left(1 + \frac{ncp}{RT^{n+1}}\right)^2.$$

The last two equations are only applicable when the density is moderate.

Saturation Values.—As a second application, let x denote a change along the line of saturated vapour; then $\left(\frac{dQ}{dT}\right)_x$ becomes σ, the specific heat of saturated vapour, and

$$\sigma = C_v + T\left(\frac{\partial p}{\partial T}\right)_v \left(\frac{\partial v}{\partial T}\right)_{\text{sat.}}$$

Now $\left(\frac{\partial p}{\partial T}\right)_v$ is always positive and $\left(\frac{\partial v}{\partial T}\right)_{\text{sat}}$ is always negative so that σ is always less than C_v and it may even be negative. This latter is the case for steam at all temperatures. The values for sulphur dioxide have also been studied in detail experimentally by Mathias (*Comptes Rendus*, t. cxix. p. 849). The importance of this substance in mechanical refrigeration warrants quoting the values in some detail:

t° C	0	20	40	60	80	100	110
σ	−0·410	−0·357	−0.300	−0·235	−0·165	+0·027	+0·062
t° C	120	125	130	140	150	155	..
σ	−0·078	−0·176	−0·306	−0·620	−1·253	−3·850	..

It appears that for this substance σ is negative except between the temperatures 97·5° C and 114° C. When plotted against temperature the curve is an inverted unsymmetrical U. This is so for all substances but in many cases it lies wholly in the negative region. The value of σ for the liquid along the saturation line has also been studied by Mathias. It is positive (because for the liquid $\left(\frac{\partial v}{\partial T}\right)_{\text{sat}}$ is positive) and changes from 0·315 at −20° C to 1·800 at 155° C.

We can start equally well from the equation

$$dQ = C_p dT - T\left(\frac{\partial v}{\partial T}\right)_p dp$$

and find
$$\sigma = C_p - T\left(\frac{\partial v}{\partial T}\right)_p \left(\frac{dp}{dT}\right)_{\text{sat}}$$

The thermodynamic equations employed above are exact. It should be noted, however, that the characteristic equations are only approximate at best. The underlying assumption that is made in deriving them is that the system consists of molecules alike in all respects. Even in such a case it is not to be expected that the p, v, T, equation should be of a simple form. It is much simplified by the fact that we are only concerned with average values. No instrument is capable of measuring either the pressure or temperature at a single point and a single moment of time. Each quantity measured is an average value over such a volume or area or time as to maintain a constant value in the equilibrium state. For real fluids molecules may be of different kinds and may be associated with one another in different ways which change with the volume and temperature. In such cases the connection between p, v and T is bound to be of a more elaborate character. The only assumption that has been made is that for a definite p, v, T, the constitution is the same whenever these return, after changes, to their original values.

Entropy.—Since $dQ = C_v dT + p dv$ for a perfect gas the entropy change is

$$d\phi = \frac{dQ}{T} = C_v\frac{dT}{T} + R\frac{dv}{v};$$

whence
$$\phi_2 - \phi_1 = C_v \log_e \frac{T_2}{T_1} + R \log_e \frac{v_2}{v_1}$$

$$= C_p \log_e \frac{T_2}{T_1} - R \log_e \frac{p_2}{p_1}.$$

For a van der Waals fluid

$$dQ = C_v dT + T\left(\frac{\partial p}{\partial T}\right)_v dv$$

$$= C_v dT + \frac{RT}{v-b} dv$$

and
$$\frac{dQ}{T} = C_v \frac{dT}{T} + \frac{R}{v-b}\, dv.$$

Now C_v for such a fluid may be a function of T but not of v, and experiment shows that, for many gases, it is very nearly a linear function of T through a range of seven or eight hundred degrees centigrade. If we write $C_v = c + gT$

$$\phi_2 - \phi_1 = c \log\frac{T_2}{T_1} + g(T_2 - T_1) + R \log\frac{v_2 - b}{v_1 - b}.$$

Thermodynamic Potentials.—It has been explained that, when the possibility of irreversible changes is taken into account the increase in entropy is always greater than that calculated from the heat entry from outside the system, *i.e.*, we may write

$$Td\phi = dQ + Pos.$$

where Pos. is a positive quantity. In the ideal case of a reversible change this positive quantity becomes zero. For any change therefore

$$dE = dQ - pdV$$
$$= Td\phi - pdv - Pos.$$

If we subtract $d(T\phi)$ from both sides

$$d(E - T\phi) = -\phi dT - pdv - Pos.$$

If the change is at constant temperature $\phi dT = 0$.

To the quantity brackets on the left Helmholtz gave the name free energy. Representing it by F we write, at constant temperature

$$-dF = +pdv + Pos;$$

i.e., the isothermal decrease of free energy is equal to the work done by the system plus a positive quantity. Since, for a reversible change, Pos = zero, the work done is then a maximum for a given isothermal diminution of free energy. This is known as the principle of maximum work.

The isothermal change of free energy may be greater or less than the change of energy, E, because nothing is specified as to whether heat enters or leaves the system during the isothermal change. For in such a change

$$dE = dF - Td\phi \quad (dT = 0)$$

and $Td\phi (= dQ)$ may be positive or negative.

If the change is made at constant temperature and constant volume $-dF = Pos.$ Hence in any such change the free energy can only decrease.

If the free energy reaches a minimum value in such a change no further decrease can occur. The system (at constant temperature and volume) must then be in equilibrium.

In ordinary mechanics a system is in equilibrium when its potential energy is a minimum. In this more general problem where thermal changes must be allowed for this property belongs to the free energy. The theorem is general; no assumption has been made in regard to the constitution of the system. Unfortunately difficulties arise in attempting to apply it excepting in the case of an ideal gas mixture.

For such an ideal mixture the various components of the system are independent of one another. The total pressure, energy, entropy, and free energy are given by the sums of the values for the separate components.

Let the constant volume and temperature be V and T, and let the contents consist of a number of gases capable of reacting according to the general law of chemical combination

$$\nu_1 A_1 + \nu_2 A_2 + \cdots = \nu_s A_s + \nu_t A_t + \cdots$$

and let them be present when in equilibrium in the proportions

$$N_1 N_2 \ldots N_s N_t \cdots$$

where the values of N are the numbers of molecules of the various kinds present. It is necessary, in the first case, to calculate the free energy per molecule of each component.

Now reckoning from any arbitrary temperature T_0 we may write

$$E = C_v(T - T_0)$$

$$\phi = C_v \log\frac{T}{T_0} + R(\log v - \log v_0)$$

$$= C_v \log T + R \log\frac{V}{N} + k$$

where k is a constant and the other quantities are the values per molecule. Hence

$$F = C_v T + TC_v \log T + RT\log\frac{V}{N} + kT - C_v T_0.$$

Since the temperature is to be treated as constant we may conveniently divide by it and write

$$F/T = C_v + C_v \log T + R\log\frac{V}{N} + k - \frac{C_v T_0}{T}$$

and for N molecules of any one kind this must be multiplied by N. Now the total value of the free energy is $\sum(NF)$ and this, or its value divided by the constant T, is to be a minimum for equilibrium, *i.e.*,

$$\sum \frac{1}{T}\left(F + \frac{dF}{dN}\right) dN$$

must equal zero. But owing to the laws of chemical combination any changes of the quantities must satisfy the equations

$$\frac{dN_1}{\nu_1} = \frac{dN_2}{\nu_2} = \cdots - \frac{dN_s}{\nu_s} = -\frac{dN_t}{\nu_t}.$$

Hence $$\sum_{1,2\text{ etc.}}\left(F + \frac{dF}{dN}\right)\nu = \sum_{s,t\text{ etc.}}\left(F + \frac{dF}{dN}\right)\nu.$$

Performing the operations after dividing by T it follows that

$$\sum_{1,\text{ etc.}}\left(C_v + C_v\log T + R\log\frac{V}{N} + k - \frac{C_v T_0}{T} - \frac{KN}{N}\right)\nu = \sum_{s,t,\text{ etc.}}(\quad)\nu;$$

or $$\sum_{1,2\text{ etc.}} R\nu \log\frac{V}{N} = \sum_{s,t\text{ etc.}} R\nu\log\frac{V}{N} + \text{function of } T \text{ alone};$$

or $$\log\frac{V^{\nu_1+\nu_2} \cdots {}^{-\nu_s-\nu_t}}{N_1^{\nu_1} N_2^{\nu_2} \cdots N_s^{-\nu_s} N_t^{-\nu_t}} = \text{function of } T.$$

This is the equation of chemical equilibrium at constant volume and temperature. If we write $\frac{N_1}{V} = n_1$, $\frac{N_2}{V} = n_2$, etc., it becomes

$$\log\frac{\cdots n_t^{\nu_t} \cdots}{n_1^{\nu_1} n_2^{\nu_2} \cdots} = \text{function of } T.$$

The quantity under the logarithm sign is the equilibrium constant for constant temperature and volume. If the equation in terms of N_1, N_2 etc. is examined it will be seen that when

$$\nu_1 + \nu_2 + \cdots = \nu_s + \nu_t \cdots$$

a change of volume will not disturb the equilibrium. On the other hand if $\nu_1 + \nu_2 + \cdots$ is the greater sum then an increase of V will increase the values of N_1, N_2, etc. and diminish those of N_s, N_t, etc.

The former case would be illustrated by a reaction such as

$$\begin{array}{ccc} H_2 + Cl_2 & \rightleftharpoons & 2HCl \\ N_1 \quad N_2 & & N_3 \end{array}$$

where $\nu_1 = 1$, $\nu_2 = 1$ and $\nu_3 = 2$; and the latter case by

$$2H_2 + O_2 \rightleftharpoons 2H_2O$$

in which the $\sum(\nu)$ on the left is one greater than of the one on the right. This is stated without prejudice to the question as to whether the above reactions usually occur or not.

The function of temperature involves the specific heats (or molecular heats), which depend upon the temperature in a way undeterminable by thermodynamics, as well as the constants of integration. The values of the specific heats can however be ascertained by experiment and thus the value of the equilibrium constant at any temperature can be calculated within a constant.

Any deviation that is found from these conclusions may leave it a moot point whether the reactions are not of the specified type or whether the deviations are due to departures from the ideal gas law.

The equilibrium constant was first given by Guldberg and Waage. They based it on the laws of probability of encounters between the reacting molecules. Taking the probability of an encounter of any molecule of the first with one of another kind as proportional to N_1, the probability that ν_1 of them will simultaneously collide is $N_1 N_1 N_1 N_1 \ldots$ to ν_1 terms; that is, it is $N_1^{\nu_1}$. Similarly for N_2 the required probability is $N_2^{\nu_2}$. Further the probability that the two groups shall collide simultaneously is $N_1^{\nu_1} N_2^{\nu}$, and so on. Some slight departure from the gas law is needed in order that collisions may occur at all; for if the molecules had no volume there would be nothing to collide against. But if the volume occupies a sensible proportion of the total system, corrections are required to Guldberg and Waage's law; and any attractions between the molecules, which will necessarily increase the number of collisions, necessitates still further corrections, so that this niethod of attacking the problem lands us in difficulties. The same is true of the thermodynamic method which has been given in detail, when other characteristic equations are employed; even the total pressure is not the sum of the "partial" pressures as it would be according to Dalton's law. The additive law breaks down also for all the other functions (E, ϕ, etc.). We shall return to the problem after dealing with heterogeneous equilibria.

But first some of the other properties of the free energy must be stated. Since for reversible changes $dF = -\phi dT - p dv$ it follows that

$$\left(\frac{\partial F}{\partial T}\right)_v = -\phi \text{ and } \left(\frac{\partial F}{\partial v}\right)_T = -p.$$

But $$F = E - T\phi = E + T\left(\frac{\partial F}{\partial T}\right)_v.$$

Therefore $$T\left(\frac{\partial F}{\partial T}\right)_v - F = -E$$

or $$\frac{\partial}{\partial T}\left(\frac{F}{T}\right)_v = -\frac{E}{T^2}.$$

It should be noted that the decrease of F in a reaction is often represented by A and the corresponding *evolution* of energy (*i.e.*, the heat of reaction at constant volume) by U. In terms of these quantities the equation becomes

$$T\frac{\partial A}{\partial T} - A = -U$$

which is of the same form as before.

Again, since F depends, in reversible changes, only upon the state (because E, T, and ϕ so depend) it follows that

$$\frac{\partial^2 F}{\partial v\, \partial T} = \frac{\partial^2 F}{\partial T\, \partial v}$$

and therefore $$-\left(\frac{\partial \phi}{\partial v}\right)_T = -\left(\frac{\partial p}{\partial T}\right)_v.$$

Since, we can write $Td\phi = dQ$ this is identical with the equation already found, viz.:

$$\left(\frac{\partial H}{\partial v}\right)_T = l = T\left(\frac{\partial p}{\partial T}\right)_v.$$

Heterogeneous Systems.—A heterogeneous system is one in which the whole system can be divided into discrete parts each of which is homogeneous but differs from its neighbours. Each is called a "phase". 'Cl'ithout at first considering such systems in general we may take the familiar case of a vessel containing a liquid and its vapour or a solid and a liquid. These can at certain temperatures be in equilibrium with one another. Putting aside the effects of gravity and other body forces, when equilibrium exists the pressure must be uniform throughout the system for mechanical reasons, provided there is no curved interface between the phases; and the temperature must be uniform throughout for reasons depending upon conduction and radiation. The values of these variables are independent of the relative amounts of liquid and vapour. Let $1-m$ and m be the masses of the two phases in a system of unit mass; and let v_1 and v_2 be their specific volumes (*i.e.*, volumes per unit mass) then the total volume is $(1-m)v_1 + mv_2$. The uniform pressure is the saturation pressure; we denote it by the symbol a the value of which experiment shows to be independent of the volume but dependent upon the temperature. The total energy is $E = (1-m)E_1 + mE_2$ where E_1 and E_2 are the energies per unit mass of the respective phases. The entropy is $\phi = (1-m)\phi_1 + m\phi_2$. Any heat that enters may be divided into two parts corresponding to the phases it passes into. Since the law of summation obviously applies throughout we can write

$$dQ = CdT + ldV \text{ as before}$$
$$= \{(1-m)\sigma_1 + m\sigma_2\}\, dT + ld\,((1-m)\, v_1 + mv_2\}$$

provided, at least, that neither of the phases vanishes. Now the same considerations as before give

$$l = T\left(\frac{\partial \pi}{\partial T}\right)_v = T\frac{\partial \pi}{\partial T}$$

since π is independent of V. The change of volume is $(v_2 - v_1)dm$ so that the equation becomes

$$dQ = ((1-m)\sigma_1 + m\sigma_2\}\, dT + T(v_2 - v_1)\frac{d\pi}{dT}\,dm.$$

The heat taken in when unit mass evaporates at constant temperature is called the latent heat of evaporation; it is equal to the coefficient of dm and is therefore

$$L = T\,(v_2 - v_1)\frac{d\pi}{dT}$$

This is the equation of latent heat for a change of phase first given in the present form in 18jo by Clausius but actually found to be verified by experiments made in the case of the change of ice into water by Lord Kelvin in 1850 before he had accepted the law of the conservation of energy. These experiments were first interpreted in terms of a calculation made by his brother James Thomson in 1849 based upon Carnot's theory of the conservation of heat (not energy)—the effect to be expected from lowering a quantity of heat through one degree being determined, *not* by theory, but by comparison with results obtained from Regnault's expcrimcnts on steam. The lowering caused by an increase of the equilibrium pressure π by 140 atmospheres is about one degree centigrade. It is a lowering in the case of ice-water because $v_{\text{ice}} > v_{\text{water}}$; it is a rise in the transition temperature (*i.e.*, the boiling point) in the case of water-steam because $v_{\text{steam}} > v_{\text{water}}$. We can conveniently take the equation in the form

$$dQ = \{(1-m)\sigma_1 + m\sigma_2\}\, dT + Ldm$$

so that the independent variables become T and m. Consider now an adiabatic change, $dQ = 0$; then

$$\frac{dm}{dT} = -\frac{(1-m)\sigma_1 + m\sigma_2}{L}$$

Since the symbols σ_1, σ_2 stand for saturation values, σ_1 is positive but σ_2 may be negative. If we write $(-\sigma_2)$ in such case for its positive numerical value we find that dm will be negative when dT is negative provided that $(1-m)\sigma_1$ is numerically less than $m(-\sigma_2)$, *i.e.*, that liquid will form in the case of water-steam when the temperature lowers. Since the water deposits most readily on particles of dust, etc., in the vessel a cloud will appear. This is obviously most likely to happen when the amount of water initially present $(1-m)$ is small compared with the amount of vapour (m). In the case of a positive value for σ_2 no cloud can form.

A reversible *isothermal* expansion of a mixture of water and steam always causes evaporation.

Phase **Rule.**—We have considered the co-existence of water and steam and of ice and water in separate phases. The possibility of this co-existence is determined by the *phase rule* due to Willard Gibbs. The dividing surfaces between the phases are presumed to be plane so as to exclude effects arising from surface tension. The phase rule asserts that the number of independent variations of which a system of co-existent phases is capable is $C+2-P$ where C is the number of independently variable *components* in the whole system. The term *component* must be carefully distinguished from *constituent*. Thus in dealing with water and steam, hydrogen and oxygen are constituents of each phase, but since they can only vary in chemically combining proportions it would be sufficient to specify either of them or even the amount of water present. Thus there is only one component in this case. If free hydrogen (or oxygen) were present as well in excess there would be an additional component and there is again an arbitrary choice as to the two components to be selected. The proof of the rule is that the system of phases is completely specified by the temperature, pressure and the data for the C components and between these $C+2$ quantities there are P independent relations (one for each phase), which characterize the system of phases.

For example, in the case of water which can exist (not necessarily co-exist) as ice, water or steam there is one component and three possible phases so that if all are present $C+2-P=0$ and there is no disposable relation—their states (defined by v and T) are absolutely fixed. If only two of the phases are present $C+2-P=1$; there is therefore one relation between various values of p and T for equilibrium. This relation gives the vapour pressure line or, in the case of ice and water, the connection between pressure and freezing-point. Again if there is only one phase present, there are two disposable relations; in other words the pressure and temperature can vary independently of each other. The number of disposable relations is known as the number of degrees of freedom (F) so that

$$C+2-P=F$$

When the number of phases that co-exist is the greatest possible the value of F is zero. Of these phases not more than one can be gaseous because the components mix in such a phase in all proportions, so that two gaseous phases would intermingle and reduce to a single phase.

In considering the equilibrium of such a system it is necessary to introduce a new function of the variables; this is done in such a way that the independent variables become T and p. As before we have

$$Td\phi=dQ+Pos.$$

where *Pos.* stands for a positive quantity. Hence

$$dE=dQ-pdv=Td\phi-pdv-Pos.$$

Adding to both sides $d\,(pv-T\phi)$

$$d(E-T\phi+pv)=-\phi dT+vdp-Pos.$$

It follows that if the quantity in brackets on the left is calculated for the whole system its value can only decrease in any change of the system that takes place at constant pressure and temperature. Or again, if an infinitesimal change, in which p' and T are kept constant, is made about a state of equilibrium, the change on the left hand side is zero. It is sometimes called the *thermodynamic potential at constant pressure and temperature* (Duhem); or since it is concerned with the equilibrium of co-existent phases it may be called the *paraphase potential* and will be denoted by ζ.

One Component System.—Let there be one component only ($C=1$). Then if there are two phases there is one degree of freedom. There must therefore be a connection between p and T; this connection is the vapour pressure curve if the two phases are liquid and vapour. Let the values of ζ per unit mass be ζ_1 for liquid and ζ_2 for the vapour. The total potential is therefore

$$\zeta=(1-m)\zeta_1+m\zeta_2.$$

Now for equilibrium

$$d\zeta=-\zeta_1dm+\zeta_2dm=0.$$

Therefore $\qquad \zeta_1=\zeta_2$

that is the potentials per unit mass are the same for the two phases. Similarly for solid and liquid

$$\zeta_0=\zeta_1$$

and for solid and vapour.

$$\zeta_0=\zeta_2.$$

These three equations specify three curves on a pT diagram. The first two curves intersect at a point given by $\zeta_2=\zeta_1=\zeta_0$. This point also satisfies all three curves. Thus the three equilibrium curves must intersect at one point. This point is called the *triple point.* Further they cannot all intersect at any other common point for according to the phase rule there are no degrees of freedom when the three phases meet—the point of meeting is absolutely determinate.

Now the equations for these potentials are:

$$d\zeta_2=-\phi_2dT+v_2dp,$$
$$d\zeta_1=-\phi_1dT+v_1dp,$$
$$d\zeta_0=-\phi_0dT+v_0dp.$$

Whence $\qquad d(\zeta_2-\zeta_1)=-(\phi_2-\phi_1)dT+(v_2-v_1)dp=0$

for all points on the curve connecting p and T which are common to both vapour and liquid. Hence this curve is also defined by

$$\phi_2-\phi_1=(v_2-v_1)\frac{dp}{dT}.$$

The left hand side is $\dfrac{\text{latent heat}}{T}=\dfrac{L_{12}}{T}$.

Therefore $\qquad L_{12}=T\,(v_2-v_1)\,\dfrac{dp_{12}}{dT}$; Liquid→Vapour.

Similarly for the two other curves,

$$L_{01}=T\,(v_1-v_0)\,\frac{dp_{01}}{dT}\text{; Solid→Liquid,}$$

and $\qquad L_{02}=T(v_2-v_0)\,\dfrac{dp_{02}}{dT}$; Solid → Vapour.

These are simply Clausius equations for the three possible changes of phase.

The trigonometric tangent to the slope of any one of the p, T, curves is given by the value of $\dfrac{dp}{dT}$ for the curve, i.e.,

$$\frac{dp_{12}}{dT}=\frac{\phi_2-\phi_1}{v_2-v_1};\ \frac{dp_{01}}{dT}=\frac{\phi_1-\phi_0}{v_1-v_0}\text{ and }\frac{dp_{02}}{dT}=\frac{\phi_2-\phi_0}{v_2-v_0}.$$

Hence at the triple point these are obviously connected by the relation

$$(v_2-v_1)\,\frac{dp_{12}}{dT}+(v_1-v_0)\,\frac{dp_{01}}{dT}+(v_0-v_2)\,\frac{dp_{02}}{dT}=0$$

and therefore, at the triple point,

$$L_{02}=L_{01}+L_{12}.$$

This relation does not hold at any other point.

It must be emphasized that in the above no assumption is made as to whether the single component is associated or not; nor whether it is equally associated in the several phases nor that the degree of association remains unchanged when the temperature changes, nor even that the matter in the phase consists of molecules. The decision in regard to such questions has no bearing on the investigations of this part of the subject. What we do assume is that each of the homogeneous phases is quite definite when the temperature and the specific volume are definitely given.

Many Components.—When there are many components in each phase the subject becomes too complicated to be dealt with in this short article. The thermodynamics potential ζ for each phase mill depend upon the masses of the components as well as upon T and p. When its value is differentiated at constant temperature and pressure and equated to zero an equation is obtained of the form $\mu_1dm_1+\mu_2dm_2+\ldots=0$. The coefficients μ_1, μ_2, etc., are called the chemical potentials of the several components in the particular phase. The final result is that the chemical potential of any one component must be the same for all the phases that are coexistent. The problem of heterogeneous equilibrium in the general case would therefore be solved if only it were possible to obtain ζ as an explicit function of all the masses. This is not possible unless the ideal gas laws are assumed.

OSMOTIC PHENOMENA

When a tube has its lower end stopped by a suitable membrane and is partly full of a solution; and the lower end is dipped in pure solvent, a difference of level is often maintained in the final state of equilibrium. It is necessary that the membrane shall be permeable to the solvent but not to the solute—it shall be only *semi-permeable* in fact. If it is permeable to both, equilibrium can only be attained when the concentration on both sides has come to the same value by diffusion. Semi-permeable membranes are easily obtained that will act for months with hundreds of atmospheres difference of pressure between the two sides.

Unglazed earthenware impregnated with colloidal ferrocyanide of copper by an electrolytic method constitutes such a membrane, impermeable to sugar and many salts but permeable to water. It is only the final state of equilibrium that will be considered in this place. When all flow is over, there is a difference of pressure between the two sides of the membrane: this difference of pressure is called the *osmotic pressure*. It is, in general, a property not of the solution alone but involves the solvent also. Loose definitions based upon the properties of dilute solutions should be carefully avoided. The thermodynamical study of osmotic pressure is based upon the impossibility of obtaining external work from an isothermal reversible cycle. (The efficiency of such a cycle is zero.) It is possible to evaporate a unit mass of the solvent from the solute, to change its pressure so that it can then be passed reversibly into the liquid solvent, and finally to pass it back into the solution through the osmotic membrane. This cyclic series of operations can all be conducted isothermally and reversibly. In order that the concentration shall keep constant during the changes it is necessary that the mass of the solution shall be practically infinite or that the unit mass be infinitesimal. The algebra can be much simplified if a modification is made in the process. Any term, representing external work done is an expression of the type $\int_1^2 p\,dv$. Now, integrating by parts, $\int_1^2 p\,dv = p_2v_2 - p_1v_1 - \int_1^2 v\,dp$; and for a complete cycle of changes $\sum(p_2v_2 - p_1v_1)$ must equal zero and consequently adding expressions such as $p\,dv$ comes, for the whole cycle, to the same thing as adding expressions such as $\int v\,dp$ for the several stages. The imagined process can be supposed carried out in an arrangement such as is shown in fig. 1 (called by van't Hoff an equilibrium box and used by him for dilute solutions only). The solution and solvent are on opposite sides of a semi-permeable membrane C and enclosed by means of ordinary pistons A and B. Lateral cylinders are also provided with pistons; these cylinders are connected with the main cylinders by means of membranes permeable to the vapour alone. The solution is at a hydrostatic pressure p and any vapour in its lateral cylinder at a pressure π_p which corresponds to the particular pressure of the solution; similarly for the solvent and its vapour we have the pressures π_o and $\pi_{o_{p_o}}$. In making these provisions it is being definitely recognized that the vapour pressure depends, not only upon the temperature but also upon the pressure of the solution or solvent (an example of this will be dealt with in connection with interfacial effects).

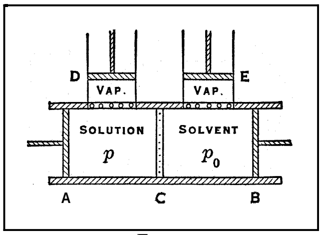

FIG. 1

The cyclic series of operations and the values of $v\,dp$ corresponding to them are as follows:—(The value of $\int v\,dp$ in each stage is denoted by S).

i. Remove unit mass (supposed infinitesimal compared with the total mass so as not sensibly to alter the concentration) of solvent from the solution by means of the lateral cylinder. Piston A requires to be moved to the right to effect this transfer. Since the pressures keep constant, $S_1 = 0$.

ii. Change the pressure of the vapour removed, from π_p to $\pi_{o_{p_o}}$: then $S_2 = \int_{\pi_p}^{\pi_o p_o} v\,d\pi$ where v is the specific volume of the vapour.

iii. Pass the vapour into the solvent reversibly at constant pressure:

$$S_3 = 0.$$

iv. Pass unit mass of solvent into solution through C at constant pressures (by moving A and B suitably):

$$S_4 = 0.$$

Adding all the values of S we obtain

$$\int_{\pi_p}^{\pi_o p_o} v\,d\pi = 0 \quad \text{whence } \pi_{o p_o} = \pi_p.$$

Thus it appears that the vapour pressure of the solution when the latter is at the pressure p must equal that of the solvent when at a pressure p_o where $p - p_o$ is the osmotic pressure. It must be remembered that the standard vapour pressures as usually measured are for the cases when the liquids are at the pressures of their vapours alone.

It can easily be seen that this must be the case. For if, otherwise, πp is greater than $\pi_{o_{p_o}}$ it would only be necessary to put the lateral cylinders into communication for a flow of vapour to take place from left to right. This would cause fresh evaporation from the solution (to maintain the equilibrium value of vapour pressure) and (for a similar reason) condensation of vapour into the solvent. Since the evaporation from the solution would increase the concentration a flow through C from the solvent would take place to maintain the equilibrium. This action would go on unceasingly and a particular kind of perpetual motion would be obtained. Unless we are prepared to admit the possibility of this type of perpetual motion, we must deny the assumption of any difference between the vapour pressures of the solvent and solution when measured under equilibrium conditions for the two *liquids*. That the vapour pressure of a pure liquid must depend upon the hydrostatic pressure was first shown by Sir William Thomson (Lord Kelvin). If a vertical capillary tube be placed in water, *e.g.*, under the bell jar of an air pump so that the air can be removed, the water stands in the tube at a higher level than outside by the amount h where $g\rho h = 2\sigma/r$, $\rho =$ density of the liquid, σ the surface tension and r the radius of the tube. (See SURFACE TENSION.) Now the vapour constitutes an atmosphere and between the inside and outside levels there is a difference of vapour pressure of $g\rho' h$ approximately where ρ' is the density of the vapour. Now the essential difference between the liquid inside and out is that at the upper level inside it is at a less hydrostatic pressure than outside (equilibrium being maintained by the effects of the curvature of the surface).

Hence
$$\frac{d\pi}{dp} = \frac{g\rho' h}{g\rho h}$$
$$= \frac{\rho'}{\rho} \text{ approximately.}$$

It is easy to show that this is not approximate merely but exact for a pure liquid. In the case of a solution however it requires modification (Porter, *Roy. Soc. Proc.* A. 79, p. 519 [1907]). To examine the case of a solution enclose a large volume V of solution in a cylinder, under pressure, fitted with a lateral chamber such as on the left of fig. 1 replacing the membrane C by a solid base. Conduct a cyclic series of operation as follows:—

i. Remove unit mass of vapour at constant pressure by means of the lateral cylinder: the volume of the solution diminishes by s (say) and the vapour increases by v:

$$S_1 = 0.$$

ii. Compress the vapour removed and the solution to new *equilibrium* values:

$$S_2 = \int_p^{p'} (V - s)\,dp + \int_{\pi_p}^{\pi_{p'}} v\,d\pi.$$

iii. Pass the removed vapour back into the solution at constant pressure for each:

$$S_3 = 0.$$

iv. Compress solution by restoring the original pressure:

$$S_4 = \int_{p'}^{p} V\,dp$$

If these changes are conducted isothermally and reversibly they must add to zero. Hence

$$\int_{\pi_p}^{\pi_{p'}} v\,d\pi = \int_p^{p'} s\,dp \text{ exactly.}$$

Since this is true, however small the change of pressure, we can write it in the differential form

$$d\pi/dp = \frac{s}{v}$$

or more precisely (owing to the fact that all the quantities depend upon the pressures)

$$\frac{d\pi_p}{dp} = \frac{s_p}{v_\pi}.$$

The quantity s stands for the shrinkage of the volume of the solution when unit mass of soivent is removed from it, the unit mass being so small (or the volume so large) that no sensible change of concentration occurs. Combining this result with the proved fact that in the state of equilibrium $\pi_p = \pi_{o p_o}$ we can obtain an expression for the osmotic pressure, $p - p_o$. For, employing the integral form, the limits being from the standard values of the vapour pressures to the equilibrium values of the pressures

$$\int_{\pi_\pi}^{p} s\,dp = \int_{\pi_\pi}^{\pi_p} v\,d\pi \quad \text{and} \quad \int_{\pi_{o\pi_o}}^{p_o} u\,dp_o = \int_{\pi_{o\pi_o}}^{\pi_{op_o}} v\,d\pi,$$

where π_π and $\pi_{o\pi_o}$ are the standard vapour pressures. Subtracting these, we obtain an exact equation for the osmotic pressure

$$s\,dp - \int_{\pi_{o\pi_o}}^{p_o} u\,dp_o = \int_{\pi_\pi}^{\pi_p} v\,d\pi + \int_{\pi_{op_o}}^{\pi_{o\pi_o}} v\,d\pi = \int_{\pi_\pi}^{\pi_{o\pi_o}} v\,dp$$

because $\pi_p = \pi_{op_o}$.

From this equation simpler approximate equations can be deduced to fit particular cases.

The equality in the equilibrium vapour pressures may be shown in another way. In fig. 2 is represented a domed chamber separated into two portions: in the lower part, by a membrane semi-permeable to solvent liquid; in the upper part, by one semi-permeable to solvent vapour. The lower part contains solution and solvent on the opposite sides of the membrane, the upper part contains, besides the vapour, sufficient air on each side to make up the total pressures to p and p_o respectively. If the pressures due to the vapours are not equal it is easily seen as before that a *perpetuum mobile* will be set up.

It ought to be added that, in the exact equation for the osmotic pressure, there is no assumption as to the molecular state. in either the liquid or vapour phases. Any influence that the degree of association or dissociation may have is all taken into account by the numerical values that can be found by direct experiment for u, s, and the standard vapour pressures. When the approximate equation is used, the values of R and u (or s) both refer to unit mass and there is no reference to molecules. If we consider (so-called) molecular values by multiplying u, s, and R by such a factor that R becomes the universal value of the gas constant it may be presumed that this multiplier is at least an approximation to the molecular weight of the vapour in the *vapour state* but still no information is obtained as to the molecular state of either solvent or solute in the liquids. Such information as we have concerning molecular states is obtained by the aid of gas theory as distinct from thermodynamics.

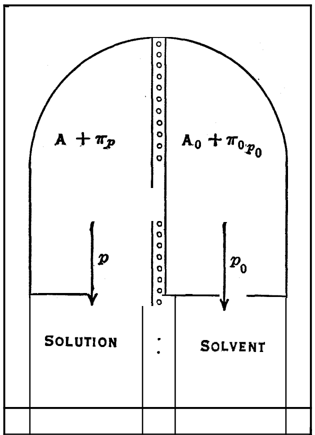

FIG. 2

General Use of Semi-permeable **Membranes.**—Imaginary semi-permeable membranes are made great use of in theoretical investigations, as in the above case. Doubt has often been raised as to the validity of this procedure at any rate in those cases for which no real membrane of the kind has been manufactured. We know that such membranes are obtainable in certain cases; *e.g.*, hot silica ("fused quartz") transmits helium and not nitrogen; hot cast iron transmits hydrogen; indiarubber is permeable to carbon dioxide. The curved surface to a liquid maintains a difference of pressure between the interior and exterior and thereby acts as a membrane semi-permeable to the *vapour;* and between a solution and the liquid solvent, as it has been already stated, very perfect membranes can be obtained. In reality, in order to employ the thermodynamical argument, it is unnecessarv that it should be possible to make any such membrane. Clerk Maxwell introduced the idea of "demons" instructed to let very fast molecules pass through an opening and stop the slow ones, thereby increasing the effective temperature on one side of a partition and diminishing that on the other. In this way he was able to show that the second law of thermodynamics does not hold for individual molecules but only for matter in the bulk. In like manner we may suppose a row of good demons turning back all the sugar molecules and letting the water molecules through in such a way that the average distribution of the water molecules in the solvent region is maintained in equilibrium. Such a row of demons will be doing precisely what our semi-permeable membrane is supposed to do and the average force per unit area they exert (viz.: $p - p_o$) corresponds exactly to the osmotic pressure. It should be noted that it is not exactly equal to the pressure the sugar molecules would exert if they were a gas with its molecules equally crowded, because there is a differential effect due to the difference of density of the water on the two sides; but in dilute solutions it is not far from this value. The most unsympathetic view that is permissible in connection with the use of membranes is that they provide a picturesque way of carrying out the virtual displacements of concentrations, etc., which are employed in the applications of the thermodynamic potentials to equilibrium problems.

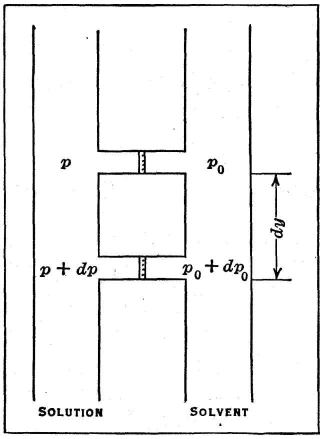

FIG. 3

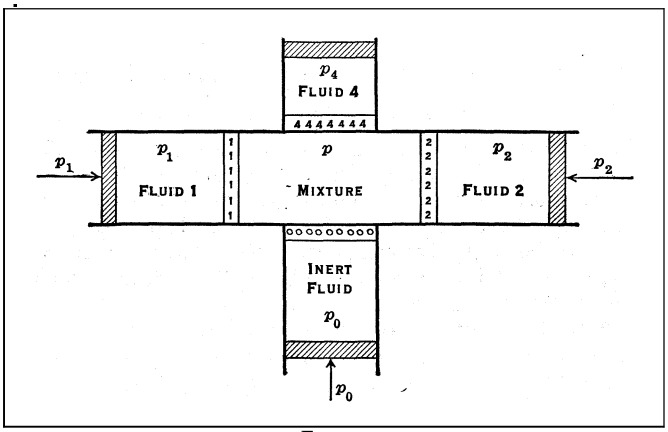

FIG. 4

Effect of **Gravity.**—We can apply the membrane method to the effect of gravity in producing a gradient of concentration with the depth In a solution. Columns of solution and solvent are connected across through semi-permeable membranes at two levels aistant dy apart (fig. 3). The densities being ρ and ρ_o we have, on the solution side, $dp = g\rho dy$ where dy is positive when measured downwards and, on the solvent side, $dp_o = g\rho_o dy$ so that $d(p - p_o) = g(\rho - \rho_o)dy$. But $p - p_o$ is the osmotic pressure, P, so the equation gives $dP/dy = g(\rho - \rho_o)$ or $dP/dp = \frac{\rho - \rho_o}{\rho}$.

If we differentiate, with respect to p, the exact equation for the osmotic pressure the result is $sdp=udp_o$

or
$$\frac{d(p-p_o)}{dp}=\frac{u-s}{s}$$

This differs from the above value; but the value just given is the variation when the concentration is kept constant; the other is the total variation. In fact we can write

$$\frac{dP}{dp}=\frac{\partial P}{\partial p}+\frac{\partial P}{\partial c}\cdot\frac{dc}{dy}$$

where c is the concentration (measured in any convenient way); i.e,

$$\frac{p-p_o}{p}=\frac{u-s}{s}+\frac{\partial P}{\partial c}\cdot\frac{dc}{dy}.$$

For dilute solutions $\frac{\partial p}{\partial c}$ follows nearly the gas law. If its exact value is known, either in consequence of this law or from experiment, the value of dc/dy can be determined. This result is of wide application. There is no assumption that it is limited to true solutions. Applied to a gamboge suspension it gives Perrin's Law of the distribution with depth when the concentration is small, and allows also a calculation to be made of the very great deviations from Perrin's Law of distribution when the concentration is great. (Trans. Far. *Soc.* XVIII. [1922]; XIX. [1923]; XXI., 63, 66 [1925]).

Application of Membranes to Homogeneous **Equilibrium.**—An interesting application can be made of semi-permeable membranes to determine the equilibrium constant for homogeneous equilibrium. Fig. 4 indicates the kind of equilibrium box required. The equilibrium which is taken as the type is that for which the chemical equation is

$$\nu_1A_1+\nu_2A_2\rightleftharpoons\nu_3A_3+\nu_4A_4;$$

and in addition an inert gas is supposed to be present, indicated by A_0; this takes no part in the reaction but modifies the total pressure of the mixture. By appropriate movement of the semi-permeable membranes a cycle of changes is carried on leading eventually to the equation

$$\nu_1\int^{p_1}u_1dp_1+\nu_2\int^{p_2}u_2dp_2-\nu_3\int^{p_3}u_3dp_3-\nu_4\int^{p_4}u_4dp_4$$
$$=\text{function of the temperature alone.}$$

This reduces to the mass action law when gas values are inserted. For detailed information in regard to its derivation reference must be made to the original paper (Trans. Far. Society, 1919). Since the membranes may be made permeable to the *vapours* of the respective components the values of u and p may be taken to stand for the specific volumes (or molecular volumes) and pressures of these vapours.

Duhem-Margules Equation.—This information is in part supplied for condensed systems by a theorem put forward by Duhem in 1887 and subsequently interpreted by Margules (1895). By means of an equilibrium box similar to that in fig. 4 we can produce the series of changes indicated in fig. 5. The case of a homogeneous mixture of two components will be considered so that only two lateral cylinders are needed. Fig. 5 consists of three diagrams, one for each separated vapour and one for the liquid mixture. It should be mentioned that from a theoretical

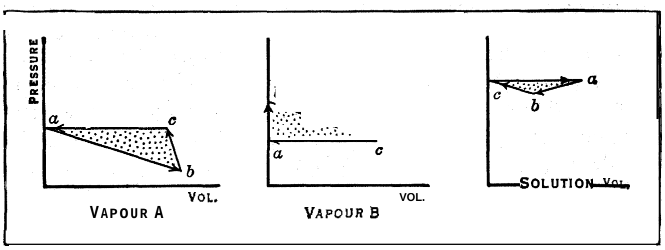

FIG. 5

point of view (thermodynamically) there is no difference between a solution and a mixture, at least, a mixture of molecular type (coarse emulsions must be excluded). Again, the operations must be isothermal and reversible. The presence of each component in the mixture lowers the vapour pressure of the other component. Throughout each change the pressure in the lateral chambers must be perpetually maintained in equilibrium with the mixture by suitably moving the pistons. The detailed changes are as follows:

i. Remove a definite fraction, say fn_1 of the molecules n_1 in the mixture. The pressure in A cylinder goes down along ab, that of B goes up—in both cases because the relative concentration of B is increased—along ab (on the B diagram). The mixture also changes along ab.

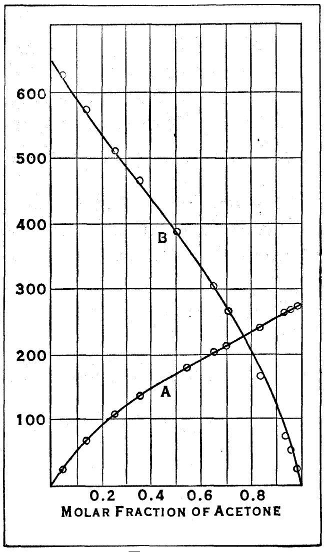

FIG. 6

ii. Remove the same *fraction* fn_2 of the molecules of B. The pressure in B goes down along bc (on B diagram) and that of A goes up along bc (on A diagram); and that of the mixture changes along bc (on the third diagram). The solution is now of the same concentration as at first and consequently the pressures at c must in each chamber be the same as at first, *i* e., as at a.

iii. Lastly return the vapours in A and B to the mixture adjusting the rates of transfer so that the concentration of the mixture remains constant. The changes in the three diagrams are in each case along ca and the original state is restored.

We will neglect the changes of volume of the solution because, for usual cases they are exceedingly small compared with the vapour changes. The total work done is the difference of the areas of the triangles on A and B; or

$$fn_1v_1\frac{\partial\pi_1}{\partial n_1}+fn_2v_2\frac{\partial\pi_2}{\partial n_1}$$

and this sum must equal zero. So far we might have considered masses instead of numbers of molecules (for,the problem has nothing essential to do with molecules). We can no put $\pi v_1=n_1RT$ and $\pi_2v_2=n_2RT$, where R is the same for both. The values of n_1 must now mean the numbers of molecules in the mixture reckoned as of the same constitution (*i.e.*, either single or double molecules, etc.) as in the vapour state; and similarly for n_2. So that

$$\frac{n_1}{\pi_1}\frac{\partial\pi_1}{\partial n_1}+\frac{n_2}{\pi_2}\frac{\partial\pi_2}{\partial n_1}=0.$$

The differential coefficients are partials, the value of n_2 being constant during the change represented. We can usefully represent the concentrations by molar fractions, that is, $\mu_1=n_1/(n_1+n_2)$ and $\mu_2=n_2/(n_1+n_2)$ so that $\mu_1+\mu_2=1$.

When this is done the equation becomes

$$\frac{\mu_1}{\pi_1}\frac{d\pi_1}{d\mu_1}+\frac{\mu_2}{\pi_1}\frac{d\pi_2}{d\mu_1}=0$$

or
$$\mu_1\frac{d}{d\mu_1}\log\pi_1=\mu_2\frac{d}{d\mu_2}\log\pi_2$$

since $d\mu_2=-d\mu_1$. The advantage of the transformation to molar fractions is that the equation has been reduced to a symmetrical form the right hand being the same function of μ_2 that the left is of μ_1. This is the Margules-Duhem equation. It is not quite exact because the vapours have been treated as ideal gases and the changes of the volume of the mixture have been neglected. For practical purposes, however, it is probably very much more accurate than experiments require. The implication of the equation is that each side of it must be the same *symmetrical* function of μ_1 and μ_2; *i.e.*, it must be of the form $f(\mu_1\mu_2)$ and this must be the *same* for both vapours. Unfortunately the law imposes no further restriction upon this function so that an endless number of cases can arise. Suitable simple values for the functions are 1, $\mu_1\mu_2$, $\mu_1^2\mu_2^2$, etc., each of which may be multiplied by an arbitrary constant and any number of terms may be taken simultaneously. For any such function the equation can be integrated and it takes the form

$$\log\frac{\pi_1}{\Pi_1}=a\log\mu_1+\beta\mu_2^2+\gamma\mu_2^2(1+3\mu_1)\ \text{etc.}$$

and $$\log\frac{\pi_2}{\Pi_2}=a\log\mu_2+\beta\mu_1^2+\gamma\mu_1^2(1+3\mu_2)\ \text{etc.}$$

where Π_1 and Π_2 are the vapour pressures of the pure components and the constants α, β, γ, etc. must be the same for both. If the first term on the right is sufficient we have

$$\frac{\pi_1}{\Pi_1}=\mu^{\alpha 1}=\left(\frac{n_1}{n_1+n_2}\right)^\alpha=\left(1-\frac{n_2}{n_1+n_2}\right)^\alpha\doteqdot 1-\frac{an_2}{n_1+n_2}$$

when n_2 is small.

This is practically Raoult's law when allowance is made for dissociation. In very many cases two terms are necessary and a is often unity. The equation then becomes

$$\log\frac{\pi_1}{\Pi_1\,\mu_1}=\beta\mu_2^2.$$

In fig. 6 the curves for a mixture of acetone and ether are given. The value of β was determined from one point on the acetone curve but it fits equally well the curve for either. The base line gives the molar % of acetone when read from left to right but it equally well gives the percentage of ether when read from right to left. The experimental points were determined by J. Sameshima (*Amer.* J. of *Sc.* XL., 1482, 1918). Examination of the equation shows that in this group of examples there is only one parameter, viz.: β. In fig. 7 the shapes of the curves are shown for different values of β, the ordinates being π/Π. Examples can be found for many values of β. For sulphuric acid and water $\beta=-0{\cdot}6$ except for dilute solutions, when a more complicated formula is necessary. Fig. 8 gives the case of gold in mercury. In this example four terms are required. If the base line is read from left to right the curve is the vapour pressure for mercury; if the base line is read from right to left the curve gives the vapour pressure (though exceedingly small) of gold in mercury. In both cases these are the values of π_1, π_2 which require to be inserted in the equations for the constant of homogeneous equilibrium. The central part of the curve, which slopes downward, is easily shown to be in an unstable region. Where the curve is horizontal (towards the right of the figure) is the concentration at which the equilibrium becomes unstable; in other words it represents the *saturation* concentration of the solution of gold. The vapour pressure of the gold should at that point be the same as that of pure gold and that is seen to be the case by examining the curve reversed. Calcium chloride in water also requires four terms; curves are shown on fig. 9 for this case at two temperatures.

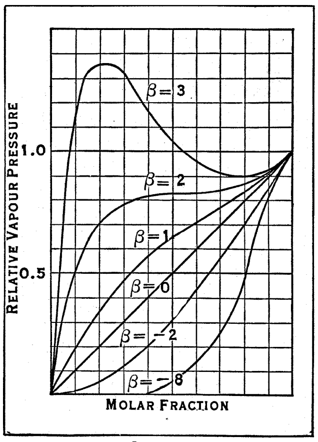

FIG. 7

Taking these cases as examples there is little likelihood of the vapour pressures required for the calculation of the equilibrium constant being determinable by any a *priori* method and resort must be made to direct experiment—at any rate for the determination of a few typical values from ahich the constants can be deduced. Further information can be found in Trans. Far. *Soc.*, 15 (1920), 24, 344, 405, 543 (1928). In the first of these papers a general form of equation is developed for three or more components.

Interfacial Effects.—In considering equilibrium the interface between any two phases was considered as being plane. It is only if it is plane that the pressure is uniform over the whole system. There is a change of pressure on crossing the boundary equal to $\sigma\left(\frac{1}{R_1}+\frac{1}{R_2}\right)$ where σ is the surface tension and R_1 and R_2 are the radii of curvature in any two mutually rectangular planes. (See SURFACE TENSION.) The pressure is greater on the concave side (as in a soap bubble.) We have seen that it increases the vapour pressure if convex outward; it increases the density also and, indeed, it may be expected to change all the properties which depend upon these. For example, the position of the triple point is shifted when either the liquid or the solid phase has curved boundaries. An equivalent change of pressure produced in any way has the same effect. As a matter of fact, the independent atmosphere of air acting in addition to the vapour pressure on ice and water shifts the triple point from .0075° C. to exactly zero. It clearly must do so because the ice water line under the pressure of one atmosphere goes through 0° C., and not .0075° C. and the triple point lies on this line. (*Phil. Mag.*, xxix. 143, 1915.)

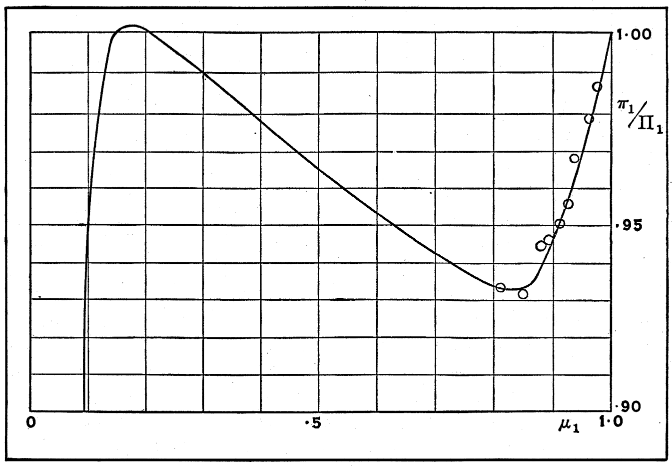

FIG. 8

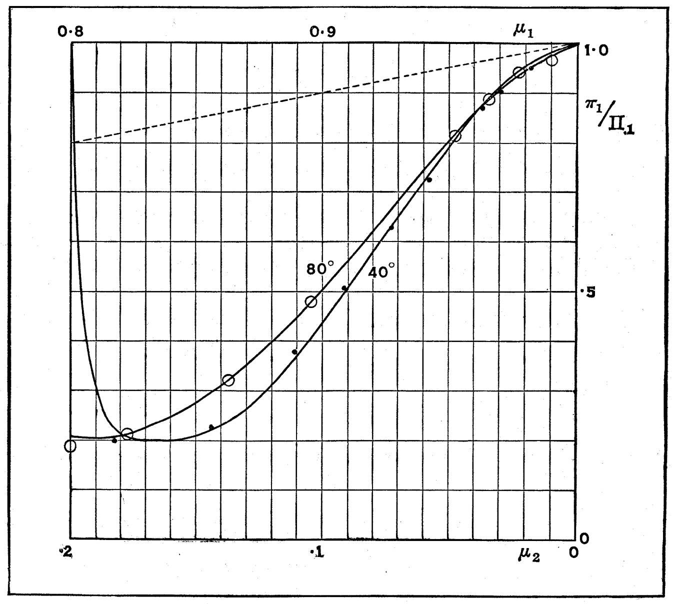

FIG. 9

There is another effect at the interface which is present even if this surface is plane. Consider a solution in equilibrium with its vapour. The presence of the solute either increases or diminishes the surface tension; for most salts it is an increase, for many organic substances such as oils, soaps, etc., it is a decrease; and the change is greater the greater the amount of the solute. Now the existence of surface tension is a demonstration of the possession by a surface lamina of more potential energy than a lamina in the body of the phase. The tendency being for the potential energy to take the lowest possible value, solute (being free to be displaced) will move toward the surface lamina or away from it according to which change will diminish the surface tension. In strictness therefore, the two phases are not delimited by mathematically sharp boundaries: there is an intervening lamina whose structure depends upon both phases and is different from that in the body of either. This subject was first studied in detail by Willard Gibbs. Following him, we replace the actual distribution of material by a uniform distribution in each phase and superimpose upon this an *extra* distribution (which may be negative) representing the excess per unit area of any component in this superficial lamina. This excess is called the surface concentration and is usually denoted by a. When a surface tension is measured experimentally it is the value as modified by the surface layer which is actually determined. One effect of this nonuniform distribution of the solute is that when the solute tends to lower the surface considerably, small traces of it added to the pure solvent are sufficient to produce very considerable lowering. In fig. 10, the curve shows the change of surface tension with the amount of soap added to the solute. An amount of soap equal to a concentration of 0.2% produces a lowering to practically the same value as for a concentrated solution and a great part of this reduction is produced by the first traces of soap that are added and go almost completely to the surface layer.

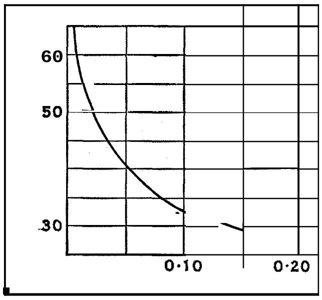

FIG. 10

Willard Gibbs investigated thermodynamically the "surface-concentration" to be expected.. External work is done not only in expansion of volume (pdv) but also in the extension of the surface area ($-\sigma dA$). Hence $dE = Td\phi - \pi dV + \sigma dA$ for reversible changes or $d(E - T\phi + \pi V) = -\phi dT + Vd\pi + \sigma dA$.

Since $E - T\phi + \pi V$ depends only upon the state

$$\left(\frac{\partial V}{\partial A}\right)_\pi = \left(\frac{\partial \sigma}{\partial \pi}\right)_A$$

Representing quantities for the liquid and vapour phases with suffixes 1 and 2 respectively, $dV_2 = \frac{RT}{a} dN_2$ is given where V is the volume of the vapour, a the vapour pressure and N_2 the number of molecules in the vapour. In the liquid let n_1 equal total number of molecules of the solute and N_1 those of the solvent in the solution. Imagine a virtual displacement from the liquid to vapour phase at constant temperature and concentration produced by an extension of the area. For unit increase of area n_1 changes by $-\frac{dn_1}{dA}$; and for the concentration to keep constant $\frac{dn_1}{n_1} = \frac{dN_1}{N_1}$ so that dN_1 molecules of solvent evaporate. But $dN_2 = -dN_1 = -\frac{N_1}{n_1} dn_1$. The change of volume dV is practically dV_2 (*i.e.*, neglecting change of volume of the liquid).

Hence $$\left(\frac{\partial V}{\partial A}\right)_\pi = -\left(\frac{RTN_1 dn_A}{n\pi dA}\right),$$

Again $$\left(\frac{\partial \sigma}{\partial \pi}\right)_A = \left(\frac{\partial \sigma}{\partial n} \cdot \frac{dn}{d\pi}\right)_A = -\frac{N_1}{\pi}\left(\frac{\partial \sigma}{\partial n}\right)_A$$

in which an approximate value of the change of π with n has been inserted. Hence finally

$$\frac{dn_A}{dA} = \Gamma = -\frac{n}{RT}\frac{d\sigma}{dn}$$

where n_A are the excess molecules of solute in unit surface layer. This is a maximum value for Γ, since more exact expressions for the vapour pressure tend to reduce it. For strong solutions of sugar the simple expression goes up to four times the more exact value; but for dilute solutions it must be very near the truth.

THERMAL EFFECTS

The thermal changes that take place in the case of dilution of solutions can be examined in a similar way to other latent heats. If we enclose a solution and the solvent on opposite sides of an osmotic membrane in an "equilibrium box" it is easy to carry out a Carnot cycle of changes for which the efficiency is $\frac{dT}{T}$.

We deduce, for the reversible latent heat of dilution corresponding to unit mass of solvent entering, the expression,

$$H_{\text{reversible}} = T\left(s\frac{dp}{dT} - u\frac{dp_0}{dT}\right) \text{ exactly.}$$

For the corresponding change of energy we must subtract the external work done, viz.: $sdp - udp_0$; whence

$$\Delta E = s\left(T\frac{dp}{dT} - p\right) - u\left(T\frac{dp_0}{dT} - p_0\right)$$

This latter must be very nearly the irreversible heat absorbed on stirring solvent into the solution instead of through an osmotic membrane; because in the stirring process, the whole being at ordinary pressure, there is very little external work done and the latent heat is practically the energy change. When p_0 is small throughout,

$$H_{\text{reversible}} \text{ is practically } Ts\frac{dP}{dT}$$

and $$\Delta E \text{ is practically } s\left(T\frac{dP}{dT} - P\right)$$

where P is the osmotic pressure. Connecting P with the vapour pressure by the usual substitution $Ps = RT \log\frac{\pi_0}{\pi_\pi}$,

$$\Delta E = T^2 s \frac{\partial}{\partial T}\left(\frac{R}{s}\log\frac{\pi_0}{\pi_\pi}\right)$$

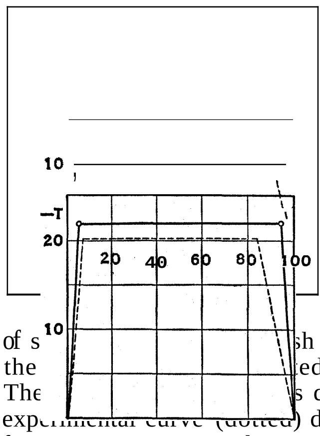
and, if s and R are independent of temperature, this becomes the same as an approximate equation given by Kirchhoff. If this irreversible heat of dilution is zero, $\log\frac{\pi_0}{\pi_\pi}$ must be independent of temperature.

This approximate law is known as von Babo's law.

Freezing Points.—When a solution is in equilibrium with the solid phase of the solvent it is at its freezing point, and must have the same vapour pressure as the solid. Different solutions in the same solvent must have the same freezing points if their vapour pressures (and therefore their osmotic pressures) are the same.

Cryohydric Points.—If, at the freezing point, the solution of one is saturated it is then at a cryohydric point. A solution of common salt is at the point at about $-22°$ C.

Freezing mixtures depend upon the fact that if salt be added to ice it will dissolve and cool the system owing to the latent heat



of s... h salt further cooling goes on until the ... ed at the final temperature reached. The ... s quantities is shown in fig. 11. The exp... (dotted) differs from the curve, calculated from an approximate theory, mainly owing to the thermal capacity of the containing vessel. It will be seen that the relative proportions of ice and salt may be varied within wide limits and the cryohydric temperature will be approached. When the material cooled by the mixture has considerable thermal capacity the greatest chance of producing the lowest temperature is when the amount of salt is about 30 per cent.

Irreversible Processes.—Owing to the universality of frictional forces every process that we can conduct is in reality irreversible. Trains require to be driven even on the level; ocean waves subside and winds cease soon after the cause producing them has ceased to be effective. The motion of the piston of an engine allows the steam to be set in motion and the kinetic energy that corresponds is ultimately transformed into molecular energy and is mainly unavailable for doing useful work. It is true that so far as a difference of temperature is set up by friction some of the temperature energy may be transferred into work but the amount is incommensurable with the loss.

The most typically irreversible process is that in which a fluid is forced through a nozzle or a porous plug. Considering the steady state of adiabatic flow only, we have (i.) an equality of the mass leaving and entering the plug, (ii.) an equality of the energy leaving and entering. The energy is in part the intrinsic energy E (per unit mass) and in part energy of motion in bulk, $\frac{1}{2}$ velocity squared (per unit mass). Further the incoming fluid does work p_1v_1 in forcing the fluid through and the outgoing fluid does work p_2v_2 in forcing out the fluid in front of it; the gain of energy on this account is $p_1v_1-p_2v_2$. Hence the total gain of energy inside the plug is

$$E_1+p_1v_1+\tfrac{1}{2}V_1^2-(E_2+p_2v_2+\tfrac{1}{2}V_2^2)$$

and in the steady adiabatic state of flow this is zero. We assume that the two positions at which the energies are reckoned are well outside the plug so that we can consider the velocity, etc., as uniformly distributed across the cross section. When the 'narrows' inside the throttle or plug are reached the velocity attains a high value and a high viscous resistance is met with so that even V_2 may be small in spite of the great difference of pressure on the two sides and further dissipation of energy takes place in the eddies that form on emergence. The result is that the fluid is much hotter on emergence than if it had expanded between the same extreme pressures reversibly and adiabatically in a cylinder. We suppose for simplicity only a small difference of pressure, etc., so that

$$d(E+pv)=-d(\tfrac{1}{2}V^2).$$

If the motion has been linear and without friction it is known from hydrodynamics that

$$d(\tfrac{1}{2}V^2)=-vdp$$

so that the equation would reduce to

$$dE+pdv=o,$$

which as we know represents the heat entry in a reversible process. To consider such a process would be equivalent, for example, to discussing the oscillation of a frictionless pendulum. Such a pendulum would go on vibrating without loss of amplitude for ever and every half period it would perfectly reverse its path. The lack of reversibility of a real pendulum is entirely due to its meeting with frictional resistance to its motion. The loss of kinetic energy on the average is represented by the extra temperature of the bob and air, together with the energy which is radiated out. This 'loss' of energy of visible motion corresponds to an increase in the internal energy of the system such as would be caused by an entry of heat from outside and it produces the same effects. Similarly in the problem of the flow of fluid if we add the frictional heat dq to the actual value of $d(\frac{1}{2}V^2)$ it may be expected by the law of conservation to give $-vdp$. Hence

$$d(E+pv)=-d(\tfrac{1}{2}V^2)=-vdp+dq$$

or

$$dE+pdv=dq.$$

Hence the actual value of the change on the left side is precisely the same as it would be if heat dq had entered *reversibly* from *outside* the system. In reality no heat has entered from outside but the frictional heat produces precisely the same effect as if it had done so. The essential difference between the two cases is that if we were to reverse the reversible system the corresponding heat would be given out; but the frictional heat is always positive in whichever sense the transformation proceeds. Since dq produces the same effects as if it had come from outside reversibly it must increase the entropy by the amount dq/T although the change is really adiabatic so far as the whole system is concerned. This can be illustrated by supposing the fluid to be an ideal gas. In such a case the increase of entropy is $C_v \log\frac{T_2}{T_1}+R\log\frac{v_2}{v_1}$. But

$$dE=C_vdT \text{ and } pv=RT;$$

hence

$$d(E+pv)=(C_v+R)\,dT.$$

Neglecting $d(\frac{1}{2}V^2)$, as we can do when the flow is slow (because it depends upon the square of V and the other changes are of the first order of small quantities), this must be zero, i.e., $dT=o$; so that no change of temperature occurs. Hence $T_2=T_1$ and $\phi_2-\phi_1=R\log\frac{v_2}{v_1}$. Further $v_2>v_1$ because $p_1>p_2$. So there is a positive increase of entropy, and its value is $R\log\frac{v_2}{v_1}=-\frac{1}{T}\int vdp$ as we inferred it to be. Since $E+pv$ (which is called the *enthalpy*) is a quantity which depends only upon the state we can calculate it for any change (adiabatic or otherwise) between the extreme states. It is most convenient to calculate it for a reversible change (which may not be adiabatic). Starting from

$$dq=dE+pdv$$

$$d(E+pv)=dq+vdp$$

$$=C_pdT-T\left(\frac{\partial v}{\partial T}\right)_p dp+vdp.$$

Hence if $E+pv$ has the same value as at first the right hand must also be zero or

$$\left(\frac{dT}{dp}\right)_{E+pv}=\frac{T(\partial v/\partial T)_p-v}{C_p}$$

The left hand side is the amount the temperature falls in the plug experiment for unit fall of pressure. It will be zero (as it is for a perfect gas) provided that

$$T\left(\frac{\partial v}{\partial T}\right)_p-v=o$$

or (by integration)

$$v=Tf(p),$$

where $f(p)$ stands for any function of the pressure. Kelvin and Joule found experimentally that at moderate pressures air and carbon dioxide cool in the process while hydrogen warms. In reality all fluids (gaseous or liquid) at certain temperatures and pressures undergo neither warming nor cooling in the prscess. At sufficiently high or sufficiently low temperatures all get hotter; in an intermediate region of temperatures they may get cooler but they fail to do so if the pressure is above a certain limit which appears to be at about 15 times the critical pressure (*Trans. Far. Soc.*, *Discussion* on the production end utilization of *cold*: President's opening remarks, 1922).

General.—The conclusions drawn from thermodynamics can be confirmed and extended by the aid of the principles generalized in mechanics which enable problems to be approached from a different aspect. The two fields of enquiry overlap. The thermodynamical way ignores the precise mechanism of the various transformations: making use of principles which are independent of the particular mechanism. This does not exclude the possibility of information being obtained in other ways which are not as independent of it and by which it may ultimately be possible to formulate with some degree of precision the nature of that mechanism. Such methods are of course less abstract in the picture with which they present us but enormous difficulties are met with in dealing even with the simpler phenomena.

It is possible to examine the movements of the hands of a watch and to detect and discuss certain regularities of their movement; but it is another matter to predict (without taking the watch to pieces) what the precise mechanism inside may be. The problems that are met with in chemical and other reactions are much more complicated than the movements of the hands of the watch. It is only very gradually that an imperfect picture is being created. Such help as is being given it by statistical mechanics is exceedingly valuable; but it is outside the scope of this article.

THERMOMETRY is the art of measuring temperature. Temperature may be defined as the thermal state of a body considered with reference to its ability to communicate heat to other bodies. Instruments used for this purpose are known as thermometers, or sometimes. when they are used to measure temperatures above a red heat, as pyrometers.

This article, treating the subject in a generally historical order, is divided into the following sections:

I. EARLY DEVELOPMENT

1. Thermometry.— Of the two commonly practised basic methods of measurement, namely, by contact and by radiation, only the first was known for more than two centuries following the invention of the faulty air thermoscope of Galileo Galilei, and the hermetically sealed Florentine thermometers first developed in the middle of the 17th century. H. L. Callendar, in the article on HEAT, states that "the type of thermometer familiar at the present time, containing a liquid hermetically sealed in a glass bulb with a fine tube attached. was first brought into general use by the grand duke Ferdinand II of Tuscany, and he is said to have possessed such instruments as early as 1654 . . . Alcohol was the liquid first employed and the degrees, intended to represent thousandths of the volume of the bulb, were marked with small beads of enamel fused on the stem. . . ."

Gabriel Daniel Fahrenheit (1686–1736), a modest German instrument maker, native of Danzig and long a resident of Holland, is said to have invented in 1714 the mercury-in-glass thermometer and the scale of temperature by which his name is daily remembered in English-speaking countries. In devising a scale for his thermometer, Fahrenheit chose as the zero the lowest temperature obtainable with a mixture of ice and common salt, and first proposed to divide the interval between this temperature and that of the limit of the heat which is found in the blood of a healthy man, into 12 divisions, subsequently increasing the number to 96, purely as an arbitrary measure of convenience. Fahrenheit had previously shown that pure water while freezing in the presence of pure ice always gave the same reading on his thermometer. and

he invented the mercury thermometer so that he could observe the constancy of the boiling point of water, a report of which he had read in the History of the Sciences issued by the Royal Academy of Paris. These two points on his thermometer (later fully recognized as fixed points) were observed at the 32nd and 212th divisions, respectively. His thermometer must have had a rather uniform bore for him to have observed 212° as the boiling point of water, but not precisely so, because the blood temperature of a healthy man was observed as 96°, and is now known to be 2° to 3° higher. The so-called Fahrenheit scale, having an interval of 180° between the freezing and boiling points of water, went rapidly into general use. and is still retained in most English-speaking countries as the most convenient? particularly for meteorological work, because of its small degrees. . R. A. F. de Réaumur, French naturalist (1683–1757), proposed in 1730 to divide the interval into 80°, and his scale is used in many countries. Anders Celsius (1701–1744), Swedish astronomer at Uppsala, is credited with first proposing to make the interval roo°. as it is on the centigrade scale.

During the century after Fahrenheit. the mercury-in-glass thermometer became an instrument of useful precision and the basis of all temperature measurements, the thermal expansion of liquids being the only recognized means for measuring temperatures. The principles of thermodynamics were not well established, nor did the knowledge of the behaviour of gases extend much beyond the information afforded by the laws of Robert Boyle (discovered independently by E. Mariotte) and J. Charles (anticipating J. L. Gay-Lussac, 1802). No material success was attained. in the experimental use of a gas thermometer, and measurements were limited to the range of the mercury thermometer graduated from −40° to 300° centigrade. The lower limit was determined by the freezing of mercury at −39.87' C. (modern value), and the upper range was roughly limited by its high vapour pressure, which reaches atmospheric pressure at approximately 357° C. (675° F.). The thermometers of that period had to be kept well below this temperature because within the thermometer in the capillary space above the mercury there was no gas under pressure, as usually found in thermometers many years later, to prevent the mercury from boiling and from distilling into the capillary. The upper limit was not affected by the softening of the glass which would probably have withstood a temperature

above 400° C.

2. Pyrometry.—In order to measure higher temperatures than these early thermometers could withstand, James Prinsep (1828), interested in alloys of gold, silver and platinum. and wanting to measure their melting points, made a large bulb of gold connected with a sensitive manometer with which to maintain the gas (air) at constant pressure within, and connected also with a reservoir of olive oil. Temperatures were measured by weighing the oil that had to be removed from the manometer, as the air expanded, in order to maintain the level constant. This could be considered the beginning of gas thermometry. Prinsep's measurements were limited in the upper range by the melting point of gold, found to be 1,063° C. near the close of the century. Others, including Sir Humphry Davy, used the Prinsep method without much improvement, until Claude Servais Mathias Pouillet (1836) made a bulb of platinum and improved the experimental procedure, which was further improved in 1847 by Henri Victor Regnault, and in the 1880s by Callendar and his associates. The high melting point (1,773° C.) of platinum extended the upper limit of measurement many hundreds of degrees. Pouillet also studied the relation between temperature and radiation from glowing solids. Thomas Johann Seebeck had discovered in 1821 that an electric current flows in a closed circuit of two dissimilar metals when the junctions of the metals are maintained at different temperatures, and Henri Becquerel had tried a platinum-palladium junction in 1830

The methods of gas thermometry continued to be improved throughout the 19th century. Regnault had shown in 1847 that the gas thermometer could afford precision in the range 0° to 100° C. He attained a precision sufficient to detect differences in the expansion coefficients of some of the more readily condensible gases. but not of hydrogen and nitrogen. which were found to expand one part in approximately 273 per ° C at 0° C. During this period the mercury thermometer remained the primary and most reliable means for measuring temperatures in practical applications.

In order to understand the trends of subsequent developments, it will be necessary to review briefly some of the scientific progress of the times. (See HEAT; THERMODYNAMICS.) Sadi Carnot, a French physicist, had described in 1824 his ideal reversible heat engine, and had endeavoured to prove on theoretical grounds that the efficiency of his ideal engine was the maximum possible and dependent only on the limits of temperature between which it works. Neither Carnot's proof nor that of many others appeared to be fully satisfactory for many years. The mechanical theory of heat, i e., the interpretation that heat is energy subject to the law of conservation, was slowly displacing the older theory that heat is an imponderable fluid uith the pouer of penetrating all substances. Quoting Callendar, "The honour of placing the mechanical theory of heat on a sound experimental basis belongs almost exclusively to [J. P.] Joule, who shoned by direct experiment that in all the most important cases in uhich heat was generated by the expenditure of mechanical work, or mechanical uork was produced at the expense of heat, there was a constant ratio of equivalence between the heat generated and the uork expended and vice versa." Joule reported his long series of brilliant experiments in a series of papers from 1840–43, and in 1848 he wrote to William Thomson (Lord Kelvin) to point out that according to his experiments, the efficiency of Carnot's engine must be proportional to $1/T$, the absolute temperature appearing in the equation $pv = \mathrm{RT}$, representing the combined laws of Charles and Boyle for the expansion of gases. This equation was known to be a good approximation for the air thermometer between 0° and 100° C if T be put equal to t(°C.) plus 273. At this time, thermodynamics was making rapid strides and the experimental work was all based on the centigrade scale as defined by the mercury thermometer and the value 273 for T-t. In 1852 Thomson gave as the expression for the efficiency of the Carnot cycle on the evidence of Joule's experiment:

$$W/Q = (t_1 - t_0)/(t_1 + 273) = (T_1 - T_0)/T_1$$

where Q is the amount of heat an engine receives and W the work

it performs. Thomson had realized that in the ideal heat engine lay a means for measuring temperature independently of the property of any substance. Four years earlier he had proposed for this purpose to write W/Q equal to a constant, but as the experimental evidence accumulated he proposed in 1854 to define the thermodynamic scale according to the above equation, thus making this equation exact, and to determine by experiment how far the scale of the gas thermometer departed from the ideal scale. With this object in mind he devised a very delicate method, knonn as the porous plug experiment (see THERMODYNAMICS), to measure the temperature change accompanying the expansion of a gas in the absence of any conversion of heat to kinetic energy. Joule and Thomson carried out a long and famous series of experiments. and finally reported in the *Philosophical* Transactions (1862) that the deviations of the air thermometer from the absolute scale as above defined are almost negligible, and that in the case of the gas hydrogen, the deviations are so small that a thermometer containing this gas may be taken for all practical purposes as agreeing exactly with the absolute scale at all ordinary temperatures.

It should be carefully noted that the above equation. defining the thermodynamic temperature scale. does not determine any numbers for temperatures, but only defines the ratio of T_0 to T_1 as equal to $1 - W/Q$. Thus any number may be selected for one fixed point, for example, the ice point. leaving the intervals between this point and all others such as the steam point subject to experimental determination; or we can select any convenient interval such as that between the ice and steam points, leaving both their values above absolute zero subject to experiment. At the time Lord Kelvin was faced with making one of the selections, Regnault had been using air thermometers in his laboratory in preference to mercury thermometers because of the capricious performance of the latter, and had been accustomed to basing his calculations on the difference between the ice and steam points. Had Kelvin suggested, and the suggestion prevailed, that a number be permanently assigned to the ice point on the thermodynamic scale, the differences of the t o scales at all other points would have had to be tabulated, and the lengthy tables revised from time to time in order to fit the results of future experiments. Kelvin chose to suggest that the ice-steam interval be fixed at 100° and this suggestion prevailed until 1954. (See below The *International* Temperature *Scale*.) The thermodynamic scale is known simply as the Kelvin scale, temperatures on it being designated °K. The symbol in equations is usually T.

3. Further Developments and Various **Inventions.**—Although the measurements of Regnault in the 1840s and '50s with his gas thermometers in the range 0° to 100° C. were in error by a few tenths of a degree according to modern data, he was probably attaining a precision of about 0.1°. and his mercury thermometers did not compare favourably with this precision, varying erratically by tenths of a degree within that range and much more at higher temperatures. Very little was known at the time about annealing glass, so it was customary to age the green or new thermometers for many weeks. during which the ice point would slowly rise by a degree or more as the strains in the glass slowly decreased. These strains would never disappear and the thermometers nould give readings at the fixed points such as ice and steam. differing by tenths of a degree, sometimes changing for months. On the other hand, it mas thought that the gas thermometer was providing measurements agreeing with the Kelvin scale to better than 0.1°. For these reasons the gas thermometers, especially the constant volume hydrogen thermometer came to be regarded as the ultimate standard for laboratory work at ordinary temperatures.

The mercury thermometer was also improved during this period by the introduction of nitrogen into the capillary bore above the mercury. Before this time the thermometers had been sealed after filling, while the bulb was kept hot enough to run the thread of mercury to the upper end of the stem. Thus when the bulb cooled, the space above the mercury contained only its vapour at a pressure corresponding to the temperature of the space. By introducing nitrogen into the bulb at some lower temperature, the pressure of the gas will increase as the mercury rises, and counteract the vapour pressure rising with increasing temperature. The use of nitrogen not only prevents the mercury in the bulb from vaporizing but also retards the vaporization into the space occupied by the nitrogen. In order to best match the varying pressure of the mercury, the proper size of the expansion chamber at the upper end is calculated according to the size of the bore. This calculation is necessary because pressures of a few hundred pounds per square inch are required at the highest temperatures at which the thermometer can be used. These gas-filled thermometers extended the useful range toward the softening temperature of the glass and in order to take full advantage of the new method of filling, harder glasses were developed; *i.e.,* glasses with higher softening temperatures. The first of these were the so-called *verre dur* of France and the type Jena 16, III, of Germany. Filling the thermometers with nitrogen spoiled them for the most precise laboratory measurements, because the varying pressures made the scale nonuniform and prevented the application of corrections, but it made them better for general and industrial applications. The useful range was raised to nearly 500° C. (932° F.), although the accuracy above 400° C. was low.

Another invention of the period was the clinical thermometer in a form much as it is currently known. This is essentially a maximum-reading thermometer, that is, designed to indicate the highest temperature to which it has been subjected after the mercury has been shaken down. It is made by collapsing a bubble blown in the stem, while the glass is soft, between the bulb and the part of the stem to be calibrated. Expert workmanship closes the bore or passage almost completely so that as the temperature falls the mercury thread breaks at the constriction, leaving all that has remained above to be observed at leisure. The bulbs of these thermometers are made small, cylindrical and thin-walled, so that they will come up to the maximum temperature as rapidly as possible. Most clinical, sometimes called medical, thermometers require three minutes or more for all the mercury to reach the body temperature. The small bulbs require that the bore also be exceptionally small, and this requirement in turn has led to the so-called lens-front stems designed to magnify the thread of mercury for easier reading. The scales of these thermometers range from about 33" to 42° C. or 92" to 108° F.

Other developments of the period were the resistance thermometer of fine platinum wire first tried by W. Siemens in 1871 without success; the pyrometric cones made of clays and other minerals for the ceramic industries, said to be used first by C. Lauth and J. H. L. Vogt in 1882 but highly developed by H. Seger and fully described by him in 1886; the thermopile consisting of a large number of closely grouped thermojunctions, devised by Francesco Rossetti in 1879, for measuring heat radiation; and many improvements in electrical measuring instruments including the moving-coil reflecting galvanometer by J. Arsène d'Arsonval in 1882. (See INSTRUMENTS, ELECTRICAL MEASURING). Attempts to estimate very high temperatures by radiation methods met slight success. Josef Stefan had suggested in 1879 that the earlier measurements by John Tyndall on the radiation from incandescent platinum could be represented by the equation $J = \sigma T^4$, and this was established as the law for total radiation (radiation of all wave lengths) by Ludwig Boltzmann in 1884, who in theory substituted radiation as the working substance in a Carnot cycle. This law has since been known as the Stefan-Boltzmann law, and has had considerable influence on theories of physics, but its use in pyrometric measurements has been limited mainly to industrial applications.

II. DEVELOPMENT OF PRECISE THERMOMETRY

1. Expansion Thermometry. — The famous researches of Callendar and his associates at the Imperial College of Science, London, and the equally well-known work of P. Chappuis at the Bureau Internationale des Poids et Mésures, Paris, began in the late 1880s and continued into the early 1900s. These were the beginnings of modern precise thermometry. Chappuis undertook the task of comparing with the highest attainable precision, the temperature scales of carefully made hard-glass mercury thermometers (not nitrogen-filled) and a constant-volume hydrogen thermometer having a platinum-iridium bulb. This work covered the range from 0° to 100° C. and was designed to aid in the establishment of standardized temperature measurements in various countries by supplying standard mercury thermometers thus calibrated. The probable accuracy of the individual degrees thus determined, *i.e.,* of the international scale of temperatures in this range, was stated by Chappuis to be 0.002°. Callendar developed a compensated constant-pressure gas thermometer with a glass or porcelain bulb and a delicate, sensitive manometer for the close maintenance of a constant pressure, and carried his measurements beyond the boiling point of sulfur. He reported with Ezer Griffiths that the sulfur point was 444.53' C. His interests led him to develop also the platinum resistance thermometer as an instrument of great precision, and to compare it with the gas thermometer up to about 550° C., and to devise the well-known Callendar formulas for expressing the relation between resistance and temperature. Applying these equations for extrapolating, he determined the melting point of silver as 961° and that of gold as 1,061° C., values in error by only 0.8° and 2°, respectively, from the values adopted in 1948 on the international temperature scale.

During the early work of Chappuis and Callendar, the platinum-rhodium thermocouple was made by Henry le Châtelier, the famous pioneer of industrial pyrometry, to combine with a high resistance galvanometer in portable form for practical purposes. At the same time C. Barus, at the U.S. geological survey in Washington, was completing a most extensive and thorough study of the thermoelectric properties of a large number of metals and alloys, finally choosing the platinum-iridium alloy to combine with platinum as a thermocouple. Barus was using a constant-pressure gas thermometer with a porcelain bulb surrounded by a rotating muffle in a gas furnace, to measure temperatures up to 1,200° C. for the purpose of calibrating his thermocouples. In the same year in which Barus published his final memoir (1892), L. Holborn and Wilhelm Wien at the Reichsanstalt in Berlin, reported their work comparing an air thermometer with the platinum-rhodium thermocouple up to about 1,300° C. Barus retired from the field in that year, but Holborn and Wien continued with a more refractory porcelain bulb which enabled them to exceed 1,400° C. a few years later. These pioneering efforts at measuring high temperatures with gas thermometers were very instructive as to methods and techniques but of little value for their numerical results.

An international committee on weights and measures passed a resolution adopted in 1887, that: "The international committee on weights and measures adopts as the standard thermometric scale for the international service of weights and measures the centigrade scale of the hydrogen thermometer; having as fixed points the temperature of melting ice (0°) and the vapour of distilled water boiling (100°) at standard atmospheric pressure, the hydrogen being taken at an initial manometric pressure of one meter of mercury — that is to say, 1,000/760 = 1.3158 times the standard atmospheric pressure."

The effect of this action and the subsequent remarkable work of Chappuis at the international bureau was felt mainly in the limited range between the ice and steam points, and here the matter stood officially for more than a quarter of a century. Chappuis had transferred the hydrogen scale to four primary standard mercurial thermometers of French hard glass made by Tonnelot, and by

The three pressure systems are designed for operating the nitrogen-filled thermometers at constant volume: (1) the main system, B,A1', (F),D,G,H,J; (2) the auxiliary system, A,C,P,M,Q, for determining the correction for the dead space, the region of large thermal gradient; and (3) the external pressure adjusting system, steel case to E to N. means of these four, many other mercury thermometers were standardized for distribution.

Precise thermometry at high temperatures may mean, for example, a precision of 0.1° at the melting point of gold (1 063° C.) as compared with 0.001° at 50° C. However, such precision at high temperatures has never been attained with gas thermometers. From 1892 to 1911 the principal contributions to high-temperature gas thermometry were by Holborn and A. L. Day at the Reichsanstalt in 1899, using a platinum bulb and nitrogen; by J. A. Harker at the National Physical laboratory of England in 1904, using a porcelain bulb and nitrogen; by A. Jaquerod and F. L. Perrot in 1905, using a silica bulb and various gases and, for the first time, an electric resistance furnace; by Holborn and S. Valentiner in 1906, using one bulb of platinum-10% iridium and another of pure iridium. both with nitrogen; by Day and J. K. Clement in 1908, using platinum alloy bulbs with nitrogen; and finally by Day and R. B. Sosrnan using the same type of bulbs of 10% iridium or 20% rhodium with nitrogen at constant volume. Day and Sosman began their work in 1904 at the U.S. geological survey where the measurements reached 1,150° C., then finished the work at the geophysical laboratory of the Carnegie institution, Washington, D.C. Here they reached the melting point of palladium reported as 1,549.2 ± 2°, determined the melting points of a series of eight metals from zinc to palladium, and transferred all their measurements to a group of platinum-10% rhodium thermocouples, for which they set up interpolation formulas. The monumental and classical work of Day and Sosman has not been duplicated and probably will not again be attempted because of the increased knowledge of other methods of measurement at high temperatures. However, for the next generation, radiation (optical) methods depended upon extrapolation from the melting points of gold and palladium, as determined by Day and Sosman.

2. Optical and Radiation Thermometry.— During these wonderful developments of gas thermometry. the laws of radiation were gradually taking form. As early as 1860. G. R. Kirchhoff had conceived the idea of the complete radiator, that is, one which has the maximum radiation possible for a given temperature, and which absorbs completely any incident radiation. This idea is experimentally realized by a hollow enclosure having a small opening. Kirchhoff's complete radiator is called a black body (*q.v.*) in physics. He had also concluded that the radiation emission coefficient of any substance is equal to its absorption coefficient, and had called attention to the simple principle that the absorption coefficient plus the reflection coefficient is equal to unity. In 1893 Wien began his studies of the laws of spectral distribution of the radiation from a black body, first reporting the displacement law, which states that the product of the wave length of maximum energy density and the absolute temperature is a constant. Later he published the results of further theoretical considerations, in which he was led to the conclusion that the radiation $J(\lambda, T)$ corresponding to any wave length λ is $J = c_1/[\lambda^5 e^{c_2/\lambda T}]$.

Wien was awarded the Nobel prize in 1911 for his work on black-body radiation. His second law was confirmed by many experimenters in the visible spectrum; but when in 1900 H. Rubens and F. Kurlbaum tested it at long wave lengths and found their results in serious disagreement with the law. Max Planck suggested that they add -1 to the denominator. This modified equation was found to fit the data, and when Planck tried to derive it, he had to assume that the energy of radiation is emitted in multiples of indivisible quanta of energy. Planck's formula remains in modern physics, although its derivation by him has been superseded by modern explanations from statistical mechanics. Planck received the Nobel prize in physics (1918), principally for his quantum theory. The Planck law was the last radiation law to appear, up to the late 1950s, which bore directly on thermometric measurements, but in the final analysis the constant c_2 in this law is best evaluated by its interrelations with many other physical constants. The Stefan-Boltzmann law has not helped precise thermometry, and the value of c_2 derived from the Stefan-Boltzmann constant, σ, is farther from the mean than is any other derived value.

E. Becquerel suggested as early as 1864 that high temperatures could be measured by the intensity of red radiation from incandescent bodies, but it was not until 1892 that the first pyrometer using the idea was invented. Le Châtelier designed a photometric instrument, one for comparing the brightnesses of two sources of light. He arranged a 45° mirror for reflecting the light from a standard source. within the beam from the source being measured. The mirror was mounted in the middle of a telescope, and the light from the standard source was matched with that from the other source by means of absorbing glasses and an iris diaphragm to reduce the brightness of the viewed source to that of the standard. in this case an oil lamp. The measuring scale was placed on the iris diaphragm. A red glass in the eyepiece limited the light to the red region and thus improved the accuracy of brightness matching, which is difficult when the two halves of a photometric field are sensibly different in colour. Preceding Wien, Le Châtelier set up empirical formulas obtained by measuring temperatures with other means to calibrate his instrument.

Others attempted to improve Le Chbtelier's pyrometer, notably Shore and again C. Fery, but none of the forms was completely successful. Perhaps the most complicated optical pyrometer to remain in use and on the market for years was that of H. Wanner (1894), who modified A. Konig's spectrophotometer for temperature measurement. Wanner retained the oil lamp as a standard of brightness but included a small carbon filament lamp as a secondary standard. Both of these pyrometers were improved somewhat by the adaptation of the standard Hefner amyl-acetate lamp. but the Wanner instrument suffered especially in that the form of the source viewed was not visible. It was made more readily portable than the former and became well known in industrial fields, being gradually displaced by the disappearing filament optical pyrometer in the Holborn-Kurlbaum (1901) form of the E. F. Morse invention. If the current through the filament of an electric lamp is slowly increased, the filament glows red at first, then orange, yellow and white. If this filament is placed in the plane of the image of an incandescent object, in a telescope or microscope, the current through the lamp can be adjusted until the filament or a part of it matches the brightness of the image. When this condition obtains, part of the filament becomes invisible against the background of the bright image, and the current required becomes a measure of the temperature of the object. Red glasses are used in the eyepiece to provide the higher accuracy of monochromatic photometry, and absorbing screens are used between the object and the filament to reduce the brightness of the image to the calibrated range of the filament.

C. W. Waidner and G. K. Burgess (1905), at the U.S. national bureau of standards (NBS), studied and reported on the optical pyrometers described above and found that only the latter, disappearing filament form gave promise of affording precision. F. Henning (1910) and C. E. Mendenhall (1911) proposed to modify this form by the substitution of a spectrometer for the red glass, and also for measurements at different wave lengths, but it was learned that this did not increase the precision and it did raise the lower limit of temperatures measurable, because of the reduced amount of light passed by the slits of the spectrometer. W. E. Forsythe (1915) showed that an effective wave length can be calculated for a proper type of red glass with just as definite results as can be obtained with the best monochromator, even when the latter has its slits so narrow that less light is transmitted. P. D. Foote, F. L. Mohler and C. O. Fairchild (1917) calculated the preferred form of spectral transmission of absorption screens to provide a perfect colour match of filament and image, and Forsythe (1915) found experimentally that sectored disks employed to reduce the illumination from the source should be placed near the image. A. G. Worthing and Forsythe (1914) constructed a laboratory form of the instrument for the special purpose of measuring the temperatures of the filaments of tungsten lamps, and found that diffraction effects at the filament of the pyrometer lamp destroyed the equality of brightness of filament and image, making it necessary to give careful attention to the limiting stops or diaphragms in the optical system. Fairchild and W. H. Hoover (1923) showed both theoretically and by experiment that the effects of diffraction can be completely eliminated by proper selection of stops and increased the precision of the instrument to a high degree, obtaining a precision of 0.2° at the melting points of gold and copper, corresponding to 0.4° at the melting point of palladium. They also studied the effects of diffraction with sharp-edged flat filaments, and Fairchild (1920) constructed tungsten pyrometer lamps with optically flat windows. These features were incorporated in the improved form of the instrument required to attain the precision noted.

While the instrument itself was being perfected: many workers in various laboratories were carrying on much experimental work needed to convert experimental data into temperature and to realize more nearly the thermodynamic scale. . Mendenhall (1911) first pointed out that the temperature scale based on the Wien-Planck law is in fact based on a single temperature and the selected value of c_2 in the equation, and that a calibration of the instrument is preferably carried out on this basis. H. E. Ives (1912), P. G. Nutting (1914), W. W. Coblentz and Emerson (1917), E. P. Hyde, Forsythe and F. E. Cady (1918), and finally K. S. Gibson and E. P. T. Tyndall (1923), in extensive and painstaking spectrophotometric tests, measured the relative luminosity function of the eyes of many observers, providing data necessary in all photometric measurements and required in the calculations of optical pyrometry. During this period also a great amount of data was accumulated on the spectral transmission (and its variation with room temperature) of the red glasses and absorption glasses used in fundamental measurements. Foote (1917), in the pyrometry symposium of the Faraday society, summarized the interrelations of the constants c_2 and σ with Planck's constant. h. A score or more of scientists from 1898 on experimentally determined values for the Stefan-Boltzmann constant, σ, among whom should be noted for their pioneer work, Kurlbaum, Féry and M. Drecq, Valentiner, W. Gerlach and Coblentz. By 1926 the value of c_2 had been fairly well established as equal to 1.432 cm. degrees, but later determinations altered this mean by a significant amount (see *The International Temperature Scale,* below).

