Congress declared all British vessels subject to capture and authorized privateering. In the aggregate, the Continental navy comprised about 60 ships and made an impressive showing. In addition to cruising against enemy merchantmen and British blockaders, the Continental vessels were required to make many voyages carrying diplomatic representatives and essential cargoes. Arrangements for the administration of the Continental vessels were not efficient, and the shortage of money imposed severe handicaps. Privateering offered much better financial inducements, and made recruiting difficult. Together the Continental navy and the privateers touched the pocketbook nerve of British merchants and each one of the many petitions to the king praying for ending of the war stressed the severe losses which the English mercantile community was suffering.

The Royal Navy enabled the British army to reduce Savannah, Ga., Charleston, S.C., and Wilmington, N.C.; it ravaged the coast of Connecticut, burned Norfolk, Va., Falmouth, Me., and other coastal towns while enabling the British army to strike at will along the seaboard. By 1778 Washington realized that he needed a superior French fleet to enable him to inflict a truly decisive defeat on the British, and thereafter he constantly urged on Benjamin Franklin in Paris the need for ships rather than French troops. In the battle of the Capes of Virginia, Sept. 5, 1781, a powerful British fleet was defeated by the comte de Grasse. The presence of the French fleet prevented the Royal Navy from rescuing the British from the Yorktown peninsula, and Washington forced the surrender of Lord Cornwallis. After the Revolution the Continental navy mas disbanded and the vessels sold. The first congress, under the constitution, provided for an army but decided that a navy was not necessary. Destruction of U.S. commerce by the Barbary states caused congress to authorize the building of six frigates in 1794 and to establish the navy department in 1798. Successes in the quasi-war with France in 1798 and in the Barbary wars gave Thomas Truxtun, Edward Preble and Stephen Decatur national reputations and provided the young navy nith experience and self-confidence.

The War of 1812 grew out of British impressment of U.S. seamen and other grievances connected with U.S. commerce. New England was not enthusiastic about the war, while the whole country was disappointed by the U.S. army's failure to occupy Canada. The overwhelming size of the British navy made possible a damaging blockade of all principal ports, enabled the British to capture and burn Washington, D.C., to attack Baltimore, Md., New Orleans, La., and various coastal towns, while driving U.S. shipping from the seas. U.S. victories in a number of frigate actions were helpful in keeping up the national spirit and added to the prestige of the navy.

Between 1815 and 1861 the U.S. navy appeared in seaports all over the world, assisted commerce, made treaties in the near east and far east, explored and surveyed unfamiliar areas, conducted many scientific expeditions and had a major share in ending piracy as well as suppressing the slave trade. The Naval academy was established in 1845 by George Bancroft, the historian, then secretary of the navy. In the Mexican war, 1846–47, the navy took over California and administered the government, besides escorting and landing the army at Veracruz for the capture of Mexico City.

When the Civil War began in 1861, the navy had about 10,000 officers and men and 90 ships. Only 42 of these ships were in commission and only 12 were in the home squadron. Many able and experienced officers "went south" and built the Confederate navy, with the assistance of about 2,000 guns and 11 ships captured with the Norfolk navy yard. On April 19, 1861, President Lincoln proclaimed a blockade of all southern ports. To many it seemed absurd to propose to blockade 3,000 mi. of seacoast with a small navy. Secretary of the Navy Gideon Welles, ably seconded by Gustavus Fox, assistant secretary, started immediately at the mouth of the James river, and before the end of Dec. 1861 more than 150 ships had been captured in attempting to evade the blockade. In November Adm. Samuel du Pont took Port Royal sound and established a base for blockading vessels. The blockade isolated the Confederate states and cut off overseas supplies of munitions. On March 8, 1862 the steam frigate "Merrimack" converted by the Confederates into an ironclad, appeared in Hampton Roads, Va., and sank two Union vessels, the "Cumberland" and the "Congress." For a time it was feared that the "Merrimack" could destroy the blockade, but on the very next day she was met by the "Monitor" in an epic fight, and she did not attack again. (See "MONITOR" AND "MERRIMACK," BATTLE OF.)

Although the Union navy had been an important element in the Civil War, it was thereafter neglected for many years. In spite of naval stagnation the U.S. Naval institute was established in 1873 for the advancement of professional, literary and scientific knowledge in the navy. The Naval War college at Newport, R.I., was established by Commodore Stephen B. Luce in 1884, and, in 1890, a member of its staff, Capt. Alfred Thayer Mahan, published The Influence of Sea Power Upon History, 1660–1783. Mahan's writings brought him academic honours at home and abroad, and the presidency of the American Historical association in 1902.

In 1883 congress appropriated money for building four steel warships and the navy took the radical step of insisting that the steel be of domestic manufacture, thus requiring the production of better steel in the United States.

The U.S. navy grew steadily in power and efficiency between 1898 and 1917. Pres. Theodore Roosevelt provided much of the impetus for the growth and aided in the national popularity of the service. He ordered a cruise around the world in 1907–08 which improved efficiency and had valuable diplomatic effects. In 1915 the office of the chief of naval operations was established, and in 1916 an important shipbuilding program, influenced largely by Japanese actions, was begun. During World War I U.S. naval vessels did not participate in any sea battles, but the navy was expanded eightfold and performed many important duties. The sea power of Great Britain, seconded by French and Italian fleets, had prevented a German victory in spite of the successes of the German armies. In April 1917, just after the U.S. entry into the war, German submarines were sinking Allied merchantmen at an alarming rate, but the assistance of U.S. destroyers, the adoption of the convoy system and a huge shipbuilding program in the U.S. overcame this threat. The navy laid an enormous antisubmarine mine field in the North sea, sent a battleship division to join the British grand fleet and a second division to Bantry bay to guard against heavy raiders, sent a naval aviation bombing squadron to France, provided a battery of heavy guns on railway cars for the western front and transported more than 1,000,000 troops to France.

World *War II.*—After the beginning of World War II in 1939 the U.S. navy began a huge building program of planes, warships, merchant ships, landing craft and various special types. A patrol was instituted in the Atlantic in 1939, Iceland was occupied in 1941 and the escort of convoys began in 1941. After the disastrous Pearl Harbor attack of Dec. 7, 1941, the U.S. navy helped seize French Morocco in Nov. 1942, and landed U.S. troops in Morocco and Algiers. It furnished sea and naval air strength for the seizure of Sicily, Salerno, Anzio and southern France. While combating German undersea warfare in the Atlantic, the navy furnished convoy escorts and special search groups including aircraft carriers, planes, destroyers and special antisubmarine vessels. In the Normandy landings of June 1944, the navy supplied large numbers of amphibious ships, landing craft, etc., as well as combat ships for fire support for troops. After the Pearl Harbor attack Japanese amphibious forces made landings in Malaya, the Philippines, South Pacific islands, New Guinea and the Netherlands Indies. Early in 1942 the Japanese were building up Rabaul as a great base and on May 8, 1942, in the battle of the Coral sea, fought by carrier planes, the U.S. navy checked the Japanese in their expansion southeastward. On June 4. 1942. the decisive battle of Midway was fought. Japanese battleships, cruisers, destroyers and submarines, as well as amphibious vessels, were in the area, and U.S. cruisers, destroyers and submarines; but the heavy blows were struck by carrier planes, and Japan lost its four best carriers together with all their planes and almost all their pilots. The U.S. navy suffered heavy casualties among carrier pilots and lost one of three carriers present, but to the Japanese the result was devastating.

Both the U.S. and Japanese navies had done far more than other navies in integrating aviation in their fleets. Japan began the war with excellent carriers and well-trained carrier pilots. The heavy losses of pilots at Coral sea and Midway were augmented in the battle of Santa Cruz and by misusing carrier pilots on shore at Rabaul later on. In consequence, Japan never replaced its "first team" of carrier pilots. In Aug. 1942 the U.S. marines landed on Guadalcanal in the Solomons, and this area became a battleground for six months. The naval battles of Savo Island, eastern Solomons, Cape Esperance, Santa Cruz, Guadalcanal and Tassafaronga were costly to the U.S. navy but even more costly to the Japanese.

Allied ground, naval and air forces under General MacArthur and Admiral Nimitz fought westward through the Solomons, Bismarck~Admiralties, Carolines and New Guinea, bypassing great bases in wide flanking envelopments, liberating and retaking the Philippines, cutting off Japan's supplies to the south and forcing the ultimate surrender. On June 15, 1944, Adm. R. A. Spruance struck the inner ring of Japanese defenses by landing marines on Saipan, and on June 19 fought the battle of the Philippine sea, which resulted in a further heavy loss of Japanese carrier pilots and planes, as well as two Japanese carriers sunk by submarines. The battle for Leyte gulf, fought Oct. 25, 1944, was one of the decisive naval victories of the war, along with Midway and the Philippine sea. Sea power was of central importance in the Pacific, destroying the Japanese merchant marine through submarine warfare, crippling its fleet and leaving great bases like Rabaul and Truk with large garrisons to die on the vine. (See WORLD WAR II: The War at Sea.)

Immediately following World War II navy development began to conform to the final lesson of that conflict, that all military forces serving the major powers must have a preponderant capability nith atomic weapons. Navy doctrine presupposed that the new age had not diminished the ancient authority of sea power but did require a radical overhaul of its floating combat structure.

World War II had proved that the main weapon of sea forces during the first half of the 20th century, the battleship, was no longer the decisive fleet element because of the ascendancy of air power, land-based and carrier-based. (See AIRCRAFT CARRIER; AVIATION. NAVAL.) The heavily armoured, heavily gunned but relatively sluggish battleship had no real utility within navy task forces and fleets which, striking at great speed over long range. were built up around the fast-moving carriers, covered by screens of cruisers and destroyers.

The essential idea controlling all navy reform mas that the fleet must be rebuilt to keep the seas under attack in any form while carrying atomic warfare against the most distant shore. The conversion program was necessarily slowed by the technical complexity of the problem and budgetary limitations. At mid-century the navy was under equal pressure to modernize and economize. While part of the fleet was being moth-balled to save money. the first experiments were run to prove that the cruiser is a suitable launching platform for guided missiles fitted with atomic warheads. Later, certain cruisers were converted into rocket ships. Of greater import was the construction of the U.S.S. "Nautilus." the first atomic-powered submarine. The "Nautilus" proved capable of cruising 50,000 mi. without refueling or overhauling. This range, more than her extraordinary speed and ability to run submerged indefinitely, infinitely extended the horizon for all sea power.

The unqualified success of the "Nautilus" established as an ultimate goal for the navy that all main fighting craft should be similarly powered. That attainment was far distant in the mid-1950's because of the costs of rebuilding. The atomic age had superinduced a trend toward supercarriers of the U.S.S. "Forrestal" class. The price of one vessel would have sufficed for a fleet in the early part of the century.

To conform with the weapons revolution, the indicated tactical change lay in a search for new dispersal systems whereby the fleet could be made more elusive under atomic attack, with its components scattering swiftly to achieve better individual concealment. All progress toward this end was perforce closely guarded by security regulations.

Being in early development, the modernization program was not importantly reflected in navy operations during the Korean conflict, 1950–53. Throughout, the navy remained unopposed by enemy sea power, and its only interference came from weak shore batteries, marine mines and occasional planes. Its vessels therefore moved with relative freedom where needed to assist land operations. One novel result was a continuing close support of the army combat line by carrier-based navy aviation.

In the decade which followed World War II, while the fundamental mission of the navy remained unaltered, the manner of its execution became transformed dramatically. This change came of U.S. leadership in the forming of the system of free-nation alliances with the object of containing Communist military power in Europe and Asia. In the pre-World War II period, navy power was based at home and its peacetime operations were in the main confined to home waters. Under the postwar policy, the preponderant parts of its striking force deployed to distant waters where they could exert, by their presence, a continuing restraining influence. One fleet became based on Formosa, another on ports of the Mediterranean and other task forces patrolled the contiguous waters. The rebuilding and resupplying of these deployed forces, toward preparation for the possibility of full-scale atomic war, continued.

After World War II the U.S. navy looked upon the attack aircraft carrier as a primary weapon in both limited and total wars. By 1960, however, a rival weapon had been developed in the area of total war. This was the large, fast nuclear-powered submarine capable of firing (even when submerged) intermediate range ballistic missiles of the Polaris type. Armed with nuclear missiles, these Polaris submarines represent a powerful weapon in modern warfare. The first three Polaris submarines were begun early in 1958. On July 20, 1960, the submarine "George Washington" successfully launched two Polaris missiles while submerged in the Atlantic ocean off Cape Canaveral, Fla.

3. Air Force.—The antecedents of the United States air force date back to the Civil War when the balloon (*q.v.*) was used for military purposes by the U.S. armed forces. In 1892 the U.S. army signal corps established a balloon section and subsequently interested itself in aeronautical experiments with heavier-than-air flying machines. On Aug. 1, 1907, less than four years after the successful flight of the Wright brothers at Kitty Hawk, N.C., the U.S. army organized an aeronautical division, consisting of one officer and two enlisted men, under the signal corps. The U.S. army accepted its first heavier-than-air flying machine, built by the Wright brothers, on Aug. 2, 1909. In 1913 the aeronautical division had a strength of 23 officers, 83 enlisted men and 15 flying machines. Before the United States entered World War I, the 1st aero squadron participated in the expedition into Mexico in pursuit of Pancho Villa in 1916. This venture was unsuccessfu! because most of the squadron's obsolescent aircraft broke down in the early stages of the campaign.

World War I.—When the United States entered World War I in April 1917 it found itself far behind the other warring powers in the quantity and quality of its military aircraft. The aviation section (the name had been changed in 1914) had 131 officers, including 112 qualified flyers, and 1,087 enlisted men organized into 7 flying squadrons with a total inventory of 103 planes, none suitable for combat. By the end of the war, the army air arm had attained a strength of 195,000 officers and men, and had organized 45 air squadrons with a complement of 740 planes, manned by 767 pilots, 481 observers and 23 aerial gunners. Until the later stages of the war, U.S. combat squadrons in France were equipped chiefly with French and British planes. In July 1917 congress appropriated $640,000,000 for the development of U.S. aircraft production capacity. By the end of the war the U.S. army in the zone of advance in France had received 2,925 airplanes, of which 696 were manufactured in the United States.

The most important U.S. combat action of the war occurred in Sept. 1918 when Col. William Mitchell (*q.v.*) led a force of almost 1,500 U.S., British and French planes in support of the offensive which reduced the St. Mihiel salient. In all, during World War I, U.S. army aviation carried out 13,000 pursuit flights, 6,600 observation flights and 215 bombing flights, dropping a total of 275,000 lb. of explosives. Losses in combat amounted to 289 planes and 48 balloons as against confirmed enemy losses of 781 planes and 73 balloons.

In May 1918 Pres. Woodrow Wilson established the air service, U.S. army, by executive order and gave it responsibility for army aviation. Not until after the war, June 4, 1920, did congress pass legislation formally establishing the air service as a combat arm of the army, with an authorized strength of 1.516 officers and 16,000 enlisted men, including not more than 2,500 flying cadets.

Rapid demobilization after World War I was followed by further retrenchment which left the air service well below the strength authorized by the Army Reorganization act of 1920. Continued use of large numbers of planes and engines left over from World War I, although economical, saddled the air service with obsolescent equipment for almost a decade after the war. Efforts to develop better planes and engines were pushed during the 1920s, but lack of funds and facilities seriously hampered such work. One of the more notable efforts of the years immediately following World War I was the developmental work on large bombing planes which, although unsuccessful in producing an acceptable plane, added much to technical knowledge. The movement for creation of a separate air force on a par with the army and navy had its most dramatic and forceful proponent in Brigadier General Mitchell, assistant chief of the air service between 1920 and 1925. Legislative attempts to establish a separate air force met with no success and Mitchell himself resigned from the army in 1926 after being court-martialed in 1925 for disobeying orders.

The Air Corps act of July 2, 1926, replaced the air service with the army air corps and created the position of assistant secretary of war for air. The air corps retained responsibility for training and logistical support of its units, but the combat units themselves were under the control of army area commands. Advances in aircraft performance, tactics and strategic thinking during succeeding years pointed to the need for more centralized control of the army's air striking forces. This need was met by the creation of the general headquarters (G.H.Q.) air force on March 1, 1935, with headquarters at Langley field, Va. Coequal with the air corps and independently responsible to the chief of staff of the U.S. army, this new mobile air force was composed of the combat air units within the conterminous United States.

World War *II*.—On the eve of World War II in Sept. 1939 the army's air arm had a strength of less than 27,000 officers and men and approximately 1,500 tactical planes. It possessed only 13 B-17 bombers, its chief claim to leadership in military aeronautical development. In all other types of aircraft, the U.S. army air corps was inferior to the German and British air forces.

Earlier in 1939, with the support of Pres. Franklin D. Roosevelt and the help of congressional appropriations, the air corps had launched a program to expand its strength to 5,500 aircraft, including reserves, organized into 25 combat groups. This program remained in effect until May 1940 when President Roosevelt called for an air force of 50,000 planes and an annual production rate of 50,000 planes. The air corps thereupon launched a series of expansion programs which did not cease until the peak strength was reached during World War II.

During 1941 the air arm gained increased stature within the U.S. army. In June 1941 the army air forces (AAF) was created and placed over both the air corps and the air force combat command (successor to G.H.Q. air force). The next logical step was taken after the outbreak of war, in March 1942, when the air corps and the air force combat command were merged into the army air forces under a single commander, Gen. Henry H. Arnold. From its headquarters in Washington, D.C., the AAF directed expansion of the army's air arm into a powerful global weapon, composed of 16 air forces (12 of them overseas), 243 combat groups, 2,400,000 officers and men and nearly 80,000 aircraft.

The rapid build-up of U.S. air power during World War II and its effective use relatively early in the war was made possible by the prewar preparedness measures begun in June 1940. The 18-month breathing spell before Pearl Harbor permitted the United States to lay the military and industrial foundations which proved so valuable once the war began. U.S. air power played a major role, and sometimes a decisive one, in every theatre of war. The strategy adopted by the United States and Great Britain in Dec. 1941 placed first priority on the defeat of Germany. It was in Europe and North Africa, therefore, that the greater part of the combat strength of the AAF was eventually concentrated and that the earliest results were achieved. But it was not until the tide of Japanese aggression had been checked in the Pacific during the summer of 1942 that the AAF could carry on a sustained build-up of air strength against Germany.

The AAF made the first major test of its doctrine of strategic bombardment against Germany. The 8th air force in England from Aug. 1942 and the 15th air force in Italy from Nov. 1943 carried out a sustained daylight bombing offensive against Germany, its allies and the occupied countries. In conjunction with the British Royal Air Force they did much to destroy and dislocate the German economic system and to weaken the morale of the German people. The B-17 and B-24 bombers and their escort fighters, P-38s, P-47s and P-51s, secured air superiority over Germany itself early in 1944, dealing the German air force such heavy blows that it was never thereafter seriously able to dispute control of the skies over western Europe with the Anglo-American air forces.

The AAF also deployed large tactical air forces against Germany and Italy. In North Africa, the 9th air force, operating from Egypt and Libya, and the 12th air force, in Algeria and Tunisia, joined with British air units to destroy Axis air strength and to sever the lines of supply to Axis ground armies. In Sicily the 12th air force helped force a quick victory in 1943 and from then until the end of the war it assured the U.S. ground forces in Italy of air superiority over the enemy. The 9th air force moved to England in Oct. 1943 and was greatly enlarged for its vital role in the campaign for the liberation of western Europe. After helping to soften up enemy coastal defenses and destroy transportation in western Europe in the weeks before D-day—June 6, 1944—the 9th air force followed closely behind the ground armies in the sweep across France and the Low Countries into Germany. It established air supremacy over the battlefields, protecting U.S. ground forces from enemy air attack and subjecting the German armies, transportation facilities and depots to incessant blows until the end of the war in May 1945.

In the Pacific the tide began to turn against the Japanese in the summer of 1942. Beginning with the conquest of Guadalcanal in 1942 (chiefly a U.S. marine corps operation), the Pacific air force—5th, 7th and 13th—joined with the army and navy in a series of island conquests which were steppingstones to Japan. New Guinea, the Marianas, the Philippines and Okinawa—in all of these campaigns the AAF, often in conjunction with U.S. navy and marine air units, secured the control of the air which had come to be indispensable to victory on the ground. On the mainland of Asia, meanwhile, the 10th air force helped turn the Japanese back from the gates of India and spearheaded the reconquest of Burma. The 14th air force in China, supplied by the massive air lift from India over the "hump" of the Himalayas, effectively challenged the Japanese in the air in spite of great odds and lack of bases. Meanwhile, the AAF had readied an instrument which was to deal out heavy punishment to Japan. After initial operations from India and China in 1944, the B-29 superfortress bombers of the 20th air force were concentrated at giant bases on Guam and Saipan in the Marianas. From there they carried out the fire raids which severely damaged the greatest Japanese cities and destroyed a large part of Japan's industrial capacity. But it was only with the dropping of atomic bombs on Hiroshima and Nagasaki on Aug. 6 and 9, 1945, that the futility of further resistance was brought home to the Japanese.

Behind the combat forces which won the air war in every theatre of operations stood a great array of manpower which provided the many services required by modern warfare. The training command, the air technical service command, the air transport command and a number of smaller commands provided the trained men, the matériel and the air transportation essential to victory. Their success demonstrated that the AAF had attained a degree of self-sufficiency which made it ready for independent status.

Post World War *II;* the Korean War.—The swift demobilization of the postwar period severely affected the combat capability of the AAF. Its strength shrank to 303,000 men in June 1947 and it could man only 38 combat groups, of which no more than 11 were operationally effective. Meanwhile, in anticipation of becoming an independent service, the AAF applied the lessons of World War II to its organizational structure, reorganizing along lines which placed emphasis on functions rather than geographical areas. The basic pattern of unit organization, in ascending order, was established as follows: flight, squadron, group, wing, air division, air force, command. The new command structure came into being in March 1946.

The National Security act of 1947 created the department of the air force and the United States air force, effective Sept. 18, 1947. As one of the three military departments under the department of defense, the air force helped develop a series of agreements which specified the functions to be performed by each of the military services. The air force received primary responsibility for air operations, particularly in the field of strategic bombardment.

Between 1947 and 1949 the air force carried out its separation from the army, progressively assuming almost all of the functions previously performed for it by the army. The Army and Air Force Authorization act of 1949 provided the air force with a legal framework, specifying its composition, personnel strength and authority with respect to expenditure of appropriated funds, procurement and research and development activities. The Air Force Organization act of 1951 for the first time placed the internal organization of the air force on a statutory basis. From its headquarters in Washington, D.C., the air force directed the operations of about 19 major field commands. Of these, the strategic and tactical air command and the air defense command carried out the prime missions of the air force. The strategic air command, based chiefly in the United States, contained the bombardment and reconnaissance units which were responsible for the conduct of long-range operations to any corner of the world. To permit the most effective use of the strategic air command's bombers, the United States built advance bases for them in Greenland, the United Kingdom, Spain and north Africa. During most of the first decade after World War II these units were equipped with B-29, B-50 and B-36 bombers. By 1954 the B-47 six-engine jet bomber had replaced the B-29 and the B-50, and in 1955 the B-52 eight-engine jet bomber began to replace the B-36 in strategic air command units. Escort fighter units were equipped with F-84s.

The tactical air command, composed of light bombers, fighters and tactical reconnaissance units, was responsible for air operations in support of the ground forces. By the end of the Korean war most of its units were deployed in oversea areas, particularly in the far east and Europe. Its most important aircraft types after 1946 included the B-26 and B-57 light bombers and the F-80, F-84, F-86 and F-100 fighter-bombers.

The air defense command received increasing emphasis after 1949 and by 1955 had equipped all of its interceptor units with jet fighters—chiefly F-86s, F-89s and F-94s. In 1954 also it became the major component of a joint army-navy-air force command charged with defense of the conterminous United States.