3. Electrical Thermometry. — Precise resistance thermometry began with the work of Callendar cited above, who found that previous efforts had evidently been careless of the contamination of the fine platinum wire by the reduction of silica in the porcelain spool on which the platinum was wound. Callendar supported the wire on the edges of clean sheet mica so that the wire would be as little contaminated and strained as possible. His results were strikingly successful and he was able to improve his precision again and again over a period of many years. It was no doubt fortunate that, from the beginning of Callendar's work, the metal platinum was available in relatively high ,purity. Owing to the tremendous difficulties of using gas thermometers in experimental work. the use of the Callendar thermometer grew rapidly in all of the principal laboratories of the world, following not only the original studies of Callendar in comparing it with a gas thermometer, but also the work of Chappuis and Harker (1900), Holborn and Henning (1908–11) and Henning and W. Heuse (1921). Various forms of instruments for measuring resistance with sufficient accuracy were developed as their need appeared. Callendar first used an ordinary Wheatstone bridge with a two-lead thermometer, but soon improved the arrangement with Griffiths by including a pair of dummy leads in the parallel arm of the bridge. F. E. Smith (1912) improved this by attaching two leads to each end of the resistor and switching the connections in such manner as to eliminate the inequality of the two current leads. He also developed special forms of the Kelvin double bridge having six decades. with which measurements could be made by a single reading after three of the leads were adjusted to equality. E. F. Mueller (1916–17) designed a six-decade Wheatstone bridge arranged to avoid the errors of contact resistances and with means for determining the bridge zero and for commutation of the leads. Provisions for readily calibrating these bridges by comparison with a single standard resistor were also included in the arrangements. In order to attain a precision of 1 part in 10,000,000 or better, the resistor coils of manganin were immersed in a thermostated oil bath. Others chose to use potentiometric measurements which require the same four attached leads plus a standard resistor with its four leads.

Precise thermometry by means of thermocouples received at least a very favourable start in the investigations of Holborn and Day at the Reichsanstalt in 1900, when they compared the platinum, platinum-10% rhodium thermocouple with the gas thermometer at several good fixed points between 300° and 1,100° C. and found that a simple parabolic expression, $E = a + bt + ct^2$ would represent the relation between electromotive force (e.m.f.) and temperature within experimental error (a few tenths of a degree). Waidncr and Burgess at the bureau of standards (1909) compared a number of these rare-metal couples with platinum resistance thermometers at five fixed points from the melting point of zinc (c. 419°) to that of copper (1,083°), and indirectly confirmed the results of Holborn and Day. However, the interpolation formulas of Day and Sosman mentioned in an earlier paragraph, extended from 320° to 1.550° C., and their temperature–e.m.f. tables were standards of reference for some years. These were not only based on gas thermometer measurements, but represented concurrent researches of the highest order of thoroughness—especially as to the purity of all the metals involved—by their associate, E. T. Allen. The precision of electrical measurements attained by another associate. W. P. White, was amazing in excellence. Improved tables were published by other associates, J. Johnston (1912) and L. H. Adams (1913–14 and 1919), the latter publications including tables for copper-constantan up to 385° C., calculated from the formula, $E = a - b(1 - e^{-ct})$, wherein e is the Naperian base. The precision implied in these tables is not attainable without the precise and accurate measurement of small voltages. Quoting from Day and Sosman's *High* Temperature Gas Thermometry: "Briefly, it may be noted in passing that all the thermoelectric measurements without exception were made with . . . a potentiometer of Wolff standard construction by direct comparison mith a saturated cadmium cell. The cell first used was one of a series described in a previous paper, which has been compared from time to time with the standard cells of the national bureau of standards and has never been found to contain an error greater than one or two parts in 100.000."

Thus the art of electrical measurements per se had kept pace with the art of electrical thermometry. The development of potentiometers (potentiometer here used is not to be confused with its use by electronic engineers to mean a voltage divider) suitable for the measurement of small e.m.f.s as required in this art had extended from 1890 to 1910, the Wolff instrument mentioned incorporating the principles developed by several different writers including H. Hausrauth, W. P. White and H. Diesselhorst. It was a five-dial instrument designed to measure 0.1 microvolt with exactness, and contained no slide-wire usually found in potentiometers designed for less accurate work. The standard of reference in the use of a potentiometer is the standard of voltage made available for practical use in the standard cell, which maintains a constant voltage when it is not drained by an appreciable current.

III. DEVELOPMENT OF INDUSTRIAL THERMOMETRY

1. Introduction in Industry.—There are no records of the slow growth of mercurial thermometry from the time of its invention by Fahrenheit in 1714 to the period of Regnault in the 1840s, and few beyond that date to the end of the 19th century, but there were many makers of these thermometers in the early part of the century and their use no doubt grew with such industries as steam power and chemicals which were making good progress in the middle of the century. Mercury thermometers enclosed in metal protecting sheaths with attached scale-housings for the ruggedness required in plant or factory were to become common articles of commerce knonn simply as industrial thermometers. Thus protected they cannot give the accuracy of a bare thermometer because of the flow of heat out through the sheath; nevertheless they have proved to be indispensable in a multitude of applications. Another instrument of industrial importance was the dial thermometer. sometimes called a pressure-spring thermometer. In this instrument, a liquid or gas is enclosed in a metal bulb connected by a capillary metal tube to the pressure spring a modification of the Bourdon tube found in pressure gauges. This may take the form of a spiral or helix of a flattened metal tube which reacts to internal pressure by a slight unwinding. One end of the tube is fixed and the other end is attached to a mechanism for turning a pointer around the dial scale. The early (before 1911) forms were crude and not compensated for simple errors such as expansion of the fluid in the connecting capillary and spring. Thermocouples made of base metals had begun to compete with the Le Châtelier couple because of their lower cost and higher thermoelectric power. Iron was still considered unsuitable for a thermocouple element and many combinations of metals and alloys were tried. The most successful of these was invented by M. A. L. Marsh, who combined an alloy of nickel-2% aluminum with nickel-10% chromium. This thermocouple was found to be serviceable as high as 1,100° C.. and generated an e.m.f. four to five times as large as did the platinum alloy couple of Le Châtelier. The optical pyrometers of the Holborn-Kurlbaum and the Wanner types were in extensive use; likewise the radiation pyrometers of Féry, C. E. Foster and C. B. Thwing. A commercial form of Callendar's resistance thermometer was having considerable success. Rugged low-resistance millivoltmeters were available for use with thermocouples and radiation receivers, and the earliest forms of recording instruments were manufactured in considerable quantities. Of these the recorder developed by Callendar with its Wheatstone bridge circuit for his resistance thermometers, various recording millivoltmeters and the Leeds and Northrup recording potentiometer were outstanding examples.

2. Industrial Thermometry up to 1920.—The earliest symposium of note was that of the Faraday society held in London in 1917. It was entitled "Pyrometers and Pyrometry" and the papers and discussion indicated primary interests in the high-temperature industries such as metals, glass and ceramics. The consensus of this symposium was that the industries mentioned would profit a good deal from the proper use of pyrometers, but that the instruments must be improved both in ruggedness and accuracy, and the persons using them must learn much more about them. In thermoelectric pyrometry, it was reported that (1) base-metal thermocouples are inhomogeneous and so cannot provide the accuracy of rare-metal couples; (2) low-resistance millivoltmeters may be robust but the errors are too large, hence high-resistance meters should be used and are on the market; (3) potentiometers are not useful in industry because they are not self-indicating; (4) recorders (millivoltmeter type) are expensive, not properly designed and give too much trouble; and (5) pyrometers should be manufactured with more uniformity so that couples and meters can be interchanged. The inherent limitations and larger errors of radiation pyrometers were discussed both on scientific and practical grounds, but their unsuitability for portable use was not yet clear. No particular type was outstanding. Optical pyrometry had not reached many hands and there mas a prevalent idea that too much knowledge was necessary to make good use of it. The disappearing-filament type was competing on even terms mith the Wanner (spectrophotometric) instrument.

Just two years after this symposium in London the first of a series of very important symposia on temperature to be held in the

United States was held in Chicago (1919). This "Symposium on Pyrometry," as it was called, was more comprehensive and rather systematically covered the whole subject as a science, and applications of varied character. The symposium was the final work of a pyrometer committee of the National Research council, which committee had been formed at the suggestion of H. M. Howe, chairman of the engineering division of the council, "for the purpose of developing a pyrometric method suitable for open-hearth steel practice so that the effects of temperature in the various stages of the processes of steel making might be correlated quantitatively with the other factors influencing the production of sound steel." The symposium constituted a special series of sessions of a meeting of the American Institute of Mining and Metallurgical Engineers, which published the 59 papers in book form.

There were a number of striking conditions revealed by this symposium: (1) Some U.S. industries had advanced tremendously during the preceding few years in the application of pyrometry, but these industries were only the high-temperature ones, particularly metals and to some extent glass, ceramics and portland cement. (2) It was taken for granted that industrial pyrometry was an important technologic field. (3) Once again there was slight scientific interest in industrial thermometry — that is, thermometry below a red heat. (4) A great many engineering colleges were teaching pyrometry and probably a little thermometry. (5) Electrical thermometry had not yet seriously invaded the field of expansion thermometry at lower temperatures. (6) Automatic control (regulation) by means of electrical instruments was barely started, as on-and-off control only, and the physicists and metallurgists currently interested in pyrometry were not in touch with mechanical engineers who had developed the art of automatic throttling control of steam engines, which the latter called governing. (7) Industrial standards of accuracy had progressed slowly and were still well behind those available from the bureau of standards and other research laboratories.

The symposium showed that base-metal thermocouples had finally found established acceptance for industrial use, the combinations — copper-constantan, iron-constantan and chromel-alumel — being well known. The last named is the combination nickel-10% chromium with nickel-2% aluminum, previously mentioned, the words chrome1 and alumel being originally trade names for these two alloys. Considerable stress was directed toward the high resistance millivoltmeter, placing the low-resistance instruments in an inferior class. Of course this developement was partially the result of the growing use of industrial forms of potentiometers, particularly the recording potentiometer invented by Morris Leeds of the Leeds and Northrup Co. It was apparent that industry was becoming accustomed to the higher costs of good pyrometers, and not only the recording potentiometer but a number of good recording millivoltmeters were to be on the market for many years. About one quarter of the symposium papers were written primarily or partially around the theory and applications of the disappearing-filament optical pyrometer. A number of these were of course concerned with laboratory methods, for example, of determining the temperatures of tungsten lamp filaments and methods of standardizing. It was forcefully brought out that industry needed a mass of new data about the emissivity of nonblack bodies, in order to make the optical pyrometer fully useful in any form. Theories of radiation as applied to nonblack bodies were more fully developed to the advantage of industrial applications. Perhaps the optical pyrometer was being used beyond its properly established sphere at this time. At any rate, the limitations of both optical and radiation pyrometry were ably treated, and ample warning was issued to persons in industry by the students of the science. A new form of resistance thermometer appeared in which a fine platinum ribbon is wound on a small tube made of fused quartz, and over this is melted down an outer jacket of the same material, completely sealing in the platinum resistor and protecting it from contamination by industrial gases. This device was to meet much success even for temperatures as high as 900° C. The errors caused by strains in the embedded platinum amounted to a small fraction of a degree at moderate temperatures, other errors being due mainly to the difficulty of protecting the leads close to the resistor. Resistance thermometers made of nickel wire protected for use up to 500° C. were also described, but there seems to have been no attention to the molecular change taking place in nickel at about 325° C., which unfits this metal for such use in this range and bevond.

IV. MODERN THERMOMETRY FROM 1920

The second and third U.S. symposia on temperature, which were held in 1939 and 1954 in New York city and Washington, D.C., respectively, revealed the remarkable growth in thermometry since the first symposium. The second symposium was held under the auspices of the American Institute of Physics and the third under the joint auspices of that institute, the national bureau of standards and the office of ordnance research, U.S. army. The papers presented at these symposia were published in 1941 and 1955 under the titles *Temperature — Its Measurement and Control in Science and Industry,* vol. i and ii respectively. (Henceforth, they will be referred to as *Temperature I* and *Temperature II*). These texts treat rather exhaustively the status of modern thermometry up to 1954. *Temperature I* contains approximately 125 papers on such widely diverse scientific and technological subjects as temperature scales, precision thermometry, temperature in biology, automatic temperature regulation and recording, etc. *Temperature II* contains 24 papers with the emphasis on standards and extremely low and high temperatures. There is only one paper on industrial thermometry and none on thermocouples, optical pyrometry or thermometry in the biological sciences. Apparently the development of applied thermometry was considerably less between 1939 and 1954 than between 1919 and 1939.

1. The International Temperature Scale.—The thermodynamic temperature scale has long been recognized as the fundamental scale to which all temperatures should ultimately refer. However, experimental difficulties inherent in measuring temperature on the thermodynamic scale led the seventh General Conference on Weights and Measures, a diplomatic body representing 33 nations and having the power to adopt recommendations concerning standards of weights and measures for international use, to adopt a practical scale in 1927. This scale was intended to be as close to the thermodynamic scale as possible but more conveniently realized and reproducible. National laboratories used this scale and urged scientists and industrial workers to do the same. The scale was named the international temperature scale and the most recent revision (as of the latter 1950s) is known as the international temperature scale of 1948. The official text of this scale is contained in the *Procès-Verbaux des Séances du Comite international des Poids et Mesures,* t. xxi (1948). The following is a translation of the official text for the defining part of the scale by H. F. Stimson in the *Journal of Research of the National Bureau of Standards,* vol. 42 (1949).

1. Temperatures on the International Temperature Scale of 1948 will be designated as "°C" or "°C (Int. 1948)" and denoted by the symbol, *t*.

2. The scale is based upon a number of fixed and reproducible equilibrium temperatures (fixed points) to which numerical values are assigned, and upon specified formulas for the relations between temperature and the indications of the instruments calibrated at these fixed points.

3. The fixed points and the numerical values assigned to them are given in Table I. These values, in each case, define the equilibrium

TABLE I. — *Fundamental and Primary Fixed Points Under the Standard Pressure of 1,013,250 dynes/cm²*

	Temp. °C.
(a) Temperature of equilibrium between liquid oxygen and its vapour (oxygen point)	−182.970
(b) Temperature of equilibrium between ice and air saturated water (ice point) *fundamental fixed point*	0
(c) Temperature of equilibrium between liquid water and its vapour (steam point) *fundamental fixed point*	100
(d) Temperature of equilibrium between liquid sulfur and its vapour (sulfur point)	444.600
(e) Temperature of equilibrium between solid and liquid silver (silver point)	960.8
(f) Temperature of equilibrium between solid and liquid gold (gold point)	1063.0

temperature corresponding to a pressure of 1 standard atmosphere, defined as 1,013,250 dynes/cm². The last decimal place given for each of the values of the primary fixed points only represents the degree of reproducibility of that fixed point.

4. The means available for interpolation lead to a division of the stale into four parts.

(a) From 0° C to the freezing point of antimony the temperature, t, is defined by the formula

$$R_t = R_0(1 + At + Bt^2),$$

where R_t is the resistance, at temperature, t, of the platinum resistor between the branch points formed by the junctions of the current and potential leads of a standard resistance thermometer The constant, R_0, is the resistance at 0° C, and the constants, A and B, are to be determined from measured values of R_t at the steam and sulfur points. The platinum in a standard resistance thermometer shall be annealed, and of such purity that R_{100}/R_0 is greater than 1 3910.

(b) From the oxygen point to 0° C, the temperature, t, is defined by the iormula

$$R_t = R_0[1 + At + Bt^2 + C(t - 100)t^3]$$

where R_t, R_0, A, and B are determined in the same manner as in (a) above, and the constant, C, is calculated from the measured value of R_t at the oxygen point.

(c) From the freezing point of antimony to the gold point, the temperature, t, is defined by the formula

$$E = a + bt + ct^2$$

where E is the electromotive force of a standard thermocouple of platinum and platinum-rhodium alloy when one junction is at 0° C and the other is at the temperature, t. The constants, a, b, and c, are to he calculated irom measured values of E at the freezing point of antimony and at the silver and gold points. The antimony used in determining these constants shall be such that its freezing temperature, determined with a standard resistance thermometer, is not lower than 630.3" C. Alternatively the thermocouple may be calibrated by direct comparison with a standard resistance thermometer in a bath at any uniform temperature between 630.3° and 630.7° C.

The platinum wire of the standard thermocouple shall be annealed and of such purity that the ratio R_{100}/R_0 is greater than 1.3910. The alloy wire shall consist nominally of go percent platinum and 10 percent rhodium by weight. When one junction is at 0° C, and the other at the freezing point of antimony (630.5" C), silver, or gold, the completed thermocouple shall have electromotive forces, in microvolts, such that

$$E_{\mathrm{Au}} = 10{,}300 \pm 50\mu v$$
$$E_{\mathrm{Au}} - E_{\mathrm{Ag}} = 1185 + 0.158(E_{\mathrm{Au}} - 10{,}310) \pm 3\mu v$$
$$E_{\mathrm{Au}} - E_{\mathrm{Sb}} = 4776 + 0.631(E_{\mathrm{Au}} - 10{,}310) \pm 5\mu v$$

(d) Above the gold point the temperature, t, is defined by the formula

$$\frac{J_t}{J_{\mathrm{Au}}} = \frac{e^{\frac{c_2}{\lambda(t_{\mathrm{Au}}+T_0)}} - 1}{e^{\frac{c_2}{\lambda(t+T_0)}} - 1}$$

in which J_t and J_{Au} are the radiant energies per unit wave length interval at wave length, λ, emitted per unit time by unit area of a black body at the temperature, t, and at the gold point, t_{Au}, respectively; c_2 is 1.438 cm degrees; T_0 is the temperature of the ice point in °K; λ is a wave length of the visible spectrum; e is the base of Naperian logarithms.

Recommendations for experimentally realizing the above defined scale also are included in the official text and may be found in Stimson's translation.

Gntil 1948 the thermodynamic scale was defined on the basis of the 100-degree temperature interval between the ice and steam points. Lord Kelvin, who originally defined the scale in this manner in 1854, recommended that when a single fixed point was sufficiently well known it would be preferable to define the scale using this one point. In 1948 the ninth general conference redefined the thermodynamic scale in this way using the triple point of pure water (temperature of equilibrium between ice, liquid water and water vapour), and in 1954 the tenth general conference approved the value of 273.16° K. for this point. The zero of the thermodynamic centigrade scale was still the freezing point of water but defined to be .0100 degrees below the triple point. Since the thermodynamic scale is the fundamental temperature scale, it is of some interest to compare it with the international temperature scale of 1948. The latter scale is not defined below the boiling point of oxygen. In the temperature range from the oxygen point to the ice point, measurements by Von W. Heuse and J. Otto at the Physikalisch-Technische Reichsanstalt in 1932 and W. H. Keesom and B. G. Dammers at the University of Leiden, Netherlands, in 1935 indicated that the two scales agreed within 0.01°. A determination of the thermodynamic temperature of the oxygen point at Pennsylvania State university, University Park, in 1953 by G. W. Moessen, J. G. Aston and R. G. Ascah gave −183.00" C. (therm. cent. 1954). Intercomparison by J. A. Beattie at the Rfassachusetts Institute of Technology. Cambridge, of two nitrogen gas thermometers with platinum resistance thermometers between the ice and sulfur points indicated that the thermodynamic scale was about 0.006° lower at the steam point and 0.1° higher at the sulfur point than the international scale of 1948. A redetermination of the gold point utilizing gas thermometry was reported in 1957 by H. Moser, Otto and W. Thomas at the Physikalisch-Technische Bundesanstalt and in 1956 by J. Oishi, M. Awano and T. Mochizuki at the Tokyo Institute of Technology. The values were 1064.76° C. and 1063.69" C. respectively. The latter workers also reported a value of 961.28° C. for the silver point. Above the gold point, differences between the fundamental and practical scales can be estimated from estimates of the difference between defined and true values of t_{Au}, c_2 and T_0. The uncertainty in T_0 can be neglected compared with that of t_{Au}. From an analysis of variance of data on atomic constants J. W. DuMond and E. R. Cohen at the California Institute of Technology, Pasadena. reported in 1955 the value of 1.43888 cm. degree for c_2; and in 1957 from a similar analysis J. A. Bearden and E. H. Watts at the Johns Hopkins university, Baltimore, Md., reported 1.43886 cm. degree. If the correct value for c_2 were 1.439 and t_{Au} were 1,064° C., the thermodynamic temperature above the gold point would be about 0.07% higher than that of the international scale of 1948.

2. Gas Thermometry.—Modern industrial gas thermometry is practised to a limited extent because of the difficulty of correcting for the expansion of the gas in the connecting tube between the bulb and the pressure measuring device, such as the Bourdon tube, or pressure spring. On the other hand. scientific interest in precise gas thermometry has not lagged. It has been directed to the accumulation of more exact knowledge of the properties of real gases such as nitrogen, hydrogen and helium and the derivation of corrections to be applied to the real gas thermometer scale to convert them to the thermodynamic scale, which would be realized by an ideal gas. Gas thermometry is intimately related to many fields of physics and chemistry through the relation of the universal gas constant R (in the equation of a perfect gas, $pv = \mathrm{RT}$) to many other constants, and through the dependence of much of the exact knowledge of these other constants on the value of the ice point, T_0, on the Kelvin or thermodynamic scale. These relations have benefited the art tremendously by maintaining a scientific interest in ever seeking to improve the accuracy of measurements not only at ordinary and high temperatures but at very low temperatures approaching zero on the Kelvin scale. The knowledge of phenomena near zero depends first on the accuracy of the value selected for T_0.

General thermodynamic theory of the departures of the properties of real gases from the laws of an ideal gas lead to the result $pv = \mathrm{KT} + Bp$ for moderate pressures (one or two atmospheres). For the three commonly used thermometric gases mentioned above, the term Bp amounts to less than 0.1% of RT at 0° C. and one atmosphere. The coefficient B, called the second virial coefficient, is a function of both temperature and pressure, but because Bp is so small. B values may be determined with satisfactory accuracy by varying pv at a constant temperature and writing $B = V - RT/p$. In the language of the investigators in this field, the slopes of the pv isotherms of any gas serve in themselves to determine the departure of the gas from ideal, without the use of any other data. Some investigators set up equations for B as a function of T and use them to smooth the data. B values can also be calculated from the Joule-Thompson coefficient, μ, and the specific heat, C_p, at constant pressure. Most of the data on gas scale corrections are, however, based on the compressibility, the pv isotherms.

Work in precise gas thermometry has been carried out principally in the laboratories of the bureau of standards, the University of

Leiden, Massachusetts Institute of Technology, the University of Wisconsin, Pennsylvania State university and the Reichsanstalt. Reports are found in the publications of the institutions and especially in *Physical Review; Zeitschrift fur Physik; Annalen der Physik; Proceedings of the Section of Sciences* of the Royal Netherlands Academy of Sciences; *Philosophical Magazine; Proceedings of the American Academy of Arts and Sciences. Temperature I* and *Temperature II* contain a number of important articles in this field and extensive references.

Some of the results of this work have been mentioned already in comparing the international temperature scale with the thermodynamic centigrade scale. In addition, Moessen, in a dissertation submitted to the Pennsylvania State university in June 1955, reported a value of 20 365° ± .005° K. for the boiling point of hydrogen. In 1954 the national bureau of standards started a gas thermometer program under the direction of Stimson to determine the ratio of thermodynamic temperatures up to the silver point to that of the steam point. An accuracy of 0 01 degree appeared to be attainable. The basis for this improvement is the precision manometer described in *Temperature II*, the extremely small dead-space volume and the excellent temperature control and uniformity of temperature inherent in the design.

3. Modern Mercury-in-Glass Thermometry.— This is by far the most important division in point of numbers of thermometers used, diversity of applications and general renonn. While the mercury thermometer has lost its standing as a primary standard, having given up such a distinction to the platinum resistance thermometer, it must still be regarded in its better grades of workmanship as an instrument capable of furnishing a highly useful accuracy of indication Particularly is this true in the range from slightly above −40° to 150° C., where accuracies of near 0.01° are attainable in experienced hands. A thermometer of such a grade has its scale etched directly on the glass stem. When one considers that the thermal volume expansion of mercury is only about 180 parts per 1,000,000 per °C at room temperature, and that an accuracy of indicating an expansion of only 180 parts in 100,000,000 is attainable, the amazing performance of so simple a device can more readily be appreciated. It is the more remarkable in view of the natural instability of glass, even of the special hard glasses employed. To be sure, such an accuracy is obtained only under carefully prescribed conditions of manufacture, calibration and use First, the thermometer must have been properly annealed during its making, filled with the purest of mercury and sealed off with the correct pressure of nitrogen in the capillary space; *i.e.*, just sufficient to prevent the mercury from easily separating during rough handling. Some manufacturers age their thermometers for extended periods at as high a temperature as they can withstand after filling and sealing. This is supposedly an inferior method. Next, the calibration must proceed at a series of successively higher temperatures. must include the ice point and must be carried out with mercury in the stem extending out of the hot bath only far enough to be seen. Now, when the thermometer is used, the measurements must be made under a similar set of conditions. If a thermometer thus calibrated is heated to a higher temperature after having been, for instance, at the ice point for several days, the bulb will expand within a few minutes to the size it had at this temperature during its original calibration. If it then is cooled back to zero the bulb will not promptly contract to the corresponding volume, but will be slightly larger and will gradually shrink to its original size over several days. During this period the thermometer reads low because the bulb is larger than normal. This error is called the ice-point depression, a uell-knonn characteristic of even the best thermometers. The depression at any temperature amounts to nearly 0.01° for every 10 degrees of cooling from a higher temperature, if the observation is made within a few minutes of the attainment of the lower temperature. Thus it is apparent that a thermometer graduated in tenths of a degree per division would reveal this phenomenon of hysteresis, but that one graduated in whole degrees would not, unless each division were very large.

The thermometer described in the previous paragraph is known as a total immersion thermometer because it has been calibrated and is normally used with all of its mercury immersed except the tiny bit required to be visible outside of the hot bath. If it is necessary to use it with a considerable part of the capillary thread of mercury extending out of the bath. corrections for this length of emergent stem can be approximated.

A formula for this is: stem correction $= 0.00016n(T - t)$ where n is the number of degrees centigrade emergent from the bath. T is the temperature in °C. of the bath and t is the average temperature of the emergent stem. If the calculation is in °F. the coefficient is 5/9 as much. This correction is seldom attempted since the advent of the resistance thermometer and the practice of making many mercury thermometers calibrated for partial immersion. Partial immersion thermometers, so-called, afford relatively accurate indications only when they are used under conditions closely approximating those prevailing during their calibration. They are nevertheless the commoner form of industrial thermometer, particularly when enclosed in a protective sheath and windowed frame.

The upper limit of temperature for which these thermometers can be designed depends not only upon the softening range of the glass but also upon the high vapour pressure of mercury. The commonest glasses made expressly for thermometers permit reliable use up to about 400° C. (752° F.). Those glasses usually contain lead, and the harder borosilicate glasses raise the limit to about 500° C. (932° F.). Still harder glasses which raise the limit to about 650° C. (1,202° F.) are used to some extent. but suffer the competition of thermocouples.

High-temperature thermometers have been made of fused silica filled with the metal gallium which melts at approximately 30° C. (86" F.) and boils above 1,600° C. The lower vapour pressure of the liquid gallium at high temperatures is a real advantage, but capillary tubes of fused silica are difficult to make because of the high melting point (1,710° C.) of this oxide, and the combination has not been extensively employed. The lower limit of mercury-in-glass thermometers has been extended by alloying thallium with the mercury in a percentage close to the composition having the lowest melting point (eutectic mixture). This is at 9.3% thallium, the melting point being −59° C. (−74° F.). Such a thermometer is easier to make than the gallium-in-silica, and has been used in limited quantities, but both meet the competition of forms of thermometers described in other paragraphs.

Thermometric Lag.—Whenever a thermometer at one temperature is suddenly immersed in a fluid medium at a higher temperature, heat flows into the thermometer, raising its temperature rapidly at first and more slowly as the temperature of the medium is approached. After a sufficient lapse of time no further change of the thermometer can be detected and it is then assumed that the temperature of the medium is indicated. Also if a thermometer is immersed in a medium whose temperature is varying, the thermometer will always be at a different temperature, lower or higher than the medium depending on whether its temperature is rising or falling. It is said that the temperature of the thermometer lags that of the medium. This subject is frequently discussed in relation to mercury-in-glass thermometers, perhaps because such a thermometer, when immersed bare in a stirred bath, lags the temperature of the bath in a manner that can be expressed by a simple law, as shown by D. R. Harper in a bureau of standards bulletin (1912). This law is usually referred to as Newton's law of cooling and as applied in this case states that the rate of change of temperature of the thermometer is proportional to the difference between its temperature and that of the bath. Perhaps it is clearer to consider the thermometer as having a bulb of glass, a poor conductor of heat, full of mercury, a far better conductor, being also a liquid in which convection currents assist in the transfer. The rate of heat flow through the glass of the bulb, according to J. B. Fourier's law, is proportional to the temperature gradient. As given by Harper:

$$\frac{d\theta}{dt} = \frac{1}{\lambda}(u - \theta)$$

where u is the temperature of the bath at time t, θ is the temperature of the thermometer at the same time and λ is a constant with respect to u, 8 and t.

Considering only the case of a constant temperature of a stirred bath, the solution is:

$$(\theta - u) = (\theta_0 - u)e^{-t/\lambda}$$

where e is the base of natural (Napierian) logarithms, approximately 2.718, and θ_0 is the temperature at the start of reckoning time, (t = o). At the time $t = \lambda$, $(\theta - u) = (8, - u)/e = .37$ $(\theta_0 - u)$, that is λ is the time required for the temperature difference to be reduced to 37% of the initial difference. This value of A is called the time constant of the thermometer under the special conditions of the bath, as to substance (water, oil. etc.) and stirring. An ordinary bare laboratory thermometer has a time or lag constant of 2 to 3 seconds in a well-stirred water bath. 5 or 6 seconds in oil and about 1 minute in well-stirred air to 3 or more minutes in still air. The time required for the difference to decrease to 1% of the initial difference is 4.6λ and the time to reach 0.1% is 6.9λ. For example a bare thermometer for which A is 2 seconds, when immersed in a stirred water bath which is 10° hotter than the thermometer, will warm 6.3° in 2 seconds, 9.9° in 9.2 seconds and 9.99" in 13.8 seconds.

Harper has shown that a bare thermometer in a bath whose temperature is rising at a constant rate lags in temperature behind that of the bath by λ seconds, if the thermometer has been in the bath long enough to attain the same rate of rise.

These simple relations do not apply to thermometers in a sheath or to other cases where more than one layer of substance is found between the bath and the mercury. Nevertheless thermometers in many forms are arbitrarily characterized by assigning them an experimentally determined lag constant equal to the time required to change 63% of the initial temperature difference as described above. Occasionally this property is based on common logarithms, in which case the constant corresponds to a change of 90% (10% residual).

Liquid-in-Glass Thermometers other than mercury-filled are employed to a considerable extent for measuring temperatures below the freezing point of mercury. The (ethyl) alcohol thermometer is the best known of these, and is used to cover the range from 70° down to −80° C. Many organic liquids can be used, the special requirements being low freezing point, low viscosity, nontoxicity and ability to dissolve a dye and remain stable. Pentane thermometers are useful from 30° down to approximately −200° C., and toluene (occasionally called toluol) thermometers are useful from 150° to −80° C. These liquids, and for that matter most organic liquids, have an expansion coefficient many times larger than that of mercury, hence these so-called spirit thermometers are characterized by a large diameter of the capillary and superior visibility of the red-dyed column of liquid. The liquids are somewhat prone to separate in the column but the droplets are readily rejoined by tapping a side of the stem. Because these liquids all wet the glass, forming a deep meniscus, the top of the column is not so accurately observable as that of a mercury column. Also, during a decrease of temperature, the receding liquid leaves a thin film on the glass, which runs down slowly. While this distributed liquid is running down, the thermometer indicates too low a temperature. In spite of these disadvantages such thermometers are widely used, often in the same ranges as mercury-filled, particularly because of the ease of observing the large red column. Before sealing the top of these thermometers after filling the bulb and sufficient of the bore, the bulb is cooled with dry ice (solid CO_2) and the space above the liquid is left full of air, which materially reduces distillation into the space and separatian of the liquid column.

Fine annealing of the glass of thermometers to be filled with an organic liquid is not generally practised nor is it as essential as in the case of mercury, because of the relatively large expansion coefficient of such liquids and the consequent lesser effect of changes in the volume of the bulb. Also these thermometers are not intended to be read as closely as the mercury-filled.

4. Modern **Dial** Thermometers. — Modern dial thermometers have great industrial importance. rivaled only by mercury-in-glass, in point of numbers manufactured and used. Though there are

many types including solid, liquid, gas or liquid-vapour filled, this article will discuss only the liquid-filled The usual liquid is mercury, again because of its long range of usefulness — from −40° to someuhat above 500° C. The major portion of the mercury is contained in a strong steel (sometimes stainless) bulb to which is welded a long steel capillary tube having a bore about .01 in. in diameter. The other end of the tube is welded to a Bourdon tube, sometimes called a pressure spring, also of steel, mounted in a case and attached through a mechanism to a rotating pointer. The entire closed system of bulb, tube and flattened pressure spring which has been wound into a spiral or helix, is filled with mercury (to the exclusion of any gas or 10%-boiling liquid) under a pressure of a few hundred pounds at room temperature. Higher temperatures increase this pressure so that it is maintained well above the vapour pressure of the mercury, while not exceeding the limited strength of the pressure spring, which is highly strained as the liquid expands. With a proper connecting mechanism. the scale of such a thermometer is very nearly uniform and the instrument is a widely accepted article of commerce. In its more highly developed form the expansion of the mercury in the tube and spring is compensated so that tubes up to 250 ft. or more in length can be used without material loss of accuracy. Two forms of compensating device are employed. One consists of a duplicate capillary tube, also containing mercury, and attached to a second pressure spring which opposes the main spring, and the other consists of a wire of nickel steel threaded through the single tube. This wire is selected to have a negligible expansion (*e.g.*, invar) and the space between it and the wall of the capillary bore is adjusted to vary with temperature in correspondence with the expansion of the mercury. A bimetallic spring can be used to separately compensate for the expansion of the liquid in the pressure spring. Such thermometers, especially with the connecting tube protected uith an armour of flexible metal or rubber, successfully compete with electrical thermometers and are also made into recorders and automatic controllers of various forms. Organic liquids are occasionally substituted for mercury, but their higher expansions are offset by the primary necessity in any case of keeping the volume of the bore and spring small compared with that of the bulb. Furthermore, none of them have a range of the liquid state comparing favourably with that of mercury. One rather surprising characteristic of the mercury-filled thermometer described in this paragraph is that the bulb, filled with so heavy a liquid, can be elevated far above the pressure spring without introducing serious errors. This is because the small error results in the main only from the distortion of the stiff walls of the bulb, uhich takes place with the change of pressure as the bulb is raised. The presence of a small amount of gas or uater, for example, entrapped in the bulb would alter this favourable performance. Details on other types of dial thermometers can be obtained from H. J. Hoge's paper on "Temperature Measurement in Engineering" in *Temperature II*.

5. Electrical Thermometry.— This is a rather loose expression and here is intended to include resistance and thermoelectric instruments; that is, in the first subdivision, "a thermometer in which the resistance of a definite part, the resistor, serves as a measure of temperature," and in the second subdivision, "a thermometer whose indications depend upon the e.m.f. of a thermocouple. It ordinarily consists of a thermocouple, connecting leads, and an instrument for measuring e.m.f." A thermocouple is "a pair of dissimilar electrically conducting materials joined together at one end, in which a difference in temperature of the junctions from that of the other ends generates an e.m.f."

The resistance thermometer affords the greatest precision of all forms of temperature-measuring devices in ranges below 660° C., and in its finest constructions is widely used in scientific and industrial laboratories. On the other hand it is made in rugged and less expensive forms for use in measuring the temperatures of manufacturing processes, rotating machines, stationary structures, air and air-conditioning equipment, and a multitude of other applications where temperatures do not exceed about 150° C. (302° F.). Most industrial forms employ a resistor of nickel wire (occasionally copper or platinum wire) wound in a helix or coil and protected in a sealed metal tube. For higher temperatures platinum is used because nickel undergoes a molecular transformation between 300° and 350° C., accompanied by troublesome changes in resistance with rising and falling temperatures; also it is not available in high purity, and cannot be annealed satisfactorily after winding in the form of insulated wire. Platinum can readily be obtained with a purity better than 99.999%, and for industrial use thermometers made of such metal do not require annealing at a high temperature, to reproduce a standard resistance-temperature relation. Platinum resistance thermometers made up in strain-free form (as taught by T. S. Sligh, Beattie and C. H. Meyers) and mounted in hermetically sealed pyrex glass or quartz tubes filled with clean dry air, nitrogen or helium for small lag, display an astonishing stability of resistance even to temperatures as high as 700° C. Slow changes of resistance of a few parts per 1,000,000 can be detected, however, during long continued use, and proper corrections to a few parts in 10,000,000 are on occasion reliably applied. These thermometers have four leads usually made of gold wire, extending from the coil to the head. Short lengths (an inch or so) of platinum wire connect the gold to the resistor in order to reduce the heat conduction to the leads. A convenient value of the resistance for most purposes is 25.5 ohms such that the variation is approximately 0.1 ohm per degree centigrade.

In 1942 Hoge and F. G. Brickwedde intercompared eight platinum resistance thermometers between −183° and 445° C. Excluding one thermometer which had an unusual characteristic, the maximum deviation among the thermometers was 0.0065° between −183° and 0° C., 0.0015° between 0° and 100° C. and 0.0105° between 100° and 445° C. As a result of the availability of purer platinum and improvements in technique of measurement and design of instruments, the above differences would certainly be less with thermometers made and measured in 1957. An upper limit of the precision available can be obtained by results at the fixed points. A precision of about ±.0002° has been attained at the oxygen point, ±.0001° at the triple point, +.0002° at the steam point and ±.002° at the sulfur point. A description of the apparatus used at the national bureau of standards and National Physical laboratory in order to achieve this precision can be found in *Temperature* II. Studies conducted by E. H. McLaren at the National Research council. Ottawa, Can., on the freezing point of high-purity zinc have shown a precision ten times greater than that realized at the sulfur point. Thus, substitution of the zinc point for the sulfur point would improve even further the remarkable precision and accuracy of platinum resistance thermometers.

J. A. Hall states in *Temperature II* that "the work with resistance thermometers at high temperatures has suggested that it may be possible to extend the range of the resistance thermometer as the standard interpolation instrument up to 1,063° C., eliminating the thermocouple entirely." Since 1957 the national laboratories have been investigating this possibility. Work by J. P. Evans at the national bureau of standards has indicated that lack of stability at the higher temperatures and development of a sufficiently sensitive and precise potentiometric method of resistance measurement are two of the major problems. Changes in thermometer calibration could be very large. even at 800° C., requiring a calibration every time the thermometer is used. Extreme care in protecting the platinum from any trace of chemical contamination reduces this change. The potentiometric method of resistance measurement appears necessary because the replacement of the gold leads with platinum (in order to reach 1,063° C.) made the lead resistance comparable to that of the temperature-measuring element and varying too rapidly to be eliminated with sufficient accuracy in a bridge measurement. In spite of these difficulties, a platinum resistance thermometer will probably replace the thermocouple as a standard thermometer to the gold point improving the precision by a factor of about ten.

The expression $R_t = R_0(1 + At + Bt^2)$ for the relation between resistance and temperature for platinum. as found above in the definition of the international temperature scale gives the same set of resistance-temperature values as the original Callendar formula:

$$t = \frac{R_t - R_0}{R_{100} - R_0}(100) + \delta\left(\frac{t}{100} - 1\right)\frac{t}{100}$$

both formulas being in the first power of R_t and the first and second power of t. The first expression above requires slightly less calculation. but the Callendar equation is still used in some laboratories. The group at the Massachusetts Institute of Technology proposed the addition of the normal boiling point of mercury to the international temperature scale, because according to their own work a cubic equation is required to fit the experimental data with platinum resistance thermometers to the gas thermometer data, and this in turn requires the addition of the third fixed point above 0° C. This group adds the term in t^3 to the Callendar formula.

These formulas are empirical, set up to fit experimental data, and have no theoretical support; in fact, modern physical theories of atomic and crystalline structure and the conduction of electricity show that theoretical support will require a great deal of data not available on the conductivity of very pure metals free from strain and a tremendous amount of mathematical calculation. It is highly probable that the precise information on pure platinum will be used to support theory, rather than the reverse.

Modern methods of measuring resistance are fundamentally the same as those described above in the paragraphs on precise thermometry. The Mueller bridge has been improved in convenience by including all the accessories in one case: including a thermostat and a dry-insulation box enclosing the resistor coils of larger values. The new gold-chromium alloy described by T. B. Godfrey in *Journal* of *Research*, national bureau of standards (1939), provides a material having a coefficient so small that (according to Mueller) the resistances of the coils will not change by more than 1 or 2 parts in 1,000,000 within the ordinary range of room temperatures. Resistors of this alloy can be made of very fine wire and are especially suited for standards of reference. It is problematical that they will replace thermostated manganin in the resistance-measuring bridges. However, since an entire bridge can be rechecked with a single reference standard, this alloy will improve the reliability of measurements from many laboratories.

In 1939 at the second temperature symposium more than ten papers directly concerned with thermocouples were presented. In 1954 at the third temperature symposium not one paper on thermocouples was given. The probable reason for this is the feeling that, except possibly at temperatures above 1,500° C., very little more could be done to significantly improve thermocouples or their use. Nevertheless, thermocouples continue to be used in science and industry. They offer such advantages as simplicity, low cost, a wide range, ease of installation and small size. The major limitation is the effect on the temperature determination when any physical or chemical inhomogeneity in the thermocouple leads exists in a temperature gradient. platinum-rhodium available in the late 1950s, an accuracy of $\pm 0.1°$ was difficult to achieve. However, whenever $\pm 0.1°$ is adequate below 500° C. and $\pm 0.3°$ above 500° C., the thermocouple is an excellent temperature-measuring instrument; and of course, between 630° and 1,063° C., it is the standard thermometer on the international temperature scale.

The thermocouples in common use are limited to those made of a relatively few combinations of metals and alloys which have been found to be suitable for the purpose. The required characteristics include: (1) a thermal e.m.f. large enough to he readily measured; (2) an e.m.f. increasing continuously with rising temperature over a considerable range; (3) freedom from significant change of e.m.f. by changes of crystalline structure or other internal phenomena; (4) resistance to oxidation, corrosion or contamination; (5) homogeneity and reproducibility to fit an established standard relation between temperature and e.m.f. The combinations that have been found to meet these requirements best are: (1) platinum with platinum–10% rhodium (also 13%); (2) copper with constantan; (3) iron with constantan; and (4) chromel P with alumel. The combination of chromel P with constantan is occasionally used because of a relatively large e.m.f. Metals and alloys having high melting points such as molybdenum (2,625° C.) and tungsten (3,410°), but which are easily oxidized at a few hundred degrees, are sometimes used successfully above 2,000° C. in an atmosphere of hydrogen. The so-called rare-metal couples (no. 1 above) are useful from 0° to nearly 1,500° for extended exposures and occasionally to 1,700° or higher. Corresponding temperatures for copper-constantan are $-200°$ to 350° (max. 1,000°); for iron-constantan, $-200°$ to 750° (max. 1,000°); for chromel-alumel, $-200°$ to 1,200° (max. 1,350°). The nominal composition of constantan, which is also used in larger quantities for resistor wire, is 55% copper and 45% nickel. Chromel, identified as chromel P to distinguish it from electrical heating wire, has retained its original composition of 90% nickel with 10% chromium, but alumel is 95% nickel with aluminum, silicon and manganese added.

The platinum, platinum-rhodium thermocouple invented by Le Chatelier is noted for its stability and freedom from internal changes. It is usually used carefully protected in a refractory porcelain insulator and tube. It is most interesting to observe that the metals of which this couple is made have a purity of the highest order, spectroscopic analysis revealing scarcely the slightest trace of impurity. This cannot be said of any of the other metals employed for thermocouples although the copper generally used is so pure as to require the spectroscope to detect slight traces of iron, silicon and dissolved oxygen. While platinum of the purity found in resistance thermometer and thermocouple wire is the primary thermoelectric reference standard, the best grade of commercial copper wire makes an excellent standard which can be relied upon to a few microvolts for a 200° C. interval.

The copper-constantan thermocouple is noted for its well-established temperature-e.m.f. relation from about $-260°$ to 350° C., its low cost, and the not inconsiderable adaptability to the use of long extension leads of the same composition and relatively low resistance. Also, as compared with iron, copper oxidizes very slowly at ordinary temperatures at which iron must be protected from rusting.

The iron-constantan couple is the most widely used of any in industrial applications because it is inexpensive and has a useful range well above that of copper. The iron is selected not for its high purity but for its reproduction of established standard tables of temperature versus e.m.f. This iron has about 0.1% of impurities, principally carbon, manganese, silicon and oxygen.

The chromel-alumel couple is well known for its outstanding resistance to oxidation at high temperatures, especially in the range from 750° to 1,200° C., where it is most often used. It suffers the peculiar limitation that it must not be exposed to reducing gases because the oxides of chromium which form in an oxidizing atmosphere are not readily reducible, such that oxidized chromel exposed to hydrogen, for example, develops a conducting coating of nickel mixed with chromium oxides. The widespread employment of controlled atmospheres in heat-treating furnaces of the metals industries accentuates this limitation on the chromium alloy couple.

The relations between temperatures and e.m.f. for various thermocouples are all based entirely on experimental data, not on any general law or relation of theoretical physics. In a simple thermoelectric circuit of two metals joined into a closed loop, there are, supposedly, four sources of e.m.f., one at each junction and one in each leg of the couple where it passes through the temperature gradient. J. C. A. Peltier discovered in 1834 that when an electric current is passed through the junction of two dissimilar metals the junction is heated or cooled depending on the direction of flow. This means that an e.m.f. exists at the junction. In 1851, applying the second law of thermodynamics, W. Thomson (later Lord Kelvin) showed that if only the Peltier e.m.f. supplied the Seebeck current, the relation between temperature and e.m.f. should be linear. This was known experimentally not to be the case, so Thomson concluded that there must be another source of e.m.f. In 1854 he showed that when an electric current flows in a homogeneous conductor through a temperature gradient, a transference of heat generally takes place along the conductor depending on the relative directions of current and gradient, and the material or substance (metal). This strongly implies the existence of an e.m.f. developed along the conductor, and this is called the Thomson e.m.f. It has never been separately detected or measured in a manner generally acceptable as conclusive, although it is conceded that the existence is reasonable. Thomson's reasoning leads to the conclusion that an e.m.f. is developed along the conductor, and all experimental data show that this is independent of the form of the temperature gradient and depends only on the temperatures of the junctions. Thus it is reasonable to conclude further that in the use of a thermocouple the reality of the Thomson e.m.f. is inconsequential, since the total e.m.f. which is all that can be measured directly, is dependent only on the temperatures of the junctions. This statement does not apply to an inhomogeneous thermocouple, as was already indicated.

FIG. 5.—A SIMPLIFIED DIAGRAM OF THE ELECTRICAL CIRCUIT OF A POTENTIOMETER FOR USE WITH A THERMOCOUPLE

Analytical expressions have been set up for the platinum, platinum–10% rhodium thermocouple and the copper-constantan couple but these are applicable over limited ranges. For example, the expression $E = a + bt + ct^2$ is used in the specifications for reproducing the international temperature scale between 660° and 1,063° C. with the former couple: and L. H. Adams used the equation $E = at + b(1 - e^{ct})$ between 0° and 350° C. for the latter couple. Adams used the same form of equation with different constants for the range 0° to $-218°$ C. The expressions are primarily useful for the calculation and construction of tables for reference, from which deviation curves or tables can be constructed for particular calibrated couples. The temperature-e.m.f. tables for iron-constantan and chromel-alumel couples reveal that no expression as simple as those given above would suffice even as a rough approximation.

The calibration of thermocouples can be accomplished by many methods depending upon the accuracy desired, the range of temperature, the type of couple and the means available. It is apparent from the definition of the international temperature scale that if a couple is expected to furnish accurate measurements agreeing with this scale, it must be compared with a platinum resistance thermometer from $-190°$ to 660° C., with a platinum, platinum–10% rhodium couple from 660° to 1,063° C. and with a proper optical pyrometer above 1,063° C. The most accurate calibrations are made in a stirred liquid bath by direct comparison with a resistance thermometer from $-190°$ to about $350°$ C.. and from this temperature to $660°$ C. by testing at established freezing points of pure substances. Between $660°$ and $1{,}063°$ C. direct comparison with a standard platinum couple is preferred, and this method and direct comparison with an optical pyrometer are both used above the latter temperature, the comparison with the couple being the more convenient up to about $1{,}450°$ C. Excellent calibrations are also obtained by testing at fixed points below $350°$ C. In all cases the data should be reduced to deviations from the standard tables of temperature versus e.m.f. identified with the couple undergoing calibration. The electrical instruments (potentiometer and galvanometer) needed are determined by the thermoelectric powers of the various couples. For example, copper-constantan has an electromotive force of nearly 17 microvolts (0.000017 volt) per degree at $-190°$ C., increasing to 32 at $0°$ and 60 microvolts at $350°$. The standard platinum–10% rhodium couple gives only 5.j microvolts per degree at 00, increasing to 10 at $500°$ and to 12 at $1{,}200°$ C. Iron-constantan gives 25 microvolts at $-190°$, increasing to 52 at $0°$, 56 at $500°$ and 60 at $1{,}000°$ C. Chromel-alumel gives 40 microvolts at $0°$, increasing to 43 at $500°$, and decreasing to 36 at $1{,}200°$ C. The range of the potentiometer need not exceed 60 millivolts (0.06 volt), but an accuracy of a small fraction of one microvolt may be needed.

Modern electrical instruments for use with thermocouples can be classified as millivoltmeters and potentiometers or as precision instruments for the laboratory and industrial instruments, or as indicators, recorders and recorder-controllers. There is an intermediate class of semiprecision portable potentiometers for general use. These and the industrial potentiometers are all built around the so-called slide-wire, that is, a resistor with sliding contact, while the precision potentiometers have three or more dial switches for connecting betneen fixed resistors, after the manner of the precision bridge. The art of manufacturing potentiometers of many forms is highly developed and, in the classes for industrial applications, has been making extensive use of photoelectric and electronic devices for rapid recording and better controlling. The developments from many other arts have been incorporated, particularly from electronics, also small motors, mass production of small parts and the vast array of new materials of construction, the light alloys and stainless steels. the synthetic molding materials and other plastics for insulation. In a few directions, practice has become standardized to some extent. Industrial instruments are provided with automatic reference-junction compensation, employing the bimetallic spring in millivoltmeters, and the Wunsch branch circuit aith its nickel or copper compensating resistor in potentiometers. Laboratory instruments are more often designed for immersion of the reference junctions in an ice bath, because of the greater accuracy intended. Recording potentiometers almost completely removed recording millivoltmeters from the industrial scene. Industrial instruments had obtained extraordinary precision considering the severe requirements for ruggedness and reliability. Industrial recording to $1°$ F. was not uncommon, and automatic control of some processes to $\frac{1}{4}°$ or even $0.1°$ had been attained.

6. Modern Optical Pyrometry consists for the most part of that of the disappearing-filament pyrometer, because this has been found to afford the greatest precision and accuracy for research work and in addition the greatest convenience for practical applications. The form of the precision instrument found at the national bureau of standards remains that developed by Fairchild and Hoover, and duplicates or similar instruments are found in many other laboratories including some of the national laboratories. The principal commercial form is that made by the Leeds and Northrup company in the United States, the optics of this instrument being similar to that of the laboratory type. It is equipped, however, as a portable instrument. with a unique type of slide-wire potentiometer, designed for rapid use. The specially constructed lamps used in these instruments are highly evacuated so that the tungsten filament of wire or ribbon form will withstand heating to $1{,}500°$ C. for hundreds of hours without serious change. While gas filling would reduce the rate of evaporation of tungsten from the surface of the filament, it would render the lamp subject to changes in ambient temperature, and introduce great lag in its response to adjustments in the heating current. Fairly high temperatures can be measured without heating the lamp much above $1{,}400°$ C. by the use of properly selected absorption screens, under which circumstance the lamp will retain its original calibration remarkably well for many years.

Such pyrometers, which are extensively used, are calibrated at the national laboratories, either by comparison with the standard instrument or by sighting them on large tungsten-strip lamps which have been calibrated for the particular purpose at the national laboratory. Primary calibrations at the gold point are made by sighting the pyrometer at a black body immersed in highly pure freezing gold. Calibrations below or above the gold point are made by sighting at a convenient source (this need not be a black body) with a calibrated screen interposed. This screen may be either a sectored rotating disk, whose open sector has been mechanically measured on a circular dividing engine, or an absorbing coloured glass whose transmission has been measured by comparison nith a sectored disk or with the interval between two fixed points. Primary calibrations above the gold point are of course all based upon this one point ($1{,}063°$ C.) and the constant c_2 in the Planck equation. A complete table of temperature-current values is tediously built up by smoothing the deviations from a reference table or curve based on an equation such as $i(\text{current}) = a + bt + ct^2 + dt^3$, the four constants of which are determined from four selected calibration points. The interval from the copper point to the palladium point is so large that it is preferable to establish at least two points in between by the use of sectored disks or absorption screens to step down from the upper point. The most accurate measurements above the gold point are obtained by keeping the pyrometer lamp at a current value nearly corresponding with that determined for the gold point, and choosing an absorption device to nearly fit the extrapolation desired, for example, from gold to the platinum point ($1{,}773.5°$ C.). However, for much higher temperatures the pyrometer lamp has to be raised toward the palladium point in order to make use of screens of accurately measurable transmission.

The equations employed in the calculations of temperatures measured with absorption screens or sector disks are derived from Planck's law:

$$J(\lambda,\theta) = c_1\lambda^{-5}/e^{\frac{c_2}{\lambda\theta}} - 1$$

where λ denotes the wave length in cm., θ the absolute temperature of a black body, $J(\lambda,\theta)$ the intensity in the wave band $\lambda - d\lambda$, c_2 a constant $= 1.438$ cm. degrees and c_1 a constant the value of which has no significance in pyrometry since it disappears in working equations. The primary working equation is found as follows. If J_1 is the intensity of radiation at θ_1, J_2 that at θ_2 and R is the ratio of J_2 to J_1, then

$$R = \frac{e^{\frac{c_2}{\lambda\theta_1}} - 1}{e^{\frac{c_2}{\lambda\theta_2}} - 1}$$

The wave length λ in the last equation is usually written λ_e to signify the mean effective wave length for the interval θ_1 to θ_2, taking into account the transmission of the red glass filter and the luminosity function of the observer's eye. When observing a non-black body, the wave length to which the brightness temperature corresponds is the mean effective wave length for the interval between the brightness temperature and the colour temperature of the source. Details of calculating mean effective wave lengths can be obtained from Forsythe's paper in *Temperature* I. Laboratory pyrometers of the Fairchild type can be calibrated with an accuracy (with respect to the international temperature scale) of about $\frac{1}{2}°$ C. at the gold point and about $3°$ C. at $2{,}300°$ C. High temperatures are readily measured with the disappearing-filament pyrometer without overheating the pyrometer lamp simply by using tno absorbing screens or one combined with a sector disk. For brightness temperatures up to about $2{,}500°$ C. tungsten strip lamps can be calibrated and used as transfer standards with an accuracy from about $\pm 3°$ at the gold point to $10°$ at $2{,}500°$ C. An interesting fixed point for high-temperature work is that of the positive crater of the carbon arc. Using a properly operated electric arc and a positive electrode of purest carbon, the apparent temperature, usually called brightness temperature, is 3,820° K.; readings can be repeated to a few degrees. The uncertainty in this value is of the order of 15°. (See *Temperature* **I**, p. 1148)

In the practical application of the above optical pyrometer. in many cases black-body conditions are not met and cannot be achieved. Here corrections can be made for the emissivity of the incandescent object, such as a stream or crucible of molten metal, a tungsten filament of an electric lamp, or the hot cathode of an electronic tube. Many values are known and published, one extensive list being furnished by A. G. Worthing in an authoritative article which includes a thorough discussion of the theories of emission (see *Temperature* **I**, p. 1164).

Some success was attained by the late 1950s in the employment of photoelectric devices to take the place of the optical pyrometer. **A** photoelectric pyrometer was being developed by C. P. Johnson, Jr., at the national bureau of standards ahich used a photomultiplier tube as a detector, a multilayer interference filter to restrict the spectral band and a block of optical glass which, when rotated, makes possible the comparison of the pyrometer lamp and unknown source by alternately projecting them on the detector. The instrument appeared to have sufficient signal to noise to improve pyrometer measurements above the gold point by at least a factor of 10. In addition, it afforded a potential means for automatic recording and making brightness measurements of sources having a short time duration.

Many different forms of so-called colour pyrometers have been invented from time to time. In these intriguing instruments the intensities of radiation of two bands of wave lengths are compared and interpreted by calibration, as corresponding to some temperature. Some designs have been highly commendatory for their simplicity, but by the late 1950s none had met marked acceptance.

7. Modern Radiation **Pyrometry.**—This is pyrometry in which heat radiation of all wave lengths is used as a measure of temperature, is generally confined to the field of industrial applications and is seldom employed in research work. Relatively useful designs have been perfected for the ceramic and steel industries but they lack the amazing precision of the optical pyrometer, and are generally set up to remain in a fixed position where they can be checked with an optical instrument and ***in situ*** corrections be determined. These pyrometers are constructed of a receiver of heat radiation consisting of a thermocouple junction or small group of junctions, mounted in a housing which can be water-cooled if necessary, and in which reference junctions of the couples are so disposed as to give the least errors from variations in the temperature of the whole receiver. Such instruments are especially valuable in those applications where recorded temperatures are essential, and where immersed thermocouples cannot withstand the heat. or corrosive vapours of gases. The practice of attaching the receiver of these instruments to the open end of a tube nhich is closed at the other end and inserted into a furnace has promoted the successful application of these instruments because it not only protects the receiver from flame and smoke but also permits sighting it through an atmosphere free from carbon dioxide and water vapour, gases which are not transparent to infrared radiation. The thermal lag that is introduced by the thick-walled tube is not a deterrent to this practice where the lag of the furnace itself is large.

Attempts to design a radiation pyrometer in which the radiation from a standard source is compared with that from the source to be measured had not been notably successful. Victory in this direction would solve the major difficulty of radiation pyrometry in which the total radiation received must always give the same response of the receiver, which means in turn that the heat lost from the receiver with a particular value of the incident radiation must always be the same. An attempt to improve the characteristics of practical radiation pyrometers is that of T. R. Harrison and W. H. Wannamaker, who described their analysis of the problem and its solution in Temperature **I**.

8. Flame Thermometry. — The measurement of temperatures in flames or hot gases, particularly above 1,500° K., requires equipment or techniques somewhat different from those already considered in this article. Thermocouples or resistance thermometers are generally not used in flames above 1,500° K. because of serious problems concerning radiation losses, disturbance of the combustion process. mechanical rigidity of the thermometer, and of course, at sufficiently high temperatures. melting of the thermometer itself. An optical pyrometcr or two-colour pyrometer can sometimes be used, but usually the emissivity is unknown or changing rapidly with wave length, producing large uncertainties in their application. Temperature **I** and *Temperature II* contain papers by B. Lewis and G. von Elbe, G. H. Dieke and H. P. Broida describing various methods of measuring flame temperatures and giving excellent bibliographies on the subject. This article will limit itself to two of the more widely used methods, the line reversal and intensity distribution in spectral lines.

In the line reversal method. the brightness of a source of radiation, such as a tungsten strip lamp, is adjusted until at a wave length corresponding to some spectrum line in the flame, the source appears equally bright when viewed directly or through the flame. The flame temperature is the temperature of a black body having this brightness; *i.e.*, the brightness temperature of the source at the same wave length. This method is based on Kirchhoff's law, which states that the fractional amount of radiation absorbed by a body is equal to the fraction it emits relative to a black body at the same temperature. Thus when the black body and the flame are at the same temperature, the amount of radiation absorbed by the flame is just equal to that which it emits and the black body appears equally bright when viewed directly or through the flame. Usually a spectrograph or a monochromator equipped with a suitable detector such as a photomultiplier is used to isolate and measure the radiation at the spectrum line. An element not found in the flame may be added in order to obtain a strong spectrum line in a convenient spectral region. Sodium, which emits strong yellow lines at 5.890 Å and 5,896 Å, has been used frequently. It is possible to obtain reversal temperatures at 2,500° K. that are reproducible to a few degrees. However, it is very questionable that the temperature measurement is this accurate. Great care must be taken with the optical path, the solid angles subtended and corrections for optical elements utilized with the tungsten source only. In addition, the brightness temperature of the tungsten source will be uncertain by at least 7° at 2,500° K. and greater at higher temperatures. Nevertheless, the reversal method is probably more reproducible than any other method known in 1957 for measuring flame temperatures; and in many cases: the measured temperature agrees reasonably well with that which can be calculated from known equilibrium concentrations.

The second method to be considered in this article for determining flame temperatures is based on measurements of the relative amount of energy emitted by a source per unit time (relative intensity) in two or more spectral lines. According to quantum theory (see PHYSICS: GENERAL SURVEY; QUANTUM MECHANICS) an atom or molecule can have only certain definite energies which are referred to as energy levels. An atom possessing an "excess" amount of energy (for example an atom in a flame) can lose this energy by making a transition to a lower energy level. There is a definite probability that this lost energy will appear in the form of radiation. This radiation will have a particular wave length (spectral line) which is inversely proportional to the lost energy. For a source containing many atoms, the intensity of a spectral line is the product of the energy from one transition, the number of atoms in the initial energy level and the probability of the transition. The relative number of atoms in two or more known energy levels for a system in thermal equilibrium depends only on the temperature; and therefore the temperature can be calculated if the relative number of atoms is known. Thus if the energy levels and the relative transition probabilities can be calculated or determined in an independent experiment, the relative intensity of two or more spectral lines emitted by a source in thermal equilibrium can be used to obtain the temperature of the source. Spectroscopists have determined many energy levels for a great number of atoms and molecules. Unfortunately, as of the late 1950s only a few relative transition probabilities had been determined experimentally or could be calculated accurately. This has been one of the major limitations of this method of measuring flame temperatures. It has the advantage over the reversal method in that another source is not viewed through the flame, thereby making the optical setup less critical.

9. Thermometry Below the Oxygen Point. — This field was still in a state of flux in the late 1950s. The international temperature scale was not defined below the boiling point of oxygen. None of the thermometers available for low temperature measurements had all the desirable characteristics of a practical standard—sensitivity, reproducibility, convenience and a simple interpolation equation. The thermometers widely used below 90° K. will be described with particular emphasis on their virtues and foibles.

From 90° to 20° K.. the platinum resistance thermometer is still the most precise thermometer available. Below 50° K. its sensitivity begins to decrease rapidly but at 17° K. it still has sufficient sensitivity to determine differences of 0.001° or less. At 11° K. the sensitivity has decreased further by a factor of about 4 relative to that at 17° K. The major limitation of using the platinum resistance thermometer below the oxygen point is that no simple mathematical relationship has been found between temperature and resistance. It has been suggested that an empirical table be substituted for the interpolation equation. The table could be adjusted for each thermometer utilizing the calibration data at several fixed points. The national laboratories are investigating this possibility.

The national bureau of standards calibrated (in 1957) platinum resistance thermometers down to 11° K. The calibration is performed by comparison with a set of six platinum resistance thermometers which were calibrated by Hoge and Brickwedde in 1939 using a helium gas thermometer. They claimed an accuracy of $\pm$0.02°. Xloessen. Xston and Ascah at Pennsylvania State university completed in 1955 a similar calibration of .resistance thermometers estimated to agree with the thermodynamic scale within $\pm$0.005°. They compared their new scale with the NBS scale of 1939 by including one of Hoge's and Brickwedde's thermometers. The agreement was well within the $\pm$0.02-degree accuracy claimed.

When considerably less precision than that available with a platinum resistance thermometer is required, a copper-constantan thermocouple can be used down to about 15° K. Another thermometer that often is useful in this region is the saturation vapour pressure of hydrogen. The vapour pressure-temperature relationship has been determined from the critical point, 33° K., where the pressure is about 9,700 mm. Hg, to the triple point, 13.8° K., where the pressure is about 53 mm. Hg. The use of the hydrogen saturation vapour pressure as a thermometer is somewhat complicated. however, by the para-ortho conversion phenomena.

Below 11° K. platinum resistance thermometers are of little value because of their small sensitivity. However, resistance thermometers made of semiconducting materials have ample sensitivity by virtue of their negative temperature coefficient; *i.e.*, the resistance increases with a decrease in temperature. By 1957 the major limitation of the semiconducting thermometers was their lack of stability. However, S. A. Friedberg at the Carnegie Institute of Technology, Pittsburgh, Pa.. has investigated germanium alloy thermometers containing extremely small amounts of indium and found them to be reproducible to 0.001° between 1° and 5° K., even after repeated warming and cooling.

Commercial carbon resistors; though not strictly semiconductors, also have negative temperature coefficients and have proved very promising between 20° and 1° K. J. R. Clement and E. H. Quinnell of the Naval Research laboratory. Washington. D.C.. found resistors that had a reproducibility of better than $\pm$.1% in the above range. Moreover, they found a convenient scheme for relating resistance to temperature. They used the equation

$$\left[\frac{\log R}{T}\right]^{\frac{1}{2}} = a + b \log R$$

where b is a constant and *a* is allowed to vary, being determined from a smoothed curve of *a* versus R constructed from actual calibration data. If these results are readily confirmed by other laboratories, the carbon resistor could well be considered as a standard thermometer between about 15° and 5° K.

Since in most low-temperature experiments, the basic cooling is produced by a bath of liquid helium. the saturation vapour pressure of helium is a convenient thermometer. Its useful range extends from the critical point (5.2° K. and 1,718 mm. Hg) to the lowest pressure conveniently measured (0.1 mm. Hg and 1° K.). The relationship between the vapour pressure of helium and its temperature has been the source of many investigations since the original measurements of Kammerlingh-Onnes at the University of Leiden in 1911. In 1948 an informal international agreement was reached establishing a tentative vapour-pressure scale. By 1955, however, measurements with various thermometers (gas, carbon resistor, magnetic) showed that this scale was in error by as much as 0.012° at 2.2° K. and 0.007° at 3.6" K. Analyzing all the thermometer measurements available in 1955, Clement, Logan and Gaffney derived a new scale by making a best fit to all the data. H. Van Dijk and M. Durieux at Leiden also derived a scale but in a different manner. They used a theoretical vapour-pressure equation and incorporated in this all the empirical thermodynamic and P-V-T data available for helium. The two scales became known as the 55E and L55 scales respectively. Between 1° and 5° K. these two scales agree within about 0.003°. Experimental attempts to decide between them were not successful due to the small differences and contemporary techniques of vapour-pressure measurement. Thus, for many practical purposes the two scales are identical, and thermometry between 1° and 5° K. is in reasonably good shape. However, it must be emphasized that accurate vapour-pressure measurements in this temperature range. particularly above 2.2° K. where thermal conductivity of the liquid is small, are extremely difficult, and highly developed techniques must be utilized. For details, *see* a publication by E. Ambler and R. P. Hudson in *Journal of Research,* NBS, vol. 56 (1956).

Below 1° K. it is extremely difficult to make precise temperature measurements. One of the chief reasons for this is the difficulty in establishing thermal equilibrium. The magnetic thermometer is one of the few thermometers that can be used. It is based on the fact that the magnetic susceptibility of a paramagnetic salt is a function of temperature. Therefore, if such a salt is placed in the magnetic field of an inductor, the inductance which depends on the susceptibility of the salt can be used as a temperature indicator. Often at temperatures below 1° K.. paramagnetic salts themselves are being investigated. Thus the unusual but convenient situation is encountered where the material under study, the coolant, cold bath and thermometer are one and the same. Another feature of the magnetic thermometer is that it is in the class of absolute instruments such as the gas thermometer. With proper corrections, it can be used to determine the ratio of thermodynamic temperatures, but the precision is not very great.

10. Special Methods and **Devices** for the measurement of temperatures are legion, but few remained in use after their faults were discovered. It has not been possible in this article to cover these or even all the thermometric methods still in existence. The interested individual should consult the references cited in the text and the bibliography. Where the measurement oi temperature is incidental to the primary purpose of measuring something else, reference should be made to the major topic. Also, reference may be made to many of the sciences in which temperature is particularly significant, such as meteorology, biology, geophysics and astronomy, heating and power, refrigeration, ceramic and metals industries and the thermal processes of the food, oil and chemical industries. *See* also HEAT; THERMODYNAMICS.

THERMOPYLAE, a Greek pass leading from Locris into Thessaly between Mt. Oeta and the Maliac gulf; chiefly famous for the heroic defense by the Spartan king, Leonidas, with 300 soldiers against the Persian army of Xerxes advancing upon Greece in 480. (See LEONIDAS.) Two other battles here are famous. In 279 B.C. Brennus and the Gauls were checked for several months by a Greek army under the Athenian Calippus; and in 191 Antiochus of Syria vainly attempted to hold the pass against the Romans under M. Acilius Glabrio. In the time of Leonidas the pass was a narrow track (probably about 14 yd. wide) under the cliff. In modern times the deposits of the Spercheius have widened it to a breadth of $1\frac{1}{2}$ to 3 mi. The hot springs from which the pass derived its name still exist close to the foot of the hill. There is one large spring used as a bath and four smaller ones, and the water, which is of a bluish-green colour and contains lime. salt. carbonic acid and sulfur. is said to produce good effects in scrofula, sciatica and rheumatism.

THERMOSTAT. A device to regulate automatically the supply of heat to, and consequently to control the temperature of, the air in a space, or of liquids or materials involved in a process.

Basically the thermostat consists of two elements, a sensing element, and an actuating or control element. The sensing element is sensitive to temperature changes that produce proportional changes in its physical dimensions, volume or electrical resistance. The actuating element translates the action of the sensing element to a proportional movement of the controlling air damper, valve or electric switch.

The principle of thermal expansion of metals, liquids and gases with temperature increase is the basis of the sensing element design for all thermostats except the electronic instrument. The range of temperature change during which the linear expansion bears a constant ratio to the temperature change is limited to approximately 250° F. The following table lists the coefficients of lineal expansion for the metals commonly used for thermostatic sensing elements.

Linear Coefficients of Thermal Expansion per Degree Fahrenheit

Metal	Coefficient
Aluminum	0.0000123
Brass	0.0000106
Graphite	0.0000044
Copper	0.0000093
Quartz	0.0000003
Wrought iron	0.0000063
Invar steel	0.0000005
Silver	0.0000105

Sensing Elements.— Four types of sensing element are commonly used in commercially produced thermostats. The bi-metal strip consists of two strips of metal having widely different linear coefficients of thermal expansion (see table). These strips are fused together and as the temperature increases, the strip bends away from the side having the greater coefficient of linear expansion. In application, one end of the strip is anchored, leaving the other end free to move. The strip may be straight, bent to a radius perpendicular to the long axis of the strip into a U shape or a helical shape, or it may be wound in a spiral whose axis is parallel to the long axis. Selection of shape is governed by the magnitude of movement desired at the free end of the strip. In some types of thermostats the bi-metal sensing element produces enough force to actuate the control directly.

The tube and rod sensing element also is designed to take advantage of the difference in the linear thermal expansion of two metals. It is composed of a tube of metal that has a high coefficient of expansion and a rod of metal that has a low coefficient of expansion. The rod is inserted into the tube and anchored at its closed end. The open end of the tube is anchored and as the length of the tube changes with a change in temperature there is a relative movement of the free end of the rod, the length of which has remained unchanged.

The bellows type of sensing element consists of a volume confined by a diaphragm of cup-shaped, very light metal, or a cylindrical vessel with a corrugated wall spun out of light weight metal. The volume is completely filled with a liquid, a vapour or a gas. In any case, an increase in temperature results in an increase in volume and an increase in axial length of the vessel.

The remote bulb type of sensing element is actually an adaption of the bellows type. It consists of a bulb attached to the diaphragm, or bellows, by a capillary tube of any desired length, all of which is completely filled with liquid, vapour or gas. The bulb is placed in the region to be controlled and any change in pressure due to a temperature change at the bulb is transferred through the capillary tube to the bellows.

The electronic sensing element consists of a small coil of wire whose resistance changes in a constant ratio with temperature changes.

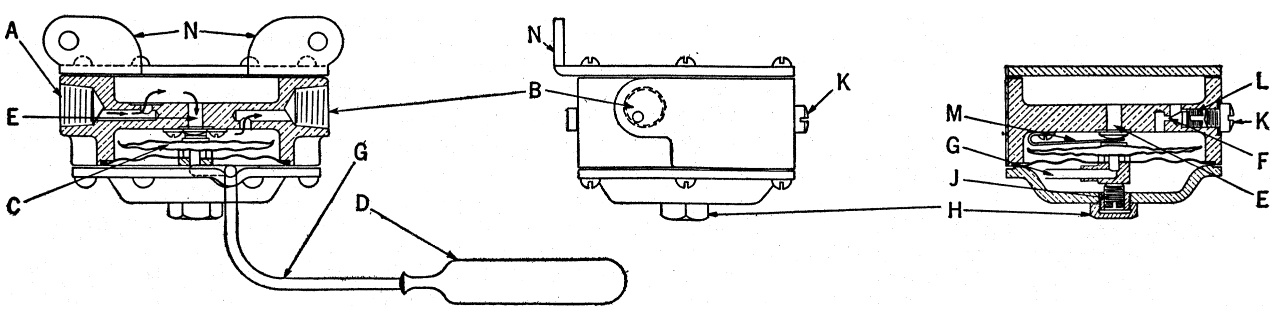
Actuating or Control Elements.— In some types of thermostats using a bi-metal sensing element, the sensing element itself functions as the control element and operates directly an air damper or valve. In other types, the sensing element acts as a pilot to the control element that regulates a supply of external energy in the form of pneumatic energy or electrical energy necessary to operate the air dampers, valves or switches.

The type of control element selected depends upon the type of action. To start or stop a burner or fan, to open or close a damper. a two-position control element is used that simply makes or breaks an electric circuit. The so-called floating control is similar to the two-position control element except that there is a neutral zone midway between the two contacts and that the action is at a constant rate toward either of the on or off positions. When the neutral zone is reached, the action stops until the sensing element makes one contact or the other at which time the action is resumed in the proper direction.

The modulating or proportional control element is piloted by the sensing element pushing a sliding contact over a potentiometer coil that controls the position of a reversible valve or damper motor, there being a motor position for each turn of wire on the potentiometer coil.

The pneumatic powered control element action controls the compressed air pressure in pneumatic air motors attached to dampers and valves. The air pressure causes movement in one direction only and a spring powers the return stroke. The position of the motor is fixed by the air pressure in the control line that is regulated by the control element. The pneumatic thermostats have modulating action that also satisfies a two position requirement.

Types of Thermostats.— There are five classified types of thermostats. (1) The room thermostat is mounted in the room that is to be controlled. It may have a sensing element of either



THERMOSTAT IN WHICH EXPANDING MEDIUM IS VOLATILE FLUID

(A) From gas supply line; (B) Gas to burner; (C) Diaphragm; (D) Bulb; (E) Main valve; (F) By-pass valve (needle type); (G) Capillary, connecting bulb to diaphragm; (H) Hexagonal cap screw; (J) Adjusting screw for lower or higher temperature; (K) Sealing cap sorew; (L) Adjusting sorew for by-pass valve; (M) Spring for opening main valve; (N) Mounting bracket

the bi-metal, bellows or electronic type, and its control element may be powered by electric or pneumatic energy. (2) An insertion thermostat is mounted on a duct with the control element in the room and the sensing element in the duct. (3) The immersion thermostat is used for the control of high pressure fluids or gases. A pressure tight bushing permits the sensing element to be immersed in the fluid and the control element to be accessible. Immersion and insertion thermostats use the bi-metal control element, either the spiral wound or the tube and rod type. The self contained direct acting tube and rod thermostat is often used to control the water temperature in gas fired water heaters. The rod is linked directly to the gas valve operating mechanism. (4) The surface type thermostat has its sensing element clamped to the surface of a tank or pipe and is an expedient substitute for an insertion or immersion thermostat. (5) The remote bulb thermostat is applied when it is desired to have the control element located at a distance from the sensing element.

Action of Thermostats in the Control of Residential Heating.—The action starts with the room thermostat, usually located in the living room. The secondary circuit is normally open and closes the circuit on a falling temperature, causes the relay to close and energize the primary (line voltage) circuit that starts the burner. When the temperature at the room thermostat rises to the desired degree at which it has been set, the secondary circuit is opened, the relay opens the primary circuit and the burner stops. Thus the room thermostat controls the operation of the burner and the source of heat. The point at which the burner starts is usually $1\frac{1}{2}°$ to 2° below the point at which it stops. As a safety measure, a limit switch is connected in series with the secondary circuit to prevent overheating. The limit switch when used with a warm air heating system, is an insertion thermostat that is reverse acting, *i.e.,* opens on a rising temperature and closes on a falling temperature, and has its sensing element in the warm air bonnet of the furnace. Its opening point is usually set about 5" above the minimum air temperature required to heat the house. Its opening point is fixed at 15° below its opening point. In case the bonnet air temperature reaches the limit, the switch opens the secondary circuit and the burner stops independently of the room thermostat. After the bonnet air cools 15° the limit closes and the burner starts again providing the room thermostat has not been satisfied in the meantime. The warm air circulating fan is controlled by an insertion thermostat in the warm air bonnet of the furnace and is set to start the fan 5° above the lowest temperature that will avoid the sensation of drafts in the living room, and to stop the fan 5° below the starting point.

With hot water systems, the room thermostat controls the operation of the circulating pump and the burner is controlled by a direct acting immersion thermostat set to open the secondary circuit at the minimum water temperature necessary to heat the house, and to close at about 10° to 15" below the opening point. When used with hot water heating systems, the limit switch is a direct acting double throw immersion thermostat with one pole in series with the primary circuit to the burner and the other in the primary circuit to the circulating pump. The circuit to the burner is normally closed+, and the circuit to the circulator is normally open. When the water temperature rises to the set point, the highest temperature for safe operation, the primary circuit to the burner opens and the burner stops; at the same time the primary circuit to the circulating pump closes and it starts independently of any controls on the secondary circuit. THÉROIGNE DE MERICOURT, ANNE JOSÈPHE (1762–1817), a Frenchwoman who was a striking figure in the Revolution, was born at Marcourt (from a corruption of which name she took her usual designation), Luxembourg, on Aug. 13, 1762. She was the daughter of a farmer, Peter Théroigne. She was educated in the convent of Robermont. She was quick-witted, handsome, passionate in temper and had a vigorous eloquence, which she used with great effect upon the mobs of Paris during the few years of her life (1789–93) which are of historical interest. She left her home because of a quarrel with her stepmother. As a courtesan she visited London (1782), and Genoa as a singer (1788).

In Paris on the outbreak of the Revolution, she was surrounded by a coterie of well-known men, chief of whom were Jerôme Pétion de Villeneuve and Camille Desmoulins.

She was again in Paris in Jan. 1792, where she often spoke in the clubs. Even in the national assembly she would violently interrupt the expression of moderatist views. Known as "la belle Liégoise," she wore a riding habit, a plume in her hat, a pistol in her belt and a sword at her side, and excited the mob by violent harangues. Associated with the Girondists and the enemies of Maximilien Robespierre, she became in fact the "Fury of the Gironde." She commanded in person the 3rd corps of the so-called army of the faubourgs on June 20, 1792, and shares a heavy responsibility for the riots of Aug. 10. She took no part in the September massacres, and, moderating her conduct, became less popular from 1793. Toward the end of May the Jacobin women seized her, stripped her naked and flogged her in the public garden of the Tuileries. The following year she became mad; she died at La Salpetrière on June 9, 1817.

THERSITES, the ugliest man in the Greek camp before Troy, a railing demagogue (see Homer, *Iliad* ii, 212), was a relative of Diomedes (*q.v.*).

THESEUS was the great hero of Attic legends and the son of Aegeus, king of Athens, and Aethra, daughter of Pittheus. king of Troezen, or of Poseidon and Aethra. The legend relates that Aegeus, being childless, went to Pittheus, who contrived that Aegeus should have intercourse with Aethra, who in due time brought forth Theseus. On reaching manhood Theseus was sent by his mother to Athens. He encountered many adventures on the way. First he met and slew Periphetes, surnamed Corynetes (Clubman). At the isthmus of Corinth dwelt Sinis, called the Pine Bender, because he killed his victims by tearing them asunder between two pine trees. Theseus hoisted the Pine Bender on his own pine tree. Next Theseus despatched the Crommyonian sow (or boar). Then over a cliff he flung the wicked Sciron, who used to kick his guests into the sea, while perforce they washed his feet. In Eleusis Theseus wrestled with Cercyon and killed him. Later he slew Procrustes, who fitted all comers to his only bed by lopping or racking them to the right length. He found his father married to Medea, who had fled from Corinth. Being a witch, she knew Theseus before his father did, and tried to persuade Aegeus to poison his son; but Aegeus recognized him. Theseus was now declared heir to the throne, and the Pallantids[1], who had hoped to succeed the childless king, conspired against him, but he crushed the conspiracy. He then attacked the fire-breathing bull of Marathon and brought it alive to Athens, where he sacrificed it to Apollo Delphinius. Next came the adventure of the Cretan Minotaur (*q.v.*).

While Theseus was on his way to Crete, Minos, wishing to see whether Theseus was really the son of Poseidon, flung his ring into the sea. Theseus dived and brought it up, together with a golden crown, the gift of Amphitrite. He landed on the return voyage at Delos, and there he and his comrades danced the crane dance, whose complicated movements were meant to imitate the windings of the Labyrinth. In historical times, this dance was still danced by the Delians round the Altar of Horns. Theseus had promised Aegeus that, if he returned successful, the black sail with which the fatal ship always put to sea should be exchanged for a white one. But he forgot his promise; and when Aegeus, from the Acropolis at Athens, descried the black sail out at sea,

[1]The sons of Pallas, the brother of Aegeus. Aegeus and Poseidon are quite possibly one and the same.

he flung himself from the rock and died. Hence, at the festival which commemorated the return of Theseus there was always weeping and lamentation. Theseus now carried out the union of the various Attic communities into a single State. He extended the territory of Attica to the isthmus of Corinth.

He transformed the Isthmian ceremony in honour of Melicertes by adding games in honour of Poseidon. Alone, or with Heracles, he captured the Amazon princess Antiope. Thereafter

the Amazons attacked Athens. Antiope fell fighting on the side of Theseus.

By her he had a son. Hippolytus (*q.v.*). Theseus is also said to have taken part in the Xrgonautic expedition and the Calydonian boar-hunt He compelled the Thebans to give up the unburied bodies of the Seven (see OEDIPUS).

The famous friendship between Theseus and Peirithous. king of the Lapiths. originated when Peirithous heard of the strength and courage of Theseus. and desired to put them to the test. Accordingly. he drove away from Marathon some cows which belonged to Theseus. The latter pursued. but nhen he came up with the robber the two heroes were so filled with admiration of each other that they snore brotherhood. At the marriage of Peirithous, a fight broke out between the Lapiths and Centaurs (*q.v.*).

Theseus and Peirithous now carried off Helen (*q.v.*). Theseus now descended to the lower world with Peirithous, to help his friend to carry off Persephone. But the two were caught and confined in Hades till Heracles came and released Theseus. \\'hen Theseus returned to Athens, he found that a sedition had been stirred up by Menestheus, a descendant of Erechtheus, one of the old kings of Athens.

Failing to quell the outbreak. Theseus in despair sent his children to Euboea. and after solemnly cursing the Athenians sailed away to the island of Scyros. where he had ancestral estates. But Lycomedes. king of Scyros. took him up to a high place, and killed him by casting him into the sea. His ghost was said to have appeared in the Athenian ranks at Marathon. When the Persian war was over, the Delphic oracle bade the Athenians fetch the bones of Theseus from Scyros and lay them in Attic earth. This was done, in *369,* by Cimon.

Theseus' chief festival. called Theseia, was on the 8th of the month Pyanepsion (Oct. 21), but the 8th day of every month was sacred to him.

The well-preserved Doric temple to the north of the Acropolis at Athens. commonly known as the Theseum, is certainly not his shrine. There were several (according to Philochorus, four) temples or shrines of Theseus at Athens.

THESMOPHORIA, a very ancient festival. celebrated by women in many parts of the Greek world (as Attica, many places in the Peloponnesus. Boeotia. several islands, the coast of Asia Minor, Cyrene, Italy and Sicily, but not generally among the Dorians) in honour of Demeter Thesmophoros.

The name does not mean, as the ancients usually supposed, *legifera* Ceres, since the festival can in no way be connected with the bringing or establishing of laws or customs (*thesmoi*). It is possibly "bringer of treasure or wealth," an obsolete sense of thesmos, of which a few traces remain; or. perhaps better. the name Thesmophoria is the primary one, from which the epithet of the goddess is derived, and it means "the carrying of things laid down," the radical meaning of thesmos referring to the fertility charms described below. As no men were admitted to the rites, and in any case they were largely secret, nothing like a full description is available.

The celebrants were women who seem to have been at least generally married, and who must be free. They observed chastity for several days (nine. according to Ovid, a likely number considering its magical connotations). and abstained from certain foods; thus, they must not eat pomegranate seeds. The festival lasted three days. although in Attica it was lengthened by the addition of other celebrations of a similar character. the Stenia and the Halamusian Thesmophoria. making five days in all. Pyanopsion 10–14. But the original days were Pyanopsion 12–14 only (*i.e.,* about the beginning of October) and shortly after the Pyanopsia (*q.v.*). The days were called respectively Anodos (or *Kathodos*), *Nesteia,* Knlligenein.

Anodos (ascent) is often taken to mean the "going up" of the women to the Thesmophorion, or precinct of Demeter; but this does not explain why the day should also be called Kathodos, or descent. As the name of the second day. which signifies "fasting." describes what the celebrants then did, it is plausible to take the first day as having been called Ascent and Descent. and to connect it with the rite known to have been performed at some time in the festival. Pigs were thrown into an underground chamber. called a megaron; they were probably alive! but the text is corrupt and uncertain. At all events they mere left there until such parts of them as were not eaten by the guardian snakes of these underground sanctuaries had had time to rot. The remains were then brought up by certain women who had observed chastity for three days and were called antletrini or "drawers up"—the verb antlein means to pump or draw off water. These women also carried, or some of the celebrants did, certain well-known symbols of fertility. including pine cones and "figures made of flour of wheat, in imitation of the shapes of serpents and of men." The remains of the pigs were laid on an altar, and if taken and mixed with seed were believed to ensure a good crop. Apparently the figures, like the pigs. were thrown into the chasms; but the authority here (a scholiast on Lucian) is both confused and manifestly corrupt; he seems to be confusing the Thesmophoria with a quite different festival, the Arrhephoria.

If, however, pigs, pine cones, figures and all were thrown into the megara and "pumped" out again, it is very intelligible magic. These objects are all. in their nature, connected with fertility—a fertile beast. a seed vessel, a preparation of grain shaped like a creature supposed to be full of earth magic (the serpent) and like a man. perhaps a phallic figure. They are then put into a holy place, left there to acquire additional mana from the sacred surroundings and the touch of the sacred serpents, real or imaginary, who live there, and finally taken out again by pure agents, whose chastity has, so to speak. insulated them. Finally, they are laid on a holy altar, whence they are taken, heavily charged now with potency, and used to bring the blessing of fertility. To mix all manner of magical things with seeds to make them sprout better is a widespread primitive custom.

The ancients tried to explain all these matters as commemorations of the abduction of Kore; but it is rather the legends that grew out of the ritual. now no longer understood. In modern times it has been found possible to conjecture a reason for them; but it is to be remembered that, because of the fragmentary state of available knowledge. the above is offered as a conjecture only, especially as regards the date of the rite.

The *Nesteia* is easily enough explained; it is known that the women fasted. sitting upon the ground Fasting is a common piece of agricultural magic, and contact with the ground is also common. The third day, *Kalligeneia,* is "the fair birth." We need not take it as originally referring to anyone so definite as Kore; it rather indicates the happy issue of all this magic, and doubtless of much more that is not known, in the fertility of the ground and doubtless of men and beasts as well. It remains only to add that the Thesmophoria, or at least a great part of it, was carried out at night by torchlight, and that it was accompanied by ceremonial coarse abuse among the women; again a common means of promoting fertility. The festival formed a setting for Aristophanes' comedy *The Thesmophoriazusae.* *See* also FEAST AND FESTIVAL.

THESPIAE, an ancient Greek city of Boeotia, on level ground commanded by the low eastward spurs of Mt. Helicon. The deity most worshipped at Thespiae was Eros, whose primitive image was an unwrought stone.

The town contained many works of art, among them the Eros of Praxiteles. dedicated by Phryne in her native place, one of the most famous statues in the ancient world. It was carried off to Rome by Caligula, restored by Claudius, and again carried off by Nero. There was also a bronze statue of Eros by Lysippus. The Thespians also worshipped the Muses. and celebrated a festival in their honour in the sacred grove on Mt. Helicon. Remains of the ancient citadel are still to be seen, solidly and regularly built. To east and south foundations show the extent of the ancient city.

The neighbouring village Eremokastro. on higher ground. was thought by Ulrichs to be probably the site of ancient Ceressus. In 1882 there were discovered, about 1,200 yd. east of Eremokastro. on the road to Arkopodi (Leuctra), the remains of a tomb of the 5th century B.C., with a colossal stone lion, probably that of the Thespians who fell at Plataea.

History.—Thespiae figures chiefly as an enemy of Thebes, whose centralizing policy it had all the more reason to fear because of the proximity of the two towns. During the Persian invasion of 480 *B.C.* Thespiae stood almost alone among Boeotian cities in serving the national cause. Seven hundred Thespians accompanied Leonidas to Thermopylae and of their own free will shared his fate.

The remaining inhabitants, though their city was burned by Xerxes, furnished 1.800 men to the Greek army at Plataea. In 424 B.C. the Thespian contingent at Delium sustained heavy losses, and in the next year the Thebans took advantage of this to accuse Thespiae of friendship toward Athens and to dismantle its walls. In 414 the Thebans interfered again to suppress a democratic rising. In the Corinthian war Thespiae sided with Sparta, and between 379 and 372 it repeatedly served the Spartans as a base against Thebes.

In the latter year the Thespians were reduced by the Thebans and compelled to send a contingent to Leuctra (371). It was probably shortly after this battle that the Thebans destroyed Thespiae and drove its people into exile. Later the town was rebuilt and in 171 B.C., true to its policy of opposing Thebes, sought the friendship of Rome.

THESPIS, Greek poet, of Icaria, in Attica (6th cent. B.C.), generally considered the inventor of tragedy, flourished in the time of Peisistratidae. According to Diogenes Laertius (iii. 56), he introduced for the first time in the old dithyrambic choruses a person distinct from the chorus, who conversed with the leader, and was hence called ὑποκριτής ("answerer"). His claim to be regarded as the inventor of tragedy in the true sense of the term depends upon the extent to which this person was really an "actor." (*See* DRAMA.) Suïdas gives the titles (of doubtful authenticity) of several of his plays (not confined to the legends of Dionysus, but embracing the whole body of heroic legends), but the fragments quoted in various writers as from Thespis (*see* Nauck, *Tragic Fragments)* are probably forgeries by Heracleides of Pontus. The statement of Horace *(Ars Poetica,* 276) that Thespis went round Attica with a cart, on which his plays were acted, is due to confusion between the origin of tragedy and comedy, and a reminiscence of the scurrilous jests which it was customary to utter from a waggon (σκώμματα ἐξ ἁμάξης) at certain religious festivals. A, and M. Croiset *(History of Greek Literature,* Eng. tr., 1904), who attach more importance to the part played by Thespis in the development of tragedy, accept the testimony of Horace. According to them, Thespis, actor and manager, transported his apparatus on a cart to the deme in which he intended to produce his drama, formed and trained a chorus, and gave a representation in public. *(See* also DRAMA.)

THESSALONIANS, EPISTLES TO THE, two books of the New Testament. These earliest extant letters of Paul mark the beginnings of Christian literature. Fortunately we can date them as written from Corinth early in A.D. 50, under the circumstances of the life of Paul (*q.v.*) related in Acts xvii. The designation "Missionary Epistles" is sometimes applied to the pair because they stand apart from the "Major" four addressed to Galatia, Corinth, and Rome, being as yet unaffected by the Judaizing reaction. They thus afford a simpler view of the normal type of gospel preached by Paul in Gentile territory, with the reactions it encountered. The designation "Eschatological" would be more distinctive, because doctrinally they chiefly reflect the difficulties raised among Greek converts by the proclamation of "Christ and the resurrection" (Acts xvii. 22–32; *cf.* I., i. 9–10). The drama of a return of the glorified Jesus to judgment and renewal of the world, represented in such books of "Prophecy" as the Revelation of John *(see* REVELATION. BOOK OF; JOHN. SAINT [the Apostle]), was taken over by the primitive Church from contemporary Jewish Apocalypse, but in Paul's letters and in Greek Christianity generally is gradually modified and pruned of its crudities. We should not fail to note that in Acts xv. 32 Silas, or Silvanus. whom Paul here associates with himself as joint author, is specifically called a "prophet."

First Epistle.—Both Thessalonian epistles are replies to communications from that newly founded church, probably not in oral form alone. I., i.–iii. reviews Paul's whole relation to it by way of defence against insinuations from outsiders ascribing his missionary activities to selfish motives. Paul reminds his converts that, when among them, he had not even called for the respect and support which were his due, but had depended for support on his own labour, supplemented by voluntary gifts from churches previously founded, showing toward them only the care and solicitude of a parent. He had been driven out by the jealous hostility of the Jews, who here showed that bitter antagonism shown against the prophets of old, against Jesus, and the mother church in Jerusalem; but he still hopes to return. If his prayers and hopes are frustrated it will be due only to the machinations of Satan, not any failure on his part. A practical section follows in iv. 1–12 urging increased efforts against sexual impurity (a besetting sin of the Greek churches), greater brotherly love, and a life of orderly industry forestalling possible charges from outsiders of idle fanaticism. Practical advice leads over to doctrinal instruction. Individuals have been disturbed in their faith by the death of some members of the brotherhood before the expected Coming. Paul re-assures them by citing a "word of the Lord." This is not, as sometimes imagined, a transmitted report of some saying of the earthly Jesus, whose authentic teachings are of very different stamp, but a message from the glorified "Lord" in "the Spirit," that is, through the type of "prophecy" illustrated in the messages of Jesus "in the Spirit" to the churches of Asia (Rev. i. 1 *ff.*). In I., iv. 13–18 Paul applies such parts of this primitive apocalypse as will serve to "comfort" those in danger of losing their Christian hope, and passes at once in v. 1–11 to further practical exhortation to watch and be sober as children of the light about to dawn, not overtaken like the sinful world by the Coming of the Lord to judgment. After direction to leaders and laity alike to co-operate toward a blameless and orderly communal life, with instructions that the letter be read in public assembly, Paul pronounces his apostolic benediction.

Second Epistle.—The second epistle continues the correspondence after an interval so brief that outward conditions appear unchanged, while leading features of the preceding letter are continued and accentuated. In particular the unfamiliar Jewish eschatology is explained and developed. Chapter i. repeats with further detail the proclamation of the Coming of Christ to judgment of I., i. 10, and justifies the doctrine of "wrath" against persecuting unbelievers in contrast with "rest" and "glory" for the saints. But in ch. ii. a new factor appears. Before the hoped-for Advent the "mystery of lawlessness" now at work in the world must culminate in a counter-manifestation of Satan's power. An Antichrist (*q.v.*) will appear "in the temple of God" claiming divine honours there after the manner of the desecration of Antiochus, self-styled "God-manifest," predicted in Daniel The programme of redemption will begin by the slaying of Antichrist by the breath of the Lord's mouth at his Coming. Momentarily Satan is held in check by Roman power. The closing chapter (iii.) resumes the admonitions of I., v. 12–28, re-enforcing disciplinary measures to be taken against the "disorderly."

Authenticity.–abjections once urged against the authenticity of I. have lapsed, but some still question II Slight changes of diction, usually toward more emphatic form in II., need not detain us. Doubts aroused by the suspicions expressed in II., ii. 2 and iii. 17, are not warranted. Actual circulation of spurious letters during the lifetime of the reputed author is indeed improbable. But this is not implied. Paul has heard of misrepresentations of his teaching and wishes to remove all conceivable excuse for it. The strong language of II., ii. 2 against an alleged Pauline doctrine of the Day of the Lord as "now present" no more presupposes actual utterance by "spirit" (*i.e.*, "prophecy"), or by "word" (of Jesus), or "by letter purporting to be from us" than the stronger language of Gal. i. 8 presupposes actual anti-Pauline preaching by "an angel from heaven." However, spurious epistles were common enough in Paul's time. It is interesting to see how he already guards himself against this possibility by the device later exemplified in Gal. vi. 11–18 and illustrated by many actual documents among the Oxyrhynchus papyri, by attaching to the dictated letter an autographed farewell "in mine own hand."

Serious objections to the authenticity of II. are of two kinds, (1) from its similarity to I. both in formal arrangement of material and in language; (2) from its unexpected attachment of the Antichrist doctrine to Paul's eschatology.

The similarity of material and structure is probably sufficient to prove dependence, possibly even literary dependence. But why not? Intrinsic probability as well as the known practice of the ancients suggests that a copy of I. would be available at Corinth for Paul's use in continuing the correspondence. There remains thus, as the only serious objection to the authenticity of II. its belated supplement to Pauline eschatology. The Antichrist doctrine, if not actually opposed to his teaching elsewhere, is almost unmentioned (but *cf.* I. Cor. xv. 24–28 and "Belial" in II. Cor. vi. 1j). Did Paul forget to mention this preliminary crisis when seeking in I., v. 1–11 to allay excitement at Thessalonica over the expected immediate Coming and to restore orderly industry? Was the working of the "mystery of iniquity" an afterthought?

For answer we must consider the occasion for his introducing the (apocalyptic) "word of the Lord" cited in I., iv. 15–17. It was to restore the hope of certain converts grieved by recent bereavement, and professedly contains but a part of the teaching. Paul purposely limited himself to the single lesson in I., v. 1–11 of watchfulness in view of the uncertainty of the hour. But his readers, reminded of the revelation, seem now to feel that a little more definite information concerning the "times and seasons" would greatly help. If the Antichrist paragraph of II. be read as in reply to an intimation of this kind, probably by letter, while the fact is kept in mind that in both letters the subject is repeatedly declared to be no new doctrine but something preached from the beginning by Paul and his fellow-missionaries, it will be easier to realize that it is not an afterthought with which we are here dealing, but rather something earlier and primitive, brought now to the surface by further development of the subject.

THESSALY, a district of northern Greece, between Macedonia and the Hellenic countries towards the south, and between upland Epirus and the Aegean. It forms an irregular square of about 60 mi. in each direction, for the most part level, but with well-marked boundaries, the Cambunian mountains on the north, Othrys on the south, the massive chain of Pindus, the backbone of this part of Greece, on the west; while at the north-eastern angle is Olympus, separated by the gorge of Tempe (*q.v.*) from the coast range of Ossa and Pelion, standing in a continuous line to the south-east. Three peaks of Pindus are over 5,000 ft., and Olympus, Ossa and Pelion reach respectively 9,570, 6,489 and 5,253 ft. The country within these limits is drained by numerous confluents, which pass into the sea through the gorge of Tempe.

Through Thessaly, therefore, lie all land routes between peninsular Greece and the north. An important pass from Petra in Pieria debouches west of Olympus on the plain north of Larissa. By this Xerxes entered (Herodotus vii. 173), and when the Greeks heard of this passage, they gave up their defence of Tempe. The main communication with Epirus passed over Mount Lacmon by the upper Peneius to Aeginium in the north-west angle. By this route Julius Caesar arrived before the battle of Pharsalia. Another pass, farther south by Gomphi, leads to the Ambracian gulf. The great southern pass of Coela crosses Mount Othrys nearly north of Thermopylae.

Though Thessaly is the most level district of Greece, it is composed of sections, divided by ranges of hills; Upper Thessaly, to the west and south-west, contains the higher course of the Peneius and all tributaries from the south—Enipeus, Apidanus, Onochonus and Pamisus. Lower Thessaly, from the central ridge west of Larissa to the foot of Ossa and Pelion, is inundated by the Peneius, the flood-water forming the Lake Nessonis, and, when that is full, pouring into Lake Boebe. The chief city of the lower Thessaly was Larissa; in the south at the pass of Coela is another plain, containing a small lake, formerly called Xynias, and low hills separate this from the town of Thaumaki, which overlooks the main upper plain "like a vast sea" (Livy xxxii. 4). The Plain of Pharsalia, intersected by the Enipeus, lies north-east of this, and still farther another battlefield, Cynoscephalae. The political divisions follow the physical, Pelasgiotis being the lower plain of the Peneius, Hestiaeotis and Thessaliotis respectively the north and the south portions of the upper; the fourth, Phthiotis, towards the south-east, was geographically separated by the watershed of Mt. Othrys and its north-east spurs. The landlocked Pagasaeus Sinus (Gulf of Volo), extends from Pagasae at its head to Aphetae at its narrow outlet, where the chain of Pelion turns at right angles to south-west in broken ridges, while on the opposite side rise the heights of Othrys. In the heroic age Phthiotis was the legendary birthplace of Greek navigation in the story of the Argonauts. Hence Achilles came and, according to Thucydides (i. 3), it was the cradle of the Hellenes. Iolcus, the centre of many legends, is near the modern Volo. Near Iolcus, later, Demetrius Poliorcetes founded Demetrias, called by Philip V. of Macedon one of the "fetters of Greece," Chalcis and Corinth being the others.

The history of Thessaly is closely connected with its geography. From the earliest times Thessaly has had a separate history controlled by its situation, The fertility of the land offered a temptation to invaders, and was thus the primary cause of early migrations. Its first Neolithic culture combined Danubian characters with elements from the "Tripolje" culture of Ukraine; a second phase reinforces the latter elements, at Dimini near Volo. Then long decadence resulted from the spread, first of "Helladic," then of "Minyan" culture from the south. Finally, just as Mycenaean exploitation was beginning in the 12th century, fresh northern invaders from Macedonia wrecked all. At this point language and legend supplement archaeology. Thessalian Greek is of the Aeolie group, akin to Boeotian; but between lie the "West Greek" dialects of Phthiotis, Malis and Doris, subsequently intruded Aeolic genealogies go back to the early part of the 14th century, whereas the Doric and West Greek expansion is referred to the 12th. Tradition brought both Thessalians and Boeotians from Arne in the northwest, imposing powerful aristocracies on the older inhabitants, who retained political coherence only among the marginal hills in Perrhaebia, Magnesia and the like. The rich lowlands were the natural home of powerful families such as the Aleuadae of Larissa and the Scopadae of Crannon; and the absence of elevated positions was unfavourable to the foundation of cities, which might have fostered freedom and democracy. The plains, also, were suited to the breeding of horses, and consequently the force in which the Thessalians were strong was cavalry, a kind of troops usually associated with oligarchy. The wealth and the semi-Hellenic character of the people (for, in race, as in geographical position, the Thessalians held an intermediate place between the Macedonians and the southern Greeks) held them aloof from national sentiment, and at the time of the Persian Wars the Aleuadae joined the enemy. United, as under Alexander and Jason of Pherae in the 4th century, the Thessalians were formidable, but they seldom combined for long and had little influence in Greece. From the 4th to the 2nd century they were usually Macedonian vassals

For several centuries during the middle ages Rumanian immigrants formed so large a part of the population of Thessaly that that district was called by the Byzantine writers Great Wallachia (Μεγάλη Βλαχία); the Jewish traveller, Benjamin of Tudela, so describes it in the latter half of the 12th century. Only a few Vlach (Ruman) colonies remained, however, principally on the west of Olympus and in some gorges of Pindus. The Turkish conquerors settled in the larger towns and in great ranches. The Greeks form so large a majority that, even while the country belonged to the Ottomans, Greek was the official language. Thessaly was ceded to the Greek kingdom by the Porte in 1881. The whole area was a battlefield in World War II. The port of Volo, almost the only outlet of trade, has a steamer service to Athens. Railways run: (1) from Volo by way of Velestino (ancient Pherae) to Larissa (*q.v.*); (2) from Velestino to the west by Phersala (Pharsala), Domokos (Thaumaki), Karditsa and Trikkala (Trika) to Kalabaka (Aeginium) in the upper valley of the Salambria (Peneios); (3) the main line from Athens to Salonika enters Thessaly by the Coela pass west of Othrys, reaches Larissa and proceeds by the gorge of Tempe and the sea front of Olympus. Thessaly is essentially an agricultural and pastoral district.

THETFORD, a municipal borough in the South Norfolk parliamentary division of Norfolk, Eng.. 29½ mi. W.S.W. of Norwich by road. It is the centre for the Breckland and is on the edge of Thetford Chase forest. Pop. (1961) 5.398. Area 11.1 sq.mi. In the time of Edward III there were 20 churches and 8 religious houses, but now there are only 3 parish churches and the remains of a Cluniac priory (excavated by the ministry of works) and a Benedictine nunnery. Castle hill, a large medieval motte, is 80 ft. high. Excavations have revealed traces of a Saxon town of some 4,000 inhabitants with considerable industry and a mint. The grammar school has a record of headmasters from 1114, and may be that mentioned in the Anglo-Saxon Chronicle as existing in 631. It mas refounded in 1567 by Sir Richard Fulmerstone. King's house, used by Elizabeth I and James I and reputed to stand on the site of the palace of the Conqueror's son-in-law, was bequeathed to the corporation in 1946 and serves as municipal offices. There have been mayors since 1272 and the town is now governed under a charter of 1573 The borough regalia is fine and interesting. Thomas Paine, the reformer, was born there in 1737 and attended the grammar school. Industries include paper-pulp manufacturing, canning, coffee milling and light engineering.

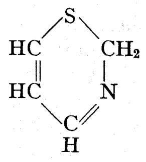
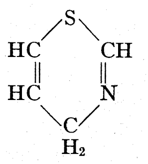
THETIS, in Greek mythology, daughter of Nereus, wife of Peleus and mother of Achilles. The chief of the 50 Nereids, she dwelt in the depths of the sea with her father and sisters. When Dionysus leaped into the sea to escape from the pursuit of Lycurgus, king of the Thracian Edones, and Hephaestus was flung out of heaven by Zeus, both were kindly received by Thetis. Again, when Hera, Athena and Poseidon threatened to bind Zeus in chains, she sent the giant Aegaeon, who delivered him out of their hands. She was married against her will to Peleus (*q.v.; see* also ACHILLES). Thetis is used by Latin poets simply for the sea.

THEURIET, CLAUDE ADHÉMAR ANDRÉ (1833–1907), French poet and novelist, was born at Marly-le-Roi. The best of his novels are: *Le mariage de Gérard* (1875); *Raymonde* (1877); Le *fils Maugars* (1879); *La maison des deux Barbeaux* (1879); *Sauvageonne* (1880); *Reine des bois* (1890); *Villa tranquille* (1899). Theuriet died on April 23, 1907.

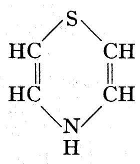
THIAZINES are organic compounds. of which some of the more complex derivatives are of importance in the manufacture of dyestuffs. They have the molecular formula C_4H_5NS, to which six-membered heterocyclic ring structures have been assigned.



1,3,2-Thiazine

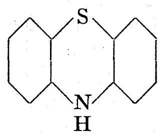


1,3,4-Thiazine

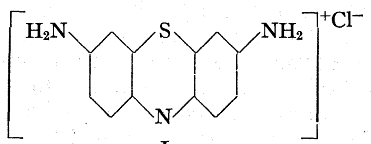


1,4-Thiazine

The thiazines themselves and their simpler derivatives are of little practical importance or theoretical interest. The so-called thiazine dyes are phenazothionium salts and may, therefore, be regarded as derivatives of phenothiazine (2,3,5,6-dibenzo-1,4-thiazine).



The simplest of the thiazine dyes is Lauth's violet (I); probably the most important is methylene blue (II).



I

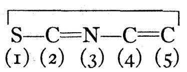
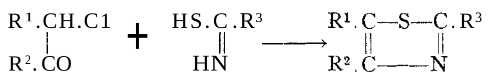
The skeletal structure of the thiazine dyes was elucidated by August Bernthsen in 1887, although methylene blue was discovered in 1876 by Heinrich Caro. (P. H. O. R.; X.)

THIAZOLES, in organic chemistry, consist of compounds containing a five-membered ring of one nitrogen. one sulfur and three carbon atoms connected by three single and two double bonds in the order:



The earliest synthesis of a compound of this type was effected in 1874, by the action of hydrogen sulfide on potassium cyanide; however, the constitution of this product remained long in doubt and was rigorously established. as 5-amino-2-thiocarbamylthiazole, only in 1947.

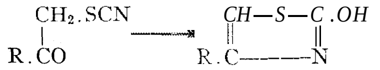
Thiazoles, as a class, were discovered in 1887 by Artur Hantzsch, who then systematically explored their chemical characteristics. They are most conveniently prepared by the condensation of α-halogenated aldehydes or ketones with thioamides:



The parent thiazole, in which R^1, R^2 and R^3 represent hydrogen atoms, is a colourless liquid that boils at 117° C. and exhibits weakly basic properties like those of pyridine; the homologous thiazoles display similar properties.

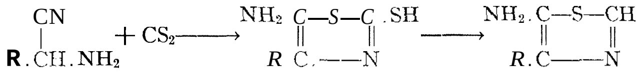
The 2-aminothiazoles, in which R^3 represents the amino group. are formed in an analogous reaction from thiourea; the sulfanilyl derivative, in which $R^1 = R^2 = H$ and $R^3 = NH.SO_2.C_6H_4.NH_2$, is the synthetic antibiotic drug sulfathiazole.

The 2-hydroxythiazoles. in which $R^3 = OH$, are produced by the action of alkali upon a-thiocyanoketones:



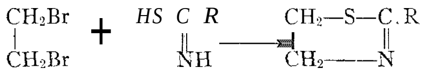
The corresponding 2-mercaptothiazoles ($R^3 = SH$), formed by the interaction of a-halogenated ketones with ammonium dithiocarbamate, find industrial use as accelerators in the vulcanization of rubber.

The 5-aminothiazolcs ($R^1 = NH_2$) have been prepared by treating a-amino nitriles with carbon disulfide and then removing the sulfydryl group (at position 2) from the product by the action of Raney nickel catalyst:



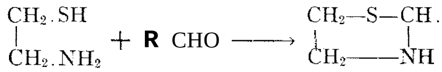
For the versatility of these compounds in synthetic reactions *see* Sir Ian Heilbron's presidential address to the Chemical society of London in the bibliography.

Dihydrothiazoles, or thiazolines. have been prepared by the action of ethylene dibromide upon thioamides:



or, less conveniently, from acid chlorides or anhydrides and β-amino thiols.

Tetrahydrothiazoles. or thiazolidines, are formed by the interaction of aldehydes or ketones with β-amino thiols:



In 1935 and the subsequent two decades the thiazole group and its hydro analogues were shown to occur in natural products: thiamine (vitamin B_1) contains a thiazole nucleus, the penicillins are derivatives of thiazolidine and there are indications that the thiazoline ring may be present in the antibiotic bacitracin. Synthetic thiazole dyes are used in dyeing cotton.

THIBAUT (Theobald) **IV** (1201–1253), count of Champagne and Brie and king. as Theobald I. of Navarre. French poet, was born at Troyes in 1201. His father. Thihaut III of Champagne, died before his son's birth, and his mother. Blanche of Navarre, was compelled to resign the guardianship of the young prince to Philip II Augustus of France: but there is little doubt that the child was acquainted with Chrétien de Troyes and the other trouvères who found patronage at the court of Champagne. Thibaut's verses belong to what is called "courtly" poetry, but they have a personal note that distinguishes them from mere exercises. It has been supposed, apparently without much justification. that they were addressed to Blanche of Castile, the wife of Louis VIII of France. and Thibaut's relations with her have been the subject of much controversy. The count took part with Louis in the crusade against the Albigenses, but in 1226 suddenly left the king and returned to Champagne. Three months later, Louis died under doubtful circumstances, and Thihaut was accused by his enemies of poisoning him. The real reason for Thibaut's desertion appears to have been a desire to consolidate his position as heir apparent of Navarre by an alliance with the disaffected nobility of the south of France, but from this confederation Blanche was skillful enough to detach him. The resentment of the League involved him in a war in which Champagne was laid waste and his capital saved only by the royal intervention. In 1234 he succeeded his uncle. Sancho VII the Strong, as king of Navarre. and from this period date his most fervent songs in praise of his lady. An obligation to go as a crusader to Palestine turned Thibaut's thoughts to religion, and he announced his intention of singing henceforth only in honour of the Virgin. The years 1239 and 1240 were spent in Palestine, and from the time of his return Thibaut devoted himself to efforts for the improvement of his dominions that won for him the title of *le Bon*. He died at Pamplona on July 7, 1253. Thibaut was the most popular of the 13th-century trouvères, and his work is marked by a grace and sweetness which he owed perhaps in part to his association with the trouhadours of the south. As many as 53 poems, including 36 love songs and 9 *jeux-partis* (elaborate discussions between two interlocutors, usually on the subject of love), can be certainly attributed to him.

Thibaut's works were published first by L. A. Lévesque de La Ravalière (1742) and then by P. Tarbé (1851). The critical edition, with introduction and commentary, was edited by A. Wallensköld for the Société des anciens textes français (1925).

THIBAUT, ANTON FRIEDRICH JUSTUS (1774–1840), German jurist. was born at Hameln. in Hanover. on Jan. 4, 1774. the son of an officer in the Hanoverian army. He studied jurisprudence at Göttingen, Königsberg and Kiel. There in 1798 he was appointed extraordinary professor of civil law, and published his earlier works, including the important treatise *Theorie der logischen Auslegung des romischen Rechts* (1799). In 1802 Thibaut was called to Jena. where he wrote his chief work. *System des Pandektenrechts* (1803). This work is. in effect, a codification of the Roman law as it then obtained in Germany. modified by canon law and the practice of the courts into a comprehensive system of pandect law. In 1805 he went to Heidelberg where he stayed till his death on March 29. 1840. His influence was great and. except Gustav Hugo and Savigny, no civilian of his time was so well known. In 1814 appeared his *Civilistische Abhandlungen,* of which the principal was his famous essay advocating a national code for Germany. This essay was inspired by the War of Liberation.

THIELMANN, JOHANN ADOLF, Freiherr von (1765–1824), Prussian cavalry soldier, was born at Dresden. Entering the Saxon cavalry in 1782, he saw service against the French in the Revolutionary Wars and in the Jena campaign and, after Jena, at the siege of Danzig and at Friedland. In 1809, as colonel of a free corps, he opposed the advance of the Austrians into Saxony and was promoted major general. becoming lieutenant general in 1810. As commander of the Saxon heavy cavalry brigade he took part in the advance on Moscow (1812), and at Borodino attracted the attention of Napoleon, who took him into his own suite. His own sovereign at the same time made him freiherr. In the War of Liberation Thielmann took a prominent part. When ordered to surrender the fortress of Torgan, of which he was governor, to the French, he resigned his command and joined the allies. As a Russian general he reorganized the Saxon army after Leipzig, and in 1814 he commanded the Saxon corps operating in the Low Countries. Early in 1815 he became a lieutenant general in the Prussian service, and in command of the 3rd army corps he took part in the Waterloo campaign, in which he fought the spirited action of Wavre (June 18–19). He was later a corps commander at Münster and at Coblenz, where he died in 1824.

THIERRY, JACQUES NICOLAS AUGUSTIN (1795–1856), French historian. who was horn at Blois on May 10, 1795. He was educated at the Blois grammar school, and at the Ecole Normale Supérieure. He embraced the ideas of the Revolution and became fired with Saint-Simon's ideal society of the future. He became the secretary, and. as he would say himself, the "adopted son" oi the visionary (1814–17); but, while most of Saint-Sinion's followers turned their attention to the affairs of life, devoting themselves to the problems of political economy, Thierry turned his to history. His imagination had been powerfully impressed by reading *Les Martyrs,* in which Châteaubriand had contrasted the two civilizations and the two races from which the modern world has sprung. His romantic ardour was later still further nourished by the works of

Sir Walter Scott. Thierry's main ideas on the Germanic invasions, the Norman Conquest, the formation of the communes, the gradual ascent of the nations towards free government and parliamentary institutions are already observable in the articles contributed by him to the *Censeur européen* (1817–20), and later in his *Lettres sur l'histoire de France* (1820). By the aid of the Latin chronicles and the collection of the Anglo-Saxon laws, he composed his *Histoire de la Conquête de l'Angleterre par les Normands* (1825). Thierry's eyesight began to fail and in 1830 he became quite blind. Nevertheless he republished (1827) his *Lettres sur l'histoire de France,* with the addition of 15 new ones, in which he described some of the more striking episodes in the history of the rise of the mediaeval communes.

Thierry was ardent in his applause of the July Revolution and the triumph of liberal ideas. He re-edited, under the title of *Dix ans d'e'tudes historiques,* his first essays in the *Censeur européen* and the *Courrier français* (1834), and composed his *Récits des temps mérovingiens,* in which he reproduced in a vivid and dramatic form some of the most characteristic stories of Gregory of Tours. These *Rtcits* appeared first in the *Revue des deux mondes;* when collected in volume form, they were preceded by long and interesting *Considrations sur l'histoire de France.* In 1841, the French academy awarded him the first *Prix Gobert,* which was renewed in his favour 15 years in succession. By the aid of zealous collaborators (including Bourquelot and Louandre) he compiled, in four volumes, a valuable *Recueil des monuments inédits de l'histoire du Tiers État* (1850–70), which, however, bear only on the northern part of France. He died in Paris on May 22, 1856.

THIERRY OF CHARTRES (d. c. 1150), in Latin called THEODORICUS or TERRICUS CARNOTENSIS, French encyclopaedist, philosopher and theologian, was a brother of Bernard of Chartres. He taught in Paris and at Chartres, where he became chancellor in 1141, having among his pupils John of Salisbury and possibly Abelard. His unpublished *Heptateuchon* (preserved in microfilms at Oxford, at Toronto, at Chartres. etc.) contains the "classics" of the seven liberal arts (works by Aelius Donatus and Priscian for grammar, by Cicero and Martianus Capella for rhetoric, by Aristotle and Porphyry for logic, etc.). His cosmology, mainly expounded in his commentary on *Genesis,* attempts to harmonize Scripture with Platonic and other physical or metaphysical doctrines. He was among the first to promote in the Latin west the knowledge of science as professed by the Arabians.

THIERS, LOUIS ADOLPHE (1797–1877), French statesman and historian, was born at Marseilles on April 16, 1797. He was educated, first at the lycée of Marseilles, and then in the faculty of law at Aix. There he began his lifelong friendship with Mignet, and was called to the bar. In 1821 Thiers went to Paris, and became a contributor to the *Comtitutionnel.* Cotta, the well-known Stuttgart publisher, who was part-proprietor of the *Constitutionnel,* made over to Thiers a share of his dividends and he was thus relieved of any money anxiety.

Meanwhile Thiers became very well known in Liberal society, and he had begun the celebrated *History of the French Revolution,* 10 vol. (1823–27; Eng. trans. 5 vol., 1895), which founded his literary and helped his political fame. Coming as the book did just when the reaction against the revolution was about to turn into another reaction in its favour, it was assured of success. In 1830 Thiers, with Armand Carrel, Mignet, and others started the *National,* a new opposition newspaper. Thiers himself took a leading part in the actual revolution. He ranked as one of the Radical supporters of the new dynasty. At first Thiers, though elected deputy for Aix, obtained only subordinate places in the ministry of finance. After the overthrow of his patron Laffitte, he became much less radical and, after the troubles of June 1832, was appointed to the ministry of the interior. He repeatedly changed his portfolio, but remained in office for four years, became president of the council and in effect prime minister; and began his series of quarrels and jealousies with Guizot. At the time of his resignation in 1836 Thiers was foreign minister, and, as usual, wished for a spirited policy in Spain, which he could not carry out. He travelled in Italy for some time, and it was not till 1838 that he began a regular campaign of parliamentary opposition, which in March 1840 made him president of the council and foreign minister for the second time. But he held the position barely six months, and resigned on Oct. 29. He now worked on his *History of the Consulate and the Empire* (1840–55; Eng. trans.. 1845–62). Though he was still a member of the chamber he spoke rarely, till after the beginning of 1846, when he was evidently bidding once more for power. When the revolution of February broke out he and Odilon Barrot were summoned by the king; but it was too late.

Under the republic he took up the position of conservative republican. The inconsistency of his conduct, especially in voting for Prince Louis Napoleon as president. was often and sharply criticized, one of the criticisms leading to a duel with a fellow-deputy, Bixio. He was arrested at the *coup d'état,* was sent to Mazas, and then escorted out of France. But in the following summer he was allowed to return. For the next decade his time was occupied for the most part on *The History of the Consulate and the Empire.* It was not till 1863 that he re-entered political life, as deputy for a division of Paris. For the next seven years he was leader of the anti-Imperialists in the French chamber. While nominally protesting against its foreign enterprises, he perpetually harped on French loss of prestige, and so contributed more than anyone to stir up the spirit which brought on the war of 1870.

After the collapse of the empire Thiers visited in the autumn the different courts of Europe in the hope of obtaining some intervention, or at least some good offices. The mission failed; but the negotiator was immediately charged with another — that of obtaining, if possible, an armistice directly from Prince Bismarck. Thiers was chosen deputy to the national assembly by more than 20 constituencies (of which he preferred Paris), and was at once elected by the assembly itself practically president. nominally *chef du pouvoir exdcutif.* He succeeded in convincing the deputies that the peace was necessary, and it was (March 1, 1871) voted by more than five to one. Thiers held office for two years after the peace. He had at first to meet and crush at once the Paris commune, and on Aug. 30 he became president of the republic.

His strong personal will and inflexible opinions had much to do with the resurrection of France; they also made it inevitable that he should excite violent opposition. In Jan. 1872 he formally tendered his resignation; and, though it was refused, almost all parties disliked him, while his chief supporters — men like Rémusat, Barthélemy Saint-Hilaire and Jules Simon — were men rather of the past than of the present. In 1873 regulations were proposed, and on April 13, were carried, which were intended to restrict the executive and especially the parliamentary powers of the president. The government was further weakened by a dissolution and reconstitution of the cabinet on May 19. Immediately afterwards the question was brought to a head by an interpellation moved by the duc de Broglie. The president declared that he should take this as a vote of want of confidence; a vote of this character (though on a different formal issue, and proposed by M. Ernoul) was carried by 16 votes in a house of 704. Thiers at once resigned (May 24). He survived his fall four years, continuing to sit in the .Assembly, and, after 1876, the chamber of deputies. He died on Sept. 3, 1877.

Thiers was by far the most gifted and interesting of the group of literary statesmen which formed a unique feature in the French political history of the 19th century. There are only two who were at all comparable to him — Guizot and Lamartine; and as a statesman, he stands far above both. Nor was this eminence merely the result of his great opportunity in 1870; for Guizot might under Louis Philippe have almost made himself a French Walpole, at least a French Palmerston, and Lamartine's opportunities after 1848 were, for a man of political genius, illimitable. But both failed — Lamartine almost ludicrously — while Thiers in hard conditions made a striking if not a brilliant success. But he only showed well when he was practically supreme. Even as the minister of a constitutional monarch his intolerance of interference or joint authority, his temper at once imperious and intriguing, his inveterate inclination towards *brigue,* that is to say, underhand rivalry and caballing for power and place, showed themselves unfavourably; and his constant tendency to inflame the aggressive and chauvinist spirit of his country neglected fact, was not based on any just estimate of the relative power and interests of France, and led his country more than once to the verge of a great calamity. In opposition. both under Louis Philippe and under the empire, and even to some extent in the last four years of his life, his worst qualities were always manifested. But with all these drawbacks he conquered and will retain a place in what is perhaps the highest, as it is certainly the smallest, class of statesmen — the class of those to whom their country has had recourse in a great disaster, who have shown in bringing it through that disaster the utmost constancy, courage, devotion and skill. and who have been rewarded by as much success as the occasion permitted.

As a man of letters Thiers was very much smaller. He had not only the fault of diffuseness, which is common to so many of the best-known historians of his century, but others as serious or more so. The charge of dishonesty is one never to be lightly made against men of such distinction as his, especially when their evident confidence in their own infallibility, their faculty of ingenious casuistry, and the strength of will which made them (unconsciously, no doubt) close and keep closed the eyes of their mind to all inconvenient facts and inferences, supply a more charitable explanation. But it is certain that from Thier's dealings with the men of the first revolution to his dealings with the battle of Waterloo, constant, angry and well-supported protests against his unfairness were not lacking. THIETMAR (DIETMAR or DITHMAR) OF MERSEBURG (975–1018), German chronicler, was a son of Siegfried, count of Walbeck, and was related to the family of the emperor Otto the Great. Born on July 25, 975, he was educated at Quedlinburg and at Magdeburg and became provost of Walbeck in 1002 and bishop of Merseburg seven years later. He took some part in the political events of the time; in 994 he was a hostage in the hands of the Northmen. He died on Dec. 1, 1018.

Thietmar wrote a *Chronicon* in eight books, which deals with the period between 908 and 1018. For the earlier part he used Widukind's *Res gestae Saxonicae,* the *Annales Quedlinburgenses* and other sources; the latter part is the result of personal knowledge. It has been edited by J. M. Lappenberg in vol. iii of the *Monumenta Germaniae historica, Scriptores;* and by F. Kurze (1889); and has been translated into German by J. Laurent (new ed. revised by W. Wattenbach [1892]).

THINKING AND PROBLEM SOLVING, PSYCHOLOGY OF. Problem solving is one kind of thinking, the kind that has been most thoroughly studied. But there are other important kinds of thinking, and the term itself has many definitions; no one of which is satisfactory to everyone. A useful one for those who attempt to study it scientifically defines thinking as that aspect of human (and animal?) activity that primarily involves processing of information.

When a person thinks, he processes information: he takes certain information that he possesses and by carrying out appropriate operations obtains information that in some sense is new. Suppose, for example, he is asked, "What is the numerical value of the seventh power of five?" After a minute or so, he map reply, "78,125," having multiplied $5 \times 5 \times 5 \times 5 \times 5 \times 5 \times 5$ in order to get the answer. This would be a simple example of processing of information and hence of thinking. An appropriate operation —in this case, multiplying five by itself the required number of times—was carried out in order to obtain information not previously possessed. Of course, it is possible that some person when asked this question would reply almost immediately, "78,125," recalling a result he had obtained on some previous occasion. In this case, he would be said to be remembering rather than thinking.

It is not easy to distinguish between behaviour involving learning or remembering and that involving thinking. Indeed, many insist that thinking involves nothing more than learning or remembering. But the view taken here is that one learns items of information, one learns the operations employed in processing information, and one may learn the information obtained from such processing; but the processing of information itself, or thinking, involves primarily implicit performance, not learning, from which it should be distinguished at least provisionally. In thinking, one deals with or processes much information that one does not necessarily learn and remember. For example, one does not in the process of obtaining the seventh power of five ordinarily learn and remember the fifth power.

The operations or processes involved in thinking are many and varied in kind and complexity. They include the simpler logical operations such as matching two items or substituting one for another, and also many more complex ones. They include the simpler mathematical operations such as addition and multiplication, and also more complex ones such as differentiation and integration. And they include many less logical processes. These processes are themselves the result of learning and hence vary from one thinker to another. Consider the differences that must exist among the processes involved in choosing moves in chess, in composing a piece of music and in diagnosing a case of appendicitis.

Thinking, as here defined: includes problem solving, decision making, creative thinking, fantasy and even dreaming. But since more is known about problem solving than about any of the other types of thinking, it will be the primary subject of this discussion. A problem exists whenever an individual has a goal, the route to which is unknown. In solving the problem, he thinks; in other words, he processes information which he already possesses or, in some cases, which he can obtain from the environment in order to produce the information that will enable him to achieve the goal. Of course, if the necessary information is obtained from the environment with no further processing required, then no thinking can be said to be involved. The kinds of goals sought in problem solving may be as varied as trapping a wild animal, finding a route by which wagons can cross a mountain range, locating the source of trouble in a television set, disassembling a mechanical puzzle, proving a theorem in geometry, identifying the killer in a murder mystery or determining the speed and direction necessary for a rocket to hit the moon when fired from the earth.

The experiments carried out by psychologists in studying problem solving are of two types: (1) One is concerned primarily with investigating the processes of problem solving; that is, what goes on when an individual solves a problem. (2) The other is concerned primarily with determining how achievement in problem solving varies as a function of a variety of experimental variables; *e.g.,* an experiment designed to determine how the number of problems solved by a group in a given length of time varies with the size of the group. There are also correlational studies concerned with achievement in problem solving as a function of other variables; since these variables; however, cannot be varied for a given individual in an experiment, such studies are said to be nonexperimental. An example of such a variable would be general intelligence. It is not possible to change the intelligence of a subject experimentally to determine how achievement in solving a given kind of problem varies with intelligence; it is possible, however. to determine how differences in such achievement are correlated among a group of subjects with differences in intelligence. Historically, the experiments concerned with the processes involved in thinking and particularly in problem solving have been of most interest and the subject of the most controversy. Accordingly, they will be given primary attention here.

Introspection. — The first systematic experiments on thinking, carried out during the first decade of the 20th century, were of this type. In the psychology then prevalent. still new as an experimental science, thinking was conceived as essentially a conscious process! directly open to the introspection (*q.v.*) of the thinker. The experimental method, therefore, was that of presenting brief thought-provoking tasks to persons and asking them to describe their experience promptly as each task was completed.

The results of this straightforward and apparently obvious procedure were such as to cast doubt on some of the basic presuppositions of psychology as it was then widely understood. Among the most thoroughgoing of the early experimental psychologists, it was commonly assumed that consciousness is a composition of elementary processes — specifically simple sensations, images and feelings — and that it is the special task of a scientific psychology to describe consciousness exhaustively in terms of these constituents, as determined by experimentally controlled introspection.

It was precisely this assumption concerning the nature of consciousness that the data from the thought experiments called into question. The subjects' reports, to be sure, mentioned sensory, affective and imaginal contents; but they referred far more prominently to conscious events which most subjects described as being unanalyzable into the expected elementary constituents. Among these were conscious attitudes such as doubt, hesitation or sudden illumination and "thoughts," noted simply as thoughts *of* or thoughts about, reported as having little or no sensory or imaginal content. Furthermore, such contentless or relatively contentless occurrences seemed to the subjects to mark critical turning points in their thinking, crucial stages in the solution of a problem.

These results were especially convincing because they were obtained independently in investigations conducted by a group of men inspired largely by O. Kiilpe at the University of Würzburg in Germany (1901–07), by A. Binet in France (1903) and by R. S. Woodworth in the U.S. (1906). They were important because they indicated that the course of thought is neither completely nor faithfully mirrored in consciousness — that important determinants of thought, as a matter of fact, are not registered in consciousness and, therefore, are outside the range of introspective observation. Moreover, in the controversy that rose over these unexpected findings, highly trained introspectionists disagreed not only concerning the interpretation of introspective data but even concerning the very nature of some of the data. This disagreement, which could not be settled by an appeal to facts—introspectively observed facts — strongly suggested that introspection is incapable of giving results sufficiently free from ambiguity to be acceptable in scientific research. To some psychologists, it seemed necessary to discard introspection altogether, not only in studying thinking, but in all psychological research. But to others. perhaps to most, the conclusion was that the possibilities of introspection had been greatly overestimated; that, like other modes of observation, it has limitations that must be recognized; but that within these limits it may be useful if properly safeguarded, especially when combined with other methods.

Implicit Muscular Activities. — John B. Watson, the founder of U.S. behaviourism, was chief among those who proposed (1914) to discard from psychology not only the introspective method but all reference to consciousness. Watson treated thinking as consisting of slight muscular movements, especially though not exclusively speech movements. His view that thought is implicit speech led to a number of attempts by others to record such movements by means of mechanical lever systems. These attempts, however, were largely inconclusive, partly because the recording systems employed were not sensitive enough or sufficiently quick acting, and partly for other reasons.

Electrical rather than mechanical recording systems subsequently were used to provide much more sensitive indication of slight muscular activity. Electrodes appropriately placed near a muscle will pick up minute changes in potential and cause deflections of a string galvanometer. By employing a vacuum tube amplifier, potential changes as small as one millionth of a volt have been recorded on photographic film. The work of L. E. Jacobson (1929–32) and of L. W. Max (1934–37) involved the most extensive applications of this technique. Jacobson's general procedure was to have subjects carry out various tasks involving thinking while recording changes in potential. or action currents, from appropriate muscles. In one experiment, for example, subjects were instructed to imagine bending the right arm. Action currents were obtained from the right arm while the subjects were imagining this act, but not while they were imagining bending the left arm or nhile they were relaxing. In another experiment. electrodes were attached to the tongue and lips while subjects imagined counting, telling the date and so forth. The records of action currents were similar in general, but not in detail, to those obtained when subjects were faintly speaking the same words or numbers. Max employed as subjects deaf-mutes, persons who normally use gesture language. When they were given various problems to solve, action currents were obtained from the muscles controlling the fingers that were much larger and more frequent than those obtained from normal control subjects under the same conditions. During sleep, occasional bursts of activity of about two or three minutes in length were recorded from the same muscles in deaf-mutes. When awakened during such bursts. these subjects usually, but not always, reported that they had been dreaming; when awakened in the absence of such bursts, they usually. but not always, reported that they had not been dreaming.

Peripheral v. Central Theory. — These results have been interpreted by some to support the peripheral as opposed to the central theory of thinking. According to the latter, all activities necessary and sufficient for thought occur in the brain. The peripheral theory, however, holds that these implicit muscular activities together with the perceptual changes to which they give rise form the necessary and sufficient condition for thinking; according to this view, the brain serves as a relay station transmitting impulses from receptors to effectors: and as the locus of awareness of thought, such awareness arising from the perception of implicit movements,

Most psychologists accept one of two other interpretations of the significance of these data on implicit muscular activity; both are consistent with the central theory of thinking. According to one view, such implicit muscular movements result from an overflow of central nervous activity; that is, they are simply a by-product of the real processes of thinking. The other view is that these movements provide a necessary neural substratum for particular thought processes, that they in some way provide reinforcement for central neural activity.

A comment may be inserted at this point concerning the possible use of the electroencephalogram as an index of the course of thinking. Brain waves are recorded by placing electrodes at appropriate points on the surface of the scalp and by greatly amplifying the rhythmic changes in potential that are picked up. Gross distortions in the frequency or form of these waves may be useful in diagnosing epilepsy, locating a brain tumour or for other purposes. But using such waves as an indicator of what a person is thinking would be, as one psychologist put it, like trying to measure the width of the edge of a razor blade with a yardstick.

Trial and Error. — Another approach to the understanding of the processes of problem solving grew originally out of investigations of animal behaviour. On the basis of observations of his dog and of other animals, C. Lloyd Morgan (1894) questioned the then widely accepted view that animals can reason. Such behaviour as that of his fox terrier learning to open a gate by raising the latch with his muzzle could best be explained, Morgan held, in terms of trial and error — that is, in terms of a gradual elimination of errors and a gradual strengthening of the correct response through repetition. E. L. Thorndike (1898, 1911) carried out more formal experiments employing specially constructed laboratory apparatus and using as subjects primarily young cats, but also dogs, chicks and monkeys. In a typical experiment, a hungry cat was placed in a barred box from which it might escape by making a certain response; the correct response varied from one experiment to another and included pressing a lever, pulling a string, licking itself, etc. His results led Thorndike to conclude that the animals showed no "seeing through the situation" but only behaviour involving trial and error.

Thorndike's methods were extended by H. A. Ruger (1910) to inquiries into the psychology of solving complex problems. Using human subjects, most of whom were intelligent and educated adults, and substituting complicated mechanical puzzles for Thorndike's maze and puzzle boxes, he followed essentially the same procedures as Thorndike, supplementing them, however, with introspective reports from his subjects. In presenting his findings, Ruger emphasized the large amount of typically "animal" trial and error in the activities of his subjects. He noted that many kinds of nonrational behaviour regularly occurred; for example, that unsuccessful reactions were often retained after they have proved to be useless; that successful variations in procedure often made their first appearance not' through foresight but even without attracting the subject's notice; that a puzzle was often solved with little or no comprehension of the principles involved. But he also presented data that in his opinion pointed to distinctively human as contrasted with animal procedures. Among the learning curves of his human subjects were some that showed sudden drops in performance time, and these drops coincided in most cases with introspective reports that the subject had seen the point of the puzzle—sometimes that it had flashed upon him suddenly, sometimes that he had worked it out deliberately.

Insight.—Thorndike's emphasis upon trial and error not only in animal but also in human problem solving was sharply criticized by Gestalt psychologists, who emphasized instead the role of insight. This concept of insight first aroused widespread interest when W. Kohler published (1925) his study of the mentality of anthropoid apes. Kohler contended that the problems Thorndike had employed artificially produced trial and error because they required for solution responses that were unnatural for the animal and because the elements necessary for solution were hidden. The cats, for example, were required to push levers, a response not a part of their natural repertory and hence one that could be hit on only by blind chance; moreover, the mechanism connecting the lever to the door was hidden and in any case would be beyond the cat's understanding. Kohler presented to his apes problems in which the elements necessary for solution were available to the animals and the solution of which required natural responses. Though he reported considerable behaviour classifiable as trial and error, Kohler stressed the point that the critical moment in the animal's solution of a problem occurred when he grasped the appropriate relational pattern—when, for example, he saw a box, upon which he could climb, as a means of making a norkable connection bet een himself and the fruit suspended beyond his farthest reach. Another example of insightful behaviour was that of an ape that was confined in a cage with food visible at some distance outside the cage and with bamboo sticks available but too short to reach the food; eventually, after signs of considerable difficulty and frustration, the ape inserted one stick into another, thus fashioning a tool by means of which the food was obtained.

The concept of insight has been used by Gestalt psychologists in dealing with human thinking. Max Wertheimer used it (1945) in giving account of so exceptional a course of thought as that which led Albert Einstein to his theory of relativity. The account mas based on a series of leisurely conversations during which Einstein described, in response to Wertheimer's questions. the course and manner of his thinking. According to Wertheimer, the successive stages reported by Einstein—among them, his first glimmerings of the problem, his preoccupation nith the Maxwell equations, his lack of surprise at the results of the Michelson experiment. his incomplete satisfaction with the Lorentz transformations—were successive configurations and reconfigurations which, being partial insights, did not give a closed relational pattern until he conceived of treating the velocity of light as an invariant, thus achieving an insight which, when elaborated, transformed classical physics and brought all the terms of the problem into a single system.

Modern **Behaviourist** Approach.—The terms "trial and error" and "insight," properly understood, are both useful in describing behaviour and experience in human problem solving. But neither concept is adequate as an explanation of the processes involved. Thorndike's early conceptions of "stamping in" of correct responses and "stamping out" of incorrect responses led many to think of trial and error as a blind process in which the responses made to a problem were determined purely by chance. This is rarely, if ever, the case. Much that may be called trial and error does occur even in the thinking of highly intelligent and educated adults. But a more adequate explanation of the underlying processes is required.

Modern behaviourism (*q.v.*), stemming from the work of Clark L. Hull (1943), provides one such explanation. The conceptual system employed in this approach is complex, and its nature can only be suggested here. Among the important concepts are habit family hierarchy, goal gradient and generalization. (1) The concept of habit family hierarchy involves the view that any given stimulus situation will be associated with a number of different responses. These responses differ in their probability of occurrence and hence form a hierarchy. The position of a given response in the hierarchy will vary with the degree to which it has been reinforced previously in similar situations. Given a new problem, the hierarchy will determine the responses that occur and the order of their occurrence. (2) The concept of goal gradient includes. but is not fully represented by, the notion that the closer (in distance or time) an organism is to the goal, the stronger its motivation will be. A direct deduction is that organisms will tend to choose the shorter of two paths to the same goal. Problem situations arise when such direct paths are blocked. Other important deductions follow from this concept singly and in combination with others in the system. For example, combining the idea of goal gradient and of habit family hierarchy yields the deduction that the probability of a roundabout path being taken in solving a problem will vary inversely with the angle between the direct and roundabout paths. (3) The concept of generalization is employed to account for the fact that rewarding an organism for making a given response to a particular situation will increase the probability that it will make that response not only to that situation but also to other similar situations, the increase in probability varying directly with the similarity of the new to the original stimulus situation. Thus, a person confronted with a need to tighten a screw but with no screwdriver may readily use a fingernail file. But a person with a need to pound a nail and with no hammer may exhibit much more trial and error before using the leather heel of his shoe to solve his problem.

Modern Gestalt Approach.—Modern Gestalt theory is not so well worked out in detail with respect to problem solving and thinking as is modern behaviourism. Its concepts need to be clarified, its implications to be much more fully explored. Gestalt theory is so named because of its emphasis upon the importance of the organized whole or *gestalt;* central to the theory is the concept of the psychological field, a concept developed by Kohler (1929) and by Kurt Koffka (1935). This field may be thought of either in terms of conscious experience or in terms of underlying brain processes because according to Gestalt theory isomorphic relations exist between the two such that the same principles apply to both. In either case, the processes involved dynamically distribute and regulate themselves, determined by the actual situation in the whole field. When a person is confronted with a problem, perceptual processes occur in the brain (and in consciousness) which by dynamic interaction with each other and with memory traces result initially in "seeing the problem." Seeing the problem sets up stresses in the psychological field that determine the subsequent course of thinking. These stresses lead to reorganization or restructuring of the field enabling the person to perceive the interrelations that form the solution to the problem. Such reörganization tends to occur suddenly, but a problem may require for solution not one but a series of progressive reorganizations, thus giving the appearance of gradual solution.

The concept of insight, which mas given a central role in Köhler's early work, received less emphasis in subsequent treatments of thinking by Gestalt theorists. Moreover, it has been employed with more than one meaning. On the one hand, it has been used as a descriptive term referring to a kind of experience that occurs in problem solving; this use seems entirely defensible. On the other hand, it has been used as an explanatory concept and more or less equated nith reorganization. Neither insight nor reorganization is adequate as an explanatory concept, even taken together with the concept of the psychological field. A more adequate account is needed of the development and nature of the processes that result in the occurrence of insight.

From Trial and Error to Insight.—An important contribution toward understanding of the development of these processes was made by Harry F. Harlow (1949). Working primarily with monkeys, he undertook to determine whether the animals could with experience progress from solving a given kind of problem by trial and error to solving the same kind of problem by insight. In one of the first experiments, each monkey was confronted with a small board on which lay two objects different in colour, size and shape. If the monkey picked up the correct object, it was rewarded by finding raisins or a peanut underneath. The position of the correct object was varied randomly from trial to trial, and the trials continued until the monkey learned to choose the correct object. The unusual feature of the experiment was that when the monkey had learned to choose correctly for a given pair of objects, it was then confronted mith a new pair, this procedure being repeated many times. The monkey solved the first such problems by slow trial and error. But the important finding was that as the monkey solved problem after problem of the same kind, each new problem was solved nith greater efficiency until eventually the monkey showed perfect insight when given a new problem of the same type, solving the problem in one trial. If it chose the correct object on the first trial, it continued to do so on subsequent trials; if it chose the incorrect object on the first trial. it immediately changed to the correct object on the second trial and subsequently continued to choose it. Similar results were obtained in other experiments mith monkeys involving more complex types of problems and also in experiments with young children.

It appears that trial and error and insight are but aspects of the same underlying processes. Harlow's data indicate that in a very real sense animals, both human and at least some subhuman, learn to think.

Information Processing.—A theory of problem solving quite different from those thus far described was advanced by Allan Newell, J. C. Shaw and Herbert A. Simon (1958). This theory explains behaviour in problem solving in terms of what are called information processes. The thinking human being is regarded as an information processing system. Such a system involves memories that contain symbolized information and are interconnected by various ordering relations. The system also includes a number of primitive information processes, which operate on the information in the memories, together with a perfectly definite set of rules for combining these processes into whole programs of processing. It is possible to deduce unequivocally from a given program what behaviour will be generated. Explanation of observed behaviour, in terms of this theory, consists in constructing the program of primitive information processes which will generate that behaviour. The writing of a program requires a precise language, and special so-called information processing languages have been created for this purpose.

Modern high-speed electronic computers work in terms of what are called machine languages. They can, however, be provided with interpretive programs that enable them to understand these special information processing languages. The important consequence is that a program written in an information processing language can be run on a computer to determine precisely what behaviour it will generate. The consequences of a program also can be determined by hand simulation. but the time required would often be excessive. It should be emphasized that this approach does not depend upon any crude analogy between the structure of a computer and that of the human brain. The only function of a computer is as a tool to determine quickly whether the consequences of a program are in fact consistent with the observed behaviour it is supposed to explain.

If a program is to be more than an *ex post facto* explanation, it must, of course, not only generate the behaviour it was written to account for, but also predict the effect on behaviour of changing conditions.

For some kinds of problems, processes are known which have the very valuable property that if the problem has a solution, the process will, sooner or later, produce it. Such a process is called an algorithm. A simple example of an algorithm would be the process of opening a safe by trying all possible combinations, testing each one in turn to see if it unlocks the safe. For some problems, algorithms are knoan but require far too much time to be practically useful. No one is able to choose his moves in chess, for example, by exploring all possible continuations of the game to termination, a procedure that would be algorithmic.

A process that may solve a particular kind of problem, but that offers no guarantee of doing so, is called a heuristic. In an algebraic problem. for example, introduction of an auxiliary unknown may lead to the solution but offers no guarantee that it will do so. For most problems, only heuristic processes are available. Even with problems for which both an algorithm and a heuristic are knoan, the heuristic process may be preferable because it requires much less time. Programs written to account for observed behaviour in problem solving involve both algorithms and heuristics, but make much more use of the latter than the former. These processes which are important in problem solving are themselves the result of learning, presumably similar to that observed by Harlow in his studies.

An example of a program that will solve problems is the Logic Theorist, a program written by Newell, Shaw and Simon and capable of discovering proofs for theorems in symbolic logic, or more precisely, in the sentential calculus. By using an appropriate interpretive program, the Logic Theorist was run repeatedly upon a high-speed digital computer. In one experiment. the Logic Theorist, employing the same axioms, definitions and rules used in the Pvincipia *Mathematica* of Alfred North Whitehead and Bertrand Russell, was presented with the problem of constructing in turn a valid proof of each of the 52 theorems in Chapter 2 of the Pvincipia in the order in which they appear there. Whenever a theorem mas proved, it was stored in memory and was available for use together with the five original axioms for use in proving subsequent theorems. The Logic Theorist succeeded in proving 38 of the 52 theorems, the time required to construct a proof varying from less than a minute to more than 15 minutes. The success of the Logic Theorist depends upon the effective use of heuristics. Heuristics are important in human problem solving, but much remains to be done to clarify their nature, variety and role.

Thinking in Relation to Other Psychological Processes.—Attempts have been made to understand thinking by considering it in relation to other psychological processes, especially those representing the basic needs, desires and urges of the organism.

Freud.—The strongest single influence in making this problem focal was that exerted by Sigmund Freud (1920, 1933). According to Freud, the function of thinking and indeed of all cognitive processes is to procure satisfactions for the primal organic needs, especially those represented by sexual desires that repression has rendered unconscious. In his early teachings, he strongly emphasized the point that all human motives spring from these primitive desires, and that by comparison the intellectual processes not only play a minor and subsidiary role in human life but are so weak as to be subject, under the influence of their powerful masters, to perversions such as rationalization, fantasy and other forms of wishful thinking. In his later writings, Freud considered the cognitive processes more directly. Here he treated perception as a device the organism develops to gain a true representation of external reality, the source of all the means to real, not merely fantasied, satisfactions; in this connection he treated thinking as a set of elaborative operations between perception and action, occasioned by inevitable difficulties and delays in obtaining such satisfactions. As means of coping with real situations, including the desires themselves, the cognitive processes were accorded a more important role than that formerly assigned them, but Freud still regarded them as secondary in function and power to the instinctual drives, a view that is highly questionable.

Genetic Approach.—The wider context of thinking includes not only its psychological setting but also its genetic and phylogenetic history and the social field in which it operates. The genetic approach to the problem of thinking is illustrated by the extensive work of Jean Piaget (1920, 1950, 1951). By systematically questioning children of different ages and by conducting experiments, Piaget and his co-workers undertook to chart the course of human intellectual development, tracing through the successive stages of childhood characteristic changes in children's concepts of the physical world and also of the social world.

Social and *Cultural* Approach.—Thinking has also been studied in its social and cultural setting. The social sciences, especially cultural anthropology, have insistently maintained that thinking is so strongly conditioned by cultural factors that very different ways of thinking develop in different cultural milieus. To take a single illustration, B. Malinowski (1938) showed that a language is largely determined by the ways of life of a given culture, and it has become increasingly evident through logical, psychological and sociological investigations that a person's language is a powerful determinant of the way in which he apprehends his physical and social environment, and hence of many of the deeply rooted, unconscious assumptions upon which his thinking operates.

THIOPHENE is an organic sulfur compound that resembles benzene physically in that it is a colourless, water-insoluble liquid boiling at 84° C. (benzene boils at 80°). It resembles benzene also in such chemical reactions as bromination, nitration and sulfonation, but differs in being more reactive. It has the chemical formula C_4H_4S (I).

Although originally isolated from coal-tar benzene by V. Meyer (1883), thiophene is prepared more easily in other ways. A convenient laboratory synthesis is dry distillation of an intimate mixture of sodium succinate and phosphorus sulfide (P_4S_7). Similarly, by heating a mixture of acetonylacetone (CH_3COCH_2-CH_2COCH_3) and phosphorus sulfide, 2,5-dimethylthiophene (II) is obtained.

In the industrial manufacture of thiophene, mixtures of butane or butene and sulfur or sulfur dioxide are heated at 600° C. for short periods. Similarly, 2-methylthiophene and 3-methylthiophene are formed when pentane and isopentane, respectively, are treated in this way. The important radicals in the thiophene series are 2-thienyl (III), 2-thenyl (IV) and 2-thenoyl (V).

A delicate test for thiophene is afforded by reaction with isatin and sulfuric acid. If thiophene is present, as in coal-tar benzene, an intensely blue solution of indophenin results. This reaction is not encountered with benzene. Others in this category are the reactions of thiophene with cyanogen bromide to yield bromothiophene and with acetyl chloride in the presence of titanium tetrachloride to yield acetothienone, the thiophene analogue of acetophenone. The thiophene analogue of phenol, 2-thienol, cannot be prepared by methods that are industrially successful for phenol but can be made from 2-thienyl-magnesium bromide by reaction with oxygen at 0° C. In contrast to phenol, thienol is quite unstable.

Although dyes, plastics, solvents, explosives and the like can be made from thiophene, they frequently are inferior to those made from benzene. Hence, uses have been slow in developing. One application is in the manufacture of pharmaceuticals such as the antihistaminic drug thenylene (or Histadyl), of the structure

$$\left.\begin{array}{r}\text{2-pyridyl}\\ \text{2-thenyl}\end{array}\right\rangle \text{N-}CH_2CH_2N(CH_3)_2$$

Certain thiophene derivatives occur in nature, one being "terthienyl" or dithienyl-thiophene, a blue solid found in the petals of marigolds. Another more complex derivative is biotin, the growth-promoting factor in yeast, liver or eggs.

THIRD DEGREE. Originally a U.S. slang or cant term, but now in common use in the United States and coming into such use in Great Britain, to designate the employment of brutal methods by police or prosecuting authorities to extort information or confessions from persons in custody. The phrase is believed to have been suggested by the third Masonic degree, that of master Mason, which is conferred with considerable ceremony.

The phrase as often employed includes not only the use of physical violence, but also such forms of torture as depriving a prisoner of food, drink, sleep and toilet facilities and the prolonged and uninterrupted interrogation of him when exhausted, suffering and broken down by such deprivations. It is more commonly applied to those forms of physical assault (such as beating with a rubber hose) which produce pain but leave no traces.

Since admissions and confessions of guilt have great probative weight when made voluntarily, it is obvious that unscrupulous officials interested in procuring convictions may be tempted to force unwilling confessions by improper means, and falsely to represent such confessions as voluntary. In several U.S. states, assertions that such methods were used to extort confessions or to elicit information were for some time so common as seriously to disturb the courts. Similar charges have been made in some criminal trials in England. (C. A. P.; X.)

THIRLWALL, CONNOP (1797–1875), English bishop and historian, was born at Stepney, London, on Jan. 11, 1797. He was educated at Charterhouse and at Trinity college, Cambridge. In Oct. 1818 he was elected to a fellowship, and went for a year's travel on the continent. On his return he settled down to study law, but without much zeal, and in 1827 he definitely abandoned law, and was ordained deacon. At Rome in 1819 he had fallen in with Christian C. J. Bunsen, and since that time had been interested in German literature. He now joined with Julius C. Hare in translating Barthold G. Niebuhr's *History* of Rome (1828). On Hare's departure from Cambridge in 1832, Thirlwall became assistant college tutor and was involved in the controversy upon the admission of Dissenters which arose in 1834. Thirlwall, in replying to objections by Thomas Turton, pointed out that no provision for theological instruction was in fact made by the colleges except compulsory attendance at chapel, and that this was mischievous. After this outburst he had to resign his position. Nevertheless he received from Lord Brougham the living of Kirby-under-Dale in Yorkshire and began his *History* of Greece (1835–44), which remained a standard work.

In 1840 Thirlwall was raised by Lord Melbourne to the see of St. David's. The great monument of his episcopate is the 11 famous charges in which he from time to time reviewed the position of the English Church with reference to pressing questions of the day—addresses at once judicial and statesmanlike, full of charitable wisdom and massive sense. Thirlwall was one of the four prelates who refused to inhibit Bishop John Colenso from preaching in their dioceses. and the only one who withheld his signature from the addresses calling upon Colenso to resign his see. He took the liberal side in the questions of Maynooth, of the admission of Jews to parliament, of the Gorham case, and of the educational conscience clause. He was the only bishop who voted for the disestablishment of the Irish Church.

During his latter years Thirlwall took great interest in the revision of the Authorized Version of the Bible, and was chairman of the revisers of the Old Testament. He resigned his see in May 1874, and retired to Bath, where he died on July 27, 1875. He lies in Westminster Abbey in the same grave as Grote.

Thirlwall's *History of Greece* (new ed. 1845–52) remains a standard book. *See* his *Remains, Literary and Theological,* ed. J. J. S. Perowne in three volumes (1877–80), two of which are occupied by his charges; *Letters, Literary and Theological,* with a connecting memoir, ed. J. J. S. Perowne and L. Stokes (1881), and *Letters to a Friend* (Miss Johnes of Dolaucothy), ed. Dean Stanley (1881). They were originally published by Dean Stanley, and there is a revised and corrected edition. For a general view of Thirlwall's life and character, *see* the *Edinburgh Review,* vol. cxliii.; for a picture of him in his diocese, *Temple Bar,* vol. lxxvi.

THIRSK, an old market town in the North Riding of Yorkshire, Eng., 23 mi. N.N.W. of York by road, on the Cod Beck, a tributary of the Swale river. Pop. (1951) 2,670. The district is known as the Vale of Mowbray. Thirsk is first mentioned as a borough in a charter granted by Roger de Mowbray to Newburgh priory in the reign of Henry II. The Perpendicular church of St. Mary with its 80-ft. tower is one of the most beautiful churches in the Riding. Thirsk was represented in parliament from 1552–53 until 1885. There is a racecourse.

THIRTY YEARS' WAR (1618–1648), the general name of a series of wars in Germany which began formally with the claim of Frederick, the elector palatine, to the throne of Bohemia and ended with the treaty of Westphalia. It was primarily a religious war and was waged with the bitterness characteristic of such wars, but at the same time political quarrels were interwoven with the religious question: with the consequence that the armies, considering themselves as their masters' retainers rather than champions of a cause, plundered and burned everywhere, military violence being in no way restrained by expediency.

Formation of the "Union" and the "League."—Fifty years before the outbreak of the war the Convention of Passau had compromised the burning questions of the Reformation, but had left other equally important points as to the secularization of church lands and the consecration of Protestant bishops to the future. Each such case, then, came before the normal government machine—a Diet so constituted that even though at least half of the secular princes and nine-tenths of their subjects were Protestants, the voting majority was Catholic. Moreover, the Jesuits had rallied and disciplined the forces of Catholicism, while Protestantism, however firm its hold on the peoples, had dissipated itself in doctrinal wrangles. The strongest side was that which represented conservatism, peace and Catholicism. Realizing this from the preliminary mutterings of the storm, the Protestant princes formed a "Union," which was promptly answered by the Catholic League. This group was headed by the wise and able Maximilian of Bavaria and supported by his army, which he placed under a soldier of long experience and conspicuous ability, Count Tilly.

The Bohemian Movement.—The war arose in Bohemia, where the Protestant magnates refused to elect Ferdinand of Austria to the vacant throne, offering it instead to Frederick, the elector palatine. But the aggrandizement of this elector's power was entirely unacceptable to most of the Protestant princes—to John George of Saxony above all. They declared themselves neutral, and Frederick found himself an isolated rebel against the Emperor Ferdinand.

Even thus early the struggle showed itself in the double aspect of a religious and a political war. Just as the Bohemians and their nominee found themselves looked upon askance by the other Protestants, so the emperor himself was unable to call upon Maximilian's Army of the League without promising to aggrandize Bavaria. Only the incoherence of the rebels saved Ferdinand. They ordered taxes and levies of soldiers, but the taxes were not collected, and the soldiers, unpaid and unfed. plundered the country-side. The only coherent force was the mercenary corps of Ernst von Mansfeld, which, thrown out of employment by the termination of a war in Italy, had entered the service of Frederick. Nevertheless, the Bohemians were conspicuously successful at the outset: they won several engagements, and appeared before Vienna itself. Moravia and Silesia supported the Bohemians, and the Austrian nobles attempted, in a stormy conference, to wrest from Ferdinand not only religious liberty but also political rights that would have made Austria and Bohemia a loose confederation of powerful nobles. Ferdinand firmly refused, though the deputation threatened him to his face, and the tide ebbed as rapidly as it had flowed. No sooner had Frederick accepted the crown than Maximilian let loose the Army of the League. Spanish aid arrived. Spinola with 20,000 men from the Low Countries and Franche Comté invaded the Palatinate, and Tilly, with a combined army of Austrians and Bavarians crushed the Bohemians at the battle of the Weisser Berg near Prague (Nov. 8–18, 1620). With this the Bohemian war ended. Some of the nobles were executed, and Frederick, the "Winter King," was put to the ban of the empire. But the emperor's revenge alarmed the Union princes. They were Protestants, and neither in religion nor in politics could they suffer an all-powerful Catholic emperor. Moreover, the alternative to a powerful emperor was a powerful Bavaria, and this they liked almost as little.

Predatory Armies.—There still remained for the army of Tilly the reduction of the smaller garrisons in Bohemia, which when finally expelled rallied under Mansfeld, the last general of a lost cause. Then there began the wolf-strategy that was the distinguishing mark of the Thirty Years' War. An army even of ruffians could be controlled, as Tilly controlled that of the League, if it were paid. But Mansfeld, the servant of a shadow king, could not pay. Therefore "he must of necessity plunder where he was. His movements would be governed neither by political nor by military considerations. As soon as his men had eaten up one part of the country they must go on to another." These movements were for preference made upon hostile territory, and Mansfeld was so far successful in them that the situation in 1621 became distinctly unfavourable to the emperor. Tilly and the League Army fought warily and did not risk a decision. Thus even the proffered English mediation in the German war might have been accepted but for the fact that in the Lower Palatinate a corps of English volunteers, raised by Sir Horace Vere for the service of the English princess Elizabeth, the fair queen of Bohemia, found itself compelled, for want of pay and rations, to live, as Mansfeld lived, on the country along the Rhine. This brought about a fresh intervention of Spinola's Spaniards who had been destined to the interminable Dutch war. Moreover Mansfeld, having thoroughly eaten up the Palatinate, decamped into Alsace, where he seized Hagenau and wintered in safety.

The winter of 1621–22 passed in a series of negotiations which failed because too many interests, inside and outside Germany, were bound up with Protestantism to allow the Catholics to speak as conquerors, and because the cause of Protestantism was too much involved with the cause of the elector palatine to be taken in hand with energy by all Protestant princes. But Frederick and Mansfeld found two allies. One was Christian of Brunswick, the gallant young knight-errant, titular bishop of Halberstadt, queen Elizabeth's champion, and withal, though he called himself Gottes Freund, der *Pfaffen Feind,* a plunderer of peasants as well as of priests. The other was the margrave George Frederick of Baden-Durlach, reputed to be of all German princes the most skilful sequestrator of ecclesiastical lands. In April 1622, while Vere garrisoned the central fortresses of the Palatinate, Mansfeld, Christian and George Frederick took the field against Tilly, who at once demanded assistance from Spinola. The latter, though engaged with the Dutch, sent a corps under his subordinate Cordova. Mansfeld and the margrave of Baden defeated Tilly at Wiesloch (April 17–27, 1622). But soon the allies had to separate to find food. Then Cordova came up, and Tilly and the Spaniards combined defeated George Frederick at Wimpfen on the Neckar (April 26–May 6). Cordova chased Mansfeld back into Alsace, while Tilly went north to oppose Christian of Brunswick on the

Main. On June 10–20 the latter's army was almost destroyed by the League Army at Höchst. Mansfeld, and with him Frederick, had already set out from Alsace to join Christian, but when that leader arrived with only a handful of beaten men, the war was practically at an end. Frederick took Mansfeld and Christian back to Alsace, and after dismissing their troops, retired to Sedan. Henceforth he was a picturesque but powerless exile, and his lands and his electoral dignity, forfeited by the ban, went to the prudent Maximilian, who was created by the Emperor elector of Bavaria.

Mansfeld and Christian of **Brunswick.**—The next act in the drama, however, had already begun with the adventures of the outlaw army of Mansfeld and Christian. After Hochst, had it not been for them, the war might have ended in compromise. James I. of England was busy as always with mediation schemes. Spain, being then in close connection with him, and the Protestant princes of North Germany being neutral, a diplomatic struggle over the fate of the Palatinate might have ended in a new convention of Passau that would have regulated the present troubles and left the future to settle its own problems. The struggle would only have been deferred, it is true, but meanwhile the North German Protestants remained powerless and inactive, while Tilly's army was kept in hand to deal with the adventurers.

These, after eating up Alsace, moved on to Lorraine, whereupon the French Government "warned them off." But ere long they found a new employment. The Dutch were losing ground before Spinola, who was besieging Bergen-op-Zoom, and the States-General invited Mansfeld to relieve it. The adventurers moved straight across Luxemburg and the Spanish Netherlands to the rescue. Cordova barred the route at Fleurus near the Sambre, but the desperate invaders, held together by the sheer force of character of their leaders, thrust him out of their way (Aug. 19–29, 1622) and relieved Bergen-op-Zoom. But ere long, finding Dutch discipline intolerable, they marched off to the rich country of East Friesland.

Their presence raised fresh anxieties for the neutral princes of North Germany. In 1623 Mansfeld issued from his Frisian stronghold, and the threat of a visitation from his army induced many princes of the Lower Saxon Circle to join him. Christian was himself a member of the Circle, and although he resigned his bishopric, he was taken, with many of his men, into the service of his brother, the duke of Brunswick-Wolfenbüttel. Around the mercenary nucleus gathered many thousands of volunteers, for the towns and the nobles' castles alike were alarmed at the progress of the Catholics, who were reclaiming Protestant bishoprics. But this movement was nipped in the bud by the misconduct of the mercenaries. The authorities of the Circle ordered Christian to depart. He returned to Holland, therefore, but Tilly started in pursuit and caught him at Stadtlohn, where on July 28–Aug. 6, 1623 his army was almost destroyed. Thereupon the Lower Saxon Circle, which, like the Bohemians, had ordered collectively taxes and levies of troops that the members individually furnished either not at all or unwillingly, disbanded their army to prevent brigandage. Mansfeld, too, having eaten up East Friesland, returned to Holland in 1624.

Foreign Intervention — The only material factor was now Tilly's ever-victorious Army of the League, but for the present it was suspended inactive in the midst of a spider's web of European and German diplomacy. Spain and England had quarrelled. The latter became the ally of France, over whose policy Richelieu now ruled, and the United Provinces and (later) Denmark joined them. Thus the war was extended beyond the borders of the empire, and the way opened for ceaseless foreign interventions. From the battle of Stadtlohn to the pitiful end 20 years later, the decision of German quarrels lay in the hands of foreign powers. France was concerned chiefly with Spain, whose military possessions all along her frontier suggested that a new Austrasia, more powerful than Charles the Bold's, might arise. James, in concert with France, re-equipped Mansfeld and allowed him to raise an army in England, but Richelieu was unwilling to allow Mansfeld's men to traverse France, and they ultimately went to the Low Countries, where, being raw pressed-men for the most part, and having neither pay (James having been afraid to summon parliament) nor experience in plundering, they perished in the winter of 1625. At the same time a Huguenot rising paralysed Richelieu's foreign policy. Holland after the collapse of Mansfeld's expedition was anxious for her own safety owing to the steady advance of Spinola. The only member of the alliance who intervened in Germany itself was Christian IV. of Denmark, who as duke of Holstein was a member of the Lower Saxon Circle, and as king of Denmark was anxious to extend his influence over the North sea ports. Gustavus Adolphus of Sweden, judging better than any the difficulties of affronting the empire and Spain, contented himself with carrying on a war with Poland.

Intervention of Christian of Denmark. — Christian IV. raised an army in his own lands and in the Lower Saxon Circle in the spring of 1625. Tilly at once advanced to meet him. But he had only the Army of the League, the Emperor's troops being occupied in a war on Gabriel Bethlen of Transylvania. Then, like a *deus ex machina,* Wallenstein, duke of Friedland, came forward and offered to raise and maintain an army in the emperor's service. It was an army like Mansfeld's in that it lived on the country, but its exactions were systematic and the products economically used, so that it was possible to feed 50,000 men instead of 20,000. This method, the high wages which he paid, and his own princely habits and commanding personality gave it a cohesion that neither a free company nor an army of mere Lower Saxon contingents could ever hope to attain.

In 1625, Wallenstein kept his new army well away from the risks of battle until he could trust it to conquer. It was fortunate for Ferdinand that he did so. Christian IV., who had been joined by Mansfeld and Christian of Brunswick, had, in 1626, 60,000 men. Wallenstein and Tilly together had only a very slight numerical superiority, and behind them was nothing. Even the hereditary provinces of Austria were threatening revolt and Gabriel Bethlen was again giving trouble. But on the other side the English subsidies failed, and the Protestant armies soon began to suffer in consequence. Tilly opposed Christian IV.; Wallenstein, Mansfeld. The latter advanced upon Wallenstein, attacked him in an entrenched position at the Bridge of Dessau and was thoroughly defeated (April 15–25, 1626). He then wandered across Germany into Silesia and joined Bethlen. Wallenstein followed up, and by taking up strong positions, compelled Mansfeld and Bethlen to choose between attacking him and starving. So, without a battle, he brought about a truce, whereby Bethlen was disarmed and Mansfeld was required to leave Hungary. Mansfeld and Christian of Brunswick died soon afterwards, the one in Hungary, the other in Westphalia. King Christian, left alone and unable without English subsidies to carry on the war methodically, took the offensive, as Mansfeld had done, in order to live on the Thuringian countryside. But Tilly, with whom Wallenstein had left a part of his army, moved as quickly as the king, brought him to action at Liitter-am-Barenberge in Brunswick and totally defeated him (Aug. 17–27).

With this, armed opposition to Tilly and Wallenstein in the field practically ceased, but their armies continued to live on the country. Christian of Denmark slowly gave up fortress after fortress to Tilly. Wallenstein, returning from the campaign against Gabriel Bethlen, drove Christian's army through Jutland and into the sea (1627). But Wallenstein, with his dreams of a united Germany free in conscience and absolutely obedient to the emperor, drifted farther and farther away from the League. Ferdinand thought that he could fulfil the secular portion of Wallenstein's policy while giving satisfaction to the Catholics. The princes and bishops of the League continued to oppose any aggrandizement of the emperor's power at their expense and to insist upon the resumption of church lands. In this equilibrium the North German Protestant cities were strong enough to refuse to admit Wallenstein's garrisons. In 1628 Wallenstein, who had received the duchy of Mecklenburg on its rightful lord being put to the ban fcr his share in the Danish war, began to occupy his new towns, and also to spread along the coasts. But the Hanse towns rejected his overtures, and Stralsund, second-rate seaport though it was, absolutely refused to admit a garrison of his wild soldiery. The result was the famous siege of Stralsund (Feb. to Aug. 1628), in which the citizens compelled the hitherto unconquered Wallenstein army to retire. The siege was, as the result proved, a turning-point in German history. The emperor's policy of restoring order had practically universal support. But the instrument of the restoration was a plundering army. Even this might have been borne had Wallenstein been able to give Germany, as he wished, not only peace but religious freedom. When the Edict of Restitution (1629) gave back 150 northern ecclesiastical foundations to the Catholics, men were convinced that one ruler meant one religion.

Gustavus **Adolphus** of Sweden.—Rather than endure this the North Germans called in Gustavus Adolphus of Sweden and, just as Gustavus landed, the resentment of the princes of the League against Wallenstein's policy and Wallenstein's soldiers came to a head, and the emperor was forced to dismiss him. His soldiers were taken over by Tilly, and for the moment he disappeared from the scene. On Gustavus's side, a thoroughly trained army, recruited from good yeomen and stout soldiers of fortune, paid good wages, and led by a great captain, was a novelty in war that more than compensated for Tilly's numerical superiority. Gustavus, however, after landing at Peenemünde in June, spent the rest of the year in establishing himself firmly in Mecklenburg and Pomerania, in order to secure the active support of the more important Protestant princes, so as to appear as an auxiliary rather than a principal in the German conflict. First the old duke Bogislav of Pomerania, then George William of Brandenburg joined him, very unwillingly. He was soon afterwards allied with France, by the treaty of Barwalde (Jan. 1631). John George of Saxony, still attempting to stifle the war by a policy of neutrality, sent a last appeal to Vienna, praying for the revocation of the Edict of Restitution. Meanwhile Tilly had marched into north-eastern Germany, where his lieutenant Pappenheim was besieging Magdeburg. This city had twice defied Wallenstein's attempts to introduce a garrison, and it was now in arms against the League. Gustavus, as yet without active allies, thought it impossible to go forward alone, and could only hope that his sudden and brilliant storm (April 3–13) of Frankfurt-on-Oder would distract Tilly from the siege.

Sack of **Magdeburg.**—But the hope was vain and when, realizing this, he moved directly to Magdeburg's relief, his passage through the territories of the Electors of Brandenburg and Saxony was delayed by the objections of the Protestant princes. While he was negotiating with them in turn, Magdeburg, although the citizens fought desperately, was stormed, sacked and burned on the night of May 10, 1631, amidst horrors that neither of the imperialist generals was able to check. The Catholics rejoiced as though for another St. Bartholomew's day, the Protestants were paralysed, and Gustavus, accused on all hands of having allowed the Magdeburgers to perish, sorrowfully withdrew into Pomerania. But Tilly, in spite of Pappenheim's remonstrances, turned westward against Hesse-Cassel and other minor principalities whose rulers had declared for Gustavus. The king of Sweden, thereupon, advanced to Werben (at the junction of the Elbe and the Havel), where his army entrenched itself, and, in spite of sickness and famine, stoically awaited the attack. The desired result was achieved. At the end of July Tilly, returning from the west, made his appearance and was twice repulsed (July 13–23 and 18–28), losing 6,000 men out of 22,000. Thereupon, turning away from Gustavus's entrenchments, Tilly invaded Saxony, being reinforced *en route* by 20,000 men from Italy. The elector John George at once made an alliance with the Swedes.

Battle of **Breitenfeld.**—Then Gustavus advanced in earnest. He crossed the Elbe at Wittenberg. 16,000 Saxons joined his 26,000 Swedes at Düben, and some of the western Germans had already come in. Tilly had just captured Leipzig, and outside that place, carried away by Pappenheim's enthusiasm, he gave battle on Sept. 7–17 to the now superior allies. The first battle of Breitenfeld (*q.v.*) was a triumphant success for Gustavus and for the new Swedish system of war. Though the raw Saxons were routed at the outset by Tilly's men, the Swedes on the other wing drove the veterans of the League off the field in disorder, leaving 6,000 dead. Tilly himself was thrice wounded and barely escaped.

All Protestant Germany hailed Gustavus as the liberator. John George, the Swedish general Horn and the Swedish chancellor Oxenstierna united in advising Gustavus to march straight upon Vienna. Richelieu was of the same mind. But Gustavus deliberately chose to move into South Germany, there to organize the cities and the princes in a new and stronger Protestant Union, the *Corpus Evangelicorum*, and to place himself in a country full of resources whence he could strike out against the emperor, Tilly and the Rhine Spaniards in turn. The Swedish army pushed on to Mainz, where it wintered in luxury. The Palatinate was reorganized under Swedish officials and the reformed religion established again. In March 1632 the campaign was resumed. Nuremberg and Donauworth welcomed Gustavus. Tilly's army, reorganized for the defence of Bavaria, stood to fight on the Lech, but the passage was forced (April 4–14) and Tilly himself was mortally wounded. Augsburg, Munich and all the country south of the Danube were occupied without resistance. At the same time John George's Saxons, advancing into Bohemia, entered Prague without firing a shot.

Wallenstein Returns.—The emperor had now either to submit or to reinstate Wallenstein. Wallenstein demanded as the price of his services the reversal of the Edict, and power to dethrone every prince who adhered to the Swedes. His terms were accepted, and in April 1632 he took the field as the emperor's *alter ego* with a new army that his recruiters had gathered in a few weeks. He soon expelled the Saxons from Bohemia and offered John George amnesty and the rescinding of the Edict as the basis of peace. The elector, bound by his alliance with Gustavus, informed the Swedish king of this offer, and a series of negotiations began between the three leaders. But John George had too much in common with each to follow either Wallenstein or Gustavus unreservedly, and the war recommenced. The Swedish king had now to meet Wallenstein's new army of 60,000, composed of the men immortalized by Schiller's play, excellent in war and in plundering, destitute of all home and national ties, and owning allegiance to its general alone. While Gustavus in Franconia was endeavouring with little success to consolidate his *Corpus Evangelicorum* Wallenstein came upon the scene. Gustavus offered him battle. But as in 1625 Wallenstein would risk no battle until his army had gained confidence. He entrenched himself near Fürth, while Gustavus camped his army about Nuremberg and a contest of endurance ensued. Wallenstein, aided by his superiority in irregular cavalry, was able to starve for three days longer than the king, and at last Gustavus furiously attacked the entrenchments (battle of the Alte Veste, Aug. 24–Sept. 3, 1632) and was repulsed with heavy losses. Thereupon he retired, endeavouring in vain to tempt Wallenstein out of his stronghold by making his retreat openly and within striking distance of the imperialists. Wallenstein had other views than simple military success. Instead of following Gustavus he marched into Saxony, his army plundering and burning even more thoroughly than usual in order to force the Saxons into peace. Gustavus followed with the swiftness that was peculiar to the Swedish system, and concentrated at Erfurt when Wallenstein had scarcely mastered Leipzig. But it was now late in the season, and Wallenstein hoped to spin out the few remaining weeks of the campaign in an entrenched position. Gustavus, without waiting for Arnim's Saxons to join him, suddenly moved forward, and on Nov. 6–16 the battle of Lutzen (*q.v.*) was fought, a battle as fierce even as Breitenfeld. Gustavus was slain, but Wallenstein's army was driven from the field.

The League of **Heilbronn.**—The fall of Gustavus practically determined the intervention of France, for Richelieu supported all electors, Catholic or Protestant, against the central power at Vienna as part of his anti-Spanish policy, and French assistance was now indispensable to the Protestants. For although Lützen was a victory and the Protestant circles formed the League of Heilbronn in April 1633, the emperor was really in the ascendant. John George of Saxony needed but little inducement to make peace. But the tragedy of Lützen was soon to be followed by the tragedy of Eger. Wallenstein, gradually forming the resolve of forcing peace on Germany with his army, relaxed his pressure on Saxony, and flung himself upon the Swedish garrisons in Silesia.

Winning a victory at Steinau (Oct. 11, 1633) and capturing one town after another, he penetrated almost to the Baltic. But he was recalled to the south-west before his operations had had any effect. The Swedish army, now under Bernhard of Saxe-Weimar, Horn and Banér, had returned to the South, and took Regensburg from Maximilian's army. But it was now late in the year and Wallenstein was intent upon peace. With this object he endeavoured to secure the higher officers of the army, but these were gradually won over by Spanish emissaries; the emperor, having decided to continue the war in alliance with Spain, dismissed his general for the second time. Wallenstein then openly attempted to unite the Swedish, Saxon and other Protestant armies with his own, so as to compel all parties to make peace. But his officers would not follow, the *coup d'état* failed, and Wallenstein was murdered at Eger by his own lieutenants, with the full sanction of the Emperor (Feb. 15–25, 1634).

All idea of German unity died with him, and for the next 14 years Germany was simply the battle-ground of French, Spanish, Austrian and Swedish armies, which, having learned the impunity and advantages of plunder in the school of Mansfeld and Wallenstein, reduced the country to a state of misery that no historian has been able to describe, save by detailing the horrors of one or other village among the thousands that were ruined. Germany remained for a century in the stillness of exhaustion.

Battle of **Nordlingen.**—Success was for the present with the emperor and Spain. Under the leadership nominally of the king of Hungary, Ferdinand's heir, but really of Gallas, the army recaptured Regensburg and Donauworth, and when the Spanish Cardinal Infante joined them with 15,000 men on his way from Italy to the Netherlands, they were invincible. Bernhard of Weimar and the Swedes attacked them in an entrenched position at Nordlingen (Aug. 27/Sept. 6, 1634) and was beaten with absolutely ruinous loss. The model army of Gustavus perished there, and for the rest of the war a Swedish army, except for some advantages of organization and technical form, was intrinsically no better than another. John George, having obtained from Ferdinand a compromise on the question of the Edict, agreed to the peace of Prague (May 20–30, 1635), wherein all that was Protestant in 1627 was to remain so, or if since resumed by the Roman Church to be returned to the Lutherans. A certain number of princes followed John George's example on the same terms. There was now no ideal, no objective, common even to two or three parties. Gustavus's *Corpus Evangelicorum* as a German institution was moribund since Nordlingen, and Richelieu and the Spaniards stepped forward as the protagonists.

The **Policy** of **Richelieu.**—The centre of gravity was now the Rhine valley, the highroad between Spanish Italy and the Spanish Netherlands. Richelieu had, as the price of his assistance after Nordlingen, taken over the Alsatian fortresses held by the Swedes, and in May, just before the treaty of Prague was signed, he declared war on Spain. The French army numbered 130,000 men in 1635, and 200,000 in the year after. One army assembled in Upper Alsace for the attack of the Spaniards in Franche Comté; another occupied Lorraine, which had been conquered in 1633; a corps under Henri de Rohan was despatched from the same quarter across Switzerland, to expel the enemy from the Valtelline, Another force, co-operating with the duke of Savoy, was to attack the Milanese. Bernhard was to operate in the Rhine and Main country. Having thus arranged to isolate the Spanish Netherlands, Richelieu sent his main army, about 30,000 strong, thither to join Frederick Henry of Orange and so to crush the Cardinal Infante. This was strategy on a scale hitherto unknown in the war. Richelieu had unified France under the single authority of the king, and his strategy, like his policy, was masterful and clear. But the event proved that his scheme was too comprehensive. Richelieu proposed to strike at each of the two halves of his enemy's power at the same time as he separated them. His forces were not sufficient for these tasks and he was therefore compelled to eke them out, both in Italy and the Netherlands, by working with allies whose interests were not his. Popular outbreaks among the Brabanters and Flemings led Frederick Henry to withdraw to his own country and in 1636 the French northern army had to face the whole of the Cardinal Infante's forces. In Italy the Franco-Piedmontese army achieved practically nothing. In Alsace and Lorraine neither side was strong enough to prevail. Bernhard waged a desultory campaign in Germany, and later, when supplies gave out he and his army were taken into the French service. In eastern Germany the consequences of the peace of Prague were that Saxony, Brandenburg and other States, signatories to the treaty, were *ipso facto* the enemies of those who continued the war. Thus John George turned his arms against the Swedes in his neighbourhood. But their commander Banér was as superior in generalship as he was inferior in numbers, and held the field until a truce between Sweden and Poland set free a fresh Swedish corps that had been held ready for eventualities in that country. This corps, under Torstensson, joined Banér in October, and on Nov. 1 they won an action at Domitz on the Elbe.

Thus Richelieu's great scheme was only very partially executed. The only important military events of the year took place outside Germany; within Germany men were chiefly occupied in considering whether to accept the terms of the peace of Prague. But the land had no rest, for the armies were not disbanded. In 1636 the movements foreshadowed in 1635 were carried out with energy. John George, aided by an imperialist army, threatened to interpose between Banér and the Baltic. But Banér was too quick for them. Before the Brandenburg contingent could join John George, he brought on a general action at Wittstock (Sept. 24–Oct. 4, 1636). The elector had 30,000 men against 22,000 and sought to attack both in front and rear. But while his entrenchments defied the frontal attack Banér threw most of his army upon the enveloping force and crushed it. The Swedes lost 5,000 killed and wounded, the combined army 11,000 killed and wounded and 8,000 prisoners. The prestige of so brilliant a victory repaired even Nordlingen, and many North German princes who were about to make peace took fresh heart.

Invasion **of** France. — In the west, though there were no such battles as Wittstock, the campaign of 1636 was one of the most remarkable of the whole war. The Cardinal Infante was not only relieved by the retreat of the Dutch, but also reinforced by a fresh army[1] under a famous cavalry officer, Johann von Weert. He prepared, therefore, to invade France from the northwest. The French were too much scattered to offer an effective resistance, and the Cardinal Infante's generals took Corbie, passed the Somme and advanced on Compikgne. For a moment Paris was terror-stricken, but the Cardinal Infante missed his opportunity. Louis XIII. and Richelieu turned the Parisians from panic to enthusiasm. The burghers armed and drilled, money, too, was willingly given, and some 12,000 volunteers went to Compikgne, where all levies and reinforcements were concentrated. Thus the army at Compiègne was soon 50,000 strong. It was only half mobile owing to its rawness and its "trained-band" character, but the Spaniards and Bavarians retired unmolested to oppose Frederick Henry in the Low Countries.