Overseas, the United States air force in Europe provided the American tactical air components of the North Atlantic Treaty organization (NATO) air force. The far east air force; stationed in Japan, Korea and Okinawa, was the other major oversea GSAF combat command. The Alaskan, Northeast (Newfoundland, Labrador) and Caribbean air commands were primarily concerned with the air defense of North America,

Supporting the combat forces were a number of commands providing essential services. The air matériel command procured the billions of dollars worth of equipment and supplies required each year by the USAF and distributed and maintained them, operating depots in the United States and overseas. The air research and development command, established in 1950, supervised an extensive program for development of more advanced weapons. The air training command provided the trained men who manned the combat and service units, while the continental air command directed the reserve activities of the air force. The U.S. Air Force academy, which enrolled its first class in 1955, gave the air force an undergraduate school comparable to the U.S. military and naval academies. The extensive graduate education system continued under the control of the air university, The air force also had primary responsibility for the operation of the military air transport service, a joint air force-navy command which provided air transport for cargo and personnel of all the services.

The Berlin air lift of 1948–49 provided a severe test of air force resources when it was still recovering from the effects of the postwar demobilization. From June 26, 1948 to Sept. 30. 1949 the air force, using chiefly C-54 transports, brought almost 2,500,000 tons of food, fuel and other supplies into Berlin to sustain the 2.250.000 people there who had been cut off from land communication with western Germany by the U.S.S.R. This costly effort, carried out in conjunction with the United Kingdom and France; had its compensations in the development or' advanced techniques by the air force.

The outbreak of the Korean war in June 1950 led to an immediate expansion of the strength of the air force. The 5th air force, which fought the air war against the North Koreans and Chinese. received strong reinforcements of fighter-bomber groups enabling it to control the skies over Korea throughout the conflict. Bombardment wings of the strategic air command also joined the battle for a time in 1950 and 1951, but the war was primarily a tactical one, and the opportunities for strategic bombing were limited.

In Europe, the United States met its commitments to NATO by deployment of additional combat wings, including B-61 guided-missile units, to the United States air forces in Europe. In the U.S. the air defense command established eastern, central and western air defense forces which increased their strength several times over by 1956. The strategic air command added more bombardment, reconnaissance and escort fighter wings to its strength, and like the other commands re-equipped its units with advanced aircraft models. Starring from a strength of 48 wings and 400,000 officers and men in June 1950, the air force reached a strength of 130 wings and almost 950,000 officers and men in 1956.

The post-World War II period was marked by a constantly accelerating technological competition among the air forces of the world. Progress in the United States between 1945 and 1950 was not as great as it had been during the preceding five years because the stimulus of war was no longer present and the possession of the atomic bomb appeared to be an overriding factor. But rapid technological progress in other countries, coupled with increasing international tensions, compelled the United States to accelerate its efforts. In the six years after the beginning of the Korean conflict, the air force equipped virtually all of its units, except for its transport fleet. with advanced jet aircraft. Developments in atomic and thermonnclear energy provided not only bombs for use in strategic bombardment, but a great variety of weapons which could be used by tactical air units against ground forces and small targets. By 1956 the air force had attained a thoroughgoing capability to use atomic and thermonuclear weapons for the fulfillment of all of its combat missions.

Even before the use of the V-2 guided missile by the Germans in 1944–45 the United States air force had been working to develop a variety of missile weapons. During the course of World War II the air force used a variety of rockets and guided bombs with varying success. But the ultimate goal of postwar research and development was the use of the atomic, and later the thermonuclear warhead, with a missile which could be guided accurately to targets many thousands of miles away. Pending the development of such a weapon—generally referred to as the intercontinental ballistic missile—the air force developed a number of special purpose missiles which met other needs. The first USXF guided missile actually placed in operational units was the B-61 Matador. a jet-powered: guided aircraft with a speed of approximately 650 m.p.h. and a range reported to be up to 500 mi. This weapon was intended for short-range tactical use, and units equipped with it were stationed in Europe beginning in 1953. The first successful U.S. air force missile for air defense use was the Falcon, an electronically controlled lightweight missile for air-to-air combat.

During the latter half of the 1950s the air force made tremendous progress in developing other air-to-air and air-to-surface missiles but its most striking advances were made with long-range ballistic missiles such as the Atlas (classed as operational in 1959), Titan and Minuteman. By 1960 the launching of earth satellites with the aid of such missiles had become almost commonplace and the air force was preparing to take a further step into space by launching and recovering a man-carrying space vehicle. *See* also AIR WARFARE; KOREAN WAR; MISSILES; ROCKETS; SPACE EXPLORATIOS; WORLD WAR II. (A. GG.)

VII. THE ECONOMY

A. GROWTH OF THE AMERICAN ECONOMY

In nearly all branches of production and trade, U.S. productivity greatly exceeds that of any other country and has, accordingly, established standards by which other nations measure their own efforts. In World Wars I and II, U.S. output of military supplies and munitions played a decisive part in determining the outcome. Finally, the United States, as the country whose productive system is the most highly mechanized, presents the foremost challenge to man's attempts to readjust his way of life and social relations under the impact of the machine age, with all its attendant problems and seemingly limitless opportunities.

Economists have become increasingly aware that U.S. industry and commerce can be adequately understood only as functions of the growth of the economy.

For the purposes of the economic historian, the interrelated growth processes of innovations in industrial methods or products provide a far more suitable framework for analysis than the political events about which the conventional historian organizes his data. Characteristically, the United States has furnished leadership in the number and extent of the transformations in economic life which it has achieved. Prominent among these are the development of shipbuilding and shipping before 1860, the mechanizations of agriculture, bulk processing of iron and other metals, the refining of petroleum for fuel, the mass production of durable goods, especially automobiles. the adaptation of electricity to practical purposes and the realization of atomic energy. But it is very likely that the most strategic redirection of the U.S. economy was set in motion by the era of railroad construction. This era may be roughly dated as occupying the second half of the 19th century, even though a final, diminished wave of construction marked the years between 1900 and World War I. From its earliest days, the new mechanical mode of transportation found a powerful ally in telegraphic communication.

The redistribution in the balance of world economic power brought about in part by this revolutionary mode of transportation favoured the continental nations far more than Great Britain, the country of its origin. At the time of the introduction of the railroad, no nation stood to gain more from exploiting its potentialities than the United States. Whatever the particular advantages enjoyed by other nations, none could claim the combination of advantages represented by a national territory second to none in its natural wealth and a system of social and political institutions which eminently fitted its people for commercial enterprise and industrial resourcefulness.

With nothing more than human or animal means of overland transportation, U.S. economic activity must have remained closely restricted to the coastal belts and inland waterways. Once mechanical means of transportation were available, however, the agricultural and mineral resources of the interior not only provided the country's industrial centres with much of their food and raw materials but also supported the markets which justified economically the introduction of heavy capital equipment for mass production.

If, measured by the criteria of industrial progress, the first half of the 19th century belonged to Great Britain, world leadership in the second half was so fully appropriated by the United States that by 1900 the nation's output exceeded that of Great Britain and Germany combined. An increase in population unprecedented for any western nation was accompanied by a similarly unprecedented rise in per capita income. Between 1860 and 1910 agricultural output more than quadrupled, although the proportion of the labour force employed on farms fell from approximately 50% to less than one-third. In 1890 manufacturing for the first time exceeded agriculture in its contribution to the national income. For these reasons, the second half of the 19th century may be regarded as the principal watershed in the economic development of the United States, separating the early and the modern periods. This threefold chronological division is in keeping with a premise of growth analysis that can scarcely be overstressed: growth, in the sense of progress rather than of mere expansion along established lines, implies the presence of elements of originality. Where powerful innovational factors are absent, economic activity is likely to remain repetitive and slow. It will generally be found that the directions of greatest advance in terms of physical volume are also those marked by the highest incidence of change in methods of operation or in the nature of products. Therefore, it is in the sources of differentiation from established patterns that the keys to the understanding of the dynamic economy are to be found.

From the First Settlements to the Mid-19th Century.— For more than two centuries, American industrial and commercial expansion took place along the lines characteristic of the colonial economy. The colonial economy is generally understood as one that is primarily dependent upon agriculture and relies on its capacity to extract raw materials to exchange for the manufactured or finished goods of more highly developed countries. The early American economy can be regarded as the classic example of its kind.

From the outset, the colonies possessed immense and comparatively rare advantages. Such natural endowments of the North American continent as its unusually high proportion of arable land and other natural resources and its extensive coastal and inland waterways are well known. Less often noted is the agricultural advantage arising from the geographic situation of the United States, which not only lies entirely within the temperate zone but also coincides with the southernmost half of that zone. This situation means a high average declination of the sun, providing long, warm growing seasons favourable to many important crops. Turning to the human resources of the colonies, circumstances were also advantageous. Consequent upon the Reformation in northern Europe, the desire for religious freedom provided a motivation for permanent settlement far more effective than the lure of adventure. The accumulation of dynamic forces was gradual. Necessarily, they demonstrated an unmistakable pattern of relationship with agriculture and the extractive industries. To cite only the most prominent examples, the establishment across the free or near-free lands of farm units larger in average size than those of densely populated Europe created an order of demand, in the form of agricultural surplus, for housewares and manufactured implements quite unlike anything known before. This demand largely explains the eventual development of a number of industries. By 1850 U.S. production of farm machinery led the world in scope as well as in the pace of technological improvements. The high relative value of human effort led to the ingenious improvement of tools, foreshadowing the great power tools and precision instruments of the 20th century. Simultaneously, a market was brought into being for what later became known throughout the world as American "specialties": the stock in trade of that primarily native institution, the hardware store, and the precursors of the 20th century's household appliances. The migratory ventures of great numbers of U.S. families necessitated the continual setting up of new households, resulting in an augmented demand for hard goods. The firearms industry thrived on the needs of pioneer settlers, preparing the way for the introduction of the system of interchangeable parts in their manufacture — a system which has become a primary technique of modern manufacture.

It was in shipbuilding and shipping that the greatest triumphs of early American industry and commerce were achieved. This great enterprise, too, rested squarely on extractive industries. Production flourished as a result of the large stands of virgin timber accessible to the sea or to river estuaries. The growing demand for ships arose from the needs of the New England fishing and whaling fleets and, even more, from the coastwise and overseas trades. The country's international trade, made up largely of exports of American raw materials and the import of European manufactures and oriental luxuries, was importantly supplemented by the "triangular trade" with the West Indies and Africa in which, dried fish and rum were exchanged for slaves and molasses.

Large numbers of ships were exported to Europe. As if either accomplishment were not impressive enough in itself, the United States concurrently made the steamboat commercially successful and produced the fastest wind-propelled vessel ever devised for commercial use. The "Yankee Clipper" symbolized, in its stark functionalism aimed directly at competitive efficiency, the spirit of U.S. enterprise. In 1855 shipyards launched a documented total gross tonnage in merchant sailing ships of 505,323, a record which was never equaled by their production of steam vessels until the defense shipbuilding of World War I. Especially in Boston and the other great ports of the northeast, the sailing and shipbuilding industries became the preponderant initial sources of U.S. capital. U.S. shipping, however, was to prove no match for British competition in the age of steam.

Subsistence farming and the domestic crafts constituted the overwhelming means of livelihood for the colonists. The principal support of the export trade, however, came from the staple or cash crops. In the southern colonies these were led by tobacco, rice and indigo until after 1793, when the cotton gin provided the keystone to the south's cotton empire, destined to produce 2,000,000,000 lb. annually by 1850. Lumbering, followed by fishing, were the main resources of New England. The fur trade ran its checkered but significant course in the inland areas. In the middle colonies, wheat early became the principal staple crop. Flour milling made rapid strides in New York, Pennsylvania and Maryland, so that by the time of the Revolution the nation's exports of flour were exceeded in value only by those of tobacco. By 1850, however, the relative importance of the staple crops had changed radically from the pre-Revolutionary era. With the opening of the Northwest Territory, especially the Ohio river valley, corn (maize), utilized mainly for livestock feed, surged ahead to a value twice that of second-place wheat. Cotton, hay, oats, potatoes and tobacco followed in that order. The ascendancy of corn signaled U.S. emergence as the world's leading meat producer, foreshadowing extraordinary advances in the technology of meat processing.

Domestic coal production found difficulty in meeting the competition of British coal, upon which the colonies largely depended before the Revolution. Copper and lead were mined in very small quantities. Britain's lack of high-grade iron ores, however, provided the colonies with profitable conditions not only for the mining of ore but also for smelting. An act of 1750, partly motivated by the British government's disinclination to become dependent on the Baltic countries for the metal, admitted colonial pig iron to the mother country duty free. The stimulus to the American mines and smelters increased steadily. By mid-19th century annual production exceeded 2,000,000 long tons.

Given the state of the industrial arts in the world at large before 1850, it is clear that the country's progress at the higher levels of production would be determined by its ability to invade textile manufacturing, the original home of the British factory system. But it was just there that Britain's head start in manufacturing efficiency, coupled with labour costs as much as 50% lower, prevented U.S. producers from competing strongly not only in overseas markets but even domestically. Moreover, the widespread dispersion of the population in rural areas favoured the continuation of household output, which as late as 1830 provided more than two-thirds of the nation's supply of cloth. Meanwhile, the opposition of the southern states kept tariffs on textile imports quite low before the Civil War.

Nevertheless, as cotton fabrics came to be accepted as substitutes for those of flax and linen, after about 1800, small mills for carding and spinning yarn sprang up along the streams of the northeastern states. Significantly, the early textile entrepreneurs were supported in one direction by capital accumulated in the shipping industry and in another by espionage measures that penetrated the jealously guarded secrets of the Lancashire cotton mills. Mechanical weaving of cloth was first successfully applied to cotton and then to wool. By 1850 the volume of cotton consumed annually by the industry, destined to approach 4,000,000 bales by the end of the century. amounted to 575,000 bales. With the value of cotton goods roughly twice that of woolens, the trade by mid-century supplied the major share of the domestic market and became for a time the country's leading industry. Not until the second half of the century, however, following the improved application of steam power and the erection of higher tariff barriers, did U.S. production challenge Britain's long-standing supremacy.

In the case of metal processing or manufacture. American progress was divided. In the 18th century domestic iron rolling and forging was extremely localized. The wars between 1776 and 1815 provided the impetus and capital for some sizable foundries, of which the largest were in Pennsylvania. In the interim, however, British technology had made giant strides, principally related to the substitution of coke for charcoal which made possible better control of the properties of steel, but also including improvements in puddling and rolling. U.S. supply conditions hindered use of coke before 1840, when the Pennsylvania mills initiated methods for the employment of the state's abundant anthracite. Consequently. the industry, despite high tariff protection, remained backward before the 1850s.

To sum up, the economic growth of the United States during this period remained in the shadow of Britain's epochal advances, which are commonly regarded as having reached their peak between 1770 and 1830. With some signal exceptions, the founders of the new nation were content to consolidate their economic hold on the new continent, exporting raw materials but remaining inferior to Britain in the production of finished goods and relying on it for much of the real and money capital they required.

Building the 20th-Century Power Base, 1850–1910.—The tremendous growth of U.S. industry in the form of mass production and of U.S. domestic commerce in the form of mass marketing manifestly proceeded on rails, first of iron, then, under the prodding of Andrew Carnegie, of steel. The great gridwork of the railroad system rapidly harnessed the resources of the North American continent, attaining a mileage of 250,000 shortly after 1910, equal to more than 25% of the world total at mid-20th century. Early in the 1850s a rate of construction in excess of 2,000 mi. annually was attained; in the peak year of 1887 nearly 13,000 mi. of track were laid. Railroads both consumed and distributed unprecedented quantities of coal. Helping to bring together the twin essentials of steel manufacture, coal and iron ore, railroads became the steel industry's best customer and the prime shipper of its products. Nor should the consequences to human mobility be slighted. Later generations, conditioned to think of speed in terms of flight, forget that relative to the preceding transportation conditions, the contribution of the railroad to the speed of overland movement was at first more impressive than that of the aircraft.

In the midst of this profound economic reorganization of the country, a new industrial departure, destined to provide the impetus for the cumulative technological progress of the modem era, was set in motion. It was heralded by Carnegie when. speaking of the technical problems in steel production, he said: "Nine-tenths of the uncertainties were dispelled under the burning sun of chemical knowledge." For more than a century industry had found one of its main resources in scientific discovery, but Carnegie, taking his cue from Germany, undertook in 1873 the employment of highly trained scientists for full-time research on the properties of minerals. Applied scientific research, adopted as a department of industry, became the key to the great chemical processes that within a few decades were to derive from metals, coal, petroleum and even common clay a myriad of novel substances in the forms of elements, alloys and synthetics.

Meanwhile, almost as if by reflex action from the centralization of industrial activity which the railroad made possible, the movement toward consolidation of industrial po er got under may. The Standard Oil trust was organized in 1882 by John D. Rockefeller and his partners. In 1901 a near monopoly of the country's then greatest industry was attained when the United States Steel corporation was formed under the financial leadership of J. P. Morgan.

Except for cyclical interruptions (notably the panic years of 1857, 1873, 1893, 1907 and 1913), the era of continual accumulation of record-breaking statistics had arrived. Coal and steel production rose in close synchronization with the increase in ton-miles of freight carried by the railroads—from about 10.000,000,000 ton-miles in 1870 to nearly 150,000,000 000 in 1910. The output of coal rose from less than 10,000,000 tons in 1850 to 500,000,000 by 1910. The output of steel, less than 100,000 long tons before 1872, passed 25,000,000 by 1910. Comparable records in terms of rates of growth were established by copper, lead and zinc smelters. Although petroleum production was not to achieve its most notable expansion until the automobile boom of the 1920s, annual domestic output exceeded 200,000,000 bbl. by 1910, and this record, as Standard Oil's successful measures for gaining control of the industry demonstrated, was almost entirely keyed to rail transportation. From 1863 to 1899 manufacturing production (W. M. Persons' index of physical production of manufacturing) rose 705.3%, a greater relative increase than the 549% of the longer period of 1899 to 1947 (National Bureau of Economic Research index of physical output, all manufacturing industries).

The consequences for U.S. living standards were pronounced. Per capita income, which had risen little more than 10% during the first half of the 19th century, more than doubled during the second half. The actual increase of 105.3% was only slightly less than the 111.2% gain between 1899 and 1949. (Estimates derived from figures computed by W. S. and E. S. Woytinsky. *World Population and Production, Trends and Outlook,* p. 383, [New York, 1953], from original estimates of Robert F. Martin and, from 1929, the United States Department of Commerce. Estimates until 1859 are rough.)

The Modern Economy and the "Standard of Living."—From the outset of the 20th century the U.S. economy has led the world both in scale and in efficiency of operation. A few of the extremely large nations equal or exceed the United States in size of population or extent of territory. Only ,Australia, New Zealand and Canada come within 10% or 20% of matching its productivity as measured by the value of output per worker. The small populations of these countries and the relatively low productivity of the other larger nations have prevented any of them from remotely approximating the total output of the United States. According to the best available estimates, U.S. industrial productivity at mid-20th century was nearly two and one-half times that of any European nation and more than four times that of the Soviet Union, even with no allowance for the shorter U.S. work day. In agriculture the discrepancy was greater.

The decisive factor in the growth of U.S. industry and commerce has been the nation's successful maintenance of a unified economy of great scale. The intensive geographical and occupational specialization which has been the foundation of cost reduction mould have been possible on no other basis. Of the many directions that specialization has taken, the most fundamental has been that between agriculture and industry. The U.S. farmer forsook the domestic crafts in order to concentrate on the production of cash crops to exchange for manufactured goods. His opportunity of doing so was contingent upon the economy's ability to afford the costs of the necessary transportation. To meet these costs two conditions had to be fulfilled: first, an agricultural surplus sufficiently generous to support a large number of workers in the transportation, manufacturing and marketing trades; and, second, efficient, overland transportation. Concurrently, advances in physical mobility were augmented by increasing social mobility, an important aid to occupational differentiation. The U.S. economy has from the outset been predicated on such mobility and it is difficult to suppose that it can cease to be so except with most serious consequences.

With the establishment in the 20th century of high and steadily expanding rates of production, the American people were free, as no other people had been before, to turn their attention to the development of novel ways of disposing of the national output for purposes of consumption. Although progress in this direction has been by no means even, it has been very great and the advances have taken place on many fronts. In business it has made itself felt in the increasing stress which management has placed on marketing activities, of which advertising is the most conspicuous branch. Trade unions and social reform movements have tended to shift their emphasis away from rather intangible ideals toward more practically considered, material objectives. Above all, the aspirations of the general public have concentrated more and more intensively on that pre-eminently American goal, the "higher standard of living," which is not far from becoming the keynote of the modern socioeconomic system.

Consequently, the realization has forced itself upon economists that consumer behaviour plays a far more fundamental and positive role in the shaping of economic development than had traditionally been thought to be the case. Advancing standards of consumption are not merely a precondition of mass production. They have helped to shape the organization of industry and the structure of modern technology.

While certain aspects of the nation's greatly improved standard of living, such as the advances in conditions of health and sanitation, may meet all the tests of rational examination, many others, such as reduced working hours and higher real income, however beneficial they may be thought to be, owe a great deal to the custom-derived and comparatively unexamined impulses of the majority toward attaining the imagined gratifications of traditional wealth and privilege. It is in this area of motivation that the guiding principle underlying much of the pattern of consumer demand in the United States must be sought, especially the enormous emphasis on the acquisition of durable goods in general and mechanical household appliances in particular. The one form of gratification customarily associated with affluence which the modern economy cannot multiply—although it may offer substitutes for it—is direct personal service.

The application of assembly-line methods, classically illustrated by the automobile industry but earlier brought to a high stage of development in the manufacture of railroad rolling stock, permitted mass production of many kinds of durable articles. The widespread use of home appliances would not, however, have been feasible to anything like the same extent without the aid of electric power dispersible in minutely divisible doses. On the production side also, electricity made possible the introduction of any number of labour-saving devices ranging from the hand power tool to the elaborate computing devices which were becoming the instruments of automatic factory administration as well as of information gathering and manipulation.

Of the first five decades of the 20th century, only the fourth, disrupted as it was by the great depression, failed to show marked growth in the output of consumer durable goods. This was largely because of the sharp decline in automobile sales, particularly in the early years. All the same, unit sales of the four next most significant appliances, electric refrigerators, washing machines, vacuum cleaners and automatic ranges, rose steadily throughout the depression. Even more significant from the long-range point of view, the reorientation in social and political outlook brought about by this decade of unemployment and economic distress strengthened labour organizations and social welfare institutions to an extent which made secure earning power at increasingly high wages possible for great numbers of people. This, in turn, bolstered the purchase of durable goods in later, highly prosperous decades. Although this drive toward improvement in material possessions may be traced back to the 19th century when the sewing machine and piano were conspicuous examples, the 1920s must be recognized as the era in which the sharp rise in appliance ownership began, with enormous gains by automobiles, telephones and radios. Between 1929 and 1956 personal consumption expenditure on durable goods increased in constant dollars from $13,000,000,000 to $30,500,000,000 or 134.5%, while personal consumption expenditures as a whole rose from $107,300,000,000 to $222,500,000,000, or 107.4%. Even this statistical index greatly underestimates the growth in importance of consumer durable goods, since allowance is made neither for improvements in the ratio of quality to cost. which have been very great, nor for costs of operation, maintenance and repair. Nor are telephones and other installations not owned by the consumer included in the figures. If account is taken of the costs of household operation incurred for fuel, utilities (telephone and telegraph) and maintenance and repair of appliances and furnishing and the costs of private automobile operation and maintenance (motorists in 1959 spent more than $11,000,000,000 on gasoline and oil and nearly $6,200,000,000 for repair, insurance and other services), it will be found that consumers devote well over one-third of all personal expenditures to housing and durable goods and their upkeep.

This is a proportion unequaled by any other nation. In the case of many major mechanical household appliances, the number in U.S. ownership exceeds the total ownership of the rest of the world, and in many cases the odds in favour of the United States are manyfold. In the case of the most popular appliances—telephones, radios, television receivers, automatic ranges and washing machines—numbers in operation approximately equal or actually exceed (because of plural installations in many homes) the number of families in the nation.

This extraordinary dependence on consumer durable goods creates more than proportional problems for the stability of the economy, since the choice to buy or not to buy at a particular time is far more discretionary or easily deferrable than is the case with most perishable commodities, especially food. As the U.S. economist, J. M. Clark, pointed out at the time, the great depression which began in 1929 was severely aggravated by the disproportionate curtailment of durable goods purchases. Moreover, much of the growth of such purchases has been made possible by consumer installment credit. After 1959 consumer installment debt rose to an amount in excess of $35,000,000,000, and the majority of automobiles and major appliances were bought on the basis of time payments. Economists are not in full agreement as to whether installment credit institutions exert in the main a stabilizing or destabilizing effect on business fluctuations. Unquestionably, however, certain aspects of their activities, such as repossessions in times of mounting unemployment and reduced willingness to extend credit to poorer risks, work on the side of instability. In the great depression of the 1930s the Hoover administration, rightly recognizing the damaging effects of the collapse in speculative confidence in the commodity, real estate and securities markets, concentrated on measures to support credit, setting up the Reconstruction Finance corporation (RFC) and the Home Owners' Loan corporation (HOLC) to bolster the liquidity of firms and to prevent mortgage foreclosures, respectively.

TABLE XVIII.—*Private Gross National Product in Constant (1947) Dollars Man-hours Employed and Real Product per Man-hour by Major Sector of the United States Economy, Selected Pears, 1919–55*

	Private gross national product (in $000,000,000 of 1947 dollars)			Man-hours employed (in 000,000,000)			Real product per man hour (1947 dollars)		
Year	private	Farm	Private nonfarm	private	Farm*	Private nonfarm	Private	Farm	Private nonfarm
1919 . . .	100.9	17.3	83.6	100.1	23.6	76.5	1.008	.733	1.093

*These farm man-hours represent adult equivalent man-hours rather than those actually worked. They are estimated by the department of agriculture from results of farm management studies and show the number of man-hours adult workers would need to work to produce the output of a particular year. Estimates of the actual hours worked by all farm workers, including women and children, are not available, particularly for the earlier years.

Source: *Productivity, Prices,* end *Inco nes,* material prepared for the Joint Economic Committee by the Committee Staff (Washington D.C., 19571. Data are revisions by staff, Joint Committee on the Economic Report, of estimates of John W. Kendrick in his paper: "National Productivity and Its Long-Term Projection," Conference on Research in Income and Wealth (May 1951).

The Roosevelt administration added measures to stabilize prices. provide relief payments for the unemployed and supplement private investment with public projects. It is significant. however, that neither administration succeeded in restoring the consumer durable goods industries to capacity levels of operation. The percentage distribution of personal consumption expenditure on the purchase of durables fell from 11.9 in 1929 to a low of 7.5 in 1932. and as late as 1939 it was no more than 10.

Outside of narrowly defined economic considerations, the achievement of the American standard of living raised problems of a political and sociological nature. Anything capable of producing so dynamic and unprecedented an effect on the human imagination was bound to set in motion profound social and political repercussions both within the nation and throughout the world. This magnified the increasingly thorny problems of national policy arising from the need lo maintain a viable balance between military and civilian expenditure. Cnfortunately. the existence of some unemployment and even temporary saturation of the consumer durable goods market did not prove to be inconsistent with inflationary pressures. Nor could a further question as to whether the levels of human energy devoted to the production and consumption of material goods and automatic services were not already unduly high in contrast to those expended on the expansion of knowledge and improvement of education be settled on purely economic grounds. (D. E. R.)

B. PRODUCTION

1. National Product and Income.—Gross national product (GYP) measures output of goods and services in market value and reflects the total dollar value of production. National income (*q.v.*) represents the aggregate earnings of labour and property from current production, and includes compensation of employees. income of unincorporated enterprise, rental income and net interest. (See WEALTH AND INCOME.)

The department of commerce began publication of official national product and income figures in 1929, and Simon Kuznets and his associates at the National Bureau of Economic Research developed figures for the years 1919 through 1938. Kuznets' figures indicate a post-World War I depression trough of $67,400,000,000 for GSP and $59,400,000,000 for national income (from $73,200,-000.000 and $64,200,000,000, respectively, in 1919), and a climb to $91,100,000,000 and $81,600,000,000 in 1926. The official figures indicate a peak of $104,436,000.000 for GNP in 1929, a year in which national income reached $87,814,000,000.

Statistics for the next few pears reflect the precipitous fall from the prosperity of 1929 into the deep depression of the 1933s—in 1933 GNP amounted to only $55,964,000,000 and national income to $40,159,000,000—and the steady climb, interrupted by the brief recession of 1938. until by 1941 GNP totaled $125,822,000.000 and national income $104,710,000,000. During World War II a major increase in national output occurred, together with some price advances, and GNP and national income rose substantially to $213,558,000,000 and $181,428,000,000 in 1945. A postwar readjustment occurred in 1945 and 1946, but this setback was only temporary. GNP advanced at a rapid rate in the late 1940s and the 1950s By 1957 gross national product was at an all-time high of $440,328,000,000 and national income reached $363.951.000.000.

If the aggregate earnings of labour and property from current production are classified according to the form in which they accrue—compensation of employees. profits of corporate and unincorporated enterprises, net interest and rental income of persons. employee compensation and corporate profits show marked proportional increases from 1929, with parallel declines in the other income shares.

With the shifts in distributive shares there have been important changes in the industrial origins of national income. Such changes are indicative of the way in which the allocation of economic resources has altered to meet changes in demand for the nation's output. Income originating in each industry measures the earnings of the resources—both labour and property—utilized by it. Therefore. the breakdown of national income by industrial origin provides a measure of the net contribution to national output of each industrial segment of the economy. Manufacturing, trade and government have shown a continual growth in their relative contribution to national income from 1929, while the shares from other sources have either declined or remained fairly stable, Thus, based on U.S. department of commerce figures, manufacturing accounted for about 25% of national income by industrial origin in 1929, 29% in 1945 and 31% in 1957. Agriculture, forestry and fisheries: over the same period. dropped from 9.4% in 1929 to 4.5% in 1957, while the government's share rose from 5.8% to 11.8%.

The rise in gross national product reflects the combined influence on current market value of total output exercised by greatly increased physical volume and by much higher prices. Adjusting gross national product to constant dollars indicates the increase in national production, corrected for price changes. Table XVIII shows the private gross national product in constant (1947) dollars for selected years from 1919-55. It also presents estimates of man-hours employed in the economy and real product per man-hour—a fairly accurate estimate of productivity. After 1919 the rate of expansion in the real volume of output in the private sector of the economy averaged about 3% per year. The real product per man-hour (in 1947 dollars) increased from $1.008 in 1919 to an estimated $2.360 in 1956, an increase of 134%.

2. Agriculture.—From the early colonial period to the latter part of the 19th century, farming provided the major sources of income and employment for the nation. Although the rapid rise in production of manufactured commodities, together with increases in the related activities of finance and distribution, diminished the relative economic importance of agriculture during the 20th century, farm output in the United States in 1958 was five times that in 1870. Agriculture has met the ever-increasing demand from a growing population with a rising standard of living by increased productivity and more effective use of available resources. This has been accompanied by a relative decline in agriculture's utilization of the nation's manpower.

There are several reasons for this expansion in agricultural output. Extension of total cropland was a leading factor in increasing production between the Civil War and World War I. Between 1870 and 1920 the number of acres of land in farms more than doubled. The large immigration and expanding population provided both a ready market and the manpower necessary to develop the nation's land resources. Usage of farm power—including horses, mules, machinery and equipment—was approximately five times greater in 1920 than in 1870.

Farm output continued upward between World Wars I and II. However, this increase was caused by different forces from those operating in the earlier period. Between 1920 and 1940 the total number of acres in farms increased only slightly. Mechanization of farming was a major force leading to increased output. A further result of increased mechanization was the release of nearly 60,000,000 ac. of cropland which had previously been utilized for feed for horses and mules.

The revolution in farming methods and production continued after 1940. Farm output increased by 36% between 1940 and 1956 with very little addition to the total area of land under crops and with a major reduction in the number of workers and hours of work in agriculture. Further mechanization increased productivity; average crop output per acre increased by 20%. The number of tractors on farms increased from 1,545,000 in 1940 to 4,515,000 in 1956, with other types of farm equipment showing similar or greater gains. Increased use of commercial fertilizers, insecticides and fungicides also helped stimulate production as did the development of new varieties of crops.

The history of farming in the United States has seen a gradual shift in the importance of various regions. Agriculture led the general pattern of industrialization and population migration with a steady westward movement. The older established farm regions of New England, middle Atlantic and south Atlantic have shown relative declines with increasing production in the south central, mountain and Pacific coast regions.

Number of Farms and Acreage.—By the middle of the 20th century there were more than 4,775,000 farms in the United States covering more than 1,150,000,000 ac., of which about 330,000,000 ac. were under cultivation.

The United States experienced a steady decrease in the number of farms from the high of 6,518,000 in 1920, except for a brief period of increase during the depression of the 1930s. This decline in number of farms was even more rapid in the post-World War II period.

The opening up of the western part of the continent was reflected in the large increase in land in farms and in acres under cultivation between 1850, when 15.6% of the total land area was classed as farm land, and 1920, when the percentage had risen to slightly over 50. This was followed by a gradual leveling off. The percentage of the nation's lands classed as farm land continued to show a slight but steady rise, reaching approximately 61% at mid-century. Cropland harvested, on the other hand, showed a much greater correlation with general economic conditions. After 1910 the number of acres harvested dropped below 300,000,000 only during the depression years of the 1930s, and reached peaks of more than 350,000,000 ac. in the prosperous late 1920s and during World War II. There was some decline in the postwar period, the 1954 census of agriculture showing slightly over 332,-000.000 ac. or 18% of the total land area under cultivation. A major part of the total farm land is utilized for grazing, woodland and other purposes.

Value of farm land and buildings has shown a steady increase, reaching a level of more than $97,500,000,000 at mid-century. This amount represents approximately one-fifth of the nation's total privately owned tangible assets used in production. The value of farm land and buildings increased from $34,800,000,000 and $5,470 ,average per farm in 1910 to $97,500,000,000 and $20,-405 per farm in 1954, with the average value per acre increasing from $40 to $84. The value of farm equipment and machines also increased greatly. In 1929 total shipments of farm machines and equipment for use in the United States were valued at $412,214,-000. compared to $1,398,052,000 in 1955. The number of grain combines on farms increased from 4,000 in 1920 to 1,020,000 in 1957. corn pickers from 10,000 to 715,000 and farms with milking machines from 55,000 to 720,000.

Farm Population and Employment.—In 1850 two-thirds of the people in the United States lived on farms and 64% of the nation's gainfully employed workers were engaged in agriculture. The nonfarm labour force multiplied 20 times while farm employment increased less than 2 times by 1956.

The number of persons on farms declined steadily after 1910. with the decline accelerating after 1940. In 1956 only 13 3% of the nation's population was on farms, compared with nearly 35% in 1910. Farm employment showed a similar decline, from 13,-555,000 in 1910 to 7,869,000 in 1956.

The trend of declining farm population and employment was the result of a number of factors: increased mechanization, larger yields and the combination of farms into larger, more efficient operating units permitted greater production with lower labour inputs. Employment opportunities in the rapidly expanding manufacturing and commercial sectors of the economy stimulated migration from the farms. At mid-century there were some signs that this trend was nearing its obvious limitations.

Farm Income and *Expenses*.—With the growing industrialization of the economy, agriculture has provided a declining proportion of the national income. In 1929 farming contributed 9.2% of national income compared to only 4.2% in 1957 Although farm income has shown a long-term growth, the much larger increase in other sectors has reduced the relative importance of agriculture.

Farm income fell drastically during the depressions of the 1920s and 1930s. It was not until 1942 that net farm income exceeded that of 1919. The demand for farm products during World War II caused a major increase in farm income, with continued increases in the immediate postwar period. The net income of persons on farms from agricultural sources reached a high point of $19.704,-000,000 in 1948. However, there was a steady decline after that time, with net income falling to $13,374,000,000 in 1956. Production costs of farms continued to rise while income was falling The parity ratio (ratio of prices received to prices paid by farmers) reflects this change. This ratio (1910–14 equals 100) was above 100 until the farm depression of the early 1920s. remained below 100 throughout the 1930s and then moved to a high of 115 in 1947. It declined steadily. reaching 82 in the mid-1950s.

Farm Output and Productivity.—Total farm output increased by 57% between 1930 and 1956, with livestock and products (meat. dairy products, poultry and eggs) increasing by nearly 60% and crops by 40%, while feed used by horses and mules declined by 83%. However, the number of man-hours required to produce this expanded output declined from 22,921,000,000 in 1930 to 14,177,-000,000 in 1956.

This reduction in man-hours accompanying an increasing production was the result of major advances in productivity. Output per man-hour for all farm labour increased by 152% between 1930 and 1956, while that for livestock and products increased by 62% and that of crops increased by 164%. Productivity increases on the nation's farms have been more rapid than for the private nonfarm sector of the economy.

Principal Agricultural Products—Ten years after the end of World War II, the total farm value of all crops harvested in the United States was more than $18,500,000,000 with field crops valued at over $16,000,000,000, vegetables at about $645,000,000 and fruits, nuts and horticultural specialties at more than $1,500 -000,000. Corn, the nation's major field crop, utilized about 78,-000.000 ac. of land and provided a farm value of more than $4,000,000,000. The farm value of production of cotton, wheat and hay was over $1,000,000,000 for each product with tobacco. oats and soybeans valued at nearly that amount. Milk products, cattle and calves had the largest production volume and value among livestock and products, followed by hogs, chickens and eggs

The composition of agricultural production changed substantially after the end of World War I. Shifts in the relative importance of various crops and livestock production resulted from a combination of factors including changes in demand and differences in technological progress, cost reduction and relative profitability to farmers. Livestock production increased much more than crop production after 1930. Output of poultry and eggs rose at an even faster rate, particularly after 1940. A rise of 50% to 75% in the production of many fruits and vegetables and tobacco after 1920 reflects the growth of population and the expansion in consumer demand for these products The much smaller increase in production of food grains, cotton and sugar crops was a reaction to a number of forces, including shifts in consumer demand, changes in export markets and production control programs of the federal government.

Government *Agricultural* Policies.—The maintenance of a strong agricultural sector has long been recognized as of vital importance to the health of the national economy. During the 18th and 19th centuries the agricultural policies of the government took the form of raising the prices of farm products by means of protective tariffs and of encouraging the development of the vast land resources.

The demand for food during World War I caused a major increase in the output of farm products and directly led to overproduction and the drastic break in farm prices and income following the war. In the 1920s the government attempted to help agriculture by giving aid to co-operatives, by providing farm credit and by raising import duties on many farm products. The Federal Farm board was the first formal program seeking to stabilize prices through storage. These governmental policies of the 1920s proved inadequate to meet the needs during the serious depression of the early 1930s.

With the Agricultural Adjustment act of 1933 the government took a much firmer hand to improve farm income and prices. The primary purpose of this act was to curtail production, reduce export surpluses and raise prices. This program inaugurated price supports for some products based on the parity formula. The Commodity Credit corporation, with its crop loan and storage program, was established to make price-supporting loans and purchases of specific commodities. Although these and other programs such as the soil conservation service and Farm Security administration did help raise farm prices, with parity moving from 58 in 1932 to 81 in 1940, it took the enormous demands of World War II to reduce the accumulated farm surpluses and to significantly increase farm income. With most farm prices rising above the support levels, the objective of the national farm program was changed for the war period and two years beyond to providing floors under prices to encourage expanded production.

The primary farm problem after 1952 was one of declining total farm income, a reduction in parity ratio and the build-up of surplus stocks. Net income fell from $14,802,000,000 in 1951 to $12,070,000,000 in 1956, with the parity ratio declining from 107 to 82. In spite of attempts to bring demand and supply into balance at close to the parity ratio, output continued to increase at record levels. The carry-over of war-induced expansion of production was a factor, but the main reason for the increase was the substantial growth in productivity resulting from mechanization and the adoption of improved technology. The soil bank program adopted under the Eisenhower administration limited the number of acres under production, but because of increased yields it did not substantially reduce output.

3. Forestry.—The United States was blessed with vast stands of timber which provided an important resource for building the country. By the middle of the 20th century the forests of the nation were estimated by the forest service to contain over 2.094,000,000,000 bd.ft. of lumber, enough to build a six-room house for every person in the United States, with lumber left over. However, it is estimated that the original forests contained over four times this volume. Much of this virgin timber was cleared to provide the growing need for agricultural lands and for fuel, building construction, shipbuilding, furniture manufacture, wood pulp for paper, paperboard and man-made materials and many other products. Although there has been a vast usage, often wastage, of timber, the productive capacity of the nation's forest lands should be sufficient to ensure the availability of this important resource for many generations if programs for better utilization, reforestation, sustained yield management and fire, insect and disease control proved successful.

Forest Lands and Species.—Of the 1,939,343,000 ac. of land in the Gnited States and coastal Alaska, 34% or 664,194,000 ac. are classified as forest land. Approximately one-fourth of the forest land is unsuitable for commercial forest production or has been set aside for parks or preserves, leaving 488,609,000 ac. classified as commercial forest lands.

In the Pacific northwest vast stands of Douglas fir predominate while redwood, Douglas fir and mixed conifer forests are scattered throughout California. East of these coastal forests in the west, ponderosa and white pine forests are most prevalent. In the Plains states there are river-bottom stringers of hardwoods and the pine forests of the Black hills. In the north and south the softwood and hardwood forests are intermingled and interspersed with farms and other nonforest lands. The eastern section of the nation contains three-fourths of the commercial forest land. The west has only one-fourth of the forest land area but nearly 70% of the nation's saw timber. The heaviest stands of virgin timber are along the Pacific coast with the three states Oregon, California and Washington containing 1,108,877,000,000 bd.ft. of saw timber, over half the nation's supply. The history of the forest products industries has been one of gradual westward movement where new timber supplies were available. As the virgin timberlands in the Pacific coast states are cut, however, there may be a movement back to the eastern and southern sections of the nation which are being reforested with second-growth timber.

Although nearly three-fourths of the commercial forest land area is under private ownership, the 26% held by federal, state and local governments—more than three-fifths of it in the west—contains nearly 50% of the nation's saw-timber resources. Of the 2,057,000,000,000 bd.ft. of live saw timber, 1,648,000,000,000 bd.ft. or 80% is softwood with the principal species being Douglas fir, southern yellow pine, ponderosa pine, western hemlock, sitka spruce, sugar and white pines and redwood. The major hardwoods, found primarily in the eastern section of the nation, are oak, poplar, maple, gum, beech, cottonwood, elm, birch, hickory, ash and chestnut.

Growth *Drain* in Forest.—In 1952 the forest service estimated that the net annual growth in the nation's forest was 47,397,000,000 bd.ft. of saw timber as compared to a drain of 48,840,000,000 bd.ft. In the following years this growth-cut ratio improved substantially. However, there remained a major disparity between regions, with the eastern part of the nation showing a much higher growth-to-cut ratio than the west and with hardwoods having a higher ratio than softwoods. In the west the annual cut of saw timber, 22,449,000,000 bd.ft., was twice the annual growth rate.

Production of Wood Products.—Major products from the forests are lumber, wood pulp, plywood, fuelwood, poles and posts, railroad ties, furniture and industrial woods and timbers. Lumber production had declined from a high of 44,510,000,000 bd.ft. in 1909 to 37,698,000,000 bd.ft. by 1956. However, with the reduction in lumber production, forest products shifted to different usages. Wood-pulp production increased from 3,518,000 tons in 1919 to 22,131,000 tons in 1956, stimulated by the enormous increase in demand for paper and paperboard and man-made fibres made from pulp. During this same period, paper and paperboard production rose from 5,966,000 to 31,428,000 tons. Between 1950 and 1960 the production of softwood plywood increased over three times with a production in 1956 of 5,421,170,000 sq.ft., $\frac{3}{8}$ in. basis. The production of wallboard, hardboard and many other forest products increased even more rapidly.

Outlook.—The major problem facing the U.S. forest industry at mid-20th century was the assurance of adequate timber supplies to meet growing needs. The forest service projected a very significant rise in the demand for wood products, based on increasing population and per capita consumption. The forest resources would be severely pressed to meet this demand.

In the early years of lumbering, the forests were looked upon as an inexhaustible source of timber. The fallacy of this reasoning became very apparent with the depletion of much of the original forest land, and the federal and state governments, as well as many of the private owners of forest resources. began to see the need of considering timber as a crop—one with a long growth cycle but still a renewable resource. The federal government, with its vast reserves of timber in national forests. provided for sustained yields over an indefinite period through reforestation and better forestry practices. Advances in methods for controlling forest fires, insects and diseases also helped to maintain the forests as growing reservoirs of timber. Tree farms were established in many areas as a supplement to natural reforestation, and much more efficient utilization of the total tree, together with the removal of a larger proportion of the timber from the forests, helped to improve yields. These policies of forest conservation and improved utilization resulted in a steadily improving balance between growth and drain. (*See* also FORESTS AND FORESTRY; LUMBERING.)

4. Mining. — From 1880 to just after the middle of the 20th century, the value of all mineral production in the conterminous United States multiplied 47 times. Total value in 1880 was $367,000.000; by the mid-1950s it was estimated at $17,000,000,000. In addition the value of minerals produced in Alaska was almost $23,500,000 and in Hawaii nearly $7,000.000.

From a level of $5,311,000,000 in 1926, the value of mineral production declined during the depression to a low of $2.000 000.000. It rose slowly during the 1930s, rapidly during World War II and continued to increase in the postwar period. Part of this postwar rise reflected the increasing price levels for most minerals and part reflected enlarged volume of production.

Of the mid-1950s total of $17,000,000,000, $2,000,000,000 represented the value of the production of metallic minerals and $15,000 000.000, that of nonmetallic mineral products. Of the latter figure, about $11,700,000,000 was accounted for by fuels. In 1880 the value of fuels — including coals, natural gas, gasoline and other petroleum products — made up only 33% of the total value of all mineral products; in 1956 fuels contributed 67% of the total.

In spite of the large increases in physical volume of production of most mineral products during the first half of the 20th century, there was a steady decline in the number of employees engaged in mining and related activities. This decrease was primarily the result of the increased mechanization of mining operations and the consequent increase in productivity. In 1915, 734,008 production workers were engaged in coal mining; in 1956 the figure was 238.693. In mines other than coal there were 152,118 workers in 1915 and 72,420 in 1956. In quarries and related industries the figures were 100,740 in 1915 and 78.701 in 1956. Total employment in the mineral industries in 1915 was 1,067,817, compared with a figure of only 454,950 in 1956. Using the year 1947 as 100, output per man-hour in mining increased from 62.9 in 1929 to 105.7 in 1950, with further increases after that year. Nowhere in the U.S. economy was there so dramatic an illustration of the impact of improved equipment and methods on productivity. (See also NATURAL RESOURCES: Minerals; and articles on various minerals: COAL AND COAL MINING: Coal *Mining* in the United States; IRON AND STEEL: Iron Ore; PETROLEUM: *U.S.* Petroleum Industry; etc.)

5. Fisheries. — United States fisheries have provided an important source of income, employment and food since early colonial days. These industries not only support a large fishing fleet but also provide income to such industries as boat and shipbuilding and fish-processing equipment. The primary fisheries for the nation are in the oceans surrounding the United States, including Alaska, with other areas all the way from Newfoundland to the Caribbean and from Alaska to the equator.

According to statistics compiled by the U.S. fish and wildlife service, fisheries production in the United States and Alaska in 1930 totaled 3,224,318,000 lb., with an average price per pound of 3.39 cents and a value to fishermen of $109,349,000. By 1940 the quantity had risen substantially, to 4,059,141,000 lb., although the average price in that year was only 2.44 cents per pound and the value to fishermen, $98,957,000. Following World War II, production remained well over 4,000,000,000 Ib. annually. In 1957 it was approximately 4,750,000,000 lb., with an estimated average price of 7.39 cents per pound and a value to fishermen of about $351,000,000.

In the late 1950s there was approximately 555,000 persons employed in fisheries; 142,000 fishermen, 3,000 transporters, 100,000 shore workers and 310,000 workers in allied industries such as gear manufacture, boatbuilding and processing equipment. Approximately 84,000 crafts were used for fishing with 12,000 vessels of five tons and over, 58,000 motorboats and 12,000 other boats.

The major fisheries at mid-century were along the south and Gulf states, with a value of more than $100,000,000, about three-fourths of which was accounted for by shellfish. The Pacific coast states were next in importance with a value of catch of more than $80,000.000, primarily pilchard or sardines, tuna.salmon and mackerel. California was the leading state, producing considerably more than half the west coast total. The New England states had a catch valued at close to $60,000,000 with haddock, perch, herring, cod. flounders and lobster the major species.