During the episode before Compiègne another storm burst on the eastern frontier of France. This was the inroad into Burgundy of Gallas with the main imperialist army. He took a few small towns, but Dijon and the entrenchments of Bernhard's army there defied him, and his offensive dwindled down to an attempt, soon abandoned, to establish his army in winter quarters in Burgundy.

War in Italy. — In Italy the duke of Savoy with his own army and a French corps under Créqui advanced to the Ticino, and an action in which both sides lost several thousand men was fought at Tornavento, a few miles from the future battlefield of Magenta, to which in its details this affair bears a singular resemblance (June 22, 1636). But the victory of the French was nullified by the refusal of Victor Amadeus, for political reasons, to advance on Milan.

The campaign of 1637, on the French and Spanish side, was not productive of any marked advantage to either party. From Catalonia a Spanish army invaded Languedoc, but was brought to a standstill in front of the rocky fortress of Leucate and defeated with heavy losses by the French relieving army under Schom-

[1]Composed partly of Bavarians, partly of Cologne troops.

berg. On the Low Countries frontier the cardinal de La Valette captured Câteau Cambrésis, Landrecies and Maubeuge.

War on the Rhine.—On the Rhine and in the adjacent countries Johann von Weert, returning from Belgium with his Bavarians, captured Ehrenbreitstein, the citadel of Coblenz, and expelled small French detachments from the electorate of Trier, whose ruler, the archbishop, had been put to the ban by the emperor. Then, passing into the Main valley, he took Hanau. The main imperialist army, still under Gallas, had departed from Alsace to the east in order to repair the disaster of Wittstock, and Charles of Lorraine was defeated by Bernhard on the Saône in June, after which Bernhard advanced vigorously against Piccolomini, the imperialist commander in Alsace. But soon Piccolomini was joined by Johann von Weert, and Bernhard retired again.

In the north-east the effect of Wittstock proved but transient. In 1638 Banér found himself the target of several opponents. The Saxons did no more than defend their own country, but the imperialists and Bavarians uniting under Gen. Geleen manoeuvred Banér out of his strongholds on the Elbe. He retreated on the Oder, but there found, not the expected assistance of Wrangel's Pomeranian army, but Gallas with the main imperial army which had hurried over from the west. Banér escaped only by a stratagem. Deluding Gallas with an appearance of retreat into Poland, he slipped northwards, joined Wrangel, and established himself for a time in Pomerania. Gallas ruined his army by exposing it to an open winter in this desolate country, and at last retired to the Elbe.

Fighting in the Netherlands and Alsace.—In 1638 the French operations in Italy, Belgium and Spain were in the main unsuccessful. In Italy the Spanish advanced to the Sesia and took Vercelli. In the Low Countries Prince Thomas and Piccolomini repulsed in turn the Dutch and the French. In the south the Prince of Condé led from Bayonne an invading army that was to dictate terms at Madrid, but failed ignominiously before the small frontier fortress of Fontarabia. But the case was different in Alsace. There Richelieu was more than ever determined to strike at the Spanish power, and there too was Bernhard, who hoped that Alsace was to be his future principality, with the survivors of Breitenfeld and Nordlingen, now in French pay under the name of the "Weimar Army." Bernhard had wintered about Basle, and began operations by taking a few towns in the Black Forest. Johann von Weert, however, fell upon him by surprise and drove him away (Feb. 28). But Bernhard reassembled his adventurers and invited them to return and beat the imperialists at once. The outcome was the battle of Rheinfelden, in which the redoubtable Weert, who had terrified Paris in 1636, was taken prisoner and nis army dissipated (March 3). Bernhard later invested Breisach and received its surrender when the garrison had eaten the cats, dogs and rats in the place, on Dec. 17.

In the course of 1638 peace negotiations were carried on at Cologne and Hamburg, but the war still dragged on. In the east, 1639 began with Banér's pursuit of the retreating Gallas. Thanks to his skill the Swedish star was again in the ascendant. Banér crossed the Elbe, inflicted a severe defeat on the imperialists at Chemnitz (April 14, 1638), and then after overrunning western Saxony advanced into Bohemia. But he contented himself, after an unsuccessful attempt upon Prague, with thoroughly eating up the country and, as winter came on, he retired into the Saxon mountains.

France and Spain.—In 1639, as before, Richelieu's attacks on Spain, other than those directed upon Alsace and Baden, were unsuccessful. In the north the French devoted this year, as they had devoted 1637 and 1638, to a methodical conquest of walled towns in view of a future *frontière de fer*. The two objectives selected, Hesdin and Thionville, were far apart, and Piccolomini, by a forced march from Liège and Huy through the Ardennes, flung himself upon the besiegers of Thionville before their "circumvallation" was completed, and being greatly superior in numbers he almost annihilated them (June 7, 1639). But on the Flemish-flank Hesdin was driven to surrender. On the side of the Pyrenees Condé as usual showed himself both unlucky and incapable. In Italy Cardinal de La Valette died after allowing Prince Thomas to win over Savoy to the emperor's side and seeing almost every French post lost.

His successor was the duc d'Harcourt, called by his men "Cadet-la-Perle" on account of his earrings, but a bold and exceedingly competent soldier. Under him served Turenne, hitherto known only as a younger brother of the duke of Bouillon. Harcourt successfully revictualled Casale, and beat the Savoyards and Imperialists in the Route de Quiers (Nov. 29).

In Alsace Bernhard was carried off by a fever just as he was preparing to fight his way to a junction with Baner. Nevertheless he was fortunate in the opportunity of his death, for his dream of a duchy of Alsace had already brought him into conflict with Richelieu, and their conflict could only have ended in one way. Another event of importance in this year was the episode of the Spanish fleet in the Downs. Now that the land route was imperilled the sea communications of Spain and Belgium were brought into use. A squadron sailed from Spain for the Netherlands, and, though it evaded the now powerful French navy, it was driven into English territorial waters by the Dutch. Charles I. of England offered France free access to the victim if France would restore the Elector Palatine, offered Spain protection if she would furnish him with funds for his army. But the Dutch, contemptuous of his neutrality, sailed in and destroyed the fleet at anchor.

In 1640 the French still kept up their four wars in Belgium, Germany, Italy and Spain. But the Belgian and Spanish frontiers were no longer directly attacked. The Catalans turned their arms against the old enemy Castile and Portugal declared herself independent under a king of the house of Braganza. In the Low Countries Louis XIII. himself presided over the siege of the important fortress of Arras, which surrendered on Aug. 8.

Casale and Turin.—In Italy, however, Cadet-la-Perle kept the moral ascendancy he had won in the brave action of the *Route de Quiers*. In April with 10,000 men he advanced from Carignan against the 20,000 Spaniards who were besieging Casale and attacked their line of circumvallation boldly and openly on April 29. Half of Leganez's army was killed or captured. After this, Harcourt promptly turned upon Prince Thomas, and then followed one of the most curious episodes in military history. Thomas, himself defending Turin, was besieging the French who still held the citadel, while Harcourt, at once besieging the town and attempting to relieve the citadel, had, externally, to protect himself against Leganez's army which was reorganized and reinforced from Naples and the Papal States. Harcourt's courage and the disunion of his opponents settled the problem. Their general attack of July 11 on the French lines was made not simultaneously but successively, and Harcourt repulsed each in turn with heavy losses. Soon afterwards the French received fresh troops: the citadel was relieved and the town surrendered. Leganez retired to Milan.

In Germany Banér's course was temporarily checked and when at last Bernhard's old army, under the duc de Longueville, crossed the Rhine and joined Banér in Thuringia, the country could not support the combined army. The Weimar army retired to the Rhine valley and Banér to Waldeck. A fresh opportunity came to Banér in the winter months of 1640–41. Negotiations for peace were constantly in progress, but no result seemed to come out of them. The Diet was assembled at Regensburg. Banér suddenly moved south to surprise the Diet, for the defence of which all available troops were hurried up by the emperor. The Weimar army under Gubbriant joined the Swedes *en route*, and the combined army reached the objective. But a thaw hindered them and gave the emperor time to concentrate his forces, and the raid failed. On May 20 Banér, worn out by fatigue, died, and Torstensson succeeded to the command. The war had now receded far from Alsace, which was firmly held by France, but Marcourt's continued success in Piedmont and the trouble to Spain caused by the Catalan and Portuguese insurrection was partly balanced by France's own difficulties in the abortive conspiracy against Richelieu.

In Dec. 1641 there began at Miinster and Osnabrück in Westphalia the peace negotiations which, after eight more years of spasmodic fighting, were to close this ruinous war. In 1642 Tors-

tensson crossed the Elbe and besieged Leipzig. The imperialist army, which was joined by the Saxons when their country was again the theatre of war, marched to the rescue. But Torstensson defeated them with enormous loss in the second battle of Breitenfeld (Nov. 2, 1642). But, although the Austrians feared an advance on Vienna itself, the victors waited for the fall of Leipzig and then took up winter quarters. The Bavarians had advanced into the lower Rhine region in order to support, in concert with the Belgian army of Spain, a fresh outbreak in France (Cinq-Mars' conspiracy). But the Spanish were attacked and defeated before the Bavarians came up, at Hulst (Jan. 17), whereupon the Bavarians took shelter under the guns of the fortress of Julich.

On the northern frontier of France, Harcourt, the brilliant commander of the Italian army, failed to prevent the Spaniards from capturing Lens and La Bassée, and another army was defeated and routed at Honnecourt (May 26). The Spaniards in the Milanese lost fresh ground. Louis XIII. himself conquered Roussillon. Richelieu crushed the conspiracy of Cinq-Mars by executing its leaders, and Marshal de la Motte-Houdencourt held Catalonia and defeated Leganez at Lerida (Oct. 7th).

The **Duc d'Enghien.**—Before the next campaign opened, Louis and Richelieu were dead. One of the last acts of the king was to designate the young duc d'Enghien, son of the incapable Condé, general of his northern army. It was no small matter to put in command a youth of 21, who might prove not merely inexperienced but also incompetent. But Enghien's victory was destined to be the beginning for the French army of a long hegemony of military Europe. Mello, the Spanish general, had selected the Meuse route for his advance on Paris. On it he would meet only the places of Rocroi and Rethel. The young duke learned at the same moment that Louis XIII was dead and that the Spaniards had invested Rocroi. With the resolution and swiftness which was to mark his whole career, he marched at once to offer them battle, though all the generals of the old school were for delay. The battle took place on May 19, 1643, in a plain before Rocroi. Mello's cavalry was routed, and nearly all the infantry, the best regiments in the Spanish army, stood their ground and were annihilated.

But even Rocroi, under the existing conditions of warfare, was decisive only in so far as, by the destruction of Spain's superiority in Belgium, it saved France from further danger from the north. The thorough establishment of the French on the Rhine and the need of co-operating with the Swedes were considered by the young general to be more important than fighting Mello in front of Brussels, and in spite of the protests of the Regent and Mazarin, he decided to attack Thionville. Taking a leaf out of Mello's book, he threatened Brussels in order to draw all the defenders thither, and then suddenly turned eastward. Enghien arrived on June 18, and on Aug. 8, Thionville surrendered.

Beyond the Rhine Guébriant was mortally wounded in the siege of Rottweil, and Rantzau, taking over the command, allowed himself to be surprised in the act of dispersing into winter-quarters, and was defeated at Tuttlingen on the headwaters of the Danube (Nov. 24).

In the East the campaign had as usual turned more upon subsistence than upon military operations. Torstensson swept through Bohemia and Moravia, his steps dogged through the devastated country by Gallas, until he reached Brunn. Thence, however, he suddenly retreated to the shores of the Baltic. For Christian of Denmark had declared war on Sweden, and threatened to isolate the Swedish forces in Germany. Torstensson, therefore, wintered in Holstein. In Italy and Spain there was no event of any importance.

In 1644 Gaston of Orleans began the conquest of the Dunkirk region in July, and Mello. having no army to oppose him, remained inactive. In Italy there happened nothing serious, while in Spain La Motte-Houdencourt lost Lerida, and was imprisoned by Mazarin in consequence. But the Rhine campaign is memorable for the first appearance of Turenne at the head of an army and for the terrible battle of Freiburg.

Freiburg.—In Suabia Mercy's Bavarians were left to oppose Turenne, who spent the first months of the year in restoring discipline and confidence in the shaken Weimar army. But Mercy was still considerably superior in strength, and, repulsing Turenne's first inroad into the Black Forest, besieged Freiburg. Turenne made one cautious attempt at relief, then waited for reinforcements. These came in the shape of Enghien's army, and Enghien as a prince of the blood took over the supreme command. But both armies together numbered hardly 17,000 men when Enghien and Turenne united at Breisach on Aug. 2. On the 3rd they crossed the Rhine and attacked Mercy's position, which was of great natural and artificial strength, in front and flank. Three separate battles, which cost the Bavarians one-third of their force and the French no less than half of theirs, ended in Mercy's retreat (*see* FREIBURG IM BREISGAU) on Aug. 10. Enghien did not follow him into the mountains, but proceeded to the methodical conquest of the middle Rhine fortresses, leaving Turenne and the Weimar army at Spire.

In the east, or rather in the north, a desultory campaign was carried on during 1644 between Torstensson and the younger Wrangel, on the one side, the Danes and Gallas on the other, and in the end Gallas retreated to Austrian territory, so completely demoralized that his army dwindled on the way from 20,000 men to 2,000. Torstensson followed him, having little to fear from the Danes. Meanwhile the prince of Transylvania, George Rakóczy, playing the part of Gabriel Bethlen his predecessor, made war upon the emperor, who not being able on that account to send fresh troops against Torstensson called for help to Maximilian of Bavaria. The Elector sent most of his own troops under Weert on the same errand—hence Mercy's defeat at Freiburg. But Torstensson pressed on towards Vienna, and on Feb. 24–March 6, 1645 he inflicted a crushing defeat on the Bavarians and Imperialists at Jankau near Tabor. In his extremity Ferdinand offered part of Bohemia and Silesia to Maximilian in return for soldiers. But the Bavarian ruler had no more soldiers to give, for Turenne was advancing again from the Rhine.

At the end of March the Weimar army marched to Heilbronn, and Rothenburg-on-Tauber, when Turenne resolved to go northward in search of supplies and recruits in the territories of his ally and cousin the landgravine of Hesse-Cassel. But at this point the army, headed by Bernhard's old colonels, demanded to be put into rest-quarters, and Turenne allowing them to disperse as they wished, was surprised by Mercy and Weert—who brought his courage, if nothing else, back from the field of Jankau—and lost two-thirds of his forces. But Turenne, instead of retreating to the Rhine, installed himself in the landgravine's country, while Enghien hurried up from the Moselle to his aid. The "Army of Weimar" and the "Army of France" joined forces, as in 1644, almost under the eyes of the enemy. Enghien at once pushed forward from Ladenburg, by Heidelberg and Dinkelsbiihl, and found the Austro-Bavarians under Mercy entrenched in a strong position at Allerheim near Nordlingen, directly barring the way to the Danube. The second battle of Nordlingen (Aug. 3, 1645) was as desperately fought as the first, and had not Mercy been killed at the crisis of the day Enghien would probably have been disastrously defeated. As it was, the young duke was victorious, but he had only 1,500 infantry left in rank and file out of 7,000 at the end. Soon afterwards Enghien fell ill, and his army returned to France. Turenne, left with a few thousand men, attempted in vain to hold his ground in Germany and had to make a hasty retreat to Philippsburg on the Rhine, almost the only remaining conquest of these two brilliant but costly campaigns. In Flanders Gaston of Orleans conquered a number of fortresses, and his army united with that of the Dutch. But the allies separated again almost at once, each to undertake the sieges which suited its own purposes best.

From Silesia Wrangel, who had succeeded Torstensson, passed into Bohemia, where he remained until the forces employed against Rakóczy and Turenne could send help to the imperialists opposed to him. He then drew away into Hesse, the Archduke Leopold and the Bavarians following suit.

Turenne's Strategy.—The campaign of 1646 in Hesse up to August was as usual uneventful, each army being chiefly concerned with its food. But at last the archduke retired a little, leaving Turenne and Wrangel free to join their forces. Turenne had no intention of repeating the experiences of Freiburg and Nordlingen. It was more profitable to attain the small objects that were sought by manoeuvre than by battle, and the choice of means practically lay between manoeuvring the enemy's army into poor districts and so breaking it up by starvation, and pushing one's own army into rich districts regardless of the enemy's army. The usual practice was the first method. Turenne chose the second.

Delayed at the opening of the year by orders from Mazarin —Turenne found it impossible to reach Hesse by the short and direct route, and he therefore made a rapid and secret march down the Rhine as far as Wesel, whence, crossing unopposed, he joined Wrangel on the upper Lahn (Xug. 10). The united armies were only 19,000 strong. But the imperialists, fearing to be hemmed in and starved between Turenne and the Rhine, fell back to Fulda, leaving the Munich road clear. The interior of Bavaria had not been fought over for 11 years, and was thus almost the only prosperous land in desolated Germany. Turenne and Wrangel marched straight forward on a broad front, and for the rest of the year they devastated the country about Munich in order to force Maximilian to make terms. An armistice was concluded in the winter, Maximilian having been finally brought to consent by an ill-judged attempt of the emperor to seduce his army. The French and Swedes wintered in southern Wiirttemberg.

In Flanders, Gaston of Orleans and Enghien took Dunkirk and other fortresses. In Italy, where the Tuscan fortresses were attacked, the French were completely checked at first, until Mazarin sent a fresh corps thither and restored the balance. In Catalonia Harcourt underwent a serious reverse in front of Lerida at the hands of his old opponent Leganez, and Mazarin sent Enghien, now prince of Condé, to replace him.

1647 was a barren year. In the Low Countries the war dissipated itself in sieges. In Italy Plessis-Praslin won an unprofitable victory over the viceroy of the Milanese on the Oglio (July 4). In Spain Condé, resuming the siege of Lerida, was repulsed and had to retire. In Germany Turenne and Wrangel parted company. The latter returned to Hesse, whence he raided into Bohemia, but was driven back by the imperialists. As the few obtainable supply areas gave out one by one, the Swedes gradually retired almost to the coast, but the imperialists did not follow, swerving into Hesse instead. Turenne meanwhile had had to send all his French troops to Luxemburg to help in the defence of northern France against the Spaniards. The Weimar army had refused to follow him to the Meuse, and mutinied for its arrears of pay. Turenne, however, promptly seized the ringleaders and after a sharp fight disarmed the rest. Thus ignominiously Bernhard's old army vanished from the scene.

In the autumn the elector of Bavaria was reconciled to the emperor and his army re-entered the field. Turenne was therefore sent back to Germany to assist the Swedes. But winter came on before any further inroads could be made into south Germany.

The campaign of 1648 brought the decision at last. Turenne and Wrangel, having refitted their forces and united in Hesse as in 1646, steadily drove back the imperialists and Bavarians, whose 30,000 combatants were accompanied by a horde of nearly 130,000 hangers-on—men, women and children—to the Danube. At Zusmarshausen (May 1;) catching the enemy in the act of manoeuvring, they destroyed his rear-guard. The victors advanced as far as the Inn, but Piccolomini, reorganizing the débris of the Austro-Bavarian army, checked their further progress and even drove them back to the line of the Isar. Meantime, however, the Swedish general Konigsmarck, had entered Bohemia and was besieging Prague. This caused the recall of Piccolomini's army, and Turenne and Wrangel invested Munich. But Mazarin ordered the French to retire into Suabia so as not to compromise the peace negotiations at the critical moment, and Wrangel followed suit. Before Königsmarck was in a position to assault Prague news came of peace. Meanwhile in Artois Condé had repulsed the Spanish invasion by his brilliant victory of Lens (Aug 5), which was a second Rocroi. After the thanksgiving service for the victory at Nôtre Dame, Mazarin arrested the leaders of the *parlement* of Paris. and in a few hours the streets were barricaded and a civil war was in progress. This was the Fronde (*q.v.*), which went on for another 11 years.

THISTLE, a name of vague application. given to almost any herbaceous plant that has spines. More strictly. it is applied to certain herbs possessing very spiny leaves. and similar bracts surrounding a head of purplish-white, tubular. five-parted flowers seated on a pitted and hairy receptacle, belonging to the Compositae family. The fruit is surmounted by a tuft of silky hairs. The species, chiefly natives of Europe, western Asia and North America, are numerous, and some are of great beauty. The blessed thistle is *Cnicus benedictus;* lady's thistle, the leaves of which are spotted uith white, is *Silybum marianum.* The common bull thistle *Cirsium lanceolatum,* seems to be the most suitable prototype for the Scots thistle, though that honour is also conferred on *Onopordon acanthium,* the cotton thistle, remarkable for its covering of white down. a doubtful native of Great Britain, and on other species.

FIELD THISTLE (CIRSIUM DISCOLOR)

The great objection to thistles from an agricultural point of view resides in the freedom with which their seeds are spread and in the vigour of their underground growth, which makes their eradication difficult. Among the so-called thistles the following, all introduced from Eurasia, are well-known noxious weeds of farmlands in the northern Cnited States and Canada. The blue thistle *(Echium vulgare)* is a biennial member of the Borage family. The Russian thistle *(Salsola kali),* so common on the Great Plains of western North America, is an introduced annual tumbleweed belonging to the pigweed family. The perennial sow thistle *(Sonchus arvensis),* a milky-juiced member of the family Compositae, because of its freely creeping root system, is one of the most persistent weeds of arable lands. *See* CANADA THISTLE. THISTLEWOOD, ARTHUR (1770–1820), principal instigator of the Cato street conspiracy, a plot to murder the British cabinet in 1820. A son of William Thistlewood. and born at Tupholme in Lincolnshire, young Thistlewood became a soldier and visited France and America. He developed republican sympathies and joined the Spencean society, a revolutionary body; associated himself with James Watson (d 1838) and other agitators; and in Dec. 1816 helped to arrange a meeting in Spa Fields. London, which was to be followed by the seizure of the Tower of London and the Bank of England and by a general revolution. The proposed rising failed, but the Habeas Corpus act was suspended and Thistlewood and Watson were tried but acquitted. Thistlewood was sentenced to a year's imprisonment for challenging the home secretary, Lord Sidmouth, to a duel. After his release in May 1819 he prepared a new and comprehensive plot. On Feb. 23, 1820, at a time of great distress and unrest caused by the death of George III, the cabinet ministers had arranged to dine at the earl of Harrowby's house in Grosvenor square. With some associates Thistlewood hired a room in the neighbouring Cato street, collected arms and made ready to fall upon Harrowby's guests. The authorities had been informed of the plot, probably by a conspirator named George Edwards, officers appeared and arrested some of the conspirators; and although Thistlewood escaped he was seized the following day. Tried for high treason, Thistlewood and four others were sentenced to death, and were hanged hlay 1, 1820.

THOKOLY, IMRE (EMERICH), PRINCE (1657–1705), Hungarian statesman, was born at Kesmark on Sept. 25, 1657. He lost both parents while still a child. In 1670, fleeing from the dangers of upper Hungary where the Protestants and imperialists were constantly in arms against each other, he took refuge with his kinsman Michael Teleki, the chief minister of Michael Xpafy, prince of Transylvania. There he came into contact with the Magyar refugees. who had great hopes of the high-born, high-gifted youth who was also a fellow sufferer, a large portion of his immense estates having been confiscated by the emperor. The discontent reached its height when Leopold (Feb. 27, 1673) suspended the Hungarian constitution, appointed Johan Gaspar Ampringen dictator, deprived 450 Protestant clergy of their livings and condemned 67 more to the galleys. Encouraged by promises of help from Louis XIV. the Magyars now rose for liberty and justice. and chose the youthful Thokoly as their leader. The war began in 1679. Upper Hungary and the mining towns were soon in Thokoly's possession. In 1681, reinforced by 10,000 Transylvanians and a Turkish army under the pasha of Nagyvarad, he compelled the emperor to grant an armistice. Thokoly's distrust of the emperor induced him to turn for help to the sultan. In the same year Thokoly captured fortress after fortress from the emperor and extended his dominions to the Waag. He refused the title of king ofiered to him by the Turks.

Thokoly was buried at Nicomedia but in 1906 his relics were transferred to Hungary.

THOLOS, in architecture, a circular building with or without a peristyle. The earliest examples are the beehive tombs at Mycenae and in other parts of Greece, which were covered by domes built in horizontal courses of masonry. The tholos at Epidaurus, built by Polycleitus (*c.* 400 B.C.), and the tholos at Olympia, known as the Philippeion, are the most remarkable examples and in both cases were covered with a sloping roof and not with a dome. *See* PRE-HELLENIC ARCHITECTURE; GREEK ARCHITECTURE.

THOLUCK, FRIEDRICH AUGUST GOTTREU (1799–1877), German Protestant theologian, was born at Breslau on March 30, 1799. He studied at Breslau and at Berlin, where he was received into the house of the orientalist H. F. von Diez (1750–1817). He came under the influence of the Pietist Baron Ernst von Kottwitz (1757–1843), who became his "spiritual father:" and of the historian Neander. In 1821 he was *Privatdocent* (official but unpaid lecturer! and in 1823 became professor extraordinarius of theology in Berlin. *Die wahre Weihe des Zweiflers* (1823; 9th ed., with the title *Die Lehre von der Sünde und dem Versöhner,* 1870), the outcome of his own religious history, secured his commanding position as the Pietistic apologist of Evangelical Christianity. In 1825, with the aid of the Prussian government, he visited the libraries of England and Holland, and on his return was appointed (1826) professor ordinarius of theology at Halle, the centre of German rationalism, where he afterward became preacher and member of the supreme consistorial council. There he sought to combine in a higher unity the learning and to some extent the rationalism of J. S. Semler with the devout and active Pietism of A. H. Francke; and, in spite of the opposition of the theological faculty of the university, he succeeded in changing the character of its theology. Tholuck was also one of the prominent members of the Evangelical alliance: and few men were more widely known or more beloved throughout the Protestant world. As a preacher he ranked among the foremost of his time. He died at Halle on June 10, 1877.

After his commentaries (on Romans, the Gospel of John, the Sermon on the Mount and the Epistle to the Hebrews) and several volumes of sermons, his best-known books are *Stunden christlicher Andacht (1839;* 8th ed., 1870).

THOMA, HANS (1839–1924), German painter whose works consist of minutely realistic landscapes, portraits and historical and biblical subjects. was born on Oct. 2. 1839. at Bernau in the Black Forest. He entered the Karlsruhe academy in 1859 and in 1868 went to Paris, where he became a pupil of Courbet. His reputation was established as the result of an exhibition of about 30 of his paintings in Munich. He died at Karlsruhe on Nov. 7, 1924. Thoma's art has little in common with modern ideas and was formed partly by his early impressions of the simple idyllic life of his native district, partly by his sympathy with the early German masters, particularly Xlbrecht Altdorfer and Cranach, and partly by his study under Courbet. In his love of the details of nature, in his precise though by no means faultless drawing of outline and in his predilection for local colouring he has distinct affinities with the Pre-Raphaelites. His works hang chiefly in German museums.

THOMAR: *see* TOMAR.

THOMAS, ST., one of the twelve apostles. The name means "twin" in Aramaic, as is recognized in John xi. 16 ("called Didymus"). Eusebius (H.E. iii. 1, 1) says Thomas was the evangelist of "Parthia," probably because Edessa (*q.v.*), where some of his bones were preserved, is sometimes called "Edessa of the Parthians." These bones were reputed to have been brought to Edessa from India, and a work known as the *Acts of Thomas* relates his missionary labours and martyrdom there. This work was originally composed in Syriac; it is indeed one of the oldest and most idiomatic monuments of Syriac literature, though many have doubted whether it is based on any historical facts. In the 4th century it was translated into Greek, and thence into Latin, almost certainly as part of the Manichaean propaganda. The Manichaean taint was soon recognised (*e.g.*, by Augustine) and the *Acta Thomae* in their original form branded as heretical. The view taken was that the framework, recounting the journeyings of the apostle, was historical, while the speeches and sermons contained the heresy. In consequence most mss., both Greek and Latin, contain very little of the speeches while retaining the framework. Even Wright's Syriac ms. has been occasionally conventionalized, and the original form is only to be found in the ancient (4th or 5th century) palimpsest fragments at Sinai.

The *Acts of Thomas* is a leading authority for the earliest Christianity in the countries east of the Euphrates: it was ascetic, marriage being discountenanced and all preoccupation with the things of this world discouraged. In the Acts Eucharistic prayers are given, but (according to the Sinai fragments and the best Greek) only bread and water were used. The Lord's Prayer is quoted in full. A curious feature is that the name of the apostle is given as Judas Thomas, and it is expressly set forth that he was the twin of Jesus Christ. As a tale the *Acts of Thomas* is remarkable for the real religious emotion that pervades it and for careful delineation of character, but above all for the hymn chanted by the apostle when in prison. This, commonly known as the "Hymn of the Soul" (Wright, pp. 238–245), is a metrical Syriac poem describing, under the parabolic form of the journey of a prince from his Eastern home to Egypt, the descent to earth and the return to its heavenly home of the soul. It is often supposed to be an independent composition inserted into the *Acts,* but for this there is no real evidence. In any case it is the great gem of Syriac literature.

"Christians of St. Thomas" is a name often applied to the ancient Christian churches of southern India; the view taken of their history is so intimately connected with the historicity of the *Acts of Thomas* that it is convenient to treat of them here. According to the tradition, St. Thomas founded the Christian churches in Malabar (south-west coast), and then crossed to Mylapur, now a suburb of Madras, where the shrine of his martyrdom, rebuilt by the Portuguese in 1547, still stands on Mt. St. Thomas, where a cross is shown with a Pahlavi inscription which may be as old as the 7th century. We know from Cosmas Indicopleustes that there were Christians of Persian (East Syrian) origin, and doubtless of Nestorian creed, in Ceylon, in Malabar, and at Caliana (north of Bombay) before 550. In 1490 they sent to the Nestorian patriarch Simeon, who gave them fresh bishops (Assemani, *Bib. Or.* iii, 1,590-f., *J. Theol. Stud.* xxix, 155). Hard pressed by the Moslems they welcomed the Portuguese and, after much controversy, a formal union with Rome was carried through in the Synod of Diamper (1599). Syriac was to remain the ecclesiastical language, but the service books were "purified from error."

Dom R. H. Connolly proved in 1914 that this revision was slight in extent, and that the Malabar liturgy remained essentially a form of the Nestorian rite. After a century and a half of union with Rome a schism took place in 1653, those who thus became independent of Rome organizing themselves under Jacobite (Monophysite) influence. (The ms. of the whole Syriac Bible and the Clementine literature [12th century] then sent to Malabar from Mesopotamia was brought to Europe by Claudius Buchanan [1811] and is now in the Cambridge university library.) Both this Church and the Roman obedience still flourish in Malabar.

From what has been said, the ancient Christian communities of southern India would be naturally regarded as a surviving branch of the extensive Nestorian missions, parallel to those which once flourished in Turkestan and China. But many of the Christians in India in fact regard St. Thomas as their founder and appeal to tradition and to the *Acts of Thomas,* in support. They claim that the *Acts* are historical, and that they refer in part to the apostle's activity in southern India. There are, indeed, objections to this view, such as the absence of compellingly clear allusions to specifically southern usages. As to the meeting of St. Thomas and the Indian King Gundaphar (the historical Gondophares, contemporary with the apostle and ruler in Gandhara, the northwest borderland of India), while a rigorously scientific proof is impossible, yet the substantial agreement of the *Acts* (the sole literary document which mentions this king) with all that is known from other sources, is best explained on the supposition that the *Acts* contain a kernel of historical truth. As to the southern journey and the martyrdom in Mylapur, it should be remarked that the agreement of the south Indian tradition with that of the Church of Edessa lends a high degree of probability to the claim that St. Thomas preached in southern India, suffered martyrdom there, and was there first buried. But difficulties remain, and no strict certainty is claimed for their conclusions by temperate investigators.

THOMAS, surnamed Magister (*i.e.,* officiorum)[1], also known as a monk by the name Theodulos Monachos, a native of Thessalonica, Byzantine scholar and grammarian and confidential adviser of Andronicus II. (1282–1328). His chief work, 'Εκλογὴ 'Ονομάτων καὶ 'Ρημάτων 'Αττικῶν, is a collection of selected Attic words and phrases, partly arranged in alphabetical order, compiled as a help to Greek composition from the works of Phrynichus, Ammonius, Herodian and Moeris. He also wrote scholia on Aeschylus, Sophocles, Euripides (with life), and three of the comedies of Aristophanes; the scholia on Pindar, attributed to him in two mss., are now assigned to Demetrius Triclinius. His speeches and letters deal with contemporary events.

Editions of the 'Εκλογ. by F. Ritschl (1832), C. Jacobitz (1833) and C. D. Beck (1836); other works in J. P. Migne, *Patrologia graeca,* cxlv.; *see* also C. Krumbacher, *Geschichte der byzantinischen Literatur* (1897).

THOMAS (d. 1100), archbishop of York, a native of Bayeux, is usually called Thomas of Bayeux. His father was a priest named Osbert, and Samson, bishop of Worcester (1086–1112), was his brother. Owing largely to the generosity of Odo, bishop of Bayeux, Thomas studied in France, Germany and Spain and then became one of Bishop Odo's officials and after 1066 one of William the Conqueror's chaplains, or secretaries. In 1070 he succeeded Aldred as archbishop of York, but declining to promise obedience to the archbishop of Canterbury, Lanfranc refused to consecrate him. King William, however, induced him to submit and he was consecrated, but his profession of obedience was to Lanfranc personally and not to the archbishops of Canterbury.

In 1071 both archbishops travelled to Rome for their palls and while there Thomas wished Pope Alexander II. to decree the equality of the sees of Canterbury and York. The pope, however, referred the dispute to a council of English prelates which met at Windsor at Whitsuntide in 1072. It was then decided that the archbishop of Canterbury was the superior of the archbishop of York, who had no rights south of Humber, but whose province included Scotland. This decision did not end the dispute which broke out again in 1092 and 1093 when Thomas protested against what he thought infringements of his archiepiscopal rights. The first of these occasions was over the dedication of the cathedral built by Remigius at Lincoln and the second was over the consecration of St. Anselm to the archbishopric of Canterbury. He died at York on Nov. 18, 1100.

THOMAS, ALBERT (1878–1932), French statesman, was born on June 16, 1878, at Champigny-sur-Marne, near Paris. His father was a baker who by great sacrifices enabled his son to receive a college and university education. Scholarships enabled him to travel in Russia and Germany. A sequel to this was his book *Le syndicalisme allemand* (1903) in which his socialist faith was propounded for the first time.

When, in 1904, Jean Jaurès launched *l'Humanité* he appointed Thomas assistant editor. Thomas played an important part as a right-wing leader in the General Confederation of Labour (C.G.T.). He published in 1908 a volume on the Second Empire in Jaurès' great *Histoire socialiste.*

He was elected to the Chamber for his native city in May 1910 and again in 1914, becoming one of the most active and prominent Socialist members.

He joined his regiment in 1914. After he had seen a few weeks of war service, the Government summoned Thomas and two other Socialists, Jules Guesde and Marcel Sembat, to organize the production of munitions. In May 1915 he entered the cabinet as under-secretary for armaments and also joined the Briand Ministry which followed at the end of the year. Towards the end of 1916 he became minister of munitions, retaining this post in the Ribot Ministry which followed. In April 1917 he was sent to Russia, where he remained for several months and succeeded in persuading Kerensky to undertake the ineffectual "great offensive" against the Central Powers.

Meanwhile in France the struggle was becoming very bitter between the majority (pro-war) and the minority (internationalist) sections of the French Socialist party, culminating in the Stockholm Conference. Leader, with Renaudel and Sembat, of the majority party, Albert Thomas was also a strong advocate of the independence of Czechoslovakia and Poland and the creation of a "Great Serbia" and a "Great Rumania." Since this "majority wing" policy was opposed by many Socialists, particularly in the Paris district, Thomas decided not to stand again in the Paris suburbs and resigned the mayoralty of Champigny. At the elections of Nov. 16, 1919, he was returned as a Socialist in the Tarn, Jaurès' former constituency.

During the first session of the International Labour Conference, held at Washington at the end of the year, Thomas was provisionally appointed director of the International Labour Office (League of Nations) by its governing body; the appointment was confirmed at the governing body's second meeting held in Paris in Jan. 1920. Apart from the organization and conduct of the administration and scientific work of the Office, he secured many national ratifications of conventions adopted by the International Labour Conference. In 1921 the claims of his work at Geneva led him to resign his seat in the Chamber of Deputies.

THOMAS, (CHARLES LOUIS) AMBROISE (1811–1896). French composer, was born at Metz Aug. 5, 1811. After studying under his father, a musician, he entered the Paris conservatory in 1828 and four years later won the Prix de Rome with *Herman et Ketty,* a cantata. He was professor of harmony and composition at the conservatory thereafter and in 1871 was named director. He was elected a member of the Académie des Beaux Arts in 1851. Among his compositions are ballets, cantatas and songs; his best known operas are *Mignon* (1866), *Hamlet* (1868) and *Françoise de Rimini* (1882). He died at Paris Feb. 12, 1896

THOMAS, ARTHUR GORING (1850–1892), English composer, was born at Ratton Park, Sussex, on Nov. 20, 1850. and educated at Haileybury College. He studied music in Paris under Durand and at the Royal Academy of Music under Ebenezer Prout and Arthur Sullivan; also under Max Bruch. The performance at the Royal Academy of a selection from *The Light of the Harem* (libretto by Clifford Harrison). induced Carl Rosa to commission him to write *Esmeralda* (libretto by T. Marzials and A. Randegger). which was successfully produced at Drury Lane on March 26, 1883. On April 16, 1885, Rosa produced at Drury Lane Thomas's fourth and best opera. *Nadeshda* (libretto by Julian Sturgis), a German version of which was given at Breslau in 1890. Besides his dramatic works Thomas's chief compositions were a psalm, "Out of the Deep," for soprano solo and chorus (London, 1878), a choral ode, "The Sun Worshippers" (Norwich, 1881), and a suite de ballet for orchestra (Cambridge, 1887). His music, which shows traces of his early French training, reveals a great talent for dramatic composition and a real gift of refined and beautiful melody. He died on March 20, 1892.

THOMAS, AUGUSTUS (1857–1934), U.S. playwright, was born in St. Louis, Mo., Jan. 8. 1857. He was educated in the public schools, served as a page boy in the Missouri legislature and in congress, for several years worked in railway freight offices, and, after serving as writer and illustrator for various newspapers, became in 1886 part editor and proprietor of the Kansas City (Mo.) *Mirror.*

The success in New York and on the road of *The Burglar* (1889), an elaboration of the earlier one-act piece, and of *A Man of the World* (1883) used by Maurice Barrymore, induced A. M. Palmer of the Madison Square theatre to offer the young playwright the post left vacant by the retirement of Dion Boucicault, and under Palmer's management *Alabama* (1891), a play about the reunited U.S., was produced. Thenceforth Thomas was one of the most prolific and successful of American playwrights, writing altogether over 60 plays. Other dramatic successes by him which made use of native materials were *In Mizzoura* (1893), *The Capital* (1895), *Arizona* (1899) and *The Copperhead* (1918). Other outstanding plays, chiefly in the vein of light comedy or romance, were *The Earl of Pawtucket* (1903), *Mrs. Leffingwell's Boots* (1905), and *The Witching Hour* (1907). An autobiographical volume *The Print of My Remembrance* appeared in 1922. He died near Nyack, N.Y., Aug. 12, 1934.

THOMAS, DYLAN MARLAIS (1914–1953), Welsh poet, was born in Swansea, Oct. 27, 1914. At the time of his death he was held to be one of the most remarkable poets of his generation. In 1934 he published his first volume of verse, *Eighteen Poems,* which was immediately recognized by Edith Sitwell and others as the work of an original and individual talent. There followed *Twenty-Five Poems* (1936); *The Map of Love* (1939) and *A Portrait of the Artist as a Young Dog* (1940), a collection of humorous autobiographical sketches. Some of his finest work was in *Deaths and Entrances* (1946) and *In Country Sleep* (1951). The theme of all his poetry is the celebration of the divine purpose which he sees in all human and natural processes. In some of the best of his later poems he seeks, like Henry Vaughan or Thomas Traherne, to recapture the child's innocent vision of the world. His poems are, in a good sense, impersonal. The wit and humour that made him an enchanting companion come out in his sketches and short stories, mainly based on memories of his Swansea childhood. In his last completed work, the radio play *Under Milk Wood,* the vision of the poet and the fun of the entertainer can be seen, for the first time. working together. His gifts as a broadcaster and the legend of his wild conviviality helped to spread his reputation. Thomas led a reckless life, but it never interfered with his sober devotion to his "craft and sullen art." He died, during a poetry-reading tour. in New York on Nov. 9, 1953. (G. S. E.)

THOMAS, GEORGE HENRY (1816–1870), U.S. general, who has been called "The Rock of Chickamauga." was born in Southampton county, Va., on July 31. 1816. He graduated at West Point in 1830, served as an artillery subaltern in the war against the Seminole Indians in Florida (1841), and in the .Mexican War at the battles of Fort Brown, Resaca de la Palma. Monterrey and Buena Vista, receiving three brevets for distinguished gallantry in action. From 1851 to 1854 he was an instructor at West Point. In 1855 he was appointed by Jefferson Davis, then secretary of war, a major of the and cavalry. His regimental superiors were A. S. Johnston, R. E. Lee and Hardee. All three resigned at the outbreak of the Civil War. Thomas finally decided to adhere to the United States. He was promoted in rapid succession to lieutenant colonel, colonel in the regular army. and brigadier general of volunteers.

In command of an independent force in eastern Kentucky, on Jan. 19, 1862, he attacked the Confederate general. Felix Zollicoffer, at Mill Springs, and gained the first important Union victory in the west. He served under Buell and was offered, but refused. the' chief command in the anxious days before the battle of Perryville. Under Rosecrans he was engaged at Stone river and was in charge of the most important part of the maneuvring from Decherd to Chattanooga. At the battle of Chickamauga (*q.v.*) Sept. 19. 1863. he gained the name of "The Rock of Chickamauga," because of his firmness. He succeeded Rosecrans in command of the army of the Cumberland shortly before the great victory of Chattanooga (*q.v.*), in which Thomas and his army played a conspicuous part, his divisions under Sheridan, Wood and Baird carrying Missionary ridge in superb style. When J. B. Hood broke away from Atlanta in the autumn of 1864, menaced Sherman's long line of communications and endeavoured to force Sherman to follow him, Sherman left to Thomas the difficult task of dealing with Hood. At the battle of Franklin, Nov. 30, 1864. Thomas's force, under General Schofield, checked Hood long enough to cover the concentration at Nashville (*q.v.*). Thomas attacked (Dec. 15–16, 1864) and inflicted on Hood the worst defeat sustained in the open field by any army on either side during the war. For this Thomas was made a major general in the regular army and received the thanks of congress. After the Civil War he commanded military departments in Kentucky and Tennessee until 1869, when he was placed over the division of the Pacific with headquarters at San Francisco. He died there March 28, 1870.

THOMAS, ISAIAH (1749–1831), U.S. printer and publisher pre-eminent in his day, was born in Boston, Mass., on Jan. 19, 1749. When he was six he was apprenticed to Zechariah Fowle, a Boston printer. At the age of 16 he ran away and worked as a printer in Halifax, Nova Scotia and Portsmouth, N.H., and later, with Fowle's consent, in Charleston, S.C. In 1770 he formed a partnership with Fowle to publish the *Massachusetts Spy*. Under Thomas' sole ownership it became a weekly publication which eventually espoused the patriots' cause and printed essays advocating independence; the paper's circulation reached a high of 3.500. On April 16. 1775, three days before the battle of Concord, in which he took part, Thomas was forced to take his presses and types from Boston to Worcester, Mass., where he was postmaster for a time. There he published and sold books, built a paper mill and bindery, and continued his paper (with the exception of the years 1776–78 and 1786–88) until about 1802, during which time the *Spy* supported Washington and the Federalist party. Thomas set up printing houses and bookstores in various parts of the country: in Boston he published the *Royal American Magazine,* which contained many engravings by Paul Revere; the New *England Almanac;* the *Massachusetts Magazine,* a monthly, with Ebenezer

T. Andrews; and, in Walpole, N.H., the *Farmer's Museum*. About 1802 he relinquished his business at Worcester, including control of the *Spy*, in favour of his son Isaiah, Jr. In 1812 Thomas founded the American Antiquarian society. He died in Worcester on April 4, 1831.

His accurate and thorough *History of Printing in America, With a Biography of Printers, and an Account of Newspapers* (1810; 2nd ed., 1874), with a memoir by his grandson B. F. Thomas, is the first history of American publishing. "Diary of Isaiah Thomas, 1805–28" was published in *Transactions of the American Antiquarian Society*, vol. ix and x (1909).

THOMAS, JAMES HENRY (1874–1949), British Labour leader. was born at Newport, Mon., on Oct. 3, 1874 He started work as an errand boy at the age of 9 and was later employed by the Great Western railway as an engine cleaner; he rose rapidly and soon became a power in Swindon (the G.W.R. headquarters) both as a trade unionist and in local government. By 1910 he had become president of the Amalgamated Society of Railway Servants and played a leading part in its reorganization as the National Union of Railwaymen (N.U.R.) of which he mas appointed general secretary after the great railway strike of 1911. Under him the N U.R. became the leader in the policy of "industrial" or "all grades" as against "craft" trade unionism. Thomas became member for Derby in 1910 and a privy councilor in 1917. He was president and chairman of the parliamentary committee of the Trades Union congress (1920–21) and president of the International Federation of Trade Unions (1920–24).

In the Labour government of 1924 Thomas was secretary for the colonies; and in that of 1929 was made lord privy seal and minister of employment, and in 1930 secretary of state for the dominions. He retained this office in the national government of 1931, and consequently resigned his office in the N.U.R. In Nov. 1935 he became colonial secretary. In 1936 it was found that Thomas was, to some extent, responsible for a serious leakage of information concerning the budget before the date of its publication; and in consequence he resigned from the cabinet and from the house of commons. He died Jan. 21. 1949, in London.

THOMAS, PHILIP EDWARD (1878–1917), British author and poet, was born on March 3, 1878, and educated at St. Paul's School and at Lincoln college, Oxford. His first book, a volume of nature studies. *The Woodland Life* (1897), was followed by *Horae Solitariae* (1902), and numerous other works. including his critical studies of *George Borrow* (1912); *Swinburne* (1912); and *Walter Pater* (1913). But his prose work was done to order, and shows signs of constraint as to subject and time. A collection of his prose fragments appeared in 1928, under the title of *The Last Sheaf;* some of these were written under less exacting conditions, and allow more scope to his leisurely and precise genius. It was not till middle age that, under the influence of Robert Frost, the American poet. Thomas discovered himself as a poet. Thomas enlisted in the British army in 191j. and with freedom from routine literary work became extremely fluent. His verse was first written under the name of "Edward Eastaway" and a volume of *Poems* under his own name appeared in 1917. He was killed in France on April 9, 1917. His poetry is not sharply distinguished from his prose, the rhythms are quiet and unstressed. He was preeminently a poet of the country.

THOMAS, SIDNEY GILCHRIST (1850–1885), British inventor, was born on April 16, 1850, at Canonbury. London As a police court clerk he found time to study chemistry at the Birkbeck institute He set himself to solve the problem of separating phosphorus from iron in the Bessemer converter. and by the end of 187j he had discovered a method which was tested by his cousin, Percy C. Gilchrist, at the Blaenavon works, and found effective. In March 1878 the first public announcement of the discovery was made at the meeting of the Iron and Steel institute. A paper was written by Thomas and Gilchrist on the "Elimination of Phosphorus in the Bessemer Converter" for the autumn meeting of the institute, but was not read till May 1879. Thomas interested E. W. Richards. the manager of Bolckow, Vaughan & Co.'s works at Cleveland, Yorkshire, in the process. and from that time its success was assured and domestic and foreign patents were taken out. The "basic process" invented by Thomas was especially valuable on the continent. where the proportion of phosphoric iron is larger, and both in Belgium and in Germany the name of the inventor became more widely known than in his own country. Thomas died in Paris on Feb. 1, 1885.

THOMAS, THEODORE (1835–1905), U.S. musician and conductor. was born in Esens, Ger.. on Oct. 11, 1835. His first public appearance as a violinist was made at the age of five. He was taken to the United States by his parents in 1845, and became first violin in the orchestra that accompanied Jenny Lind (1850), Sontag (1852) and Grisi and Mario (1854). In 1862 he began to organize his own orchestra, and in 1864 he inaugurated the series of Irving Hall symphony concerts, which for 14 years were regarded as one of the great musical institutions of New York city. To Theodore Thomas is largely due the popularization of Wagner's works in America, and it was he who founded the Wagner Union in 1872. In 1891. Thomas organized the Chicago Symphony orchestra, which has continued to be one of the foremost organizations of its class in the world. He died Jan. 4. 1905, in Chicago.

See biography by George P Upton; Charles Edward Russell, The *American* Orchestra and Theodore *Thomas* (1927).

THOMAS, WILLIAM ISAAC (1863–1947), pioneer U.S. sociologist, who specialized in social psychology as applied to cultural analysis and personality development. was born on Aug 13, 1863. in Russell county, Va. After graduating from the University of Tennessee. Knoxville, in 1884, he taught English there and at Oberlin (O) college for ten years. Turning to sociology, he received his Ph.D. in 1896 at The University of Chicago, where he studied physiology, neurology, philosophy and social psychology. He taught sociology consecutively at The University of Chicago, the New School for Social Research. New York city. and Harvard, and was a consultant at Yale. He died on Dec. 5, 1947, in Berkeley, Calif.

Thomas' *Source-Book for Social Origins* (1909) and *Primitize Behavior* (1937) reflected his interest in ethnography. His *Sex and Society* (1907) was the first fully secular approach to the subject written by an American sociologist His major work, *The Polish Peasant in Europe and America, j* vol (1918–21), prepared with F Znaniecki, illustrated his comparative approach to the study of nationalities and his analysis of social problems by means of personal history. *The Unadjusted Girl* (1923) and *The Child in America* (1928) were outstanding psychological studies of personality. His important methodological contributions mere the technique of personal history, described in the "Methodological Note" to his *Polish Peasant,* and his later "point-by-point procedure," based on the contention that theoretical formulations in sociology must be regarded as tentative until checked and developed by further research.

THOMAS À KEMPIS (*c.* 1380–1471), the name by which the Augustinian canon and writer Thomas Hammerken (Hammerchen, Malleolus) is commonly known. He was born in 1379 or 1380 in the town of Kempen, near Düsseldorf, in one of the many patches of territory between the Meuse and the Rhine belonging to the archiepiscopal principality of Cologne. His father was a poor hard-worked peasant; his mother kept a dame's school for the younger children of the town. John and Gertrude Hammerken had two sons. John and Thomas, both of nhom found their way to Deventer, and thence to Zwolle and to the convent of Mount St Agnes. Thomas reached Deventer when he was barely 12 years old, mas taught by a dame the beginnings of his learning, and in a few months to his great joy entered the classes of Florentius Radeuyn. After the fashion of the time he was called Thomas from Kempen, and the school title, as was often the case then, pushed aside the family name. Thomas Hammerken was forgotten; Thomas & Kempis has become known to the whole Christian world.

The school at Deventer had become famous long before Thomas à Kempis was admitted to its classes. It had been founded by Gerhard Groot (*q.v.*), a wealthy burgher nho had been won to pious living mainly through the influence of Ruysbroeck, the Flemish mystic. At Deventer, in the midst of this mystical theology and hearty practical benevolence, Thomas à Kempis was trained Gerhard Groot was his saintly ideal. Florentius Radewyn and Gerhard's other early disciples were his heroes; their presence was his atmosphere. the measure of their lives his horizon. But he was not like them; he was not an educational reformer like Radeuyn, nor a man of affairs like Gerhard. He liked books and quiet corners all his days, he says; and so, when conviction of sin and visions of God's grace came to him in the medieval fashion of a dream of the anger and forgiveness of the Virgin, Florentius told him that a monk's life would suit him best, advised him to join the Augustinian order, and sent him to Zwolle to the new convent of Mount St. Agnes, where his brother John was prior. Thomas was received there in 1399, professed the vows in 1407, received priest's orders in 1413, became sub-prior in 1425 and died on Aug. 8, 1471, at the age of ninety-one.

Works. — The convent of Mount St. Agnes was poor, and most of the monks had to earn money to support their household by copying MSS. Thomas was a most laborious copyist; missals, books of devotion and a famous MS. Bible were written by him. He also wrote a large number of original writings, most of them relating to the convent life, which was the only life he knew. He wrote a chronicle of the monastery and several biographies— the life of Gerhard Groot, of Florentius Radewyn, of a Flemish lady St. Louise, of Groot's original disciples; a number of tracts on the monastic life—The Monk's Alphabet, The Discipline of Cloisters, A Dialogue of Novices, The Life of the Good Monk, The Monk's Epitaph, Sermons to Novices, Sermons to *Monks,* The Solitary Life, On Silence, On Poverty, Humility and Patience; two tracts for young people—A Manual of Doctrine for the Young, and *A Manual* for Children; and books for edification— On True Compunction, *The* Garden of Roses, The Valley of Lilies, The Consolation of the Poor and the Sick, The Faithful Dispenser, The Soul's Soliloquy, The Hospital of the Poor. He also left behind him three collections of sermons, a number of letters, some hymns and the famous Imitatio *Christi* (though his authorship of this has been disputed).

Character. — These writings help us to see the man and his surroundings, and contemporary pious records make him something more than a shadow. We see a real man, but a man helpless anywhere save in the study or in the convent—a little fresh-coloured man, with soft brown eyes, who had a habit of stealing away to his cubiculum whenever the conversation became too lively; somewhat bent, for it is on record that he stood upright when the psalms were chanted, and even rose on his tiptoes with his face turned upwards; genial, if shy, and occasionally given to punning, as when he said that he preferred Psalmi to Salmones; a man who perhaps led the most placid uneventful life of all men who ever wrote a book or scribbled letters. His brethren made him oeconomiae prefectus, but he was too "simple in worldly affairs" and too absent-minded for the post, and so they deposed him and made him sub-prior once more. And yet it is this placid kindly fresh-coloured old man who has come down to us as the author of that book the Imitation of Christ, which has been translated into more languages than any other book save the Bible, and which has moved the hearts of so many men.

On the controversy as to the author of the Imitatio, see the article IMITATION OF CHRIST. See also James Williams. Thomas of Kempen (1910). The classical edition of the works of Thomas à Kempis by Sommalius—Thomas Malleoli *à* Kempis opera *omnia* (3 vols. in 1, 1607)—has been many times reprinted. A critical edition in 8 vols. by M. J. Pohl has also been undertaken. The best accounts in English of Thomas à Kempis are those by S. Kettlewell (1882) and F. R. Cruise (1887), written from the Protestant and the Catholic standpoints respectively. A penny tract by F. R. Cruise, entitled Outline of the *Life* of Thomas *à* Kempis (1904), contains substantially all that is known concerning him. (T. M. LI.)

THOMAS OF CELANO, Franciscan friar and disciple and biographer of St. Francis of Assisi. Born at Celano in the Abruzzi, he joined St. Francis probably about 1214, and he appears to have been one of the first band of friars who went into Germany. He was commissioned by Gregory IX. to write the Life of St. Francis, and in 1229 he completed the First Legend; in 1247 at the command of the minister general he composed the Second Legend, and a few years later the Tract on the *Miracles* of *St.* Francis. He also composed in 1255 the Legend of St. Clare; and he is one of those to whom the sequence Dies irae is attributed.

Thomas' of Celano's writings on St. Francis have been critically edited by E. d'Alençon in 1906. An English translation (The Lives of S. Francis of Assisi by Brother Thomas of Celano) by A. G. Ferrers Howell appeared in 1908. See FRANCIS OF ASSISI. (E. C. B.)

THOMAS OF ERCELDOUNE, called also THE RHYMER, and sometimes given the surname of LEARMONT (*fl.* ? 1220– ? 1297), poet and prophet in the legendary literature of Scotland. The historical person of that name figures in two charters of the 13th century, and from these it appears that he owned lands in Erceldoune (now Earlstoun), in Berwickshire, which were made over by his son and heir on Nov. 2, 1294, to the foundation of the Holy Trinity at Soltra (or Soutra) on the borders of the same county. This would imply that Thomas the Rhymer was already dead, but J. A. H. Murray, who edited The Romance and Prophecies (E.E.T.S., 1875), thinks that he was living three years later in a Cluniac priory in Ayrshire. He figures in the works of Barbour and Harry the Minstrel as the sympathizing contemporary of their heroes, and Walter Bower, who continued the *Scotichronicon* of Fordun, tells how he prophesied the death of Alexander III. in 1285.

In the folk-lore of Scotland his name is associated with numerous fragments of verse of a gnomic and prophetic character. The romance of Thomas and the elf-queen was attributed to Erceldoune by Robert Mannyng de Brunne, but the earliest text, in the Auchinleck ms. in the Advocates' library, Edinburgh, is in a dialect showing southern forms, and dates from the beginning of the 14th century. It may be based on a genuine work of Thomas, a version by him of the widely diffused Tristan Saga. The most widely accepted opinion is that it is a translation of a French original.

Murray's edition of The Romance and Prophecies (E.E.T.S., 1875); Brandl's Thomas of Erceldoune (Berlin, 1880), and Kolbing's *Die nordische und* die *englische* Version der *Tristransage* (Heilbronn, 1882); also McNeill's Sir Tristrem (S.T.S., 1886); Lumby's Early Scottish Prophecies (E.E.T.S., 1870), and the reprint of the Whole Prophesie of Scotland (1603) by the Bannatyne Club (1833); J. THOMAS OF MARGA, a Nestorian bishop and author of an important monastic history in Syriac, who flourished in the 9th century A.D. He was born early in the century, probably of Persian parents, in the region of Salakh to the north-east of Mosul. As a young man he became in 832 a monk of the famous Nestorian monastery of Beth 'Ābhē, about 25 m. due east of Mosul when he acted as secretary to Abraham, who had been abbot of Beth 'Ābhē, and was catholicus (patriarch) of the Nestorians from 837 to 850. Thomas was promoted by Abraham to be bishop of Margā, and afterwards to be a metropolitan of Beth Garmai. It was during the period of his life at Beth 'Ābhē and his bishopric that he composed The Book of Governors, which is in the main a history of his own monastery, but includes lives of holy men in other parts of Mesopotamia and elsewhere.

The Book of Governors has been edited with an English translation and a copious introduction by E. W. Budge, 2 vol. (1893).

THOMOND, EARL AND MARQUESS OF, Irish titles borne by the great family of O'Brien. the earldom from 1543 to 1741 and the marquessate from 1800 to 1855. Thomond, or Tuaidh-Muin. was one of the three principalities of Munster, forming the northern part of the province. Its earls were descended from Turlough O'Brien (*c.* 1009–1086), king of Munster, and through him from the celebrated king of Ireland. Brian

Boroimhe. Turlough's descendants, Conchobhar O'Brien (d. 1267) and Brian Ruadh O'Brien (d. 1276), kings of Thomond, nere both typical Irish chieftains. Conchobhar's tomb and effigy with a crown are still to be seen in the ruined abbey of Corcomroe, County Clare. His descendant Conor O'Brien (d. 1539), prince of Thomond, took part in the feud between the great families of Fitzgerald and Butler and was the last independent prince of Thomond Conor's brother, MURROUGH O'BRIEN (d. 1551), prince of Thomond, the succeeding chief of the race, gave up his "captainship, title, superiority and country" to Henry VIII in 1543, when he was created earl of Thomond. By special arrangement the earldom descended, not to his son Dermod, but to his nephew. Donough, who became the 2nd earl. Dermod, however, inherited the barony of Inchiquin, which was conferred upon his father at the same time as the earldom.

CONOR O'BRIEN, the 3rd earl (c. 1534–*c.* 1582), was for some years at the outset of his career, harassed by the attacks of his discontented kinsmen. Then in his turn he rose against the English, but was defeated and fled to France; in 1571, however, he was pardoned and formally surrendered his lands.

DONOUGH O'BRIEN, the 4th earl (d. 1624), called the "great earl." mas the son and successor of the 3rd earl. He served England well in warfare with the rebellious Irish during the closing year of Elizabeth I's reign and was made president of Munster in 1605. The 8th earl, Henry (1688–1741), was created an English peer as Viscount Tadcaster. When he died the earldom of Thomond became extinct

The estates of the earldom descended to the last earl's nephew, PERCY WYNDHAM (*c.* 1713–1774), a younger son of Sir William Wyndham, Bart. He took the additional name of O'Brien and was created earl of Thomond in 1756. When he died unmarried the title again became extinct.

In 1800 MURROUGH O'BRIEN, 5th earl of Inchiquin (c. 1724–1808), was created marquess of Thomond. His brother James, the 3rd marquess (*c.* 1768–1855), was an officer in the navy and became an admiral in 1853. When he died the marquessate became extinct.

See John O'Donoghue, *Historical Memoirs of the O'Briens* (1860).

THOMPSON, SIR BENJAMIN (COUNT VON RUMFORD) (1753–1814), British-American scientist particularly noted for his researches on heat, and a founder of the Royal institution, was born at Woburn. Mass., on March 26, 1753. In 1766 he was apprenticed to a storekeeper in Salem, Mass , and became interested in chemical and mechanical experiments and in engraving. On the evacuation of Boston by British troops in 1776 he went to London, where he was appointed to a clerkship in the office of the secretary of state. Within several months he was advanced to the post of secretary of the colony of Georgia and in 1780 became undersecretary of state. During this period he continued his scientific pursuits, however, and 1779 was elected a fellow of the Royal society. Thc explosive force of gunpowder, the construction of firearms and a system of signaling at sea were subjects which particularly interested him. On the resignation of Lord North's administration Thompson left the civil service and went to Austria. At Strasbourg he was introduced to Prince Maximilian, afterward elector of Bavaria, and was invited by him to enter the civil and military service of that state. Having obtained permission from the British government to accept the prince's offer and having received the honor of knighthood from George III, he remained at Munich 11 years as minister of war, minister of police and grand chamberlain to the elector. During his stay in Bavaria he reorganized the Bavarian army, improved the conditions of the industrial classes, did much to suppress mendicancy and also contributed a number of papers to the *Philosophical* Transactions.

In 1791 he was created a count of the Holy Roman empire and chose his title of Rumford from the name of the American township to which his wife's family belonged. In 1795 he visited England. where he lost all his private papers including the materials for an autobiography. In London he investigated methods for curing smoky chimneys and for improving fireplace construction. For a short time he was recalled to service in Bavaria, but in 1798 he returned to England. That year he presented to the Royal society his celebrated "Enquiry Concerning the Source of Heat Which is Excited by Friction," in which he regarded heat as a mode of motion, as opposed to the then current view that it was a material substance. In 1799, with Sir Joseph Banks, he projected the establishment of the Royal institution, which received its charter from George III in 1800, and selected Sir Humphrey Davy as scientific lecturer there. Rumford died at Auteuil, near Paris, on Aug. 21, 1814.

He was founder and first recipient of the Rumford medal of the Royal society, founder of the Rumford medal of the American Academy of Arts and Sciences and founder of the Rumford professorship in Harvard university. His complete works, with a memoir by George H. Ellis, were published by the American Academy of Arts and Sciences in 1870–75.

THOMPSON, SIR D'ARCY WENTWORTH (1860–1948). Scottish biologist and hellenist. was born in Edinburgh on May 2, 1860. After graduating at Trinity college, Cambridge, he became professor of natural history at University college, Dundee, and then at St. Andrews university, holding the chair for 64 years. He was a fellow (1916), vice-president (1931–33) and Darwin medalist (1946) of the Royal society, president of the Classical association (1929), knighted (1937) and honoured by learned institutions the world over. For more than 50 years he was a leading member of national and international bodies investigating sea fisheries. His classic work On Growth and Form (1917; new ed., 1942), written in rich literary style, exemplifies best his great erudition in physical and natural sciences, ancient and modern languages and the humanities. Herein growth and structure in organisms are expressed in mathematical and physical terms and an important "theory of transformation" developed—that one species evolves into another not by successive minor changes in individual body parts but by large-scale transformations involving the body as a whole. He died at St. Andrews on June 21, 1948.

THOMPSON, FRANCIS (1859–1907), English poet, whose best-known poem, "The Hound of Heaven," describes the divine pursuit of the human soul, was born at Preston, Lancashire. on Dec. 18, 1859. He was the son of Charles Thompson, a doctor, and the nephew of Edward Healy Thompson, the friend of Cardinal Manning and professor of English literature at the Catholic university in Dublin. After his father became a convert to Roman Catholicism, Francis was educated in the Catholic faith at Ushaw college. In 1877 he proceeded to Owen's college, Manchester, to study medicine. He took more interest in Aeschylus, Blake and De Quincey's Confessions of an English Opium Eater than in his work, however; and. having failed the examinations three times, he went to London in Nov. 1885 to seek a livelihood. Ill-health drove him to opium, and poverty reduced him to selling matches and newspapers. Eventually he found light work with a Leicester square bootmaker and wrote his first poems. In 1888 Wilfrid Meynell published two poems in Merry England, which aroused the admiration of Browning. Discovering the young author on the verge of starvation, the Meynells induced him to enter a hospital, aided him through his long convalescence and in 1893 arranged for the publication of his first volume, Poems, which was highly praised by Coventry Patmore, among others. Sister Songs (dedicated to the Meynells' children) followed in 1895, and New Poems (dedicated to Patmore) in 1897. From 1893 to 1897, apart from short intervals, Thompson lived near the Franciscan monastery in Pantasaph, North Wales. He died in London on Nov. 13, 1907, of tuberculosis, and was buried in the Catholic cemetery at Kensal Green.

Thompson's language is customarily orotund, ornate and farfetched; too often the reader is aware of the poet's self-conscious posturing. The common comparison with Richard Crashaw is misleading. The older poet, though he has something of Thompson's equivocal sensuousness, displays greater care for the meaning of words and maintains a more consistent dignity. Subject aside, the kinship is rather with the Keats of *Endymion*. Thompson is, undeniably, a poet of the "aesthetic" 1890s. His simpler poems (*e.g.*, about children) are frequently marred by a mawkishness of which the poet seemed perversely proud. It is likely that his place in literature will depend entirely upon "The Hound of Heaven," where language and subject matter are more properly matched, and which, by virtue of its dramatic quality, is in fact nearer in spirit to the religious poetry of the 17th century (*cf.* George Herbert), though in this too the somewhat florid religiosity of the 1890s may occasionally repel the reader.

Thompson also wrote several prose works, including *Health and Holiness* (1905), *Life of St. Ignatius Loyola* (1909), *Life of Blessed John Baptist de la Galle* (1911) and *Essay on Shelley* (1909). His *Literary Criticisms* were edited by T. L. Connolly (1948). Thompson's *Works* were edited by W. Meynell, 3 vol. (1913); *Poems* were reprinted in 1 vol. (1937); *Selected Poems* (1908) includes an obituary by W. Meynell.

THOMPSON, SIR JOHN SPARROW (1844–1894), Canadian jurist and statesman, was born at Halifax. Nova Scotia, on Nov. 10, 1844. of Irish descent. In 1877 he was elected to the local legislature for Antigonish as a Conservative. and in 1878 became attorney general. In May 1882 he became premier. but in June was defeated at the general election, though retaining his own seat, and in July was made a judge of the provincial supreme court. In Sept 1885 he was appointed minister of justice in the federal cabinet, and soon after was elected member for Antigonish. In 1886 he successfully defended in the federal parliament the hanging of Louis Riel (*q.v*), which had greatly angered the French Roman Catholics: in 1887–88, together with Mr. Joseph Chamberlain and Sir Charles Tupper, he arranged a Fisheries treaty with the U.S. commissioners, which was afterward thrown out by the United States senate. During the following years he defended the government with great skill in various politico-religious disputes, and in Nov. 1892 he became premier of Canada. He died suddenly on Dec. 12, 1894, at Windsor castle, a few minutes after having been sworn in by Queen Victoria as a member of the privy council.

His *Life* has been written by J. C Hopkins (Toronto, 189;).

THOMPSON, WILLIAM TAPPAN (1812–1882), U.S. humorist remembered for his realistic character sketches of Georgia-Florida backwoodsmen, was born Aug. 31, 1812, in Ravenna, O He early moved to Georgia, where as a self-made man whose education came from the printing press, he identified himself with Georgia life and culture. In 1838 he founded the *Augusta Mirror*, a literary magazine. Discovering that the south would not support literary periodicals, he turned in 18jo to newspaper editorship. founded the *Savannah* (Ga.) *Morning News*, and continued as editor until his death in Savannah on March 24. 1882. A Democrat throughout his editorial career, he typified the ideals, attitudes and prejudices of middle-class Georgians.

Influenced by Augustus Baldwin Longstreet, his personal friend, Thompson wrote amusing dialect letters which were collected in 1843 as *Major Jones' Courtship;* the book achieved nation-wide popularity. Other volumes followed. Thompson had a demonstrable influence on Mark Twain. Richard Malcolm Johnston and Joel Chandler Harris, his literary protégé. His popular antebellum humour is accepted as convincing Georgia dialect and as realistic local colour.

THOMSEN, (HANS PETER JÖRGEN) JULIUS (1826–1909), Danish chemist best known for his work on thermochemistry, was born in Copenhagen on Feb. 16, 1826, and spent his life in that city. From 1847 to 1856 he was engaged in teaching chemistry at the Polytechnique, of which from 1883 to 1892 he acted as director. From 1856 to 1866 he was on the staff of the military high school. He and his brother August founded the important *Journal of Chemistry and Physics*, one of the principal scientific periodicals in Denmark, of which he was editor from 1862–78. In 1866 he was appointed professor of chemistry at the University of Copenhagen and retained that chair until 1891 when he retired. He was awarded the Davy medal in 1883 and elected a foreign member of the Royal society in 1902. He was a member of the municipal council for about 35 years. and the gas, water and sewage systems of Copenhagen mere largely the results of his civic activity. He died on Feb. 13, 1909.

He was attracted to thermochemistry as early as 1852, as his first published paper, entitled "Contributions to a Thermochemical System." shows. But his comprehensive work in this subject was not started until some years later. The results first appeared in 1869, and were published from time to time until 1882. They were collected in *Thermochemische Untersuchungen*, 4 vol (1882–88), and a summary in Danish appeared in 1905. The latter was translated into English as *Tlzermochemistry* by Katherine Burke.

In the course of his thermochemical work Thomsen made about 3,500 calorimetric measurements and he determined the heat evolved or absorbed in a very large number of chemical reactions. Incidentally he verified Kirchoff's equation connecting the change of heat of a reaction with temperature and the specific heats of the reactants and resultants, and also used his measurements to confirm Guldberg and Waage's theory of mass action (1867). Thomsen introduced the term "avidity" to indicate the tendency of an acid to unite with a base and used his results to draw up the first table of relative strengths of acids He also worked on selenic acid, platinum compounds and hydrogen peroxide and made accurate determinations of the atomic weights of oxygen and aluminum In 1853 Thomsen devised a process for manufacturing soda from cryolite, which was first worked on a large scale in 1857 and made him rich. His polarization battery received many awards at international exhibitions and was used in the Denmark telegraphic service. In 1895 he predicted the existence of a group of inactive gases.

THOMSON, SIR CHARLES WYVILLE (1830–1882), Scottish naturalist especially remembered as a student of the biological conditions of the depths of the sea and as director of the scientific staff in the "Challenger" expedition (*q.v.*), was born at Bonsyde, West Lothian (Linlithgowshire). on March 5, 1830, and was educated at Edinburgh university. At first a botanist by profession, he was lecturer in botany at Aberdeen university from 1851 to 1852, and professor of botany at Marischal college from 1852 to 1853. His leanings, however, were toward zoology, and between 1853 and 1868 he taught natural sciences at Cork and at Belfast. Having been for a short time (1868–70) professor of botany at the Royal College of Science. Dublin. he finally (1870–79) was professor of natural history at Edinburgh. He died at Bonsyde on March 10, 1882. Thomson's interest in crinoids was stimulated by the results of the dredgings of the Norwegian zoologist Michael Sars in the deep sea off the Norwegian coasts. With W. B. Carpenter son of the Unitarian minister Lant Carpenter and brother of the philanthropist Mary Carpenter, he succeeded in obtaining the loan of H.M.S. "Lightning" and "Porcupine" for successive deep-sea dredging expeditions in 1868 and 1869. These operations showed that animal life exists in abundance down to depths of 650 fathoms, that all invertebrate groups are represented (largely by Tertiary forms previously believed to be extinct) and, moreover, that deep-sea temperatures are by no means so constant as was supposed, but vary considerably, indicating an oceanic circulation. The results of these expeditions were described in ***The***

Depths of the Sea (1873). The government realized the value of the work and provided H.M.S. "Challenger" for a circumnavigating expedition. Thomson sailed at the end of 1872 as director of the scientific staff, the cruise lasting three and one half years. On his return he received many academic honours, and was knighted. In 1877 he published two volumes of a preliminary account of the voyage *(The Voyage of the "Challenger"*; and *The Atlantic)* and, with John Murray, superintended the preparation of the full reports until the time of his death.

THOMSON, CHRISTOPHER BIRDWOOD, 1ST BARON, cr. 1924 (1875–1930), British soldier and statesman) was born on April 13, 1875. Educated at Cheltenham and the Royal Military academy, Woolwich, he served in the Mashonaland campaign and in the South African War. From 1902–05 he was instructor at the military engineering school at Chatham. In 1909 he passed on to the Staff college and in 1911 to the war office. During World War I he served as military attach6 and chief of the British military mission in Rumania (1915–16), and in Palestine (1917) and was on the supreme war council in 1918. Having attained the rank of brigadier general, he resigned from the service in 1920 as a protest against Allied intervention in Russia. He joined the Labour party, and accompanied, as military expert, the commissions of enquiry dispatched by that body to Ireland and to the Ruhr; later, he visited Russia. In 1922, and again in 1923, he stood for parliament in the Labour interest, but was unsuccessful. In 1924, he was appointed air minister in the first Labour government, with a seat in the cabinet, and raised to the peerage. A graceful and effective speaker, Lord Thomson also possessed marked literary gifts and published various writings including *Old Europe's Suicide* (1922); *Victors and Vanquished* (1924). He was killed in the crash of the airship R·IOI in 1930.

THOMSON, ELIHU (1853–1937), U.S. inventor, was born in blanchester, England, March 29, 1853, but moved to Philadelphia, Pa., with his parents in 1858. He received a public school education and in 1876–80 was professor of chemistry and mechanics at the Central high school in Philadelphia. In 1880 he went to New Britain, Conn., as electrician for the American Electric company and two years later he united with Edward J. Houston to found the Thomson-Houston Electric company in Lynn, Mass. In 1892 a merger took place between this company and the' Edison General Electric company to form the General Electric company, the largest manufacturer of electrical equipment in the world. Thomson remained as director of the large laboratory in Lynn, renamed after him the Thomson laboratory. Thomson made the first important research into the nature of the laws governing the electric arc, disclosing the fact that the resistance of the arc varies inversely with the current. He invented and constructed an arc light dynamo with a spherical three-coil armature, and the first with an automatic regulator, which went into commercial use in 1880. He was the first to utilize a magnetic field to move an electric arc, a principle which found many uses, notably in the construction of the magnetic blowout switches. In his notable discovery of the so-called alternating current repulsion phenomena he laid the basis for successful alternating current motors. He made the first high-frequency dynamo in 1890 and shortly afterward the first high-frequency transformer, and was a pioneer in the development of other high-frequency apparatus. In 1886 he invented the art of electric welding by the incandescent method which was simpler and less expensive than previous methods and applicable to a wider range of metals.

Thomson also invented the electric watt-hour meter, while the arc lamp, incandescent lamp, alternator, alternating current transformers and railway motors found improvement at his hands. He made many contributions to the field of radiology and was the first to make stereoscopic X-ray pictures. He published many articles in scientific journals, held over 700 patents, and received the Rumford, John Fritz, Kelvin and Faraday medals as well as other honours.

THOMSON, SIR GEORGE PAGET (1892–), English physicist, a co-winner of the Nobel prize for physics in 1937 for his work on the diffraction of electrons in crystals, was born in Cambridge, Eng., May 3. 1892, the only son of Sir Joseph John Thomson (*q.v.*), the eminent physicist and Nobel prize winner (1906). After taking his degree at Trinity college, Cambridge, in 1914, he saw service in World War I in France and was later a member of the British war mission in the U.S. At the end of the war he worked in the Cavendish laboratory at Cambridge. In 1922 he was appointed professor of natural philosophy in the University of Aberdeen, and it was there that he did work on the diffraction of electrons in crystals which established the wave properties of moving electrons and also had important practical applications. By means of the electron diffraction camera it is possible to determine the arrangement of the atoms in many solids and liquids, and this threw much light on the question of stress and resistance in metals. From 1930 to 1952 Thomson was professor of physics in the Imperial College of Science and Technology, University of London. During and after World War II he was one of the principal scientific advisers to the British government and to the UN Atomic Energy commission. He was elected a fellow of the Royal society in 1930 and was awarded the Hughes medal in 1939 and the Royal medal in 1949; he was knighted in 1943. In 1952 he became master of Corpus Christi college, Cambridge.

He wrote *Applied Aerodynamics* (1919); *The Atom* (1930; 5th ed., 1955); *Wave Mechanics of Free Electrons* (1930); *Theory and Practice of Electron Diffraction* (with William Cochrane, 1939); and *The Foreseeable Future* (1955); he also helped revise his father's *Conduction of Electricity Through Gases* (3rd ed., 2 vol., 1928–33). THOMSON, JAMES (1700–1748), English poet, author of *The Seasons*, was born at Ednam, in Roxburghshire, on Sept. 11, 1700—the third son and fourth child of Thomas Thomson, minister of that place. About 1701 Thomas Thomson removed to Southdean near Jedburgh. Here James was educated at first by Robert Riccaltoun, to whose verses on winter he owed the idea of his own poem, and then at a school at Jedburgh. In 1715 he went to Edinburgh university. He became a divinity student, and it was partly to make a reputation as a preacher that he went to London in March 1725. He had already friends in London in Lady Grizel Baillie and Duncan Forbes of Culloden, and he was introduced by them to literary society in London, where he supported himself partly by acting as tutor.

The Seasons.——Thomson's *Winter* appeared in March 1726. It was dedicated to Sir Spencer Compton. the speaker, uho rewarded the poet. to his great disgust, with a bare 20 guineas. *Summer* appeared in 1727, dedicated to Bubb Dodington. In the same year Thomson published his *Poem to the Memory of Sir Isaac Newton. Spring* appeared in 1728, published by Andrew Millar. In 1729 he produced *Sophonisba*, a tragedy now only remembered by the line "O Sophonisba, Sophonisba, 0," and the parody "O Jemmy Thomson, Jemmy Thomson, O." A poem, anonymous but unquestionably Thomson's, to the memory of Congreve appeared in the same year. In 1730 *Autumn* was first published in a collected edition of *The Seasons.* It was dedicated to the speaker, Onslow. In this year, he accompanied the son of Sir Charles Talbot, solicitor-general, upon his travels. In the course of these he projected his *Liberty* as "a poetical landscape of countries, mixed with moral observations on their government and people." In Dec. 1731 he returned with his pupil to London. His pupil died soon after, and Talbot, who became chancellor, gave Thomson a sinecure in chancery. The first part of *Liberty* appeared in 1734–35, and it was completed in five parts in 1736. The poem was a failure; its execution did not correspond with its design; in a sense indeed it is a survey of countries and might have anticipated Goldsmith's *Traveller.* The truth is that Thomson's poetical gift was for many years perverted by the zeal of partisanship.

His patron died in Feb. 1737 and he lost his sinecure. His tragedy *Agamemnon* appeared in April 1738, not before he had been arrested for a debt of £70, from which, according to a story which has been discredited on quite insufficient grounds, Quin relieved him in the most generous and tactful manner. The incident took place probably a little before the production of *Agarnemnon,* in which Quin played the leading part. The play is of course modelled upon Aeschylus and owes whatever of dignity it possesses to that fact; the part of Cassandra, for instance, retains something of its original force. But most of the other characters exist only for the purpose of political innuendo. Agamemnon is George, absent in Germany; Aegisthus is Walpole, and so on. As a result his next tragedy, *Edward and Eleanora,* was banned. This event sufficiently accounts for the poet's next experiment, a preface to Milton's *Areopagitica.* He joined Mallet in composing the masque of *Alfred,* represented at Clieveden on the Thames before the prince of Wales, on Aug. 1, 1740. There can be little question that "Rule Britannia," a song in this drama, was the production of Thomson. The music of the song, as of the whole masque, was composed by Arne. In 1744 Thomson was appointed surveyor-general of the Leeward Islands by Lyttelton with an income of £300 a year; this improved his circumstances considerably, and whilst completing at his leisure *The Castle of Indolence,* he produced *Tancred and Sigismunda* at Drury Lane in 1745.

Eventually *The Castle of Indolence,* after a gestation of 15 years, appeared in May 1748. It is in the Spenserian stanza with the Spenserian archaism, and is the first and last long effort of Thomson in rhyme. The great and varied interest of the poem might well rescue it from the neglect into which even *The Seasons* has fallen. It was worthy of an age which was fertile in character-sketches, and excels in the lifelike presentation of a noteworthy circle. It is the last work by Thomson which appeared in his lifetime. In walking from London to his house at Richmond he became heated and took a boat at Hammersmith; he thus caught a chill and died on Aug. 27, 1748. He was buried in Richmond churchyard. His tragedy *Coriolanus* was acted for the first time in Jan. 1749. In itself a feeble performance, it is noteworthy for the prologue which his friend Lyttelton wrote, two lines of which—

> He loved his friends—forgive the gushing tear!
> Alas! I feel I am no actor here—

were recited by Quin with no simulated emotion.

Precursor of Romanticism.—It may be questioned whether Thomson himself ever quite realized the distinctive significance of his own achievement in *The Seasons,* or the place which criticism assigns him as the pioneer of a special literary movement and the precursor of Cowper and Wordsworth. His avowed preference was for great and worthy themes of which the world of nature was but one, but fortunately his readers were wiser than himself. And though he recalled the minds of his contemporaries from the town to the country, in his feeling for nature, he is a true man of his age; his descriptions are general, and purely objective. There is no hint yet of the emotional reactions of the Romantic school. He has many audacities and many felicities of expression, and enriched the vocabulary even of the poets who have disparaged him. Yet it is difficult to believe that he was not the better for that training in refinement of style which he partly owed to Pope.

The first collected editions of *The Seasons* bear dates 1730, 1738, 1744, 1746. Lyttelton tampered both with *The Seasons* and with *Liberty* in editions after his friend's death. Among the numerous lives of the poet may be mentioned those by his friend Patrick Murdoch, by Dr. Johnson in *Lives of the Poets,* by Sir Harris Nicolas (Ald. ed., 1860), by M. Morel, *James Thomson, sa vie et ses oeuvres* (Paris, 1895), and *James Thomson,* in the English Men of Letters Series, by G. C. Macaulay (1908). *See* also Dr. G. Schmeding's *Jacob Thomson, ein vergessener Dichter des achtzehnten Jahrhunderts;* the life prefixed to the Aldine edition of his works in 1897; and an excellent edition of *The Seasons* in the Clarendon Press Series by J Logie Robertson. THOMSON, JAMES (1834–1882), British poet, best known by his signature "B.V.", was born at Port-Glasgow, in Renfrewshire, on Nov. 23, 1834, the eldest child of a mate in the merchant shipping service. His mother was a deeply religious woman of the Irvingite sect. On her death, James, then in his seventh year, was procured admission into the Caledonian Orphan asylum. In 1850 he entered the model school of the Military asylum, Chelsea. As assistant army schoolmaster at Ballincollig, near Cork, he encountered the one brief happiness of his life: he fell passionately in love with, and was in turn as ardently loved by, the daughter of the armourer-sergeant of a regiment in the garrison, a girl of very exceptional beauty and cultivated mind. Two years later he suddenly received news of her fatal illness and death. The blow prostrated him in mind and body. Henceforth his life was one of gloom, misery and poverty, rarely alleviated.

While in Ireland he had made the acquaintance of Charles Bradlaugh, then a soldier stationed at Ballincollig. In 1860 was established the paper with which Bradlaugh was so long identified, the *National Reformer,* in which, among other productions by James Thomson, there appeared (1861) the powerful and sonorous verses "To our Ladies of Death," and (1874) his chief work, the sombre and imaginative *City of Dreadful Night.* In Oct. 1862 Thomson was dismissed from the army, in company with other teachers, for some slight breach of discipline. Through Bradlaugh, with whom he lived for some years, he gained employment as a solicitor's clerk. From 1866 to the end of his life, except for two short absences from England, Thomson lived in a single room, first in Pimlico and then in Bloomsbury. He was intemperate in his habits, and made few friends. In 1869 his long poem, "Sunday up the River," appeared in *Fraser's Magazine.* In 1872 Thomson went to the western states of the U.S., as the agent of the shareholders in what he ascertained to be a fraudulent silver mine; and in 1873 he received a commission from the New York *World* to go to Spain as its special correspondent.

On his return to England he continued to write in the *Secularist* and the *National Reformer,* under the initials "B.V."[1] In 1875 he severed his connection with the *National Reformer,* owing to a disagreement with its editor; henceforth his chief source of income (1875–81) was from the monthly periodical known as *Cope's Tobacco Plant.* Chiefly through the exertions of his friend and admirer, Bertram Dobell, Thomson's best-known book, *The City of Dreadful Night, and other Poems,* was published in April 1880, and at once attracted attention; it was succeeded in the autumn by *Vane's Story, and other Poems,* and in the following year by *Essays and Phantasies.* All his best work was produced between 1855 and 1875 ("The Doom of a City," 1857; "To our Ladies of Death," 1861; *Weddah and Om-el-Bonuin,* "The Naked Goddess," 1866–67; *The City of Dreadful Night,* 1870–74). He died at University College Hospital, in Gower Street, London, on June 3, 1882, and was buried at Highgate cemetery, in the same grave, in unconsecrated ground, as his friend Austin Holyoake.

To the productions of James Thomson already mentioned may be added the posthumous volume entitled *A Voice from the Nile, and other Poems* (1884), to which was prefixed a memoir by Bertram Dobell. If James Thomson has distinct affinity to any writer it is to De Quincey. The merits of Thomson's poetry are its imaginative power, its sombre intensity, its sonorous music; to these characteristics may be added, in his lighter pieces, a Heine-like admixture of strange gaiety, pathos and caustic irony. The same may be said of his best prose. His faults are a monotony of epithet, the not infrequent use of mere rhetoric and verbiage.

See the *Life, by* H. S. Salt (1905 edition).

THOMSON, SIR JOHN ARTHUR (1861–1933), British naturalist known chiefly for his popular books and writings on biology, was born at East Lothian, Scot., on July 8, 1861, and was educated at the universities of Edinburgh, Jena and Berlin. He was, for a time. lecturer on zoology and biology at the school of medicine in Edinburgh, and in 1899 he became regius professor of natural history at Aberdeen university. Apart from his purely zoological work, chiefly on alcyonarians, Thomson did much, both by his lectures and his numerous attractive books and writings, to popularize biological science, and he was indefatigable in his efforts to correlate science and religion. He was knighted in 1930 and died Feb. 12, 1933.

His publications include: *Outlines of Zoology,* 9th ed. (1944); *The Wonder of Life* (1914); *The System of Animate Nature,* Gifford Lectures (1920); *Science, Old and New* (1924); *The New Natural History* (1925); *Science and Religion* (1925).

[1]Bysshe Vanolis: "Bysshe," as the commonly used Christian name of Shelley, Thomson's favourite writer; and "Vanolis," an anagram of Novalis (F. von Hardenberg).

THOMSON, JOSEPH (1858–1895), Scottish explorer and the last who, during the late 18th and part of the 19th centuries revealed the interior of Africa, was also the first who served the chartered companies developing the new discoveries. Born on Feb. 14, 1858, at Penpont, Dumfriesshire, he studied geology at Edinburgh university under Archibald Geikie, and in 1878 was appointed geologist and naturalist to the Royal Geographical society's expedition to east central Africa, under Keith Johnston. Johnston's early death left Thomson in command and, with David Livingstone's Chuma as his headman, he led the expedition to the north end of Lake Nyasa and thence to Lake Tanganyika. An attempt to reach the Congo was thwarted by the hostile Warua, and he returned to the coast by Tabora, discovering Lake Rukwa on the way. He investigated some spurious coal mines on the Rovuma for the sultan of Zanzibar in 1881.

In 1882 the Royal Geographical society launched an expedition led by Thomson to probe the shortest route from the sea to the Nile headwaters, a may hitherto barred by the warlike Masai. Thomson traveled from Mombasa by way of Mounts Kilimanjaro and Kenya, discovered Lake Baringo and, surviving numerous encounters with the Masai, reached Lake Victoria on Dec. 10, 1883.

Thomson received the Royal Geographical society's founder's gold medal for 1885. In 1885 he undertook a mission for the National African (afterward the Royal Niger) company, securing trade treaties with the sultans of Sokoto and Gando, in 1888 he traveled privately in Morocco and in 1890 he entered the service of Cecil Rhodes' South Africa company, on whose behalf he made trade and mining agreements in what is now Northern Rhodesia. Thomson's splendid constitution at last gave way, and he returned to Gatelawbridge in 1891 in permanently impaired health. He died in London on Aug. 2, 1895.

Thomson's maxim when traveling was the Italian saying: "Who goes slowly, goes safely; who goes safely, goes far," and he was notable for his abhorrence of force. He wrote *To tlze Central African Lakes and Back* (1881), *Through Masui Land* (1884), *Travels in the Atlas and Southern Morocco* (1889).

THOMSON, SIR JOSEPH JOHN (1856–1940), English physicist, the discoverer of electrons and the recipient of the 1906 Nobel prize in physics for his work on the conduction of electricity through gases, was born at Cheetham Hill, near Manchester, on Dec. 18, 1856. At the age of 14 he enrolled at Owens college, Manchester. In 1876 he went to Cambridge and entered Trinity college as a minor scholar; he remained a member of this college, in one capacity after another, during the rest of his life. In 1884 he was elected a fellow of the Royal society and upon the resignation of Lord Rayleigh that same year was chosen his successor in the Cavendish professorship at Cambridge, a chair which he held until 1919.

Thomson's treatise on vortex rings, which won him the Adams prize and which may be taken as an indication of his early interest in atomic structure, appeared in 1883. Ten years later, in 1893, his *Notes on Recent Researches in Electricity and Magnetism* appeared. This book covers results obtained after the appearance of James Clerk Maxwell's great *Treatise* in 1873, and is often alluded to as "the third volume of Maxwell." *A Textbook of Physics,* in four volumes, was the joint work of Thomson and John H. Poynting. These books had a wide use, as did Thomson's *Elements of the Mathematical Theory of Electricity and Magnetism* (1895; 5th ed., 1921).

In 1896, Thomson gave a course of four lectures at Princeton university. These summarized his researches on the *Discharge of Electricity Through Gases.* Several years later, at Yale university, he gave a series of six lectures on *Electricity and Matter* (1904) in which some keen suggestions looking toward atomic structure were offered. It was, however, between these two series of C.S. lectures that he accomplished the most brilliant work of his life. This was the highly original study of cathode rays, in which he measured the ratio $\frac{m}{e}$ (where m is mass and e the charge of an ion) and discovered that its value is nearly 1,000 times less than in the electrolysis of liquids. He immediately proceeded to measure the charge of electricity, e, carried by various negative ions and found it to be the same in the gaseous discharge as in electrolysis. In this manner the fact was established that the particles which constitute cathode rays are much smaller than the smallest atoms known. They are the particles now called "electrons." This discovery of a body smaller than the hydrogen atom was first announced in his Friday evening lecture at the Royal institution on April 30, 1897.