For the entire nation the most important fish by volume is the menhaden, used primarily for oil and fertilizer. In 1957, for example, the menhaden catch amounted to 1,684.300.000 Ib., as compared with 297,100.000 Ib. of tuna and tunalike fish, 271,900,000 lb. of herring and 257,200,000 lb. of salmon, the three species ranking next in volume. On a value basis, however, tuna and salmon were of greatest importance. Other species of importance to the fishing industry include mackerel, haddock, ocean perch, pilchard and cod. Shrimp provides the largest volume of shellfish, followed by crabs and oysters. Shrimp ranks after salmon in value for U.S. fisheries as a whole.

Of the 4,750,000,000 lb. of fish caught in 1957, approximately 1,428,000,000 lb. were sold fresh or frozen, 1,130,000,000 Ib. were canned, 88,000,000 lb. were cured and 2,104,000,000 lb. were used for the production of by-products, such as fish meal and oil. Canned fish products increased from 643,848,000 lb. in 1935 to 986,938,000 lb. in 1957 with value increasing from $74,999,000 to $334,766,000. The total value of canned and processed fishery products in 1957 was $379,656,000. According to the fish and wildlife service the major canned-fish products by species were tuna and tunalike fishes, salmon, sardines, mackerel, clam products, shrimp and oysters.

With the decline in production of many valuable fishery products, the U.S. fish and wildlife service directed its attention to the study of means for maintaining the nation's major fisheries. In line with this policy, the U.S. entered into agreements with Canada, Japan and other countries for the protection and maintenance of the nation's fishery resources.

6. Power. — From the start of the nation's industrial development, the progress made in the United States toward greater production, increased productivity and a higher standard of living can be traced by the spectacular increase in the use of energy from mineral fuels and water power. Between 1870 and 1900 the annual supply of power from mineral fuels and water power increased fivefold. With a labour force in 1956 little more than twice as large as in 1900, accompanied by more capital, better technology and with a fivefold expansion in energy use, the nation's economy produced more than five times the 1900 total volume of goods and services measured in constant dollars.

With increased energy utilization and expanding production a major shift occurred in the relative importance of various energy resources. J. Frederic Dewhurst and associates in America's Needs and Resources (1955) estimated that the percentage share of manpower as a source of energy in total work output, had declined from 13 in 1850 to 5.3 in 1900 and 0.9 in 1950. For the same years, the percentage share of animal power fell from 52.4 to 21.5 to 0.6; inanimate sources rose from 34.6 to 73.2 to 98.5.

In addition to the shift from animate to inanimate sources of energy, there have been major changes in the relative importance of the various inanimate sources. In the mid 1800s wind and water were the primary sources of energy with fuelwood and coal also of importance. By 1900 coal, anthracite and bituminous, provided 88.9% of the energy from mineral fuels and water power. Anthracite subsequently declined but bituminous increased substantially. However, because of major increases in other mineral fuels, the per cent of energy from coal had declined to 32.2 by 1957. Crude petroleum showed a major increase, providing 36.3% of the energy supply in 1957 as compared with only 4.7% in 1900. Natural gas had a similar expansion from 3.2% to 27.7%. The use of water power as a source of energy grew steadily although its proportion of total energy in 1957, 3.9%, was just slightly above the proportion in 1900.

Electrical energy provided only a minor part of the nation's total energy supply prior to 1900. In 1902, 5,969,000,000 kw.hr. of electric energy were produced in the nation. By the late 1950s more than 700,000,000,000 kw.hr. were being produced annually, an increase of 120 times. Between 1940 and 1957, kilowatt hours utilized increased by nearly 300%.

Although some of the major producers of electric power are the hydro plants located on the nation's rivers and streams, hydroelectric power made up only about 20% of the energy source for electric-power production in the late 1950s, and the proportion was declining. Coal provided slightly more than 50% of the energy source, oil about 6% and natural gas approximately 18%. The decline in electric power from hydroelectric sources resulted partly from the greater flexibility of steam plants using mineral fuels. In 1920 it took three pounds of coal (or coal equivalent in other fuels) to produce one kilowatt hour of electricity. By 1957 this had been reduced to only 0.93 lb. of coal per kilowatt hour. This increased efficiency provided a cost advantage for fuel-fired over hydroelectric power in most sections of the nation.

Vast undeveloped sources of hydroelectric energy remained as reservoirs of power for possible future needs. In 1956 the nation's hydroelectric plants had an installed capacity of 26,386,000 kw. The Federal Power commission estimated that there remained 90,102,000 kw. of undeveloped water power, located primarily in the mountain states, with a potential of 21,333,000 kw., and the Pacific states with 33,722,000 kw. However, relatively little undeveloped hydroelectric power was available in the more populated eastern section of the nation, which used over 75% of the electric energy.

The Federal Power commission estimated that future U.S. power requirements would continue to show an upward trend. It seemed probable that the major source of energy for meeting this demand would be fuel-fired plants using bituminous and lignite coals which are in plentiful supply, are located close to centres of major power usage and permit low-cost, efficient operations.

Another possibility was the production of electric power from efficient atomic power plants. In the early 1960s, more than two-thirds of the nuclear reactors in operation in the U.S. were owned by the federal government and the remainder by private industry. The majority of these were research reactors with small power output.

In the United States, where other sources of cheap power were widely available, nuclear reactors could not, at mid-century, produce power at a competitive cost. (See also ELECTRIC POWER; ATOMIC ENERGY: *Peacetime Applications*.)

7. Industries.——After the Civil War, the United States changed from an agrarian economy to one with a highly complex industrial structure. With the advent of increasingly advanced industrial technology, manufacturing grew rapidly and caused major shifts in output, income and employment as well as other basic socioeconomic changes. In 1820 only 12% of gainfully occupied persons in the U.S. were engaged in manufacturing, hand trades and construction. By 1880 this percentage had increased to 18.5. By 1899 there were about 4,502,000 production workers engaged in manufacturing who received $1,893,000,000 in wages and produced value added to products of $4,647,000,000. The mushrooming growth of industries in the nation had begun, bringing with it parallel expansion in wholesale and retail trade, financial activities and other services supported by industrial activity.

This trend of growth continued during the 20th century. Manufacturing employment by 1919 was 10,534,000 and by 1957 it was 16,800,000. Manufacturing has become the major source of income for the economy. By 1929 it provided income of $21,888,000,000, nearly 25% of total national income. By 1957 manufacturing contributed $112,517,000,000 or 31% of national income. The growth in income from manufacturing between 1929 and 1957 was over 400%.

Number of Firms and Value of Products.—Between 1899 and 1954 the number of manufacturing establishments in the United States increased from 204,754 to 286,817. The number of production workers in these establishments multiplied nearly threefold from 4,501,919 in 1899 to 13,134,683 in 1956. Value added to the products processed increased steadily over this period, except for the depression years of 1920–21 and the early 1930s. Between 1939 and 1956 value added by manufacture rose from $24,487,304,000 to $139,682,978,000, an increase of 470%.

The growth of industrial production accelerated after the end of World War I. The federal reserve board's index of industrial production increased from 100 in 1947 to 143 in 1957. This 43% increase in output was accomplished with only a 10% increase in manufacturing employment, indicating major increases in productivity. Between 1948 and 1957, output per man-hour in manufacturing rose by 30%

Major Industry Groups.—In number of establishments, those manufacturing food and kindred products led all others at mid-century. In second place were establishments manufacturing lumber and wood products, followed by printing and publishing plants.

In the same period establishments manufacturing such transportation equipment as automobiles, trucks, aircraft and ships led in number of production workers. In second place were establishments manufacturing such nonelectrical machinery as machine tools, office equipment and construction and mining equipment; and in third place were establishments manufacturing food and kindred products. Transportation equipment manufactures also led in value added by manufacture. In second place were food and kindred products manufactures followed by nonelectrical machinery. After 1939 there were notable changes in the relative positions of the various manufacturing industries as indicated by both production workers and value added. The food and kindred products, textile, apparel, leather and lumber industries declined, whereas the transportation equipment, machinery, metals and chemical industries increased in relative importance.

Location of Manufacturing Activity.—Manufacturing is concentrated in the middle Atlantic and east north central sections of the United States. These two regions provided more than 50% of the value added nationally in the mid-1950s. The Pacific states were third in importance, followed by the south Atlantic area, New England, the west north central, west south central, east south central and mountain regions in that order. In spite of the predominance of the northeastern section of the nation as the manufacturing hub, there was strong evidence of a growing dispersion of these activities to the southern and western regions of the nation. The Pacific states provided 6.3% of the national value added in 1939 and 9.9% in 1956. The west south central region's percentage increased from 3.3 in 1939 to 5.3 in 1956. By contrast the New England area had 9.9% of national value added in 1939 and only 7.5% in 1956.

At mid-20th century the manufacturing industries of the United States were continuing the basic trends that had been in evidence from the middle of the 19th century. Automation and technological improvements continued to provide the basis for further major increases in output and productivity, and the trend toward increasing productivity with a continually decreasing proportion of the nation's workers showed no signs of changing. (See ECONOMIC PRODUCTIVITY; see also under names of principal industries.) (F. E. K.)

C. TRADE AND FINANCE

1. Domestic Commerce.—Domestic commerce developed only slowly in colonial America. Foreign trade, especially with England, was quite significant in marketing certain crops and products and in supplying commodities not produced in the colonies, but in the absence of good roads, railroads or other adequate transportation, internal commerce was not extensive. Most domestic commerce was by coastwise shipping and a large portion of this was for the distribution of imported goods.

The constitution gave congress power to "regulate Commerce with foreign Nations, and among the several States," and numerous judicial decisions thereafter defined the nature and limits of interstate commerce (*q.v.*). These rulings limited the development of state barriers to commerce. In the leading case of *Gibbons* v. Ogden (1824), Chief Justice John Marshall invalidated a state restriction on steamboat navigation; this decision established national government supremacy over interstate commerce and laid the basis for later federal regulation of transportation, based upon the inclusion of transportation as commerce.

During the 19th century regional specialization—manufactures in New England and the iron and steel industry in western Pennsylvania, for example—brought with it the need for increased domestic commerce. Improvement of transportation facilities—the Cumberland road, the steamboat and its use on the Ohio, Mississippi and other rivers, the success of the Erie canal and the building of other canals and the completion of the first railroad in 1830—created arteries for commerce. As population spread westward, "Yankee peddlers" began to be supplemented and replaced by wholesale houses and the general store. Later. organized markets for staples developed and, still later, manufacturers who wished to gain the advantages of dealer distribution of branded merchandise began direct retail distribution through branch warehouses and dealer agreements.

Wholesaling began to assume greater importance and major markets for staple commodities were established, such as the wheat market in Chicago and the cotton exchanges in New York and New Orleans. Rail transportation helped make possible such developments as that of the mail-order house. Retail distribution was further modified by the development of the chain store—especially in variety goods (the five- and ten-cent store), groceries and drugs. By 1914 chain stores had begun to be significant in replacing the individually owned general store. Specialization in retailing spread as the general store began to be displaced by stores which sold only drugs, groceries, hardware or dry goods.

After World War I other developments caused further changes in the nature of domestic commerce. The supermarket began to supersede the grocery store. Decentralization and the growth of the planned shopping centre enhanced the importance of suburban retailing. Self-service and self-selection became more widespread and tendencies to circumvent the wholesaler became more significant. In many lines the trend toward specialization seemed partially to reverse itself in a trend toward "one-stop service."

Another important development was the gro th of installment selling, as the expansion of income and of sales of durable goods. especially automobiles, created needs for new types of retail financing. (See Growth of the American Economy, above.)

Wholesale Trade.—Data on wholesale establishments beginning in 1929, the year of the first official census of wholesale distribution, show a steady increase in number, volume of sales and employment. In 1929 there were 168,262 wholesale firms; in 1948 there were 216,099; and by 1954 there were 252,318. Wholesale trade accounted for 4.8% of national income by industrial origin in 1929 and for 5.5% in 1954. (Retail trade and automobile services accounted for 10.4% in 1929 and 11.3% in 1954.)

Within the wholesale trade, merchant wholesalers accounted for by far the largest number of establishments and paid employees and the greatest value of sales. Manufacturers' sales branches and sales offices were second in number of employees and sales, but followed petroleum bulk plants, terminals and liquefied petroleum (LP) gas facilities in number of establishments. Grocery, confectionery and meat wholesalers and farm products distributors accounted for almost a fourth of total sales by merchant wholesalers. and led other types of business in number of establishments and employees as well.

Wholesaling is, of course, primarily a big-city activity. In the state of Washington, for example, King county, containing the state's largest city, Seattle, and approximately a third of the state's population, accounted for over half of total wholesale trade but only about a third of total retail trade. Since more than half of the U.S. population lived in standard metropolitan statistical areas, shown in fig. 10, these are the major wholesaling centres. At mid-20th century these areas accounted for approximately 85% of the sales of merchant wholesalers and more than 95% of the sales of manufacturers' sales branches and sales offices.

Wholesaling may be considered to have reached a peak in importance toward the end of the 19th century and to have declined slightly thereafter in terms of the total value of products handled. In terms of employment, the share of the labour force employed in uholesaling did not decline relative to that in retailing.

Retail Trade.—The first complete measure of retailing for the Cnited States was contained in the 1929 census of retail distribution. For that year the total sales of retail stores (1,543,138 establishments) amounted to $49,100,000,000. The trough of the depression in retailing came in 1933 when sales dropped to $24,-500.000.000. By 1935 a total of 1,587,718 stores had sales of $32.-800,000,000 and by 1939 a total of 1,770,355 stores had sales of $42,000,000,000. Nine years later a smaller number of stores had sales of $128,800,000,000.

In both number and sales, retail food establishments far outdistanced other types of retail business, food stores and eating and drinking places together accounting for more than a third of the total number of establishments and almost a third of the dollar value of sales. The number of food stores, however, showed a tendency to decrease even though sales were rising, reflecting the continuing trend toward an increase in the volume of sales in large supermarkets.

Also high in number of establishments were gasoline service stations, apparel and accessories stores and lumber, building materials, hardware and farm equipment dealers. The leaders in sales volume included automotive dealers, general merchandise stores and the lumber and building materials group. The increasing number of retail establishments handling apparel, furniture, home furnishings and appliances reflected the growing population and high level of home building as well as the development of new products.

Retail establishments in the standard metropolitan statistical areas, accounted for more than half the total number of retail establishments and almost two-thirds of total retail sales in dollars.

Taken together, wholesale and retail trade employed an increasing percentage of the labour force after 1870. While the number of workers engaged in commodity production and construction was about three times larger in 1950 than in 1870, the number engaged in wholesale and retail trade had increased tenfold. This trend was caused in part by a relatively rapid decline in hours of work per week in wholesale and retail trade (from 66 in 1870 to 44 in 1949), in part by an expansion of the scope of wholesale and retail trade and probably to some extent by added functions. On balance, however, it was evident that productivity (output per man-hour) in distribution increased much more slowly than in manufacturing, agriculture and mining. One authority estimated the rate of growth of output per man-hour at 1.1% per year in wholesale and retail trade and 2.6% in agriculture, mining and manufacturing between 1869 and 1949. Technological innovations have been less significant in trade than in the other fields.

2. Foreign Commerce.—The United States occupies a dominant position in the world economy. Although it has only about 7% of the total world population, it produces more than 40% of the total world output of goods and services. It generates more than half of total world savings and as a result is the most important creditor country. In 1951–55 U.S. exports amounted to approximately 20% of total world exports and U.S. imports to about 15% of total world imports. The level of U.S. foreign commerce is thus of great significance to the world economy; its fluctuations have wide repercussions.

The United States foreign commerce is not as significant, however, in relation to national product and national income as is commerce in a number of other countries. U.S. merchandise exports amount to about 5% of national income and merchandise imports to about 34%. Exports of such countries as Argentina, Australia, Belgium, Canada, Great Britain and Sweden amount to about 20% of national income and exports of such countries as Denmark, the Netherlands, New Zealand and Norway amount to 30% to 40% of national income.

From these comparisons it should not be inferred that foreign commerce is of little importance to the United States. For many commodities much more than 5% of total production is exported. At mid-20th century over 40% of the rice grown was exported, over 33% of the cotton, wheat and inedible tallow, 25% of the soybeans and tobacco, over 20% of the lard, over 30% of the rolling-mill machinery and parts, over 20% of the tractors, sewing machines and textile machinery and between 10% and 20% of the printing machinery, oil-field machinery and tools, office appliances, motor trucks and coaches and agricultural machinery (other than tractors).

In certain commodities the United States is entirely dependent on imports; *e.g.,* natural rubber, tin, industrial diamonds, coffee, cocoa and tea. It imports 90% or more of its nickel, cobalt, chromite, asbestos and manganese, more than one-half of its tungsten and more than one-third of its copper, lead and zinc.

Balance of Payments.—A record of transactions with foreign areas during a given period is called a balance of payments, although the term is somewhat misleading because all transactions, whether payment is involved or not, are included. This record shows imports and exports of goods and services and unilateral transfers (gifts) (current account section) and changes in international claims such as loans, foreign bank deposits and gold movements (capital account section). Since the principles of double-entry accounting are followed, the balance of payments should balance; but because statistics are obtained from many different sources (customs reports, steamship companies, questionnaires to tourists, etc.), there is always an errors and omissions item. (See INTERNATIONAL PAYMENTS.)

Estimates of the U.S. balance of payments have been compiled by the US. department of commerce from 1919. Dollars supplied to the rest of the world by U.S. imports. payments for services and the outflow of long-term capital dropped sharply after World War I; and, after partial recovery during the 1920s there was another sharp drop from 1929 to 1933. In 1939 dollars supplied totaled less than $4,000,000,000 as compared with more than $10,000,000,000 in 1919.

Foreign trade during World War II was dominated by government wartime transactions. During the postwar period, United States exports of goods and services far exceeded imports. Foreign countries purchased much more goods and services from the U.S. than they were able to pay for from funds derived from sales of goods and services to the U.S.. and in most cases their dollar balances had been seriously depleted during the war. The resulting "dollar gap" was met (in some cases more than filled) by unilateral transfers, both private and government. In some years such transfers enabled foreign countries to add substantial amounts to their gold and dollar reserves, improving their liquidity position for international payments.

By the late 1950s the U S. was still exporting more goods than it was importing, although the margin was relatively narrow in certain years. Recovery after World War II had by this time enabied western Europe and Japan to compete more strongly with the U.S in world markets A rise in U.S. imports, relative stability of the trend in U.S. exports and a continuation of military expenditures abroad and loans and grants to foreign countries combined to create a balance of payments deficit, and hence foreign countries gained substantial amounts of gold and dollars. Relative proportions of foreign holdings of gold and of short-term dollar investments were determined by such factors as customary practices and relative levels of interest rates; in 1958 these factors combined to cause a large gold outflow, and in 1959 the gold outflow was also substantial, although smaller. An upturn in exports which began in mid-1959 reduced the deficit in the succeeding year, but gold outflow and the size of short-term dollar liabilities were still important factors influencing trade and monetary policy as the 1960s began.

Merchandise Trade.—United States merchandise exports averaged $44,000,000 annually in value in the last decade of the 18th century; by the corresponding decade of the 19th century, they averaged nearly $1,000,000,000 in value; by the middle of the 20th century they exceeded $15,000,000,000 annually; and in 1957, a peak year, they exceeded $20,000,000,000.

Imports, which averaged $56,000,000 in the last decade of the 18th century, rose to nearly $750,000,000 by the end of the 19th century and to more than $10,000,000,000 by the middle of the 20th century. With the great expansion of United States industry and commerce in the 1870s, the country developed an excess of exports over imports which continued into the second half of the 20th century (see Table XIX).

In the depression of 1929–32 exports dropped from more than $5,000,000,000 to less than $2,000,000,000; by 1940 they had recovered only to $4,000,000,000. During World War II they reached a peak of nearly $17,000,000,000 in 1944, approximately three-fourths of which was accounted for by lend-lease shipments. After World War II, in addition to ordinary exports, shipments of military goods were made under aid programs. These were not large in amount until 1951, when they totaled more than $1,000,000,000; in 1953 they totaled over $3,500,000,000, and smaller amounts in the following years. Even excluding these shipments, exports exceeded imports by large amounts.

TABLE XIX.—*U.S. Exports and Imports of Merchandise**
(in $000,000)

Yearly average or year	Total	Exports		Imports	Total exports and imports
		Domestic	Foreign		
1790–1800	44	..	..	56	100
1801–10	74	38	36	93	167

*Figures are for fiscal years ended Sept. 30, 1790 to 1842, and June 30, 1843 to 1915, subsequently for calendar years; gold and silver are inciuded prior to 1821. †Period beginning Oct. 1, 1841, and ending June 30, 1850. $Period July 1, 1915 to Dec 31, 1920. §Beginning with 1934 import figures are the imports for consumption; prior to that time they are general imports.

Source: U.S. Department of Commerce, Bureau of Foreign and Domestic Commerce.

Imports were even more adversely affected by the depression of 1929–32 than were exports. Imports dropped from over $4,000,000,000 to somewhat more than $1,000,000,000. A sharp drop in imports also occurred with the recession of 1937–38, from $3,000,000,000 to $2,000,000,000, and even the relatively mild recession of 1949 brought a drop in imports from $7,500,000.000 in 1948 to less than $7,000,000,000 in 1949. Fluctuations in imports in dollar terms have been greater than fluctuations in gross national product, and up to 1950 even minor business recessions resulted in substantial declines in dollars available to foreign countries from sales of goods to the United States. In the recessions after 1950 the declines were less substantial but still of some significance. In the long run there has been a decline in the ratio of imports to gross national product (GNP); this ratio dropped from over 7% of GNP in the 1870s to less than 3% in 1946–50.

Merchandise exports exceeded merchandise imports every year after World War I as reported by the census bureau, although if silver shipments are included, this was not true in 1935 and 1936.

Principal *Imported* Commodities.—More than half of the total value of United States imports at mid-20th century was accounted for by ten commodities or groups of commodities; nonferrous metals and ores, coffee, newsprint, sugar, crude rubber. raw wool, crude petroleum, wood pulp, cocoa and burlap. Imports of crude foodstuffs were higher after World War II than previously, partly because of a substantial increase in per capita consumption of coffee. Imports of manufactured foodstuffs increased much less, partly because of introduction of sugar import quotas.

Shifting consumer demand and technological developments caused changes in fibre and textile raw material imports—imports of raw silk and of burlap declined (reflecting the increased use of such substitutes as man-made fibres and paper bags) and imports of wool, which increased until 1951, dropped thereafter. On the other hand, increased demand, combined in some cases with a decline in available domestic supplies, caused an increase in imports of copper, lead, zinc, tin and crude petroleum. Imports of finished manufactures increased sharply in 1950 and 1951 after the currency devaluations of 1949 which reduced dollar prices of some of these products. Some statistical studies suggest that United States demand for finished manufactures is relatively

METROPOLITAN STATISTICAL

elastic with respect to price; if so, increase in such imports may depend upon the extent to which foreign productivity increases and foreign monetary policies keep prices low enough to be competitive with U.S. domestic products.

Leading Export *Commodities*.—Industrial manufactured and finished products accounted for about two-thirds of the total value of U.S. exports, followed by agricultural crude materials and foodstuffs, which accounted for about 20% and manufactured foods, about 6%. Foodstuff exports rose very sharply during World War II and in the immediate postwar period.

Exports of some mineral and metal products declined as demand in the United States increased and as domestic supplies became less adequate to meet total demand. By 1956 capital equipment and producers' supplies and materials constituted three-fourths of total exports. The percentage increase in exports of capital equipment over the levels of the 1920s and 1930s was exceptional; during the postwar period large exports of capital equipment were made to such areas as Canada and Latin America.

Although values of exports of consumer goods other than foods and drugs increased from their levels of the 1920s and 1930s, these exports comprised a relatively small part of the total and showed little increase in the decade 1946–55. Partly this was because of the existence of import and exchange controls in many markets; these controls usually restrict imports of consumer goods more than other products. The percentage increase in exports of foods and drugs was not as large as that of exports of capital equipment, but such exports approximately tripled in value from 1926 to 1956 as new major markets for foodstuffs (*e.g.,* Japan) became important, especially after World War II.

Percentages of the cotton and tobacco crops exported declined markedly, accentuating the shift to nonagricultural exports. A smaller percentage of the output of passenger cars was also exported than before World War II. On the other hand, such industries as the civilian aircraft industry exported increasing percentages of total production, and a greater share of the output of machinery was exported than before World War II.

Sources *and Destinations* of *Foreign Trade*.—In the years 1876–80 more than half of U.S. imports of merchandise came from Europe, while 83% of all exports went to Europe. Other countries on the North American continent supplied 23% of all United States imports and absorbed 10% of all merchandise exports. Latin America supplied 31% of all imports and purchased nearly 9% of all exports. Asia was a source of supply of 11% of imports, but took less than 2% of exports. By 1929, however, Europe supplied only 30% of Cnited States imports and by 1937, only 27%. Exports to Europe dropped to 45% of the total in 1929, and to approximately 40% in 1937. This decline in exports to Europe was caused chiefly by a decline in the importance of the United Kingdom as a market for United States exports. Especially in the post-World War II period, because of the dollar shortage the Lnited Kingdom purchased a greater proportion of its imports from the sterling area.

World War II caused other important shifts in United States foreign commerce. Canada and the Latin-American republics, which took only one-third of U.S. exports in 1936–38 and supplied only slightly more than that proportion of imports. were the destinations of 40% of all exports in 1951–55 and the source of more than half of all imports. Exports to Asia increased much more than imports from Asia. The decline in raw silk imports, the disturbed political conditions in many parts of Asia and the increase in population (especially in Japan) which necessitated increased imports were all factors. Exports to certain areas such as Korea, Formosa and Vietnam, were financed by government aid necessitated by the economic difficulties of those areas. Some shipments to India and Pakistan were also made under special government programs, but the increasing importance of these countries as markets was also attributable to their new political status and programs of economic development.

Invisibles.—The so-called invisible items in United States foreign commerce, including receipts and payments for transportation services, travel and tourist expenditures, miscellaneous services and income on investments, are important items in the U.S. balance of payments. In 1955 these items accounted for approximately 25% of the total value of exports of goods and services and for approximately one-third of the total value of imports of goods and services. Between World Wars I and II payments generally exceeded receipts. and although this situation was reversed from 1940 to 1952, beginning in 1953 there was again an excess of payments over receipts. An important component of total payments was expenditures of United States armed forces abroad—expenditures of members of the armed forces themselves and expenditures for construction of airfields. support of troops, etc. These expenditures totaled $2,500.000.030 in 1953 and were increased in following years. In spite of heavy subsidies of the U.S. merchant marine, foreign competition was significant, and after 1951 transportation payments were not much lower than receipts Expenditure of U S tourists abroad increased much more slowly than personal disposable income from the 1920s to the 1950s, but such expenditures exceeded $1,000,000,000 in 1954. The substantial growth of U S. foreign investments resulted in an inflow of income which in 1955 reached $2,500,000,000—twice the net outflow of private U.S capital in that year.

Unilateral Transfers—Some unilateral transfers have always been made in the form of remittances and gift shipments. During World War II, however, unilateral transfers became a very substantial element in the U.S. balance of payments, exceeding $14,000,000,000 in 1944. They reached $6,700,000,000 in 1953. Lend-lease during World War II, the United Nations Relief and Rehabilitation administration (UNRRA) and other aid in the immediate postwar period and the Marshall plan and its successors after 1948 provided a flow of aid funds which totaled approximately $90,000,000,000 (net) in the 15-year period 1941–55. Private remittances amounted to approximately $500,000.000 annually.

Capital Movements—The net outflow of private capital from the U S., which had been relatively sizable during World War I and during the 1920s and uhich had reached $1,500,000,000 in 1928, dropped sharply to negligible proportions in the depression of 1929–32 and thereafter did not recover until after World War II. The international financial collapse of 1931 and the depression, together with political and military uncertainties, made potential investors hesitant. After World War II foreign investment began to revive, chiefly in the form of direct investment in branch plants and similar productive facilities rather than the purchase of foreign securities. Most of this foreign investment was made in Canada and in Latin America, with investment in the middle east (chiefly by oil companies) ranking third. Although by 1952 the outflow of private capital was almost as large in dollar terms as in 1927–28, its increase was far less than that in private domestic investment. Lack of knowledge on the part of business executives concerning foreign investment, the restrictions imposed by countries resentful of foreign influence and insufficient earnings differentials hindered the expansion of foreign investment. Thus private capital outflow financed only a small part of the export surplus; and in 1954 and 1955 repayments exceeded the outflow of government long-term capital. (See also CAPITAL. EXPORT OF.)

Commercial Policy.—The major instrument of U.S. commercial policy has been the tariff (see TARIFFS), although import quotas. subsidies to shipping and other measures have had some importance Because of the strength of the dollar vis-8-vis other currencies, the United States has never imposed the exchange controls or negotiated the clearing agreements which have been features of the commercial and international financial policies of many countries.

The first U.S. tariff act. that of 1789. was primarily for revenue, but it contained certain elements of protection. Duties on exports were prohibited by the constitution, but import duties became an important feature of United States law. Alexander Hamilton gave the classic arguments for protection in his Report on *Manufactures*, and after the War of 1812 the movement for protection grew as manufacturing interests increased in strength. From 1832 until the time of the Civil War southern influence succeeded in reducing duties, but this trend was reversed by the Morrill Tariff act of 1861. During the Civil War the tariff was used as one of many means of raising revenue; the high protective tariff was firmly established in the act of 1864.

After the election of Woodrow Wilson in 1912, the Underwood Tariff act of 1913 made some reductions in duties, although other rates were raised. After the Republican party had returned to power in 1920 upward revision of the tariff was made in an emergency act of 1921, followed by the Fordney-McCumber act of 1922. The Hawley-Smoot act of 1930 raised rates still further. These acts adopted the principle that duties should offset the lower costs of foreign producers, a principle which, if carried to its logical conclusion, would eliminate much of international commerce. The Hawley-Smoot act was followed almost immediately by tariff increases in many other countries. (See History, above.)

Reciprocal Trade *Agreements* Progrant.—No tariff act was passed by congress after 1930. The precipitous decline in world trade which accompanied the depression of 1929–32 and the spread of trade restrictions. especially after 1931, provided a basis for reconsideration of tariff policy. The Trade Agreements act of 1934 empowered the president to enter into agreements with foreign countries, reducing (or raising) U S. import duties by not more than 50% in exchange for tariff changes by foreign countries This act was renewed many times, with some modifications. The renewal in 1949 included a "peril point" provision which required the president to explain to congress any reductions below points designated by the tariff commission as likely to injure domestic industries, and that in 1951 included an "escape clause" provision which required him to withdraw concessions found by the tariff commission to be injurious or to explain to congress his reasons for not doing so. The renewal in 1955 permitted reductions of 5% of the duty a year for each of the following three years, and reduction of any duty above 50% ad valorem to that level The renewal in 1958 was for four years and permitted further gradual reductions.

Tariff reductions under the reciprocal trade agreements program resulted in reduction of. duties collected from 53% of the value of total dutiable imports in 1930–33 (under the Hawley-Smoot rates) to 13% in 1952. Calculations of average rates, however, cannot adequately measure the restrictiveness of tariffs. Many reductions are made just to the point at which substantial increases in imports might result; administrative provisions and valuation practices are often significant barriers; and reduction of a duty may have less effect than its imposition. Trade channels, once disrupted, may be difficult to re-establish. In any event, the reciprocal trade agreements program has not resulted in unusual increases in imports; although increasing absolutely, imports have declined in relation both to exports and to gross national product.

General Agreement on *Tariffs and* Trade.—In 1947 a new tariff negotiation procedure was used; concessions agreed upon by pairs of countries were incorporated in a single General Agreement on Tariffs and Trade (G.A.T.T.). Concessions in this agreement were made applicable to all signatory countries (most-favoured-nation treatment). These and subsequent concessions negotiated at Annecy, France, in 1949, Torquay, Eng., in 1951 and Geneva, Switz., in 1955 and 1956 superseded bilateral concessions; most concessions under the trade agreements program thus became embodied in the General Agreement on Tariffs and Trade. A charter for an International Trade organization (ITO), which would have provided for reduction or elimination of trade barriers, was never adopted, primarily because the U.S. congress did not ratify it; and a later proposal for an Organization for Trade Cooperation (OTC), supported by President Eisenhower, seemed to have small chance of passage. However, G.A.T.T. continued in force and periodic meetings of the contracting parties performed some functions of an international trade organization. (See TARIFFS AKD TRADE, GEKERAL AGREEMENT ON.)

Quotas.—The United States has not made extensive use of the quota (*q.v.*), but quotas have been of some importance on certain agricultural products. Sugar import quotas were introduced under the Jones-Costigan Sugar act of 1934 and quotas for such products as wheat, wheat products, flaxseed, peanuts, butter and other dairy products, fats and oils and rice were established by the secretary of agriculture under authority of sections of the Agricultural Adjustment act adopted in 1935. The conflict betneen agricultural policy and trade policy gave rise to serious problems of over-all foreign commercial policy.

Foreign Trade Zones and *Customs* Simplification.—Such things as delay and uncertainty in classification of merchandise, valuation procedure and marking requirements have been extremely important as invisible tariffs One effort to aid foreign commerce was the Foreign Trade Zones act of 1934, which provided for foreign trade zones in which goods might be sorted, graded and manipulated and then re-exported without being entered through customs. or might be entered after such handling. In 1950 manufacturing and exhibiting were authorized in such zones. Importers may eliminate damaged goods (which then need not be entered through customs), modify goods (making them subject to a lower rate of duty) or store goods in a zone pending entry. Six zones were established by 1950; in New York city, New Orleans. San Francisco, Los Angeles, Seattle and at the municipal airport at San Antonio. Tex. The San Antonio zone ceased operation in Oct. 1953, and the Los Angeles zone in Jan. 1956.

The Customs Simplification act of 1953 changed many administrative provisions so that unnecessary marking requirements, delay in entry, harsh penalties and accounting procedures might be eliminated, reduced or simplified. The Customs Simplification act of 1956 provided for use of "export value" only, for valuation of most goods subject to ad valorem duties; previously the law required the use of export value or foreign value (basically the wholesale price in the foreign country of exportation), whichever was higher. (See also PROTECTION. United States; TRADE. INTERNATIONAL)

3. Banking and Currency.—Early Developments.—In colonial America an "unfavourable" balance of trade continually drained gold and silver money out of the colonies; at times such commodities as wheat. corn and tobacco were designated legal tender in an effort to meet the shortage of currency. The currency that circulated in the colonies was a mixture of English. Spanish, French and Portuguese coins, the Spanish dollar being the commonest. A number of-the colonies issued paper money, or bills of credit. because the colonial governments felt the shortage of money acutely and desperately needed to meet defense and administrative expenses. Issues of paper money by the colonies were often termed "banks," and the money in some cases was lent to borroners who paid interest, which could be used for improvements by the colonial government.

In the colonies there were also some associations of private persons which issued bills of credit and lent them to memhers on the security of real estate mortgages. These associations performed one of the major functions of banks, that of providing a medium of exchange, but they were not an important influence on later banking development. Banking, in fact, was restrained in the colonies by the Bubble act of 1720, passed by the English parliament to prevent excesses such as those of the South Sea company (see SOUTH SEA BUBBLE) ; application of the Bubble act was expressly extended to the colonies in 1741.

Unlike banking in Europe, which originated in the'storing of gold and silver with goldsmiths who in turn made loans, banking in America began as a result of a shortage of funds. By forming banks and combining funds and by the issue of bank notes, merchants could obtain needed money. In the modern sense U.S. banking may be said to date from the incorporation of the Bank of North America, which obtained a charter from congress in 1781. Two other banks were in operation before 1789—the Bank of Massachusetts in Boston in 1784 and the Bank of New York. which began operations in 1784 although it was not incorporated until 1791.

With the establishment of the new government, the need for a better monetary system was recognized. Art. 1, sec. 8 of the constitution gave congress the power to "coin Money" and "regulate the Value thereof," and art. 1, sec. 10 stated that "No State shall . . . coin Money; emit Bills of Credit; make any Thing but gold and silver Coin a Tender in Payment of Debts. . . ."

Notes concerning a mint and coinage written by Jefferson and a report on this subject by Hamilton exercised substantial influence on the Coinage act of 1792. which provided for a bimetallic monetary system (see BIMETALLISM) based upon a dollar consisting of $24\frac{3}{4}$ gr. of pure gold or $371\frac{1}{4}$ gr. of pure silver—a ratio of 1 to 15. This act also provided for unlimited and gratuitous coinage by the mint. to be established in Philadelphia. of both metals at the option of any holder: and it designated gold and silver coins to be minted. Hamilton had argued that "to annul the use of either of the metals, as money, is to abridge the quantity of circulating medium "

It appears to have been the intention of the framers of the constitution to prohibit issuance of paper money by the federal government; the experience with paper money issued by the continental congress and by the colonies was bitter. The constitution made no reference to banks or banking; according to one authority this is probably because the subject was too controversial.

Growth of *U S* Banking.—In 1790 Hamilton submitted his plan for a bank to conduct a commercial banking business and also to aid the government in public finance and lend to the treasury. The first Bank of the United States was established by an act of congress in 1791. One-fifth of its capital was to be subscribed by the government, and the bank was given the power to issue bank notes, to accept deposits and to establish branches. It was prohibited from dealing in goods, from owning real estate other than that "requisite for its immediate accommodation in relation to the convenient transacting of its business, and such as shall have been bona fide mortgaged to it by way of security, or conveyed to it in satisfaction of debts. . . ." It was also specified that the tctal debts of the bank should not exceed the "monies then actually deposited in the bank for safe keeping" by more than $10,000,000, thus establishing the principle of fractional reserves for note issues. Deposits were exempted from similar restriction by not specifying a limit for them. because at that time deposits meant primarily deposits of specie, not deposits created in the process of lending. Hamilton's model was the Bank of England (*q.v.*), and in fact the first Bank of the United States was a kind of central bank (*q.v*), performing services for the government and exercising a stabilizing influence on banking generally. In the decade 1790–1800, about 24 banks were established, all of them in towns and cities of commercial importance.

During its 20-year life considerable controversy arose over the first Bank of the United States. Its charter was not extended when it expired in 1811, although one of the chief stockholders acquired the bank and continued a private (unincorporated) banking business. The War of 1812 and accompanying "runs" on banks, which caused bank suspensions and varying depreciation in the value of bank notes, combined with the difficulties of federal finance. resulted in a changed attitude and a desire for establishment of a second Bank of the United States to help restore a sound monetary system. Votes of southern and western senators and representatives were significant in the passage of the act to incorporate the second bank, in 1816. Although the new bank was larger, its powers were very similar to those of the first bank. Opposition to it developed on several fronts. however, and in 1832 President Jackson vetoed a bill to extend its charter, which expired in 1836. (See History, above.)

With the end of the central banking functions of the second Bank of the United States and with the growing popularity of the free banking system (under which any persons or group of persons meeting certain conditions could organize a bank), the number of banks and the amount of their note issues increased rapidly. Many of these banks did not, and could not, maintain enough reserves to redeem the quantity of notes presented for redemption. and bank notes began to circulate at varying discounts. In most sections of the country banking conditions were unsatisfactory and bank notes were of uncertain value. (Government funds were held in subtreasuries under the independent treasury system established in 1846 after an abortive attempt in 1840.) These conditions, plus the need of money by the government to finance the Civil War, led to passage of the legislation generally referred to as the National Bank act of 1863.

This act provided for incorporation of banks under federal law, for issue of bank notes on the security of government bonds and for minimum cash reserves against both notes and deposits, with permission for deposit of a portion of such reserves in major banking centres (central reserve cities and reserve cities. as they came to be known). Although it had been expected that state banks would soon convert themselves into national banks, they were slow to do so, and a heavy tax was therefore imposed on state bank notes. This resulted in a period, from about 1865 to 1893, when national banks were more numerous than state banks. However, the growing need of the country for banking services and the growth in importance of deposits as compared with bank notes resulted in the establishment of so many state banks that these became much more numerous after 1900 and remained so.

Although part of the cost of the Civil War was financed by taxation and by borrowing, these were insufficient; congress authorized issues of United States notes, or greenbacks, as legal tender. The greenbacks depreciated in value, the extent of their depreciation varying with the quantity of money in circulation, the success of the Union armies and, later, the prospects for redemption. The Resumption act of 1875 provided for gradual retirement of the notes and their redemption in specie beginning in 1879. As redemption approached. their value increased; the greenbacks are one of the few instances in which government wartime issues of paper money have been successfully restored to their face value (See *History:* From 1865 to 1910.)

Silver v. Gold.—Shortly after the establishment of a bimetallic monetary system in 1792, silver declined somewhat in value. A French coinage law of 1803 provided for bimetallism in that country, with a ratio of $15\frac{1}{2}$ to 1. The greater economic importance of France in that day and the mint overvaluation of silver combined to attract silver to the mint, while gold was driven out of use as money. Special circumstances caused silver dollars to be drained out of the country to the West Indies, where they could be exchanged for heavier-weight Spanish dollars at one to one; the Spanish dollars were then imported and sent to the mint for coinage into a larger number of United States dollars. This process could then be repeated, with profit.

In effect, these conditions resulted in a de facto silver standard until the coinage acts of 1834 and 1837 adopted a ratio of 16 to 1 (15 988 to 1 in the act of 1837). The gold dollar was defined as 23.2 gr. of fine gold (23.22 gr. in the act of 1837), resulting in increased gold coinage and a flow of silver out of circulation. New gold discoveries in the period 1845–50 made the supply of gold more plentiful, and the market value of gold in relation to silver declined accordingly. By 1853 the amount of silver in the fractional coins was reduced. making them less valuable, and bullion for coinage of these was to be purchased by the director of the mint. If the silver dollar had at that time been omitted from the list of coins to be minted. the United States would have had a de facto gold standard.

In 1873 the silver dollar—which had not been coined for some time because silver was more valuable as a commodity—was omitted from the list of coins to be minted. The volume of national bank notes was limited, state bank notes had been taxed out of existence and gold production was smaller than formerly. All of these factors combined to limit the increase in money; yet the volume of production was increasing rapidly. After the panic of 1873 a general desire for more money, combined with the attempts of silver interests to benefit themselves, resulted in legislation for purchase and coinage of silver. The Bland-Allison act of 1878 provided for the purchase of $2,000.000 to $4,000,000 of silver per month for coinage into silver dollars. The Sherman Silver Purchase act of 1890 directed the secretary of the treasury to purchase 4,500,000 oz. of silver per month and to issue treasury notes based upon it. Silver advocates gained control in the Democratic party in 1896 and William Jennings Bryan campaigned on a platform of free silver coinage in both 1896 and 1900. The defeat of Bryan in 1900 ended this effort; and earlier that year the Gold Standard act had designated the gold dollar of 25.8 gr. of gold ($\frac{9}{10}$ fine) as the standard of value. Gold production had begun to increase in 1890 and the general price level began to rise in 1896; the need for silver money was not so apparent. (See History: From *1865* to 1910, above.)

The *20th Century.*—The panic of 1907 created added interest in banking reform, and the Aldrich-Vreeland act of 1908 created a National Monetary commission. Only a year after the commission submitted its report. a bill sponsored by Rep. (later Sen.) Carter Glass and supported by President Wilson established the federal reserve system (*q.v.*), thus giving the country a central bank aiter a lapse of three-quarters of a century. The 12 iederal reserve banks serve as bankers' banks for their respective districts, serve as agents for the treasury and issue federal reserve notes, which in the mid-20th century constitute the chief form of paper money.

The banking system of the United States in the second half of the 20th century included over 14,000 banks, which at the end of 1957 had nearly 23,000 banking offices. Of these, about 4,600 were national banks. About 1,800 state banks (out of nearly 9,000) were members of the federal reserve system. The national and state member banks had about 85% of the total deposits held by all commercial banks, and were in most cases larger and more important. There were a few notable exceptions, among them the state-chartered Chase Manhattan bank, second largest in the country. There were somewhat over 500 mutual savings banks (*q.v.*) located in 17 states that had in 1958 nearly $35,000,000,000 in deposits.

This structure was strongly influenced by the banking legislation of the 1930s, especially the Banking act of 1933. This law provided for state-wide branch banking by national banks in any state in which this was permissible for state banks, required separation of commercial irom investment banking. established a system of deposit insurance and prohibited payment of interest by banks on demand deposits. The Banking act of 1935 modified and made permanent the deposit insurance plan, made changes in the organization and powers of the board of governors of the federal reserve system, giving it power to increase or decrease reserve requirements of member banks within specified limits, and made many technical changes in banking law.

Important monetary legislation also was passed in the 1930s. The depression and accompanying bank failures had created a serious demoralization of the banking system, and immediately aiter his inauguration President Roosevelt proclaimed a four-day banking holiday. Congress passed an Emergency Banking act on the last day of this holiday, and banks considered sound were permitted to reopen. A joint resolution of congress on June 5, 1933. made all obligations payable in any legal tender currency instead of in gold and an amendment to an agricultural act, enacted May 12, 1933, authorized the president to issue greenbacks, devalue the dollar, provide for free and unlimited coinage of silver and take other measures to increase the quantity of money. The objective was to raise prices as a means of restoring prosperity. This "inflation amendment" also made all coins and currencies issued "by or under the authority of the United States" legal tender.

The Gold Reserve act of 1934 transferred legal title to all gold held by federal reserve banks to the United States government, provided for withdrawal of gold coin irom circulation, prohibited redemption of currency in gold (except with authorization of the president), specified that the gold dollar should be reduced to not more than 60% and not less than 50% of its former weight, authorized a stabilization fund for the dollar from the "profit" from devaluation and made other changes. This legislation thus established a provisional international gold bullion standard. Gold did not circulate, henceforth, in the domestic monetary system, but the fact that it could be exported, subject to treasury licence, made it possible for foreign central banks and governments to maintain deposits in the United States with the assurance that these could probably be converted into gold upon demand. In some years, in fact, gold flowed out of the United States in response to such demand.

During World War II control of consumer credit was added to the margin requirements which the federal reserve had been authorized to impose in 1934 as a means of checking the use of credit for speculative purposes. War finance was aided by permitting federal reserve banks to purchase a limited amount of treasury obligations directly instead of in the open market, by exempting war loan deposits from reserve requirements and by reducing the minimum reserve requirement of the federal reserve banks to 25% of their note and deposit liabilities. The iederal reserve system supported prices of government securities and during the war maintained a fixed pattern of yields for various maturities These actions led some to refer to the iederal reserve system as "an engine of inflation." and the persistent rise in prices in the period after World War II led to fears that inflation was a continuing problem. The fear of inflation led to temporary reimposition of consumer credit control (regulation W) in 1948–49 and again in 1950–52. Similar control of credit for purchases of real estate (regulation X) was imposed in 1950–52 and a program of voluntary credit restraint (VCR) was in effect for a time.

An "accord" between the federal reserve system and the treasury in March 1951 gave the federal reserve freedom to use instruments of monetary policy without the necessity of maintaining fixed yields for government securities. Although it endeavoured to maintain "orderly conditions" in the markets for government securities. the actions of the iederal reserve in the following years were aimed at the use of monetary policy (changes in discount rates, open market operations and changes in reserve requirements) to achieve relatively full employment, reasonable stability in the general price level and long-term economic growth. Beginning in 1949 a series of hearings of congressional committees attempted to throw light on these policies and their relationship to management of the public debt and to the growth of financial institutions other than commercial banks. By 1957 there was consideration of a new national monetary commission, similar perhaps to that of 1908–12. Several factors prevented establishment of such a commission officially, but the Committee for Economic Development, a business group of some influence, announced that it would sponsor such a commission. (See also BANKING: *History of* Banking *in the United* States.)

4. National Finances. — Early History. — Under the Articles of Confederation, the federal government was empowered only to borrow and to make requisitions on the states, not to tax. Consequently. its financial position was extremely difficult. In its first two years it received little more than one-tenth of the amount requested from the states, and during its life it obtained barely enough funds to meet current expenses (and not enough to meet interest requirements on the debt). National finances finally broke down completely in 1786 Further borrowing had become virtually impossible and requisitions yielded practically nothing.