In 1903 he published his most remarkable book, *Conduction of Electricity Through Gases,* described by Lord Rayleigh as a summary of "the work of Thomson's great days at the Cavendish laboratory." A later edition, in two volumes, was published in collaboration with his son, George P. Thomson (*q.v.*) in 1928 and 1933.

Thomson's later researches led to an exceedingly important discovery, namely, a new method of separating different kinds of atoms and molecules. This consists in the use of "positive rays," the deflection of which in a magnetic or electric field varies, other things being equal, with the atomic weight. This idea, in the hands of Francis W. Aston, A. J. Dempster and others, led to the discovery of many isotopes (*q.v.*).

Thomson was president of the Royal society from 1915 to 1920 and master of Trinity college from 1918 to 1940. He died in Cambridge on Aug. 30, 1940; his ashes were buried in Westminster abbey. His autobiographical *Recollections and Reflections* was published in 1936.

THONBURI, a city and province in central Thailand on the west bank of the Chao Phraya river across from Bangkok. Area of province 174 sq.mi., pop. (1956 est.) 445,093. Approximately 28% of the city's population (1957 est., 319,909) is of immediate Chinese descent, 16% being China-born. Connected by three bridges with Bangkok, the city has in effect become a suburb of the capital.

Thonburi is a centre for sawmilling, rice milling and light manufacturing industry. Many of its people live on *khlongs* or canals, on which "floating markets" can be seen. The most prominent landmark is Rat Arun, the Temple of Dawn. During the reign of King Taksin (1767–82), Thonburi was the national capital. Paddy production for the province averages about 40,000 metric tons annually. (G. W. Sk.)

THONET, MICHAEL, (1796–1871), Austrian manufacturer, originator of bentwood furniture, was born July 2, 1796, at Boppard in the Rhineland. A humble artisan, Thonet by the age of 40 developed a system of steam-bent veneers, glued four or five together, from which he made complete chairs, light and curvilinear. Similar techniques were simultaneously used, but less freely, by the German-born Henry Belter in New York city, and bent plywood had even been used by the ancient Egyptians for mummy cases. Thonet's inventiveness attracted Prince Metternich, another native Rhinelander, who in 1842 invited Thonet to settle in Vienna, where for the next five years he worked on the masterly neorococo interiors of the Liechtenstein palace.

Some of Thonet's work there included bent, solid wood, formed by methods familiar to wheelwrights; these pieces were subcontracted through the important firm, Carl Leistler and Son, decorating the palace.

By 1856 Thonet had perfected the bending of solid wood and was ready for mass production. From then on, success attended Thonet's enterprises. He died on March 3, 1871, in Vienna where his firm was producing furniture in hitherto unheard-of quantities, around 400,000 pieces annually. Solid bentwood furniture, never out of production, was again made fashionable by Le Corbusier in the 1920s. In 1953 the centenary of Thonet's firm was celebrated internationally. (Er. K.)

THONGA (properly Tsonga), a group of Bantu-speaking peoples inhabiting the southern part of Mozambique and stretching into neighbouring territories. Culturally and linguistically the Thonga are related to other Mozambique peoples such as the Chopi, Lenge and Inhambane Tonga.

The Thonga group comprises a number of formerly independent tribes, each of which occupied its own territory which was under the domination of a powerful patrilineage, whose name was also the name of the territory. During the 19th century they were conquered by Nguni-speaking raiders from the south, who formed the Shangaan and other kingdoms.

The people dwell in scattered homesteads, each inhabited by a group of males. related by agnatic descent, with wives and children. The Thonga have patrilineal succession and inheritance. They allow polygamy and husbands give bride wealth for their brides. A man's cattle herd is apportioned among the households of his wives for their support and for ultimate inheritance by the children of the household. The principal heir is the senior son of the chief wife. Children are also closely linked to their mother's lineage. They have a joking relationship with their mother's brother and may make free with his property. Divorce is rare. On the death of a man, his wives are usually inherited by other males of his lineage.

They are agriculturalists and pastoralists, much of the agricultural work falling upon the women, but also practice some fishing and hunting. For a cash income they are dependent upon wage labour. At any one time a large proportion of the able-bodied men are away at work in the Union of South Africa or in the cities of Mozambique. They have a highly developed set of ritual systems. Males are initiated into adult life through an initiation school and circumcision.

There is a strong cult associated with ancestral spirits who may be approached only by members of their own lineage. Illness and other misfortune are usually attributed to the breaking of a taboo, to the anger of the ancestors or to sorcery. Detection of the agent is done through divination. Sorcery accusations are most commonly leveled at women married into the lineage, rarely at lineage mates.

THOR, a mythological deity of the Scandinavians, is represented as a middle-aged man of enormous strength, an implacable foe to the harmful race of giants (demons), but benevolent toward mankind. His figure is somewhat secondary to that of Odin, represented as his father. But in Iceland and indeed, perhaps, in all northern countries except among the royal families, he was apparently worshiped more than any other god. There is evidence that a corresponding deity named Thunor or Thonar was worshiped in England and on the continent, but little is known about him beyond his identification with the Roman Jupiter. His name is the Teutonic word for thunder. Outside the Teutonic area he has close affinities with Jupiter or Zeus, and still more with the Lithuanian god Perkunas, whose name (which likewise means "thunder") appears to be connected with that of Thor's mother (Fiorgyn). THORAX, the anatomical term for the chest, in man and other mammals that part of the body between the neck and abdomen. The bony framework consists of the 12 thoracic vertebrae, 12 pairs of ribs and the sternum or breastbone. It contains the chief organs of respiration and circulation; namely, the lungs, some air passages, the heart and great vessels. Below, it is bounded by the diaphragm. The bony framework is encased with muscles, fat and cutaneous tissues. (See SKELETON, VERTEBRATE.)

In insects the thorax is the middle of the three major divisions of the body. It is composed of three parts, each of which commonly bears a pair of legs; the rearward two parts usually bear each a pair of wings. (F. L. A.; X.)

THORBECKE, JAN RUDOLF (1798–1872), Dutch statesman, was born at Zwolle, in the province of Overijssel, on Jan. 14, 1798. He studied at Leiden, and, on the completion of his course, visited the principal German universities. At Giessen he lectured as an extraordinary professor, and at Göttingen, in 1824, published his treatise, Ueber *das Wesen* der Geschichte. After his return to Amsterdam in 1824 Thorbecke wrote his Bedenkingen *aangaande* het Recht en den Staat ("Objections Anent Law and the State"), which procured him in 1825 a chair as professor in Ghent university. The Belgian revolt of that year drove him from Ghent to Leiden, where he became professor of jurisprudence and political science. His standard work. *Aanteekeningen op* de *Grondwet* ("Annotations on the Constitution," 1839; 2nd ed., 1841–43), became the textbook and the groundwork for the new reform party in the Netherlands, as whose leader Thorbecke mas definitely recognized.

Thorbecke's political career until his death, which occurred at The Hague on June 4, 1872, is sketched under HOLLAND: History.

See biographies *by* Buys (Tiel, 1876) and J A. Levy (1876). There are two collections of his *Speeches,* 6 vol. (1867–70; 1900). His *Correspondence With Groen van Prinsterer* appeared in 1873.

THOREAU, HENRY DAVID (1817–1862), U.S. writer, poet and philosopher who invested his life in his native village to the end of enacting the doctrines of New England Transcendentalism as expressed by his friend and associate Ralph Waldo Emerson (*q.v.*), among others. A naturalist chiefly in the sense that nature was his field of action and contemplation, Thoreau was concerned primarily with the possibilities for human culture provided by the American natural environment. He believed that "All things invite this earth's inhabitants/To rear their lives to an unheard-of height"; to meet this "expectation of the land" (Collected *Poems* of Henry Thoreau, edited by Carl Bode, p. 135, Packard and Co., Chicago, 1943), he domesticated ideas garnered from classical, oriental, English and the then current romantic literatures in order to extend U.S. libertarianism and individualism beyond the political and religious spheres to those of social and personal life. In a society which Henry James said was "not fertile in variations" (F. O. Matthiessen, The *James Family,* p. 441, Alfred A. Knopf, Inc., New York, 1947), Thoreau pioneered the life of an artist and like Emerson opened vistas to new vocations and intrinsic successes. "The life which men praise and regard as successful is but one kind. Why," he asked in Walden, where his example was the answer, "should we exaggerate any one kind at the expense of the others?" (This and all following quotations from the prose works of Thoreau — the standard Walden edition, The Writings of Henry David Thoreau, 1906— are by permission of Houghton Mifflin Company, Boston.) In a commercial, conservative, expedient society rapidly becoming urban and industrial, he upheld the right to self-culture, to an individual life shaped by inner principle. An artist whose life was his material, he demanded for all men the freedom to follow unique life styles, to make poems of their lives and living itself an art. Wholeness and being were his aims, not the limited fulfillment of specialization; the artisan was to become an artist, the partial man "spheral," the factitious man authentic. In a restless, expanding society dedicated to practical action, he demonstrated the uses and values of leisure, contemplation and rootedness.

Thoreau's writing not only enriched the New England landscape with human associations, but taught men how to take up the land without despoiling it — with .their imaginations. He established the tradition of nature writing developed by John Burroughs and John Muir, and his pioneer study of the human uses of nature profoundly influenced such conservationists and regional planners as Benton MacKaye and Lewis Mumford. More important, his life, so fully expressed in his writing, has had a pervasive influence because it was an example of moral heroism and an example of the continuing search for a spiritual America. One of the classic U.S. writers, he became a culture hero because he had shown that "the intransigence of the spiritual unit . . . alone gives edge to democracy" (The Seven Arts, II, July, 1917, p. 385).

Early Life. — Although Thoreau playfully linked his genealogy with that of the first discoverers of America, the Viking descendants of Thor, and characterized himself as a follower of the "trade of heroism," Thoreau's outward life offered little adventure for the annalist. The son of John Thoreau, whose father had emigrated from the Channel Islands, and of Cynthia Dunbar, daughter of a Congregational minister, he was born July 12, 1817, in the rural village of Concord, where his unsuccessful father finally settled and set up a small graphite pencil factory. This home industry, which Thoreau dutifully served all of his life, and his mother's boardinghouse, where he lived except for the intervals at the Emersons' and at Walden pond, were his permanent background.

Thoreau prepared at the Concord academy, and, at great sacrifice to his family, entered Harvard college in 1833. There he came abreast of his age, encountering both the intellectual heritage of the 18th century. which he would soon abandon, and the new thought that provided the philosophical basis for his experiment in life. Jones Very, a minor Transcendentalist poet, was his tutor in Greek; Orestes Brownson (*q.v.*), soon to become a Transcendentalist publicist, helped him with German during a schoolteaching vacation; Edward Tyrel Channing, professor of rhetoric, assigned compositions in which Thoreau sketched his conception of the superior man and recorded the increasing Transcendental tendency of his thought. A good student but indifferent to the rank system and preferring to use the library to his own ends, he graduated midway in the class of 1837. But, as he announced in his commencement piece on "The Commercial Spirit," with its scorn for getting and spending, with its plea for cultivating "the moral affections" and the powers to enjoy and admire the "wonderful" world, he was eager to follow a vocation for which few of his classmates had the inclination, preparation or heart.

Emerson called Thoreau to that vocation. During commencement week he delivered his challenging Phi Beta Kappa address, "The American Scholar." In it he summoned the younger generation to follow his own calling—that of the independent intellectual at the service of the republic—and to fulfill in action the program for nurturing American genius and culture that he had outlined in *Nature* (1836). "He shall see," he promised the self-reliant truth seeker, "that nature is the opposite of the soul, answering to it part for part. . . . Its beauty is the beauty of his own mind. Its laws are the laws of his own mind. Nature then becomes to him the measure of his attainments. So much of nature as he is ignorant of, so much of his own mind does he not yet possess. . . . in fine, the ancient precept, 'Know thyself,' and the modern precept, 'Study nature,' become at last one maxim." This "correspondence" between the subjective and the objective, the inner and the outer, the indwelling spirit in man and the immanent spirit in nature, were at the core of the Transcendentalist faith. To discover the identities between man and nature, to translate the external world into consciousness, to humanize science by making fact flower into truth. was now the work of the scholar. Thoreau undertook this exploration of "whole new continents and worlds within" when, on his return to Concord, Emerson suggested that he keep a journal; eventually running to 39 manuscript volumes, the journal became the principal archive of Thoreau's arduous experience of assimilating nature to himself.

After Haward.—Immediately following his graduation Thoreau kept a school; privately he continued his apprenticeship to his chosen craft by writing poems and literary essays. He began his long service as lecturer and curator for the Concord Lyceum and published his first poem in the newly launched magazine the *Dial*, edited by Margaret Fuller (*q.v.*) and Emerson. He fell in love with Ellen Sewall of Scituate and was rejected. Unwilling to postpone his life and already lamenting that he was an Apollo enslaved to Admetus, he gave up teaching; on Emerson's request, he went to live with his mentor, exchanging his skills as handy man and editorial assistant on the *Dial* for the freedom to pursue his own work.

Emerson turned Thoreau to nature writing by prompting Thoreau's first major essay, "Natural History of Massachusetts"; he severely pruned Thoreau's poems; and he tried to bring his protégé to market by sending him as tutor to the William Emersons of Staten Island, where he might find it easier to sell his wares in New York. Thoreau, however, was unsuccessful. As he put it, his essays were not "companionable"; "Paradise (To Be) Regained" destroyed the popular assumptions of utilitarian progress, and "A Winter Walk," one of the best of his early spiritual excursions, was better fitted for the *Dial*. Confirmed in his distaste for city life, disappointed by his failure, and in debt, he returned home and with Yankee brevity noted in his autobiographical record. "Made pencils in 1844."

The Walden Years.—In 1845, Emerson provided the few acres Thoreau needed for his Walden experiment, which was to make good his losses and permit him at last to have his life while living it; but Emerson did not approve what seemed to him a withdrawal into solitude and an abdication of the "Napoleonic" leadership he expected of his "brave Henry." For Thc eau. however. going to nearby Walden pond was an act of independence, the act of precipitating his fate (in *Walden* he began the account of his residence there on Independence day). Not only did he aish to solve by simplicity and subsistence farming his economic problems as a writer, he wished by means of his intimacy with nature to meet "the great facts of his existence" and to live an uncommitted life open to spirit. To him the landscape of his new life bordered the "Elysian fields"; measured by his ecstatic communion with nature, the two years at Walden were the great occasion of his life.

Thoreau left the pond in September 1847 in order to manage the Emerson household during Emerson's absence on a lecture tour in Great Britain and because, with *A Week on the Concord and Merrimack Rivers* completed, he felt ready to retrieve his early failure. He was unable to find a publisher, however, and the publication of this, his first book, was delayed until 1849, when Thoreau issued it at his own expense. It mas so poorly received that Thoreau resisted the appeals to publish *Walden* until the debt he had incurred mas paid. Just as poorly received were his attempts as a lecturer to find a public. Having "not made it worth any one's while" to buy his delicately woven wares, as he explained in *Walden*, he tried to "avoid the necessity of selling them." He no longer tried to maintain himself by writing; he returned to the pencil factory and to surveying, his occupations for the rest of his life.

The Fruits of **Walden.**—Thoreau's greatest books, *A Week* and *Walden*, were indebted to the Walden years. Companion volumes, the first covers Thoreau's spiritual history from 1839 to 1849, the second the years from 1845 to 1854 *A Week* takes its joyousness from the vacation mood and spiritual communion of these early years and the years at Walden where it was nritten. An excursion in thought, its narrative framework is the boat trip Thoreau had made with his beloved brother John in 1839; the literal adventure carried with it his thoughts on religion, friendship, politics, reform, art and nature—the experience of a decade of exploration. The book enacts Thoreau's belief that "the order of things should be somewhat reversed; the seventh day should be man's day of toil . . . and the other six his Sabbath of the affections and the soul,—in which to range this widespread garden, and drink in the soft influences and sublime revelations of Nature. . . ." A meandering, meditative book, successfully uniting action and contemplation; a series of days on the stream of consciousness; a voyage into America, to the headwaters of inspiration: *A Week* covers Thoreau's life from youth to maturity, from the easy availability of inspiration to the more conscious use of inspiration in the creation of art.

Thoreau's relation to nature in *A Week* was "one and continuous everywhere"; inspired, his life was "constantly as fresh as this river." He was "a long-lived child/As yet uninjured by all worldly taint/. . . whose whole life is play." In *Walden*, he was the "mature soul of lesser innocence" who, "from the sad experience of his fate," had consciously earned "the ripe bloom of a self-wrought content" (Bode, p. 225).

Walden was begun in 1846–47, but was considerably modified and amplified in six revisions, material being incorporated almost until the time of publication in 1854. The book therefore did not literally record the Walden experience, for this experience was refracted by what Thoreau felt was the "decay" of the following years during which it was brought to completion. A symbolic book, then, treating his experience not so much retrospectively as prospectively, to the end of self-therapy and hope, *Walden* affirmed Thoreau's faith in "the unquestionable ability of man to elevate his life by conscious endeavor." By his definition, the book was a scripture, the sacred testament of a man living through the process of revelation; its myth, secured by the seasonal movement of the narrative from summer to spring, was that of a return to the springs of life—a fable of spiritual renewal.

Later Writings — Thoreau's actual life in these and the remaining years did not bring renewal. Now his problem was a more difficult one than that of living by writing. His inspirational relation to nature itself had been broken by the deterioration of his friendship with Emerson, by his involvement in the antislavery movement, by the impurity that he felt was due to the coarse life required of the surveyor, and by the intense strain of the outdoor life and the scientific studies he imposed on himself. The goal of self-culture, he found, could not be fully realized in nature; personal and social relations were also necessary. The inevitable awareness of manhood had destroyed the unconsciousness of youth and, with it, the communion with nature he now desperately tried to regain by discipline.

Though his sense of losing his innocence and purity was great, his powers as a writer were increased by his more objective investigation of nature and by his social concerns. "Civil Disobedience," his most famous essay (it influenced Gandhi, among others), was his defense of the private conscience against majority expediency; published in 1849, it announced the moral intransigence of later essays such as "Slavery in hfassachusetts" and "Life Without Principle." and those essays written in behalf of John Brown, who carried the political faith of the Transcendentalists to the conclusion of bloody action.

The finest essays, however, like his travel books *(The Maine Woods, A Yankee in Canada* and *Cape Cod)*, were the fruit of a more strenuous undertaking, that of rediscovering and repossessing the aboriginal environment of America which had sustained his own spirit. Composed of his accounts of his three trips to Maine, in 1846, 1853 and 1857, *The Maine Woods* presents at its finest Thoreau's zest for outdoor adventure. Less symbolic than his other works (the essays were intended to be of practical help to campers), the book does however indicate his retreat from primitivism to the more human pastoralism of Concord. *A Yankee in Canada* took Thoreau into the country explored by the French discoverers whom he admired, but the old world institutions there provoked him to praise of the freer institutions of New England. *Cape Cod* introduced him to the first frontier, the sea, and enabled him to recount the history of the new world from the time of the Northmen, Cabot and Columbus to that of his own excursions; and the incidents of shipwreck made it possible for him to transform death into a passage to the last frontier, the spiritual west. At home, in Concord, with failing strength (the signs of fatal tuberculosis appeared as early as 1852) he laboured on his "Kalendar." His most grandiose project, it was to put on record all of his knowledge of nature's year as this knowledge had been mixed with human aspiration, growth and fruition—his, his countrymen's, and man's throughout history. He completed only "Autumnal Tints" and "Wild Apples"; appropriately they were essays on the values of maturity, an autumnal victory over the tragic loss of his springtime. The first is a pean to the flaming, courageous leaves that taught him how to die; the latter is a transparent parable of his own life and his desire to grow wild that he might, in Emerson's words, "yield that peculiar fruit which each man was created to bear." These travels, in New England at large and in his own backyard, provided the inspiration for his final testament, "Walking." Walking had been his spiritual exercise; his holy land was the west. The west was the freedom, the "mild" that nurtured civilizations and men. This ecology of man and his environment was Thoreau's largest gift to America.

Thoreau did not relinquish civilization for primitivism; in the interests of human culture, he wished only to keep civilization open on one side that others, as he had, might bear their peculiar fruits. For health as well as because of his devotion to the west, Thoreau went to Minnesota in 1861. He died in Concord on May 6, 1862.

Editions. — The standard edition is *The Writings of Henry David Thoreau*, in 20 volumes (1906); vol. vi, *Familiar Letters*, was edited by F. B. Sanborn; vol. vii–xx, the *Journals*, were edited by Bradford Torrey and Francis Allen. *Consciousness in Concord*, edited by Perry Miller (1958), contains the "lost" journal of 1840–41. Other primary sources are *Collected Poems of Henry Thoreau*, edited by Carl Bode (1943), and *The Correspondence of Henry David Thoreau*, edited by Walter Harding and Carl Bode (1958).

THORFINN KARLSEFNI (fl. 1002–07), Scandinavian leader of the first medieval expedition for the colonization of North America, was born in Iceland around 980. He must have been given his nickname at an early age, for *karlsefni* means "promising boy." His grandfather, Snorri Bjarnason, is a historical figure as one of the aristocrats who, about the year 900, led the westward-swarming Norwegians to Iceland. Many of them felt so pressed for stock-farming land by 986 that they followed the lead of Eric the Red and migrated to Greenland. By the year 1000 there were probably more than 1,000 Scandinavian stock farmers in what is now the Julianehaab district of Greenland. Karlsefni, finally caught up in the westward sweep from Iceland, reached what was known as the eastern settlement of Greenland during the autumn 1003 with two ships and about 80 colonists. No doubt the ships would have continued to or beyond the western settlement had not Eric invited all hands to spend the winter with him at his farm, Brattahlid. From the *Saga of Eric the Red* it appears that there may have been a motive behind the hospitality. The saga tells of banquets, jollity and glowing talk of a country to the southwest, beyond the sea, that had been discovered three years before by one of Eric's sons, Leif *(see* Leif Ericsson), and named by him Vinland (*q.v.*). The impression one gets from the saga is that both father and son were persuasive, trying to divert the two Icelandic vessels from prosecuting a further northwestward colonization along the shore of Greenland, directing them instead toward Vinland, perhaps in part because the previous year Eric's son Thorstein had died in the western settlement, and his widow Gudrid had come to stay at Brattahlid. Eric now married her off to Thorfinn; and it was arranged that a Greenland ship would join the Icelandic ones and they would pick up Gudrid's property on their way to Vinland.

In the spring of 1004 about 130 men and women, in three vessels, with livestock and household goods, sailed northwest from the eastern to the western settlement, picked up Gudrid's property, and crossed from the Greenland coast at Bear Island (Disko) toward Baffin Island, apparently striking that shore near Cape Dyer. They named the coast Helluland, meaning "Land of Flat Stones" (Flagstoneland) and continued to use this name as long as they saw no trees while coasting in a southerly direction. After crossing Hudson strait they saw trees and then called the shore Markland, meaning "Forest Land."

Farther south they came to a section which they took for Leif's Vinland district and which sounds in the narrative as if it probably was some part of the Gulf of St. Lawrence, perhaps the south shore. Reaching the heavily wooded region, the colonists built houses, made hay and spent the winter hunting and fishing, much as if they were still in Greenland; but they noted that the meadows were grassier and that the winter was shorter.

The first winter the Scandinavians met no people but the next summer they were visited by friendly natives with whom they traded and who, from the description, were Eskimos. After wintering in a different place, or perhaps scattered in several wintering places, they were again visited by natives, this time more numerous and no longer friendly. A battle ensued; the Europeans won it, but at the cost of some lives. Following still another winter, during which the colonists evidently thought things over, Thorfinn decided to return to Greenland. There was no longer unity among the colonists. Although all decided to abandon Vinland, they did not all head for Greenland and some. perhaps intending to reach Iceland, were shipwrecked on a western coast of Europe.

With his wife, and a son who had been born to them in Vinland, Thorfinn spent the winter of 1006–07 in Greenland. Later they returned to Iceland, where Thorfinn's was already a powerful family.

Snorri, the Vinland-born son whom Thorfinn had named after his Norwegian grandfather, became the progenitor of a line of clergy. The clergy were not celibate in those days and their numerous descendants came to include two bishops during the first few generations — and bishops were nobility in both Greenland and Iceland under the new dispensation. In a genealogically minded modern Iceland, many people of consequence trace their descent, through Karlsefni, to the U.S. or to Canada; for though the Vinland of the 1004–05 wintering almost certainly was in Canada, some argue that one or both of the other winterings may have been in New England.

Among the persisting results of the Karlsefni voyage was a North American activity of the Roman Catholic Church in the Markland-Vinland region. There resulted, too, commerce between Greenland (*q.v.*) and Labrador (Markland) that is mentioned in both Icelandic and Norwegian records as late as 1347. The seafarers of northwestern Europe never lost memory of coasts west of Greenland that stretch to the south. A theory developed that these coasts would curve eastward in the far south to connect with northern Africa. But in the period between the 13th and 15th centuries nobody seems to have been much interested in this knowledge until after Columbus had the idea that these lands beyond the Atlantic might be a northward extension of Marco Polo's rich Cathay.

THORIANITE, a strongly radioactive mineral with the idealized composition thorium dioxide, ThO_2. It ordinarily contains more or less uranium in solid solution and is then transitional to the structurally related mineral uraninite (*q.v.*), UO_2. Rare earths and radiogenic lead and helium also are present. Thorianite forms hard, black to brown isometric crystals of high specific gravity, 9.7–10. The mineral was originally found as waterworn grains and crystals in the gem gravels of Ceylon. It also has been found sparingly in the black sands of rivers and beaches in Alaska and other parts of the United States, Madagascar and Siberia. Varieties containing much uranium occur in pegmatites in Quebec and Ontario, and in serpentine at Easton, Pa. The refractory nature and the small supply of thorianite has restricted its commercial use as a source of thorium (*see* also MONAZITE). (CL. F.)

THORILD, THOMAS (1759–1808), Swedish poet and critic who led the revolt against the influence of French classicism. Born, April 18, 1759, at Svarteborg, Bohuslan, he studied at Lund and Uppsala. He visited England (1788–90). In 1793 he mas banished from Sweden as a result of a political libel after the assassination of Gustav III. He went to Germany and in 1795 was appointed professor and librarian at Greifsmald where he died, Oct. 1, 1808. A born fighter, Thorild attacked the taste for French culture, writing unrhymed verse inspired by Ossian, Shakespeare, Klopstock and Goethe. Among his best works is *Passionerna* (1785), a philosophical poem expressing a pantheistic feeling for nature. The powerful style of his prose essays resembles that of the old Swedish laws. His famous *En critik ofver critiker* ("A Critique of Critiques," 1791–92) is a plea for positive literary evaluations. After his banishment he continued to write essays of which Om *qvinnokonets naturliga hoghet* ("The Natural Greatness of Womankind," 1793) is one of his best.

Thorild's collected works were first published in 4 vol. (1819–35). A critical edition by Stellan Arvidson was begun in 1932; vol. iv appeared in 1946.

THORITE, a mineral consisting of thorium silicate, is one of the most important thorium minerals. The theoretical formula, $ThSiO_4$, requires 81.5% of thoria, but analyses show only 50%–70%. there being also some uranium, cerium, etc. The mineral is almost always altered by hydration and is then optically isotropic and amorphous. Because of alteration and differences in composition. the specific gravity varies from 4.4 to 5.4. The colour is usually light brown, but in the gem variety known as orangite it is orange-yellow. It crystallizes in the tetragonal system and is isomorphous with zircon (*q.v.*). The mineral occurs as isolated crystals and small masses in the augite-syenite near Brevik in south Norway; also at Arendal. and in the gem gravels of Ceylon. Good crystals are found on Stove mountain, El Paso county. Colo. Thorite is mined commercially at Cripple Creek, Colo., and at Hall mountain, Idaho. (L. J. S.; W. F. FG.; X.)

THORIUM. The metal thorium and its oxide are comparatively rare materials. In spite of this fact, they have played an important role in technology for many years and have been the foundation of at least one large industry, the manufacture of gas mantles. The oxide is also important as an additive to metallic tungsten filaments for controlling metallurgical properties. In electronic devices thorium oxide is widely used as a source of primary electron emission.

The advent of atomic energy, jet turbines and rockets brought an unusual demand for new metals and alloys. Important alloys containing thorium mere developed for improving the high-temperature strength of metals, in particular the magnesium base alloys.

Thorium has great potential use in nuclear reactors. Its abundance in the earth's crust is at least three times that of uranium. The particular advantage of the use of thorium in the field of atomic energy is as a "breeder" material. It functions in an atomic pile in such a way as to yield a net increase in atomic fuel; see *Industrial Applications,* below. *(See* ATOMIC ENERGY: *Peacetime Applications.)*

ELEMENTAL THORIUM

Thorium was identified as an element by J. J. Berzelius in 1828. The element is named after Thor, Scandinavian god of war.

Freshly cut massive thorium is silvery white in colour but turns gray or black on exposure to air. The stability of the surface is a function of the oxide content and surface potential. A cold rolled sheet processed to a high finish remains remarkably stable, retaining a high metallic lustre for years.

The metal may be extruded, rolled, forged, swaged and spun. Drawing is a difficult operation because of its low tensile strength. Most of the operations with the exception of extruding and spinning may be performed cold. Work hardening is moderate, and annealing is usually *in vacuo* at 800°–1,000° *C*. The major embrittling element is carbon, which dissolves in thorium with resulting lattice expansion. Thorium powder is relatively stable in air, but spontaneous combustion has occurred and the storage of large quantities is hazardous. The solid metal is not readily oxidized in air at high temperatures. High-temperature steam is more effective.

Thorium metal is practically nonreactive to acetic acid (0%–50%) and also to sodium hydroxide in all concentrations. It is attacked by hydrochloric acid (0.1%–36%) but only slightly by nitric acid in all concentrations, provided traces of fluorides are absent.

OCCURRENCE AND PRODUCTION

Mineral Deposits. — Minerals in which thorium is the major constituent are silicate, thorite and orangite, auerlite, calciothorite, mackintoshite and thorianite. Deposits of these minerals are usually too small to be of industrial importance.

The major source of thorium is monazite (*q.v.*), essentially a phosphate of the rare earths. Important deposits are found in Travancore-Cochin, former Indian state, and Brazil. Significant deposits have been found in the Scandinavian peninsula, Ceylon, Tasmania (Australia) and the Ural mountains (U.S.S.R.). U.S. deposits are in Idaho, Colorado, North Carolina, Virginia and Florida. Monazite sands usually contain 2%–10% thoria (ThO_2). The poorer ores are concentrated to an oxide content of 5%–10% prior to refining. Domestic sources of thorium rarely exceed 4% ThO_2.

Extraction. — The recovery of thorium compounds, in particular the oxide (ThO_2) from monazite concentrates depends upon the separation of this element from cerium and other rare-earth phosphates and substantial amounts of silica, calcium oxide and iron oxide.

In some monazites the cerium content (CeO_2) is 40%–50% and the phosphorus content (P_2O_5), 20%–25%. The separation is accomplished by a variety of methods, including precipitation after digestion with an acid or base, direct reaction with chlorine, separation by an organic liquid, reduction with calcium and electroylsis.

Precipitation. — Commercial extractive processes in use for many years involve the digestion of pulverized monazite in hot concentrated sulfuric acid to dissolve the thorium and rare earths. If the solution is diluted or partially neutralized with ammonia, thorium phosphate separates, and the ratio of ThO_2 to rare earths is increased.

For the complete removal of phosphors and the remaining rare earths several operations have been used. The important ones are sulfate separations, carbonate extractions, oxalate separations and iodate separations.

The sulfate separation procedure depends upon the low solubility of thorium sulfate, $Th(SO_4)_2{\cdot}8\ H_2O$, compared with the sulfates of cerium, neodymium, praseodymium and lanthanum. In carbonate extraction. thorium forms a soluble double carbonate, and cerium precipitates. The precipitation of thorium as the oxalate from dilute acid solutions is commonly used to separate small amounts of the rare earths and some common metals. It is also used as a final step prior to conversion to oxide which is obtained by ignition.

Some monazites yield to sodium hydroxide extraction, with thorium and the rare earths precipitating. It is used as a means of separating thorium from phosphorus.

The precipitation of thorium iodate from strong nitric acid solution affords an excellent separation of thorium from the rare earths and common metals, but it is too expensive for commercial practice.

In spite of the complicated procedures involved in precipitation, thorium oxide of over 99% purity is produced. The major contaminants are small amounts of cerium, rare-earth oxides, silica, calcium and magnesium. None of these impurities is present in amounts exceeding 0.1%, and many are of the order of 0.04% or less.

Reaction With Chlorine. — Production processes have been suggested which involve the extraction of thorium chloride by the direct reaction of the ore. the oxide or the oxalate nith chlorine. Efficiency of chlorination is increased by mixing the materials with carbon. Chlorine gas saturated with sulfur chloride or carbon tetrachloride may also be used. The direct formation of the chloride affords the preparation of a soluble compound of thorium which may be easily purified or if sufficiently pure may be used directly for metal production.

Extraction by Organic Liquid. — Processes have been developed for separating thorium from the rare-earth nitrates. Calcium nitrate and nitric acid are added to a solution of the nitrates and thorium nitrate extracted into an organic liquid phase (alcohol or ketone). The extraction is accomplished by mixing the two fluids by passage in opposite directions through a vertically packed column. The rare earths and other impurities remain in the water phase. The organic phase containing the thorium nitrate is then back-extracted, the thorium nitrate entering the water phase from which the oxide may be recovered by evaporation and ignition. Oxide with a purity of 99.7% has been produced.

Reduction With Calcium. — Several processes have been proposed which include reduction of the fluoride (ThF_4) and oxide (ThO_2) with calcium. These reactions are carried out on a large, scale in closed metal containers usually referred to as "bombs." The reactants are heated to initiate the reaction. The thorium as a metal powder is recovered by leaching the charge with suitable acids which dissolve the by-products of the reaction. A method of preparation is to add metallic zinc to the charge to form a zinc alloy with the thorium, which fuses. Thorium is recovered by vacuum distillation of the zinc followed by vacuum casting of the thorium. A particular advantage is the elimination of a powder step in the process.

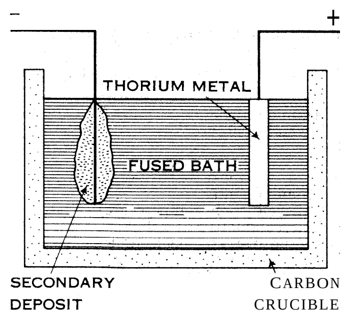

FIG. 2. — ELECTROLYTIC CELL FOR THORIUM REFINING

Electrolytic *Methods.*—Electrolysis of thorium compounds such as the chloride ($ThCl_4$) from alkali metal baths have shown promise of replacing the "bomb" type of reaction. Such processes may be continuous, requiring only the insertion of electrodes with occasional bath replacement. Thorium is deposited on a metal cathode (molybdenum), and the crucible containing the charge serves as the anode. The deposit upon withdrawal from the bath contains thorium powder plus solidified salts and is recovered by grinding and acid leaching.

. Metal of very high purity is obtained by subjecting the primary deposition product to an electrolytic refining operation in which the compressed deposit acts as the anode in a fused salt bath and the thorium is redeposited on a metallic cathode. Lowering occurs in the concentrations of many contaminants, including boron, beryllium, copper, chromium, iron, nickel and silicon. The basic principles of the electrolysis and refining operations are shown in fig. 1 and 2.

Thorium is also refined by the thermal decomposition of the iodide (ThI_4) on a hot wire. The process is similar to that used for zirconium production in which iodine and chips of metal are placed in a closed evacuated container that is heated to form thorium iodide vapour. As the vapour comes into contact with a heated filament in the same vessel, thorium of a very high purity is deposited with the liberation of iodine.

Billets for rolling are produced from the powder by standard powder metallurgy (*q.v.*) practice or by direct arc casting. The former practice is to press the powder in steel dies under 20–30 tons per square inch; the resulting green compacts are vacuum sintered. Casting of powder compacts is sometimes made in beryllia crucibles.

Thorium is also cast in a water-cooled copper cup. The powder may be compressed into a rod which acts as a consumable electrode, and the arc is struck between the electrode and solid thorium with the formation of a liquid pool. Melting takes place under a partial pressure of helium or argon gas.

GENERAL CHEMISTRY

Thorium is an electropositive element. It lies between beryllium and magnesium in reducing strength and is more electropositive than zirconium and cerium. In solution. thorium shons only the +4 oxidation state. The standard electrode potential is +1.77 v. Salts of thorium are white although thorium solutions are colourless. The hydrolysis of thorium in solution is less than that of zirconium. Because of its high charge. the thorium ion is strongly adsorbed from solution by an ion exchanger. Thorium forms complex ions and double salts. The nitrate is soluble in organic liquids and can be extracted from water solutions by alcohols, ketones, ethers and esters. Thorium compounds are not generally volatile with the exception of the acetylacetonate,

$Th(C_5H_7O_2)_4$, thorium borohydride, $Th(BH_4)_4$, and a group of organic compounds of the general formula Th(OCRR′R″) R, R′ and R are radicals.

The dioxide, thoria (ThO_2), is very refractory. Thoria may be prepared by ignition of the peroxide (ThO_4), nitrate. $Th(NO_3)_4$, hydroxide, $Th(OH)_4$, sulfate, $Th(SO_4)_2$, or of an organic thorium compound. Compounds such as thorium fluoride (ThF_4) may be converted to oxide by treatment with superheated steam. Thorium peroxide is precipitated from acid solutions with hydrogren peroxide. Ignition yields thorium oxide. The alkalies and ammonia precipitate thorium hydroxide.

The common commercial salt of thorium is the nitrate. which is tetrahydrated. Double nitrates of thorium are known with sodium and potassium and also with some bivalent ions such as magnesium. zinc, cobalt and manganese.

Hydrogen gas reacts with thorium metal to produce thorium hydride of composition ThH_2 and ThH_4. Thorium hydride is used as a substitute for thorium powder in some applications. A particular advantage is its greater resistance to atmospheric oxidation. Fluorine reacts with thorium hydride or thorium to form thorium fluoride. Thorium fluoride may be separated from solutions by addition of the fluoride ion, but it is hydrated and must be treated with hydrogen fluoride gas to yield the anhydrous fluoride.

Chlorine or hydrogen chloride reacts with thorium hydride or metal to form thorium chloride ($ThCl_4$), which sublimes at temperatures in excess of 750° C., in *vacuo*. Bromine or hydrogen bromide converts the hydride or metal to bromide, and a corresponding reaction occurs nith iodine. The chlorides. bromides and iodides are soluble in mater but hydrolyze. Thorium iodate, $Th(IO_3)_4$, is formed upon addition of an iodate to thorium solutions. The salt may be dried to the anhydrous state.

Normal thorium sulfide (ThS_2) is yellow and may be prepared by the action of hydrogen sulfide on thorium hydride. This sulfide is stable up to 1,900° C., above which sulfur is evolved and Th_2S_3 or ThS formed. These compounds resemble metals and may be machined. filed and polished.

Thorium sulfate, $Th(SO_4)_2$, crystallizes from aqueous solutions in several hydrates depending upon temperatures. Heating in *vacuo* produces the normal salt and ignition yields the oxide. Double sulfates are also known. Chromates, phosphates and molybdates may be recovered from water solutions.

Thorium carbides, both ThC and ThC_2, have been identified and are prepared by heating the metal or oxide with carbon at high temperatures. These react with water to yield hydrocarbons. Thorium carbonate, $ThOCO_3$, is difficult to prepare from solution, but double carbonates are easily prepared. Thorium salts with organic acids are usually insoluble. The formate and the acetate are exceptions. Examples of insoluble salts are the oxalate, picrolonate and the sebacate. Thorium acetylacetonate. $Th(C_5H_7O_2)_4$, is formed by the reaction of thorium salts and acetylacetone. It is one of the few volatile salts of thorium. Several volatile compounds of thorium have been prepared by synthesis with tertiary alcohols Borides of the formula ThB_4 and ThB_6 are knonn and also the borohydride $Th(BH_4)_4$.

Two thorium nitrides have been identified. ThN and ThN_4. The nitrides are unstable at high temperatures in the presence of nater vapour with the elimination of ammonia.

INDUSTRIAL APPLICATIONS

Nonnuclear.— The earliest use of thorium oxide was in the incandescent gas-mantle industry. In 1885 Carl Auer von Welsbach patented a mixture of 99% thoria and 1% ceria which was impregnated into a combustitile fabric (cotton or ramie) as nitrates. Ignition resulted in oxide formation which when heated in a gas flame emitted white light for illumination. The use of gas mantles has declined, having been replaced by electrical lighting. (See LIGHTING: Historical Development.)

Thorium oxide is used in the electrical lighting industry for controlling the grain size of tungsten filaments used in lamps as a radiant source of energy. Pure tungsten is unsatisfactory because the metallic grains continue to grow when the filament is heated. causing some grains to slip along grain boundaries. The addition of 0.8%–1.0% ThO_2 to the tungsten produces a stable structure. Such filaments also exhibit increased vibrational strength.

Thorium oxide-metal systems have been used for years in electronics as a source of primary electron emission. The thorium oxide content is usually 1%–2%. So-called "cermets" which are oxide-metal compositions, in particular Mo-ThO_2 have been used as an emission source. A desirable property of these latter combinations is that the electrical resistance may be easily controlled by changes in composition. (See THERMIONICS: Reduction in Electron *Affinity*.)

The oxide has gained wide use as a component of electrodes for arc welding. The addition of 1%–2% ThO_2 to tungsten results in improvement in arc stability over that exhibited by pure tungsten. A practice embodying the same principle is the incorporation of the oxide in tungsten electrodes used in arc-casting metals. The addition of thorium oxide lowers the work function of the metal, that is, the ease with which electrons may be emitted thermionically.

Thorium oxide crucibles are used to a limited extent for melting some of the common and transition metals. Its use is quite selective. It is not satisfactory for melting oxygen-sensitive metals such as zirconium and titanium. Its relatively high cost and poor resistance to thermal shock limit its use to operations where it shons marked superiority over other competing ceramics.

Thorium sulfide crucibles have been investigated and show promise up to 1,800° C. The monosulfide (ThS) is the more stable compound.

FIG. 3.— TWO-REGION AQUEOUS BREEDER REACTOR

Thorium oxide, as well as the oxides of beryllium, zirconium and aluminum, is of importance as a current-carrying compound in high-temperature furnace design and insulation. These oxides have negative temperature characteristics, and the limiting factor in their use is excessive conductivity. Thorium oxide compositions have been used experimentally where the resistor element is composed of 85%–95% ThO_2 and 5%–15% yttrium oxide (Y_2O_3) or lanthanum oxide (La_2O_3).

Thorium oxide is an efficient catalyst in reactions involving oxidation, hydrogenation and cracking of hydrocarbons. In many cases it is used as a mixture with aluminum oxide.

A very important alloy application of thorium is its addition to magnesium and magnesium alloys for improving their high-temperature strength. The addition of 1%–5% thorium to these alloys permits their use in temperatures up to 650° F., in compressor housings.

Thorium metal has been used as a deoxidant in molybdenum. It is also used in electronic tubes and lamps for lowering the starting voltages and maintaining stability in such lamps over their useful life.

Thorium is used in photoelectric cells for measurement of a wide band of the ultraviolet spectrum. The response of commercial tubes extends from 2,000 A–3,750 Å.

Nuclear Applications.—*Isotopes.*—Ordinary thorium consists almost entirely of the isotope Th^{232}, which has a half life of radioactive decay by emission of alpha particles of 13,900,000,000 years. This activity is the start of the 4N, or thorium, series. Another alpha-emitting isotope of thorium, Th^{228} (radiothorium), occurs in this series and because of its much shorter half life (1.89 years) constitutes only about one part in 1,000,000,000 of ordinary thorium. Thorium isotopes are found also in the actinium (4N + 3) decay chain: Th^{227} (radioactinium) with a half life for alpha emission of 18.9 days, and Th^{231} (uranium-Y), which emits beta particles at a half life of 25.6 hours. Th^{234} (uranium-X_1, emitting beta particles with a half life of 24.1 days) and Th^{230} (ionium, with a half life of 81,000 years) are members of the uranium (4N + 2) decay series. Although ionium occurs in a concentration of less than two parts per million in uranium ores it has been recovered. (See RADIOACTIVITY, NATURAL: *Ionium.*)

A number of synthetic thorium isotopes have been prepared by transmutation reactions or through the further decay of transmutation products. The most important is Th^{233}, produced by neutron reaction on ordinary thorium, since this decays to U^{233}, which is fissionable with the liberation of energy similar to that produced from U^{235}. The synthetic isotope Th^{229} has a very long life with a half life of 7,340 years and is a member of the wholly artificially produced neptunium (4N + 1) radioactive decay series. Other synthetic shorter-lived thorium isotopes are Th^{223}, Th^{224}, Th^{226}. (See RADIOACTIVITY, NATURAL: Transformations *of Thorium.*)

Nuclear Reactors.—As discussed under isotopes, Th^{232} is not capable of sustaining a nuclear chain reaction. Thorium will, however, absorb a thermal neutron coming from the controlled fission of U^{235} to become Th^{233}, which in turn transmutes to U^{233}, which is fissionable.

The nuclear reaction, from thorium to protactinium to uranium follows:

$$Th^{232}_{90} + n \rightarrow Th^{233}_{90} + \beta^- \rightarrow Pa^{233}_{91} + \beta^- \rightarrow U^{233}_{92}$$

Thorium is referred to as a "fertile material" and its transformation into U^{233} as the "breeding cycle." When the efficiency of this cycle is unity. the amount of U^{233} produced in an atomic pile will equal the U^{235} consumed. There are a number of calculated breeding ratios for various combinations of fuels. For example, for Pu^{239} (plutonium) the ratio is 1.03, and for U^{233} obtained from the Th^{232} the ratio is 1.25.

Major solid-fuel reactors utilize either U^{235} alloyed with zirconium and thorium or zirconium-clad thorium using deuterium as a moderator. Water or liquid sodium is used as a coolant. (See NUCLEUS: *Utilization* of the Energy of the *Nucleus.*)

Reactors employing liquid fuels utilize, for example, UO_2SO_4 (uranium sulfate) with deuterium (heavy water) as a moderator. The breeding ratio for one such reactor is 1.13. The slurry-type reactor employing thorium oxide in slurry form appears to have considerable merit over the solid-fuel type. In addition to an excellent breeding ratio the slurry type permits partial withdrawal of the slurry for chemical processing during operation of the reactor and also addition of reprocessed fuel. See fig. 3 for illustration of the basic principles involved in the use of thorium in reactors.

THORN (Polish TORUN), a town of Poland, in Bydgoszcz province situated on the right bank of the Vistula, 85 mi. N.E. of Poznan by rail, and 92 mi. S. of Gdansk (Danzig). Pop. (1950) 80,600. Torun has always been important because of its position in Poland proper between the former German Pomerania and East Prussia and because of its strategical location commanding the passage of the Vistula. The old town and the new tow-n, founded in the 13th century, were united in the 15th; both retain interesting buildings dating from the 14th, 15th and 16th centuries when Torun was a flourishing member of the Hanseatic league. The ruined castle of the Teutonic knights, part of the old walls, the town hall, the churches of St. John, of the Virgin and of St. James are the most interesting edifices. There is a monument to Kopernik (Copernicus), who was born in Torun. The old wooden bridge has been succeeded by a massive iron railway viaduct 3,300 ft. long. Torun carries on trade in grain, timber and foodstuffs and has ironworks, sawmills and other manufactures. Torun was founded in 1231 by the Teutonic Order, which was given land and invited to help the Poles against the heathen Prussians. It became a subject city of the order and an important member of the Hanseatic league, but political and commercial interests bound it to Poland. In 1454 the city revolted against the order and was annexed to Poland in 1466 at the peace concluded there. A religious riot in 1724, terminating in a brutal execution, made a great stir in Europe. The town was seized by Prussia at the second partition, was returned to the grand duchy oi Warszawa, and again granted. in 1815, to Prussia, in which it remained until 1918. Germany seized Torun in 1939; it was returned to Poland in 1945.

THORN, in botany, a hard pointed structure, also termed a spine. It may be an attenuated branch, leaf or root, but generally represents a small branch, as in hawthorn, where a normal branch arising in the axil of a leaf is replaced by a sharply pointed thorn. Accessory buds on either side of the thorn and developed in the same leaf axil will grow in the next season into ordinary branches. The similarly developed thorns of the honey locust (Gleditsia) are branched. In other cases, as the sloe or the wild pear. branches become spiny at the apex tapering into a stiff leafless point. On a cultivated tree these branches disappear as a result of their more vigorous growth. Leaves may be modified into spines, as in barberry, the leaves of which show every gradation between a leaf with a spiny-toothed edge and those which have been reduced to simple or multiple spines. In some species of *Astragalus* the petiole or supporting stalk of the pinnately compound or bisymmetrical leaf persists after the fall of the leaflets as a sharp spine. In the false acacia (Robinia) the stipules are represented by spines. The thorns of desert cacti protect the succulent plant body from animal predators; and, unlike leaves: they do not give off precious water to the air. (See also CACTUS.)

Thorn is also a common name for the species of the genus *Crataegus* or hawthorn (*q.v.*), and when combined with other words is applied to many other plants such as blackthorn (*Prunus spinosa*), Christ's-thorn (*Paliurus spina-christi*), Jerusalem thorn (Parkinsonia *aculeata*) and others.

THORNABY-ON-TEES, a municipal borough in the North Riding of Yorkshire, England, 3 mi. S.W. of Middlesbrough by road, in the hliddlesbrough West parliamentary division. Pop. (1951) 23,416. Area 3 sq.mi. It lies on the Tees river. opposite Stockton-on-Tees. with which it is connected by a bridge. In the 8th century the Danes called it Thormodby; in Domesday Book it appears as Tormozby. The parish church on the village green is Norman. Thornaby's industrial development dates from the 19th century. It was incorporated as a separate borough in 1892. The population is employed chiefly in bridge building, heavy engineering, foundries. wire ropemaking, shipbreaking, flour milling, the production of sugar and preserves.

THORNDIKE, EDWARD LEE (1874–1949), U.S. psychologist. whose most significant contributions to world thought perhaps were made in the science of behaviour. was born at Williamsburg, Mass., Aug. 31. 1874. His professional career. save for one year at Western Reserve university, Cleveland. O., was spent at Teachers college, Columbia university. An unusually creative and productive scholar. he, or he and collaborators, published more than 500 books and articles. His influence upon psychological and educational thought has been world-wide.

Thorndike's pioneer nork on animal intelligence. in the late 1890s, established animal psychology as a natural science and introduced a new concept of the nature of mind. His laws of learning, an outgrowth of his experiments on animal intelligence, and subsequent modification and elaboration of them, hold a central place in learning theory.

Almost immediately after joining the faculty of Columbia he turned his energies to learning in school situations. He was largely responsible for the early development in the United States of the field of psychology, including applications of psychology to such fields as arithmetic, algebra. reading, handwriting and language. Other major contributions to education include works on the theory of mental measurement, educational and psychological tests, compilations of the words occurring most frequently in English reading matter and a series of dictionaries designed for school use.

Best knoan is his three-volume work *Educational Psychology* (1913–14). Additional works of special interest treat mental life of monkeys; prediction of vocational success; wants. interests and attitudes: and principles of education. Thorndike died at Montrose. N.Y.. on Aug. 9, 1949. (J. B. SD)

THORNDIKE, ISRAEL (1755–1832), U.S. merchant. financier and politician, was born in Beverly, Mass.. on April 30, 1755. He became a sea captain at the age of 21 and then a merchant shipowner in partnership with Moses Brown of Waltham. He was a Revolutionary War privateer owner and master. In 1810 his interests outgrew Beverly and he moved to Boston. His customary title of "colonel" derived from a brief tour of duty with the Massachusetts militia. With money made in foreign trade he engaged in unprofitable speculation in Western Reserve (Ohio) and Maine lands, in highly successful investment in Boston real estate and in the early cotton textile manufacture with Francis C. Loaell and Nathan Appleton.

Thorndike was an ardent Federalist in politics and served in the Massachusetts legislature for 12 years. He gave the Ebeling library of Americana of Hamburg, Germany, to Harvard college. His estate was valued at more than $1,100,000. He died May 8, 1832, in Boston.

THORNDIKE, DAME SYBIL (1882–), British actress, whose unusual versatility enabled her to build up a reputation in tragedy, melodrama and comedy. was born at Gainsborough, Lincolnshire, on Oct. 24, 1882, and was educated at the high school in Rochester, where her father was a canon of the cathedral. After experience on tour in the U.S. with Ben Greet in Shakespearean repertory (1903–07) and with Miss A. E. Horniman's company in Manchester (1908–09 and 1911–13), she joined the Old Vic company in London (1914–18) and helped to establish not only the theatre's name as a home of Shakespeare but also her own as the most promising English tragic actress of the day.

Having set the seal on this reputation in 1919–20 with performances as Hecuba in *The Trojan Women* and as Medea. she went on to prove her versatility in a multiplicity of parts, modern as well as classical, comic as well as tragic. In 1924 she created the name part in Shaw's *Saint Joan;* and though many admired actresses followed her, none realized the character more completely.

Her superb health and vigour did not desert her as she grew older! and she was able to tour the world in exacting classical parts at an age when many of her contemporaries had been content to retire. Also. in her 60s, she broke new ground, giving, in such plays as *The Linden Tree* (1947), *The Foolish Gentlewoman* (1949), *Treasure Hunt* (1949), *Waters of the Moon* (1951) and *A Day* By *The Sea* (1953), a whole gallery of portraits of elderly ladies having in common nothing but the meticulous and humorous observation which the actress had brought to their creation. She married Lewis Casson in 1908. She was created a dame of the British empire in 1931. (W. A. DN.)

THORNHILL, SIR JAMES (1675–1734), English painter, the first to excel in historical painting, whose style was in the Italian baroque tradition, was born at Melcombe Regis, Dorset. He became the history painter and sergeant painter to George I and George II, master of the Painters' company in 1720, fellow of the Royal society in 1723, member of parliament from 1722 to 1734, and was knighted in 1720.

He was one of the original directors of Kneller's Academy of Painting, and when this closed, and he had failed to establish a "royal academy." he opened his own drawing school, which also proved unsuccessful. Thornhill died at Thornhill, Dorset, on May 13, 1734.

The eight scenes in the dome of St. Paul's cathedral (1715–19) and the allegories in the Painted hall, Greenwich hospital (1708–27), are his two most considerable works. His paintings were largely executed, on the ceilings and stairs of such country houses and palaces as Hampton Court, Blenheim and Chatsworth. Among Thornhill's few canvases are the altarpiece for St. Mary's parish church, Weymouth, and a group portrait of the members of the house of commons in which he was assisted by William Hogarth, his son-in-law. Thornhill also did portraits (his sitters including Isaac Newton and Richard Steele), book illustrations, theatre scenery and the rose window of the north transept of Westminster abbey (1721). (WM. O.;X.)

THORNHILL, a village in the civil parish of Morton, Nithsdale, Dumfriesshire, Scot., 14 mi. N.N.W. of Dumfries by road. Pop. (1951) 1.262. Its broad village street is lined with lime trees. planted in 1861. Thornhill, in the valley of the Nith, near wooded country, stands on the site of a Roman signal camp. Morton parish church is in the village, and there is a museum, containing some relics of Robert Burns. Sales of livestock are held every Thursday and an agricultural show occurs annually in July. Agriculture and forestry employ most of the inhabitants. but there is also a bacon and sausage factory. Morton castle, 2½ mi. N.E. and now ruined. was built *c.* 1080. Drumlanrig castle (3 mi. N.N.W.) is a seat of the duke of Buccleuch and Queensberry (the two dukedoms were united in 1810), whose family had much influence in the district and actually possesses the village land. Drumlanrig was built in the latter half of the 17th century, and the retreating Jacobites spent a night there in 1745. The ancient Dalgarnock churchyard contains many Covenanters' tombs and a cross commemorating 57 of the martyrs.

THORNTON, WILLIAM (1759–1828), British-U.S. architect. inventor and public official who created the original design for the Capitol at Washington, D.C., was born May 20, 1759, at Tortola, V.I. He studied medicine at the University of Edinburgh (1781–84) and received his M.D. from Aberdeen university (1784). After travel on the continent he returned to Tortola and went to the United States in 1787. In the following year he became a United States citizen and settled in Philadelphia. The Library company of Philadelphia promoted a competition (1789) for its new building that Thornton won without formally having studied architecture. As inventors he and John Fitch (*q.v.*) early experimented with paddle steamboats.

From 1790–92 he was again at Tortola, where he first heard of the important competition for the Capitol at Washington. He submitted designs that were received months after the competition closed; yet the judges, not satisfied with those previously submitted, selected Thornton's. His revised Georgian design of 1795 was executed as the exterior of the north and south wings adjacent to the central rotunda, though B. H. Latrobe (*q.v.*) completely redesigned the interiors. From 1794–1802 Thornton was a commissioner of the city of Washington. He designed the Octagon, Washington (1798–1800), a residence for John Tayloe. From 1802–28 he served as first superintendent of the patent office. He died in Washington on March 28, 1828, and was buried in the congressional cemetery. (P. F. N.)

THORNYCROFT, SIR (WILLIAM) HAMO (1850–1925), English sculptor, was born in London on March 9, 1850, and studied under his father, Thomas Thornycroft, at the British museum, at the Royal Academy schools and in Italy, where he was particularly interested in Michelangelo. In 1872 he contributed the figures of Shakespeare. Fame and Comedy to the Poets' fountain, Park lane (later removed), designed by his father. His independent success began with "Artemis" (exhibited 1880), and in 1881 he showed the bronze "Teucer" (Tate gallery. London) at the Royal Academy, of which he was then elected associate. He executed many public monuments, including those to Gen. Charles George Gordon (1888, formerly Trafalgar square), Oliver Cromwell (1899, Westminster), Dean John Colet (1902, St. Paul's school, Hammersmith), William Gladstone (1905, Strand) and the architect Richard Norman Shaw (bas-relief, 1914, New Scotland Yard). His style, at first an enlivened classicism, was affected in the mid-1880s (in "The Mower," 1884, Walker art gallery, Liverpool; "A Sower," 1886) by J. F. Millet's peasant realism and later (*e.g.,* "The Kiss," 1916, Tate gallery) was influenced slightly by Auguste Rodin. Thornycroft was elected Royal academician in 1888 and knighted in 1917.

Thornycroft died at Oxford on Dec. 18, 1925. He was the brother of Sir John Thornycroft (*q.v.*).

THORNYCROFT, SIR JOHN ISAAC (1843–1928), British naval architect and engineer who was responsible for the introduction of special designs of ships' hulls and improvements in machinery was born in Rome on Feb. 1, 1843. He was sent by his father, Thomas Thornycroft. a sculptor, who was also an amateur engineer, to Glasgow university, after nhich he worked for a short time in John Elder and Palmer's shipyards. In 1866 he started his own launch-building and engineering works at Chiswick, London. Gaining a high reputation for his boats. he was given the order for H.M.S. "Lightning," the first torpedo boat of the Royal Navy. Later he took into partnership his brother-in-law, John Donaldson. Thornycroft took a leading part in introducing water tube boilers into the British and into other navies and was granted a number of patents, including one of the earliest for ship stabilizers. He served as a member of Lord Fisher's committee. which produced the design for the battleship "Dreadnought" and introduced oil fuel for the Royal Navy. He was knighted in 1902 and died on June 28, 1928, at Bembridge, Isle of Wight. (J. E. Tt.)

THÓRODDSEN, THORVALDUR (1855–1921), Icelandic geographer who specialized in exploration of the interior of Iceland, was born on the island of Flatey in Breidi fiord. Iceland, on June 6, 1855. Having studied at the University of Copenhagen, he began his long series of Icelandic explorations by joining J. F. Johnstrup in a study of the volcanic districts of Iceland in 1876. Thóroddsen held teaching posts at Mddruvellir in northern Iceland (1880) and at Reykjavik (1885–95), but his journeys in Iceland continued almost annually. diversified only by brief visits to England and the continent of Europe. From 1895 to 1898 he made his expeditions from Copenhagen. where he had settled. and he died there on Sept. 28, 1921. Thóroddsen wrote several books on the volcanoes of Iceland.

THOROUGH BASS, in music, a system of accompaniment (*q.v.*) customary during the 17th and 18th centuries, whereby the bass line is written out all "through" the composition, but its harmonization is left to the accompanist to provide more or less impromptu. Usually. though not invariably, he is kept generally informed as to the harmony resulting from the melodic part or parts which he is accompanying, so as not to conflict with it in his own harmonization. This information is conveyed by figures added to the bass line, which is then more specifically described as figured bass.

The accompanist is said to "realize" the bass. He may do this impromptu, *i.e.,* reading it strictly at sight in course of performance: a very skilled achievement to which not many modern performers are trained. But it was always customary to look through the music in advance if opportunity occurred. This allows the performer to improve on his first thoughts, and, in music suited to an elaborate accompaniment, is normally the best course. It hardly matters whether his preparations are memorized or written out in whole or part, but it does matter that the result shall sound free, flexible and spontaneous, as if it had been improvised. Modern editors who provide printed realizations usually bear this in mind. keeping their parts on the light side.

The information conveyed by the figures is never complete and is often so sketchy, not to say inaccurate, that the performer, when no preparation has been possible, has to rely on his own grasp of where the music is going. This came more easily to a contemporary performer than it does to present-day musicians, but the faculty can be cultivated. Indeed it is one of the most enjoyable parlour games. According to J. F. Daube's *General-Bass* (1756), the style of improvised accompaniment was brought to its height by J. S. Bach: "He knew how to introduce a point of imitation so ingeniously in either right or left hand and how to bring in so unexpected a counter-theme, that the listener would have sworn that it had all been composed in that form with the most careful preparation . . ." The true reason for thorough bass is the freshness of the invention. Thorough bass was thus not merely a convenient shorthand for saving the composer's time; it was a means of giving zest to the accompaniment by inviting the performer to draw on his capacity for spontaneous enjoyment.

The figures themselves are numerals set one above the other to indicate the intervals, as counted up from the bass note, of the harmonies required. In realizing these intervals, the performer can invert them in any order of notes; *i.e.,* he can manipulate the spacing of the chord, though he will not normally go above the solo part for long at a time, if at all. The figures are kept to the minimum necessary to determine the harmony by indicating its most characteristic intervals, the remainder of the chord being taken as understood. Necessary accidentals are shown. Only the main harmonies, and not the passing harmonies, are normally shown. There is great scope for varying and enriching the indicated harmony by introducing passing notes, especially accented passing notes. The same recourse is invaluable for contriving an interesting and convincing melodic outline to the accompaniment.

The elaboration given to the realization will vary from the simplest harmonization in plain part-writing to an exploitation of all the harmonic and contrapuntal possibilities. Four-part harmony is standard, though the nature of the music to be accompanied sometimes requires only three or two parts and occasionally the unharmonized bass line. Alternatively, a "full accompaniment" requires as many notes to each hand as the fingers can accommodate and in such realizations all rules forbidding consecutive fifths, etc., may be waived except as between the two outside (bottom and top) parts.

Good figured-bass accompaniment, taking into account not only the character of the piece but, as C. P. E. Bach specified, the remaining performers, the soloist, the auditorium and the audience, thus made almost as heavy a demand on the performer's judgment as on his imagination.

THORPE, JIM (James Francis Thorpe) (1888–1953), U.S. athlete, recognized as the greatest all-around athlete of the first half of the 20th century, was born May 28, 1888, near Prague, Okla., of American Indian descent. A star in both college and professional football, he was twice named halfback on Walter Camp's -411-America teams (1911, 1912); in 1912 he scored 25 touchdowns and 198 points for Carlyle (Pa.) institute.

Standing 6 ft. tall and weighing 190 lb., Thorpe was a standout in the 1912 Olympic games at Stockholm, where he won the pentathlon and decathlon. Later, however, when it was discovered that he had played semiprofessional baseball in the summer of

1911, his gold medals and trophy were taken from him and his Olympic records erased from the books.

Signed by John J. McGraw of the New York Giants for $4,500 in 1913, Thorpe spent most of the time on the bench. He finished his six-year major-league baseball career in 1919 with the Boston Braves, where he played in 60 games and hit .327. He died in Lomita, Calif., March 28, 1953. (J. D. McC.)

THORPE (Thorp). **THOMAS BANGS** (1815–1878), U.S. humorist. was one of the most effective portrayers of frontier life and character before Mark Twain; he is the author of "The Big Bear of Arkansas," a tall tale so outstanding that some historians have named certain southwestern contemporaries of Thorpe the Big Bear school of humorists.

Born at Westfield, Mass., on March 1, 1815, and educated in New York schools, Thorpe studied painting under John Quidor and at the age of 18 exhibited his "Ichabod Crane" at the American Academy of Fine Arts, New York city. In 1836, after two years' study at Wesleyan university, Middletown, Conn., he moved to Louisiana. An active Union Whig, he published successively five newspapers, chiefly in New Orleans and Baton Rouge.

It was during this period that Thorpe wrote "The Big Bear of Arkansas," published in 1841 in the New York magazine *Spirit of the Times*.

Following a political defeat, Thorpe moved in 1854 to New York city and published his finest sketches as *The Hive of the Bee Hunter*. During the Civil War he saw service in New Orleans; afterward he returned to New York and spent his remaining years painting. working at the customhouse and writing for *Harper's*, *Appleton's* and other journals.

He died at New York, on Sept. 20, 1878.

Thorpe's painting and writing show the influence of Washington Irving and of sporting literature, a love of romantic scenery and a continuing attempt to define the distinctively American character, which, he believed, the western frontier was producing.

THORPE, SIR THOMAS EDWARD (1845–1925), British chemist. was born at Harpurhey. Manchester, on Dec. 8, 1845. Thorpe is perhaps best known for his work as an organizer in connection with his direction of the British government laboratories and as a brilliant lecturer and writer. He studied at Owens college. Manchester, and then under Robert W. von Bunsen at Heidelberg, where he obtained his doctorate (1869). In 1870 he became professor of chemistry at Anderson college. Glasgow, and four years later at the Uorkshire college, Leeds. In 1885 he obtained the chair at the Normal School of Science (later the Imperial College of Science), London, and remained there until appointed director of the government laboratories in 1894. On his retirement, he returned to the Imperial college (1909–12). He was elected to the Royal society in 1876, was made a companion of the Bath in 1900 and knighted in 1909. He died at Salcombe, South Devon, on Feb. 23, 1925. He brought out, with the cooperation of a number of specialists, the well-known *Dictionary of Applied Chemistry* (1890; rev. ed., 1927). He was also the author of *Essays in Historical Chemistry* (1894) and a biography of Joseph Priestley (1906). His contributions to chemical knowledge include an accurate series of measurements of the specific volumes of chemical substances of related composition. With A E. H. Tutton, he studied the oxides of phosphorus (*q.v.*) (1886 *et seq*); they discovered phosphorus tetroxide (P_2O_4) and investigated this and phosphorus trioxide (P_4O_6). From 1884 to 1886 he made a long series of measurements (with J. W. Rodger) of the viscosities of organic substances and attempted to correlate fluidity and composition.

With Sir Arthur Rucker, Thorpe carried out (1884–88) a magnetic survey of the British Isles.

THORVALDSEN (Thorwaldsen), **BERTEL** (1768–1844), Danish sculptor, who was the most successful of the neoclassical sculptors, was born in Copenhagen on Nov. 19, 1768. His father was an Icelander who had settled in Denmark and there carried on the trade of a wood carver. Thorvaldsen entered the Copenhagen school of art, where he won the highest prize, the traveling studentship. In 1797 he went to Rome, where Antonio Canova was at the height of his popularity. Thorvaldsen's first success was the model for a statue of Jason, highly praised by Canova, which he was commissioned to execute in marble by the English author and connoisseur Thomas Hope. From that time Thorvaldsen's success was assured, and he did not leave Italy for 23 years. In 1819 he returned to Denmark. where he was commissioned to make the colossal series of statues of Christ and the 12 apostles that are now in the Vor Frue Kirke in Copenhagen. These were executed after his return to Rome and were not completed till 1838, when Thorvaldsen again returned to Denmark. He died in Copenhagen on March 24, 1844, bequeathing a great part of his fortune for the building and endowment of a museum in that city. His collection of works of art and the models for all his sculpture went to furnish the museum, in the courtyard of which he was buried under a bed of roses, by his own wish.

Many of Thorvaldsen's statues of pagan deities are modeled with much of the antique feeling for breadth and purity of design. For Christian sculpture he had no real feeling, and the tomb of Pius VII in St. Peter's and the "Christ and Apostles" at Copenhagen are less successful. One of his best-known works is his statue of a lion, at Lucerne, Switz. He worked sometimes with feverish eagerness; at other times he was idle for months.

THOTH, Greek form of the name of the Egyptian god Djhowtey, whose cult was centred in the town of Khmun (Lat. Hermopolis Magna; mod. El Ashmunein) in upper Egypt. At first he was probably the moon-god and, as such, was called "reckoner of time" and his name was given to the first month of the Egyptian year. In consequence he became the god of reckoning and of learning in general, and was held to be the inventor of writing, the founder of social order, the creator of languages, the scribe. interpreter and adviser of the gods and the representative of the sun-god Ra (Re) on earth. He was also the patron of scribes and officials. Thoth played an important part in the myth of Osiris, protecting Isis during her pregnancy and healing the injury inflicted on her son Horus by Osiris' adversary, the god Set. Thoth weighed the hearts of the deceased at their judgment, and reported the result to the presiding god Osiris and his fellow judges.

Thoth's sacred animals, for reasons which are not quite clear, were the bird ibis (*Threskiornis ethiopica*) and the baboon (*Cynocephalus hamadryas*); numerous mummified bodies of these two animals were found in cemeteries near Hermopolis and Thebes. Thoth himself was sometimes represented as an ibis or as a baboon, but more usually in human form with an ibis' head. The Greeks identified Thoth with their god Hermes and traced back to "Thoth, the thrice great" (Hermes Trismegistos; *q.v.*) the authorship of powerful magical books.

See P. Boylan, *Thoth, the Hermes of Egypt* (1922). (J. Cy.)

THOU (Thuanus), **JACQUES AUGUSTE DE** (1553–1617), French historian, was the grandson of Augustin de Thou, president of the *parlement* of Paris (d. 1544). He studied law at Orléans, at Bourges and finally at Valence. He was at first intended for the church; he received the minor orders, and on the appointment of his uncle Nicolas to the episcopate succeeded him as a canon of Notre Dame. As *conseiller d'état* he served faithfully both the effeminate, bigoted and cruel Henry III and Henry IV, a skeptic, because they were both the representatives of legitimate authority. He succeeded his uncle Augustin as *président à mortier* (1595), and used his new authority in the interests of religious peace, negotiating, on the one hand, the Edict of Nantes with the Protestants, while in the name of the principals of the Gallican church he opposed the recognition of the Council of Trent. This attitude exposed him to the animosity of the League party and of the Holy See, and to their persecution when the first edition of his history appeared.

The history mas the work of his whole life. His materials for writing it were drawn from his rich library, which he established in the Rue des Poitevins in the year 1587, with the two brothers, Pierre and Jacques Dupuy, as librarians. His object was to produce a purely scientific and unbiased work, and for this reason he wrote it in Latin. giving it as title *Historia sui temporis.* The first 18 books, embracing the period from 1545–60, appeared in 1604 (1 vol. folio), and the work was at once attacked by those whom the author himself calls les *envieux* et les *factieux.* The second part, dealing with the first wars of religion (1560–72), was put on the Index *librorum prohibitorum.* The third part (to 1574). and the fourth (to 1584), which appeared in 1607 and 1608, caused a similar outcry, in spite of de Thou's efforts to remain impartial. In answer to his detractors. he wrote his *Mémoires,* which are a useful complement to the History of His Own *Times.* After the death of Henry IV, the queen regent refused him the position of first president of the *parlement,* appointing him instead as a member of the *Conseil* des finances. He continued to serve under Marie de Nedicis, and took part in the negotiations of the treaties concluded at Ste. Menehould (1614) and Loudun (1616). He died at Paris on May 7, 1617. Three years after the death of de Thou, Pierre Dupuy and Nicolas Rigault brought out, nith part 5, the first complete edition of the *Historia sui* temporis, comprising 138 books; they appended to it the *Mémoires,* also given in Latin (1620). A hundred years later, an Englishman, Samuel Buckley, published a critical edition, the material for which had been collected in France itself by Thomas Carte (1733). De Thou's history is a model of exact research, drawn from the best sources. and presented in a style both elegant and animated. The standard translation is *Histoire* universelle, by Le Beau. Le Mascrier, the Abbé Des Fontaines (1734). The *Mémoires* had already been translated by Le Petit and Des Ifs (1711); in this form they have been reprinted in the collections of Petitot. Michaud and Buchon. To de Thou we also owe certain other works: a treatise De re *accipitraria* (1784). a Life, in Latin, of Papyre Masson, some *Poemata* sacra, etc.

THOUGHT, LAWS OF. Traditionally, special importance has been attached to three of the simplest laws of logic, the law *of* identity, the law of contradiction, and the law of *excluded middle* (or *tertium non datur*). These were called the "laws of thought," a name which may conveniently be retained even by those who do not accept the implications which the name suggests.

As examples of axioms (see AXIOM) Aristotle cites that, of two contradictories. one must be true, and that it is impossible for anything both to be and not to be. These are the principles which were afterward known as the laws of excluded middle and of contradiction respectively. They occur in Aristotle also in other forms, which are regarded as being expressions of the same laws, *e.g.,* that there is no middle ground between contradictories, and that it is impossible for anything both to be predicated and not to be predicated of the same thing in the same sense. Aristotle partly exempted future contingents from the law of excluded middle, holding that it is not (now) either true or false that there will be a naval battle tomorrow, but that it is (now) true that either there will be a naval battle tomorrow or not; against this, Chrysippus (see LOGIC, HISTORY OF) maintained that all propositions. even about the future, are either true or false.

The law of identity has usually been stated (for example by Leibniz) as: A is A

To render the three laws in modern logical notation (see LOGIC), the best choices would seem to be: $F(x) \supset \cdot F(x)$ (law of identity), $\sim \cdot p \sim p$ (law *of* contradiction), $p \vee \sim p$ (law of excluded middle). However. the law of identity is also often given as $(x)\, x =$ x, a form which differs from the other (on the basis of the definition of $=$ in the article LOGIC) only by the insertion of a quantifier.

The three laws may also be understood in a semantical sense (see SEMANTICS IN LOGIC), the traditional statements of them generally not making a sharp distinction between such metatheoretic principles and principles which are rather to be expressed in the notation of propositional calculus or functional calculus. Thus the law of identity would be that a term must preserve the same denotations in all its occurrences, at least throughout any one context; the law of contradiction, that a sentence and its negation. S and $\sim S$, are not both true; the law of excluded middle, that either S or $\sim S$ is true. In this interpretation the "laws of thought" are to be regarded as being about some particular language—or else as general principles of sound notation, demands which any acceptable language or system of notation is required to satisfy.

That the lans of thought—or even only the laws of identity and contradiction—are a sufficient foundation for the whole of logic, or that all other principles of logic are mere elaborations of them, nas a doctrine common among traditional logicians of the 19th century, and though it appears already in the *Vernunftlehre* (1756) of H S. Reimarus, its widespread adoption is perhaps traceable to Kant's characterization of an analytic judgment (see LOGIC. HISTORY OF) as one for recognition of whose truth the law of contradiction suffices. It is, however, difficult to give this doctrine a precise meaning in such a way as to make it tenable. For example it is not true that the three laws, say in the forms $F(x) \supset_x F(x)$, $\sim \cdot p \sim p$, $p \vee \sim p$, are a sufficient set of axioms for logic, or even for the most elementary branch of logic, the propositional calculus, or for the traditional theory of the categorical syllogism

Criticisms and Rejections of the Laws of Thought.—The law of excluded middle and some related laws of propositional calculus and functional calculus of first order are rejected by L. E. J. Brouwer and the school of mathematical intuitionism (see LOGIC, and MATHEMATICS, FOUNDATIONS OF), not in the sense that the negation of the law is asserted, but in the sense that use of the law is not admitted as a valid method of mathematical proof in cases in which all members of an infinite class are involved. For example, Brouwer would not accept the disjunction that either there occur ten consecutive 7's somenhere in the decimal expansion of the number π or else not (since there is no proof known of either alternative), but he would accept that there occur ten consecutive i's somewhere in the first 10^{100} digits of the decimal expansion of π or else not (since this could in principle be settled by carrying out the computation of the decimal expansion to the required point).

On the basis of Aristotle's doctrine of future contingents, but not without some modification of it, Jan Łukasiewicz was led in 1920 to formulate a propositional calculus which has a third truth-value (for future contingents) in addition to the usual two, and in which the laws of contradiction and excluded middle alike fail. Propositional calculi with n truth-values, $n \geqq 3$, were published independently by E L. Post in 1921 and by Łukasiewicz in 1930. Corresponding many-valued functional calculi of first order were formulated still later by other writers.

Other criticisms or rejections of one or more of the laws of thought—*e.g.,* by Epicurus (*q.v.*), by Hegel (*q.v.*), by Alfred Korzybski (see SEMANTICS, GENERAL)—are in a different category from those of Brouwer and Lukasiewicz, as they offer no precise formulation of a usable logic in which these laws fail or are modified. *See* also Index references under "Thought, Laws of" in the Index volume.

THOUSAND AND ONE NIGHTS (Arabic, ALF LAYLA WA LAYLA), popularly known as the Arabian Nights, a collection of Arabic short stories of uncertain date and authorship. With the possible exception of the Koran, no other work of Arabic literature has been better-known or more influential in the west: indeed, certain stories, such as those about Aladdin, Ali Baba, and Sindbad the Sailor (*q.v.*), have almost become part of the folklore of western Europe. The stories are grouped round a central situation or frame story, in a manner familiar in medieval European literature as, for instance, in Chaucer's Canterbury *Tales* and Boccaccio's Decameron. The scene is in central Asia or, as the text puts it. "in the islands, or peninsulae, of India and China." King Shahryar discovers that his wife has been regularly unfaithful to him during his absences from the palace Killing her, and the other guilty parties, he is filled with a loathing of all womankind. Henceforward he marries, and kills. a new wife every day. Soon no further candidates can be found for the royal hand. The vizier, or prime minister, has two daughters, Shahrazad, the elder, and Dunyazad. Shahrazad insists that her father give her in marriage to the king. having worked out a scheme whereby she can save both herself and her people. Each evening she tells a story to her sister and the king, but does not finish it, promising to do so on the following night, if she survives. The stories are so entertaining, and the king is so eager to hear how each one ends that he puts off the execution of Shahrazad from day to day and ultimately gives up his cruel plan altogether.

Texts and Translations. — Antoine Galland (1646–1715; *q.v.*) produced not only the first translation, but also the first printed edition of the *Nights*. He traveled in the near east first in the French diplomatic service, then as a collector of objects for museums. Returning to France, he made a French translation of the *Nights* from a Syrian manuscript in four volumes. This translation, *Les Mille et Une Nuits, contes arabes traduits en français,* was published in 10 volumes between 1704 and 1712. Volumes xi and xii appeared after his death, in 1717. The later volumes contained many stories from other sources; and there is really no "canonical" text of the *Nights,* in respect to either the stories included or the actual wording of them. Galland translated freely, molding the stories into a form acceptable to Europeans of his day. But he was a born storyteller and his work enjoyed enormous popularity. For over a century it was the standard European version, and parts of it have even been translated back into Arabic.

The Arabic text was first published in Calcutta in an incomplete form in two volumes (1814–18); and again in four volumes (1839–42). However, it mas the Egyptian recension which was the basis of 19th–20th century European translations. The first Bulaq (Cairo) edition dates from 1835, and there have been several Cairo editions since. The text was also printed in Breslau (1825–43) as *Tausend und eine Nacht, Arabisch. Nach einer Handschrift von Tunis,* edited by Maximilian Habicht.

During the 19th century, there were several European translations of varying degrees of accuracy and fullness. The question of expurgation troubled some translators, as certain stories in the original are certainly not for juvenile reading. The translation (1838–40) of E. W. Lane (*q.v.*) is incomplete, but has useful notes. John Payne's, in nine volumes, appeared during 1882–84. There were three supplementary volumes in 1884 and a 13th volume in 1889. The most famous English translation is that of Sir Richard Burton (*q.v.*), which is based on Payne's, from which it sometimes quotes passages verbatim. It was published in ten volumes (1885) with six supplementary volumes (1886–88). It has been reprinted since, both in full and in a shortened form. Lady Burton's edition (1886–88) was ruthlessly expurgated. Smithers' edition in 12 volumes (1894) restored most, but not all, of the omissions. Burton had considerable knowledge of the seamy side of eastern life, and his version is much sought after for its notes and commentary. The French translation of J C. Mardrus, begun in 1899, is well known, but not highly esteemed among scholars Not only is the text inaccurate, but it also includes stories which do not really belong to the *Nights*. Space does not permit the listing of the many translations into various European languages, but an outstanding example is the German translation of E. Littmann first published at Leipzig in six volumes (1921–28) with second and third editions in 1953 and 1954.

Origins and Contents. — European orientalists have been interested in the origins of the nork from the beginning of the 19th century onward. Antoine Isaac Silvestre de Sacy (1758–1838; *q.v.*) realized that it could not be the work of a single writer; though Lane thought otherwise. There is now general recognition that it is a composite work which consists of popular stories, probably originally told orally. it has grown in the course of the centuries, material being added somewhat haphazardly in different periods and places. This is borne out by the style, which is largely unstudied and unaffected, with a number of colloquialisms, and even grammatical errors, such as no self-respecting Arabic author would have permitted himself. The varied character and wide geographical diversity of origin of the material also makes a single authorship unlikely. The component elements can be traced to India, Iran, Iraq, Egypt and Turkey. and Gustave von Grunebaum in *Medieval Islam* (2nd ed., 1953) also postulated Greek elements. The general framework may be Indian, though the names of the chief protagonists are Iranian. There are Indian, Iranian, Turkish and even European proper names, but, as is only to be expected in an Islamic work, the majority of names are Arabic. The stories come under several categories. Some of them may be classed as fairy tales. *Aladdin and the Magic Lamp, Ali Baba and the Forty Thieves*, the *Merchant and the Djinni*, etc. There are also romances and love stories; adventure stories such as *Sindbad;* humorous tales such as *The Sleeper Awakened* and *Khalifa the Fisherman;* fables and parables; and a few Arab legends. But the Arab background portrayed is largely that of the Baghdad of Harun al-Rashid and the Cairo of the Fatimids and Mamelukes.

Nabia Abbott discovered the first known reference to the *Thousand and One Nights (See* "A Ninth-Century Fragment of the 'Thousand Nights ," in *Journal of Near Eastern Studies,* 1949). Next, the work is mentioned by al-Masudi (*q.v*) in his *Muraj al-Dhahab* (947). In discussing legendary stories which have come from Iran, India and Greece, he instances "the book *Hazar Afsana,* nhich in Persian means 'A Thousand Tales' .. "The people," he says, "call this book 'A Thousand Nights,' " and it is the story about the king, the vizier, the latter's daughter and her servant girl. These, two are named Shirazad and Dinazad. The *Fihrist* (987) of Ibn al-Nadim mentions the *Hazar Afsana* and outlines the frame story. It then goes on to describe how a certain Abu Abdullah ibn 'Abdus al-Jashyari (d. 942) began writing a collection of 1,000 stories of the Arabs, Iranians, Greeks and other peoples. At his death, he had only completed 480 of them. The existence of some form of the work in Fatimid Egypt is vouched for by al-Qurti, who wrote a history of Egypt under the last Fatimid ruler (1160–71).

August Müller, in 1887, distinguished several layers in the work, including one belonging to Baghdad, and another, much larger and later, written in Egypt. This idea was worked out in greater detail by T. Noldeke, and especially by J. Oestrup in *Studier over 1001 Nat* (1891). The contents were also discussed by J. Horowitz in his article "Die Entstehung von Tausendundeine Nacht" in the *Review of Nations,* no. 4 (April 1927). Nabia Abbott suggests the following successive forms of the *Nights:* (I) An 8th-century Arabic translation of the *Hazar Afsana,* probably full and literal, and entitled *Alf Khurafa.* (2) An 8th-century Islamized version entitled *Alf Layla.* (3) A 9th-century version based on the above, and augmented by other current stories, such as those about Sindbad. (4) Ibn 'Abdus' work, mentioned above, possibly containing much material from 1, 2, and 3. (5) A 12th-century collection, including Egyptian stories. The title *Alf Layla wa Layla* may date from this period. (6) The final form of the nork, extending into the 16th century. Additional material probably included stories of Islamic counter-crusades and far-eastern tales brought to the middle east by the Mongols.

The original title, *A Thousand Stories* was not meant to be accurate, but merely to indicate a large number Littmann suggests that the change to '1,001" came under Turkish influence, from the Turkish idiomatic expression *bzn bir* ("1,001") for a large number. Later, it was felt necessary to justify this title by adding stories, in order to complete the number.

THRACE, a name applied at various periods to areas of different extent. Since 1923 'Ihrace has been divided betneen Greece (Western Thrace) and Turkey (Eastern Thrace) The boundaries of the Rornan province of Thrace nere — north, the Haemus; east, the Euxine sea; south, the Propontis, the Hellespont and the Aegean; and west, the Nestus. The distinguishing features of the country were the chain of Rhodope (Despotodagh) and the river Hebrus (Maritza). The greater part of the country is hilly and irregular; besides Rhodope two other tolerably definite chains intersect it, one of which descends from Haemus to Adrianople, while the other follows the coast of the Euxine at no great distance inland. One district in the extreme north-west of Thrace lay beyond the watershed separating the streams that flow into the Aegean from those that reach the Danube: this was the territory of Sardica, the modern Sofia. On the southern shore are found the Greek colonies of Abdera and Mesambria on the Aegean, Perinthus on the Propontis, and, the most famous of all, Byzantium (*q.v.*). Colonies were also planted in the Thracian Chersonese, between the Hellespont and the Bay of Melas; among its cities were Sestos and Callipolis (Gallipoli). In order to prevent the incursions of the Thracians, a wall was built across its isthmus.

History. — The most striking archaeological monuments of the prehistoric period are the sepulchral mounds, which are found especially in the neighbourhood of the ancient towns. Roman implements and ornaments have been found in some of them. The country was overrun several times by Darius and his generals, and the Thracian Greeks contributed 120 ships to the armament of Xerxes (Herod. vii. 185). The most powerful Thracian tribe was the Odrysae, whose king, Teres, extended his dominion so as to include the greater part of Thrace. During the Peloponnesian War his son Sitalces was an ally of the Athenians against the Macedonians. During the early period of the Roman empire the Thracian kings were allowed to maintain an independent sovereignty, while acknowledging the suzerainty of Rome, and it was not until the reign of Vespasian that the country was reduced to the form of a province. It was much exposed to the inroads of barbarian invaders, was overrun by the Goths on several occasions, and subsequently by the Huns; but its proximity to Constantinople caused its fortunes to be closely connected with the capital of the Eastern empire. In the middle ages the northern parts of Thrace were occupied by Bulgarians; in 1361 the Turks made themselves masters of Adrianople, which became the Turkish capital. When Constantinople fell in 1453, the whole country passed into the hands of the Turks, and in their possession it remained until 1878, when the northern portion of it was placed under a separate administration, with the title of Eastern Rumelia; this province has now become a part of Bulgaria.

Ancient **Peoples.**—The name "Thracians," from being used both ethnically and geographically, has led to confusion. There were the indigenous Thracians, and also Celtic tribes, such as the Getae. These were the "red" Thracians of Greek writers, and they differed not merely in complexion, but also in their customs and religion, from the native Thracians. The chief native deities were Dionysus, Ares and Bendis (Artemis). The ancient Dionysiac rites, including a ritual play by "goat-men" carrying a wooden phallus, may still be seen at Bizye, the old residence of the Thracian kings. The true Thracians were a dark-complexioned, long-skulled race, which had been in the Balkan peninsula from the Stone Age, closely akin to the Pelasgians (*q.v.*), to the Ligurians, and to the Iberians. There is no well-defined difference between aboriginal Thracians and Illyrians (*see* ILLYRIA). Thus there was an Illyrian tribe, Brygi; a Thracian tribe, Bryges; and, in Strabo's time, a tribe called Dardanii, then reckoned Illyrian, living next the Thracian Bessi (in whose land was the oldest oracle of Dionysus), was probably as much Thracian as Illyrian. All the Thracian and Illyrian tribes tattooed, thus being distinguished from the Celtic tribes. The Thracians differed only dialectically from the Illyrians, their tongue being allied to Greek. The Thracians from Olympus to the Pangaean district struck coins almost as early as the Greeks. (See NUMISMATICS.) (X.)

THE 20TH CENTURY

Thrace was one of the three theatres of the first Balkan war of 1912, when the Bulgarians entered it and defeated the Turks in the great battle of Lule Burgas, subsequently marching up to the ramparts of Chatalja, where the armistice with the Turks was signed. With the assistance of Serbian troops the Bulgarians took Adrianople, and the Treaty of London of May 30, 1913 put back the frontier of European Turkey to a line drawn from Enos on the Aegean to Midia on the Black Sea. Nearly all Thrace had thus fallen to the share of Bulgaria, but her quarrel with her allies over the spoils in Macedonia led to the second Balkan war of 1913, and the Turks took the opportunity to recapture Adrianople, to reoccupy Western Thrace and create the "independent government of Gumuljina," a mainly Moslem district.

The treaty of Constantinople of Sept. 29, 1913 set back the Turco-Bulgarian frontier in Thrace to the mouth of the river Rezvaya on the Black Sea, considerably to the north of Midia, and, while making the right branch of the Maritsa the frontier on the Aegean, so drew the line between those points as to include Kirk Kilisse and Adrianople within Turkish Thrace. But Giimuljina was restored to Bulgaria, with the result that 14 Moslem deputies of Western Thrace held the balance of power in Bulgaria and, under the influence of their compatriot Talaat, helped to bring Bulgaria over to the Central Empires. Meanwhile the third Treaty of Bucharest fixed the Greco-Bulgarian frontier at the mouth of the Mesta; thus the Thracian coast from the Mesta to the Maritsa gave Bulgaria her coveted outlet on the Aegean. But the frontier cut the latter river and the Mustafa-Pasha (Svilen) Adrianople-Dedeagach railway so that Bulgarian trains had to traverse Turkish territory before reaching their Bulgarian port. The Maritsa was consequently declared free to the transit of both states till they had made fresh lines on their own territories. The cession of this awkward bend in the railway to Bulgaria in 1915 was a further inducement to enter the War on the Turkish side. Thrace was not long left in peace, for the operations at the Dardanelles brought her again within the war zone. The Treaty of Neuilly of 1919 again changed her boundaries. Bulgaria was moved back from the Thracian sea coast in favour of Greece, which by Article 27 of the Treaty of Sèvres of 1920 obtained the lion's share of Thrace as far as "a point near the mouth of the Biyuk Deré" on the Black Sea, and "a point on the sea of Marmora about one kilometre southwest of Kalikratia"—in other words, up to the Chatalja lines.