The constitution of 1789 gave the iederal government broad powers in the field of public finance, including the power to lay and collect taxes, duties (except on exports), imports and excises and to borrow money, pay debts, coin money and regulate the value thereof. States were forbidden to coin money, issue bills of credit, make anything other than gold and silver legal tender or lay any duties on imports or exports.

The treasury department was created with a single head (instead of a proposed commission). Customs duties (somewhat protective in character), excises and sale of public lands provided revenue. Funding of debt owed in France, Holland and Spain and domestically (both by the federal government and by individual states) was provided for in the Funding act of 1790. Continental currency had long since ceased to circulate as currency and had been bought and sold by speculators at from 500 to 1,000 to 1; a small amount was funded into the new debt at 100 to 1, while much of the continental currency was not presented to the government.

Until the Civil War customs duties constituted the main source of revenue of the federal government. Sales of public lands yielded some revenue. Revenue sources mere more than sufficient to provide for current expenses, and the national debt was reduced to zero in 1835—but debt was quickly incurred again as a result of the depression of 1837 and the Mexican War.

The Civil War Through World *War* I.—The Civil War created great public-finance problems. Greenbacks issued by the federal government could not be redeemed in specie and depreciated substantially in terms of gold. In spite of the introduction of internal revenue taxes and an increase in import duties, deficits were large.

Marketing of bond issues was aided by the National Bank act, which required bonds to be used as collateral for bank notes After the war national finances improved: wartime taxes were repealed and rising customs revenues helped provide budget surpluses in the years 1866–93. Specie payments were resumed by the treasury in 1879 and the public debt was reduced continually—to less than $1,000,000,000 in 1888

The history of federal expenditures has been one of gradual increase between wars and tremendous increases in wartime. Peak expenditures in 1814 reached nearly $35,000,000, in 1865 almost $1 300 000.000, in 1919 over $18,000,000,000 and in 1945 more than $95.000.000.000 The same is true of federal expenditures as a percentage of national product for the period after 1870 (for which national product estimates are available). By 1916 gradual increase had raised federal spending to a level approaching that of the Civil War peak. although per capita spending was only slightly higher than the 1870 peak (which had been followed by a sharp drop).

The 16th amendment to the constitution authorizing income taxes was ratified in 1913. By 1920 over two-thirds of federal revenue came from income and profits taxes whereas in 1910 over 96% had come from internal revenue and customs receipts

Even such revenue. however, could not meet even half the cost of World War I. and deficit financing was conducted chiefly through sale of short-term obligations to obtain funds initially, then by funding into large popular bond issues. Five such loans during the war and shortly after the Armistice raised about $21,000,000,-000. and the public debt reached a peak of over $26,000.000 000 in 1919 Thereafter, honever, it was reduced—by about $10,000,-000,000 over the next decade.

With the decline of federal spending from the wartime high, taxes also mere reduced. The excess profits taxes on corporations were repealed (although the corporation income tax was raised), individual income tax rates were reduced and a number of excise taxes were eliminated. During the 1920s further tax reductions occurred

An important fiscal development was the inauguration of an executive budget under an act of congress of 1921. A bureau of the budget was established to prepare the annual budget and other estimates At first the budget was largely an accounting document designed chiefly to secure economy in government. As the years went by. however, the budget became the chief document for presentation of the president's views on fiscal policy and expenditure programs designed to achieve goals of governmental policy. (See BUDGET, GOVERNMENTAL. *United* States)

During and immediately after World War I, the United States government made substantial loans to foreign governments for war and relief and reconstruction purposes. The principal debtor governments sought to condition their payments of interest and repayments of principal on receipt of reparations from Germany, and no satisfactory method of obtaining repayment of these loans was ever derised Ultimately all debtor nations defaulted, in whole or in part. and by the 1950s the unpaid amounts were generally regarded as uncollectible.

Depression Finance—National finances in the decade 1930–39 were influenced primarily by the world-wide depression Unemployment necessitated large outlays for relief, work programs and emergency credit institutions.

The Roosevelt administration, departing from the approaches used under Hoover, instituted monetary reform, banking reform. an industrial recovery program, agricultural subsidies, public works and relief programs, Social Security and unemployment legislation. Deficit financing, begun because of necessity, became to some extent a policy to aid in recovery. A gift tax. a group of manufacturers' excise taxes and other miscellaneous taxes were enacted in 1932 to add revenue; other taxes were added in 1933 and 1934. Rates of estate and gift taxes were increased and exemptions were decreased. Personal exemptions in the income tax were also reduced and rates of both individual income and corporate income taxes were raised. Taxes were imposed on both employers and employees to provide funds under Social Security. beginning in 1935. As a result. the national debt more than doubled from 1930 to 1939; interest payments did not rise proportionately because bank excess reserves made it possible to sell short-term government obligations at relatively low yields.

World War II and After.—During World War II there was a great rise in the national debt, a policy of supporting government obligations at an almost fixed pattern of yields and use of wartime controls (allocations, rationing, price and wage controls and credit controls). National security expenditures, which constituted less than half of budget expenditures in 1941, constituted about 85% in 1945, and although they dropped to about one-third in 1950 they climbed again to nearly two-thirds in 1955. In the budget for fiscal 1959, in the midyear review. it was estimated that major national security expenditures would total nearly $47.000,-000.000, international affairs and finance nearly $1,500,000,000 and veterans' services and benefits over $5,000,000,000—a total of $53,500,000,000 or more than 67% of the total budget of $79,223,000,000. Major receipt and expenditure items for selected years are shown in Table XX.

TABLE XX.—*Budget and Expenditures Receipts of the Federal Government by Major Function**

After reaching a peak of over $269,000,000,000 at the end of fiscal 1946. the public debt declined somewhat to just above $250,-000.000.000 in the period 1948–1949. With the outbreak of the Korean conflict in 1950 the debt began to rise again (see Table XXI) and by the end of fiscal 1958 it exceeded $275.000.000,000. A debt limit, set by congress, had been raised to $300,000,000,000 by the end of World War II and then lowered to $275,000,000,000. Heavy expenditures, combined with the economic recession of 1957–58, necessitated raising the limit in 1958 to $288 000.000.000 as a temporary limit and $283,000,000,000 as a presumably more permanent ceiling.

Tax revenues needed for World War II and for the relatively

high level of expenditures thereafter were obtained chiefly from increased personal and corporate income taxes and corporation excess profits taxes during certain periods; some revenue was obtained from excise taxes. Some tax reduction occurred after World War II, and the corporate excess profits tax was abolished in 1946. Exemptions allowed in the personal income tax were increased, and in 1948 legislation permitting "splitting of incomes" between husband and wife reduced taxes for married persons (this "splitting" had been possible previously only in community property states). The Korean conflict necessitated an increase in taxes again; this was followed by some tax reduction in 1954. The Revenue act of 1954 included a provision termed a dividend income credit, designed to reduce, to some extent, the double taxation of corporate dividends.

The great growth of the public debt, which made government obligations the chief item of secondary reserves for banks (see Table XXII, showing ownership of government securities), and which made the government bond market an extremely important segment of the money market, caused concern over the management of the public debt. The Patman committee hearings in 1952 provided information concerning the relationship of the debt to the monetary and banking system, and later hearings also focused attention on such significant problems as the status of the board of governors of the federal reserve system. the relationship of fiscal policy (relating to public finance — taxation, budgeting, debt, management, etc.—and its effect on income distribution) to monetary policy (relating to the money supply), the effects of debt management policies and the use of fiscal and monetary policy to achieve economic growth, mitigate business cycles and at the same time maintain "reasonable" stability in the general price level. Reports of the joint economic committee of congress emphasized the importance of tax policy and expenditure policy in achievement of these goals. Necessity of adequate defense, probably requiring rising levels of defense spending, was recognized, together with the need for careful attention to the destabilizing effects of government spending at certain times. (C. N. HG.)

D. TRANSPORTATION AND COMMUNICATIONS

It is easy to forget that 200 years after the establishment of the first English colony in 1607 virtually all important towns were on tidewater and nearly all freight was carried in small sailboats. Overland transportation was confined to unsurfaced roads and trails which were impassable to wheeled vehicles during much of the year. It is not surprising that contemporary writers believed that many centuries would be required to fill the vast territory acquired by the Louisiana Purchase. Yet within 160 years that territory, and much more, was populated to an average density greater than that of the coastal strip at the time of the Revolution. The successive revolutions in transportation had much to do with this.

1. Historical Development. — Roads were the first of three major transportation developments to follow the American Revolution. Their expansion continued for several decades in spite of increasing and soon overwhelming competition from canals and railroads for long-distance bulk carriage. All-weather surfaces of various types, including wooden planks, were installed, materially increasing the loads that could be drawn with a given number of horses.

In addition to the cost advantages of such roads, the power of the English navy provided compelling military reasons for building roads parallel to the coast that could not easily be cut off by sea. Although there were several comprehensive plans for a network of national highways, only one of any importance, the Cumberland road, was constructed with national funds. Public interest was expressed by land grants and other aids. The numerous roads built predominantly by private turnpike and plank-road companies sooner or later ran into financial difficulties and were, for the most part, turned over to local control where the obligation to keep them passable fell to abutting property owners with a private interest in their maintenance.

Interest in highways revived with the invention of the safety bicycle and became an overriding interest with the development of the automobile. Highway construction was initiated by the states; federal aid began in 1916 and a system of national highways, financed 90% by the federal government, was undertaken in 1944 and expanded in 1956. These developments, together with expansion of the state highway systems, placed the highways back in contention with the railroads as prime movers of both passengers and freight.

Technological considerations seem to explain the fortunes of the various transportation mediums. Teams of horses could move heavier loads over all-weather surfaced roads than over unsurfaced roads. The same teams could draw still heavier loads over canals. Neither could compete with the load-drawing power of the steam locomotive. Although steam could be economically applied to larger ships, the amount of useful cargo space rises rapidiy with the size of steamships, putting steam-powered canal boats at a serious disadvantage.

Some canals, like some roads, were abandoned, but characteristically, no general mode of transportation ever disappeared. Coastwise shipping, roads, canals, railroads and other forms of transportation all have some advantage. The mammoth tanker, the towboat and barge, the railroad, the pipeline, the truck, the automobile and the airplane — each provides the lowest-cost service for some type of freight or passenger movement. As technological advances occur, the type of transportation favoured by each advance expands and the others become limited to their most advantageous services.

Erich Zimmermann declared that land that is useful to man for agriculture in the United States would not be so in a country such as the China of the early 1930s. The main difference is the availability of transportation. With efficient transportation China may be able to double its area of useful land. In any nation, an area enjoying cheap transportation need not produce even its necessaries if it can produce a surplus of some product that can be sent out and exchanged for other goods and services. Thus efficient transportation makes it possible to concentrate production of the various raw materials where nature provides them most abundantly and to produce new commodities with near-maximum economies of scale.

Illustrative of this type of specialization is the concentration of iron- and steelmaking at Pittsburgh, where good coking coal, iron ore and local water transportation made possible much lower costs than could be obtained nearer the centres of population on the coast where ore and fuel were of lower quality. A more complicated structure of the industry followed the installation of locks at Sault Ste. Marie, bringing together the midwestern coal fields at the base of Lake Michigan and the rich iron deposits near Duluth, Minn. The location and efficiency of U.S. agriculture is likewise a result of changes in transport. To take a single example, the fresh-meat industry was once local by necessity. It had to be concentrated close to the final markets so that herds could be driven — in relatively small numbers — to local slaughterhouses. With the development of the railroad and particularly of the refrigerator car, ranchers on the western plains could raise cattle on the free grass of the public domain and ship great numbers with moderate weight loss to huge packing plants at the railroad centres. From there the products were distributed to major consumer markets. The modern highway brought still another change.

Farmers who own their own trucks can compare prices at several packing plants by means of frequent radio reports and transport their cattle accordingly. In this way they avoid part of the weight loss that accompanied longer shipment of livestock to central markets. The resulting reorganization of the industry reduced the importance of meat packing at the great rail junctions such as Chicago.

Some idea of the growth of various types of transportation in the U.S can be gained by a brief comparison of statistics. According to U.S. department of commerce figures. the mileage of surfaced roads rose slowly during the 19th century, from about 27,000 mi. in 1830 to 128,000 mi. in 1900. By 1940 it was 1,340.000 mi. and by the late 1950s, more than 2,000,000 mi. This increase was paralleled by the rise in the number of registered motor vehicles — from about 8.000 in 1900 to more than 70,000.000, 60 years later. The number of ton-miles of freight moved by intercity motor vehicles rose from 62.000.000.000 in 1940 to 173,000,000,000 in 1950 and to about 250,000,000,000 in the late 1950s.

Railroad mileage in operation, on the other hand, reached a peak somewhat earlier. In 1914, as the great era of railroad building drew to a close, it stood at 256,547. There was a slight increase thereafter — in 1930 the figure was somewhat more than 260.000 mi. — followed by a steady decline. Slightly more than 230,000 mi. of first-line track were in operation by the late 1950s. With some fluctuations relating to the state of the economy. the volume of railroad freight tended to hold steady or even increase, although the percentage of total freight traffic carried by rail declined from 63 in 1940 to 47 in 1958 (as compared with a rise from 9.5% to 20% for motor vehicles over the same period). Railroad passenger-miles fell from 47,370,000,000 in 1920 to 23,295,000,000 in 1958. a year in which railroads were surpassed by the 25,343,000,000 passenger-miles flown by domestic aircraft.

Airlines. while carrying less than 1% of total freight, rose in this capacity from 14,000,000 ton-miles in 1940 to more than 570,000,900 ton-miles by the late 1950s The other two principal freight carriers, inland waterways and pipelines, showed less spectacular increases. In 1940 inland waterway transport — including the Great Lakes — accounted for 118,000,000,000 ton-miles of freight or about 18% of the total. By the late 1950s the volume had risen to almost 190,000,000,000 ton-miles but the percentage had declined to 15.5%. Volume carried by oil pipelines rose from 59,000,000,000 ton-miles or almost 10% to 211,000,000,000 ton-miles or about 17% during the same period.

Communication has played a role similar to that of transportation in producing a unified nation from a far-flung, sparsely populated land. Congress recognized its importance when it established the post office in the first year of the republic. The breakthrough in modern communications came with the application of electricity to the sending of messages. The telegraph, which put the pony express out of business, was followed by the telephone, the ocean cable. radio and television. Telecommunications are an indispensable part of air and sea transportation as well as an important adjunct to nearly every business, national defense and entertainment

Telecommunication has virtually annihilated space and time. Transportation is not far behind They represent triumphs of technology which have laid the basis for a growing world consciousness that may presage a world community. It is a simple fact that from the standpoint of communication time and transportation time the globe is smaller today than was the American republic of 1803.

2. Roads. — The road system of the United States can be divided into rural farm-to-market roads, rural intercity highways and city streets. In the late 1950s there were more than 400,000 mi. of city streets and about 2,300,000 mi. of farm-to-market (locally controlled) roads, as compared with almost 750,000 mi. of state and federal highways.

Rural Roads. — Farm-to-market roads are the last to receive all-weather surfaces. primarily because of the great area to be improved and the high cost as compared with the amount of use, but by the mid-1950s more than 60% of such roads had some kind of all-weather surface. Good rural roads have increased the ability of the farmer to market his own products to greater advantage. They have also removed much of the isolation of rural life. Along with the increased use of farm machinery and the spread of rural electrification to more than 95% of U.S. farms, improved roads helped to transform farm life after 1900. greatly reducing the historic distinction between city and rural ways of living.

Intercity Roads — Until the coming of the automobile and truck, virtually no roads or streets were provided with all-weather surfaces except in the most heavily traveled parts of the cities. Hence, construction and maintenance costs were low. The national highway system began to take shape during World War I. although the initiative remained with the states. Gasoline taxes provided a ready source of revenue which could be tapped to finance high ay construction, and the growing popularity of the private automobile gave widespread acceptance to this form of governmental enterprise.

Roads built primarily for private passenger cars were available for motor trucks as well. and the amount of truck traffic rose from none in 1903. when truck production began, to 41 trillion vehicle-miles in 1930 and to 116 trillion in 1956. only 35% of which was in cities. Tonnages increased even more. The greater weight of trucks and the traffic congestion on hills occasioned by them produced controversy. It has been contended that trucks do not pay for the added highway construction and maintenance costs which their great weight and width make necessary. However, trucks have demonstrated speed and convenience, resulting from ease in packing and handling and avoidance of time lost in switching yards, sufficient to enable them to take over many of the more profitable types of shipment formerly handled by the railroads in spite of the trucks' higher ton-mile cost.

Trucks are relatively most efficient for small-lot and short-haul shipments, and it is in this field that they have cut most severely into railroad business. Local distribution of products is almost completely handled by trucks because of their flexibility.

In the late 1950s intercity bus lines using the public highway provided almost as many passenger-miles as the railways and more than two-thirds as many as the airlines. Buses fill certain transportation needs better than any rival method Because roads exist to all towns. greater coverage can be given. Operating with a seating capacity less than that of a railway coach and with only one hired operator per unit. buses can offer frequent schedules to localities where comparable railroad service might be unprofitable. Fares are often lower by bus than on any other form of transportation, and the average speed, including stops, may be as fast as that of the private automobile.

City Streets. — Transportation of passengers within and between cities was revolutionized by the automobile, but not before a prior revolution by the street railways had taken place. With the advent of the electric motor, trolley cars running on rails appeared in cities all across the nation. In many cases these streetcar systems branched out into interurban services which competed directly with the railroads for passengers on intercity runs. At its peak, street-railnay mileage exceeded that of the railways proper.

The residential sections of cities grew along the streetcar lines, the streets remaining unsurfaced in most cases, but with inexpensive sidewalks providing good footing to the houses. A tremendous incentive was thus provided toward centralization of business in the downtown sections where the trolley lines converged. Businesses a little way out were sharply penalized, since the shopper was on foot and home delivery was still a luxury.

With the advent of the automobile and surfaced roads, the spaces between the elongated residential districts filled up. The flexibility of the automobile brought business districts miles apart into competition with each other, and the great advantage of a downtown location was, at least partially, offset by the advantage of large parking lots at suburban shopping centres. Nor was delivery so much of a problem. Many shopkeepers who had built businesses based on the telephone and rapid delivery found that when women started to drive as a matter of course, they preferred to shop and carry their orders home in their own cars, saving. at least in their eyes, the delivery cost.

Street railways went into sharp decline and by the 1960s had all but disappeared in cities of less than 500,000 population. Some subways and elevated trains and many transit buses remained. All showed declining traffic and poor financial health. Many were being subsidized in one way or another in the belief that they provided an indispensable service. (See also ROADS AND STREETS: Road and Road Construction in the United States; MOTOR TRANSPORT, COMMERCIAL; ELECTRIC TRACTION.)

3. Inland Waterways. — Two major divisions of inland water transportation exist in the U.S.—shipping on the Great Lakes (*q.v.*) and shipping on the rivers and canal systems. Nearly all of this traffic is freight, although a few excursion and passenger-car ferries on the Great Lakes and numerous short ferry lines continue to operate. Although the relative importance of water traffic declined with the growth of railroads, the total volume of shipping rose to new highs, both on the Great Lakes and on the Mississippi river (*q.v.*) and other river systems. Great Lakes commerce was given additional impetus by the opening of the St. Lawrence seaway (*q.v.*) to larger ocean-going ships in 1959.

Historically, the opening of the Erie canal which connected Lake Erie (above Niagara falls) to the Hudson river and New York city, diverted much trade, particularly in grain. from the long trip down the Mississippi river system to New Orleans and then by sailing vessels to the east coast or abroad. This canal, greatly deepened and widened, continues to function as the New York State Barge canal. The shift of trade from a north-south to an east-west direction set a permanent pattern for U.S. freight traffic.

Heavy products that can be handled on a very large scale predominate in waterway movement. Iron ore, coal, grain, petroleum products, sand and gravel, cement and similar products are the principal commodities moved. On the Ohio-Mississippi river system automobiles and similar items are moved by barge, but even when placed in many layers they fail to weigh enough to be considered a full load.

The application of steam power to water transportation occurred at the most rapid rate on the Mississippi system. Prior to the river steamboat, produce was rafted down the river to New Orleans where the rafts were broken up for lumber while the crews returned north overland. With steam, upriver traffic was possible even with large loads. The combination of upstream and downstream trade served to lower costs, enabling New Orleans to hold much of the mid-continental trade. However, the growth of railroad routes to serve the river ports effectively put an end to passenger traffic and all but the heaviest freight traffic by water.

By mid-20th century virtually all inland water freight, except on the Great Lakes, was carried in barges. Towboats are lashed to groups of barges in such a manner as to make each unit virtually a single ship. River-channel depths are maintained by dredging, construction of jetties and similar devices. The day of the shallow-draft river boats is gone, and it is difficult to imagine that steamboat service at one time reached more than halfway across Montana. The Great Lakes are likewise a flourishing waterway, the locks at Sault Ste. Marie being the busiest in the world in terms of tonnage passed. There, immense but rather slender ships carry tremendous tonnages, especially of iron ore, during the ice-free months. (See also INLAND WATER TRANSPORT: United States and Canada.)

4. Railways. — The 19th century was a railway age in the United States. In the 20th century railways remained the largest carriers of freight, in spite of the rise of competitors on the land, under the land and in the air.

During the Civil War railroads proved their great military value. Not only was it difficult to keep a railroad out of operation, but railroads revolutionized the speed of movement, especially of supplies. Three decades after the Civil War, the railway network of the United States was virtually completed. At that time it was the only economical form of transportation for much of the country. A comparison made in 1873 for the period 1866–73 reported rail rates of 5.2 cents a mile per passenger — 7.3 cents below stagecoach rates — and rail freight rates at 8 cents per ton-mile — a saving of 21 cents as compared with wagon freight. The rail charges given in this comparison are higher than others reported for the period. By 1880 freight charges were about & of a cent per ton-mile and passenger fares about 2.1 cents a mile.

The railway age greatly accentuated the shift in the main flow of traffic, begun in the canal era, to an east-west rather than a north-south direction. Interregional specialization within a national market, made possible by the railroad, contributed greatly to the tremendous and sustained rise of production during the century. Finally, along with the development of telecommunications, the railroad bound the nation into greater political unity. Loyalty to localities and states began to be surpassed by loyalty to the nation as economic interdependence and the physical mobility of the population brought greater cultural homogeneity.

The rapid completion of the railway network was stimulated bv government activity at all levels. The federal government offered construction loans, later repaid with interest, and grants or parcels of land amounting all told to 131,350,534 ac. or about 9.5% of the areas of the states served along the rights of way. State and local governments gave concessions, provided land for terminals and purchased railway bonds to attract railways to their territories.

At the outset this participation was unaccompanied by restrictive regulation, but the monopolistic power of railways where not confronted by rivals. and "cutthroat" rate setting where rivals did exist brought a demand for public regulation to which both the federal government and most states responded by establishing regulatory commissions. Because of the constitutional limitation of federal power to interstate commerce, the federal Interstate Commerce commission (ICC), set up in 1887, left to state commissions the regulation of railways insofar as purely intrastate transportation was concerned. While this distinction remained valid, the scope of federal regulation was gradually widened by increasingly broad interpretation as to what could be said to "affect interstate commerce." Designed at first to prevent excessive earnings as a result of monopoly power on the one hand, and to prevent predatory competition intended to establish monopoly power where rival railway systems existed on the other, the regulation of railroads came to be primarily directed toward establishing a rate structure that would enable the railways to enjoy a "fair share" of the traffic and at least moderate financial health in the face of increasing competition. (See also RAILWAY: Railways in the United States; INTERSTATE COMMERCE.)

5. Pipelines. — In the 20th century pipelines became major carriers of fuels. Oil, natural gas and, after late 1958, coal move in quantity and for considerable distances in underground pipes. First used in the 1860s to avoid high railroad rates for oil, pipelines to gather oil from the wells and bring it to refineries or tank farms where it could be transshipped soon became common. Later, lines carrying refined petroleum products were laid. Some delivered petroleum to ocean ports for loading on tankers large enough to provide economical transportation to the east coast or elsewhere. Others penetrated areas otherwise served only by rail or road. Different products may be carried in the same line. At one time a "plug" of water separated one product from another, but experience showed this to be unnecessary since very little mixing occurs in the line.

The resulting economical handling of crude and manufactured petroleum products led to a tremendous expansion in their use, contributed greatly to the development of the private car, the truck, the bus and the farm tractor, led to the widespread use of oil in home heating and provided a cheap fuel superior for many industrial purposes in which close control of temperature and lack of ash are important.

Another spectacular achievement of the pipeline was to convert natural gas from virtual uselessness into a principal source of power. Formerly much natural gas, produced as a by-product of the petroleum industry. was vented into the air, usually burned or "flared" in the process. Although many uses for natural gas have been found, such as providing raw material for some of the man-made fibres, its basic use is as an industrial and household fuel. Natural gas is distributed almost exclusively by pipeline although some is liquefied for shipment by tanker. Pipelines built during World War II for the transmission of oil to the east coast, at a time when German submarines were taking a heavy toll of tankers between the Gulf coast and the eastern seaboard, were subsequently converted to natural gas, and new lines extending from the mid-continent as far as Seattle were built in the postwar period Thus, an enormous amount of power which formerly went largely to waste was utilized to produce benefits over a wide area. Together with oil, natural gas supplies more British thermal units of energy than any other source in the United States.

New possibilities for the pipeline industry were opened with the construction of a 108-mi. line from Cadiz, O., to Cleveland, capable of delivering coal at the rate of 1,200.000 tons annually. Small lump coal. used to produce electricity, is pumped with water through the line.

6. Transmission Lines. — Although not ordinarily classified as a form of transportation, the transmission of electricity is a direct substitute for the movement of coal, petroleum and gas since large quantities of these are converted into electricity before final use. The cost of transportation of coal, oil and gas has also affected the extent to which electricity is developed by water power rather than by coal. oil or gas-burning plants. In general, the power lost in transmitting electric power over long distances is sufficiently large to make it profitable to move fuels close to the poaer-consuming markets. However, improved methods of transporting electricity have enabled steam plants to locate at more favourable sites at moderate distance from users.

Inherent advantages exist in large monopolistic systems in which many plants can feed power into grid which serves a large area. Electricity flows toward the points of highest drain in a predictable way, and the various plants can be activated to provide overall economies not available to smaller systems. Such grids can come close to making full use of water-power resources, often using steam plants to stabilize production as demand and stream conditions vary. In the second half of the 20th century, the availability of cheaply transported power contributed to the suburban and rural relocation of industrial enterprises. This, in turn. produced the long urban strips characteristic of certain areas in the east. the midwest and the west. *(See* also *Power,* above.)

7. Shipping. — During and after World War II ocean shipping rose in significance. Discoveries abroad, more economical methods of transportation. depletion of many U.S resources and greater dependence of the free world upon U.S. investment all worked to this end. Although the U.S. continued to export uheat, cotton and other agricultural materials, it also exported large amounts of industrial materials and imported considerable quantities of basic raw materials and fuels, particularly iron ore, oil and wood pulp, shipping continued to rise in volume with world prosperity. but the gross tonnage of U.S. merchant vessels engaged in foreign trade declined from the wartime peak. *(See* SHIPPING INDUSTRY: *United States.)*

8. Air Transport. — Civil aviation, more than any other form of transportation. owes its development to military applications during World Wars I and II. It has grown most rapidly and is most significant competitively in the transportation of passengers and mail. No other form of transport must use power both to support the cargo and to move it. As a result, air transport inevitably involves high costs per ton-mile, making it impractical for shipping large quantities of heavy freight. Nevertheless, a surprising amount of heavy equipment is shipped by air. In cases where whole operations may be halted by the breakdown of a single piece of equipment and the cost of shutting down exceeds the cost of moving the part by air, or where it is less costly to use air express than to stock replacement parts in quantity when the probability of breakdown is small, air transport may actually result in savings. In sparsely settled areas! and especially where road and railroad building is expensive because of bogs, permanent frost, lack of suitable rock for ballast or rugged terrain, air transport, which saves the capital cost of extensive roads, may be more economical than its alternatives.

It was, however, in the field of passenger service that the airlines made the most startling gains, surpassing both commercial motor carriers and railroads by the late 1950s. It seemed entirely possible that in this field, at least, aviation would revolutionize U.S. transportation in the 20th century much as the railroad had revolutionized it in the 19th. One parallel was provided by the manner in which localities, looking to future economic advantages, offered inducements in the form of airport and terminal facilities to the airlines, much as they had once offered special favours to the railroads.

By the second half of the 20th century, civil aviation was itself being transformed by the rapid introduction of jet aircraft. resulting in faster airspeeds and larger craft, many of them capable of carrying well over 100 passengers. This conversion to jet service brought with it additional problems in the form of the need for larger airports situated well outside the built-up portions of cities. Thus the discrepancy between the speed of air travel and the inconvenience of terminal locations in relation to city centres became more apparent.

The use of private aircraft showed steady gains after World War II, a trend that was encouraged by the return to civilian life of many men who had learned to fly in the armed forces. In absolute terms this was a very minor part of the total transportation picture. In the late 1950s almost 90% of intercity passenger traffic was by private automobile, and the trend was upward

In overseas traffic, the jet airliner was providing formidable competition to the ocean liner. Making up in speed and frequency of scheduling what it lacked in size, a single aircraft could carry as many passengers as a large cruise ship over a year's time. Furthermore, initial costs were lower and the crew required was substantially less. *(See* also AVIATION, CIVIL: *United States.)*

9. Communications. — The size of the U.S. communications industry is impressive. The post office, the only government owned and operated communications system in the C.S., was handling more than 60,000,000,000 pieces of mail annually in the 1950s. Although domestic telegraph has declined, the number of intercity and international messages has grown substantially. In the early 1960s most of the telephones in the United States could be dialed directly and direct international connections were under active investigation. There were about 400 telephones for every 1,000 persons. More than 4,500 AM. FM and television stations mere in operation in the late 1950s, and according to the department of commerce estimates, less than 4% of U.S. homes were without radio receivers and only about 10% were without television sets. *See* also BROADCASTING: *U.S. System;* POSTAL SERVICES: *United States;* TELEGRAPH; TELEPHONE; TELEVISION.

UNITED STATES SHIPPING BOARD: *see* MARITIME ADMINISTRATION, U S.

UNITED STATES STEEL CORPORATION is the largest steel producer in the world. Incorporated on Feb. 25, 1901, it was the first $1,000,000,000 corporation in the United States. Its chief purpose was to produce steel more efficiently and economically by including all steps in the process, from raw materials through the mills. Carnegie Steel company and Federal Steel company formed the nucleus of the corporation. They and the eight other original member companies brought into the new corporation the necessary facilities to achieve integrated operations.

The primary business of the corporation is the production of steel and its manufacture into a wide variety of steel products that are further processed by other industries, often in combination with other materials, into finished products for virtually every economic activity of the nation. To conduct its business. it operates iron ore and coal mines, limestone quarries, railroads, ore vessels, steel-producing and fabricating plants and other operating units.

UNITS, DIMENSIONS OF: *see* DIMENSIONAL ANALYSIS.

UNIVERSAL. Universal words are those which can be applied to more than one particular thing (in the widest possible sense of "thing"); *e.g.,* the word "red" applies to more than one object, and the word "prime" applies to more than one number. Such words are sometimes called "universals." But it is more usual to call them "general words" and to reserve the title "universal" for that which each member of a given class must possess if the same general word is to apply to them all. But what must they all possess? Is it something which exists in the same way that particulars exist? In one way it seems that this is how it exists, since, like a particular, it has a name which is a noun. But in other ways universals are quite unlike particulars; *e.g.,* redness, unlike red objects, cannot be picked up, and primeness, unlike prime numbers, cannot be multiplied. Then do universals exist at all? This question has been debated from the time of Plato.

Plato held that universals exist, and so was a realist (this use of the word is quite distinct from its application to those who hold that material objects exist; *see* REALISM). He called them

One of his most important arguments was that goodness stands apart from and is more perfect than any of its manifestations on earth. Another, scientific rather than ethical, was that particulars are too shifting and changeable to be objects of precise knowledge; which therefore must be concerned with universals. A third argument was logical—namely, that there must exist a universal corresponding to every general word (or any ay to most general words). It is not obvious that these three arguments, if successful, would all establish the existence of the same kind of thing. For it is impossible to attain precise knowledge about all classes of particulars. so that the scientific argument would seem to establish the existence of universals which are fewer than and perhaps different in kind from the universals of the logical argument. Also. there is nothing ethical about redness, and it is only by a metaphor that particular red objects may be said to endeavour to realize it. Furthermore, Plato did not draw the important distinction between generality and abstractness. "Red" is general, but not abstract, since particular red objects are concrete; whereas "prime" is both general and abstract, since particular prime numbers are not concrete. So generality and abstractness do not always go together. It is not clear how much of the ethical part of Plato's theory depended on the generality of "good" and how much it depended on the abstractness of "good" when it is applied to particular virtues (which are obviously not concrete). In any case it certainly relied chiefly on a third feature of goodness; viz.. that it is the ideal aim of human endeavour.

Plato's ethical approach had led him to attribute separate existence to his universals, since it seems that this is how ideals ought to exist. Aristotle used an abundance of logical arguments to prove that universals exist, not separately from particulars. but in them. This is a different variety of realism, which, as Aristotle pointed out, avoids some of the difficulties of Plato's variety. For instance, if manhood were a separate thing just like a man, then one could argue for the separate existence of a second manhood with as much justification as Plato had when he argued for the separate existence of ordinary manhood. This is the famous "third man'! argument. Again, if a universal like redness is literally a separate thing, then, since it cannot manifest its complete self in all red particulars simultaneously, it seems to follow that none of these particulars can be completely red. This argument from literal participation was cited later by hnicius Boethius against Augustine's version of Platonic realism. Plato himself was aware of these two arguments. Probably he would have moved on to Aristotle's kind of realism if his approach had been more exclusively logical. For, apart from the difficulties of its rival,, Aristotle's kind of realism is very persuasive in itself. Nobody would apply a general word to a group of particulars unless he had noticed something common to all of them.

Realism, in one of these two versions, was orthodox in the middle ages, the Aristotelian version tending to predominate after Thomas Aquinas. But meanwhile a third rival, which had been recessive in antiquity, took the field—this was nominalism (*q.v.*). Nominalists deny that universals exist, arguing that the existence of a general word does not imply the existence of a general thing named by it. The middle ages also saw the clear emergence of a fourth view, conceptualism (*q.v.*), which is sometimes regarded as a rival of nominalism and of the two varieties of realism. A conceptualist is one who holds that we have concepts or general ideas. Some conceptualists (*e.g.,* John Locke) say that we form these general ideas by abstracting a common element from each particular of a given class (hence he calls these general ideas abstract, but not for the same reason that numbers are abstract: the point is not that they are not concrete—though of course they are not—but that they are formed by abstraction). Clearly conceptualism is not incompatible with either variety of realism; Aristotle and his medieval followers, for instance, combined realism with conceptualism. Conceptualism can be regarded as a rival of realism only to this extent: a philosopher who asks the question "How is it that we are able to think and speak in general terms?" might hold that conceptualism provides the complete answer; then, if he had no other reasons for accepting realism, he would reject it.

Some would maintain that the only right approach to the problem is through the question just cited, which is a logical question (in the widest sense of "logical"). This view entails that there can be no other reason for accepting realism, so that supporters of this view would accept realism (usually the more sober, Aristotelian variety) only if they found that it was a necessary part of the answer to that question. Such an approach is characteristic of empiricism and particularly of empiricism since the time of John Locke. On the other hand, there have always been philosophers who have held that there are independent reasons for asserting or denying the existence of universals, reasons which they would call "ontological." For example, in the middle ages, while the Platonic tradition was still dominant, Platonism was associated with the immutability of moral standards, and Plato's Forms were sometimes interpreted as a limited number of fixed ideas in the mind of God.

It would be an exaggeration to say that the dividing line between these two kinds of approach to the problem is clearly marked. But philosophers have been made increasingly conscious of it by the various attempts to determine the powers and limitations of the intellect which have appeared since the Renaissance and particularly by the work of the logico-analytic school since the beginning of the 20th century. Consequently it is now more revealing to classify philosophers' treatments of this problem according to their approach rather than according to their conclusions. Those who think that ontology is partly an independent subject fit their solutions of the problem into metaphysical systems and perhaps give them connections with theological doctrines.

Those who think that the only right approach to the problem is through logic are less ambitious. The most that they would claim is that the world must contain such ieatures as recurrent similarities if we are to be able to think and speak as we do; and, if they call their inquiries ontological, this is only in order to emphasize that, though they cover far less ground than the traditional inquiries whose pattern was set by Plato, still they do cover part of the same ground. (D. F. P.)

UNIVERSALIST CHURCH, a body of religious liberals organized in the United States, and represented chiefly by parishes and churches in that country and Canada. A distinction should be noted between Cniversalism and the Universalist denomination. Universalism—the belief that the whole human race will be "saved'!—was a doctrine of some of the greatest of the church fathers, notably Clement of Alexandria and Origen, and is held by many in other communions. The Universalist denomination arose in the United States in the latter part of the 18th century.

History.—The origin of this church is commonly associated with the landing and preaching of Rev. John Murray at Good Luck, S.J., in Sept. 1770. Murray. a disciple of James Relly (1720–78), a Calvinistic Universalist of London, was seeking refuge in the new world from sorrow and trouble. Persuaded that he should be an apostle of this new faith, he became an itinerant minister in Massachusetts, New York, New Jersey, Pennsylvania and settled in Gloucester, Mass. (1774). His Universalism was a protest against the doctrine of endless punishment.

Under the leadership of Hosea Ballou (1771–1852), the most influential minister of the sect for half a century, Universalists became largely unitarian and broke with the Calvinism of Murray. The first period of the denomination's history was controversial. Religious and sectarian feeling for and against Universalism was intense. After 1820, ministers and churches began to multiply; colleges, seminaries, and newspapers were established.

Doctrine.—The fundamental tenet of Universalism may be said to be the illimitable love and goodness of God, assuring triumph over evil in society and in the life of every individual. Following its organization, the denomination officially summarized the faith of its adherents four times. These brief statements permitting the widest possible variety of interpretation within the bounds of reason and conscience were: the Articles of Faith adopted at Philadelphia in 1790; the Winchester Profession, Winchester, N.H., 1803; the Boston Declaration, Boston, Mass., 1899; and the Washington Avowal of Faith, Washington. D.C., 1935.

The Avowal of Faith adopted at Washington in 1935 restated American Cniversalism without departing in essentials from historic convictions as follows:

"The Bond of Fellowship in this church shall be a common purpose to do the Will of God as Jesus revealed it and to co-operate in establishing the Kingdom for which he lived and died.

"To that end We Avow Our Faith in God as eternal and all conquering love, in the spiritual leadership of Jesus, in the supreme worth of every human personality, in the authority of truth known or to be known, and in the power of men oi good will and sacrificial spirit to overcome all evil and progressively establish the Kingdom of God.

"Neither this nor any other statement shall be imposed as a creedal test."

Emphasis on "the authority of truth known or to be known" expresses acceptance by Universalists of the application of scientific method to the realm of values and meanings. The affirmation of "the supreme worth" of personality makes explicit the historic and continuing concern of Universalists for relations of justice and good will between individuals, races and differing religious groups. Standing within the Judeo-Christian tradition, Universalists. nevertheless, are committed to the conviction that valid religion is always universal and so not to be justly claimed as the only true revelation by any one religion. Seeking to express the universal spirit of Christianity, Universalists extend the hand of fellowship to world religionists of other historic faiths.

Polity.—Universalist churches govern themselves They formerly "acknonledged the authority" of The Universalist Church of America, houever, and in May 1960 members approved consolidation with the American Unitarian association to form the Unitarian Universalist association Before formal consolidation one year later, there were more than 70.000 Universalists in about 400 churches *See* UNITARIANISM.

UNIVERSAL LANGUAGE. The term universal, or international, language refers commonly to an auxiliary language rather than to a superidiom replacing national languages. It is sometimes thought that an international language, by overcoming linguistic barriers, would contribute to greater understanding and peace among men. In the biblical story of the Tower of Babel, unintelligibility is indeed viewed as a calamity visited upon human beings by the wrathful deity. But not all ills can be cured by better linguistic communication: as is shown by the continued and often bloody controversies among speakers of the same tongue.

Types.—There are four basic types of international languages:

1. A philosophical, artificial idiom without conventional vocabulary and grammar, being a system of acoustic (including musical) or optic (including numerical) signs based on a philosophical classification of everything men need and wish to talk about. Francis Bacon and Descartes in the 17th century and others thereafter proposed such languages. None of the projects proved feasible, mainly because they were unsuited to oral discourse and because the intellectual demands they made were too great.

2. A revived dead language, in particular Latin. Few supported this plan, even when a simplified Latin without inflection was devised (in 1903). An attempted revival of Latin solely for scholarly purposes is equally unpromising because scholars must learn foreign languages in any event in order to read writings of the past, and translating all such writings into Latin would be impossible.

3. A constructed, semiartificial language that, uses material available in current idioms. Among these, Esperanto (*q.v.*), published by L. L. Zamenhof in 1887. is the best known; it mas followed by (among others) Ido, Volapük (*q.v.*), Novial and Interlingua. Most constructed languages derive their lexicon chiefly from Latin and the Romance languages, and their grammar is Indo-European in character, though generally simplified; consequently. speakers of the non-Indo-European languages of Africa and Asia, who constitute a large percentage of the world's population, might find such a type of speech exceedingly difficult or even repugnant. Use of these languages, restricted to a relatively small number of devotees, has penetrated only sporadically into international affairs. From the point of view of the scientific linguists (very few of whom are among the authors or champions of universal languages); the ideal constructed language should. at least [illegible]

But this severity would make the constructed language, as compared with a natural tongue, a difficult rather than an easy instrument of communication: even a slight deviation, caused by normal human shortcomings of production and perception, would, in a grammar wrought with mathematical precision and logic, impede if not prevent intelligibility.

4. A modern spoken language extended, in its current or a modified form (for example, simplified Basic English; *q* v.), to the greatest possible number of speakers. Actual developments are moving in this direction, but in such a way that several languages rather than one are obtaining increasing international currency. especially English. Russian and Chinese, for obvious reasons of political and economic prestige. Unfortunately this evolution, though in harmony with the aims of the international-language movement in that it permits a steadily growing number of persons to overcome linguistic isolation. tends to enhance rather than diminish a dangerous political and philosophical polarity.

Requirements.—The requirements usually postulated for the structure of an international language are a simple grammar; a simple spelling where each sound (phoneme) is rendered by one symbol only and each symbol represents but one sound; a limited vocabulary; and a large number of speakers. None of the four types of languages mentioned satisfies all the requirements, and any single requirement is fulfilled in various degrees by a given type. The philosophical system may be left out of consideration since it is not a language in the normal sense of the term. A revived dead language starts with few speakers, none of them native Latin. unless reshaped to the point of becoming a different language, scarcely qualifies as possessing a simple grammar (presuming that simplicity includes regular paradigms and minimal morphology). In orthography Latin would rate well. Limiting the size of the vocabulary in Latin, or in any other language, sounds helpful in theory but means little in reality since a lexicon is by nature open-ended; that is, grows larger or smaller according to the wishes and needs of the speakers. So control is possible, except perhaps that exerted by Basic English, in which, for example, "get up" stands for "rise," "get well" for "convalesce," "get low" for "decrease," "get" (and similar words) being coupled with recurrent meaningful particles to synthesize meanings. But Latin in its customary structure is not suited for this particular device. The third type, a constructed language, offers the best opportunities to satisfy the first three requirements, but the facts that it would not have a large number of speakers and would lack a literature in belles-lettres and scholarship constitute a weakness of considerable significance. Further drawbacks are the reliance on Indo-European (especially Latin and the Romance languages), and the paradox that the scientifically ideal construction would be less than humanly ideal for everyday intercourse. The fourth type, an internationalized national language, falls victim to national or ethnolinguistic prejudices even more easily than a constructed language. But it has the immeasurably great advantage of possessing numerous speakers and extensive written records. As for the requirement of grammatical simplicity, virtually all natural languages are congenitally encumbered by what. in terms of optimal design. one must call irregular and complex grammars. The requirement concerning orthography, or mode of spelling, is met variously by various idioms Russian, Spanish. Italian and languages recently reduced to writing (including Chinese in the Latin alphabet) are good; French and German are fair; English is notoriously poor.

The Outlook.—In various periods of the past some natural languages attained the status of international auxiliary languages, notably Hellenistic Greek; spoken, nonclassical Latin; Arabic; and French But none of them ever was a truly popular second language, widespread among all speakers, although some, ceasing in fact to be auxiliary languages and supplanting previous tongues, became the native idioms over extended regions (for example, Latin in countries of the Romance languages). Pidgin English and other speeches of the lingua franca type have been largely ignored by language planners as being corruptions of standard languages. Nonetheless, some have been successful [illegible] interlanguage communi[illegible]

All languages which heretofore expanded to serve as international auxiliary languages had in common that they were the languages of cultural entities or nations or empires which enjoyed cultural prestige or political supremacy or both. and that their currency grew out of the necessity and the willingness of men to co-operate. The past is of course no sure indication of future development. But since language is chiefly a tool of co-operation and only remotely and vicariously its cause, the need for the tool and the will to use it seem essential to its adoption. A universal language will come about when and if the world needs and wants it, and it will be either the natural idiom most favoured by the prestige and the social power of its native speakers or (though this is less likely) a constructed language. The role of the propagators of a universal language is in the meantime to tell the world, with insistence but without exaggeration, of the benefits resulting from an end to the confusion of tongues.

UNIVERSAL POSTAL UNION. The first international convention governing letter mail for a significant number of countries was concluded in Berne, Switz., on Oct. 9, 1874; it created the General Union of Posts with, originally, 22 member countries. Because of the early accession of a great number of other countries, the union took in 1878 the name of Universal Postal union. It became a "specialized agency" of the Cnited Nations in 1947 In 1959 there were 100 member countries.

The Universal Postal convention contains compulsory provisions for all member countries concerning the organization of the union and the handling of international letter mail, based on unity of the postal territory of all member countries, common scales of weight and charges, freedom of transit, simplification of the sharing-out of charges between postal administrations participating in the conveyance of mail, arbitration, etc. Optimal agreements govern certain specialized aspects of the international postal service, such as insured letters and boxes, money orders, parcels. collection of payments. newspaper subscriptions and post-office savings banks.

The plenipotentiaries of the, member countries normally meet every five years in congresses to revise the acts of the union in order to adapt them to economic and technical development. An executive and liaison committee, composed of representatives of 20 member countries, meets every year in Switzerland. It maintains contact with the United Nations and other international organizations, and takes part in the supervision of the activities of the international bureau and in the appointment of the high-ranking officials of the bureau. A consultative committee for postal studies, composed also of representatives of 20 member countries, was created by the Ottawa congress in 1957 to undertake a more thorough study of economic, technical and operational problems in the postal service. The international bureau, whose seat is in Berne, is the only permanent organ of the union. It serves as a connecting link, as a centre of information and consultation for the postal administrations of the union's member countries and as a clearinghouse in the settlement of certain accounts. It serves also as a general secretariat for the higher organs of the union and plays a part in the arbitration procedure.

(FR. H.)

UNIVERSE OF DISCOURSE. in logic, is the limited sphere of reference within which an assertion is intended to hold good. Hence the alternative name. "limited universe." The expression "universe of discourse" was first introduced by A. De Morgan, who states his meaning as follows: "For the most part the objects of thought which enter into a proposition are supposed to be taken, not from the whole universe of possible objects, but from some more definite collection of them. Thus when we say 'All animals require air' . . we should understand that we are speaking of things on this earth: the planets, etc. . . . not being included" (*Formal Logic,* ch iv). Subsequently the notion was extended so as to include also merely imaginary spheres of reference. In logic the question is of some importance in connection uith the problem of the existential import of propositions, especially of categorical propositions.