But the Allies undertook to make the Maritsa an international river and "to ensure the economic outlet of Bulgaria to the Aegean" by Article 48 of the Treaty of Neuilly. This they effected —in theory—by "the Thracian Treaty," signed on the same day as that of Sèvres, which decreed, as a condition of the recognition of Greek sovereignty over the former Bulgarian territories in Thrace, that Bulgaria should have "freedom of transit over the territories and in the ports assigned to Greece in the present Treaty," that "in the port of Dedeagach Bulgaria will be accorded a lease in perpetuity, subject to determination by the League of Nations, of a zone," and that Dedeagach be "declared a port of international concern," free to all members of the League. In practice, Bulgaria did not avail herself of this provision, rejecting Venizelos' offer in 1922 of a lease of the port and preferring a corridor and actual possession. The Greek tenure of Eastern Thrace was brief. After the disaster in Asia Minor, Article 2 of the second Treaty of Lausanne of July 24, 1923 restored Eastern Thrace up to the Maritsa to Turkey, leaving Western Thrace, *minus* the enclave of Karagach, to Greece. By conventions 3 and 6, on either side of these Greco-Turkish and Bulgaro-Turkish frontiers in Thrace demilitarized zones of about 30 km. were established and existing fortifications ordered to be dismantled and the Moslem inhabitants of Western Thrace were exempted from the obligatory exchange of populations. Thus Thrace became divided between Turkey, Greece and Bulgaria.

THRASEA PAETUS, PUBLIUS CLODIUS, Roman senator and Stoic philosopher, lived during the reign of Nero. At first he was treated with great consideration by Nero, probably because of the influence of Seneca, and became consul in A.D. 56. In 59 Thrasea retired from the senate without voting after the emperor's letter justifying the murder of Agrippina had been read. In 62 he prevented the execution of the praetor Antistius, who had written a libel upon the emperor. From this time (63) until his death in 66 Thrasea retired into private life. Various charges were brought against him, and the senate, awed by the presence of large bodies of troops, condemned him to death. When the news was brought to Thrasea at his house, where he was entertaining a number of friends, he retired to his room and had the veins of his arms opened.

THRASHER, a group of birds belonging to the same American family Mimidae as the mockingbird (*q.v.*). Perhaps the best of these accomplished songsters is Sennett's thrasher (Toxostoma longirostre) of southeast Texas and northeast Mexico, but the brown thrasher (T. rufum) of eastern North America also has a fine song. A third species is the sage thrasher (Oreoscoptes *montanus*) of the southwestern United States. All thrashers are birds of bushy thickets, where they build fairly bulky cup-shaped nests of twigs, in which they lay three to six whitish or pale greenish eggs, heavily speckled with brown. In spite of their arboreal nature, thrashers to a large extent feed on the ground.

The catbird (*q.v.*) has a cat-like mewing sound as well as a song. Unlike most of its relatives, it lays deep glossy blue-green eggs. Thrashers are beneficial in view of their insect-eating habits. (HT. FN.)

THRASYBULUS, an Athenian general, whose public career began in 411 B.C., when he frustrated the oligarchic rising in Samos (see PELOPONNESIAN WAR). Elected general by the troops, he effected the recall of Alcibiades and assisted him in the ensuing naval campaigns, contributing to the victories of Cynossema (411) and Cyzicus (410). He commanded a ship at Arginusae and was commissioned with Theramenes (*q.v.*) to rescue the men on the wrecks. In 404, when exiled by the Thirty Tyrants, he retired to Thebes. Late that year, with 70 men, he seized Phyle, a hill fort on Mt. Parnes. Thrasybulus then gained the Peiraeus, 1,000 strong, and held Munychia against the oligarchs. Eventually a Spartan expedition under king Pausanias arrived and the democracy was restored. Thrasybulus was now the hero of the people; but a decree by which he secured the franchise for all his followers was rescinded as illegal. In 395 Thrasybulus induced Athens to join the Theban league against Sparta, and in 389 he led a new fleet of 40 ships against the Spartans at Rhodes. Sailing first to the Bosporus he effected a democratic revolution at Byzantium and renewed the corn toll. After a successful descent on Lesbos and the renewal of the 5% import tax at Thasos and Clazomenae he sailed south and was killed at Aspendus.

THREE BODIES, PROBLEM OF, the problem of determining the motion of three heavenly bodies moving under no influence but that of their mutual gravitation. No general solution of this problem is possible. As practically attacked it consists in the problem of determining the perturbations or disturbances in the motion of one of the bodies around the principal or central body that are produced by the attraction of the third. Examples are the motion of the moon around the earth as disturbed by the action of the sun, and of one planet around the sun as disturbed by the action of another planet.

For application of the problem to asteroids, see TROJAN PLANETS.

THRING, EDWARD (1821–1887), who ranks with Thomas Arnold as one of the outstanding English schoolmasters of the 19th century, was born at Alford, Somerset, on Nov. 29, 1821, and educated at Eton and King's college, Cambridge. Ordained in 1846. seven years later he was appointed headmaster of Uppingham school, which he transformed from a small country grammar school into a large public school, in spite of opposition from his governors. Fearing that the independence of the school was threatened by the Endowed Schools commissioners, he formed in 1868 the Headmasters' conference, which thereafter had a great influence in English public school education. Thring remained as headmaster until his death on Oct. 22, 1887. He believed that every boy could do something well and that the business of the master was to discover what this was.

He built the school chapel, opened in 1859 the first school gymnasium in England, started wood and metal workshops, and provided a swimming pool and opportunities for school gardening. At the same time he stressed a sound training in classics, mathematics and English. Thring realized the refining and stimulating power of music in education and built up a strong, musical tradition at Uppingham.

To help young teachers, he wrote Theory and Practice of Teaching (1883).

THROAT (PHARYNX), in human anatomy, a passageway leading from the oral and nasal cavities to the esophagus (gullet) and larynx (voice box). According to strictest dictionary definition, pharynx is a broader term than throat, the latter being restricted to only part of the pharynx. In medical practice, however, the two terms ordinarily are used interchangeably, and they will be so used in this article.

The throat passes the intake of solids and liquids to the esophagus and conducts air to and from the larynx in inspiration and expiration. The throat also communicates on either side with the cavity of the middle ear by way of the auditory (Eustachian) tube; this provides for equalization of air pressure on the eardrum membrane, which separates the cavity of the middle ear from the external ear canal. (See EAR, ANATOMY OF.)

Anatomy. — The throat has roughly the form of a funnel flattened from front to back, about five inches long and narrowing from a width of about two inches at the base of the skull to one inch at its junction with the esophagus. The wall of the pharynx is attached by its connective tissue and muscles to surrounding structures. The firmest attachments (in addition to continuities with the walls of the oral cavity, Eustachian tubes, esophagus and larynx) are with basal parts of the skull, mandible, tongue, hyoid bone and the thyroid and cricoid cartilages of the larynx. The outermost connective tissue is in most areas loose enough in organization to admit gliding of the pharyngeal wall, in the movements of swallowing, against the surrounding structures.

Three main divisions of the throat are distinguished: oral pharynx, nasal pharynx and laryngeal pharynx (see figure). The latter two are airways, whereas the oral pharynx is shared by the respiratory and gastrointestinal tracts. Some of the boundaries of these divisions may be observed in a person whose mouth is held wide open. The limit between mouth cavity and oral pharynx may be approximated by studying the positions of structures appearing in this view. On either side is the palatine tonsil, enlodged between two vertical folds of mucous membrane (in front, the glossopalatine arch; behind, the pharyngopalatine arch). A plane coinciding with the glossopalatine arches on the sides of the throat, and with the junction of the front two-thirds and back one-third of the tongue on its floor, represents the approximate boundary between mouth cavity and oral pharynx. Above, the hard palate separates the oral cavity from the nasal cavities; the soft palate partitions the oral pharynx from the nasal pharynx. The free edge of the soft palate is prolonged in the mid-line as the teatlike uvula. The laryngeal pharynx and the lower part of the oral pharynx are hidden by the bulging of the root of the tongue. An important feature of this obscured region is the epiglottis, a laryngeal flap that guards the glottis as a deflector between the laryngeal pharynx and the lowermost oral pharynx.

The wall of the throat is divisible into principal layers, from within outward: (1) mucous membrane, consisting of epithelium and fibrous connective tissue, of which the outermost part is a tough membrane called the pharyngeal aponeurosis, especially concerned with the upper and lower attachments of the throat; (2)

muscle; (3) connective tissue. The muscle is subject to voluntary control and is concerned in the mechanics of swallowing. The mucous membrane contains numerous minute salivary glands (*q.v.*).

The throat is the seat of the tonsils. The term "tonsil" may suggest only the palatine tonsils, whose position is described above, but these are only components of a series of tonsils encircling the wall of the pharynx. On either side, in addition to the palatine tonsil, is the tubal tonsil, near the orifice of the Eustachian tube. On the roof of the nasopharynx is the pharyngeal tonsil, which is frequently so enlarged in children (adenoids; *q.v.*) as to obstruct the airway. On the floor of the oral pharynx, in the back one third of the tongue, is the lingual tonsil. All these tonsils are masses of lymphoid tissue imbedded in the mucous membrane; this tissue is composed principally of lymphocytes, a variety of white blood cell. Normally, these masses of lymphoid tissue tend to become smaller in adulthood.

Comparative Anatomy.— Broadly defined, the pharynx is the segment of the alimentary tract in direct continuity with the mouth cavity. The invertebrates are widely diversified in degree of complexity, and in the simpler representatives the pharynx does not exist because at this level of structural organization there is no alimentary tract equivalent to that of higher forms. Even in some invertebrates that possess an alimentary tract the pharynx as such is absent, the passage leading from the mouth being termed esophagus or stomach. The invertebrates that have a pharynx exhibit variations of its construction and functions. of which examples are cited. In leeches the pharynx has a robust musculature and serves as a suction pump to extract blood from the prey nhose skin has been pierced by the teeth of the leech. In certain marine worms the wall of the mouth cavity and pharynx may be turned out and protruded for the ingestion of food; the interior of the pharynx

may bear papillae or even horny teeth that aid in the process of ingestion.

The pharynx in invertebrates as a whole is not the strict homologue of the pharynx in vertebrates. The likeness between them is only the analogy of their sequential relations in the alimentary tract. and they are no more homologous than the wings of insects in comparison with the wings of birds. In chordate animals (that is, vertebrates and their immediate kin, illustrated by the lancelet, tunicates and "acorn worms") the pharynx is consistent not only in the fundamentals of structural relationship but also in embryologic derivation, hence homologous throughout.

The classes of vertebrates present wide variation in the character of the pharynx. In all lung-breathing forms (mammals, birds, reptiles and most amphibians in their postlarval stages) the pharynx is constructed in principle like that of man, though varying in anatomical details. Gill-breathing vertebrates reflect the basic pharyngeal pattern that characterizes the chordates as a group. The possession of gills in relation to the pharynx is a primitive feature. Gills are retained throughout life in fishes and in some tailed amphibians (*e.g.*, Necturus, the mud puppy). Gills in some animals (*e.g.*, larval amphibians and the adults of forms such as Necturus) are tufted external appendages. Typically in fishes, however, the gills are internal and in more direct relation with the pharynx. A shark, for example. presents on each side of the "neck" a series of gill slits, usually five in number, exclusive of the front opening known as the spiracle. These slits are communications between the pharynx and the outside, the gills being anchored within the slits where they are bathed with water issuing from the pharynx. A characteristic of bony fishes is the operculum on each side of the "neck." a protective flap overlying the gills and bordering the single gill opening. In all cases the gills are respiratory organs. Their rich capillary beds, fed by pharyngeal blood vessels, provide for the exchange of oxygen and carbon dioxide between blood and the surrounding water, just as the same exchange takes place betneen blood and air within lungs.

In the embryonic history of lung-breathing vertebrates the pharynx is first modeled in the primitive pattern—as if gills were to develop, which they actually do in abortive and transitory fashion in the embryos of some animals that lack gills. As an occasional anomaly in human development, one or more "gill slits" may persist. with or without opening into the pharynx.

THROAT, DISEASES OF. Diseases of the throat (*q.v.*) may affect its muscular wall, as in paralysis, or its lining, as in infection by bacteria, viruses or fungi. Infection by streptococci usually produces acute tonsillitis (*q.v.*) with swelling, pain and fever. If the infection reaches the space behind the tonsil, an abscess may form and produce quinsy, with extreme pain, difficulty in swallowing and inability to open the mouth. Scarlet fever (*q.v.*) is a streptococcal throat infection accompanied by a skin rash.

Although streptococcal infections of the throat may produce kidney and heart complications, they are to be less dreaded since the discovery of sulfonamide drugs and penicillin, as these agents, particularly penicillin, control such infections effectively.

Repeated infections usually result in enlarged tonsils and adenoids (*q.v.*), with obstruction to breathing and swallowing. Enlarged adenoids are the commonest cause of deafness in children. Adenoidectomy, usually done with tonsillectomy, restores normal hearing in such cases. These structures, which normally serve a useful purpose, should not be removed unless they are the site of repeated or intractable infection.

Diphtheria (*q.v.*), an acute specific bacterial infection of the throat, is rare where routine immunization is carried out in childhood. It can be cured by antitoxin if recognized early, but untreated it is often fatal. Other throat infections may be caused by viruses (mononucleosis, herpangina) or may occur when the body's resistance is weakened by a scarcity of white blood cells, a condition often due to drug sensitivity and occasionally to prolonged X-ray exposure.

The muscular wall of the throat may be weakened or paralyzed by virus infections of the supplying nerves (poliomyelitis, rabies, etc.), by toxins from diphtheria or infected food, by chemical agents (lead or methyl alcohol) or by circulatory disturbances of the brain, especially in the aged. Spasm of the lowermost constrictor muscle may result from emotional tension, producing the sensation of "lump in the throat."

Cancer of the throat is not common. It may begin as a painless swelling in the region of the tonsil, diagnosable by biopsy. X-ray treatment is often effective in controlling it.

Infections of the larynx or voice box (laryngitis; *q.v.*) may produce hoarseness, and in young children, a difficulty in breathing, known as croup (*q.v.*), which is treated by steam inhalation and antibiotics. A rare but rather severe form of croup, due to diphtheria, may require surgical opening of the windpipe to provide an airway. Tuberculous laryngitis is effectively controlled by streptomycin.

Hoarseness may be due to "singers' node" of the vocal cord, usually associated with overuse of the voice, or to vocal polyp, often found in excessive smokers. Since hoarseness is also an early symptom of cancer involving the larynx, it should be investigated by a physician if it lasts more than two weeks. Laryngeal cancer can be cured in most cases if discovered early. X-ray therapy can cure most small cancers of the vocal cord, whereas surgical removal of the larynx is required for extensive growths.

THROCKMORTON (or THROGMORTON), **FRANCIS** (1554–1584), English conspirator, was the son of Sir John Throckmorton of Feckenham in Worcestershire, and his wife Margery Puttenham. Sir John had been concerned in Wyat's rebellion against Queen Mary Tudor, but was afterward known as a sympathizer with the Roman Catholic party in the reign of Queen Elizabeth, and in 1580 was removed from his office of chief justice of Chester for irregularities in his office, but probably because he was suspected of disloyalty by the government. Francis entered Hart hall. Oxford in 1572, and in 1576 he was enrolled in the Inner Temple.

At Oxford Throckmorton came under the influence of the Roman Catholics, and when Edmund Campion and Robert Parsons (*qq.v.*), the first of the Jesuit missionaries, came to England in 1580 Francis Throckmorton was one of a society of members of the Inner Temple who united to hide and help them. In that year he went abroad. where he consorted with exiled papists, and engaged in treasonable intrigues. In 1583 he returned to act as the confidential agent of a conspiracy which had for its object the invasion of England by a French force for the purpose of releasing Mary Queen of Scots and restoring the papal authority.

Throckmorton occupied a house on Paul's wharf. London, which served as a meeting place for the conspirators. The suspicions of the government being aroused, Throckmorton was arrested in Nov. 1583. He was ciphering a letter to Queen Mary when the constables came upon him, but he found time to send a casket of compromising papers to Mendoza, and a card in cipher in which he promised to reveal nothing. On being threatened with a second application of the torture. however, his strength and courage failed and he made a full confession. His trial took place on May 21, 1584, and he was executed at Tyburn on the 10th of July. The arrest and confession of Throckmorton eventually led to the expulsion of the Spanish ambassador and so to war with Spain.

THROCKMORTON (or THROGMORTON), **SIR NICHOLAS** (1515–1571), English diplomat and politician, was the son of Sir George Throckmorton of Coughton in Warwickshire, and uncle of Francis Throckmorton (*q.v.*). A member of the household of Catherine Parr, the last wife of Henry VIII, he was favourable to the reformers in religion. He sat in parliament from 1545 to 1567. During the reign of Edward VI he was in high favour. When on the death of Edward VI an attempt was made to place Lady Jane Grey on the throne, he contrived to appear the friend of both parties, and secured the favour of Mary Tudor. He was, however, suspected of complicity in Wyat's rebellion in 1554, was brought to trial but was acquitted; though he was detained in the Tower till the following year. But he made his peace with Queen Mary. After the accession of Elizabeth he rose rapidly into favour. He became chamberlain of the exchequer. and from May 1559 to April 1564 he was ambassador in France. During this embassy, in which he was from Sept. 1562 associated with Sir Thomas Smith, Thockmorton was a strong supporter of the Huguenots and uas taken prisoner at the battle of Dreux. He also conducted the negotiations which accompanied Mary Queen of Scots's return to Scotland, and though he supported the reformers on political grounds, he became her personal friend.

On returning to England Throckmorton was sent as ambassador to Scotland in May 1565, to prevent Queen Mary's marriage with Darnley, which however he was unable to do. After the murder of Darnley he mas again sent to Scotland in June 1567 with the still more hopeless task of persuading the Scottish barons who had just imprisoned the queen to restore her to her authority.

Throckmorton's known friendship for Queen Mary, and his constant support of her claim to be recognized as Elizabeth's successor, made him an unwelcome representative of England in that crisis. In Edinburgh Throckmorton could effect little, but he exerted himself to secure the personal safety of the queen. He offended his mistress by showing his instructions to the Scottish barons, and was recalled in August.

In 1569 Throckmorton fell under suspicion during the duke of Norfolk's conspiracy in favour of Mary, and was imprisoned for a time at Windsor, but was not further proceeded against. He died on Feb. 12, 1571.

Sir Nicholas married Anne Carew, and his daughter Elizabeth became the wife of Sir Walter Raleigh.

THROMBOSIS AND EMBOLISM. In health the blood remains fluid in the circulatory system, but under certain conditions a thrombus, or clot within a blood vessel, may form and obstruct the passage of blood. Should part of the clot detach and become free to travel in the circulatory system as an embolus. it will lodge in another part of the vascular system, also interfering with blood flow. The symptoms of thrombosis or embolism, as the processes are called, are determined by the site of the obstruction and may be similar.

Thrombosis tends to occur in an artery, vein, or chamber of the heart (see CIRCULATION OF BLOOD) when the velocity of blood flow is reduced, the lining of the vascular system is roughened, or the clotting tendency of blood is enhanced. Injury, surgery, general or local infection, arterial disease, heart failure. pregnancy and certain disorders of the blood all predispose to thrombus formation.

The incidence of thrombosis increases with age. It occurs most often in the large veins of the pelvis and legs, the small arteries of the heart and the brain, and in the chambers of the left heart, but, under appropriate circumstances, may occur anywhere in the circulatory system.

If the intravascular clotting occurs in a vein, the process is called phlebothrombosis and may produce no symptoms unless productive of embolism. Usually there is also an element of inflammation present which may cause local pain and smelling of the region drained by the affected vein, and then it is designated thrombophlebitis.

While venous thrombosis may sometimes lead to embolism, it is not the threat to life that is met with in arterial thrombosis. The coronary and cerebral arteries to the heart and brain (see CIRCULATION OF BLOOD) are often the site of arteriosclerosis, thickening and irregularity of the vessel lining. which may predispose to clot formation. Should this occur. the mass of heart muscle or brain ordinarily supplied by the thrombosed vessel dies, and. if the victim survives the initial insult, healing follows with scar formation. A favourable course in such an instance will depend upon the extent of involvement and the absence of complicating thromboses, either attached to the lining of the injured heart wall or arising in the veins of the leg, which may give rise to fatal emboli.

Thrombosis depends upon the coagulability of the blood. The blood clot begins as a few blood platelets which adhere to som'e irregular or injured area of vessel wall and form microscopic ridges at right angles to the blood flow. Then, rapidly joined by white blood cells, they initiate precipitation of multitudinous strands of fibrin in which become enmeshed all the formed elements of the blood. The thrombus may then propagate itself, filling the involved vessel and extending back to it's origin. The "tail" of the thrombus thus formed may lie free in a parent vessel and. should it break free, an embolus is born. After its development, the thrombus begins a gradual process of contraction, disintegration and reabsorption, which ultimately may permit some return of blood flow through the clogged vessel.

Emboli are usually composed of coagulated blood but may rarely consist of tumour cells, air, fat particles or bacterial clumps (septic emboli). They are a common cause of sudden death but are by no means always fatal. The embolus arising anywhere in the venous system or in the right side of the heart will lodge in the ramifications of the pulmonary artery. If the embolus is large enough, one of the main pulmonary arteries is obstructed and death occurs. Should it be smaller, the segment of lung dependent upon the obstructed artery dies. In certain types of heart disease an embolus may originate from one of the chambers of the left side of the heart, or from the mitral or aortic valves therein. in which case the blood stream will carry it to one oi the branches of the peripheral arterial tree. Should such an embolus lodge in certain internal organs, pain might be the only consequence; but occlusion of even a small artery to the heart, the eye, the brain, the intestine or one of the extremities will lead also to the death of enough tissue to cause severe disruption, if not cessation, of function of the part. However, tissue death does not occur in all arterial obstructions, for in many locations there are neighbouring collateral arteries which can carry enough blood into the affected area to allow adequate circulation.

In the years after 1940 there were rapid advances in the treatment and prevention of thrombosis and embolism by the use of anticoagulants. Heparin, dicoumarol and related chemicals were shown to greatly reduce the frequency of thrombosis and complicating embolism when administered to postoperative and cardiac patients.

Surgical ligation of the vein proximal to a thrombosis in order to prevent subsequent embolism has been attempted. After embolism has occurred, surgical removal oi the offending clot may frequently save a limb if it can be achieved within six to eight hours after onset.

THRONE. A throne is the seat of a sovereign. potentate or dignitary, secular or religious, and a symbol of rule and authority.

Modern usage incorrectly applies the name to the seat alone, but historical evidence shows that not only the seat, but the dais on which it stands and the canopy over it, iorms the throne (Gr. *thronos* "elevated seat"!. Thus. at the end of a papal conclave. the canopies are lowered over the throne of each cardinal except that of the newly elected pope. On occasion the dais alone is referred to as a throne; *e.g.*, that on which two small altars were set at Louis XIII's funeral is described as a *petit trosne*. The throne cannot therefore be the forerunner of chairs. as is often supposed.

In the ancient world, particularly in the east, thrones were almost invariably of a symbolic magnificence: *e.g.*, Solomon's throne of ivory set on a dais approached by six steps flanked by lions. On the throne of the Byzantine emperors. said to be imitated irom it, the lions were mechanical, moving and emitting sounds. In the British museum. London. is a chryselephantine iragment incrusted with gold. ivory, lapis lazuli and cornelian, believed to have come irom the throne of Sargon II oi Assyria (722–705 B.C.).

The "Peacock Throne" of the rulers of Delhi, set with jewels and raised on a dais with silver steps. is of legendary splendour. The oldest surviving throne is probably that (much restored) built-in with the walls at Cnossos (c. 1800 B.C.). The earliest remaining post-Christian throne, the chair of St. Peter, for which Bernini created an elaborate *cathedra* in St. Peter's. Rome, is built of oak and ivory with iron carrying-rings (4th–5th century). The magnificent ivory throne of Archbishop Maximian at Ravenna dates from the following century. The so-called throne of King Dagobert from the treasury of St. Denis (now in the Bibliothèque Nationale, Paris). is a iolding stool of bronze, probably 8th century but with 12th-century additions prescribed by Abbot Suger. Thrones were oiten of silver in the later 17th and early 18th centuries (examples at Hanover and Copenhagen); later thrones nere generally of gilt wood. The English coronation throne in Westminster abbey is more properly a ceremonial chair, and the real throne of Great Britain is the oak chair in the house of lords, used

by the sovereign during the opening and prorogation of parliament. (*See* also CHAIR; CROWN AND REGALIA.)

THROTTLE is a valve that controls admission of steam to an engine or turbine or of an explosive mixture to an internal-combustion engine or of draught to a boiler furnace. The amount of opening can be regulated by hand, by foot or by a governor in different cases. The butterfly throttle is an established type for large valves, and is a favoured type in the small passages which lead from carburetors in automobile and airplane engines. The turning of the spindle causes the valve gradually to close the passage. An altitude cock is employed in conjunction with the throttle for airplane engines to compensate for the different conditions at various heights. Large throttle valves for steam engines have a piston valve construction with packing rings, and the action is such that opening and closing can be periormed with great ease.

Governor control acts on a throttle to regulate the engine speed; in hoisting engines the safety overwinding apparatus closes the throttle and applies the brakes in case of neglect on the part of the operator to reduce speed or stop at the correct times.

Big rolling-mill engines are throttled and reversed with great precision by a steam servomotor mechanism set in motion by the operator's control lever.

THROWING THE DISCUS: see DISCUS THROWING.

THRUSH, generally, any bird of the family Turdidae, a world-wide group which includes many excellent songsters. Specifically, the name is applied to several species of *Turdus,* old-world thrushes, and to species of *Hylocichla,* American thrushes.

The song thrush or mavis (T. *ericetorum*), one of the finest songsters in Europe, has a brown back and a speckled breast in both sexes. It ieeds very largely on worms and snails, which latter it shells by beating on a stone. It is an early breeder, rearing two broods a year; the nest, a deep cup, is lined with mud, cow dung and rotten wood, formed into a smooth layer by the pressure of the bird's breast. The eggs, iour or five in number, are a bluish green, spotted with black.

The missel thrush (T. *viscivorus*) is also called mistletoe thrush, from its fondness for the berries of that plant, and stormcock, from its habit of singing in squally weather. It is larger than the last species, reaching a length of 11 in. Otherwise it resembles its relative in appearance, but is greyer and has a white edge to the tail. Its song is loud and wild, but less sweet than that of the mavis. The bird boldly attacks marauding crows, jays and even cats, driving them away from its nest. The hermit thrush (*Hylocickla* guttata) of North America is the finest songster of the continent. The rufous tail and whitish eye ring are distinctive features. The wood thrush (H. mustelina), is little inferior to the last as a singer and has spotted sides as well as breast. The olive-backed thrush (H. *ustulata)* has a similar lovely song.

The genus *Turdus* includes also the blackbird (*q.v.*), ring-ousel, fieldfare (*q.v.*), redwing (*q.v.*), and others. Included in the Turdidae are the wheatears, stonechats and whinchats (see WHEATEAR), redstarts (*q.v.*), robins (see REDBREAST), and hedge sparrows (see SPARROW). The "ant-thrushes" belong to a different family (see PITTA).

THRUSH is a disease of the mouth and throat, caused by a yeastlike fungus. *Candida (or* Monilia) *albicans.* It brings about the development of grayish-white adherent membranes. Often the fungus is an inhabitant of the birth canal and the mouth of the newborn infant is contaminated from there during delivery. In older children and adults the infection rarely occurs inside the mouth, more frequently in the mouth corners. causing unsightly cracks. Moreover, the same iungus may invade the skin (moniliasis) under special circumstances. In bartenders and housewives whose hands are exposed to moisture over unduly long periods of time, the fungus causes erosions in the webs of the fingers and also may attack the nails.

The skin folds of obese diabetic persons are highly susceptible to moniliasis because of moisture and high sugar content of the skin. All these localized forms can easily be cured by competent medical treatment. In emaciated undernourished persons with decreased resistance, the whole body surface may become involved. An often fatal intestinal disease of infants. acrodermatitis enteropathica. with severe diarrhoea, promotes widespread monilial infection of the skin; this condition can be cured by eradicating the underlying intestinal disease with the drug Diodoquin.

Candida albicans, however, may also invade and attack internal organs. This systemic moniliasis up to the mid-1950s invariably ended fatally. Attempts to find antibiotic materials which kill *Candida albicans* in the body without harming the host were most promising at that time, however. (S. Ros.)

THUBURBO MAIUS (mod. HENCHIR-KASBAT), an ancient city of Roman North Africa, in the province of Africa proper; 2 mi. N. of the station of Pont-du-Fahs on the railway from Tunis to Kef. Octavian founded it near a native town, which was fused with it under Cornmodus.

The forum and its surroundings have been completely excavated. The Capitolium is well preserved.

THUBURSICU NUMIDORUM (mod. KHAMISSA), some 20 mi. by road S.W. of Souk Ahras. the junction of the railway to Tebessa from the main line from Algiers to Tunis. It was originally a native town, and became a Roman municipality under Trajan. There are extensive Roman remains, including two temples, a large civil basilica. and a well preserved theatre.

THUCYDIDES (fl. second half of the 5th century B.C.), greatest of Greek historians, was the author of the (incomplete) History of *the Peloponnesian War*. All that we know (perhaps all that ancient scholars knew) of his life is what he tells us himself in the course of his narrative. He was an Athenian, old enough when the war began (431 B.C.) to estimate its importance and that it was likely to be a long one, and to determine to write an account of it. observing and making notes from the beginning. He was probably born, therefore. not later than 460 — perhaps a few years earlier since his detailed narrative begins with the events provocative of the war which belong to the years just before 431. He was certainly over 30 when he was elected strategos in 424 (see below). That is, he belongs to the generation younger than Herodotus. His father's name was Oloros. This is not otherwise known as an Athenian name: and Oloros was probably of Thracian descent on his mother's side, and Thucydides related in some way to the great Miltiades, who had married the daughter of a Thracian prince of this name. He himself had property in Thrace. including mining rights in the gold mines opposite the island of Thasos, and was, he tells us, a man of influence there.

He was in Athens when the great pestilence of 430–429 raged there and caught the disease himself and saw others suffer. Later in 424 he was elected one of the ten strategoi of the year, and, because of his connections, given command of the fleet in the Thraceward region which was based at Thasos. He failed to prevent the capture of the important city of Amphipolis by Brasidas (*q.v.*), who launched a sudden attack in the middle of winter. He was recalled and tried and sentenced to exile. This, he says later. gave him greater opportunity for undistracted study for his History and for travel and wider contacts, especially with the Peloponnesian side. He survived the war and his exile of 20 years ended only with the fall of Athens and the peace of 404. The time and manner of his death are uncertain. but that he died shortly after 404 is probable. and that he died by violence in the troubled times following the peace may well be true, for the History stops abruptly long before its appointed end. His tomb. perhaps a cenotaph, and a monument to his memory, were still to be seen in Athens in the 2nd century A.D.

Scope and Plan of **the** History. — The History, which is divided into eight books (probably not Thucydides' own division) stops in the middle of the events of the autumn of 411 B.C., rather more than six and a half years before the end of the war. This much at least is known: that three historians. Cratippus. a younger contemporary. Xenophon a generation later and Theopompus in the last third of the 4th century. began their histories (of Greece as a whole, for a limited period) where he had stopped. Xenophon, one might almost say, beginning the next paragraph — nearly as abruptly as Thucydides ends. From this it is certain that Thucydides' work was well known soon after publication and that no more of it was ever published than the eight books that have survived; and it may reasonably be inferred from the silence of the available sources that no separate section of the work was published in his lifetime. It may also be inferred that parts of the History are defective, in the sense that he would have written at greater length had he known more and that he was trying still to learn more— *e.g.,* of internal Athenian politics in the years of "uneasy truce" (his existing narrative is in parts barely understandable without some imaginative guesswork). A good deal of the last book is defective.

We may assume. then, three fairly definable stages in his work: first. the "notes" he made of events as they occurred. always being supplemented by fresh inquiries; secondly, these notes arranged in their order and rewritten as consecutive narrative, as a "chronicle," but by no means in the final form that Thucydides intended— (*e.g.,* some, but not all, of the story of the "uneasy truce" in book v, and, surely, most of book viii); thirdly. the final, elaborated narrative — of the preliminaries of the war (book i), of the "Ten Years' War," and of the expedition to Sicily. No documentary evidence exists of the note stage but there are passages that are only chronicle embedded in the more finished parts. Many of these, however. Thucydides intended to leave as they are. Even the most elaborated parts of the History may have been added to right up to his death — certainly many additions were made after the war was over.

All this is significant because Thucydides was writing what scarcely another (of eminence) has attempted, a strictly contemporary history, of events which he lived through and which succeeded each other almost throughout his adult life. Sir Winston

Churchill has said of his own *Second World War*, based as it is on a unique collection of documents giving a current account of events, of the day-to-day conduct of the war: "I do not describe it as history, for that belongs to another generation. But . . . it is a contribution to history which will be of service to the future" (Introduction to vol. i, The *Gathering Storm;* Cassell and Company Ltd., 1948). Thucydides too was ariting of events in some of which he took an active part. of all of nhich he nas a direct or indirect spectator; but he attempted the final history, what, it might have been said. was "for another generation" and, as far as a man can, and as no other man has. he succeeded. It will be observed that he did not rush his work: the last of the complete narrative (stage three, above) took him to autumn 413. eight and a half years before the end of the war, the last of stage two to six and a half years before. During these last years he was observing, inquiring, mriting his notes, adding to or modifying nhat he had already written; at no time before the end. during all the 27 years of the war, did he know what that end would be (unlike Churchill in this). nor therefore what would be the length and the final shape of his own *History*. It is evident that he did not long survive the war since he did not leave any connected account, even at stage two, of the last six years. But, in what he lived to complete, he wrote a history, not a contribution to history.

It should however here be stated that in the opinion of some scholars *(see* BIBLIOGRAPHY), Thucydides did wait till after 404 to compose his *History* from his accumulated notes; and that much of the earlier part. especially Pericles' speeches in book ii, is only to be fully understood in the light of the final defeat of Athens. He was of course, as stated, always thinking about and sometimes modifying what he had already written; but the view that he, in any real sense. "began" his work after 404 seems to be untenable.

Diagnosis of the Causes of the **Peloponnesian** War.—The conflict which he set out to describe, in detail. as truthfully as possible, with strict observation of the chronology was, as he saw it, twofold. In its simpler aspect it was caused by the rapid rise of Athens in wealth and political power after the Persian Wars, which was a challenge to the generations-old Spartan leadership in Greece. This leadership was traditional and had been widely accepted—so much so that in 480 Athens, in spite of a sharp conflict with Sparta over its internal affairs 30 years before and its proud consciousness that it had stood alone, and successfully, at Marathon in 490, was ready to accept it, nith all the other Greek states who shared in the resistance to the second Persian invasion *(see* GRAECO-PERSIAN WARS).

In 431 Sparta, though "ever slow in going to war," took up the challenge and declared war. But Athenian power was something more than that of an ambitious rival. To the Greek world, accustomed as it was to the autonomy of cities under democratic rule, and even to the Athenians themselves at times, it appeared "like a tyranny"—moderately used as they asserted, contrary to all Greek custom as their enemies said It had begun in Athens' chosen leadership of the Delian league in which a number of Greek states were bound together for common defense against a further Persian attack. They had taken an oath not to secede from this league; but a few did—some of the larger ones nho were also geographically safer from Persian menaces—and Athens, followed by the rest, reduced them to subjection. One or two others, originally outside, were forced in. Most of the states contributed money for the league. the amount from each being decided by Athens (moderately enough); the common treasury mas transferred to Athens and Athenian officers controlled it. Athens encouraged. and sometimes imposed, the adoption of its onn kind of democracy in recalcitrant cities and made, sensibly enough. or tried to make, its own excellent coinage common for all in the league, to the great advantage of trade. By arranging that delegates conveying the tribute should come there for the most important of the dramatic festivals. and in other ways. Athenians encouraged all to look upon their city as a religious and intellectual centre (the latter it had already, by its own radiant genius, become'). All this attempt at unity under one leadership nas new in Greece and dangerous, both to the influence of Sparta and to Greek political institutions; and Thucydides makes this clear, and why general opinion in Greece favoured the Peloponnesian cause. But he also makes clear that Athenian rule was no "empire" in any ordinary sense (Persian, Roman or modern)—not only were there no "provinces" with Athenian governors to administer them, because each state was individually attached to Athens, but free institutions in them survived and were active, and indeed the commons in most were favourable to Athens, or at least preferred its rule to the risk of seeing their own richer classes put in power by Sparta.

Character Studies of the Leading Participants.—There was another aspect of the conflict which interested Thucydides and which he emphasizes: it was also between the ever-active, innovating, revolutionary, disturbing Athenians and the slower-moving, more cautious Peloponnesians, especially the Spartans. "not excited by success nor despairing in misfortune)" but quietly self-confident. This was a conflict between two types of character; but also it in some degree crossed the conflict between states. Thucydides was not much concerned with individuals, rather with the actions and sufferings, the characters of states ("the Athenians," "the Syracusans," etc.); but he understood the significance of personalities. and besides making clear by their words and deeds the characters of some who influenced events, as Cleon the harsh demagogue of Athens and Hermocrates the would-be moderate leader in Syracuse, the brave Nicostratus and the incompetent Alcidas, he goes out of his way to make clear the characters and influence of four men: Themistocles (in a digression, the Athenian hero of the second Persian War), Pericles. Brasidas and Alcibiades (*qq.v.*). All four of them were of the active. revolutionary type—Pericles indeed was unique for Thucydides in that he combined caution and moderation in action, and great stability of character with a daring imagination and intellect; but he was a leader of the new age. During the war each of them.—Pericles and Alcibiades in Athens. Brasidas in Sparta,—was in conflict with a conservative. quietist opposition; and one expression of this in Thucydides deserves especial notice. Pericles, trying to restore the confidence of the Athenians struck down with the pestilence: told them that risk and labour were unavoidable by an imperial city—"quietism" was only for those who sought security in servitude—and that ex-en in defeat they would leave behind an imperishable name. Nicias the cautious, on the other hand; is described as believing that he could save his name by taking no risks and that to make peace meant to take no risk. In Sparta it was the wise and strong King Archidamus who led at first the cautious and conservative side, Brasidas the other; and Brasidas had his enemies at home. The conflict between the revolutionary and the conservative thus ran across that between the (on the whole) daring Athenians and the (on the whole) cautious Peloponnesians; and it is a great loss that Thucydides did not live to write the story of the last years of the war when Lysander (*q.v.*); the other great revolutionary Spartan. played a larger part than any other single man in the defeat of .Athens. This defeat was in one aspect the defeat of intellectual brilliance and daring by "stupidity" and stability of character (this last the quality most lacking in Alcibiades, the most brilliant Athenian of the second half of the war); but it was largely brought about by the two Spartans who rivaled Athenians in daring and intellect.

Study of the Technical Aspects of the War.—There is another aspect of the war in which Thucydides was much interested—the technical. One problem was the limitations of normal Greek heavy-armed land fighting. conducted mainly by peasant farmers who could not long be away from their fields or the harvest would be ruined, against other peasant farmers who must defend their fields to prevent a destruction of the crops which might mean near starvation. There was the special case of Sparta. which was free of these limitations because it had helots for its agriculture; the citizens also had time for harder training and for longer warfare. A quite different case was that of Athens. which could if necessary bring all the population behind walls. sacrificing the highly developed fields and farms of Attica. Athens could import all the food needed. because it was powerful at sea and rich enough by silver mines, manufacture and trade and by accumulated capital to pay for the import. Other problems concerned the difiiculties and possibilities of war between an all-powerful land force (Sparta and its allies) and an all-powerful navy; many of these were peculiar to the conditions of Greece and the Mediterranean at that time, but some endured to modern times. Thucydides studied the details of siege warfare; the difficulties of the heavy-armed in mountain country or of the Greeks fighting the fierce but unruly barbarians of the north; an army trying to force a landing from ships against troops on shore; the one great night battle, at Syracuse; the skill and the daring maneuvers of the Athenian sailor and the way these were overcome by the Syracusans; the unexpected recovery of the Athenian fleet after the Sicilian disaster. In all these aspects of the war he took a keen professional interest.

This is too the reason why in Thucydides' introductory pages on the early history of Greece he lays so much stress on the development of sea trading and naval power and on the accumulation of capital resources: they help to explain the great war between a land power and a sea power.

Thucydides' **Style.**—Thucydides himself of course was an intellectual of the Athenian kind; markedly individualist as he was, his whole style shows the man brought up in the company of Sophocles and Euripides, with Anaxagoras, Socrates and the contemporary sophists.

Of this style something should be said here and the analysis given by R. C. Jebb in the previous article on THUCYDIDES. in the ninth edition of the *Encyclopaedia Britannica,* cannot be bettered. Jebb begins by contrasting the styles of Antiphon (*q.v.*), said, very improbably, to have been Thucydides' master, and of Thucydides himself:

"Antiphon wrote for hearers, Thucydides for readers; the latter, consequently, can use a degree of condensation and a freedom in the arrangement of words which would hardly have been possible for the iormer. Again, the thought of Thucydides is often more complex than any which Antiphon undertook to interpret; and the greater intricacy oi the historian's style exhibits the endeavour to express each thought. Few things in the history of literary prose are more interesting than to watch that vigorous mind in its struggle to mould a language of magnificent but immature capabilities. The obscurity with which Thucydides has sometimes been reproached often arises irom the very clearness with which a complex idea is present to his mind, and his strenuous effort to present it in its entirety. He never sacrifices thought to language, but he will sometimes sacrifice language to thought. A student of Thucydides may always be consoled by the reflexion that he is not engaged in unravelling a mere rhetorical tangle. Every light on the sense will be a light on the words; and when, as is not seldom the case, Thucydides comes victoriously out of this struggle of thought and language, having achieved perfect expression oi his meaning in a sufficiently lucid form, then his style rises to an intellectual brilliancy—thoroughly manly, and also penetrated with intense feeling—which nothing in Greek prose literature surpasses."

Method, Aims and Authority as an Historian.— Ina prefatory note near the beginning of the *History* Thucydides speaks a little of the nature and difficulties of his task and of his aims. It was difficult, he says, to get at the truth both of the speeches made, whether he heard them himself or got the report from others. and of the actions of the war. For the latter, both for those at which he had been present and for the others, he made as thorough an enquiry as he could—for eyewitnesses did not always say the same things. either from faulty memory or from bias. For the speeches, he says, in order to meet the difficulties, he had written out in his own words what was appropriate to the occasion, keeping as closely as possible to the general sense of what had actually been said. He could not do without speeches, for it is through them that he explains the motives and ambitions whether of leading men or of states; and this, the study of the human mind in time of war, is one of his principal aims. (The omission of speeches from the last book is a great loss and is due, no doubt, to the difficulty he had in getting information about Athens at this period.) They are reported in direct speech though in Thucydides' own words. in his own unique style, partly because he must not pretend that they were exact reports, partly because long passages in indirect speech would be scarcely tolerable and no more "authentic." He avoided, he says, all "storytelling" (this is his one criticism of Herodotus), and his work might be the less attractive in consequence; "but I have written not for immediate applause but for posterity, and I shall be content if the future student of these events, or of other similar events which are likely in human nature to occur in after ages, finds my narrative of them useful." This is all that he expressly tells us of his aim and methods, Moreover in the course of his narrative (except for the pestilence of 430 and his command in 424) he nowhere gives his authority for a statement: neither which speeches he had heard nor the other campaigns he had taken part in, nor what places he had visited, nor what persons he consulted. He insisted, as Gilbert Murray said, in doing all the work himself; and he gives us, for the parts he completed, the finished structure, not the plans and the consultations as well, not the "scaffolding."

His authority is hardly equaled by that of any other historian. He kept to a strict chronological scheme, and where it can be accurately tested, *e.g.,* by the eclipses that he mentions, it fits closely. There are also a fair number of contemporary documents recorded on stone which almost all confirm his account in general and in detail There is the silent testimony of the three historians who began where he left off, not attempting, in spite of much independence of opinion, to revise what he had already done, not even the last book which he clearly did not complete (it is here that occurs the one serious divergence from him in a later writer—Aristotle; *see* below). Another historian, Philistus (*q.v.*), a Syracusan who uas in Syracuse as a boy during the Athenian siege, had, it seems, in his *History of Sicily,* little to alter or to add to Thucydides. Above all there are the contemporary political comedies of Aristophanes (the production dates of which are fortunately known): Aristophanes (*q.v.*) was about 15 years younger than Thucydides and a man of as different a temper and writing with as difierent a purpose as could well be. but his comedy remarkably reinforces the reliability of the historian's serious picture of Athens at war, and as well supplies much to this picture of a kind which Thucydides deliberately did not give. The modern historian of this war is in much the same position as the ancient: he cannot do much more than translate, abridge or enlarge upon Thucydides.

For he kept rigidly to his theme, the history of a war, that is, a story of battles and sieges, and of a truce or a peace and alliance hastily made and soon broken, but also, more important, of the behaviour of peoples as the war lasted longer and longer, and of the inevitable "corrosion of the human spirit." He has vivid narrative of exciting episodes and careful descriptions of tactics on land and sea. He gives a picture, direct in speeches, indirect in the narrative, of the ambitious imperialism of Athens—controlled ambition in Pericles, reckless in Alcibiades, debased in Cleon—ever confident that nothing was impossible for them, resilient after the worst disaster; and the opposing picture of the slow steadiness of Sparta, sometimes so successful, at others so accommodating to the enemy. The speech he records of Pericles on those killed in the first year of the war is the most glowing account of Athens and its democracy as its leading citizen hoped it might prove itself. It is followed (in of course due chronological order) by a minutely accurate account of the symptoms of the pestilence ("so that it may be recognised by medical men if it recurs") and a moving description of the demoralizing despair which took men after so much suffering and such heavy losses—probably more than a quarter of the population, most of it crowded within the walls, died. Equally moving is the account of the last battles in Syracuse harbour, and of the Athenian retreat. In one of his best-known passages he analyzes by a most careful choice of words, almost creating the necessary language as he writes, the effects, moral as well as political, of civil strife within a state in time of war. By a different method, in speeches, he portrays the hard fate of Plataea due to the long-embittered envy and cruelty of Thebes and the faithlessness of Sparta, the harsh brutality of Cleon against Mytilene and the cynicism of the Athenians at Melos 12 years later, when the premises that it is in human nature for the strong to dominate the weak, and that Athens must for its safety control all islands, are used to justify any aggression and a demand for immediate submission, and slaughter if submission is not immediate. Occasionally he is forced into personal comment, as on the pathetic fate of the virtuous and much liked Nicias.

He had the strongest feelings, as a man, as a citizen of Athens whose part was the largest in the tragedy that he recorded, above all in his passion for the truth as he saw it, which not only kept him free from vulgar partiality against the enemy, whether state or party. but served him as a historian in the accurate narrative of events, accurate not only in their detail and their order, but in their relative importance — he does not for example exaggerate the importance of the campaign in which he was himself in command. That is why he offers no self-defense for his failure. (Characteristically he mentions his exile not in its order as an event of the war, but in his "second preface" — after the peace of 421 — to explain his opportunities of wider contacts.)

Subsequent Fame. — 'The story of his later fame is a curious one. It has been mentioned above that in the two generations after his death three historians began their work where he had left off; but apart from this silent tribute and late stories, credible enough, of his great influence on the orator Demosthenes (*q.v.*), Thucydides is nowhere referred to in surviving 4th-century literature! not even in Aristotle, who, in his *Constitution* of Athens, gives a narrative of the revolution in Athens in 411 that diverges in many ways from that of Thucydides. It was not till the end of the 4th century that Theophrastus coupled him with Herodotus as a founder of history properly so-called. We know little of what the scholars of Alexandria and Pergamon did for his book; but copies of it were being made in considerable numbers in Egypt, and so doubtless more elsewhere, from the 1st to the 5th centuries A.D. Suffice it to say, that by the 1st century B.C. as is clear from the writings of Cicero and Dionysius (who vainly disputed his preeminence), Thucydides was established as the great historian, and from that time onward his fame has been secure wherever he has been known.

THUGS, or THAGS, a well-organized confederacy of professional assassins, who traveled in gangs through India. wormed themselves into the confidence of wayfarers and, when a favourable opportunity occurred, strangled them by throwing a handkerchief or noose round their necks and then plundered and buried them (Sanskrit *sthag,* "to conceal,'! hence sthaga, "a cheat," in modern vernaculars *thag*). A11 this was done according to certain ancient and rigidly prescribed forms and after the performance of special religious rites, in which the consecration of the pickax and the sacrifice of sugar formed a prominent part. From their using the noose they were also frequently called *phansigars,* or "noose operators." Though they themselves traced their origin to seven Mohammedan tribes, Hindus appear to have been associated with them at an early period; at any rate) their religious creed and practices as staunch worshipers of Kali (Devi, Durga), the Hindu goddess of destruction, had certainly no flavour of Islam. The fraternity possessed a jargon of their own (*Ramasi*), and signs by which its members recognized each other.

Though sporadic efforts were made toward the extinction of the gangs, it was not till Lord William Bentinck took vigorous steps (1828–35) that the system was seriously attacked. His chief agent, Captain (afterward Sir William) Sleeman, with the cooperation of a number of native states, succeeded so well in grappling with the evil that between 1831 and 1837 no fewer than 3,266 thugs had been committed, of whom 412 were hanged, 483 admitted as approvers and the remainder transported or imprisoned for life.

According to the *Thuggee* and Dacoity Report for 1879, registered Punjabi and Hindustani thugs then still numbered 344; but all of these had already been registered as such before 1852, and the whole fraternity thereafter became extinct.

THUGUT, JOHANN AMADEUS FRANCIS DE PAULA, BARON (1736–1818), Austrian diplomatist, was born at Linz on May 24, 1736. In 1769 he was appointed charge d'affaires at Constantinople, and in that capacity secured a grant of money and a promise of the territory of Little Wallachia from the Turks during the negotiations connected with the first partition of Poland. (See POLAND: Histovy.) In 1771 he was ennobled and appointed internuncio at Constantinople and was actively engaged, under the direction of Prince Kaunitz. in all the diplomacy of Austria in Turkey and Poland until he secured the cession of the Bukovina on May 7, 1775.

After 1775 Thugut traveled in France and Italy, partly on diplomatic service. In 1778 he acted as intermediary in Maria Theresa's negotiations with Frederick the Great. In 1780 he was Austrian envoy in Warsaw. but in 1783 applied for leave and spent four years in Paris, where he invested his savings and became acquainted with many of the leaders in the Revolution. From 1787 to 1789 he was minister at Naples. In 1790 he was sent by the emperor Joseph II to Bucharest, nominally as commissioner with the hospodar of Wallachia, but in reality in order that he might open negotiations for peace with the Turks. In 1792 he was associate diplomatic agent at the headquarters of the allied army which invaded France: and was then appointed director of the foreign affairs of Austria (March 25, 1793), becoming chancellor in 1794 on the death of Kaunitz.

The selfish policy which Thugut followed (1793–1800) in Austria was bitterly resented by Austria's allies, and although Thugut probably thought that he was only doing his duty, he committed many acts which were more than dubious. After the defeats of Austria in Italy in 1796–97 and the peace of Campo Formio, it became a fixed object with the French, and with a growing party in Austria who held him responsible for the disasters of the war. to secure Thugut's removal. The battle of Hohenlinden (Dec. 3, 1800) made his position untenable. so retiring from public life he left Vienna for Pressburg. He later returned to Vienna where he died on May 28, 1818.

THULE, Greek and Roman name for the most northerly land in the world. Pytheas (c. 300 B.C.), according to Polybius' account of his voyage, reached it after six days' sail from Britain; it was inhabited, but corn grew there sparingly and ripened ill; in summer the nights were long and bright. The few surviving fragments of his works do not determine where his Thule was. Scholars at various times have believed it to be the Shetlands, Iceland, or some section of the Norwegian coastline.

Agricola's fleet in A.D. 84 sailing up the east coast of Scotland is said to have espied but not to have reached Thule (dispecta est Thule) but the phrase is merely literary. The actual point meant may be the Orkneys or the Shetlands, or even some fragment of Scotland seen across the water. In some later wrtiers (Procopius, etc.) Thule seems sometimes used to denote Scandinavia. The phrase "ultima Thule" is commonly used to describe the farthest limit possible.

THULIUM (symbol Tm, atomic number 69, atomic weight 168.94. one stable isotope. Tm^{169}), a very rare metallic element belonging to the rare earth group. It was discovered by P. T. Cleve in 1879 while examining crude erbium oxide. The name is derived from Thule. Latin for the northernmost part of the inhabitable world; whence the phrase "ultima Thule" meaning a remote goal or end. It was first obtained in a fairly pure compound by C. James in 1911 by the fractional crystallization of its impure bromate; this separation involved more than 15,000 operations. Thulium occurs in very small amounts along with its commoner associates in the minerals gadolinite, euxenite, xenotime, etc. The oxide (Tm_2O_3) has a greenish-white colour. Salts of thulium possess a pale green colour and the solutions show strong characteristic absorption spectra. In 1946 there was some doubt as to whether the salts of this element had ever been prepared in the pure iorm since the atomic neight as determined by a mass spectrograph gave a value of 168.95 nhile the best chemical value was 169.4. The chemical methods would be influenced by the presence of other rare earths and this difference seems to indicate that some of the other rare earths must have been present.

Thulium can be separated fairly rapidly from the other rare earths by ion-exchange methods. The metal is produced by reducing the anhydrous fluoride with calcium. It has a melting point between 1,550° and 1,650° C. and boils at about 1,800° C. The X-rav densitv is 9.372 grams per cubic centimetre. It crystallizes in the hexagonal close-packed system with $a = 3.533$ and $c = 5.551$. It has an appreciable vapour pressure at the melting point.

When thulium is irradiated in a nuclear reactor, Tm^{170} with a 129-day hali life is formed. This isotope strongly emits an 84 Kev X-ray, and is very useful in making small portable X-ray units for medical use. No electrical equipment is required and the units only have to be recharged with a reactivated thulium button every few months. (See RAKE EARTHS.) (F. H. SP.)

THUN, a town in the Swiss canton of Bern. on the banks of the Aare, just as it issues from the Lake of Thun. and by rail 19 mi. S.E. of Berne. Its population in 1960 was 29.034, mostly German-speaking and Protestants. From 1798 to 1502 Thun mas the capital of the canton Oberland of the Helvetic republic. It is now the capital of the Rernese Oberland.

THUN, LAKE OF, in the Swiss canton of Bern. the second lake (the first being that of Brienz) into which the river Xare (*q.v.*) expands. These two lakes occupy an ancient terminal basin of a glacier and are separated by a lacustrine delta on which Interlaken stands. Lake Thun (with the town of Thun at its north-western end) is 11½ mi. long. 2 mi. wide. its maximum depth is 712 ft., while its area is 18½ sq.mi., and its altitude 1.831 ft.

THUNDER, the noise that accompanies lightning (*q.v.*). The electrical discharge causes sudden heating and therefore expansion of the air along the lightning channel. This is followed by sudden cooling and contraction, thereby creating air vibrations similar to those caused by an explosion. Thunder is characterized by its prolonged duration and undulating intensity. Since every point along the lightning path represents an individual sound source and the various points are at different distances from the observer, the arrival time and loudness of the sounds produced vary. Intensity fluctuations are also caused by interference of the sound waves, but not by echoes from clouds, because clouds absorb, rather than reflect. sound, Most of the thunder energy lies in the subaudible frequency range; it often makes houses vibrate and windows and dishes rattle. Because of the great difference in speed between light and sound, lightning apparently precedes thunder by roughly five seconds for every mile separating the nearest lightning point from the observer. See ELECTRICITY, ATMOSPHERIC; METEOROLOGY; THUNDERSTORM. (Hs. H. S.)

THUNDERSTORM. A thunderstorm is a large cumulus cloud in which localized centres of electric charge have developed. Lightning, and the accompanying thunder from which the storm derives its name, represents a spark discharge between these centres, or between one of them and the ground. So universal is the development of charge centres in large intense cumulus clouds that the term "thunderhead" is used to describe a large cumulus even though the physical processes which lead to the development of the convective cloud may be only indirectly related to the processes which bring about the lightning and thunder.

Thunderstorms are sometimes referred to as "weather factories" because they are accompanied by a wide variety of weather elements such as hail, showery rain, strong and gusty winds and sudden temperature changes at the earth's surface. The violence of the weather accompanying thunderstorms is indicative of the strong vertical air currents and the complex physical processes operating within them.

Cumulus clouds are manifestations of convective overturning in the atmosphere; *i.e.,* a cumulus cloud represents an air parcel which is rising through its environment because it is warmer and more buoyant than other air parcels at the same levels. In principle, this overturning is similar to that in any thermally unstable fluid. When the atmosphere becomes sufficiently unstable, convective overturning is locally severe enough to cause thunderstorm development.

Thunderstorm Structure and Circulation.— The average thunderstorm consists of three to five convective cells, each of which undergoes a life cycle characterized by changes in the direction and magnitude of the strong nearly vertical air currents. Three stages in this life cycle are recognized. In the initial stage, the cell contains strong upn-3rd-moving air currents which extend from below the cloud base to the cloud top. The updrafts may reach speeds of seven to ten metres per second. If the air is sufficiently unstable, there will be a continual supply of energy for the updraft and the cell will continue to develop in size and intensity. With increase in size comes an increase in total cloud water content. About 15 to 20 minutes after the establishment of an active updraft, precipitation particles will have grown to a size where they become of importance both in the further development of the cell and in the formation of the charge centres. The precipitation usually will be in the form of snow and snow pellets in the upper parts of the cell (colder than about – j° C.) and raindrops in the lower, warmer regions of the cell. At this time the cell passes into the mature stage of development.

In the mature stage of development, both upward- and downward-moving air currents are present within the cell. The updraft of the cumulus stage gives way to downdraft as the size and number of precipitation particles increase. This reversal of the updraft is also aided by evaporational cooling which occurs as clear air from outside the cloud is mixed into the cloud by the turbulent motions. At first, the downdraft is small and located on one side of the updraft. Gradually, however, it works its way across the cell and squeezes off the updraft, at which time the cell goes into the final or dissipating stage.

It is with cells in the early mature stage that thunderstorms reach their greatest violence. Updraft speeds are usually 10 to 15 m. per second, but may occasionally reach values as high as 35 m. per second. Downdrafts may be as strong as 1j m. per second. At the ground, the onset of heavy rain marks the beginning of the mature stage. The downdraft, which coincides closely with the rain area, reaches the surface a few minutes after the first rain. Because of the continued evaporation, air in the downdraft is cold. which fact accounts for its great downward speed. As the downdraft nears the ground, it is diverted and spreads outward in all directions as a cold gusty wind blowing from the rain area. Even in arid regions where the rain may completely evaporate before reaching the ground, the cold downdraft spreading over the surface is a well-known signal of a nearby thunderstorm.

A thunderstorm cell in the dissipating stage is filled throughout by weak subsiding air and light precipitation. Rain at the earth's surface is much less intense than was the case during the mature stage. The cold outflow gradually subsides as a result of the waning downdraft.

The visual appearance of thunderstorms varies greatly from place to place and with kinds of storms. In arid regions, thunderstorms appear as giant towering cumulus clouds, standing in bold relief against the clear blue sky. Frequently in such regions one can see the uppermost parts of the cloud carried off by high winds to form what is known as an anvil top. In other more humid regions,' thunderstorms are frequently surrounded by smaller clouds which obscure the active parts of the storm to a ground observer. From an airplane, however, one can see the thunderstorm thrusting upward above the lower clouds.

The time duration of a thunderstorm is somewhat variable; however, observations show that the first two stages of development usually last about 1j to 20 minutes each. During these stages the visual cloud will frequently reach heights of 30,000 to 60,000 ft. (average about 40,000 ft.) and horizontal dimensions of several miles. The duration of a cell in the final stage varies over wide limits. Some storms end abruptly, whereas others may linger for several hours as a gentle rain from a large, formless cloud mass.

These differences result from differing conditions of the air masses in which the clouds form.

Thunderstorm Electricity.— Electrical charge centres become well established during the mature stage. In a typical thunderstorm. the charge structure will consist of an upper positive charge centre locnted in the regions where the temperature is approximately $-10°$ to $-20°$ C. and a lower negative charge centre in the vicinity of the freezing level. A second positive centre in the rain area at the base of the cloud is occasionally observed. Typical values for the charges in the upper positive and lower negative centres are 20 to 30 coulombs. The lower negative centre is thought to be fairly compact (estimates of a one kilometre radius sphere have been offered) whereas the upper positive centre may consist of a central region of compacted charge surrounded by a large region of diffuse charge.

Lightning is a crash discharge between the upper positive centre and the lower negative centre or between one of these and the ground. Occasionally one also observes a lightning flash from one of the centres into the clear air around or above the cloud. The first electrical discharges usually take place entirely within the cloud between the two main charge centres. These discharges will be rather small at first and will increase in magnitude as the storm continues to develop. Evidence indicates that the great majority and possibly all of these lightning strokes transport negative electricity from the cloud to the ground. The charge transferred by a lightning flash ranges from 5 to 200 coulombs (averaging about 25). Each lightning flash usually consists of several strokes in rapid sequence with time separations of a few hundredths of a second. Each stroke follows the ionized path of the preceding one.

The sound of thunder originates in a compression wave formed along the highly heated path of the lightning stroke. Each portion of the path of a lightning stroke sends out intense sound waves which travel different paths to the observer. Since sound travels at the rate of approximately 330 m. per second, and since the strokes may be several kilometres in length. the thunder is usually hesrd :ts a drawn-out rumbling. having character and time duration depending upon the length and shape of the flash and upon its distance from the observer. Under ordinary atmospheric conditions. thunder cannot be heard at distances greater than 1j to 20 km.. although under some conditions of temperature inversion (temperatures increasing with height as opposing the normal decrease of temperature with height) it may be heard at a distance of 40 km. Since light travels at a very great speed, and the sound of thunder travels at a speed of about 1,000 ft. per second, one can estimate the distance to a thunderstorm by timing the interval between the sighted lightning flash and the sound of the thunder. The time in seconds equals the distance in thousands of feet.

Answers to questions as to how a storm generates electrical charge and separates this charge into two major centres continued to elude scientists throughout the early 1950s. By 1957 there were two schools of thought on this problem. One group of scientists believed that electric charges are generated in some manner by the coexistence of liquid and solid phases of water (snow and rain) within the upper parts of the cloud. A second group suggested that the primary source of the charge generation is with ions which are continually being formed in the atmosphere by cosmic radiations and radioactive disintegrations from materials at the earth's surface. Both groups believed that the charges, once generated, could be separated into two centres by the falling precipitation. Experiment indicated that in the upper parts of the cloud the particles (mostly snow and ice crystalsj are predominately positively charged; near and below the freezing level the particles (mostly rain) are predominately negatively charged. In the middle regions charges of both signs are intermingled.

Thunderstorm **Formation.**—A deep layer of moist air and a vertical temperature distribution favourable for the development of intense local overturning are essential for thunderstorm development. One of the tools used by meteorologists to determine the possibilities for thunderstorms is a plot of air temperature as a function of height above the earth's surface. The rate of decrease of temperature with height is known as the lapse rate. In general, steep lapse rates (rapid decrease of temperature with height) are most favourable for thunderstorms since it is under these conditions that an air parcel made warmer than its environment is capable of rising through the atmosphere because of buoyancy forces. After any given parcel of air is lifted to the point of condensation at the cloud base, the released latent heat of condensation will be added to the parcel. This will assist further ascent. In the upper parts of the thundercloud! where snow and ice crystals are found, the latent heat of fusion will also contribute to sustaining the updraft currents.

Thunderstorms can be classified according to factors that contribute to the development of steep lapse rate with resultant convection. Five important classes are given:

1. Heating of air by contact with warm surfaces. (a) When the surface of the ground is warmed by radiation from the sun, water vapour may be carried up by convection currents to a level at which condensation occurs. With favourable lapse rates of temperature in the air above this level, thunderstorms may develop. A special case of this class is the heating of mountain slopes at high levels, which frequently contributes to the development of thunderstorms near the summits. (*b*) When air flows over warmer ground or warmer water, the air may become warmed sufficiently from below for convection and possibly thunderstorms to occur.

2. Lifting of warm air over cold currents. If a current of cold air meets a current of warm air, the warmer air, being lighter, is forced upward either by cold air underrunning warm air or by warm air overrunning cold air. Clouds form in the rising warm air; and if conditions are favourable, tower upward to form thunderstorms.

3. Converging air flow within warm air currents. A converging flow may force warm air up to its condensation level, releasing convection.

4. Interaction of cold and warm air currents at different levels. The underrunning of cold air by warm air may initiate convection. Similarly, overrunning of warm air by colder air as well as combinations of these factors may be effective in releasing convective overturning and thunderstorms.

5. Lifting of air by movement upslope from lower to higher ground. Movement of air against a mountain range or other upslope surface may lift air to its condensation level and initiate convection.

The Distribution **of** Thunderstorms.— A substantial fraction of the thunderstorms over the world form because of surface heating by sun's radiation (class 1*a*) often combined with special convergence effects (class 3). Summer thunderstorms over humid continents and over mountain regions in the temperate latitudes and the almost daily storms of large regions of the tropics are of this type. These storms show a well-marked diurnal variation; they develop generally during the afternoon. Storms of class 1*b* are characteristic of the rear of barometric depressions occurring over the sea in winter especially just off the east coasts of the large continents where cold air may pass over comparatively warm water.

The "frontal" storms of class 2 are found in middle latitudes. They are associated with line squalls (squall lines) and "warm front" precipitation in extratropical cyclones.

Storms of classes 3 and 4 frequently occur in advance of "cold fronts" or troughs of low pressure in the temperate zone and tend to occur more frequently at night than during the day.

Storms of class 5 occur especially on windward mountain slopes in middle latitudes.

Thunderstorms have been known to occur in almost every part of the world; however, they are rare in the polar regions and infrequent poleward of latitude 50° N. and 50° S. According to a study by C. E. P. Brooks, the places of maximum thunderstorm activity in the world are Java (22j days per year). central Africa (150), Panamá (135), southern Mexico (142) and central Brazil (106). In the United States the areas of maximum activity are the Florida peninsula and the coast of the Gulf of Mexico (70–80) and the mountains of New Mexico (50–60). Central Europe and Asia average less than 20 thunderstorm days per year. Brooks estimated that at any one moment there are about 1,800 thunderstorms in progress throughout the world.

Thunderstorms and Severe Weather.— Thunderstorms are associated with many kinds of severe weather phenomenon. Squall lines are lines of thunderstorms mhich sweep across the surface as a single unit. Usually associated with advancing cold fronts, squall lines are well known for their regions of high wind, heavy rain and hail. Tornadoes are another type of severe weather associated with thunderstorms although the exact details of this association are not known.

Thunderstorms also play a key role in tropical hurricanes. It is well known that hurricanes, when viewed by radar, are characterized by lines of convective storms which spiral inward toward the eye of the hurricane. It is likely that the thunderstorm plays a major role in the vertical circulation of the hurricane.

Because of the turbulence which accompanies the updrafts and downdrafts, thunderstorms are regarded as hazards to airplane flight. Pilots are unanimous in their opinion that light planes should not be flown into thunderstorms. Military and commercial planes of the types flown in the late 1950s were sufficiently sturdy and well enough instrumented to permit a flight through a thunderstorm with little more danger than passenger discomfort.

THÜNEN, JOHANN HEINRICH VON (1783–1850), German agriculturalist, best known for a pioneering work on the effect of transportation costs on the location of production, was born in Jever on July 24, 1753. Vol. 1 of his *Der isolierte Staat*, containing the important theoretical contribution, appeared in 1826, and later volumes presented Thunen's own agricultural accounts in support of his theory. Thunen imagined an isolated city, set in the middle of a level and uniformly fertile plain without navigable waterways and bounded by a wilderness. His analysis showed how agricultural products would be grown in zones forming concentric rings around the city. Heavy products. in proportion to value, and perishables would be produced close to the town; lighter and durable goods would be produced on the periphery. As transport costs to the city increased with distance, the returns to the land would diminish. At a certain distance from the city, land rent would become zero. The exact distance would be a function of price relationships. Moreover, if land rents vary, then the methods of cultivation will vary, with land being used less intensively as it becomes less valuable. Subsequent writers often built upon Thunen's model, although his simplifying assumptions eliminated many of the most critical problems. Thunen died in Tellow, Sept. 22, 1850. (J. P. CA.)

THURBER, JAMES GROVER (1894–1961). writer and artist, considered by many the best American humourist since Mark Twain, was born in Columbus. O., Dec. 8. 1594. and educated at its public schools and at Ohio State university. Columbus. He was a newspaper reporter in Columbus, in Paris. France, and in New York city before becoming associated with the *Sew Yorker* 3s 3 staff member (1927–33) and a leading contributor.

Seriously a writer and only incidentally a comic artist. Thurber produced both writings and drawings showing odd characters in astonishing situations, amusing aspects of the war between men and women, startling forays into the subconscious and fascinating dogs and other animals, real and imaginary.

His writings reveal a sensitive literary style and skill in many forms. *My Life and Hard Times* (1933) is a hilarious autobiography. "The Secret Life of Walter Mitty," his best-known short story, presents an unforgettable character in the meek, henpecked husband who in his daydreams is a fabulous hero. Thurber's fables blend delightful nonsense with much wisdom about humanity. A play, *The Male Animal* (1940), written with Elliott Nugent, is an effective plea for academic freedom as well as a gay comedy. While a keen satirical sense is shown in many essays, parodies and burlesques, a gentle humour pervades such fairy tales as *The 13 Clocks* (1950). *The Thurber Album* (1952) is an affectionate account of family and friends in the midwest. and *The Years With Ross* (1959) is a witty record of associates on the *New Yorker*. The best collection of the writings and drawings is *The Thurber Carnival* (1945). Thurber died in New York city on Nov. 2, 1961. (WM. B.)

THURET, GUSTAVE ADOLPHE (1817–1875), French botanist, noted for his work on the reproduction of algae, was born at Paris on May 23, 1517. He received a law degree in 1838 and then studied under algologist Joseph Decaisne. He traveled to Constantinople in 1840 as French attaché, and after returning to France. being a man of independent means, devoted himself entirely to science. Thuret's first paper (1840) detailed the discovery of flagella of spermatozoids in *Chma*. In 1844 Decaisne and Thuret announced the finding of spermatozoids in *Fucus*. The first accounts of fertilization and hybridization in *Fucus* mere given by Thuret (1854), and later (1867), jointly with Edouard Bornet, he determined the complicated life cycle of Florideae, a group of red algae. His *Études phycologiques*, a folio volume containing observations on and illustrations of marine algae, was published posthumously in 1878. Before 1857, Thuret spent much of his time studying algae on the Atlantic coast of France. In 1857 he moved to Antibes on the Riviera, where he established an outstanding botanic garden. Thuret died at Nice on May 20, 1875.

THURGAU, a canton of northeast Switzerland, bordered by the Lake of Constance and, for a short distance, by the Rhine below the lake. It is in contact with Schaffhausen and Zurich to the west and St. Gall to the south. Thurgau is divided into three well-wooded hill masses running northwest to southeast by the middle course of the river Thur (rising in the Toggenburg, *q.v.*) and by its affluent, the Murg.

The canton is a highly prosperous agricultural area, and though termed the "garden and granary of Helvetia" it also possesses an important cotton spinning, dyeing and printing industry. The population in 1960 was 166.420. Its capital is Frauenfeld on the Murg, pop. 14.702. Other towns are Arbon (11,608), Kreuzlingen (12.597) and Romanshorn (7,755).

History.— The Thurgau originally took in all the country, roughly speaking, between the Reuss, the Lake of Lucerne, the Rhine and the Lake of Constance; but many smaller districts (Ziirichgau, Toggenburg, Appenzell, St. Gall) were gradually carved out of it, and the county was reduced to about the size of the present canton when in 1264 it passed by the gift of the last count of Kyburg to his nephew Rudolph of Habsburg. chosen emperor in 1273. In 1460–61 it was seized by the confederates and henceforth it was ruled as a "subject district" by seven members of the League—Bern occupied in the west, not being admitted to a share in the government until 1712, after one of the mars of religion. In 1499 the confederation obtained from the emperor the supreme jurisdiction.

In 1798 it became free, and was one of the 19 cantons of the Helvetic republic, being formally received (like the other "subject lands") as a full member of the Swiss confederation in 1803 by the Act of Mediation. The very advanced Cantonal constitution dates to 1869.

THURIBLE, the ecclesiastical term for a censer, a portable vessel in which burning incense (*q.v.*) can be carried. The censer, to use the more general term, is a vessel which contains burning charcoal on which the aromatic substances to be burned are sprinkled. The early Jewish portable censer would seem to have been a bowl with a handle, resembling a ladle. A similar form was used by the ancient Egyptians long prior to the Jewish use. The Greek and Roman censers (*thumiaterion* and *turibulum* or *thuribulum*) are of quite different shape. They are small portable braziers (*foculi*) of bronze or sometimes of silver and of highly ornate design.

The censers or thuribles in Christian usage have been specially adapted to be swung, though many early specimens of heavy weight were obviously not meant to be used in this way.

THURII or THURIUM, Italy. a city of Magna Graecia on the Gulf of Tarentum, near the site of the older Sybaris (*q.v.*). It owed its origin to an attempt made in 452 B.C. by Sybarite exiles and their descendants to repeople their old home. The new settlement was crushed by Crotona, but the Athenians lent aid to the fugitives, and in 443 Pericles sent out to Thurii a mixed body of colonists from various parts of Greece. among whom were Herodotus and the orator Lysias. In 390 it was severely defeated by the Lucanians, and at length called in the help of the Romans against the Lucanians. and then in 282 against Tarentum. Thenceforward it was dependent, and in the Second Punic War it was depopulated and plundered by Hannibal (204). In 194 a Roman colony was founded, known for a time as Copiae, but afterwards as Thurii.

THURINGIA (Land THÜRINGEN), former German Land and Free state, after 1933 a Land of the German reich; it consisted of the former Thuringian states of Saxe-Weimar-Eisenach, Saxe-Meiningen, Reuss, Saxe-Altenburg, Saxe-Gotha (Coburg having been merged with Bavaria), Schwarzburg-Rudolstadt and Schwarzburg-Sondershausen. which decided in 1919 to combine into one state.

After World War II, Thuringia became a Land of the German Democratic Republic, but it was later (1952) divided into administrative districts including those of Erfurt, Suhl and Gera.

A considerable part of the country is occupied by the Thuringian forest. Among the chief elevations are the Beerberg (3,222 ft.), the Schneekopf (3,209 ft.) and the Inselsberg (3,005 ft.). The Altenburg district in East Thuringia is traversed by the westerly offshoots of the Erzgebirge, while the Rhon mountains extend into West Thuringia. The southeastern portion of Thuringia belongs to the bleak, mountainous region of the Frankenwald and the Vogtland. The principal river is the Saale, which runs in a northwesterly direction as far as Saalfeld. and then flows northeast by Rudolstadt and Jena. Among the other rivers are the Werra, Ilm, Gera, Unstrut, Elster, Weisse, Wipper, Helbe and Pleisse. The district watered by the Pleisse contains some of the richest agricultural soil in Germany. The chief mineral resources of Thuringia are lignite (found mainly in the Altenburg district), and potash in the valley of the Werra and in the Sondershausen district. Iron ore, marble, cobalt, copper, slates, chalk and basalt are also found; and there are salt works at Salzungen and Neusalza, and brine springs at Heinrichshall and elsewhere. Among the principal industrial products of Thuringia are textiles, glass and porcelain, iron goods and machinery, paper and leather goods, musical instruments, beer, chemicals, toys and optical instruments. In 1950 Thuringia had 2.837,641 inhabitants and an area of 6,022 sq.mi.

Leading cities include Weimar, the capital of the former Land, Gera, Jena, Gotha, Eisenach, Altenburg and Greiz.

History.— In the 5th century the Thuringians lived between the Harz mountains and the Thuringian forest. They were tributary to Attila the Hun. under whom they served at the battle of Châlons in 451. In the 6th century they n-ere conquered by the Franks and remained under the direct rule of the Frankish kings until 634. when King Dagobert I appointed Radulf duke of the Thuringians. under whom they became virtually independent. They were again brought under Frankish rule by Charles Martel, who abolished the office of duke and divided the country among Frankish counts. About 804 Charlemagne. in order to defend the line of the Saale against the Slavs. founded the Thuringian mark. In 849 King Louis the German recognized Tlakulf as duke and some of his successors bore the title of margrave until the death of Burkhard in 908, when the country was seized by Otto the Illustrious. duke of Saxony. Thuringia was retained by Otto's son and successor. Henry I the Fowler.

In the 11th century a new dominion was founded by Louis the Bearded. who by purchase. gift or marriage obtained several counties in Thuringia. These passed on his death in 1056 to his son Louis the Springer (d. 1123), who took part in the Saxon risings against the emperors Henry IV and Henry V. His son Louis was appointed landgrave of Thuringia in 1130 by the emperor Lothair II; by his marriage with Hedwig of Gudensberg in 1137 he obtained a large part of Hesse. Louis was succeeded in 1140 by his son Louis II the Hard. who married Judith, a sister of the emperor Frederick I, and on his behalf took a leading part in the opposition to his powerful neighbour Henry the Lion, duke of Saxony. In 1172 he was succeeded by his son Louis III the Pious. He acquired the Saxon palatinate in 1179, on the death of Adalbert, count of Somrnerschenburg, went to Italy to assist Frederick I in 1157, joined in the war against Henry the Lion in 1180, and distinguished himself at the siege of Acre in the Third Crusade. on the return from which he died at Cyprus in 1190. He was succeeded by his brother Hermann I. during whose reign Thuringia suffered greatly from the war between Philip duke of Swabia and Otto of Brunswick. The next landgrave (1217–27) was his son Louis IV, a celebrated figure in medieval German literature, who married St. Elizabeth. daughter of Andrew II, king of Hungary, and died at Otranto while accompanying the emperor Frederick II on crusade. The next ruler was Henry Raspe, who made himself regent on behalf of his nephew Hermann II from 1227 to 1238 and in 1241 succeeded his former ward as landgrave.

After a disputed succession to the landgraviate it fell in 1263, together with the Saxon palatinate, to Henry III margrave of Meissen. Two years later Henry apportioned Thuringia to his son Albert the Degenerate, who sold it in 1293 to the German king Adolph of Xassau for 12,000 marks of silver. Albert's sons Frederick the Undaunted and Dietrich contested this transaction, and the attempts of Adolph and his successor Albert I to enforce it led to the infliction of great hardships upon the Thuringians. Frederick defeated Albert decisively and in 1314 was formally invested with Thuringia by the emperor Henry VII. His son Frederick II the Crave (1323–49) consolidated the power of his dynasty against rebellious vassals and the neighbouring counts of Weimar and Schwarzburg. His son Frederick III the Strong (1349–81) and his grandson Balthasar (1381–1406) further extended their dominion by marriage and conquest, and the latter of these founded the university at Erfurt (1392). Balthasar's son. Frederick the Peaceful, became landgrave in 1406 but left the government largely to his father-in-law Günther, count of Schwarzburg. He died childless in 1440, and Thuringia then passed to the electoral dynasty of Saxony. After a joint rule by Frederick II and his brother William, the latter in 1445 became sole landgrave as William III and died without sons in 1482. In 148j his nephews and heirs Xlbert and Ernest made a division of their lands, and Thuringia was given to the Ernestine branch of the family of Wettin, with which its history down to 1918 is identified.

THURLES, a town of County Tipperary. Ire., lies on both banks of the Suir. 92 mi. S.W. of Dublin by road. Pop. (1961) 6,421. Originally called Durlas O'Fogarty, in 1174 it was the scene of the defeat of Strongbow by Roderick O'Connor and Donal O'Brien. A preceptory was founded there by the Knights Templars, who held a 13th-century castle. The Cistercian abbey of Holy Cross, founded by Donal O'Brien (1168–94), stands $3\frac{1}{2}$ mi. S.W. of the town. Thurles is the seat of the Roman Catholic archdiocese of Cashel. In the town, which is a marketing and distributing centre for a large agricultural area, is a large beet sugar factory.

THURLOE, JOHN (1616–1668), English politician, son of Thomas Thurloe, rector of Abbot's Roding in Essex, was baptized on June 12, 1616. He studied law, entered the service of Oliver St. John. through whose interest he was appointed a secretary to the parliamentary commissioners at Uxbridge in 1645; other employments followed. On March 29. 1652, he mas appointed secretary to the council of state. His duties included the control of the intelligence department and of the posts, and his perfect system of collecting information and success in discovering the plans of the enemies of the administration astonished his contemporaries. In the parliaments of 1654 and 16j6 he represented Ely; he was appointed a member of Cromwell's second council in 1657.

After Oliver's death Thurloe supported Richard Cromwell's succession, and took part in the administration. sitting in the parliament of Jan. 1659 as member for Cambridge university. Appointed secretary of state on Feb. 27, 1660. he appears to have steadily resisted the Restoration, and his promises of support to Hyde in April inspired little confidence. On May 1j, 1660, he was arrested on the charge of high treason, but was freed on June 29, subject to the obligation of attending the secretaries of state "for the service of the state whenever they should require." He subsequently wrote several papers on the subject of foreign affairs for Clarendon's information. He died on Feh. 21, 1668.

His extensive correspondence, the originals of which are in the Bodleian Library at Oxford and the British Museum (*Add. MSS.* 4156, 4157, 4158), is one of the chief sources of information for the prriod. A portion was published with a memoir by T. Birch in 1742, and other correspondence is printed in R. Vaughan's *Protectorate of Oliver Cromwell* (1836).

THURLOW, EDWARD THURLOW, 1ST BARON (1731–1806), was twice lord chancellor of England (1778–83; 1783–92). Though his tenure was a long one, he is remembered more for his oratory, his caustic wit and his bad temper than for his legal acumen. Thurlow was born at Bracon Ash, Norfolk. on Dec. 9, 1731, the first son of an Anglican clergyman of modest economic circumstances and no connections. After going down from Cambridge without a degree because of indolence and insubordination, traits he retained throughout his life, he was admitted to the Inner Temple in 1752 and called to the bar in 1754. His signal triumph over Fletcher Norton. in a case tried before Lord Mansfield in 1758, marked the turning point of his career. He precociously took silk in 1762. An impromptu argument in Kando's coffeehouse—whose barmaid was to become mother of his three daughters though not his wife—caused him to be retained in his greatest success as counsel in the case involving the heirship to the great Douglas estates. In 1765 he entered commons as a member lor Tamworth. There, his strong opposition to Wilkes was followed by his appointment as solicitor general in 1770. His speeches against jury trial in libel cases and his prosecution of the publishers and printers of the "Junius" letters brought him the attorney general's post in 1771. His oratorical capacities, well displayed in his venomous attacks on Lord Clive and the American colonies and his defense of the slave trade, caused his party to elevate him to the peerage and the woolsack. He ruled in the house of lords with an iron hand. A 'Tory by declaration, his sole guiding principle was expediency. which generally led him to support the will of King George III. a course which permitted him to retain his high post in such disparate ministries as those of North, Rockingham. Shelburne and Pitt. He died on Sept. 12, 1806 at Brighton. Thurlow had few friends and many enemies, the latter including the greatest politicians of his time: the younger Pitt, Charles James Fox and Edmund Burke. In law, his greatest claim on posterity derives from his sponsorship of John Scott, later Lord Eldon. Perhaps equally important mere his kindnesses to the poet George Crabbe and to Samuel Johnson. His portraits, painted by Reynolds, Romney and Lawrence, among others: reveal a swarthy complexion, harsh but regular features, sparkling dark eyes and a severe demeanor. But not even these masters could portray the voice which was his outstanding feature and the cornerstone of his career.

THURMAN, ALLEN GRANBERY (1813–1895), U.S. jurist and statesman, was horn at Lynchburg (Va.), on Nov. 13, 1813. In 1819 he removed with his parents to Chillicothe (O.), where he attended the local academy for two years, studied law in the office of his uncle, William Allen, and in 1835 was admitted to the bar, becoming his uncle's law partner. He began to take an active part in politics in 1844, and in 1845–47 was a Democratic representative in congress, where he advocated the Wilmot Proviso.

He was Democratic candidate for governor of Ohio in 1867, and was defeated by Rutherford B. Hayes by a majority of less than 3,000 votes; but the Democrats gained a majority in both branches of the state legislature. and Thurman was elected to the Cnited States senate. where he served from 1869 until 1881—during the 46th Congress (1879–81) as president *pro tempore.* Here he became the recognized Democratic leader and in 1879–81 was chairman of the judiciary committee. He introduced the Thurnian bill. for which he was chiefly responsible. which became law in May, 1878, and readjusted the Government's relations with the bond-aided Pacific railways.

Thurman was a member of the electoral commission of 1877, and was one of the American delegates to the international monetary conference at Paris in 1881. In 1876, 1880 and 1884 he was a candidate for the presidential nomination, and in 1888 was nominated for vice-president on the ticket with Grover Cleveland. but was defeated in the election. He died at Columbus (O.), on Dec. 12. 1895.

THURROCK, an urban district (1936) in the Thurrock parliamentary division of Essex. Eng.. lying along the north bank of the Thames. This area, mainly agricultural, was largely reclaimed from the marshes by the Dutch. who also used chalk from the Purfleet quarries in the embankment of the Thames in the 17th century. Area 63.4 sq.mi. Pop. (1061) 114,302.

Grays, 23 mi. E. of Charing Cross. London, by road, is the administrative centre. From being a fishing village it became a large river port for the hay and corn market and it mas further enlarged when the Tilbury docks ($2\frac{1}{2}$ mi. S.E.) were built. In 1906 an artificial beach of fine sand was made there.

Tilbury docks (*q.v.*) were constructed in 1884–86 on land that had been, until 1852, uninhnhited marsh. They were built by the East and \West India Dock company and are now owned by the Port of London authority. The original blockhouse at Tilbury, which was built by Henry VIII. was rebuilt in the 17th century. It was taken over by the ministry of works in 1949 and opened to the public in 1958. The fort has a gateway by Inigo Jones. It was at West Tilhury that Elizabeth I made her iamous speech to her troops in 1588 just after the defeat of the Armada. East Tilhury is built on the site of a 7th-century monastery. and the church, like many others in the district. dates from the 13th century.

At Mucking (Anglo-Saxon, "much pasture") is St. Clere's hall !formerly New Jenkins). dating from Elizabethan times: Ford place, at Stifford. rebuilt in 1655. has beautiful plaster ceilings. In 1381 Jack Straw. the revolutionary priest of Fobbing, led the peasants in revolt against the poll tax. and in the marshes nearby the last great prizefight with bare knuckles is said to have taken place. Orsett was once the seat of the bishops of London. Aveley is a residential area on rising ground and near the village is the mansion of Belhus in what is now a public park.

Thurrock's industries stretch along the 20 mi. of Thames-side. There are a paperboard mill. soap and margarine works at Purfleet; several cement works: timber yards at Grays; a shipbreaking yard: Tilbury docks with a passenger landing stage; a large shoe factory with its own technical college (1948) at East Tilbury; and, at the eastern end of the district, the Shell Haven oil refinery at Thames Haven and a refinery at Coryton for storing, blending and refining oil. The Wet Thurrock industrial estate along the river bank covers over 4 sq.mi. and special facilities and concessions are granted to occupiers.

THURSDAY ISLAND, an island belonging to Queensland, Austr.. about 22 mi. N.W. of Cape York in Torres strait. Area: $1\frac{1}{4}$ sq.mi. Pop. (1954) 2.062. The island was granted some self-government in 1939. Pearl fleets operate from Port Kennedy and pearls, mother-of-pearl and trochus shell and *bêche-de-mer* are main products.

THURSQ, a small burgh and seaport of Caithness, Scot.. at the mouth of the Thurso river. on Thurso bay, 20 mi. W.S.W. of John o'Groats by road. Pop. (1961) 8,038. It is the most northerly town on the mainland of Scotland. In Sir John square there is a statue of Sir John Sinclair (*q.v.*), who did much for the improvement of Scottish agriculture. The town hall contains a public library and museum. which possesses the geological and botanical specimens of the "Thurso baker," Robert Dick (1811–66), and a collection of northern birds. To the east is Thurso castle, and near it is Harold's tower, built over the grave of Earl Harold, once owner of half of Caithness and half of the Orkneys and Shetlands, who fell in battle with Earl Harold the Wicked at the end of the 12th century. About $\frac{3}{4}$ mi. W. stand the ruins of the bishop of Caithness' palace, destroyed by fire in 1222.

Thurso was the centre of the Norse power on the mainland when at its height under Thorfinn (1014), and afterward till the battle of Largs (1263). In 1330 the weights and measures of Thurso were adopted for all Scotland. Today its main industry is fishing, and it also has a market. At Dounreay (8 mi. W.) the second atomic power station in Great Britain was begun in 1954.

THURSTAN or TURSTIN (d. 1140), archbishop of York, was the son of a certain Anger, or Auger, prebendary of St. Paul's, London, and a brother of Audoen (d. 1139), bishop of Evreux. He himself was a prebendary of St. Paul's, and was also a clerk in the service of William II and then of Henry I, who secured his election as archbishop of York in Aug. 1114. He then entered upon the great controversy which occupied him during a large part of his subsequent life and made him for several years an exile from England. Archbishop Ralph of Canterbury refused to consecrate him unless he made a profession of obedience to the southern see; this Thurstan refused and asked the king for permission to go to Rome to consult Pope Paschal II. Henry I declined to allow him to make the journey, while Paschal declared against Archbishop Ralph. At the Council of Salisbury in 1116 the English king ordered Thurstan to submit, but instead he resigned his archbishopric. although this did not take effect. The new pope, Gelasius II, and also his successor, Calixtus II, espoused the cause of the stubborn archbishop, and in Oct. 1119, he was consecrated by Calixtus at Reims.

Enraged at this the king refused to allow Thurstan to enter England. and he remained for some time in the company of the pope. At length, however. his friends succeeded in reconciling him with Henry, and. after serving the king in Normandy, he was recalled to England. In 1138 he made a truce at Roxburgh between England and Scotland. and took active part in gathering together the army which defeated the Scots at the Battle of the Standard in Aug. 1138. Early in 1140 he entered the order of the Cluniacs at Pontefract where he died on Feb. 6. 1140. Thurstan displayed marked generosity toward the churches of his diocese during his bishopric and was also the founder of a number of religious houses.

See his life in the *Fasti eboracenses,* ed. J. Raine (1863).

THURSTONE, LOUIS LEON (1887–1955), U.S. psychologist who pioneered in the application of mathematical and statistical methods to psychological problems, was born in Chicago, Ill., May 29. 1887. After taking an engineering degree from Cornell university. Ithaca, N.Y.. he served as assistant to Thomas Edison and taught engineering at the University of Minnesota, Minneapolis. An interest in the mathematical relations between amount of practice and improvement in performance led him to The University of Chicago, where he received a Ph.D. in psychology and where he remained for most of his professional life thereafter. He died in Chapel Hill: N.C., Sept. 29, 19jj.

Most notable among Thurstone's accomplishments were improved methods of measuring intelligence and his development of multiple-factor analysis. The latter is widely used in research on the nature of human ability and for the practical purpose of constructing tests to measure different types of ability. His literary output was comparatively small. including a score or two of research papers and a few books and monographs. but these were so influential that he was one of the United States' most frequently quoted psycholopists. Thurstone's major books were *Vectors of the Mind* (193j) and *Multiple-Factor Analysis* (1947).

THYME. The genus *Thymus* (family Labiatae) comprises a number of fragrant aromatic undershrubs, with very small leaves and whorls of small purplish, nectar-bearing flowers in the axils of the leaves or at the ends of the branches. The common garden thyme, a native of the Mediterranean region, is T. *vulgaris;* the wild thyme of English banks is T. *serpyllum,* naturalized in eastern North America. Pot marjoram (*Origanum*) and sweet marjoram (*Majorana*) are also closely allied. All these plants, easily grown from seed or cuttings in ordinary garden soil, are useful culinary flavouring agents and are remarkable for their essential oil, from which thymol, a widely useful medicinal, is produced.

THYMELAEACEAE, a family of dicotyledonous plants, with about 43 genera and in excess of 700 species recognized. They are mostly shrubs or trees, rarely herbaceous, and representatives occur in most parts of the world, even in arctic regions. Large genera are *Gnidia,* with about 175 species, chiefly African, *Wikstroemia,* with 120 species, chiefly Indo-Malaysian, and *Pimelea,* chiefly Australian, with 100 species. The bast fibres of many species are very strong, and are extensively utilized in various parts of the world, and especially in Japan, for manufacturing thin tough writing paper. Some species of *Daphne* (*q.v.*) are cultivated for ornamental purposes. Eaglewood or agalloch, prized because of its pleasant odour, is the product of representatives of the genus *Aquilaria.* (E. D. ML.)

THYMUS. The thymus is a soft, flattened organ lying behind the breastbone. Its function is not well understood. It consists of two lobes of unequal size, which partly cover the trachea, the large vessels in the chest and the serous covering of the heart, the pericardium. As a food, the animal thymus is called the sweetbread or, more specifically, neck sweetbread, to differentiate it from the pancreas, the stomach sweetbread. During life, the thymus changes markedly in absolute and relative size. It is proportionately largest at birth, averaging about 12 g. or 0.42% of the total body weight. At the age of puberty the thymus reaches its absolute maximum size (about 37 g.). After puberty the organ gradually decreases in size (involutes) until, between age 60 and 70, the average weight is around six grams. Large individual deviations from these averages may occur. In addition to physiologic involution, a much more rapid so-called accidental involution may take place as a result of infection, poisoning or starvation.

Functions. — Although the thymus has the microscopic structure of a lymphatic organ and as such participates in the production of lymphocytes, many studies have seemed to show that the thymus is an endocrine organ. The fact that the thymus reaches its maximum size during puberty and then involutes has suggested to some investigators that the organ plays an active role in processes of growth and sexual maturation. Experiments with injections of thymus extracts into rats have led to similar assumptions. However, the growth of the thymus as well as its involution is essentially no different from the same process in other lymphatic organs, and the experiments with thymus extracts have not been substantiated. Injections with pituitary growth hormone result in an increase in the size of the thymus, while removal of the pituitary as well as administration of steroid hormones, including the sex hormones, tends to decrease its size. It is possible that these hormones are instrumental in the normal growth and involution of the thymus. It has been suggested that accidental involution may be caused by a high level of secretion of adrenal cortical steroid hormone.

Operative removal of the thymus is sometimes employed with variable results in the treatment of myasthenia gravis, a disease characterized by a progressive weakening of the musculature.

A condition in children known as status thymicolymphaticus was believed to be associated with sudden death occurring under circumstances that normally do not lead to death. This term indicates an overgrowth of lymphatic tissue. including the thymus, accompanied by a constitutional susceptibility to sudden death. The theory that there is such a causal relationship, however, appears to have been abandoned.

Microscopic Structure. — The thymus is encased in a thin capsule of connective tissue. This connective tissue penetrates the interior of the organ in the form of walls that branch and fuse, thus dividing the thymus into a multitude of connecting lobules having a diameter of .05 to 2 mm. The thymus tissue itself contains two types of cells. reticular cells and lymphocytes. The reticular cells. which are larger than the lymphocytes. are characterized by a large pale nucleus; they form a three-dimensional network in the meshes of which the lymphocytes are found. In the peripheral areas of the lobules, the so-called cortex, the lymphocytes are more densely packed and the reticular cells relatively more sparse. The central zone of the lobule, the medulla, contains fewer lymphocytes and more reticular cells than the cortex. The reticular cells of the thymus differ from the reticular cells of other lymphatic tissues in that they are derived embryologically from epithelial tissue and not from the mesenchyme (the embryologic connective tissue). The lymphocytes of the thymus are not only morphologically identical with the lymphocytes of other lymphatic tissues; they also exhibit the same physiologic behaviour and the same reactions to noxious stimuli. In the medulla of the thymus are the so-called Hassall's bodies. These structures are composed of concentrically arranged cells, which are degenerated at the centres of the bodies where also processes of cornification can frequently be seen. The function of Hassall's bodies, if any, is unknown.

The involution of the thymus consists microscopically of a decrease in the amount of thymus tissue, which is replaced by fat tissue originating in the interlobular connective tissue. This process affects first the cortex but gradually extends also to the medulla, which decreases in quantity. Finally the thymus becomes a mass of fatty tissue containing centrally a remnant of the medulla with varying numbers of Hassall's bodies.

Embryology. — The thymus arises from the third branchial pouch in the form of two epithelial cell masses, which at first are tubular but subsequently become solid. Lymphocytes wander in from the surrounding mesenchyme, thus separating the densely packed epithelial cells and converting the solid cell mass into a reticulum. The lymphocytes of the thymus are not derived from the epithelial cells. See also LYMPH AND LYMPHATIC SYSTEM.

THYMUS, DISEASES OF. Many functions have been attributed to the thymus (*q.v.*), but thus far the function of this organ and its relationship to clinical disease are not well understood. Classical extirpation experiments in animals have given no conclusive results. *Myasthenia gravis* (see PARALYSIS) is associated in many instances with a tumour of the thymus; in many cases of hyperthyroidism, a disease associated with thymic enlargement, muscular weakness is a prominent feature. In a number of cases a thymic tumour has been associated with depressed red blood cell formation and anemia which is at times relieved by surgical removal of the tumour. Certain relationships have been found between the thymus and the transmissibility of leukemia in experimental animals. A great deal has been written about the relationship of thymus enlargement to sudden death in infants, particularly during anesthesia. Evidence indicates, however, that the thymus — originally described as enlarged and as associated with the syndrome known as lymphatic constitution or status thymicolymphaticus — is normally developed in such cases. The symptoms in such patients are usually caused by infections of the respiratory tract and other local or general conditions. There is evidence to indicate a relationship between previous irradiation of the upper chest in children and the development of carcinoma of the thyroid. Prophylactic irradiation to prevent sudden death in infants is not warranted. All tumours originating in the thymic area should be regarded as potentially malignant.

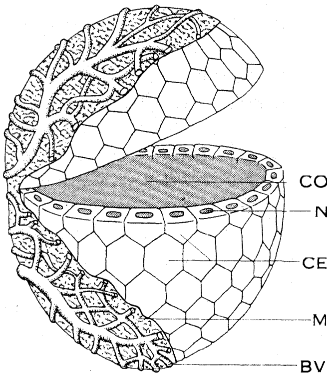
THYROID GLAND, an endocrine gland situated below the "Adam's apple," consisting of two oblong lobes lying on either side of the windpipe and connected by a narrow band of tissue called the isthmus. The lobes of the gland as well as the isthmus consist of numerous tiny hollow sacks called follicles, more or less rounded in shape and varying from 0.05 to 0.5 mm. in diameter. The shell of each follicle is built of cells closely packed together and is wrapped in a thin membrane (see figure). The membrane is covered with a dense mesh of blood capillaries, which ensure a steady and abundant supply of fresh plasma through the membrane to the cells; in fact the thyroid gland is one of the most extensively vascularized organs. Besides blood vessels, there are also lymph vessels and nerves around the follicle. The space inside the follicle is filled with a viscous fluid called colloid.

Every follicle of the thyroid gland makes thyroid hormone, stores it and secretes it into the blood stream. This hormone consists of two chemically closely related substances, L-thyroxine (or L-tetraiodothyronine) and L-triiodothyronine. Under normal conditions, most of the hormone is made up of thyroxine. The four and three atoms of iodine present in these two molecules account, respectively, for 65% and 58% of the hormone weight. It is possible to administer radioactive iodine and trace its progress in the thyroid, to observe how the gland uses it to make up the hormone. The iodide diffusing from the blood capillaries into the cells is retained by and concentrated in the cells. Then the iodide is taken up into organic compounds to form thyroxyl and triiodothyronyl radicals, which are thyroxine and triiodothyronine attached to a large protein called thyroglobulin. This phenomenon occurs at the edge of the cells next to the colloid. The new thyroglobulin becomes mixed with the thyroglobulin present in the colloid and stays there, thus providing a hormone store. Release of the hormones occurs when an enzyme, presumably secreted by the thyroid cells into the colloid, breaks down thyroglobulin to its amino acid components. The thyroxine and triiodothyronine molecules thus freed are small enough to cross the cell wall and to enter the blood vessels around the follicle; they become distributed over the entire body.



THYROID FOLLICLE
From periphery to centre are shown blood vessels (BV), membrane (M) and cells (CE) which make up the shell of the follicle. Appearing on the section plane are the *nuclei* (N) and the colloid (CO) which fill up the space inside the hollow follicle

In blood the thyroid hormone binds loosely to plasma proteins, mainly to a-globulin. To measure the level of thyroid hormone in the blood, the hormone is separated from inorganic iodine (iodide) by isolating plasma proteins, and the iodine content of these proteins is determined. The amount of so-called protein-bound iodine indicates whether or not the thyroid hormone level is normal. Too low or too high levels cause widespread functional disturbances, since the hormone controls the oxidation rate of foodstuffs inside the cells over the entire body.

The amount of thyroid hormone secreted by the thyroid gland is controlled by another endocrine gland, the pituitary. When the level of thyroid hormone in blood diminishes, due to its utilization in the tissues, the pituitary gland releases a hormone which stimulates the thyroid. This thyroid-stimulating, or thyrotrophic, hormone first induces the release of the thyroid hormone stored in the colloid by accelerating the breakdown of thyroglobulin. The amount of colloid in the follicle diminishes and may even nearly disappear under prolonged stimulation. The thyroid cells increase in size by protruding inside the follicle, and thus increase their capacity to produce the hormone. Under normal conditions, the appropriate level of thyroid hormone in the body is readily re-established; this higher level induces the pituitary to stop releasing thyrotrophic hormone; the thyroid stimulation ceases, the stores of thyroglobulin are repleted and the cells regress to their original size. Thus the level of thyroid hormone in the body is kept within a constant range by a mechanism in which the effects of thyroid hormone and of thyrotrophic hormone work in closed cycle (feedback mechanism), each hormone controlling the secretion of the other. THYRSUS, a kind of staff carried by Dionysus (*q.v.*) and his votaries (Gr. thyrsos). It was a reed, sometimes having a spear point at one end, topped with a pine cone. Another form terminated in a bunch of grapes and vine leaves, or ivy berries and leaves. The pine cone or bunch of leaves was sometimes supposed to cover the head of a spear, and the thyrsus was termed *thyrsologchos*.

See F. J. M. de Waele, *The Magic Staff or Rod* (1927).

THYSANOPTERA, the name of a small order of insects commonly known as *thrips.* Most of the species are not far from $\frac{1}{25}$ in. in length, though some of the tropical and Australian giants of the order measure about $\frac{1}{2}$ inch. To the group belong such destructive species as the greenhouse thrips, pear thrips, orange thrips and onion thrips, as well as some which carry virus diseases of tomato, pineapple, bean, sugar cane, etc. Though extremely abundant as individuals, possibly outnumbering beetles or flies or ants, they are commonly overlooked, even by entomologists, because of their small size; and not more than 3.000 species have been described. Their distribution is world-wide and includes all areas that are sufficiently warm for the development of a summer vegetation. They feed upon the sap of nearly all kinds of seed plants (and also a few ferns), extracting it from the buds, flowers, leaves or stems by means of their sucking mouth-parts. Others take juices from decaying plant remains, fungi, small insects and mites. One has been reported to ingest human blood occasionally; and one large group of species takes in the minute spores of various fungi, instead of juices. Some are restricted closely to a single kind of plant, while others occur in approximately equal abundance upon many kinds of unrelated

plants. Certain leaf-feeders produce a curling of the leaf, or even its folding along the mid-vein, thus creating a shelter for the insects within. Others, found only in galls in Australia, are thought to be the direct cause of these enveloping plant growths, though it is possible that the galls are induced by other insects.

They are elongate, slender-bodied insects, with antennae consisting of four to nine true joints, and with asymmetrical piercing mouth-parts. The wings are almost invariably long and strap-like, with greatly reduced venation and long fringes of marginal hairs. The tarsi are two-segmented; the apex of each tarsus contains a minute protrusible bladder nhich enables them to climb even the smoothest surface. The young closely resemble the adults in general form, though generally paler and more brilliantly coloured. Before becoming adult, they pass through a prepupal stage and one or two pupal stages. Wings, commonly present in the adults of both sexes, are invariably lacking in the males of certain species and frequently reduced in both females and males, especially under optimum environmental conditions. Parthenogenesis is frequent in the order, and males are either unknown or very rare in several species. In other species parthenogenesis occurs, although males are common. In a few highly specialized species embryonic development is largely, or even fully, completed within the body of the mother, the young being born alive in the latter event.

The Thysanoptera are divided into two suborders: (1) Terebrantia, in which the female has a saw-like ovipositor and usually a conically-pointed abdomen, the male having the abdomen bluntly rounded; and (2) Tubulifera, in which the female is without an ovipositor, both sexes having the last segment of the abdomen (except in a very few instances) tubular in form. The Terebrantia are the more primitive group, with more veins in the wings and often with the wings relatively broad. Most of the species of this group feed upon living plants. The female usually inserts the eggs under the epidermis of the plant by means of her ovipositor. A number of fossil species are known, particularly from Baltic amber. The Tubulifera, on the other hand. are more specialized: the ovipositor has been lost, the antennae have usually fewer segments, the wings are narrow and the veins have been reduced to a single median vestige. Most of the species of this group are found under and on the bark of living or dead trees, on fungi, in turf and under leaves, although a few live on foliage or in flowers, or are predacious. Lacking an ovipositor, those species which lay eggs usually hide them in protected places. This group is almost unknown as fossils.

BIBLIOGRAPHY.—H. Priesner, *Die Thysanopteren Europas* (1926–28) is the most useful and most important work, and contains a very complete bibliography. Earlier works of importance include H. THYSANURA, an order of primitive wingless insects comprising the bristletails, silverfish (*q.v.*) and firebrats. They are recognizable by their elongate feelers and tail processes (cerci). Active chiefly at night, they scurry about for cover—crevices about buildings, undersides of rocks, leaf mold—when exposed to light. See also APTERYGOTA.

THYSDRUS, an ancient city of north Africa (the site is occupied by the modern village of El Djem, 43 mi. S. of Sousse by rail). It acquired importance because of the fertility of its environs, and also as the meeting place of six ancient roads. The amphitheatre, 163 by 133 yd., is the finest Roman monument in north Africa, and is second in size only to the Flavian amphitheatre (the Colosseum) in Rome.

THYSSAGETAE, an ancient tribe described by Herodotus (iv, 22, 123) as occupying a district to the northeast of Scythia separated from the Budini by a desert seven days' jouney broad.

THYSSEN, AUGUST (1842–1926), German industrialist, "steel baron of the Ruhr territory," was born at Eschweiler, May 17, 1842. Thyssen's rolling mill, founded in 1867, became Thyssen and Co. in 1871 when he originated "vertical cartelization," unifying the financial. technological and market controls of facilities for producing basic steel with operating properties in related industries, such as coal mining. Thyssen sought additional private gain by vertical cartelization and was pressed to accelerate it by Bismarck. who saw in the technical integration which accompanies cartelization. a means of speeding military production. In addition to his practical motives. Thyssen had a pronounced technological bent. being first among German steel men to introduce the blast furnace as well as the Thomas process for utilizing the rich bed of phosphoric ore in Alsace-Lorraine in conjunction with the abundant coking coal of the Ruhr valley. Thyssen's great financial power. later augmented by collaboration with his son, Fritz Thyssen (1873–1951), was used after World

War I for political manipulations detrimental to the Weimar republic and beneficial to Adolf Hitler.

Thyssen died at Landsberg castle, near Kettwig, April 4. 1926. (G . Z.)

TIARA, the papal crown, a bee-hive shaped, somewhat bulging head-covering, ornamented with three crowns (whence *triregnum* or "triple crown"). It has no sacral character, being solely the ensign of sovereign power (cf. Innocent III Serm. vii in *S. Silvest.*), and is therefore never worn at liturgical functions, when the pope always wears the mitre. The tiara is first mentioned, under the name of *camelaucum,* in the *Vita* of Pope Constantine (d. 715), and next under the name of *pileus phrygius* or *phrygium,* or the *Constitutum Constantini,* the so-called "Donation of Constantine." In the 9th century it appears in the 9th *Ordo* of Mabillon in connection with the description of the consecration of the pope. On papal coins it first appears on those of Sergius III (d. 911) and then on those of Benedict VII (d. 983). At this period it was, according to the *Ordo* above mentioned, a sort of cap of white stuff, and helmet-shaped. Before the 9th century the tiara was certainly without any crown; any such ornament mould not have been in keeping with the circumstances of the time and seems also to be excluded by the terms of the *Constitutum Constantini.*

At the beginning of the 12th century, however, the papal tiara was already decorated with a circlet, as the 12th *Ordo* and statements made by Bruno of Segni (d. 1123) and Suger, abbot of St. Denys (1121–51), prove; but it is only in representations of the tiara dating from the late 13th century that the circlet appears as a regular spiked crown. The two pendants at the back of the tiara (*caudae, infulae*) are likewise traceable only to this period. The second circlet was added by Boniface VIII, as is proved by three statues executed during his lifetime (one in the Lateran church and two in the crypt of St. Peter's).

The earliest effigy of a pope with a triple-crowned tiara is, therefore, that of Benedict XII (d. 1342), of which the head is preserved in the museum at Avignon, while an effigy of the same pope in the crypt of St. Peter's at Rome has a tiara with only two crowns.

TIARET (*Tahert*), a town of Algeria: in the Tell Atlas, *département* of Tiaret, 122 mi. S.E. of Mostaganem by rail. Pop. (1954) 22,503. It occupies an important strategic position on a mountain pass at an elevation of 3,552 ft. The Wadi Tiaret flows through the town in a series of cascades. The upper town, the residential quarter, is on the right bank of this stream. The citadel occupies a separate hill on the other side of the wadi. The chief business centre is the lower town, where are also the principal public buildings. On another hill opposite the citadel is the native town.

TIBER, a river of central Italy (anc. *Tiberis;* Ital. *Tevere*). It traverses the Tuscan Apennines—in which it rises at a point about 12 mi. N. of Pieve San Stefano, 4,160 ft. above sea level, nearly 20 mi. E. from the headwaters of the Arno—in a series of picturesque ravines, flows nearly south by Borgo S. Sepolcro and Città di Castello, then runs between Perugia and Todi to Orte, where it receives the Nera (which brings with it the waters of the Velino; see TERNI), skirts the west foot of the Sabine mountains in a broad shallow valley, then crosses the Roman Campagnn, cutting its way through Rome, and finally enters the Tyrrhenian (Mediterranean) sea by two arms at Ostia and Fiumicino, the latter artificial. Its principal tributaries are the Paglia, the Nera and the Anio or Teverone. and it is generally navigable by boats up to the confluence of the Nera, a distance of 104 mi.. though, because of the rapidity of the current, there is very little navigation above Rome. The total length of the river is 252 mi., of which 21 mi. lie between Rome and the sea. This latter portion of the river's course is tortuous, but in spite of this. and although the depth varies from only 7 to 20 ft., and in places at low water does not exceed 4 ft., it is nevertheless navigated by vessels up to 180 tons burden. The area of the Tiber basin is 6.719 sq.mi., and it is the largest in Italy except the Po. The stream is heavily charged with sediment, and from that circumstance got its ancient epithet of *flavus* (tawny). The discharge at the mouth is 230 cu.m. per second, but it can fall as low as 90, and in floods rises to 3,400. It has advanced at each mouth about 2 mi. since Roman times, while the effect of the sediment it brings down is seen on the northwest almost as far as Palo (anc. *Alsium*), and on the southeast beyond Tor Paterno (see LAVINIUM) in the gradual advance of the coast. The rate of advance at Fiumicino is estimated at 13 ft. per annum. From Rome to the sea the fall is only 6 per 1,000. The arm which reaches the sea at Fiumicino is a canal, dug by Claudius and improved by Trajan (see PORTL-s).

In the prehistoric period the mouth of the Tiber must have been situated at the point where the hills which follow it on each side cease, about 12 mi. below Rome. On the right bank they are of Pliocene gravel, on the left of tufa; and on the latter, on a cliff above the river (the ancient *Puilia saxa*) stood Ficana (marked by the farmhouse of Dragoncello), which is said to have owed its origin to Ancus Martius. Beyond these hills the low coast belt formed by the solid matter brought down by the river begins; and on each side of the mouth in the flat ground were salt marshes. (See OSTIA, PORTUS.)

TIBERIAS, a town formerly in Palestine and from 1948 in Israel, on the western shore of the Sea of Galilee, attractively situated on a narrow strip of land between the high ground and the water, 680 ft. below sea level; pop. (1956 est.) 17,400. The old city lay to the south of the modern.

History.—Tiberias was built about A.D. 21 by Herod Antipas, and was so called after the emperor Tiberius. Herod made it his capital and developed its life on Greek lines. The town was built on an ancient site, probably Rakkath (Josh. xix, 35), and in the course of construction a graveyard was disturbed. In consequence the Jews. fearful of uncleanness, refused to live there, and Herod had to resort to compulsion to people his town (Joseph, *Antiq.*, xviii, 2. 3). No mention is made of Tiberias in the Gospels. except the casual reference in John vi. 23. The city was of too recent date and too Hellenistic in outlook to invite attention, and it is unlikely that Christ ever visited it. It flung open its gates to Vespasian and his legions to earn considerations and favour. Hadrian sought to implant paganism by erecting a temple, but with no marked success. Toward the close of the 2nd century the Sanhedrin transferred itself thither from its first Galilean home at Sepphoris.

From the rabbinic school at Tiberias came Judah hak-Kadhosh, the collector and editor of the Mishnah (*c.* 220). The Talmud was edited there 200 years later. The Jewish philosopher Maimonides and Rabbi 'Xkiba were buried there.

Christianity found in Tiberias no congenial soil. and not until the 4th century could it make headway. In the 5th century there was a bishop of Tiberias, who subscribed to the acts of the council of Chalcedon. In 63; the Arabs arrived. \\!hen the crusaders established their kingdom of Jerusalem. Tancred was appointed ruler in Galilee; Tiberias became his capital and was in part rebuilt on a new site farther north. In 1187, before the battle of Hattin. it fell into the hands of Saladin. In the 18th century Dhahir el-Armi fortified the town; and in their advance on Damascus, British troops seized it in Oct. 1918.

In 1948. when the new state of Israel was proclaimed, many of the Arabs living there were evacuated. (E. Ro.; X.)

TIBERIUS (TIBERIUS CLAUDIUS NERO) (42 B.C.–A.D. 37), Roman emperor. was born on Nov. 16, 42 B.C. His father. who bore the same name. mas one of Julius Caesar's officers. He had proposed to confer honours on Caesar's assassins, then joined Mark Antony's brother in his attack on Octnvian, took refuge with Mark Anton!;. and returned to Rome when the general amnesty was proclaimed in 39 B.C.

Livia, the mother of Tiberius. was also of the Claudian family, out of which her father had passed hy adoption into that of the Livii Drusi. Her husband ceded her to Octavian (the future Augustus) in 38, and three months after her new marriage Drusus, brother to Tiherius. was born. Livia had no children by Augustus and therefore devoted all her remarkable gifts to the advancement of her sons.

Tiberius passed through the list of state offices in the usual princely fashion, beginning with the quaestorship at the age of 18 and attaining the consulate for the first time at 29. From the capacity for civil affairs which he displayed as emperor it may be inferred that he applied himself with determination to learning the business of government.

But from 22 to 6 B.C. and again from A.D. 4 to 10 by far the greater part of Tiberius' time was spent in the camp. His first service was as legionary tribune in one of the desperate wars in the Spanish peninsula. In 20 B.C. Augustus sent Tiberius with an army to seat Tigranes of Armenia on the throne as a Roman vassal. This he did without opposition. He spent the following year as governor of Transalpine Gaul. In 15 he was dispatched to aid his brother Drusus in subjugating the Raeti and Vindelici in the mountains at the source of the Rhine and Danube. Drusus attacked from the eastern side while Tiberius operated from the upper waters of the Rhine, and the mountaineers were subdued, which ensured the safety of communications between northern Italy and Gaul.

In 12 B.C. Agrippa, the great general of the emperor Augustus, died at the age of 51, leaving Julia, the emperor's only child, a widow. Vipsania, who was the daughter of Agrippa by an earlier marriage, was wife of Tiberius, and had borne him a son, Drusus. Livia, with great difficulty, prevailed upon Augustus to replace Agrippa by Tiberius, who was compelled to exchange Vipsania for Julia: with bitter grief on his part. During the year of mourning for Agrippa, which delayed his new marriage, Tiberius was occupied with a victorious campaign against the Pannonians, followed by successful expeditions in the three succeeding summers. For this he received the triumphal insignia, now first separated from the triumph itself.

On the death of Drusus in the autumn of 9 B.C., Tiberius, whose reputation had hitherto been eclipsed by that of his brother, stepped into the position of the first soldier of the empire. The army, if it did not warmly admire Tiberius, entertained a loyal confidence in a leader who, as Velleius (the historian who served under him) reports, always made the safety of his soldiers his first care.

In the campaign of the year after Drusus' death Tiberius traversed all Germany between the Rhine and the Elbe, and met with slight opposition. He was rewarded with the full triumph, the military title of "imperator" and his second consulship. In 7 B.C. there was another but insignificant campaign in Germany. Next year Augustus bestowed on his stepson the tribunician authority for five years.

Tiberius was thus in the most formal manner associated with the emperor in the conduct of the government on the civil side. Tacitus goes too far, however, when he says that this promotion marked him out as the heir to the throne.

Tiberius at this time suddenly begged permission to retire to Rhodes and devote himself to study. He seems to have declined absolutely at the time to state his reasons for this course, but he obstinately adhered to it. The departure from Italy was as secret as it could be made. Years afterward, when Tiberius broke silence about his motives, he declared that he had retired in order to allow the young princes, Gaius and Lucius, sons of Agrippa and Julia, a free course.

There was perhaps a portion of the truth wrapped up in this declaration. Like Agrippa, who retired to Mytilene to avoid the young Marcellus, Tiberius had clearly no taste to become the servant of the two children whom Augustus had adopted in their infancy and evidently destined to be joint emperors after his death. But it may well be believed that Tiberius, unlike Agrippa, had no burning ambition to see himself in the place destined for his stepsons; and it may have been in his eyes one of the attractions of exile that it released him from the obligation to aid in carrying out the far-reaching designs which Livia cherished for his sake. But the contemporaries of Tiberius were no doubt right in believing that the scandal of Julia's life did more than all else to render his position at Rome intolerable. His conduct to her from first to last gives a strong impression of his dignity and self-respect. When at length the emperor's eyes were opened, and he inflicted severe punishment upon his daughter, her husband, now divorced by the emperor's act, made earnest intercession for her and did what he could to alleviate her suffering.

At Rhodes Tiberius lived simply, passing his time mainly in the company of Greek professors, with whom he associated on fairly equal terms. After five years' absence from Rome, he begged for leave to return; but the boon was angrily refused, and Livia with difficulty got her son made nominally a legate of Augustus, so as in some degree to veil his disgrace. The next two years were spent in solitude and gloom. Then, on the intercession of Gaius, Augustus allowed Tiberius to come back to Rome, but on the express understanding that he was to hold aloof from public functions. He had scarcely returned before death removed (A.D. 2) Lucius, the younger of the two princes, and a year and a half later Gaius also died. The emperor was thus left with only one male descendant, Agrippa Postumus, youngest son of Julia, and still a boy. Four months after Gaius' death Augustus adopted Agrippa and at the same time Tiberius. The emperor now indicated clearly his expectation that Tiberius would be his principal successor. The two essential ingredients in the imperial authority—the *proconsulare imperium* and the tribunicia potestas—were conferred on Tiberius and not on Agrippa, who was too young to receive them.

Tiberius' career as a general now began anew. In two or three safe rather than brilliant campaigns he strengthened the Roman hold on Germany, and established the winter camps of the legions in the interior, away from the Rhine.

In A.D. 5 it became necessary to attack the formidable confederacy built up by Maroboduus, with its centre in Bohemia. At the most critical moment, when Pannonia and Dalmatia broke out into insurrection, Maroboduus accepted an honourable peace. The four serious campaigns which the war cost displayed Tiberius at his best as a general. When he was about to celebrate his well-won triumphs, the terrible catastrophe to Varus and his legions (A.D. 9) produced a profound change in the Roman policy toward Germany. Although Tiberius with his nephew and adopted son Germanicus made in A.D. 9 and 10 two more marches into the interior of Germany, the Rhine was permanently accepted as the frontier. Tiberius was thus robbed in great part of the fruit of his campaigns; but nothing can deprive him of the credit of being a chief founder of the imperial system in the lands of Europe. From the beginning of 11, when he celebrated a magnificent triumph, to the time of the emperor's death in 14 Tiberius remained almost entirely in Italy, and held rather the position of joint emperor than that of expectant heir.

Tiberius ascended the throne at the age of 56. What struck every one of his contemporaries most was his absolute impenetrability. All his feelings, desires, passions and ambitions were locked behind an impassable barrier, and had to be interpreted by the very uncertain light of his external acts. It is recorded of him that only once did he as commander take counsel with his officers concerning military operations, and that was when the destruction of Varus' legions had made it imperatively necessary not lightly to risk the loss of a single soldier. The penalty of his inscrutability was widespread dislike and suspicion. But behind his defenses there lay an intellect of high power, cold, clear and penetrating all disguises.

Few have ever possessed such mental vision, and he was probably never deceived either about the weakness of others or about his own. For the littleness and servility of public life below the court he entertained a strong contempt. It is a question whether he ever liked or was liked by a single being; but he did his duty by those with whom he was connected after a thorough though stern and unlovable fashion. As a general he commanded the full confidence of his soldiers, though he was a severe disciplinarian; yet the men of his own legions greeted his accession to the throne with a mutiny.

Tiberius proved himself capable in every department of the state more by virtue of industry and application than by genius. His mind moved so slowly and he was accustomed to deliberate so long that men sometimes made the mistake of deeming him a waverer. He was in reality one of the most tenacious of men.

The persuasion entertained by many at the end of his life that he had always been a monster of wickedness. but had succeeded in concealing the fact until he became emperor, has slightly discoloured the narratives of his earlier years. Tiberius was called "the gloomiest of mankind" by the elder Pliny and he came to be disposed to brood over mysteries and superstitions. As this gloom deepened his will grew neaker. and his power tended to fall into the hands of unworthy instruments.

The change of masters had been anticipated by the Roman world with apprehension, but it mas smoothly accomplished. Livia expected to share the imperial authority nith her son. At first Tiberius allowed some recognition to the claim; but he soon shook himself free of her. and later became estranged from his mother and held no communication with her for years before her death.

The history of Tiberius' relations with other members of his family is hardly less miserable. Perhaps with any other commander than Germanicus the dangerouc, mutiny of the troops on the Rhine which broke out soon after Tiberius' accession would have ended in a march of the discontented legions upon the capital. The perilous episode of Arminius caused the recall of Germanicus and his dispatch to the east on an honourable but comparatively inactive mission. Tiberius seems to have set Piso to watch and thwart him. but there is no authority for the suspicion that he had him poisoned.

The death of Germanicus was followed four years later by that of the emperor's son Drusus. When Drusus died, Tiberius nominated two of the sons of Agrippina. Germanicus' widow. as his heirs. But Sejanus, Tiberius' minister, had grown strong by nursing the emperor's suspicions and dislike for the household of Germanicus. and the mother and the princes were imprisoned on a charge of crime.

In his memoirs of his own life Tiberius declared that he killed Sejanus because he had discovered that he entertained a mad rage against the sons of Germanicus. But the destruction of Sejanus did not save Agrippina and her two children. The third son. Gaius Caesar (Caligula), lived to become emperor when Tiberius died in 37.

Throughout his reign Tiberius strove earnestly to do his duty to the empire at large: his guiding principle was to maintain with an almost superstitious reverence the constitutional forms which had been constructed by Augustus. Only two changes of moment were introduced. The imperial guard, hitherto only seen near the city in small detachments. was by the advice of Sejanus encamped permanently in full force close to the walls. By this measure the turbulence of the populace was kept in check. The officer in command of the guard became at once the most important of the emperor's lieutenants. The other change was the practically complete abolition of the old comitia. But the senate was treated with an almost hypocritical deference and a pedantically precise compliance with the old republican forms was observed toward the senatorial magistrates.

The care expended by Tiberius on the provinces was unremitting. Soldiers, governors and officials of all kinds were kept in wholesome dread of vengeance if they oppressed their inferiors or encouraged irregularity of any kind. Strict economy permitted light taxation and enabled the emperor to show generosity in periods of exceptional distress. Public security both in Italy and abroad was maintained by a strong hand. and commerce was stimulated by the improvement of communications. Jurisdiction both within and without the capital was on the whole exercised with steadiness and equity, and the laws of the empire were at many points improved.

The social and moral reforms of Augustus were upheld and carried further. Such risings against the emperor's authority as occurred within the Roman domain were put down with no great difficulty. The foreign or rather the frontier policy was a policy of peace, and it was pursued with considerable success. With few exceptions the duties of the Roman forces on the borders were confined to watching the peoples on the other side while they destroyed each other. On the Rhine. at least, masterly inactivity achieved tranquillity which lasted for a long period.

Historians of Rome in ancient times remembered Tiberius chiefly as the sovereign under whose rule prosecutions for treason on slight pretexts first became rife, and the hateful body of informers was first allowed to fatten on the gains of judicial murder. Xugustus had allowed considerable licence of speech and writing against himself. and had made no attempt to set up a doctrine of constructive treason.

But the history of the state trials of Tiherius' reign shows conclusively that the straining of the law. proceeded in the first instance from the eager flattery of the senate. was in the earlier days checked and controlled to a great extent by the emperor, and was by him acquiesced in at the end of his reign. with a sort of contemptuous indifference, until he developed, under the influence of his fears. a readiness to shed blood.

Ancient authorities are Tacitus, to some extent biased by senatorial traditions; Suetonius, a rather scandalous biographer; and Velleius Paterculus, the nesreit in point of time, an officer who had served under him. Dio is probably dependent on Tacitus. Thr chief account of Tiberius in English is that containrd in Charles Merivale's *History of the Romans Under the Empire* (1850–64). E. S. Beesly wrote an interesting defense of him in his *Catiline, Clodius and Tiberius* (1878). Another history of this period is Hermann Schiller's *Geschichte der römischen Kaiserzeit* (Gotha, 1883). Much historical information is given in the editions of the *Annals* of Tacitus. of which the best in English is that of Henry Furneaux (Oxford, 1884): Freytag, *Tiberius and Tacitus* (Berlin, 1870) (following Stahr, *Tiberius*, Rcrlin, 1863), exposes the inconsistencies of Tacitus' account. *See* also Ihne, *Zur Ehrenrettung des Kaisers Tiberius* (Strassburg, 1892); Gentile, *L'Imperatore Tiberio secondo la moderna critica storica* (1887); J. TIBESTI, a mountainous region of the central Sahara. inhabited by the Tibbu people. Tibesti includes the highest summit of the Sahara, the volcanic massif of Emi Koussi, which reaches 11,204 feet. The eruptive rocks have forced their way through a substratum of crystalline rocks covered by horizontal Silurian grits. the scarp of which is quite brusque above the surrounding plains, which are hundreds of metres above sea level.

Great dry watercourses, deeply cut in all the faces of the massif, ndicate a climate formerly more humid. The daily variations of temperature reach 30° at times.

The inhabitants, at most 10,000, are chiefly nomads, although there are some sedentary elements.

Tibesti had been partly explored by Gustav Nachtigal in 1870. After that no European went there until 191j, when Col. S. Tilho wrote a very complete description of it and mapped it. The frontier was fixed by the Franco-English convention of Sept. 8, 1919.

TIBET, a country of central Asia. annexed to the People's Republic of China in 1951 and since regarded as an autonomous region of China. Tibet is called by Tibetans Bod (Bodyul), by Indians Bhot, by Mongols Tobet and by Chinese Tufan and Hsits'ang. Xrca 469.413 sq.mi. Pop. (1953 est.) 1,273,969. The inhabitants are scattered on a mountainousplateau extending approximately irom 74° to 100° E. long. and from 2i° to 37° S. lat.

Culturally Tibet includes parts of the Chinese provinces of Szechwan, Kansu and Yünnan, and Ladakh in Kashmir (*qq.v.*). Although the people in this vast area differ ethnologically in customs, dress and dialects, they have a common written language. Tibet is known as the land of lamas. and Lhasa. the capital. is the mecca of Lamaist Buddhism. Before Outer Mongolia and China fell under Communism, pilgrims flocked to the holy city from remote Manchuria and Mongolia, some even irom the U.S.S.R.

Historically, Tibet has on occasion ruled, and long influenced the frontier states of Nepal. Sikkim and Bhutan on the southern slopes of the Himalayas. From the 13th century until 1951 it was ruled by a religious hierarchy and the pontiff of the Lamaist Church wielded temporal power. In the 17th century. the head of a reformation Lamaist sect (Ge-lug-pa, known as the Yellow Hat sect) achieved political ascendancy. He was officially acknowledged by the Chinese emperor as the dalai lama. This marked the beginning of 250 years of Chinese tutelage over the heads of Lamaism. In 1911 China became a republic. Years of civil wars and internal dissension ensued. With the encouragement of the British, Tibet openly defied Chinese overlordship. Though nominally under Chinese sovereignty or suzerainty, Tibet was, to all intents and purposes. an independent nation from 1913 to 1950. In 1950 Communist China invaded Tibet nhich capitulated and signed an agreement in Peking in 1951. However, sporadic revolt against Chinese rule immediately broke out. Even the announcement by the Communist regime in 1957 that it would not attempt to introduce any "democratic reform" in Tibet during the second five-year plan period (1958–62) did not bring about the desired pacification for the Tibetans love their own nay of life and resent any outside interference. The crisis came to a head in March 1959 with a mass revolt against the Chinese occupation forces. This was ruthlessly crushed and culminated in the flight of the dalai lama to India.

PHYSICAL GEOGRAPHY

Geology. — The Tibetan plateau was an ingression area of the Mesozoic and the Cenozoic eras and is geologically very young. Millions of years ago there were no mountains and the whole area was a huge sea. The Himalayas, the world's highest mountain mass. were uplifted in the course of ages and are still growing. The horizontal strata of conglomerate rock is composed of pebbles, pressured together through time, and limestone! containing marine fossils. The lakes in the Chang Thang area are the remnants of the ancient sea. This Cenomanian transgression did not extend to the Kunlun complex which is much older than the Himalayas. The Runlun is composed essentially of Devonian limestones and slates of the Paleozoic era while the metamorphosed limestones and quartzites of the Himalayan ranges were classified as Jurassic. It is probable that during the glacier periods the whole highland was covered with ice sheets. The Pleistocene deposits are enormously thick in many places, an estimated deposit of 3.000 ft. was formed in the upper Sutlej valley.

Physiography. — Tibet is on a high plateau surrounded by mountain masses. In Tibet proper, the mountain ranges run from northwest to southeast with deep or shallow valleys forming innumerable furrows between them. The lofty Himalayan chain sprawls along the entire southern frontier and shuts off the warm monsoon from the Indian ocean.

The great Himalayas extend over 1,500 mi.. and to their north, four other ranges stretch across Tibet: the Ladakh, the Kailas range (*q.v.*) or Trans-Himalaya (in Chinese Kang-ti-szu Shan), the Rarakorum .range (*q.v.*), and the Kunlun (*q.v.*) or Kuen-lun. The highest point of the Ladakh range is Gurla Mandhata (25,354 ft.), 12 mi. S. of Lake Manasarowar. North of Manasarowar the Kailas range contains a crowded cluster of peaks. several of mhich exceed 20.000 ft. The Kunlun range, extending from longitude 77° to 93° E.. forms the northern border of the Tibetan protuberance (see also HIMALAYA).

In eastern Tibet the mountain ranges transverse from north to south. The meridional chains for many years steadfastly resisted the penetration of Chinese culture into Tihet, but they permitted the beneficial moist air to flow northward along the river beds of the Yangtze, Mekong and Salween, into the deep ravines and broad valleys cloaked with vegetation and extensive forests.

Most of the large rivers of Asia rise in the Tibetan highlands. The Yangtze has its uppermost source south of the Wu-lan-wu-la (Ulan Ula) range. The Mekong and the Yellow river rise on the eastern fringe of the Thanglha Ri (Dangla range). The Salween rises north of Lhasa near Ngachuka. The Irrawaddy has its origin near the eastern tip of the Kailas range. The Indus. Sutlej and Brahmaputra all rise in the deep valley south of the Kailas complex near Lake Manasarowar. The Brahmaputra (Tsangpo) is the longest river inside of Tibet and flows for 800 mi. before entering India. Many tributaries swell its stream in its course: Kyi Chhu and Giamda from the north, Nyang Chhu from the south and Yigrong and Nagong from the east.

Between the Kailas and the Kunlun ranges is Chang Thang. an extensive lake basin. studded with innumerable lakes. The lake region covers two-thirds of the territory of Tibet, but three of the largest lakes of geographic Tibet, Koko Nor, Manasarowar and Yarndrog Tsho, lie outside of the lake basin. (See also articles on the individual rivers and lakes.)

Climate. — The precipitation in Tibet decreases from south to north. because of the increasing distance from the ocean. The Himalayas capture most of the rainfall of the summer monsoon and on the southern slopes it often reaches 200 in. annually. A little rain may get through the mountain passes, but is deposited on the Kailas range, beyond which is a region of extremely arid climate. The total fall of rain and snow over most of Tibet is under eight inches per year. The temperatures are low, as befitting the high altitude. Climate is generally rigorous. Its severity is much aggravated by the winds which blow with gale force during the greater part of the year. The temperature varies considerably in 24 hours, a climatic condition that differs little throughout the year. It is always bitterly cold in the morning and evening and the temperature usually drops below zero. At noon it may rise to 100° F. and the sun is scorching. Only during three to four months in the year is the Tibetan highland free from frost, and snow may fall in summer. However, in the lower land (under 12,000 ft.), in river basins and in southeastern Tibet, the climate is mild and pleasant. The air is dry, and, in the absence of dust storms, the sky is eternally blue.

Vegetation. — In the expansive wind-swept, cold, dry, northern plain which comprises two-thirds of the area of Tibet proper, there are no trees. The average elevation is over 15.000 ft. In sharp contrast. the Sutlej river valley in Ngari district and the Chumbi valley (*q.v.*) in southeastern Tibet, have vast areas of profuse virgin forests. Trees found include giant conifers, varnish trees! spruce, fir! cypress, oak, walnut, maple and poplar. Cereals, mainly barley and buckwheat are grown in the river valleys between the Himalayas and the Kailas. In the woodlands many kinds of medicinal herbs are grown which are in demand in China and India. *Peimu* (*Fritillaria roylei*), acanthus, rhubarb, saffron (*Crocus sativus*) and calamus (*Acorus* calamus) are some of the popular drugs found in Tibet.

Animal Life. — Domestic animals, raised mainly in eastern Tibet include sheep. goats. yaks, horses and donkeys. The sheep provide the nomadic people of northern Tibet with skins for garments, and meat. milk and butter for food. The yak. a long-haired domesticated ox. is the typical draft animal and the chief means of conveyance for highland travel. It carries heavy loads (160 lb.) on bad roads. through steep passes and at high altitudes, but it cannot withstand the warmer climate and dense air of lower altitudes or be used for tilling land. Its meat and milk form the stable food of all Tibetans and its tail is highly valued in India. Herds of about 1,000 sheep and 200 yak are not uncommon.

The horse of eastern Tibet once famous for its small stature and stocky nimbleness, has degenerated in the 20th century, so much so, that the riding horses in Tibet now come from the steppes of Tsinghai province, China.

Among the wild animals' found in Tibet the following are the commonest: wild yak. wild horses or ass (*kyang*), snow leopard, lynx, brown or black bear. wild sheep (*yuan*), gazelle (gon), antelope (*cho*), marmot and deer. The musk deer (*q.v.*), a hornless species, is found abundantly in eastern Tibet. The musk sac is a gland or pouch under the skin of the male deer's abdomen. Musk is dark-purplish or brown in colour. is unctuous to touch and has a remarkable permanence and stability of colour. Its scent is most penetrating and persistent, hence its importance for making perfumes. It is exported to Europe via India and China.

The common birds of Tihet are swan, stock or heron, hawk, gull, fishing eagle, bar-headed goose, raven, chough lark. sparrow, woodpecker and pigeon. The Tibetan chicken has an elongated body. and at night it perches either on treetops or on roofs. Tibetan farmers raise poultry. but they eat only the eggs and not the meat. In eastern Tibet there are several rare and handsome varieties of pheasants.

GEOGRAPHIC REGIONS

The boundaries of Tibet were never clearly defined. The country is large and difficult of access Lying on the borders are tracts of no man's land. or the habitats of roving bands of primitive natives. Tibet is generally divided into five main regions: U (pronounced Wei), Tsang, Ngari. Chang Thang and Kham. U, meaning "the centre," is both the political and cultural centre of modern Tibet. U covers the valleys of Kyi Chhu and Yarlung, tno large tributaries of the Brahmaputra river. Both Lhasa and the ancient capital Yarlung are located in the U district. West of U is the Tsang district, of which Zhikatse (Shigatse) is the capital. North of Zhikatse is the self-contained religious-political centre of Trashi Lhdmpo. After the return of the panchen lama in 1952, his entourage, with Communist Chinese support, set up a semiautonomous political organization, Panchen Kanpo Lija committee. (See History and Government sections below.) Further west is Ngari, a sparsely populated highland nith snow-clad mountains and deep river canyons, where the nomads drive their flocks and herds from one valley slope to another seeking scanty pasturage. Chang Thang, the vast windsnept northern plain, is an inhospitable waste of frozen desert with few inhabitants. Of all the Tibetan regions. Kham. comprising eastern Tibet. is the most fertile and the most populated. Lower in elevation and heavier in rainfall the river gorges are covered nith extensive forests. The lower river basins are cultivated. The eastern boundary of Kham was long disputed. The Tibetans held that Kham should embrace the whole territory extending from Taichao (Giamda) on the west to K'ang-ting (Tatsienlu) on the east; precisely the same area nas designated by the Chinese government to form the province of Sikang As a result armed conflicts occurred frequently in the first three decades of the 20th century. In 1933 a temporary settlement was reached to demark the border line along the north-south course of the Yangtze river. This line now forms the eastern boundary of the so-called Tibetan Autonomous region. East of the line was Sikang province, which in 1956 was transformed into the Kantse Tibetan Autonomous chou and became a part of the Chinese Szechwan province. Kham is under military occupation administered by the People's Liberation committee of Chamdo area.

THE PEOPLE

Racial Characteristics. — The Tibetans belong to the Mongolian race and are closely related to the aborigines inhabiting the mountains in western China. There are also numerous similarities between the Tibetan language and that spoken by the Shan and Kuki (*qq.v.*) of northern Burma. The Tibetans are a homogeneous people with black hair: brown eyes and brown skin, and are sparsely scattered over an area from Ladakh in Kashmir to the northwest provinces of China. They divide themselves into three racial groups: Bodpo in central and western Tibet, Khampa in eastern Tibet and Xmdo in northwest China. There are no appreciable racial differences in the three groups, all uphold the Lamaist religion, and use the same language. The people in eastern Tibet may be slightly taller. The chief difference is in culture. The people in central Tibet look down on the Khampa as inferior in culture, while the Amdo have closer contact with elements of Chinese civilization. (See also MONGOLS.)

Language. — The Tibetans possess a language which was reduced to writing in the 7th century, about the same time the Mahayana form of Buddhism was introduced into the country. The Tibetan alphabet is based on the Sanskrit alphabet in use in Rashmir at that time. The Tibetan language is a singularly refined language. There is a honorific and nonhonorific word for each expression. Sometimes there are three distinctions the most honorific used in addressing the high priests and the nobility, the less honorific to equals and nonhonorific to inferiors. Hence for a learned person there are three sets of vocabularies. The ability in employing the correct expression is a measure of one's standard of culture. (See also TIBETAN LANGUAGE.)

Social Organization. — There are three main classes of people in Tibet: nomads, farmers and townsfolk. The country is too high for ordinary agriculture; even pasturage is too scanty to sustain animal husbandry on a large scale. Few towns have populations exceeding 5,000 and Tibetans are designated according to the following occupations: clergy (lamas), nobility, traders, herders and peasants.

Lamas. — Prior to Communist Chinese domination it was estimated that about 20% of the population belonged to the clerical order. The priests of the Yellow Hat sect observed celibacy. Theoretically, the doors of the monasteries were open to all and no age limit and no academic qualifications were set for entrance. Sons of the rich and of the poor, sons of the nobles and of the commoners were all admitted on an equal basis. However, monks from the upper classes had better chances for advancement within the church, because their wealth allowed them to pay fees and buy exemptions.

In Tibet there were no public schools; the monasteries were the only seats of learning. These were well organized and efficiently administered, and offered planned curriculums for student lamas. After completing a 16-year course a graduate was given the coveted title *geshi*. **A** geshi was respected all over the country and was qualified to serve in the government or on the administrative board of the monasteries. Not all the enrolled lamas intended to acquire a serious education and many came for vocational training as calligraphers, printers, painters and craftsmen. A large number specialized in performing rituals for the sick or engaged in farming, Groups were also trained as warrior-lamas and wore long hair, special uniforms and took vigorous physical exercises daily. They guarded the monasteries, enforced discipline, maintained public order during the new year festivals, acted as bodyguards to high lamas while traveling and at the order of the abbot, would take up arms against another monastery, against any private person, against foreign invaders or even against the government. Thus in one sense they formed a sort of national or home guard.

Monasteries obtained endowments from both the government and private persons. Government endowments may have included subsidies in kind, fund, real estate and even magistrate's districts. Private endowments included alms and donations in money and kind from members of the congregation or from outsiders. To this must be added interest and dividends on usury and trading, in nhich all monasteries freely engaged. The three large monasteries of Drepung. Sera and Gaden (Ganden) owned sizable real estate, and enjoyed considerable autonomy.

The highest lamas were the "incarnations," of whom there were more than 100, including the dalai lama and the panchen lama. A unique phenomenon in lamadom was the female incarnation of Pan-Dan Lha-Mo, the patron goddess of the dalai lama, at the famed Samding monastery, on a beautiful lake about two days' journey east of Gyangtse. (See LAMAISM.)

Nobility.—There were about 150 noble families. The Tibetan nobleman traced his descent to one of three sources. The first could be from an ancestor who was ennobled for service to the country. The founder of the Pa lha family, for example, was a former Bhutanese priest of the 17th century whose work in the service of the Lhasa government nas rewarded by the gift of an estate near Gyangtse containing 130 farms. The second, from the family in which a dalai lama or a panchen lama took rebirth, which however lowly was ennobled and received large estates from the government. Some of the leading Lhasa nobles were descended from brothers of the previous dalai lamas. The third class of the aristocracy was the oldest and smallest of all. Its members traced their lineage to the early monarchs who ruled Tibet before the 10th century. However. a rich commoner could apply for and be granted a nobleman's estate for which there was no issue.

Traders — Petty trading was a side occupation of many people, and professional traders were few. Commercial transactions requiring long journeys mere carried on by the men. while the women managed the shops and small retail trade. Nobles and monks alike engaged in trade. The large monasteries traded nidely and had administrative departments in charge of trade. Chinese, Indians, Nepalese and Kashmiris also played a part in the commercial ac-

Herdsmen.—The nomadic herdsmen and shepherds were hardy and independent, and pastured their flocks mainly in the uplands at altitudes of more than 14,000 ft.. mainly in the high wilderness of northwestern Tibet. Some pastoral groups practised seasonal migration; during the winter they stayed in the lowland and in the summer grazed their animals on mountain slopes.

Peasants. — The peasants inhabited mainly the south and southeast. Women. in addition to their domestic duties, laboured in the fields with their menfolk. Some peasants worked as tenants for the government, monasteries, high lamas or noblemen. and the land was granted to them as family allotments in return for which they paid taxes and labour service. Some worked as drafted or hired labour, and the land was directly managed by the government, the monasteries or the nobility. Only a very small number owned and worked plots of land.

Religion. — In Tibet everything began and ended with religion. It is said the Tibetans would not die for their country, but they would die for their religion. The early animistic religion of Tibet was Bon-po (Bon or Pon) a shamanism (*q.v.*) or nature worship. Buddhism was first introduced into Tibet in the 7th century, at a time when Buddhism had already degenerated. A corrupt form of Buddhism. known as tantrism, with emphasis on magic and exorcism was prevalent in India. For several centuries there mas a fierce struggle between the Bon-po religion and Buddhism and the two faiths eventually compromised. Bon-po followers accepted the principal Buddhist tenets and even claimed Buddha as one of their own divinities, while into Buddhism were incorporated many of the hideous Bon-po deities and rituals. The devil dance which was performed in every Buddhist temple during the year's end for the purpose of expelling the evil spirits. was borrowed from Bon-poism, and also the common practice of offering stones and hanging festoon flags over sacred spots. Tibetan Buddhism is commonly referred to as Lamaism by westerners, a term neither used nor resented by Tibetans who always regarded their religion as unadulterated Buddhism, and lama was their venerable appellation for a high priest.

By the mid-11th century. Buddhism gained complete ascendancy in Tibet. new monasteries sprang up everywhere. Remnants of the Bon religion still exist among the herdsmen in Chang Thang, and the aborigines of Kongpo and the eastern Himalaya regions. In the 13th century Lamaism spread to Mongolia. The high priest of Sakya Gompa monastery converted Kublai Khan to Lamaism, who, after he became the emperor of China, made the Sakya Gompa hierarch the imperial preceptor and sovereign of central Tibet. This marked the beginning of theocracy in Tibet. With power, grew the moral decadence of the priesthood. The priests indulged in mundane pleasures. Different religious sects rivaled for power and moral codes became degraded.

In the 15th century there was a successful reformation movement led by Tsong-kha-pa, who advocated celibacy and abstention from intoxicants and other worldly pursuits. To distinguish him and his followers from those of older religious sects he wore a yellow hat. Hence the reformed sect was commonly known as the Yellow Hat sect and the older sects as the Red Hat sects. Tsong-kha-pa and two of his disciples founded the three large monasteries Drepung, Sera and Ganden, in Lhasa. His youngest disciple, Gentun Drupa, founded the Trashi Lhiimpo monastery at Zhikatse. Gentun Drupa was the first of the dalai lama incarnations. (See TIBETAN BUDDHISM and also History below; for Tibetan religious art see TIBETAN ART.)

Customs. — Shut off from the rest of the world for centuries by insurmountable mountains and tremendous gorges, the Tibetans developed peculiar customs and habits. They formed a small world of their own and fairly successfully resisted the penetration of outside influence until 1950 when the Chinese People's Liberation army began its drive on Tibet.

Dwellings. — 'The finest dwellings in Tibet were the mansions of the nobility. With the exception of a few minor nobles who lived in Zhikatse and Sakya Gompa, all the noble families maintained town houses in Lhasa which were built of stone around a rectangular courtyard. On three sides of the courtyard were stables and storehouses; on the fourth side. opposite the gate was the mansion itself, generally three stories high. The family quarters and chapel were located on the third floor where the rooms, unlike those, below which were dark and ill-ventilated, may have had glass windows and doors. The walls and the ceiling were painted with pictures and auspicious designs.

The common people lived in one or two story buildings. The roof was flat and made of clay like the earthern floor, but unpolished. Windows were plentiful but glass was rare. Instead the windows were covered by wax paper or other similar material, protected by strong wooden shutters. The houses of the village peasants were, as a rule, solid and substantial. There. too. the walls were of stone or sun-dried bricks, though occasionally of clods of earth. 'Flat roofs of beaten earth were usually used throughout the Tibetan interior. but in the Chumbi valley and other rainy districts the roofs were gently sloped. Where pine trees grew, the roofs were constructed of pine shingles, kept in position by heavy stones. The herdsmen dwelled in tents of yak hair, rectangular in shape and ranging from 12 to 50 ft. in length. An aperture about 2 ft. in width along the middle of the roof let out the smoke.

Food and Drink. — The staple diet of the ordinary Tibetan is yak's meat. mutton, barley flour. cheese and tea. Tibetans eat neither chicken nor fish. Those who dwell in the lower altitudes, also eat rice. fruit and vegetables in small quantities.

The main beverage is tea. Brick tea from China is used, and is boiled in water flavoured with soda ash. When thoroughly boiled, the mixture is taken but with a ladle and poured through a strainer into a churn. Butter and salt are added and the whole churned until it is well mixed. The consumption of this beverage among Tibetans is enormous. for they drink on an average from 30 to 50 cups of tea a day. The other chief beverage is beer. It is brewed from barley and is only mildly intoxicating.

Dress. — The Tibetan dress consists of a very full gown with a high collar and long sleeves. The summer gown is usually of ordinary Tibetan cloth, but the wealthier classes may wear silk. The winter gown is sometimes of sheepskin, sometimes of cloth lined with lambskin or wadded cotton. Tied tightly around the waist with a woolen or cotton band, it is puffed out above. and in the capacious pocket thus formed are carried drinking cups and other odds and ends. For laymen the robe reaches to the knee, for priests and women to the ankle. In central Tibet and in parts of eastern Tibet the women wear aprons, woven in varied colours and often so broad that they nearly meet at the back. Shirts are of cotton or silk; trousers differ greatly in shape from the western pattern and are of silk or cloth. The boot is of cloth, felt or leather. and of various colours. It rises to the kneecap, with a slit behind the knee. and is tied with gay-coloured woolen garters three or four feet long. Men's hats are of various Binds. It is only in a few districts that men wear necklaces. Earrings are very common and, among the official classes! universal.

The women of Tibet, especially those who rank among the upper classes, display their headdress made of pearls, turquoise and coral on a wooden frame. Herdswomen plait their hair into many tiny queques which are then bundled into a big one below the nape of the neck and adorned artistically with red and yellow stones. Some women drape over their hair a large cloth sewn with silver and brass coins and shells mhich jingle at every step they take. They are physically strong and perform heavy manual tasks. When not tanned by exposure to the elements, they are often fair, and those of the upper classes take great care of their complexions. Throughout Tibet it is a general custom for women to smear caoutchouc on their faces. Rough pads of felt, soaked in a red colouring matter, are also used. In addition to the headdress, numerous ornaments are worn including rings, earrings. necklaces and girdles. The women wear charm boxes on the chest immediately below the throat. These usually contain a small image of a deity and a talisman written for the wearer by a lama.

Family Organization. — Tibetan women, after marriage, held a comparatively high family status, but in religious affairs their position was lower. For instance, of the three forms of blessing accorded by the dalai lama to different suppliants (touching the head with both his hands, with one hand or merely with a tassel) the last and lowest form was the one used for all women. Although the Tibetan woman enjoyed a great measure of independence, she usually had little or no share in the choice of her husband. A son was consulted by his father as to the bride proposed for him, but the parents rarely consulted a daughter.

Priests of the Red Hat sect were permitted to marry. Their wives were in charge of the lama's belongings, leaving their husbands free to devote themselves to religion.

Monogamy, pologamy and polyandry were all common in Tibet. Polyandry was the predominant form of marriage. The husbands were generally brothers, sometimes partners of a business. When a woman married the elder brother she married all the younger brothers as they became of age. A more unusual case was that of a widowed father and a grown-up son marrying the same woman. The preservation of the family estate seemed to underlie the marital oddities, for it was always the woman who controlled the family finance.

The aristocracy could only marry in their own class and this rule mas strictly applied. Relatives did not intermarry as inbreeding was avoided. Divorces were rare and had to be approved by the Tibetan government.

Calendar.—The Tibetan calendar is basically the lunar calendar in use in oriental countries for thousands of years. In the calendar certain days are marked as auspicious and certain others as inauspicious. The Tibetans consider the days of the full moon and the new moon and the days lying in between as particularly auspicious. To keep away from possible bad luck on ominous days they strike off these days in the calendar. And to make up the loss they duplicate the lucky days. So if Jan. 10 is a lucky day, two Jan. 10 days may be found in succession; while if Jan. 14 is an evil-portending date, that day may not be shown at all. The years are marked by matching the five elements against the 12 zodiacal signs (*e.g.*, 1953 was a Wood-Tiger year and 1958 a Fire-Dog year), making one complete cycle every 60 years.

Festivals.—The Tibetan year was marked by numerous saints' days and festivals in which both lamas and laity took part. In addition to the great national holidays, each locality had its own particular auspicious days on which the tutelary deities were worshiped and local religious ceremonies were performed. The 8th, the 10th; the 25th and 30th days of each month were considered especially auspicious, also the days of the full moon and the new moon. On these last two days the people made their way to the local monastery, clad in gala robes and carrying offerings of flowers. incense and money. Butter was also presented for the sacred lamps on the altar. The presentation of offerings to the gods is followed by prostration before the altar and the performance of devotions. Birthdays are unimportant dates in Tibet; they are generally not known and never celebrated.

The most important yearly event was the New Year or the Great Prayer festival at Lhasa. Commencing on New Tear's Eve, which usually falls sometime in February according to the Tibetan-Chinese lunar calendar the ceremony and celebrations lasted the greater part of a month. First, houses and doorways were decorated with juniper boughs; puddings were prepared and a stock of wine laid in. The people passed the time in eating, drinking, dancing, singing and all kinds of merrymaking, combined with prayer when they felt so inclined. On the morning of the third day began the Great Prayer festival (*Monlam Chempo*).

From the dawn of the new year, monks from the neighbouring monasteries began to pour into Lhasa. By noon, thousands of priests had assembled. The next ten days were occupied by religious services, held thrice daily in the Great Temple of Lhasa. The festival of lights was performed on the 15th day of this month. All the local monasteries and larger houses in the district were illuminated with thousands of small butter lamps. The 20th day marked the commencement of sports, and one of the most important events was horse racing.

During each year's prayer festival, the civil authority of Lhasa was turned over to two proctors of the Drepung monastery. After an impressive installation ceremony at the public square, the proctors appointed their o n staff and policemen whose principal duties were to maintain order, for, during the festival, thousands of lamas roamed the streets and affrays among themselves and with the civilians were common. But the lama magistrates also collected business taxes and inspected private abodes. Heavy fines were imposed for uncleanness and disorderly conduct. Invariably the proctors derived a sizable fortune from the fines during the Great Prayer festival which lasted 21 days. It provided also an opportunity for financial gain for the other lamas because three services were held daily during this period and after services alms were doled out to the congregation by rich patrons.

The daily services during the Great Prayer festival were conducted by the chief abbot of the Ganden monastery who is considered the successor of Tsong-kha-pa. On the 15th day the dalai lama conducted a sermon himself and bestowed benedictions to the multitude.

HISTORY

Prior to the 7th century A.D. Tibetan history is wrapped in myth and legend. According to the orthodox tradition. the forefathers of the Tibetan people were a monkey and an ogress. However another story relates that in the very beginning the void gave birth to a most wonderful egg. When it burst open five months later, space, heat, fire, oceans and mountains issued from it; and from its very interior came forth man.

Tibetan histories usually refer to the division of the Tibetan people into four or six tribes or clans. The most ancient accounts give Shipuye or Pugye as the first king of Tibet, but the later Buddhist chronicle of central Tibet depicts Tibetan royal genealogy as commencing with Nyakhri Tsanpo, the son of an Indian king whose name varies in the different texts. After the first king, five groups of kings are: seven heavenly **Khri** ("thrones"); two upper Teng ("high ones"); six middle Legs ("good ones"); eight earthly De ("worldly"); four lower Tsan ("mighty"). With some slight difference, this system is essentially the same in all the chronicles. During the time of Shipuye, the principal metals mere discovered, agriculture and irrigation were introduced, the great castle of Yarlung was built and the Bon-po religion arose. After the mythical series of kings, Namri Sontsan appears as the first historically identified ruler. He conducted expeditions to western China, northern India, Nepal and even faraway Persia.

Early *Kings.*— In the 7th century Tibet was not a unitary state. Independent chieftans continued to maintain a great deal of power and constituted a strong and warlike nobility that furnished many generals and ministers to the state. In their turbulence, they often revolted against the royal authority. Kivalry between individual chiefs was very common and the struggle was mainly within the state for predominance in the government. The principal offices in the court were hereditary. The nobility, who held landed property, constituted the real power outside the court. Songtsen Gampo (620–649) and Khrisong Detsen (755–797) are two famous kings. The former is credited with the invention of Tibetan writing and the introduction of Buddhism. The most important personalities under his reign were Thonmi Sambhota, his envoy to India, and Gardon Tsan (d. 667), his capable minister. Tibetans came into contact with Chinese, Nepalese, Turks and the people of Khotan and Kucha, and a little later with the Arabs. The petty kingdom of Namri Sontsan grew in less than a century to be a major central Asian power. During the reign of Khrisong Detsen. Tibetan power reached its peak and Buddhism was affirmed as the chief religion of the state. Padmasambhava, a famous tantric teacher. came to Tibet from Kashmir; the monastery of Samye was built in 762–66; and the first seven monks ordained. Under this king. Tibet gained prominence by military victories in its old struggle with the T'ang empire in China.

A third famous king, Ralpachan (815–838), was the most fervent Buddhist who ever rose to the throne in Tibet. The peaceful nature of the king manifested itself in a lull in military activity. In his zeal for Buddhism, the king gradually removed the aristocracy from positions in the court and filled their places with Buddhist monks. A real persecution of the old Bon-po religion seemed inevitable. All this contributed to a growing tension that ultimately burst into revolution. In 838 a conspiracy was formed and the king was assassinated by two noblemen of the families of Sbas and Cog ro. The conspirators placed on the throne the elder brother of the murdered king. Lang Darma, a Bon-poist. Buddhist temples were closed and destroyed, and monks were forced to break their vows or flee. In 842 Lang Darma was murdered by a monk, but his persecution had inflicted a heavy blow on Buddhism.

Religious Renaissance. — The old kingdom of Songtsen Gampo dissolved into a great number of petty local chieftaincies. The descendants of Lang Darma succeeded in founding a strong state in the west (Guge, Ladakh). but they could not exercise any effective power in central Tibet. During this period the Bon-po followers resorted to plagiarism, appropriating many Buddhist books, which they claimed to have dug out from places where their ancient masters had hidden them. This removed many fundamental differences between the two religions and compromised the position of Bon-po. This animistic religion borrowed so freely from the abundant tenets of Buddhism that it eventually lost its own characteristics and became absorbed into its rival.

At this time the kings of Guge sent groups of young students to India to rejuvenate Tibetan Buddhism and specifically to clear up certain doubts in the teachings of the occultist school. The most notable of these was Rinchen Zampo (958–1055), who with his associates and pupils translated many Buddhist texts on Vajrayana. The greatest event took place in 1032 when the great Bengali teacher Atisa (982–1054) was invited to Guge by its king. Atisa carried his evangelistic work far from the monastery Thoding, then the cultural centre of Guge, to central Tibet, including such places as Samye, Lhasa and Nye thang. During this period the Buddhists, like the Bon-po followers before them, now claimed to have rediscovered many buried texts (*terma*). This new wave of translation and reintroduction of Buddhist texts gave rise to later schools rivaling the old school (Nyingmapa). The old school recognized Padmasambhava as its earthly master. The newer school, Kadampa, returned to Atisa and Rinchen Zampo; another new school. Kagyurpa. claimed descent from Tilopa, Naropa. Marpa (1012–96) and Milaraspa (1041–1123); yet another new school. Sakyapa. claimed the Indic Siddha, Virupa, as its first master. 'Brog mi (992–?), a famous translator, belonged to this school.

Relations With the Mongols. — In the 13th century Tibet was still divided between an uncertain number of chiefs. religious leaders and laymen who ruled by right of succession or of election over different territories. In 1239, during the time of Godan, Ogadai's second son, Mongol troops were sent to attack Tibet. In this perilous moment the Tibetans turned to Sapan (1182–1251), the abbot of Sakya Gompa monastery. who seemed to possess the greatest authority and influence in the whole country, and empowered him to deal with Godan.

Sapan's nephew, Phaspa (1235–80), was not only a Buddhist saint but a remarkable genius. While still in his teens, he so much impressed Kublai Khan (1260–94). who had conquered the eastern part of Tibet and was soon to become emperor of China, that he was requested by Kublai Khan to initiate him into Lamaism and was thus acclaimed the imperial preceptor. Phaspa also won a debate before the emperor over the Nestorians, Mohammedans and the Taoist theologians of China. The emperor Kublai Khan made Lamaism the national religion of his empire. At the age of 31, Phaspa was ordered to invent a writing system for the Mongols. He accomplished this task within five years, basing it on the Tibetan alphabet. But his composition did not prove satisfactory and it disappeared in less than a century without having been very widely used.

The Mongols made the Sakya Pandit the ruler of central Tibet, and Lamaism the national religion of China. However, the Mongol rule in China was short-lived. The power of the Sakya hierarchy declined with the downfall of the Mongols and Tibet soon fell a prey to anarchy. The nobility, taking advantage of such disorder, often took arms to claim rights or avenge injuries. In these chaotic times, several rival religious sects emerged.

Toward the end of the 14th century, a great religious reformation movement was gathering momentum in Tibet. Tsong-kha-pa was born about 1357 at Tsongka near Sining and came to central Tibet in his early teens; after a mixed education in the existing monasteries, he founded the Yellow Hat sect (Ge-lug-pa), and instituted a stricter code of morals. In 1409 he built the Ganden monastery.

Two of his renowned disciples were Gyethub (1364–1432) and Khedru (1385–1438); both were prolific writers. Other outstanding members of the Yellow Hat sect were Jamyang Chorje who in 1417 founded the monastery of Drepung, and Gyamchen Chorje who in 1418 founded the monastery of Sera. In 1447, Gentun Drupa, Tsong-kha-pa's youngest disciple, founded the Trashi Lhiimpo monastery at Zhikatse. Gentun Drupa died in 1474, but his spirit was believed to have entered the body of a baby born two years later. This child became his successor; and thus began the system of priestly incarnation which was of tremendous significance in later Tibetan history.

All through this period the fortunes of the various noble families and different sects of Tibetan Buddhism were intricately related. The Phamo Drupa family allied itself with the Drikunpa sect. rose against the Sakya hierarchy, won recognition from the Chinese emperor and took control of all central Tibet. Internal dissension in the 15th century broke its position and the power of the Phamo Drupa family devolved upon one of its subordinates. The succeeding family. Rinpung. seized Zhikatse in 1436 and gradually occupied the whole of Tsang. They in turn were replaced in 1556 by one of their subordinates. who had also started his conquest of Tsang from Zhikatse and who became the ancestor of the so-called Tsangpa kings. The latter remained in power until 1642. Both Rinpungs and Tsangpa kings were patrons of the Red Hat sect. Karmapa. During this period Tibet was torn by wars. Monasteries gradually succeeded in taking the upper hand, guiding the political life of Tibet. Landed property confiscated or seized when someone died without legitimate or recognized heirs passed into the hands of the monasteries. The centre of the struggle for power involved the Red Hat sect, supported by the rulers of Tsang, and the rising Yellow Hat sect which opposed the Karmapa's corrupt formalism.

In 1566 the Ordos Mongols attacked Tibet and some captured lamas were taken to their chief, Altan Khan, who was attracted to the form of Buddhism preached by the Yellow Hat sect. and who subsequently sent a mission to Lhasa. In 1577, upon the invitation of Altan Khan, Sonam Gyatso. one of the incarnations at the Drepung monastery and third of the dalai series, visited Mongolia, converted the Mongolian chief to the Ge-lug-pa faith, and received in return the title. Vajradhara dalai lama ("holder of the thunderbolt," "ocean lama"). This marked the first time the incarnation came to bear the name dalai, a Mongolian translation of Gyatso, "the ocean." Altan Khan died in 1582 and at the earnest request of the khan's son, Sonam Gyatso, the 3rd dalai lama. visited Mongolia a second time. He died while on a journey to China.

After the death of the 3rd dalai lama in 1588 the grandson of the hlongolian Altan Khan was selected as the reincarnation. The high priest's rebirth in a princely family of Mongolia served above all to weld together still more firmly the relations between the Yellow Hat sect and its Mongolian patrons and to lead toward new developments. the alliance between the former and the power of Mongol arms. This young reincarnation traveled along the road outside of the Great Wall of China, stayed in Koko Nor for three months and then resumed his journey through the whole of Tibet. He won great popularity among Mongols and Tibetans alike.

At the beginning of the 17th century the chief of Tsang extended his power and occupied Lhasa. The 4th dalai lama, Yonten Gyatso (1588–1615), had to seek safe abode in Samye. It was through the insistence of the Yellow Hat sect that a Mongol army commanded by two of Kholoche's sons entered Tibet and induced the Tsang king to halt aggression. In 1621 the Mongol troops again descended on Tibet. The Tsang king was defeated and besieged in Lhasa. Yellow Hat sect leaders acted as peacemakers and retrieved most of the monasteries that were annexed to

Tsang's doininion as well as the monasteries that were obliged to change their sect by the domination of the Red Hat chaplains.

In 1638 Gushi Khan, the chief of the Oelet Mongols and upholder of the Yellow Hat sect: sent envoys to invite the 5th dalai lama, Kgag-Wang Lobsang Gyatso, but the invitation was not accepted. In 1641 the 5th dalai lama and his regent with Gushi Khan's help defeated the Tsangpa king. He moved from the Drepung monastery to the Potala, which he rebuilt on the ruins of a palace, formerly occupied by King Sontsan Jampo. The Yellow Hat sect then held complete spiritual sway and temporal power over the entire Tibetan nation. The 5th dalai lama died in 1682, but his regent Sanggye Gyatso, unwilling to desist from his task concealed the death and ruled in his master's name. He consolidated the Tibetan unification and finished the work of building Potala palace.

The 6th dalai lama, Tsangyang Gyatso, was a romantic young man, given to drinking, women and song. He incurred the displeasure of the commander of the Mongol forces, Latsang Khan, who. in 1705, disposed the dalai lama and replaced him with a candidate of his own choice. The deposed dalai lama died mysteriously. The interference of the khan was resented by all of the Yellow Hat sect, and representatives of the three monasteries of Lhasa went for help to the Junkars, another Mongolian tribe in Sinkiang. In 1716 the Junkars swept down through the vast northern plain. deieated the Latsang Khan, and sacked the monasteries. This caused direct intervention by the Manchu empire.

Domination by the Manchu Empire. — Tibetan relations with the Manchus were established while the Manchu kingdom was still a dependency of the Ming empire. The western Rlongols were instrumental in bringing about this relationship. In 1612 and 1644 the 5th dalai lama twice sent overtures to Mukden. In 1646 when informed of Manchu's success in China he sent a letter pledging allegiance. In 1651 the Manchu court sent an official invitation to the 5th dalai lama and to the panchen lama. Lozang Chorgyen (1569–1662). The latter, taking his advanced age as an excuse, declined, but the 5th dalai lama started for China in 1652 and won official recognition. In 1713 the emperor K'ang Hsi extended his patronage to the panchen lama, Lozang Yeshi (1663–1737), proclaiming him panchen ratna (in Tibetan, panchen erdeni, meaning "great pandit, the gem").

The Junkar's invasion caused prompt reaction on the part of the Chinese emperor. In 1717 K'ang Hsi sent a small relief army which was trapped by the Mongols near Nam Tsho and was annihilated. In 1718 the emperor, now acting against his counsellors' advice; sent a new army from Koko Nor and another from Szechwan. In 1720, having wiped out all the Junkars in Tibet. he put on the throne in the Potala, a boy incarnation from Litang as the 7th dalai lama (1708–57).

In 1726 the emperor Yung Chêng dispatched a civil officer to Tibet to arbitrate a dispute among the Mongolian generals. This marked the beginning of the appointment of the ambans (resident ministers). In 1750 the ambans killed the Tibetan regent. The people in their turn massacred the Chinese in Lhasa. The emperor Ch'ien Lung dispatched an army, restored Chinese authority and strengthened the power of the ambans.

In 1788 the Gurkhas, who had recently gained ascendancy throughout Nepal, occupied some Tibetan districts near the Nepalese frontier. Three years later they pillaged Zhikatse. The Manchu government dispatched an army, composed partly of Chinese and partly of Tibetans, under Manchu leadership. This army marched through Tibet during the bitterly cold winter, defeated the Gurkhas decisively during the spring of 1792 and dictated peace terms within a short distance of Kathmandu. the Gurkhas' capital. Suspecting also that the British, who were by then established in India. had helped the Gurkhas, the Chinese closed Tibet as far as possible to foreign influence. It was decreed that all foreign questions should be dealt with by the ambans, not by the Tibetan government.

In 1855 another Gurkha invasion occurred, and this was more successful. The resulting treaty empon-ered the Gurkhas to establish an agency in Lhasa and other centres. gave them an annual subsidy of 10,000 rupees and extraterritorial rights. In return the Gurkha government undertook to aid Tibet if the latter were attacked by another nation.

At the time of the Younghusband mission (see below). when British troops entered Tibet, the 13th dalai lama (1876–1933) fled to Urga (Ulan Bator) Mongolia, where he remained until 1907. In November of that year he arrived at Koko Kor on his way back to Tibet; he was invited to Peking by the Manchu emperor and arrived on Sept. 28, 1908; after a brief sojourn returned to Lhasa in Dec. 1909. During the period of the dalai lama's exile, China, aroused by the British action, was taking measures to strengthen its hold upon eastern Tibet. In April 1905 a revolt broke out in Bathang (Ba-an), and the disorders spread through southwestern Szechwan and northwestern Yiinnan, where several monasteries were involved. Chao Erh-feng, viceroy of Szechwan, was appointed to subdue this rebellion. His drastic methods during the following four years temporarily brought order to eastern Tibet. In Jan. 1910 Chao with 2,000 troops marched into Lhasa. For a time his vigorous administration gave China effective control of Tibet. The dalai lama fled to India upon the arrival of the Chinese force and remained there about two years. In 1911, revolution broke out in China and Manchu rule was overthrown. The Chinese garrison in Lhasa after days of riots and looting, was forced to withdraw. The dalai lama returned to Lhasa in 1912.

Relations With the British. — British official relations began in 1774, when Warren Hastings was in charge of the British East India company. The dalai lama steadfastly refused to receive any British emissary, so Hastings approached the other pillar of Lamaism. He sent George Bogle to the panchen lama at Trashi Lhiimpo, but because of some opposition from the Nepalese, trade relations were not opened up as had been hoped. In 1783 a second mission. under Samuel Turner. was sent to the panchen lama and was able to obtain trading privileges for the Indians only.

When the Manchu empire became corrupt and tottering, it failed to give effective protection against the Gurkha invasion of Tibet in 1855 and looked on helplessly while its tributary states, Burma, Sikkim, Nepal and Bhutan were made dependents of Great Britain. In the spring of 1903, Lord Curzon, the viceroy of India, sent Col. Francis Younghusband with a small escort to Kampa Dzong, 15 mi. N. of the alleged frontier, to meet Tibetan and Chinese delegates in order to discuss the problems of boundary and trade, but they were unable to persuade the Tibetan government to undertake negotiations. At last, in Nov. 1903. Younghusband advanced to Gyantse. On Jan. 8, 1904, British forces on their way to Gyantse had reached Düna without encountering any armed resistance. On March 31, when they attempted to move beyond Diina, they were obstructed by Tibetans, and a bloody battle took place. After 16 engagements in which several thousand Tibetans lost their lives, the British reached Lhasa on Aug. 3. The dalai lama fled to Ulan Bator. The regent, national council and assembly entered into negotiations with the British which resulted in a convention between Tibet and Great Britain, and in a treaty signed on Sept. 7, 1904 to which China was not a party. The main terms were: (1) the opening of two new marts to foreign trade, one at Gyantse, and one at Gartok in western Tibet; (2) the abolition of trade duties between Tibet and India; and (3) Tibetan territory not to be ceded or leased to any foreign power. On Sept. 22, 1904, T'ang Shao-yi was sent to India by the Chinese government to negotiate with the British government in regard to Tibetan affairs. The resulting Anglo-Chinese treaty was signed on April 27, 1906. A year later, on Aug. 31, 1907, an Anglo-Russian convention was concluded. Under its terms Russia recognized the special British interests; the two powers agreed that neither would enter into negotiations with Tibet except through the Chinese government and that neither would send representatives to Lhasa. In Oct. 1913, a conference was held in Simla at which the Chinese republic, Tibet and Great Britain were represented. The convention provided for a division of Tibet for administration purposes into two sections. Inner and Outer Tibet. Inner Tibet was to be administered by China, while Outer Tibet was to be autonomous. But China repudiated the action of its commissioner and never signed this agreement. It was signed, however, by British and Tibetan representatives July 3, 1914.

Rivalry Between Dalai and **Panchen.**—The dalai lama with his private church, the triumvirate of Drepung, Sera and Ganden, the two esoteric academies of Gyeme and Gyuto and the oracle of Naichung. formed the nucleus of the Yellow Hat sect organization. Tibetans refer to them as the Seven Great Symbols. The panchen lama, with his Trashi Lhumpo monastery at Zhikatse, maintained a court and a separate organization exactly like those of the dalai lama but on a smaller scale. The panchen lama is considered an incarnation of Amitabha (Tibetan Erpame, "Buddha of the boundless light"), and the dalai lama an incarnation of Avalokitesvara (Tibetan Chenrezi, "the compassionate"). Theoretically, in the ranking of the living Buddhas, the former stood higher than the latter. But in fact the first panchen lama was originally only the teacher of the 5th dalai lama. who, out of gratitude to him. had declared him to be an incarnation and had conferred on him the Trashi Lhiimpo monastery with its enormous benefices. This monastery was founded by the first in the line of the dalai lamas.

During the intricate development of world politics in the 20th century, the dalai lama and the panchen lama became deeply involved. The panchen lama had for generations been supported by the Chinese as a rival to the dalai lama.

In 1904 the 9th panchen lama took the absence of the dalai lama from the country during the Younghusband mission as an opportunity to contest the leadership of Tibet. He courted the favour of the invaders by signing a truce with them at Gyangtse and later even visited Calcutta to solicit British support. But the British, who had succeeded in imposing a convention with the representatives of the dalai lama, preferred to deal with Lhasa.

Shortly after the return of the dalai lama to Lhasa in 1909, a sharp disagreement broke out over a proposal for a political reorganization between the Chinese and the dalai lama, who was forced to leave the country and took refuge in Darjeeling, India. The panchen lama this time curried the favour of the Chinese and for several months lived in the Potala, the dalai lama's palace. Following the revolution in China in 1910, the dalai lama was restored to power and retribution was immediately taken. The landed estate of the Trashi Lhumpo monastery was forced to pay taxes directly to Lhasa, thus depriving the panchen lama of his source of income. The dalai lama in trying to be independent of China resorted to British influence and signed a bilateral treaty with them at Simla in 1913. The situation grew to be very uncomfortable for the panchen lama who in 1924, fled to China with his retinue. In 1933 the 13th dalai lama died. Escorted by a strong Chinese contingent the 9th panchen lama planned to return to Tibet. but his health failed and he died enroute in 1937.

The 14th dalai lama was born in Tsinghai in 1935 and discovered in 1939. A year later in the province a boy reincarnation of the panchen lama was found by his followers. The Lhasa government announced shortly afterward that it had discovered two claimants of their own. The dispute prevented the Tsinghai incarnation from being installed in Trashi Lhumpo which was directly controlled by Lhasa. In the last days of the Chinese Nationalist government, the Tsinghai boy was officially installed as the 10th panchen ratna at the Kumbum monastery in Tsinghai. When the Chinese Communists came into power in 1949, the entourage of the new panchen swiftly pledged their allegiance to the new masters of China.

Chinese Military Occupation. — The independence of India on Aug. 15, 1947, and the Communist revolution in China during 1948–49 marked a new era in Tibetan history. In early 1950 the Communist army reached the bank of the Yangtze river, just east of the Tibetan frontier fortress of Chamdo. Then in mid-Oct. 1950, the Chinese Communist army advanced into Chamdo, about 370 mi. E. of Lhasa, where Tibetan troops accepted defeat. In December the regent resigned to give place to the 14th dalai lama. The Tibetan government moved to the southern border of Tibet. The first official act of the 16-year-old dalai lama after coming to power was to grant a general amnesty to all political prisoners in Tibet. At the same time he appointed the minister captured at Chamdo to head a mission to Peking, to be followed by another mission under his commander in chief. On May 23, 1951, a Chinese-Tibetan treaty was signed in Peking, the essence of which may be summarized under four points: (1) Tibet was to retain its autonomy, with no change in the dalai lama's political system or in his status, function and power: Tibetan religion, monastic institutions and customs n-ould be respected; (2) the old position that the panchen lama enjoyed in the time of friendly relations between the 13th dalai lama and the 9th panchen lama was to be restored; (3) the Chinese Communist government was to set up a military and administrative committee, with regional military headquarters in Tibet: the Tibetan army was to be reorganized and systematically absorbed into the Chinese Cominunist army; (1) Tibet's external relations were to be handled by the Chinese Communist government. On hug. 17, 1951, the dalai lama returned to Lhasa. the city from which he had fled on Dec. 19. 1950. By this time, three forces of the Chinese Communist army had entered Tibet simultaneously, one from Chamdo on the east. another from Koko Nor on the north and still another from Iigari on the west. to take over strategic garrisons in Tibet; a fourth party comprising administrative and technical staffs arrived via India.

Both the dalai lama and the panchen lama were given seats on the National Committee of the Chinese People's Political Consultative conference held in Peking on Nov. 1, 1951. In the spring of 1952 under the shadow of the Chinese Communist troops. the 10th panchen lama, now 15 years old, scored a triumphant entry into the Tibetan capital. On June 23, 1952. the panchen lama was entrenched on the throne of his predecessors in the Trashi Lhumpo monastery which had been without its spiritual leader for 28 years. In Sept. 193'4, both the dalai lama and the panchen lama attended the first Chinese National People's congress in Peking, and in 1956 they toured India together as guests of the Indian government.

Britain transferred to India its relations with Tibet in 1947 and the British mission in Lhasa and two trading agencies were taken over by Indian representatives. In 1950, India. hearing of the imminent Chinese invasion. on the ground that military action might cause unrest and disturbance on the Indian-Tibetan border, sent notes of protest to Communist China. India's objections were summarily dismissed by Red China as an interference in Chinese internal affairs. On April 20. 1954 India signed an eight-year agreement with Peking to promote trade and cultural intercourse, and to facilitate pilgrimage and travel between the two countries. Under the agreement India retained the right to establish trading agencies at Tatung. Gyangtse and Gartok. and a number of other Tibetan towns were designated as markets for trade. No Tibetan representative participated in the negotiation, and the language of the agreement inferred India's complete recognition of China's sovereignty over Tibet.

For political consolidation and military build-up Communist China embarked on a program of extensive roadbuilding in Tibet, and hundreds of thousands of Tibetans were pressed into the work. The hazards involved in bridging high precipices and deep ravines apparently caused the deaths of many workers. Resentment was general. The lamas who were always exempted from government conscription, especially hated the new masters because no special consideration was accorded them. Further opposition was aroused by the attempt to impose land reform on the feudal religion-dominated society. Insurrection first broke out in Litang and Chamdo in eastern Tibet, then spread to the Golok tribe in southern Tsinghai and the local Chinese garrisons were attaclred. Red Chinese retaliated by bombing the Litang lamasery and killed most of the inmates. The wanton destruction of their seat of worship further infuriated the Khambas, natives of eastern Tibet. Unable to beat the Red Chinese on frontal attack, they resorted to guerrilla warfare and frequently intercepted communications on the newly constructed highways. An announcement from Peking in April 1957 not to carry out "democratic reform" in the next six years and a promise to withdraw most of the Chinese military personnel in Tibet did not achieve the desired pacification. By the winter of 1958 the Khambas and Goloks had joined forces and moved into the Brahmaputra valley south of Lhasa. The trading route from Gyangtse to Yatung was cut. The rebels, who were joined by many discontented Tibetans from central Tibet, moved from Gyangtse area toward Lhasa in Feb. 1959. The situation became tense. The commander of the Chinese Communist troops put pressure on the dalai lama to deploy Tibetan army in suppressing the revolt, which the god-king declined. On March 10, 1959 an invitation to the dalai lama from the Chinese commander to a theatrical performance at the latter's headquarters was looked upon with suspicion by the Tibetans who feared their god-king might be held as hostage. Led by the *Mimaung* ("people's committee"), Tibetans overtly and under cover of a gigantic parade, prevented the young ruler from attending the banquet. As the Red soldiers tried to break up the demonstration, riots broke out. Reinforced by Tibetan troops the rioters stormed the Red garrison and the arsenal. Street fighting lasted five days. The Communist soldiers bombarded the dalai lama's summer residence and the Drepung and Sera monasteries, inflicting severe damage on the two ancient religious institutions.

The dalai lama, his family, three cabinet ministers and many high government functionaries escaped and sought refuge in India. In a statement on arrival, the dalai lama denounced Communist China as having broken all its promises to respect Tibetan autonomy as provided in the 1951 agreement. The government of India granted the dalai lama and his followers political asylum. Red China accused India of inciting revolts in Tibet and relations between India and China became critical.

After the flight of the dalai lama, Communist China on March 28, 1959 decreed the dissolution of the Lhasa government. The country was henceforth to be directly administered by the Preparatory Committee for the Tibet Autonomous region, and the panchen lama was named acting chairman. The panchen lama moved from Zhikatse to Lhasa in the same manner as his predecessor in 1910. He pledged full co-operation in suppressing rebellions and bringing about socialistic transformation of Tibet. He attended the Second National People's congress at Peking on April 17 and participated in the election of Liu Shao-chi as the second president of Communist China. Both he and the dalai lama (in absentia) were elected to be the vice-chairmen of the said National People's congress.

On Oct. 21, 1959, the United Nations General Assembly, by 45 votes to 9 (with 26 abstentions) approved a resolution which deplored the events in Tibet and called ior Chinese respect for the fundamental human rights of the Tibetan people.

Reports of sporadic fighting continued to reach the outside world in 1960, indicating that the Chinese Communists were still having trouble with pockets of rebellious Tibetans. By mid-1960 more than 17,000 refugees had fled to India for sanctuary, attesting to the continuing wave of suppression in the mountain-kingdom.

POPULATION

No census has ever been taken of the population of Tibet. The Peking national bureau of statistics reporting on the result of a general census carried out in other parts of China in June, 1953. estimated the population of Tibet at 1.273.969. This figure may be assumed to be reasonably accurate since the Tibetan government had previously estimated the number of persons under Lhasa's jurisdiction as between 1,000,000 and 1,500,000. Many Tibetans live in the Chinese provinces of Szechwan, Tsinghai and some even in Kansu and Sinkiang. The principal urban centres are Lhasa, Zhikatse, Gyangtse and Gartok (*qq.v.*). The Chinese government estimates the total number of Tibetans in Tibet and in China as 2,800,000.

All indicators point to a declining population. High infantile mortality, lack of medical knowledge, prevalence of venereal diseases and the strains on the heart and lungs due to rarefied air, account for the abnormally high mortality rate. In addition, the family practice of sending one male child out of three to join the clerical order and the marital system of polyandry where several men share one wife formed a kind of arbitrary birth control and further limited the growth of population. On June 20. 1960 the International Commission of Jurists in Geneva concluded an 11-month investigation of the Tibetan affair, and thereby announced Communist China guilty of genocide in Tibet, in an attempt to destroy the Tibetan people as a religious group. The Peking government was accused of upholding a systematic policy of killing, imprisonment and deportation of anti-Communist Tibetans.

The extent of Chinese colonization is not known, but a statement issued by the exiled dalai lama in Nov. 1959 indicated a marked acceleration in Chinese colonization.

ADMINISTRATION

Dalai Lama.—Prior to the Chinese conquest, Tibet was the last theocratic country in the world. At the head of the government was the god-king dalai lama who held both spiritual and temporal power. He was, and still is, believed to be the embodiment of the compassionate Buddha Chenrezi, patron god of Tibet. When a dalai lama died, he was succeeded by a reincarnation boy who was found by following the indications provided by the preceding dalai lama on his deathbed, the guidance given by the state oracle and the revelations derived from the mirage over the sacred lake Nam Tsho. The rebirth may be discovered only after a long search. Sometimes more than one boy fulfilled all the indications. In such cases a preliminary selection narrowed down the number of candidates to three. The three candidates were summoned to Lhasa. Their names were written on scrolls of paper and deposited in a golden urn. After seven days of prayer, the lot was drawn before the Buddha image in the Central temple. The first name coming out of the gold urn was proclaimed the future ruler of the land of lamas.

During the absence of a dalai lama! such as the interval between his death and the finding of a successor incarnation or during the successor's years of minority, a regent was normally elected from among the highest incarnation lamas of Tibet, approved by a great assembly summoned by the government for that purpose. and invited to assume full responsibility for the government. The regent could also be appointed by the dalai lama before the latter's death. When the dalai lama attained his majority between the age of 16 and 18, the regent surrendered to him all governmental authority.

Under the dalai lama there were clerical officers recruited from the three monasteries, and lay officers! recruited from the nobility. Two first-class incarnation lamas were responsible for the dalai lama's education. A lord chamberlain. with three assistants, was in charge of the dalai lama's food, daily living and religious ceremonies. Under the lord chamberlain a secretariat was formed. There was a liaison office between the dalai lama's inner court and the outside world, including the Tibetan government,

Tibetan Government.—The highest office in the Tibetan government was called *shor*. This could be either a clerical or secular organization, and headed either by the dalai lama or by a regent. Skor also had a liaison office either staffed by the clergy or headed by a prime minister who was an eminent nobleman or a member of the dalai lama's family. Under the shor, was the cabinet (*kashag*), normally in the charge of four ministers (*shapes*). The leader of these ministers must be clerical: while the other three were secular. Under the cabinet was the secretariat headed by four monk officers and the finance office headed by four laymen. There was no organized law court and legislature in theocratic Tibet. The important business of government was handled by the 12 men mentioned above. A litigation case could be assigned to any government official and important cases entrusted to a committee by the cabinet. If the defendant considered he was unjustly condemned he could appeal to the dalai lama.

Special offices of industry and agriculture, and tea and salt taxation were created in the beginning of the 20th century. A bureau for external affairs was established in 1926, but abolished in 1951.

There was a national assembly (*tsongdu*) which did not meet regularly; both the agenda and the summoning were beyond the poner of the constituent members. The assembly was convoked by the order of the government to deal only nith specific issues. The four cabinet ministers fixed the number of participants on each occasion, and only those whom they invited could attend.

The assembly was composed of all state officials of. and above, the fourth rank, the abbots of important monasteries in and around Lhasa and certain members of the nobility. The cabinet ministers did not directly participate in the deliberations but sat in a secret chamber. The four grand secretaries and the four finance ministers presided over the conference. A motion was never put to vote. It was considered carried when all opposition was silenced. A resolution was submitted to the cabinet ministers and in turn transmitted to the dalai lama. When a resolution was found unacceptable, it could be referred back to the assembly for further deliberation, but such an occasion seldom arose.

The state owned most of the land which could be granted to individual lama dignitaries and incarnations, or monasteries or assigned to different offices in the government for their maintenance. Family estates fell into two groups: one group was made up of granted estates which were perhaps given to the nobility and held by the male heirs of the families concerned, on the basis of one heir for one estate, and were indivisible and inalienable; the other group included the private holdings of the nobility and the small percentage owned by commoners. Eastern Tibet was ruled by hereditary noblemen who drew their incomes from the land cultivated by their subjects. On July 3, 1959, a program of reforms involving large-scale redistribution of land to the peasants and the abolition of feudal customs was announced in Peking. The estates of the temples and monasteries would not be exempted from this land reform.

In 1951 the representatives of the Tibetan government signed an agreement with the Communist government of China in Peking. Under this agreement the Communist authorities promised not to alter the existing system in Tibet, and would respect the established status, functions and powers of the dalai lama. Tibetan officials of various ranks were allowed to hold office as usual; and the people of Tibet had the right of exercising national regional autonomy. In April 1956 a preparation committee for Tibet Autonomous region was formally inaugurated. This committee had authority over the Chamdo Military commission, the Tibetan government under the dalai lama and the panchen kanpo lija, *i.e.,* its jurisdiction extended over all the territories under Tibetan control before "liberation." The dalai lama was the chairman of the committee, and the panchen lama and Chang Kuohua, the Peking representative in Lhasa were the two vice-chairmen. After the flight of the dalai lama to India in March 1959, the committee was reorganized and the panchen lama was made acting chairman.

Local Government. — Beside Lhasa and its suburbs, which were under the charge of two local administrations, there were in Tibet eight regional governments each under a governor. The most important of these was Kham which comprised the entire eastern Tibet. The governor of this region, stationed at Chamdo on the western bank of the Yangtze river, was given the rank of a cabinet minister. In 1950 eastern Tibet was occupied by the Chinese Communist forces and administered by a military commission. Under the jurisdiction of the regional governments were more than 50 magistracies. Most of the local areas were administered by both clerical and secular officers. Some local officers lived in luxury in Lhasa, while the local governments were in the charge of their private secretaries or stewards. Villages were administered by headmen.

ECONOMY

The economy of Tibet is still in a primitive stage. The nature of the terrain, the lack of rainfall and the severity of the climate impose a serious limitation on the development of agricultural resources. Industry is practically nonexistent. Trade is negligible, and mineral resources still await exploration. There is great livestock and timber potential, the principal drawback is the lack of modern transportation. After invasion by the Communist Chinese army in 1950, a few trunk highways were constructed. Subsequent surveys appear to confirm the conjecture of western explorers in the 18th and 19th centuries, that the Tibetan plateau is rich in mineral wealth.

Agriculture. — Agriculture in Tibet is almost completely of the subsistence type. Without irrigation the country is too arid to grow crops and cultivation is limited to river basins and the lowlands in southeastern Tibet. The soil is alluvial, often composed of sand blown by the wind to form a layer over gravels and shingles. and its colour is light brown or grayish, according to humus content, which is poor. For fertilizer, human excrement, ashes of cow dung and sometimes the fine silt from flood waters are used.

Barley is the staple food of Tibet. Rape turnips and peas are grown in sufficient quantities. In lower altitudes, wheat, buckwheat and millet are raised. Rice grows only in a limited quantity in the southeast section of the land. The Brahmaputra basin is the granary of Tibet and supports about 60% of the population. Whenever hill streams are available, water mills are used for the grinding of barley into flour. In the northern plain radishes and potatoes are grown sparsely.

In the 1950s the Chinese Academy of Science set up experimental stations at Lhasa, Zhikatse and Chamdo. It was reported that barley of Shantung variety, spring wheat of northern China, cabbage. cauliflower, tobacco, hemp, tomatoes, sunflower and millet were found suitable to the local soil and climate.

Forestry. — In Tibet the most valuable woodland is in the Kham district, though extensive forest clad mountains are also found in the valley of the Sutlej river in western Ngari and in the Chumbi valley in central Tibet. The Pome area in Kham is estimated to contain 17,300 sq.mi. of virgin forests. In the late 1950s 30 kinds of trees including those of comparatively high economic value such as varnish trees, spruce and fir, were discovered. Conifers averaging 90 ft. high and some trees as high as 200 ft. with a girth of 5 ft. were reported and the estimated total forest timber resources in this part of Tibet alone was placed at more than 130,-800.000 cu.yd. Accessibility is the principal factor which controls its development. Chayre (Dzayul) is another district known for its profuse primeval forests.

Minerals. — Prior to 1950 no systematic mineral exploration was carried out or permitted by the Tibetan government, and mineral resources were the subject of wide speculation.

A modern scientific investigation was conducted by Swami Pranavananda, an Indian who made surveys in the 1930s and 1940s in the Mount Kailas and Lake Manasarowar districts in western Tibet. The specimens of minerals he collected were analyzed at Benares Hindu university. He discovered extensive gold fields in the district of Sankora; radium, iron, titanium and emery on the eastern shores of lakes Manasarowar and Rakas Tal; lead near Gemuk, arsenic and serpentine near Kungri-bingri pass; and large deposits of borax on the shore of Lake Tseti Tsho.

Following the capitulation of Tibet, the geological section of the Chinese Academy of Science dispatched investigation teams who reported the existence of many useful minerals including oil shale, asphalt, iron. magnesium, copper, lead, zinc, molybdenum, antimony, salt. soda, borax: glauber salt, sulfur, sylbite, alum, mica, barite, graphite, talc, gypsum, jade and china clay. A belt of iron deposits was located on the western bank of the Mekong river stretching for almost 25 mi. S. of Chamdo. The graphite obtained from Ningtsin was over 50% fine. Coal was also reported plentiful around Chamdo. Iron deposits mere also found in the Thanglha range on the border of Tibet and Tsinghai, containing ore in concentrated seams, of high quality and extractable depth. Three rich crystal deposits were found in the glaciers of the Sane range. In addition oil-bearing formations, large reserve of oil shales. arid coal mines were also unearthed as well as valuable lead. zinc and manganese deposits. The iron and coal mines in the Ngachuka area were reported in production in the late 1950s.

Water Power. — The swift-flowing rivers and mountain streams of Tibet have immense hydroelectric power potential, especially the Brahmaputra. However, only one small hydroelectric plant at Lhasa generating 2,000 kw. was in operation in the late 1950s. Communist China established a hydrographic station at Lhasa and ten substations in various parts of the country to measure the speed of the current and water level of the Brahmaputra, Kyi Chhu and Kyang rivers at different seasons.

Industries. — KO single modern industrial establishment existed in Tibet in the early 1960s. The largest handicraft industry is the weaving of woolen cloth. The spinning is done by hand and weaving by a wooden frame loom. All Tibetans do spinning in their spare time, and the weaving is done solely by women. The finished fabric is a kind of heavy coarse serge which, in addition to supplying the local needs, is exported to parts of China where there are Tibetan colonies. The second largest handicraft industry is carpetmaking which is centred mainly at Gyangtse.

Under the Communists the Lhasa power station was repaired and reinforced with three 360-kw. generators and in 1952 the Chinese army built an iron and woodworking factory. A new thermal electric station was installed in Zhikatse. An automobile repair works began operation in 1957 and a leather tannery was built in 1958.

Trade. — The Tibetans lead simple primitive lives; their wants are few. The main product is wool, which formed the principal item of export to northern India and Bombay. A small quantity came to the United States for carpetmaking. The famous fine "shaw wool," known as cashmere came from western Tibet. Other items of export were borax, salt, animal and animal products and medicinal herbs. Gold dust once important in the 18th century has dwindled to nothing. Some rock salt and borax was exported to Nepal. Bhutan and northern India.

Tea. the principal import was imported in the form of bricks from western China. The bulk came from Yaan. Tea bricks were packed in yak hides, which were not tanned but merely dried in the sun. Tea also served as a form of currency for a traveler in Tibet, was readily accepted everywhere, and was convertible into butter, barley flour or the local currency. Other exports from China were brocades, silks, chinaware, enamelware, canned foods, shoes and socks, shearing scissors; from India, felt hats, cotton and woolen cloth, tobacco, indigo, glass and ironware, petroleum, firearms, dried nuts; and from Nepal and Bhutan came rice and dried fruits.

Since 1953 Tibetan trade became a monopoly of the Chinese State Trading company. In India it is represented by the Hamalaya Trading company owned partially by Chinese and partially by Tibetans.

Finance. — The Tibetan government, prior to Chinese domination: derived its revenue from taxes, from landed estates owned by the government and from public funds loaned to private individuals at interest. Because of the scarcity of money most taxes including import and export duties were paid in kind. The taxes were paid to the district (dzong) offices and to special tax collectors who toured the country to assist with the collections. The district officers did not receive any salary from the central government. but subtracted a percentage of the take. The landlords paid their dues in grain which was stored in government granaries. Cash. butter. oil and meat was sent to the revenue office in Lhasa. Other articles were stored in the office of the local government to be disposed or sold as need arose. The tenants who worked on land directly controlled by the government paid poll taxes. The government also loaned its surplus to a privileged few, high government officials. priests and wealthy traders who made a profit by lending out the money at high rates of interest.

The chief expense of the government was the maintenance of the large monasteries in and near Lhasa. The government provided free breakfasts for thousands of lamas and spent large sums every year for building repairs but a far greater amount was spent on butter, used as oil for the myriads of lights which were kept burning day and night. The government paid only a nominal salary to the civil servants. The landed nobility lived on the income of their family estate and worked for the government as a duty. Those families which had no male heir or whose heir was too young to serve were obliged to pay the government an exemption fee. Those whose private incomes were too meagre to meet the demands of public officialslooked on gifts from interested parties as part of their remuneration.

The dalai lama had a private treasury and he owned some of the best landed estates in the country. He received offerings from pilgrims and from deceased persons and he shared the profit from wool and gold monopolies of the trade caravans. The accumulated treasures of his predecessors in the form of precious stones, diamonds, pearls, gold, silver and rare silks were part of his treasury. These had been hoarded for centuries and their value was incalculable. The expenses of the dalai lama consisted of the maintenance of his own household and private chapel, and gifts to his relatives and priests of the large monasteries.

Tibet had a currency system of its own, although much of its internal trade was transacted on barter basis. The monetary unit, the tanka, is a silver piece. The Tibetan government also attempted to mint gold pieces, but the mint was burned down after coining only a small number which are much sought by collectors. There was no bank in Tibet before 1950. Wealthy families left their savings with reputable traders who paid them interest or a share of their trade profit. The Chinese have established branches of the People's Bank of China in Lhasa, Zhikatse, Gyangtse, Chamdo and Gartok, have extended both commercial and agricultural credit and have introduced the Chinese currency.

Transport and Communications. — Before 1950, traveling in Tibet was done in the most primitive manner, either on foot or on the backs of animals. It was the deliberate policy of the Tibetan government to balk modern means of communications in order to keep the country difficult to access and to keep away outsiders.

For trading, the Tibetans relied on the centuries-old caravan routes, of which the most important were: Tsinghai (via Nag Chhu), Sikang (via Chamdo), India (via Kalimpong and Yatung) and Kashmir (via Gartok and Leh).

Under the Communist regime, a network of motor roads was planned. Several trunk lines were completed, notably the Tsinghai and Sikang highways, and many secondary lines are under construction.

Air Transport. — The first air communication between Tibet and outside world was inaugurated in April 1956. The airport is located near Lhasa. There is unscheduled service with Chengchow via Jyekundo (Yushu). There are military airfields at Chamdo, Zhikatse and Gartok.

Railways.—There are no railways in Tibet. Ground survey for a new railroad was underway, preceded by aerial survey. The projected railway will be 807 mi. long with Sining and Nagchhudzong as terminals. It will pass through complicated geological and topographical regions and its average altitude will be more than 12,000 ft.

Postal and Telegraph Service. — There are about 50 postal and telecommunication stations in Tibet. including mobile units that serve remote border areas and geological, hydrological and construction teams. Tibet's postal network in 1956 covered 4.500 mi. according to an official Chinese report. See also Index references under "Tibet" in the Index volume. (T.-L. S.)

TIBETAN ART

TIBETAN ART is a religious art; it is an anonymous expression of the Tibetan religion, Lamaism (see TIBETAN BUDDHISM). It is anonymous because the artists regarded their work as an expression of religious faith and, therefore, a meritorious act. Buddhist art in Tibet was a continuation of medieval Buddhist art of the Pala kings who ruled in north India 750–1150 A.D. The art style is very conservative in that it follows definite rules which are described in the Buddhist canon (Tri-pitaka). The first paintings of this style are to be found in the cave temples of India. The

TIBETAN PAINTINGS

1. Painting of the learned Atisa. Figure of naked heretic near the halo, together with the figures of a sorcerer and his disciples, is reminiscent of Indian art. Numerous visits of this saint are represented by miniature scenes. At the top of picture (to the right of the aureole) he is seen acting as mediator between two armies about to fight

2. Representation of Lchang-skya Rol-pa' i rdo-je. Chinese influence shown by architecture of the monasteries in painting. The saint carries a book and sword, attributes of his patron, the celebrated reformer, Tsong Ka-Pa

3. Painting of the fifth Dalai Lama Ngagdbang Blo-bzang-rgya-mcho. He carries the thunderbolt and bell of the Buddha Vajradhara. Disciples and seven jewels are picturesquely grouped at bottom of picture

earliest images came to Tibet in the 8th century A.D. Before this time there was no literature, and except for prehistoric images, no art in Tibet. Buddhism introduced into Tibet not only religion, but culture, writing, art and other humanizing influences. Tibetan art should be discussed in order of precedence. Though there are innumerable images of the Tibetan pantheon, the painted scrolls or thang-kas are richer in iconographical material and yield more information on religious ideas and symbology.

Banners **(Thang-kas)**.—These paintings, or embroidered or appliqued pictures, are usually hung in temples or at family altars, carried by itinerant lamas in religious processions or used to illustrate sermons. A sized canvas is stretched on a frame and then rubbed down and prepared for the paint. An outline or transfer is usually used. The colours are made of vegetables, flowers and minerals boiled or ground and held together by glue or a binder. The important details of the work, such as the faces of the deities and the religious inscriptions are put in by the lamas. These paintings are mounted on a brocaded silk border; a flat stick is put at the top and a roller at the bottom. Sometimes, a thin silk dust curtain is put over the canvas to protect it from the smoke of the butter lamps used in the temples or on the altars. The materials used are fine Chinese or Japanese brocades. The paintings are used essentially for meditation. There are several general types.

Buddha. — Surrounded by deities or lamas, Buddha is depicted in episodes from his life and teachings. The saints are also shown in this way, preaching or teaching with their disciples around them.

Assemblage of Divinities. — This type is called Tshog Shing, "assembly tree," and shows a cosmic tree arising from the waters, through the earth and up into the heavens. On its branches are shown the various deities of the pantheon. It varies according to the four principal sects (Red Cap, Yellow Cap, Sa-kya-pa and Kargyupa).

The *Wheel* of Life. — Bhavacakramudra is the "Wheel of Transmigration." Buddha explained this to his disciples as the conception of the idea of birth and death, judgment according to karma, and rebirth. This is, perhaps, the most important tenet of Buddhism.

The *Intermediate* State. — This is a special type of banner. depicting the symbolic visions that occur to the deceased between the moment of death and rebirth in accordance with his karma, in one of the six regions depicted in the Wheel of Life.

Mandala.—Sometimes called the magic circle. This is usually geometric in design (an inner circle enclosed in a square nith four entrances). These mandalas have always exerted a particular fascination because in them art, magic and psychology combine. C. G. Jung, Richard Wilhelm and Heinrich Zimmer have made interesting attempts at psychological interpretations of the mandala. There are two kinds: painted mandalas, and sand or butter mandalas. The symbology of these mandalas probably comes from the yoga doctrine which teaches that by meditation and concentration the soul can obtain complete union with the divine. It is one of the means used by Tantric sects to achieve supernatural powers. The mandala is believed to be the "dwelling of the god." The deity resides in the innermost circle and by various incantations, offerings and disciplines, the devotee (sadhaka) invokes and finally identifies himself with him. The mandala is also a symbol of spiritual power because the devotee achieves the power of the deity. Coloured sand mandalas are usually used for ceremonies of initiation. They are technically of the same type as the painted mandalas, but are impermanent, being made on the ground and destroyed when the rite is over. The coloured butter mandalas are made for certain festivals and are used only for 24 hours and then destroyed.

Horoscopes. — These are banners with mystic symbols and diagrams, Chinese trigrams, signs of the zodiac, etc. They are used by the astrologer-lamas to prophesy the future according to the birth date of the person for whom the horoscope is cast. These are also painted on silk or paper, according to the wealth of the applicant.

Great Teachers. — Dalai and Tashi lamas and their antecedents are usually depicted in historical or geneological paintings and some of these are attempts at portraiture. Related to these are the "Eighty-four Great Sorcerers" (Musée Guimet, Paris).

Images. — The earliest images seem to have been imported from China and Nepal. Images cast in the northern monasteries, even in comparatively modern times, show Chinese influences, while those cast in southern Tibet show Nepalese influences. They are of enormous variety; there are from 300 to 500 deities in the pantheon, depending on the sect and the number of local deities. The materials used are gold, silver, copper, bronze, stone, wood, clay, butter and agglomerated materials. These images are of all sizes; huge ones are used in the temples, smaller ones are used on family altars, and others are carried about in little pocket shrines. The images are usually sculptured or cast in molds, or made by the cire perdue (lost wax) method and finished by hand. (See SCULPTURE TECHNIQUE.) A cavity is always left at the base of the image or at the back and this is filled with rolls of prayers or sacred relics. The image is then closed and consecrated by the lama. The contents are sometimes referred to as "sacred intestines."

Images are divided into two main types: the pacific and the angry. The pacific deities have mild, compassionate expressions and wear either simple monastic robes or elaborate princely robes with jeweled ornaments and crowns. These are the Buddhas and Bodhisattvas (potential Buddhas). Those of the angry group wear ornaments of skulls and carved human bones; they are called Dharmapala. Other images include fairies, heavenly musicians, astrologers, great magicians, the Great Teachers, Dalai and Tashi lamas and historical persons. Among the most interesting is a type called Yab-Yum ("father-mother"), which shows Buddhas in the embrace of their Shaktis or female energies. These symbolize the merging of Compassion (the male) and Knowledge (the female) and indicate the method and the way of attaining nirvana.

There are also a goodly number of images of a grotesque nature, such as winged or horned figures on mythical animals. Their origin, significance and dating are not known. They most likely relate to the earlier Pon religion.

Ritual Objects. — Lamaism, a religion with an abundance of rites, developed a wealth of ritual objects. Among these are thunderbolts and bells, prayer wheels. magic daggers, rosaries, clay tablets, wood blocks and too many others to mention. There are also butter lamps and bowls on the altars to hold incense, flowers and water. The eight auspicious Buddhist symbols, as well as musical instruments, are always in evidence. The thunderbolt (vajra) and bell (ghanta) are held in the hands of some of the Buddhas. The thunderbolt is the symbol of power, and the bell a symbol of the void or emptiness of existence. The prayer wheel is a round metal case or cylinder which revolves on a stick and is filled with a roll of prayers. Each revolution of this wheel is a repetition of the most popular Tibetan prayer, *Om.mani.pad.me.* hum ("Hail to the Jewel in the Lotus"). Magic daggers (phurbus) are used to exorcise evil. Ghost traps made of a frame ork of wood and surrounded in intricate fashion by multicoloured threads are used to entangle evil spirits or demons, and prevent them from entering the home and injuring the inhabitants. Prayer flags and prayer stones (mani) serve the same purpose.

Chronology. — There exists, as yet, no infallible means of identifying any Tibetan art work on stylistic criteria alone. Works have not been grouped chronologically in dynasties or periods as in China.

Dating is extremely difficult and, except when images are inscribed, unreliable. Since each type. gesture and symbol is prescribed in the canonical rules, it is practically impossible to differentiate an old from a more recent image. Images of historical teachers or Dalai or Tashi lamas, of course, cannot antedate the individual portrayed.

The dating of banners is controversial; rolled paintings or thang-kas did not appear until about the 10th century AD. Unless they are among the very few dated banners. such as the Lha-mo banners (illustrated in A. K. Gordon's Tzbetan Religious Art, pp. 36–39), it is difficult to assign them to a specific period The banner of Lha-mo has an inscription in four languages — Chinese, Mongol, Manchu and Tibetan — "Made by command of the Emperor Ch'ien Lung in the 42nd year of his reign" (A.D. 1777).

Collections. — At the Musée Guimet in Paris, there are several paintings showing Gsen rabs Mibo, the prophet of Pön, and some of the Pon deities. In the American Museum of Natural History, New York city, there is also a large group of unidentified images. The most comprehensive collections of Tibetan art in the United States are to be found at the American Museum of Natural History, New York; the Newark Museum of Arts and Sciences, Newark, N.J.; and the Cniversity of Pennsylvania museum, Philadelphia.

TIBETAN BUDDHISM. This article deals with the special form of Buddhism (*q.v.*) which has gradually evolved in Tibet since the 7th century A.D., when Tibetan rulers first began to take an active interest in this religion. It is also convenient to include the pre-Buddhist cults (known as Eon), for very little is known of them in their primitive form, whereas subsequently they have been so affected by Buddhist beliefs and practices as to have become just a rather incongruous sect of Tibetan Buddhism.

Lamas and Monasticism. — Tibetan religion attracts interest in the west mainly on account of its special system of reincarnating lamas. There are several hundreds of them, of whom the dalai lama and the panchen lama are incomparably the most important. Lama (*bla-ma*) means simply "superior," and is the normal polite title for senior monks and for those in the villages who act as the "priests" of their small communities as well as for the heads of teaching faculties in the larger monasteries and the principals of religious institutions, both small and large. In the case of such senior lamas suitably respectful epithets are added, but the term itself is of as wide application as the title "father" for a Christian priest. The reincarnating lamas (*sprul-sku*) are normally principals of monasteries and they have steadily increased in number since the 15th century (when the idea of identifying successors in this way gained general acceptance), for it greatly adds to the prestige of an institution to have an "incarnation" as its head. Nevertheless there still remain many institutions where other methods of succession are in vogue: by inheritance from father to son (in the case of married religious practisers), from uncle to nephew or by selection according to merit and learning. Of these last the abbot of dGa'-ldan (Ganden), one of the three enormous dGe-lugs-pa (Ge lug pa) monasteries on the outskirts of Lhasa, is the most important.

The widespread monastic system itself is but an elaborate development of the type of monastic life which is fundamental to Buddhism in all its forms. What is remarkable is the zeal with which the Tibetans have taken to religious life; no census has ever been made in the country, but a quarter of the population are probably members of religious institutions. Their religion serves as the basis of their whole culture.

Early History. — The first temples were built in the reign of Sron-btsan-sgam-po (or Songtsen Gampo; d. A.D. 649), who was also responsible for founding Lhasa as well as for establishing an official Tibetan alphabet based on the studies of one of his ministers, Thon-mi Sambhota. in Kashmir, which was then still a Buddhist country. Two of Sron-btsan-sgam-po's queens, one Chinese and one Nepalese, are popularly regarded as the earliest patrons of Tibetan Buddhism and thus identified as "incarnations" of the Buddhist saviouress (Tara). No spectacular progress was made with the new religion during the next hundred years, for the Tibetan leaders were engaged in conquering and controlling a huge central Asian empire, recognized under duress by the Chinese, from whom they wrested the important city-states of Kashgar, Kucha, Karashahr and Khotan on the ancient silk route, which skirts the Takla Makan desert. This brought them into contact not only with Buddhist communities but also with Manichaeans, Nestorian Christians, Arabs and Persians, followers of Islam. Central Asian Buddhism evoked active interest among the Tibetans: monks fleeing from Khotan were hospitably received by the Chinese wife (d. A.D. 739) of the Tibetan king Mes-'ag-ts'oms. monasteries being built for them presumably near Lhasa; moreover large collections of Tibetan Buddhist manuscripts preserved at Tun-huang attest the existence of Tibetan religious communities in the area. It seems that the royal family was eager to foster Buddhism, while ponerful ministerial chiefs were opposed to it. Royal authority was established during the long reign (755–797) of K'ri-sroṅ-lde-btsan (Khrisong Detsen), notable for three major events: the building of the first proper Tibetan monastery at bSam-yas (Samye) between Lhasa and Yarlung; the ordaining of the first seven Tibetan monks; and the holding of a council to decide the relative merits of Chinese and Indian forms of Buddhism. The Indian masters Sāntarakshita, representing orthodox Mahayana teachings, and Padmasambhava, manifesting the magic powers of a *mahasiddha* ("master yogin," of whom there are 84 in Sivaist and Buddhist Tantric tradition), nere responsible for the founding of bSam-yas; the views of Śāntarakshita's disciple Kamalaśīla prevailed at the council. Buddhist monks appear as ministers of state as early as the beginning of the 9th century. The third "religious" king of Tibet, Ral-pa-can (Ralpachan), who is credited with systematizing the methods of translating texts and establishing the Vinaya (monastic discipline) of the Mūlasarvāstivādin order or of Indian Buddhism as the sole orthodox Tibetan one, was murdered (838) by his brother, who thereupon set about destroying the new religion, at least in the region of Lhasa.

Ban.-Explicit references to Bon occur in the cycles of quasi-historical texts concerning Padmasambhava, who is honoured as the chief queller and converter of all forces hostile to Buddhism. The character of original Bon beliefs can be surmised from such textual references, but, since literature began in Tibet as a deliberate Buddhist concern, with the whole wealth of Indian literary traditions behind it, the Bon-pos were bound to use Buddhist terminology, often without realizing perhaps that it implied ideas that might be specifically Buddhist. That they later tried to have recourse to Hindu mythology indicates the fundamental weakness of their position. The original features of Bon seem to have been a cult of divine kingship whereby the kings were regarded as manifestations of the sky-divinity; an order of oracular priests; a cult of the gods of the atmosphere, the earth and subterranean regions; and the practice of blood sacrifices. All these features in a transmuted form have been absorbed into Tibetan Buddhism. While Bon-pos and Buddhists must both have had their interested supporters in 8th- and 9th-century Tibet, the chiefs of the country seem often to have used them as factions in political intrigues.

Tibetan Translations of Buddhist Texts. — Royal sponsors appeared again in the 10th–11th centuries, this time in western Tibet (mNa'-ris), namely Ye-Ses-'od and his brother Lha-lde, then the latter's sons, 'Od-lde, Byaṅ-c'ub-'od and Śiba-'od. They fostered learning and sent young Tibetans to India to study, of whom the most famous is probably the great translator Rin-c'en-bzaṅ-po (Rinchen Zampo; 958–1055). Large sums were expended buying the services and knowledge of Indian masters. One of the most renowned of these was Atīśa (or Atisha; 982–1054), who spent the last 12 years of his life in Tibet, surrounded by Tibetan disciples. From now on Buddhism seems to have had no determined opponents; the Bon-pos had already begun to produce their own literature on Buddhist models and were presumably often as interested in the latest Tibetan translations from Sanskrit as mere the Buddhists proper. When one remembers that much of this work was done by individual practisers of 'the doctrine, all folloning their own bent in translating philosophical or doctrinal texts, tantric cycles and their manifold commentaries, works on medicine, astrology, etc., it is remarkable what uniformity was eventually achieved.

By the 14th century the Tibetans had succeeded in translating all available Buddhist literature in India and Nepal. After the destruction wrought in the name of Islam, Buddhism had practically disappeared from India by A.D. 1200, and Nepal (primarily the Kathmandu valley) remained the sole representative of Sanskrit Buddhist culture. Practice of the doctrine rapidly began to deteriorate there, now that Indian inspiration was gone; meanwhile Tibet began to manifest itself as the chief inheritor of the whole Indian Buddhist tradition. No complete Indian canon of Mahayana Buddhism seems ever to have existed. But having collected and translated over the course of some six centuries all canonical and quasi-canonical texts, as well as the works of all Indian Buddhist writers, the Tibetans gradually produced their own canon, which had assumed by the 13th century more or less its present form. Consisting originally of a massive collection of manuscripts, this great work has appeared in several editions (printed page by page from incised wooden blocks) since the 16th century. It is arranged as 100 or 108 (depending on the edition) massive volumes of supposedly canonical texts (Kanjur, or Kagyur, "translated word") and 225 volumes of commentaries, scholarly treatises and miscellaneous writing by Indian masters (*Tenjur*, or Tangyur, "translated treatises").

Later Developments. — It has often been said that the Tibetans adopted only the more debased forms of Indian Buddhism, and the use of the term "Lamaism" has been used (like papism) to suggest a curious and falsified form of original teachings. In fact they adopted the whole of Indian Buddhism with its monastic life, its scholarly disposition, its ideal of the beneficent sage and its more popular conception of the wonder-working tantric yogin. Thus there are religious men of all kinds in Tibet: the wealthy benefactor sponsoring a new community, the independent seeker after knowledge (and sometimes the wealth that such knowledge brings), the pious monk spending his whole life translating texts, or the converted Bon-po striving to gain those special powers associated with proficiency in tantric practice.

Thus the earlier orders of Tibetan Buddhism began to develop quite spontaneously around the traditions associated with certain revered masters, but with no deliberate doctrinal or practical differences to distinguish them. The rÑiṅ-ma-pa (or Nying mapa; "old order") claimed to transmit the original teachings of Padmasambhava, the great tantric master of the 8th century, who was now identified as a Buddha. In support of their doctrines they began to "discover" texts, which had been "hidden" during the persecution following the murder of Ral-pa-can. Many of these texts, which were put together in the 12th and 13th centuries, do in fact contain very ancient traditions. The Bon-pos likewise began to discover their "hidden" literature, and the texts they produced were, needless to say, permeated by the same type of teachings. The founder of Sa-skya (Sakya) monastery (founded 1073), after which the Sa-skya-pa (Sakyapa) order is named, was simply a rÑiṅ-ma-pa who wished to establish sound doctrine. During the historical vicissitudes of the next two centuries. his successors, who were certainly learned, became the religious masters of the great Mongol Khans, from whom they received in return the mandate of political power throughout the whole of Tibet. (This political power was not held unchallenged; it endured about a century and even then the country remained more or less divided in allegiance to powerful monasteries and rival clans.)

Another important order, the bKa'-rgyud-pa (Kagyurpa; "order of the transmitted word"). was founded by the translator Mar-pa, aho had acquired his initiations and doctrines from the Indian tantric yogin Nāropa. Mar-pa was a householder; his chief disciple Mi-la ras-pa, the most renowned of Tibetan sages, was a solitary hermit. This line developed into a large number of subsects, all monastic in type.

Another order, generally reforming in intention, was associated with Atīśa or rather with his disciple 'Brom-ston, who founded Rva-sgreng monastery to the northeast of Lhasa. His order, known as the bKa'-gdams-pa (Kadampa; "precept giving") was absorbed in the 15th century by the last and now the most powerful of Tibetan religious orders, the dGe-lugs-pa (Ge lug pa; "the virtuous"), the order of the dalai lama and the panchen lama.

This last order was founded by an east Tibetan, Tson-k'a-pa (Tsong kha pa; 1358–1419), a scholarly writer and skilful preacher. who was intent on establishing monastic celibacy as the only legitimate form of religious life. He established a following in Lhasa, where he founded dGa'-ldan (Ganden) monastery. His immediate disciples founded two other monasteries, 'Bras-spuṅs (Drepung) and Se-ra, also on the outskirts of Lhasa. These subsequently became the main dGe-lugs-pa strongholds, dominating the capital with a joint total of about 20,000 monks. (The nickname "Yellow Hats" for the dGe-lugs-pa, commonly used by westerners. is possibly of Chinese origin. The corresponding nickname "Red Hats," as applied to all the other older orders, is a mistaken usage of foreigners, for it applies properly to only one subsect.) One of the most energetic organizers of the new order mas dGe-'dun-grub-pa (Gentun Drupa; 1391–1474), abbot of 'Bras-spuṅs, who was retrospectively recognized as the first rGyal-ba Rin-po-c'e ("precious conqueror"), the title by which Tibetans refer to the dalai lama.

The two foremost disciples of Tson-k'a-pa, namely rGyal-ts'ab-rje and mK'as-grub-rje (Khedru), acted as abbots of Tsoṅ-k'a-pa's own monastery, dGa'-ldan, and when mK'as-grub-rje died in 1438 dGe-'dun-grub-pa seems already to have resolved to find as his successor a boy born in the same year. Precedents for this practice can be traced back to the 13th century at least. The idea of a divine being manifest as a human teacher was already established in Indian Buddhism, and the theory of rebirth is of course fundamental to Buddhism in all its forms. It was by combining these ideas and claiming the ability to recognize one after another the representatives of such a series that the Tibetans devised a unique system of heredity. dGe-'dun-grub-pa died at the monastery of bKra-śis-lhun-po (Tashihlunpo or Trashi Lhümpo), which he had built (1447–52) in honour of his departed master, and a worthy successor was found as abbot. It was only later that his "reincarnation" was discovered. Thereafter however the system of reincarnations was accepted as the general rule. 'Bras-spuns became the seat of the "precious conquerors," and bKra-śis-lhun-po that of the "precious sages" (*Paṇ-c'en Rin-po-c'e*, the panchen lama). Political power over the whole of Tibet came to the fifth "precious conqueror" by the arms of the Mongols, who had been reconverted to Buddhism by his great predecessor, the third.

All the different orders have developed their own literary traditions, biographical, historical, doctrinal and liturgical, and thus the scope of Tibetan literature is now enormous.

Religious Theory and Practice. — In general, Tibetan religion represents the developed Mahayana Buddhism of India, which includes tantric theory and practice, known either as Vajrayāna ("vehicle of mystic power"; literally "thunderbolt") or Mantrayāna ("vehicle of mystic spells"), together with indigenous Bon notions which were easily adaptable. Thus the Bon idea of divine kingship finds a new Buddhist form in the theory of reincarnating lamas; the old priests of Bon now have Buddhist oracular soothsayers as their counterparts; the old local gods are now conceived of as serving the new religion and receive sacrificial offerings as a kind of fee for their continuing good will; the offerings consist of conventional sacrificial cakes, and the "flesh-offerings" prepared for bloodthirsty divinities are simply specially prepared cakes made to look sufficiently gruesome. Religious practice proper (study of religious texts. meditation, self-discipline and the practice of morality) is entirely Buddhist in character, and its efficacy as a way of perfection (in terms of the Buddhist ideal of blissful equanimity pervaded by loving kindness', is proved by the undoubted existence of a minority of very deeply religious men. as well as by the far greater number whose well-balanced personalities manifest the results of such a training. This is not to claim that Tibetans are always more virtuous than other peoples, though they are probably more morally conscious. Their religious susceptibilities are certainly highly developed, ranging from fervent and well-directed faith to vague superstition. Since 1950, however. when the Chinese communists invaded the country, Tibetan religion and culture have been put to a severe test; thus their future is dark and uncertain.

TIBETAN LANGUAGE, spoken in Tibet and in surrounding areas by about 5,000,000 persons, constitutes the aesternmost branch of the Tibeto-Burman languages (*q.v.*) and comprises a large number of dialects which fall into three main groups, the western, the central and the eastern. The literary form of Tibetan has been known since the 7th century. At that time Thonmi Sambhota. minister to King Songtsen Gampo, a devout Buddhist, nent to India. learned Sanskrit and invented the alphabet in which the Buddhist scriptures survive and which became the alphabet commonly used in modern times. The earliest stages of the language that have been reconstructed show a morphology consisting of prefixes and suffixes. By the time the written form became fixed the prefixes and suffixes were tending to disappear and to be replaced by features of tone accompanied by simpler forms with complex consonant clusters. This development was uneven in the various dialects. in some the clusters tended to remain; in others the tonal system developed. In general the colloquial language of modern times depends on word order and the use of particles to indicate syntactic relationships.

TIBETO-BURMAN LANGUAGES. The Tibeto-Burman group comprises languages spoken from Tibet in the north to Burma in the south, and from the Ladakh *wazárat* of Kashmir in the west to the Chinese provinces of Szechwan and Yiinnan in the east. Various Tibetan dialects are spoken all over Tibet and in the neighbouring districts of India and China. The Himalayan dialects are spoken in the southern Himalayas, from Lahul in the west to Bhutan in the east. East of Bhutan, to the north of the Assam valley, a third small group, the north Assam group, consists of three dialects. A fourth group, the Bodpo group, comprises a series of dialects from Bhutan in the north to the Tippera state in the south, which at one time extended over most of Assam west of Manipur and the Naga hills, and even far into Bengal proper. To the west of the Bodpos, and in the neighbourhood of the Naga hills is a fifth group, the so-called Naga group. It comprises dialects of very different kinds. Some of them approach Tibetan and the dialect of the north Assam group. Others lead over to the Bodpo languages, and others again connect the Naga dialects with their Tibeto-Burman neighbours to the south and east. To the south of the Naga hills, in the long chain of hills extending southnard, is a sixth group, the Kuki-Chin dialects. The old Meithei language of Manipur lies midway between this group and the easternmost branch of the Tibeto-Burman family, the Kachin group, in the tract of country to the east of Assam and to the north of upper Burma. including the headwaters of the Chindwin and the Irraa-addy. Finally there is Burmese, the language of the ancient kingdom of Burma.

The dialects spoken in the Himalayas and in Assam can be viewed as a double chain connecting Tibetan with Burmese, the two principal languages of the group. In the first place the Kachin languages run from the easternmost Tibetan dialects in Szechwan down to the Burmese of upper Burma. The second chain has a double beginning in the north, one line through the north Assam group, the Naga, Bodpo and Kuki-Chin groups, another line proceeding from Tibetan through the Himalayan and Bodpo groups into Kuki-Chin. and finally into Burmese.

The Tibeto-Burman languages are closely related to Chinese and perhaps distantly to Tai. The agreement is apparent in the phonetic system, in vocabulary and in grammar. Together all these languages are said to form one great family, called Sino-Tibetan or Indo-Chinese.

TIBULLUS, ALBIUS (d. c. 19 B.C.), Roman poet, the second in the classical sequence of Latin writers of elegiacs that begins with Cornelius Gallus and continues through Tibullus and Propertius to Ovid. Apart from his own poems, the only sources for the biography of Tibullus are a few references in ancient writers and an extremely short ***Life*** of doubtful authority. He was of equestrian rank (according to the ***Life)*** and inherited an estate, but seems to have lost most of it in 41 B.C. when Mark Xntony and Octavian confiscated land for their soldiers (Virgil, Propertius and Horace suffered in the same way). As a young man. however, Tibullus won the friendship and patronage of M. Valerius Messalla Corvinus, the statesman, soldier and man of letters. Despite personal reasons for staying at home, he mould even have accompanied Messalla on a mission to the east if sickness had not obliged him to remain behind when the party left Corcyra. and it is sometimes alleged that he accompanied Messalla's expedition against the Aquitanians. In any case, Tibullus was a prominent member of Messalla's literary circle. This circle, unlike that of Maecenas, kept itself aloof from the court of Augustus. whom Tibullus does not even mention in his poems. Tibullus seems to have divided his time between Rome and his country estate, strongly preferring the latter. The Albius addressed by Horace in Odes, i, 33, and *Epistles,* i, 4, is generally identified with Tibullus.

Tibullus' first important love affair, the main subject of book i of his poems, was with the woman whom he calls Delia but whose real name, according to Apuleius, was Plania. It is impossible to give an exact account of their intimacy, as the poems about her are not arranged in chronological order: sometimes he presents her as unmarried, sometimes as having a husband (unless the term *conjunx* is to be interpreted as meaning merely "protector"). It is clear, however, that Tibullus took advantage of the "husband's" absence on military service in Cilicia to establish his relationship with Delia and that this relationship was carried on clandestinely after the soldier's return until Tibullus discovered that Delia was receiving other lovers as well as himself; then, after fruitless protests, he ceased to address himself to her. In book ii of his poems Delia's place is taken by Nemesis (also a fictitious name). This Nemesis was a courtesan of the higher class, with several lovers. Though he complains bitterly of her rapacity and hardheartedness, Tibullus seems to have remained subjugated to her for the rest of his life. He died young, very shortly after Virgil (19 B.C.), as is proved by an epigram of his contemporary, Domitius Marsus. Ovid commemorated his death in his *Amores* (iii, 9).

Character and Style.—The character of Tibullus, as reflected in his poems, is an amiable one. He was a man of generous impulses and a gentle unselfish disposition. His loyalty to his friends is shown by his leaving Delia to accompany Messalla to Asia, and he was constant to his mistresses with a constancy that they scarcely deserved. His tenderness toward women is enhanced by a refinement and delicacy which are rare among the ancients.

Horace and the rest taunt those who reject their claims with the damage that the years will do to their beauty, but if Tibullus refers to old age, he does it by way of warning, not in a spirit of triumph or revenge. Cruelly though he may have been treated by his love, he does not invoke curses upon her. Instead he goes to her little sister's grave, hung so often with his garlands and met with his tears, and bemoans his fate there. Tibullus has no leanings to an active life: his ideal is a quiet retirement in the country with the loved one at his side. He has no ambition and no yearning for immortality. As he loved country life, so he clung to its faiths, and in an age of crude materialism and strange new cults he was religious in the old Roman way.

The poetry of Tibullus is distinguished by an idyllic simplicity, hut this is the simplicity of high art, not of unadorned nature. For grace and tenderness, for exquisiteness of feeling and expression, he stands alone among the Roman elegists: Quintilian, indeed, puts him at their head. In many of his poems, moreover, a symmetry of composition can be discerned, though they are never forced into any fixed or inelastic scheme. His clear and unaffected style, which made him a great favourite with Roman readers, is far more polished than that of his rival Propertius and far less loaded with Alexandrian learning; but in range of imagination, in power and originality of conception, in richness and variety of poetical treatment Propertius is much superior to him. In his handling of metre, likewise, Tibullus is smooth and musical, whereas Propertius, with occasional harshness, is vigorous and varied.

"Corpus **Tibullianum.**"—The works of Tibullus, as they have survived, form part of what is generally known as the *Corpus Tibullianum*, a collection of poetry which seems most probably to have been deliberately put together to represent the work of Messalla's circle; when and by whom this was done must in the present state of the evidence remain obscure.

The first two books of the collection are the undoubted property of Tibullus. Book i contains the poems inspired by Delia and also three elegies (4, 8 and 9) addressed to Marathus, a beautiful boy. These three elegies may reflect a literary convention, not the poet's actual feelings, as many of the sentiments throughout the book are those expected of the professed elegist: for instance, Tibullus' alleged poverty (i, 1) is at variance with the facts if he is the Albius addressed by Horace. The most interesting of the Marathus poems is that (4) in which the god Priapus is made to deliver a brief sketch of the art of love, the prototype of Ovid's fuller treatment of the same theme in the *Ars amatoria*.

Book ii is by no means entirely devoted to the liaison with Nemesis: it contains one of Tibullus's most characteristic and delightful poems, the description of a country festival (1).

The rest of the *Corpus Tibullianum* forms one book in the manuscripts; the division into two books, iii and iv, in modern editions is due to Italian scholars of the 15th century. Book iii contains six poems, the work of a poet who styles himself Lygdamus, an obvious pseudonym. They celebrate a lady named Neaera and are cultivated but on the whole undistinguished compositions. The writer's identity has been much debated, but remains unknown. If the *Corpus* does indeed represent the poets associated with Messalla, this Lygdamus should have been a contemporary of Tibullus and Ovid; and one couplet (5, 17–18) seems to indicate that his birthday was the same as Ovid's. This, together with the striking verbal resemblances which are found in his poems, has led some to identify him with Ovid; but neither this nor any other of the proposed identifications (with Ovid's brother, with Propertius, with Tibullus himself) mill stand scrutiny. (It seems certain, however, that the resemblances between the two poets are due to Lygdamus' having copied Ovid, not vice versa.)

The first poem of book iv, a panegyric on Messalla, is a turgid and worthless composition. The next 11 poems were occasioned by the love of Sulpicia (*q.v.*) for a young man called Cerinthus: poems 7–12 are Sulpicia's; 2–6 are usually thought to be by Tibullus. The whole cycle forms a unique and charming document for the literary life of Augustan Rome. The last poems (13 and 14), addressing an unnamed love, are likewise generally attributed to Tibullus.

The best texts are in the editions by J. P. Postgate, 2nd ed. (1915) and by F. W. Lenz (1959); that by K. F. Smith has an excellent introduction and commentary (1913). There are English translations by J. P. Postgate, in prose, with Catullus, in the Loeb series (1913), and by A. S. Way, in verse (1936).

TIC, a word derived from the French, means "a twitching"; a habitual, unpleasing gesture. A tiqueur is one who is afflicted with tic. "Tic" has largely replaced the obsolete term "habit spasm." It may be defined as a sudden, rapid, recurring contraction in a muscle or group of muscles; the movement is always brief, irresistible and limited to one part of the body. It does not interfere with the use of the part involved, and may be halted voluntarily but only for a time. As the tic movement becomes ingrained it is looked upon as a habit; the possessor becomes relatively unaware of its occurrence. Then a tic may be considered as involuntary. These characteristics of tic help to differentiate it from other involuntary movements, such as spasm, or the capricious, uninhibitable movements that may occur in chorea (St. Vitus' dance; *q.v.*) or in epilepsy (*q.v.*). Tics are not mannerisms.

While very nearly all tics are of psychological origin, similar repetitive movements have been observed in the late stages of encephalitis (*q.v.*). These movements that accompany brain disease may persist for years, but they tend to cease eventually.

Nervous children between 5 and 12 years of age are those most likely to have tics. but no age is immune. The movement appears when the subject is tense, and distraction will reduce it. The sufferer knows that he has a certain control of the movement but feels impelled to go through with it in order to feel better. Sometimes a group of tics occur in rapid succession, and the condition is then termed convulsive tic, a more severe form of the disease.

Tics frequently involve the face and air passages. The commonest tics are a repetitive grimace, blink, sniff, snort or click in the nose or throat, a twitch or a shrug. Tics occur in decreasing frequency from head to foot. The involuntary play of the facial muscles can be particularly looked upon as a model for tics.

Tics are the involuntary motor expression of emotional activity, a mimetic expression of the emotions, and they depend primarily upon the manner in which the *tiqueur* has experienced his early psychological and sexual development. Compulsion neurosis is common among *tiqueurs* (see NEUROSES). Compulsive neurotics are in conflict about certain of their feelings; they suffer from the irresistible impulse to perform some act contrary to the conscious will. In other words, the energy derives from the unconscious. The need to "get rid of" something is implicit in tic activity.

The use of the muscles for immediate discharge indicates intolerance of tension and inability to wait; the tiqueur feels impelled to make the movement in order to feel better. The tension is thereby discharged; in other words the person temporarily relieves himself—of what, he does not know. Such inability to wait is characteristic of the activity of children who have to learn how to accept delay of their gratifications and to channel their energies into socially acceptable activity. Should they continue this kind of intolerance into adulthood, the nervous patterns may gradually narrow their target to become a tic as the movement becomes more automatic than willed.

In persons with tic it can be determined that the usual outlets for expression of the emotions were denied in childhood: restriction of motility has resulted in an increased motor urge; overprotection, usually based on the mother's fear: has made the child emotionally dependent and lacking in self-control. Tics thus may be accompanied by other indications of maladjustment, such as bedwetting, feeding and digestive disorders and exaggerated fears.

The muscles are among the main avenues used by infants in the expression of the emotions, such expression appearing before that of speech in the developing child. It follows that primitive emotion relatively untempered by learning, or vulnerable because of bodily disease, may show itself by may of the muscular system. Somewhat later in development the musculature may be used to repress or restrain certain emotional expression. Confusion of muscular usage during formative years may result in awkwardness and other muscular problems such as "growing pains," and later, writer's cramp or certain arthritic conditions.

The treatment of the child with tic consists in paying little or no attention to it except as a warning that something in the family situation requires looking into. This most often turns out to be parental instability or disturbed family relationships. The older tic personality may respond to psychotherapy devised to mature the subject (learning why he behaves the way he does), who has usually retreated—in a defensive maneuver—to an earlier stage of psychological development where he feels more secure.

Usually there are features of both the compulsion neurosis and hysteria in tiqueurs. In hysteria (*q.v.*) repressed sexual energy is converted into symptoms. Where there is the capacity for relationship, prolonged uncovering psychotherapy may be helpful. (C. D. AR.)

TICHBORNE CLAIMANT, THE. Roger Charles Tichborne (1829–1854), whose family name became a household word because an impostor in 1868 attempted to impersonate him and obtain his heritage, was born at Paris on Jan. 5, 1829.

He sailed in March 1853 from Le Havre for Valparaiso, whence he crossed the Andes, reaching Rio de Janeiro in 1854. In April of that year he sailed from Rio and was lost at sea. His insurance was paid and his will proved in July 185j. The baronetcy and estates passed in 1862 to Roger's younger brother, Sir Alfred Joseph Doughty-Tichborne. who died in 1866. The only person unconvinced of Roger's death was his mother. She advertised for the wanderer, and in Nov. 1865 she learned, through an agency in Sydney, that a man "answering to the description of her son" had been found in the guise of a small butcher at Wagga Wagga, in Queensland. Lady Tichborne "acknowledged" him as her son when he reached Paris in 1867.

Other members of the family, however, obtained evidence that the claimant was identical with Arthur Orton (1834–1898), the son of a Wapping butcher, who had deserted a sailing vessel at Valparaiso in 1850, and had received much kindness at Melipilla in Chile from a family named Castro, whose name he had subsequently elected to bear during his sojourn in Australia. An ejectment action against the trustees of the Tichborne estates (to which the heir was the 12th baronet, Sir Henry Alfred Joseph Doughty-Tichborne, then two years old) finally came before the court of common pleas on May 11, 1871.

During a trial that lasted over 100 days over 100 persons swore to the claimant's identity, the majority of them—and they were drawn from every class—being evidently sincere in their belief in his cause. But the evidence of the Tichbornes finally convinced the jury, who declared that they wanted no further evidence. Orton was arrested on a charge of perjury and was brought to trial at bar before Chief Justice Cockburn in 1873.

The indiscretion of his counsel, Edward Kenealy, the testimony of his former sweetheart, and Kenealy's refusal to put the Orton sisters in the box, proved conclusive to the jury, who, on the 188th day of the trial, found that the claimant was Arthur Orton. Found guilty of perjury on two counts, he was sentenced on Feb. 28, 1874 to 14 years' penal servitude.

Orton died in obscure lodgings in Marylebone on April 2, 1898 (T. S.)

TICINO, a wedge-shaped Swiss canton, driven into Italy. Its northern boundary runs along the Lepontine-Adula alps, and its southern tip reaches beyond Lago di Lugano almost to Como. Historically, it represents early Swiss conquests from the duchy of Milan (see SWITZERLAND: *Hzstory*) loosely amalgamated to form one of the six cantons admitted to the Confederation in 1803. It is inhabited by Italian-speaking Catholics (see below). Its dominant physical features are the three river systems occupying steep-sided valleys which extend from a mountain frontier and drain southwards to Lago Maggiore. The most important system is the river Ticino, which rises in the canton southwest of St Gotthard, flows tomards that mass through the Val Bedretto, and then swings round at Airolo to a southeast course through Valle Leventina; near Biasca it receives the left-bank Brenno from the Val Blenio; the combined stream flows through the wide, low valley—the Riviera—until slightly above Bellinzona. where it receives another large left-bank affluent which has draihed the southeast slopes of the Adula group and reaches the Ticino via the Valle Mesolcina; the main stream curves again below the junction and enters the lake from the east. The Ticino receives no important right-bank tributaries. and the western part of the canton is drained largely by the Maggia and by its numerous right-bank tributaries, which receive torrent water from the western frontier. Between the Ticino and the Maggia is the Valle Verzasca.

The remainder of the canton lies south-southeast of this and consists of a triangular fragment of broken hill country, with a complicated drainage reaching the irregularly shaped Lago di Lugano.

Its total area is 1,085 sq.mi., of which approximately three-quarters are reckoned as "productive" (forests covering about 275 sq mi.). while of the remainder 28 6 sq.mi. consists of lakes. chiefly parts of Maggiore and Lugano; 13 sq.mi are occupied by glaciers. The canton is fifth in point of size, but only the much larger Valais and Vaud exceed its vine-growing area. The highest points are the Basódino (10,738 ft.), near the western border, southeast of the source of the Ticino, and the Rheinwaldhorn (11.161 ft.) in the Adula alps.

The amount of lowland is small, and occurs only in the lower river valleys and near the lakes. The lowest commune (669 ft.) is Vira (Locarno) on Lago Maggiore.

The main St Gotthard railway traverses the canton for about 75 mi. from Airolo, at the southern mouth of the tunnel, via Valle Leventina. Bellinzona, Lugano to beyond Mendrisio. Locarno is connected with this line; another follows the eastern shore of Lago Maggiore, and light railways ascend Valle Maggia to Bignasco, Valle Blenio to Acquarossa, and Valle Mesolcina to Mesocco; the latter two are electric railways. Mountain railways for the ascent of Monte S Salvatore (2.992 ft) from Lugano, and of Monte Generoso (5,584 ft.) from Capolago, have also been constructed in the extreme south of the canton.

In 1950 the population was 175,055 and in 1930 it was 159,223, of whom 145.347 were Italian-speaking, 11,662 German-speaking, and 1.278 French-speaking. The highest commune, Bosco-Vallem, near the western border and reached by the V. di Campo, had many German-speaking inhabitants, the result of an early movement eastward from Valais. There were in all 145,859 Catholics, 8,178 Protestants and 239 Jews.

In 1888 the diocese of Lugano (since joined to Basle) was created to replace the former purely Italian control over the canton by the dioceses of Milan and Como. Bellinzona (pop., [1950] 12.062) was the permanent political capital after 1881; formerly Lugano (pop., [1950] 18.122) and Lccarno (pop., [1950] 7,767) alternated with it at six-year intervals. Mendrisio (pop., [1950] 4.602) is the only other large settlement.

The canton has 261 communes and eight administrative districts; its constitution dates back to 1830, but the later political disturbances which characterize the canton have caused, and still cause, considerable modifications. The legislature (Gran *consiglio*) is composed of 65 members elected (since 1892) in the proportion of one to every 1,500 of the Swiss inhabitants. The executive (*Consiglio* di stato) of five members, is elected directly by the people. Both bodies hold office for four years. Any 5,000 electors have the right (facultative referendum) of claiming a popular vote as to bills passed by the legislature, while the same number of electors have the right of "initiative" in legislative matters, though 7,000 signatures are required in case of a proposal to revise the cantonal constitution.

History. — The canton is made up of all the permanent conquests (with one or two trifling exceptions) made by different members of the Swiss confederation south of the main chain of the Alps.

From an historical point of view Italian Switzerland falls into three groups: (1) the Val Leventina conquered by Uri in 1440 (previously held from 1403 to 1422); (2) Bellinzona (previously held from 1419 to 1422); the Riviera and the Val Blenio, all won in 1500 from the duke of Milan by men from Uri, Schwyz and Nidwalden, and confirmed by Louis XII of France in 1503; (3) Locarno, Val Maggia, Lugano and Mendrisio, seized in 1512 by the Confederates when fighting for the Holy League against France, ruled by the 12 members then in the league, and confirmed by Francis I in the treaty of 1516. These districts were governed by bailiffs holding office two years and purchasing it from the members of the league; each member of group 3 sent annually an envoy, who conjointly constituted the supreme appeal in all matters.

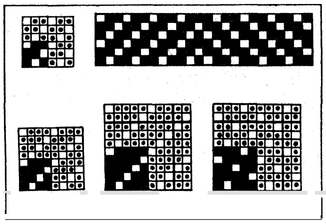
This government was very harsh and is one of the darkest pages in Swiss history. Vet only one open revolt is recorded—that of the Val Leventina against Uri in 1755. In 1803 all these districts were formed into one canton — Ticino — which became a full member of the Swiss confederation. After 1830 the local history of the canton was disturbed by friction between the Radical and Ultramontane parties.

TICINO RIVER (Ger. TESSIN, anc. TICINUS), of Switzerland and north Italy, which gives its name to the Swiss canton of Ticino (*q.v.*), and gave it in classical times to the town of Ticinum (Pavia). It rises at the foot of the Gries pass to the west of Airolo; from Airolo to the Lago Maggiore its valley bears the name of Val Leventina, and is followed as far as Bellinzona by the St. Gotthard road and railway. It flows through Lago Maggiore, leaving it at its south end at Sesto Calende, and thence flows south-southeast into the Po, which it joins a little way south of Pavia.

TICKELL, THOMAS (1686–1740), English poet and man of letters, the son of a clergyman, was born at Bridekirk near Carlisle in 1686. In 1715 Tickell brought out a translation of the first book of the Iliad contemporaneously with Pope's version. Addison's reported description of Tickell's version as the "best that ever was in any language" roused the anger of Pope, who assumed that Addison himself was the author, or had at any rate the principal share in the work. Addison gave Tickell instructions to collect his works, which were printed in 1721 under Tickell's editorship.

In 1724 Tickell was appointed secretary to the lords justices of Ireland — a post which he retained until his death, which took place at Bath on April 23, 1740.

TICKING. A strong linen, cotton or union fabric usually woven in stripes of colour; blue and red with white being the most common. The name is derived from a word "tick," common in various forms to many languages, signifying a case or sheath. Its original use was to enclose feathers, flocks or the like for beddings, but its use has been extended to include the covering for mattresses, and for awnings and tents. In some qualities it is also used as a foundation for embroidery.



VARIOUS TYPES OF TICKING

Top left, ordinary three-leaf twill; top right, "Arrow head" twill; left bottom and centre, four- and five-thread straight twills; right bottom, five-thread steen twill

White, gray or brownish warp threads are usually flax. while the coloured threads are often cotton. The weft is flax or tow. The warps of many of the cheaper kinds are made entirely of cotton, and jute is used for weft in the cheapest grades.

A feather tick should be made of fine flax yarns set closely! and there should also be a large number of weft threads per inch.

TICKLE GRASS (*Agrostis hiemalis*), a North American grass, called also hair grass and rough bent, found widely throughout the continent and in various districts occurring in weedlike abundance. The name is applied also to the somewhat similar witch grass (*Panicum capillare*), a common North American weed with hairlike flowering branches, and to some other grasses. At maturity the fruiting panicle breaks away and is blown about as a tumbleweed (*q.v.*).

TICKNOR, GEORGE (1791–1871), U.S. author and educator, was born in Boston, Mass., Aug. 1, 1791. He was educated at home by his father until at the age of 14 he entered Dartmouth college, Hanover. N.H.. as a junior, graduating two years later. In 1813 he was admitted to the bar, but soon decided against the legal profession as a life work. From 1815 to 1819 he studied in Europe, returning to the U.S. in the latter year to become Smith professor of French and Spanish languages and literatures. and professor of belles-lettres at Harvard. During his 16 years at Harvard, Ticknor was responsible for notable improvements in the university curriculum. In his own department. he introduced the study of contemporary writers, particularly in the romance languages, the language and literature curriculum having previously been confined almost exclusively to the classics. He was the first to suggest that Harvard be organized on departmental lines, a suggestion that was adopted a few years later during Charles William Eliot's presidency. From 1835 to 1838 Ticknor traveled in Europe, returning to work on his monumental History of *Spanish* Literature, which was published in three volumes in 1849, the first comprehensive study of Spanish literature. Ticknor was a founder of the Boston Public library and on his death left to it his large and valuable collection of books on Spanish literature. He was the author of a number of other works, of which the chief was a biography (1864) of William H. Prescott, the historian. Ticknor died in Boston, Jan. 26, 1871.

TICKNOR, WILLIAM DAVIS (1810–1864), U.S. publisher, head of one of the leading publishing houses of his time, was born in Lebanon, N.H., Aug. 6, 1810. Educated in the village school, at the age of 17 he went to Boston, where he spent several years as a clerk in the brokerage office of his uncle. and as a bank teller. In 1832 he entered the publishing business as a partner of John Allen, who retired the next year, leaving the business to Ticknor.

The company operated under various names during Ticknor's lifetime, eventually becoming Ticknor and Fields, when James T. Fields (*q.v.*) became his partner. The firm published the Atlantic

Monthly and the *North American Review* in addition to the works of such writers as Hawthorne, Emerson. Thoreau, Whittier. Longfellow, Holmes, Lowell. Browning. Tennyson and De Quincey.

Ticknor was a public-spirited man and a publisher of high integrity. In a day when piracy was rampant throughout the publishing business he consistently paid foreign authors for the American rights to their writings, and his example was instrumental in persuading other publishers in both England and the United States to do the same. He had a wide acquaintance among New England literary men and was a habitué of Boston's Old Corner bookstore, a rendezvous for writers. His most celebrated friend-was that with Nathaniel Hawthorne, which began in 1850. He often accompanied Hawthorne on travels and managed his business affairs. Ticknor died in Boston on April 10, 1864.

See Caroline Ticknor, *Hawthorne and His Publisher* (1913).

TICKS, the name for Acari of the order Arachnida (*q.v.*), of the families Ixodidae and Argasidae. They have on the head a median probe, armed with recurved teeth, which projects forwards. Ticks are of relatively large size, female specimens of some species measuring half an inch or more in length when distended after being gorged with blood. The mouth parts consist of two small retractile mandibles, a pair of short palpi and the toothed probe or hypostome. By means of the hypostome ticks pierce the skin and adhere to the host whose blood they

suck. In the Argasidae the palpi are simple; there is no sucker beneath the claws and there is only a slight difference between the sexes. In the Ixodidae the second and third segments of the palpi form a sheath for the hypostome; there is a sucker beneath the claws and the males have the dorsal integument continuously chitinized, whereas in the females only its anterior portion bears a chitinous plate. Both families contain pathogenic species. *Ornithodoros moubata,* belonging to the Argasidae, is widely distributed in tropical Africa from Uganda in the north to the Transvaal in the south. It is the carrier of the spirochaete of relapsing fever in man. An allied species, *O. turicata,* occurs in Mexico and Texas, where it is a pest to mankind and to poultry. *Argas miniatus* is the carrier of the spirochaete causing spirillosis in fowls in Rio de Janeiro and New South Wales. Among the Ixodidae several forms are injurious to man and domestic animals. *Dermacentor venustus* is the carrier of the human disease known as Rocky Mountain spotted fever. *Dermacentor reticulatus,* widely distributed in Europe, Asia and America, infects dogs with the hematozoon causing biliary fever. The same disease results in South Africa from the bite of *Haemaphysalis leachi. Amblyomma hebraeum,* the bont tick of the Cape Colonists, infects sheep with the sporozoon causing heartwater sickness, and in Europe sheep are inoculated with the same disease by *Rhipicephalus bursa.* The coast fever in cattle in South Africa is conveyed by *Rhipicephalus appendiculatus* and *R. simus. Margaropus annulatus* is the carrier of the germ causing the cattle disease known as Texas or xed water fever in America, South Africa and Australia. With one or two exceptions, no species of tick is confined to a particular host, and reptiles are infested as well as mammals. The bite of some ticks may produce a peculiar tick paralysis which disappears with the removal of the tick.

TICONDEROGA, a village in the township of Ticonderoga, Essex county, N.Y., U.S., on the outlet of Lake George, 100 mi. N.E. by rail of Albany. The settlement of the region was begun soon after the close of the French and Indian War and the township of Ticonderoga was set apart from the township of Crown Point in 1804. The village of Ticonderoga was incorporated in 1889. The name is a corruption of an Indian word said to mean "place between two lakes." The water from Lake George falls there about 222 ft., providing water power, and among the manufactures are paper pulp, fine grade paper and graphite. The population in the early 1960s was about 3.600.

Commanding a portage on the line of water communication between Canada and the English colonies, Ticonderoga was a place of considerable strategic importance during the French and Indian War. On an eminence overlooking the present village and Lake Champlain the French began building a fort of earth and timber in 1755 and called it Ft. Carillon. In 1758, uhen the marquis de Montcalm had gone to Quebec to oppose James Wolfe and a force of only 400 men was left at Ticonderoga, Lord Amherst with 11,000 men invested it, and on July 26 the garrison blew up and abandoned the fortifications. The fort was renamed Ticonderoga.

During the American Revolution, on May 10, 1775, a small expedition under Ethan Allen captured the fort by ruse instead of costly assault, securing large military stores. When the American expedition against Canada was driven back from Quebec they garrisoned Ticonderoga so strongly that the British commander, Carleton, shrank from attacking it. In 1777, however, Burgoyne's counter invasion from Canada arrived before the fort and occupied the precipitous Sugar Loaf hill which commanded the fort. The garrison, already reduced in numbers and supplies, felt compelled to evacuate it and on July 6 the British occupied it. Burgoyne, pressing onward to the Hudson, was driven to surrender at Saratoga in October; Ticonderoga was abandoned by the British immediately after this disaster, but was reoccupied by them in 1780. After the war it was allowed to fall into ruins but has been restored.

TICUNAN, a small group of tribes of South American Indians, constituting an independent linguistic stock. The Ticunas and their related tribes lived in western Brazil, on the lower Yavary river and on the main Amazon for some distance below the junction of the two streams.

TIDAL POWER. The idea of utilizing the rise and fall of the tides for power purposes has long attracted the attention of inventors, and many ingenious schemes have been suggested. So far, however, the only practicable method is based on the use of one or more tidal basins, separated from the sea by dams or barrages, and of hydraulic turbines through which the water is passed on its way between basin and sea or between one basin and another.

Types **of** Schemes.—Briefly outlined the more promising of the schemes of tidal power development are as follows:—

(a) A single tidal basin is used, divided from the sea by a dam in which are placed the turbines. The basin is filled through sluices during the rising tide. At high tide these are closed. When the tide has fallen through about one-half its range, the turbine gates are opened and the turbines operate on a more or less constant head until low tide or slightly after. If A be the surface area of the basin in square feet; if H ft. be the tidal range; if a constant working head of h ft. be adopted; and if the turbines operate until low tide; the volume of water used during the falling tide will be $A\ (H-h)$ cu.ft., and the energy available in the water will be

$$64A\ (H-h)\times h,\ \text{ft.lb. per tide.}$$

This expression is a maximum when $h=H\div 2$, that is, when the working head is one-half the tidal range, and then equals 16 AH^2 foot-pounds.

If A is in square miles, and if the efficiency of the turbines is 75%, the output in h.-p.-hours per tide is given by

$$\frac{0\cdot75\times64(5280)^2AH^2}{4\times33000\times60}=169AH^2.$$

The cycle of operations is shown in fig. 1 where AB denotes the working period and CD the period of replenishment of the basin. The sine curve represents the level of the sea outside the basin. Owing to the great variation in the rate of efflux of the water, in this constant-head method of operation, the power out-

Fig. 3.—Two tidal basins with turbines in dividing walls. Fig. 4.—Two tidal basins with turbines installed in walls dividing sea from each basin. The heavy lines show the water level in the basin at any instant, and the light lines show the sea level at the same instant. The shaded areas represent the working heads when the turbines operate

put varies very largely during the falling tide. This variation may be reduced considerably by allowing the turbines to operate on a more or less constant fall of level in the basin as shown by the straight full line AB. By this method of operation the necessary turbine capacity for a given output may be greatly reduced. By extending the working period beyond low tide, as indicated by the light line AE, a greater amount of energy may be developed per tide and the idle period is diminished, but at the expense of an appreciably greater variatior in head. The most efficient combination of working period and of working heads can only be determined by detailed examination of the particular site, and with a knowledge of the exact form of the tidal curve.

(*b*) A single tidal basin is used, with the turbines operating on both rising and falling tides. The cycle of operations is indicated in fig. 2. The working period per complete tide now extends from A to B and from C to D. Slightly before low water, at B, the basin is emptied through sluice gates, and at D, a little before high water, the basin is filled through the sluice gates. With a working head equal to one-half the tidal range, the period of operation is approximately 60% greater than in system *(a)* with operation down to low tide, and the work done is some 60% greater.

(c) Two basins of approximately equal areas are used, with turbines in the dividing wall. Each basin communicates with the sea through suitable sluice gates. In one of'these basins called the upper, the water level is never allowed to fall below one-third of the tidal range, while in the lower basin the level is not allowed to rise above one-third of the tidal range. The working head then varies from 0·53 H to 0.80 H, with a mean of approximately 0·66 H, and operation is continuous as indicated in fig. 3 which shows the cycle of operations. Between A and B, the upper basin is filled from the sea through appropriate sluice gates, and the lower basin discharges into the sea from C to D. For a given total basin area and a given tidal range the output is only about one-half that obtained in system *(a)* and one-third that obtained in system (b), so that except where the physical configuration of the site is particularly favourable the cost per h.p. is likely to prove very high.

(d) Two tidal basins of approximately equal areas are used. Turbines are installed in the walls dividing the sea from each basin. Fig. 4 shows the cycle of operations. From A to B the upper basin discharges through its turbines into the sea. From B to E the sea enters the lower basin through its turbines. The upper basin is filled from the sea through its sluice gates between C and D, and the lower basin is emptied through its sluice gates from F to G. The head varies from 0·25 H to 0·62 H, and the output is some 25% greater than in system *(c)* but the number of turbines required is much greater.

It is possible to arrange in each of these systems that the head shall be maintained constant during any one working period, but since this means that the working head is then limited to the minimum obtaining during that period, a loss of energy is involved, with a great additional cost of construction and complication in manipulation and with little compensating advantage. For any scheme of development involving the use of a tidal estuary of such types as are found in the Severn or Dee, the cost of any of the multiple basin systems would appear to put them definitely out of court. A scheme involving operation only on a falling tide has the disadvantage that the output is only about 60% of the output theoretically possible with double-way operation. On the other hand the output per unit of turbine capacity is sensibly the same, while it enables a much more efficient type of turbine setting to be used, and halves the number of sluice gates.

The Severn Scheme.—Up to 1928 no tidal scheme of any magnitude had been constructed. The possibilities of such an installation on the estuary of the Severn are, however, now under consideration by a committee appointed by the British Government. This would consist of a single tidal basin of about 25sq.m. in area formed by a barrage probably in the neighbourhood of Sudbury, along with a storage reservoir some 500ft. above sea-level and about 5m. away above the Wye valley. It is estimated that the scheme would be capable of developing some 500,000h.p. over a 10-hour working day throughout the year.

Fundy Bay Scheme.—Two schemes, each of the two-basin type, have been suggested for utilizing the tides in the Bay of Fundy (*q.v.*). From one of these, at Passamaquoddy Bay, where the average spring tidal range is 23·2 ft., it is estimated that from 500,000 to 700,000 h.p. can be generated. The other, which is a smaller but relatively less costly scheme, is at Hopewell at the head of Shepody Bay, and utilizes the estuaries of the Petitcodiac and Memramcook rivers as the two tidal basins. Here the spring tidal range is 45.5 ft. and the available power about 200,000 h.p. Both schemes have been before the New Brunswick Government.

Aber-Vrach Scheme.—A combined tidal and river-power scheme to which the French Government is giving financial assistance is projected at Aber-Vrach on the coast of Brittany. For the tidal station a barrage 490ft. long is to be constructed in the estuary. Four turbines connected to synchronous generators are to be installed, each capable of developing 1,200h.p., under the maximum head available at spring tides. The turbines are to operate both on the ebb and flow tides. This station will work in conjunction with an auxiliary water-power station some 4m. away on the river Diouris. The river is to be dammed at this point, forming a fresh water reservoir from which turbines having a maximum capacity of 2,700h.p. are to be supplied. Electrically driven centrifugal pumps of a capacity of 3,200h.p. will also be installed.

TIDES. The word tide refers to those alternating relative motions of the matter of a planet, satellite or star, which are attributed to the gravitational actions of external bodies. Such motions are known to occur in all three principal divisions of the earth. The alternating slight changes of shape of the solid body or lithosphere of the earth attributed to the gravitational action of the moon and sun are known as bodily tides. Similarly, there are the atmospheric tides in the atmosphere. and the familiar ordinary ocean tides in the hydrosphere. A still wider use of the word is based on descriptive instead of on causal and astronomical ideas, and takes for its criterion that the motions in question have certain features in common with ocean tides. This extension includes those long waves of the sea, or tsunamis, which are sometimes caused by earthquakes, as well as effects on the sea of variable atmospheric pressure and wind, known as meteorological tides. In this article tides will be considered under these sections:

I. ORDINARY TIDES

General Description of Phenomena.— At most seaside places the water reaches its highest level approximately twice a day, the average interval between two successive high waters being 12 hr. 25 min., though this interval varies considerably during the course of a week. At certain places in the East Indian seas two successive high waters are separated by an interval of 12 hr., while at certain places in the China sea the interval is often more than 24 hr. At places on the shores of the oceans the time taken by the tide in rising is about equal to the time taken in falling on the same day, but in estuaries the tide usually rises more quickly than it falls. At certain places, such as Southampton, Eng., the high waters are often doubled; *i.e.*, the water reaches a maximum height, falls a little and then rises to a maximum again. At other places the low waters are often doubled. As one goes along any stretch of coast the time of high water generally becomes progressively earlier or later, while as one goes up an estuary from the sea the time of high water always becomes progressively later.

At most places, on the average, a high water is about as much above the mean level of the sea as the succeeding low water is below it. The difference in level between successive high and low waters is called the range of tide. The range of tide at any place may vary much from day to day. At most places it reaches a maximum once a fortnight, and a minimum at times midway between two successive maxima. At London bridge the greatest range of the fortnight has an average value of 21 ft. while the least range of the fortnight has an average value of 15 ft. At the head of the Bay of Fundy the range of tide reaches 50 ft. while at certain islands of the Pacific and over most of the Mediterranean the range never exceeds 2 ft. At many places outside the Atlantic the heights of two successive high or low waters are markedly different, a phenomenon known as the diurnal inequality.

At a place in a strait or narrow sea the tidal current usually flows for about 6 hr. 12 min. in one direction, and then for about the same time in the opposite direction. At the reversal of such a current there is the state of rest usually called slack water. In estuaries the current generally flows downstream for a greater length of time than it flows upstream. At a place in the open sea the direction of the current often takes all points of the compass, making the complete revolution in the tidal period. During this period there are usually two times of maximum current and two intermediate times of minimum current. The times of maximum current are separated by about half the tidal period and the directions of maximum current are nearly directly opposite; similarly for the two minimum currents. There is no fixed general relation between the time of high water and the time of maximum current. If the current flows directly in and out of a bay it will reach its inward maximum nearly a quarter period before high water at the head of the bay, so that slack water is simultaneous with high water. On the other hand, in an estuary the current continues to flow upstream for some considerable time after high water and to run downstream similarly after low water. When the current is directed toward land or up an estuary it is called the flood current; when it runs away from land or down an estuary it is called the ebb current. The speeds of tidal currents vary greatly from place to place; *e.g.*, in the Seymour Narrows, British Columbia, the maximum current reaches ten knots; in the North sea it rarely exceeds one. At some distance up certain rivers—as, for example, where the Colorado river meets the tide—a wave ten or more feet high travels up the river almost like a wall of water. This phenomenon is called a bore. Near a headland separating two bays there is sometimes a swift current termed a race.

Relation to Motions of Moon and Sun.—The times of high water bear an intimate relation to the positions of the moon and sun. The period of 12 hr. 25 min. is half that of the moon's apparent revolution around the earth. The length of time between the moon's crossing of the meridian of a place and the next high water at that place is known as the lunitidal interval, or the high-water interval, for the place. Similarly, the length of time between the moon's crossing of the meridian and the next low water is called the low-water interval. For Philadelphia, the lunitidal average is 1 hr. 30 min. In many cases, including those of British waters, the chief variation in the lunitidal interval is associated with the phase of the moon. The average value of the lunitidal interval on the days of new and full moon is known as the establishment of the port. For London bridge the establishment of the port is 1 hr. 58 min.

The range of tide may be similarly correlated. In British waters it reaches its maximum a day or so after new and full moon and its minimum a day or so after the quarters. In these circumstances the maximum tides are known as spring tides and the minimum tides as neap tides. About the time of the equinoxes spring tides are generally larger and about the time of the solstices they are generally smaller than usual. The average interval between new or full moon and the next following spring tide is known as the age of the tide at the place in question. At certain places in Canadian waters the chief variation in the range of tide is associated with the varying distance of the moon from the earth, while at others it is associated with the varying declination of the moon. The diurnal inequality is always associated with the declination of the moon or sun. But the most complete correlation between the tides and astronomical variables is provided by the harmonic methods.

II. HISTORY OF THE STUDY OF TIDES

The writings of various Chinese, Arabic and Icelandic authors show that they paid some attention to the tides, but the theories advanced are fantastic. The writings of the classical authors of antiquity contain but a few references to the tides, for the Greeks and Romans lived on the shores of an almost tideless sea.

Johann Kepler in the early 17th century recognized the tendency of the water of the ocean to move toward the sun and moon, but Galileo's explanation referred the phenomenon to the rotation and orbitalmotions of the earth. It was Isaac Newton who, in his *Principia* of 1687, laid the foundation of the modern theory of the tides when he brought his generalization of universal gravitation to bear on the subject. He gave a geometrical construction for the tide-generating force, and calculated the magnitude of the solar equilibrium tide. He considered a canal encircling the earth and applied to each particle of water the laws which he had deduced for a satellite. He accounted for many of the general properties of the tides, such as the phenomenon of springs and neaps, priming and lagging, diurnal and elliptic inequalities. The only important factor which he did not mention is the dynamical effect of the earth's rotation. Newton's work was continued by D. Bernoulli, L. Euler and C. Maclaurin who adopted not only the theory of gravitation but also Newton's method of the superposition of two ellipsoids. In 1746 Jean le Rond d'Alembert wrote a paper on atmospheric tides, but this work, like Maclaurin's, is chiefly remarkable for the importance of collateral points.

The theory of the tidal movements of an ocean was almost untouched when in 1773 Pierre Laplace first undertook the subject. In his *Mécanique célèste* he formulated the equation of continuity and the dynamical equations, and applied them to the case of an ocean covering the whole earth. He also established the principle of forced oscillations, which forms the foundation of the harmonic methods.

The connection between the tides and the movements of the moon and sun is so obvious that tidal predictions founded on empirical methods were regularly made and published long before mathematicians had devoted their attention to them. The best example of this kind of tide table was afforded by Moses Holden's tables for Liverpool, based on 20 years of personal observation by a harbour master named William Hutchinson. The use of automatic tide gauges appears to have begun about 1830.

The work of J. Lubbock, Sr. and W. Whewell is chiefly remarkable for the co-ordination and analysis of data at various ports, and for the construction of tide tables. Sir George Airy in his *Tides and Waves* of 1842 studied profoundly the theory of tidal motions in canals, while in 1847 and 1857 F. W. Beechy published the results of a survey of tidal currents over the Irish sea, the English channel and the North sea.

About 1863 W. Thomson (afterward Lord Kelvin) became interested in the problems presented by earth tides. In 1866 he took up the analysis of ordinary tidal observations and established the harmonic methods, which quickly developed. He introduced the rotation of the earth into the tidal dynamics of small seas, and in 1872 he designed a tide-predicting machine.

In 1874 W. Ferrel, of the U.S. coast and geodetic survey, published his *Tidal Researches* which included a harmonic development of the generating potential, and from the same year A. W. Baird, of the survey of India, organized a service of observation and harmonic analysis for Indian tides. In 1882 G. H. Darwin took up harmonic analysis and produced memoirs which for a long time formed the standard manual on the subject, and about this time J. E. Pillsbury. of the U.S. coast survey, began the observations of currents by means of current meters. In 1885 C. Borgen introduced new ideas into the methods of harmonic analysis. Between 1870 and 1890 F. A. Forel made illuminating studies of the seiches of Lake Geneva. Switz., and about 1890 M. Margules investigated the dynamics of atmospheric tides.

From 1894 to 1907 R. A. Harris, of the U.S. coast survey, published his *Manual* of *Tides*. This work contained charts showing cotidal lines for the whole world, based on theories and hypotheses the leading feature of which was the principle of resonance. It was assumed that in each ocean there exists regions capable of free oscillation with a period near one of the principal tidal periods, and that the nature of these free oscillations may be calculated approximately, without allowing for the earth's rotation or the interaction with neighbouring regions.

After 1900 a number of Scandinavian oceanographers, notably V. W. Ekman, O. Pettersson and J. P. Jacobsen, invented current meters and L. Favé observed tidal elevations in the open sea by means of his self-registering instrument.

In 1912 A. Blondel applied the narrow sea theory. through the principle of least action, to the tides of the Red sea. From 1913 to 1920 R. Sterneck and A. Defant developed the narrow sea theory with special reference to the Adriatic sea. Defant applied this theory to the Red sea, the Persian gulf, the English channel and the Irish sea.

After about 1895 the dynamical theory of tides and seiches was much advanced by the mathematicians: H. Lamb, H. H Hough, J. H. Poincaré. Lord Rayleigh. G. Chrystal. E. Fichot. G. R. Goldsbrough. G. I. Taylor, Harold Jeffreys, G. Bertrand, S. Goldstein and J. Proudman; while between 1920 and the latter 1950s much was done on the analysis of observations by A. T. Doodson, K. Hessen and H. Rauschelbach.

III. TIDEGENERATING FORCES

Dynamics of Earth-Moon System.—The moon attracts every particle of the earth and ocean. By the law of gravitation the force acting on any particle is directed toward the moon's centre, and is jointly proportional to the masses of the particle and of the moon, and inversely proportional to the square of the distance between the particle and the moon's centre. If one can imagine the earth and ocean subdivided into a number of small particles of equal mass, then the average, both as to direction and intensity, of the forces acting on these particles, is equal to the force acting on that particle which is at the earth's centre. If every particle of the earth and ocean were being urged by equal and parallel forces there would be no cause for relative motion between the ocean and the earth. Hence it is the departure of the force acting on any particle from the average which constitutes the tide-generating force. Now it is obvious that on the side of the earth toward the moon the departure from the average is a small force directed toward the moon; and on the side of the earth away from the moon the departure is a small force directed away from the moon. All around the sides of the earth along a great circle perpendicular to the line joining the moon and earth the departure is a force directed inward toward the earth's centre. Thus it can be seen that the tidal forces tend to pull the water toward and away from the moon, and to depress the water at right angles to that direction. In fig. 1 this distribution of forces is illustrated graphically. The relative magnitudes of the forces are given by the numbers on the figure, M being in the direction of the moon. The

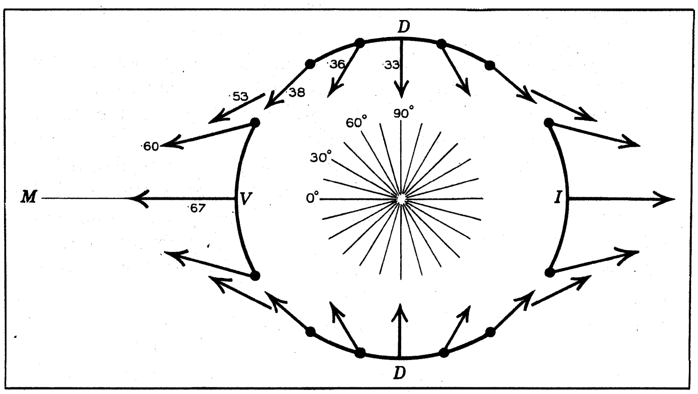

FIG. 1.— TIDE-GENERATING FORCE

separate attractions of the moon at the earth's centre and at a point on the earth's surface are each inversely proportional to the square of the moon's distance, so that the difference between the two, which gives the tide-generating force, is approximately inversely proportional to the cube of the moon's distance.

The vertical component of the tide-generating force coincides in direction with the gravitational force of the earth itself, and thus acts as a slight modification of weight. This component does not tend to alter the position of equilibrium which the water would take up in the absence of any disturbance from an extraterrestrial body. The effective tide-generating forces, therefore, are the horizontal components of those indicated in fig. 1.

Equilibrium Form of the Tide.—For many purposes it is convenient to specify the distribution of the tide-generating forces at any instant by reference to a fictitious tide. If a completely rigid earth were completely covered by a layer of ocean, and if the tide-generating forces were to remain constant, there would be an invariable elevation of water at each point of the ocean surface and no tidal currents. If the distribution of forces were the same as that of the actual tide-generating forces at any instant, then the consequential elevation of water might be used as a specification of these forces. This distribution of fictitious tidal elevation is known as the equilibrium form of the tide. It is a real and accurate specification of the actual tide-generating forces throughout the earth's body as well as on its surface. When the equilibrium form is stated for every instant there is a complete specification of these forces, and henceforth the terms equilibrium tide and tide-generating force will be used interchangeably.

In this equilibrium form the inclination, to the horizontal, of the surface of the water would be always such that the consequential pressure gradient would everywhere balance the tide-generating force. It is therefore clear that the surface of the water would slope upward from DD toward the points V and I, the water being raised by a maximum amount at V and I and depressed by a maximum amount along the great circle through DD. The surface of the water would be nearly that of an ellipsoid of revolution. The volume of this ellipsoid would be the same as that enclosed by the surface of the undisturbed ocean. Owing to the motion of the moon relative to the earth, the tidal ellipsoid moves over the earth so that V is always directly under the moon and I always directly opposite, while owing to the varying distance of the moon the equilibrium ellipsoid changes slightly in shape.

The tide-generating forces attributable to the sun's gravitation may be similarly specified. The sun's mass is nearly 27,000,000 times the moon's mass and the sun's distance is about 390 times the moon's distance from the earth. Consequently the sun's tide-generating forces are to those of the moon in the ratio of 27,000,000 to 390^3; *i.e.,* .460 or $\frac{1}{2.17}$. This means that at corresponding points of the two ellipsoids representing the lunar and solar equilibrium forms the tidal elevations on the average will be in the ratio of 2.17 to 1.

Harmonic Constituents.— The study of tides on the earth has been greatly facilitated by the fact that the tidal motions, whether in the atmosphere, hydrosphere or lithosphere, are to a high degree of precision linear with respect to the tide-generating forces which cause them. This will be demonstrated later in the case of the dynamics of the ocean tide.

The significance of this linearity is that the tide-generating force can be considered as the sum of a number of constituents, the actual tide being the sum of the individual effects that each constituent would produce separately in the absence of all the others. As an example, the lunar and solar tides can be considered separately. The tide which would be produced under the combined action of moon and sun would be almost exactly what one would obtain by adding the separate contributions of moon and sun. In other words, there is little interaction between the lunar and solar tides.

The tide-generating forces can be expressed quite precisely by a finite series of harmonic terms, and in practice it has been found. that about 30 terms generally give an adequate approximation. Furthermore, linear systems have the important property that their response is harmonic when they are acted upon by a force varying harmonically with time, the response having the same frequency as the force. The above two facts form the basis of the harmonic development of the tide, which has been in use since the time of Pierre S. Laplace.

Each term of the series representing the elevation of the equilibrium tide at some particular point on the earth's surface will be of the form H $\cos(nt-\epsilon)$, where t is time, H is the amplitude. n is the frequency or speed (commonly expressed in units of degrees per hour), and ϵ is the epoch. For any given constituent the speed is constant, while the amplitude and epoch are constant in time but may depend on geographical location. The harmonic terms representing actual tides will be of the same form. In the case of the ocean tides H may represent the amplitude of the elevation of the water surface relative to the ground, for bodily tides H may represent the amplitude of a component of particle displacement, and for atmospheric tides H may represent the amplitude of a pressure fluctuation.