UNNERSITIES. The medieval Latin term *universitas* was originally employed to denote any community or corporation, When used in its modern sense of a body devoted to learning and education. it required the addition of other words. such as *magistrorum et scholarium.* The more ancient and customary designation of such communities in medieval times (regarded as places of instruction) uas *studium* (and subsequently *studium generale).* The university appears to have started as a scholastic guild—a spontaneous combination, that is to say, of teachers or scholars. or of both combined, and formed, probably, on the analogy of the trades guilds and the guilds of aliens in foreign cities, which, in the course of the 13th and 14th centuries, sprang up in most of the great European centres.

It was a first stage of development in connection with these primary organizations when the chancellor of the cathedral or some other authority began to accord to other masters permission to open other schools than the cathedral school in the neighbourhood of his church; a further stage was reached when a licence to teach — granted only after a formal examination — empowered a master to carry on his vocation at any similar centre.

It uas a still further development uhen it began to be recognized that, without a licence from either pope, emperor or king, no *studium generale* could be formed possessing this right of conferring degrees, which originally meant nothing more than licences to teach.

Meaning of **"Studium Generale."**—In the north of Europe licences to teach were granted by the chancellor scholasticus or some other officer of a cathedral church; in the south it is probable that the guilds of masters (when these came to be formed) were at first free to grant their own licences, without any ecclesiastical or other supervision. Gradually, however, toward the end of the 12th century, a few great schools claimed, from the excellence of their teaching, to be of more than merely local importance. Practically, a doctor of Paris or Bologna would be allowed to teach anywhere; and those great schools began to be known as *studia generalia; i.e.,* places resorted to by scholars from all parts. Eventually the term came to have a more definite and technical significance. The emperor Frederick II in 1225 set the example of attempting to confer, by an authoritative bull, upon his new school at Naples the prestige which the earlier *studia* had acquired by reputation and general consent. Gregory IX did the same for Toulouse in 1229 and added to its original privileges in 1233 a bull by which anyone who had been admitted to the doctorate or mastership in that university should have the right to teach anywhere without further examination. Other *studia generalia* were subsequently founded by papal or imperial bulls, and in 1292 even the oldest universities, Paris and Bologna, found it desirable to obtain similar bulls from Nicholas IV. From this time the notion began to prevail among the jurists that the essence of the *studium generale* was the privilege of conferring the *ius ubicunque docendi,* and that no new *studium* could acquire that position without a papal or imperial bull. There were, however, a few *studia generalia* (*e.g.,* Oxford) whose position was too well established to be seriously questioned, although they had never obtained such a bull; these were held to be *studia generalia ex consuetudine. A* few Spanish universities founded by royal charter were held to be *studia generalia respectu regni.* The word *universitas* was originally applied only to the scholastic guild (or guilds) within the *studium,* and was at first not used absolutely; the phrase was always *universitas magistrorum* or *scholarium* or *magistrorum et sckolarium.* By the close of the mediaeval period, however, the distinction between the terms *studzum generale* and *universitas* was more or less lost sight of, and the term *universitas* began to be used alone.

ITALIAN UNIVERSITIES IN THE MIDDLE AGES

Rise of University of **Salerno.**—To understand why the earliest universities arose it is necessary to take account not only of their organization but also of their studies. By the 6th century the secular pagan schools of the Roman empire had been swept away. By the 12th, the cathedral and monastic schools which replaced them had attained to their highest degree of influence and reputation. But these schools taught only what was supposed to be necessary for the education of the priest and the monk. The *studia* arase out of efforts to provide instruction beyond the range of the cathedral and monastic schools. Salerno, the first great *studzum,* became known as a school of medicine as early as the 9th century. Its medical system was originally an outcome of the Graeco-Roman tradition of the old Roman world. In the first half of the 9th century the emperor at Constantinople sent to the caliph Mamoun at Baghdad a collection of Greek manuscripts. These texts were translated into Arabic by Syrian Christians, and the Arabic was later rendered into Latin for the use of teachers in the west. Of the existence of such versions we have evidence. according to C. M. G. Bréchillet-Jourdain, long before Constantine the African (d. 1087) began to lecture on medicine at Salerno. Under his teaching the fame of Salerno as a medical school became diffused all over Europe. It was distinguished by its catholic spirit; at a time when Jews were the object of religious persecution throughout Europe, they were to be found both as teachers and learners at Salerno. In 1231 it was constituted by the emperor Frederick II the only school of medicine in the kingdom of Naples. It remained a medical school only. "Nothing approaching a regular university ever existed there" (H. Rashdall, The *Universities of Europe in the Middle Ages*, vol. i, part 3, p. 82).

Bologna.—The great revival of legal studies which took place at Bologna about the year 1000 had been preceded by a corresponding activity elsewhere—at Pavia by a famous school of Lombard law and at Ravenna by a yet more important school of Roman law. In Bologna itself we have evidence that the Dzgest was known and studied before the time of Irnerius (1100–30), a certain Pepo being named as lecturing on the text about the year 1076. The secular character of this new study and its close connection with the claims and prerogatives of the western emperor aroused papal suspicion, and for a time Bologna and its civilians were regarded by the church with distrust. But the appearance of the *Decretum* of Franciscus Gratianus, about 1140, invested the studies of the canonist with fresh importance. It was quickly regarded as official canon law, and so numerous decrees of past and almost forgotten pontiffs now claimed to take their stand side by side with the enactments contained in the Corpus *Juris Civilis*. They constituted, in fact, the main basis of those new pretensions asserted by the papacy in the course of the 12th and 13th centuries. It was necessary, accordingly, that the *Decretum* should be known and studied beyond the walls of the monastery or the episcopal palace. Such a centre of instruction was found in Bologna, which became recognized as the chief school of both civil and canon law. But the statement that university degrees were instituted there as early as the pontificate of Eugenius III (1145–53) rests on no good authority. The students found their first real protector in the emperor Frederick I, Barbarossa. Finding that their grievances were real, especially against the landlords in whose houses they were domiciled, he granted the foreign students substantial protection by conferring on them certain special immunities and privileges (Nov. 1158). These privileges were embodied in the celebrated Authentzca, Habita, in the Corpus *Juris Civilis* of the empire (book iv, tit. 13), and were eventually extended to all the other universities of Italy.

Nevertheless, Bologna did not possess a university as early as 1158. Its first university was not constituted until the close of the 12th century. The "universities" at Bologna were, as H. S. Denifle has shown, really student guilds. These were originally only two in number, the Ultramontant and the Citramontani, and arose out of the absolute necessity under which residents in a foreign city found themselves of obtaining by combination that protection and those rights which they could not claim as citizens. Originally, they did not include the native student element and were composed exclusively of students in law. Denifle thinks that the "universities" at Bologna were at one time certainly more than four in number, and we know that the Italian students alone were subdivided into two—the Tuscans and the Lombards. In the centres formed by secession from the parent body a like subdivision took place. At Vercelli there were four *universitates*, composed, respectively, of Italians, English, Provençals and Germans; at Padua there were similar divisions into Italians, French (*i.e.*, Francigenae, comprising both English and Normans), Provençals (including Spaniards and Catalans). According to Odofred, in the time of the eminent jurist Azo, who lectured at Bologna about 1200, the number of the students there amounted to about 10,000, of whom the majority were foreigners. It seems, therefore, reasonable to conclude that the number of these confederations of students (societates scholarium) at Bologna was yet greater.

The Rector.—In marked resemblance to the guilds, these confederations were presided over by a common head, the rector scholarium, an obvious imitation of the rector societatunz or *artium* of the guild, but to be carefully distinguished from the rector scholarzim, or director of the studies, with whose function the former officer had, at this time, nothing in common. Like the guilds, again, the different nations were represented by their *consiliarii*, a deliberative assembly with which the rector habitually took counsel. The students at Bologna were mostly of mature years. As the civil law and the canon law were, at first, the only branches of study, the class they attracted was often composed of men already filling office in some department of the church or state—archdeacons, heads of schools, canons of cathedrals and like functionaries forming a considerable element in the aggregate.

About the year 1200 were formed the two faculties of medicine and philosophy (or the "seven liberal arts"), the former being somewhat the earlier. It was developed, as that of the civil law had been developed, by a succession of able teachers, among whom Thaddeus Alderottus was especially eminent. The faculty of arts, down to the 14th century, scarcely attained to equal eminence. The teaching of theology at Bologna remained for a long time exclusively in the hands of the Dominicans, and it was not until the year 1360 that Innocent VI recognized the university as a *studium generale* in this branch.

The term "college" at Bologna long had a different meaning from that it now ordinarily conveys. The masters formed themselves into collegia (that is, organizations), chiefly for the conferment of degrees. Places of residence for students existed at Bologna at a very early date, but it was not until the 14th century that they possessed any organization; the humble *domus*, as it was termed, was at first designed solely for necessitous students who were not natives of Bologna. A separate house, with a fund for the maintenance of a specified number of scholars, was all that was originally contemplated. Such was the character of that founded by Zoen, bishop of Avignon, in Feb. 1256 (O.S.), the same month and year, it is to be noted, in which the Sorbonne was founded in Paris. It was designed for the maintenance of eight scholars from the province of Avignon, under the supervision of three canons of the church, maintaining themselves in the university. The college of Brescia was founded in 1326 by William of Brescia, archdeacon of Bologna, for poor foreign students, without distinction as to nationality. The Spanish college was founded in 1364 for 24 Spanish scholars and two chaplains.

Other Italian Centres.—The earliest foundations in Italy after that of Bologna were the universities of Reggio nell' Emilia and Modena, both of which had flourishing schools of civil law before the close of the 12th century. Vicenza (founded 1204) and Padua (1222) both originated in migrations of students from Bologna. The University of Naples was founded by the emperor Frederick II in 1225 and was temporarily suppressed after his death. It was reconstituted in 1258. Piacenza, founded by papal charter in 1248, had little importance until 1398 when it was reconstituted by Galeazzo Visconti, duke of Milan, who caused the University of Pavia to be transferred to Piacenza. Pavia had long been famous as a school of Roman law, and for a time its fame was transferred to Piacenza. From 1404 to 1412 both universities ceased to exist. But after that date Pavia became almost as famous a school of civil law as Padua itself. Arezzo was a centre for legal study from 1215 to 1470. Rome (1303) had schools of canon and civil law for poor foreign students througho centuries. Perugia (1308) specialized in civil law, Pisa (1343) was closed from 1403 to 1476, when it was reopened by Lorenzo dei Medici. The University of Florence (1349) had a brilliant existence in the first half of the 1 jth century, but was closed in 1472. Graduates of Siena, whose importance dates from 1357 though it was nominally founded in 1241, were accorded the same privileges as those of Bologna. Ferrara was famous in the latter half of the 15th century. The University of Turin was founded about the year 1400, that of Parma not until 200 years later.

PARIS IN THE MIDDLE AGES

Origin of University of Paris.—The commencement of the University of Paris well illustrates the fact that the universities arose in response to new needs. The study of logic. which, prior to the 12th century, was founded exclusively on one or two meagre compends, received about the year 1100 a powerful stimulus on two occasions—first from the memorable controversy between Lanfranc and Berengarius, and second from the no less famous controversy between Anselm and Roscellinus. The belief arose that intelligent appreciation of spiritual truth depended upon correct use of prescribed methods of argument. Dialectic was looked upon as the "science of sciences"; and when, somewhere in the first decade of the 12th century. William of Champeaux opened in Paris a school for the more advanced study of dialectic as an art, his teaching was attended with marked success. Among his pupils was Peter Abelard, in whose hands the study made a yet more notable advance. By the middle of the century John of Salisbury could say that all learned Paris had gone well-nigh mad in its pursuit and practice. Abelard taught first at the cathedral school at Notre Dame and later at the schools on the Mont Ste. Genevieve, of which he was the founder and where he imparted to logic its new development.

The schools out of which the university arose were those attached to the cathedral on the Île de la Cité and presided over by the chancellor—a dignitary who must be carefully distinguished from the later chancellor of the university. For a long time the teachers lived in separate houses on the island, and it was only by degrees that they combined themselves into a society and that special buildings were constructed for their classwork. The flame which Abelard's teaching had kindled was not destined to expire. Among his pupils was Peter Lombard, who was bishop of Paris in 1159 and widely known to posterity as the compiler of the famous volume of the *Sentences*. The design of this work was to place before the student, in as strictly logical a form as practicable, the views (sententiae) of the fathers and all the great doctors of the church upon the chief and most difficult points in the Christian belief. The logicians seized upon it as a great storehouse of indisputable major premises, on which they argued with renewed energy and with endless ingenuity of dialectical refinement. It was probably this development of new methods of instruction concurrently with new material upon which to exercise them which finally distinguished the university from the cathedral schools.

Early Organization.—The University of Paris, as already stated, took its rise entirely out of the movement carried on by teachers on the island, who taught by virtue of the licence conferred by the chancellor of the cathedral. In the second decade of the 13th century, it is true, we find masters repairing to the left bank of the Seine and placing themselves under the jurisdiction of the abbot of the monastery of Ste. Genevieve; but it was around the bestowal of this licence by the chancellor of Notre Dame, on the Île de la Cité, that the university grew up. It is in this licence that the whole significance of the master of arts degree is contained; for what is technically known as admission to that degree was really nothing more nor less than receiving the chancellor's permission to "incept," and by "inception" was implied the master's formal entrance upon, and commencement of, the functions of a duly licensed teacher and his recognition as such by his brethren in the profession. The previous stage of his academic career, that of bachelordom, had been one of apprenticeship for the mastership; and his emancipation from this state was symbolized by placing the magisterial cap (biretta) upon his head, a ceremony which, in imitation of the old Roman ceremony of manumission, was performed by his former instructor. He gave a formal inaugural lecture, and was then welcomed into the society of his professional brethren with set speeches and took his seat in his master's chair.

Some time between the years 1150 and 1170 the University of Paris came formally into being. Its first written statutes were not, however, compiled until about the year 1208, and it was not until long after that date that it possessed a "rector." Its earliest recognition as a legal corporation belongs to about the year 1211, when a brief of Innocent III empowered it to elect a proctor to be its representative at the papal court. By this permission it obtained the right to sue or to be sued in a court of justice as a corporate body. Papal recognition did not imply episcopal recognition, but with papal support Paris became the great transalpine centre of orthodox theological teaching. Successive pontiffs, down to the great schism of 1378, cultivated friendly relations with the university and systematically discouraged the formation of theological faculties at other centres. In 1231 Gregory IX, in the bull *Parens Scientiarum* (which has been called the Magna Carta of the university), gave full recognition to the right of the several faculties to regulate and modify the constitution of the university. The fully developed university was divided into four faculties: three "superior," those of theology, canon law and medicine; and one "inferior," that of arts, which was divided into four "nations." These nations, which included both professors and scholars, were: (1) the French, composed, in addition to the native element, of Spaniards, Italians and Greeks; (2) the Picard, representing the students from the northeast and the Netherlands; (3) the Norman; (4) the English, comprising, besides students from the provinces under English rule, those from England, Ireland, Scotland and Germany. The head of each faculty was the dean, of each nation the proctor. The rector, in the first instance, was head of the faculty of arts. Eventually he became the head of the collective university, by the incorporation under him, first, of the students of the canon law and of medicine (which took place about the end of the 13th century), and, second, of the theologians, which took place about half a century later.

In the course of the 16th and 17th centuries this democratic constitution of. the middle ages was largely superseded by the growth of a small oligarchy of officials. The tribunal of the university—the rector, deans and proctors—came to occupy a somewhat similar position to the old "Hebdomadal board" of heads of colleges at Oxford and the caput at Cambridge. Moreover, the teaching functions of the university, or rather of the faculty of arts, chiefly because of the absence of any endowment for the regents or teaching graduates, practically passed to the colleges. Almost as much as the English universities, Paris came to be virtually reduced to a federation of colleges, though the colleges were at Paris less independent of university authority, while the smaller colleges sent their members to receive instruction in the larger ones (*collèges* de *plein* exercice), which received large numbers of nonfoundation members. This state of things lasted till the French Revolution swept away the whole university system of the middle ages. It may be noted that the famous Sorbonne (see PARIS UNIVERSITY) was really the most celebrated college of Paris—founded by Robert de Sorbon in 1257—but as this college and the College of Navarre were the only college foundations which provided for students in theology, the close connection of the former with the faculty, and the use of its hall for the disputations of that body, led to the word Sorbonne becoming a popular term for the theological faculty of Paris.

In the 14th century the University of Paris had 40 colleges, governed either by secular or religious communities, and numbered among its students representatives of every country in Europe. The university became known as the great school where theology was studied in its most scientific spirit, and the decisions of its doctors upon those abstruse questions which absorbed so much of the highest intellectual activity of the middle ages were regarded as almost final. The popes, as already stated, discouraged the creation of faculties of theology elsewhere. The apparent exceptions to this policy are easily explained: the four faculties of theology which they sanctioned in Italy—Pisa (1343), Florence (1349), Bologna (1362) and Padua (1363)—were designed to benefit the Italian monasteries, by saving the monks the expense and dangers of a long journey beyond the Alps; while that at Toulouse (1229) took its rise under circumstances entirely exceptional, being designed as a bulwark against the heresy of the Albigenses. The popes, on the other hand, favoured the creation of new faculties of law, and especially of the canon law, as the latter represented the source from which Rome derived its most warmly contested powers and prerogatives.

ENGLISH MEDIAEVAL UNIVERSITIES

Oxford.—The University of Paris became the model for French universities north of the Loire and for those of central Europe and England. Of the universities modelled on that of Paris, Oxford would appear to have been the earliest. Certain schools, opened within the precincts of the dissolved nunnery of St. Frideswyde and of Oseney abbey, are supposed to have been the nucleus round which it grew up. In the year 1133 one Robert Pullen, a theologian of considerable eminence (but whether an Englishman or a Breton is uncertain), arrived from Paris and delivered lectures on the Bible. Denifle maintains that there is, at best, only presumptive evidence of a studium generale at Oxford in the 12th century. Rashdall inclines to find the beginning in a migration of English students from Paris about 1167 or

1168. In the first-mentioned year we are told by John of Salisbury that "France, the mildest and most civil of nations," has "expelled her foreign scholars" *(Materials for the History of Thomas Becket,* ed. by Robertson, vi, pp. 235–236). At about the same time we hear of an edict of Henry II, during the quarrel with Becket. recalling all clerks holding benefices in England (as they loved their beneficesj and forbidding all clerks in England to cross the channel *(ihid.,* i, pp. 53–54). Paris was at this time the great place of higher education for English students. Immediately after 1168 allusions to Oxford as a *studium* and a *studium generale* begin to multiply. The natural inference is that the breaking off of relations between England and Paris, in 1167 or 1168, led to the growth of a *studium generale* in Oxford, formed, no doubt, in the first instance of seceders from Paris. In the 13th century mention first occurs of university "chests," especially the Fridesmyde chest, which were benefactions designed as funds for the assistance of poor students. Hall, or places of licensed residence for students. also began to be established. In the year 1257, when the bishop of Lincoln, as diocesan, had trenched too closely on the liberties of the community, the deputies from Oxford, when preferring their appeal to the king at St. Albans, could venture to speak of the university as *schola secunda ecclesiae,* or second only to Paris. Its numbers about this time were probably about 3.000; but whenever plague or tumult led to a temporary dispersion, a serious diminution in its numerical strength generally ensued for some time after. Against such vicissitudes the foundation of colleges proved the most effectual remedy. Of these the three earliest were University college, founded in 1249 by William of Durham; Balliol college, founded about 1263 by John Balliol, the father of the king of Scotland of the same name; and Merton college, founded in 1264. The last-named is especially notable as associated with a new conception of university education; viz., that of collegiate discipline for the secular clergy, instead of for any one of the religious orders, for whose sole benefit all similar foundations had previously been designed. The statutes given to the society by Walter de Merton are not less noteworthy, being characterized not only by breadth of conception but also by a careful and discriminating attention to detail, which led to their adoption as the model for later colleges not only at Oxford but at Cambridge.

Cambridge. — The University of Cambridge, although it rose into existence somewhat later than Oxford. may reasonably be held to have had its origin in the same century. There was probably a certain amount of educational work carried on by the canons of the church of St. Giles, which gradually developed into the instruction belonging to a regular *studium.* In the year 1112 the canons crossed the river and took up their residence in the new priory in Barnwell, and their work of instruction acquired additional importance. In 1209 a body of students migrated there from Oxford. Then, as early as the year 1224, the Franciscans established themselves in the town and, somewhat less than half a century later: were followed by the Dominicans. At both the English universities. as at Paris, the mendicants and other religious orders were admitted to degrees, a privilege which, until the year 1337, was extended to them at no other university. Their interest in and influence at these three centres were consequently proportionably great. In the years 1231 and 1233 certain royal and papal letters afford satisfactory proof that by that time the University of Cambridge was already an organized body, with a chancellor at its head. In 1229 and 1231 the numbers were largely augmented by migrations from Paris and from Oxford. Cambridge, however, in its turn suffered from emigration; while in the year 1261, and again in 1381, the records of the university were wantonly burned by the townsmen. Throughout the 13th century, indeed, the university was still only a very slightly and imperfectly organized community. Its endowments were of the most slender kind; it had no systematic code for the government of its members; the supervision of the students was very imperfectly provided for. Although both Oxford and Cambridge were modelled on Paris, their higher faculties never developed the same distinct organization; and while the two proctors at Cambridge originally represented "north" and "south," the "nations" are scarcely to be discerned. An important step in the direction of discipline was, however, made in the year 1276, when an ordinance was passed requiring that everyone who claimed to be recognized as a scholar should have a fixed master aithin 15 days after his entry into the university. The traditional constitution of the English universities was, in its origin, an imitation of the Parisian, modified by the absence of the cathedral chancellor. But the feature which most served to give permanence and cohesion to the entire community at Cambridge was, as at Oxford, the institution of colleges. The earliest of these was Peterhouse, first founded as a separate institution by Hugh Balsham, bishop of Ely, in the year 1284. In 1324 was founded Michaelhouse, and two years later, in 1326, Edward II instituted his foundation of "king's scholars," afterward forming the community of King's hall. Both these societies, in the 16th century, were merged in Trinity college. To these succeeded Pembroke hall (1347) and Gonville hall (1348). All these colleges were expressly designed for the benefit of the secular clergy. The foundation of Trinity hall *(Aula)* in 1350 by Bishop William Bateman. on the other hand, as a school of civil and canon law was probably designed to further ultramontane interests. That of Corpus Christi (1352), the outcome of the liberality of a guild of Cambridge townsmen, was conceived with the combined object of providing a house of education for the clergy, and at the same time securing the regular performance of masses for the benefit of the souls of departed members of the guild. But both Trinity hall and Corpus Christi college were, to a great extent, indebted for their origin to the ravages caused among the clergy by the great plague of 1349.

FRENCH AND SPANISH MEDIAEVAL STUDIA

France.—Montpellier was a recognized school of medicine as early as the 12th century Before the end of the century it possessed also a faculty of jurisprudence. The university of medicine and that of law continued, however. to be totally distinct bodies, with different constitutions. On Oct 26. 1289. Montpellier was raised by Nicholas IV to the rank of a *studium generale.*

The University of Toulouse is to be noted as the first founded in any country by virtue of a papal charter. It took its rise in the efforts of Rome for the suppression of the Albigensian heresy. and its foundation formed one of the articles of the conditions of peace imposed by Louis IX on Count Raymund of Toulouse. In the year 1233 it first acquired its full privileges as a *studium generale* by virtue of a charter given by Gregory IX. The University of Orléans had a virtual existence as a *studium generale* as early as the first half of the 13th century, but in the year 1305 Clement V endowed it with new privileges and gave its teachers permission to form themselves into a corporation. The schools of the city had an existence long before — as early, it is said. as the 6th century. In the 14th century its fame as a school of law was surpassed by no other university in Europe. Before the 13th century it had been famed for its classical learning.

The other French universities famous in the middle ages were Angers, Avignon, Cahors (1331) and Grenoble (1339). At Perpignan and Orange there were schools of small note.

Spain.—Valladolid, which received its charter from Pope Clement VI in 1346, attained great celebrity. In 1418, at the Council of Constance, Martin V decreed that Valladolid should take rank not only as a *studium generale* but also as a *universitas tkeologiae.* From this time, accordingly, the advance of the university in numbers was steady and continuous throughout the 15th century, and. along with Salamanca, it served as the model for Alcalá in 1409.

Seville aas founded in 1253 by Alphonso the Wise, simply for the study of Latin and of the Semitic languages, especially Arabic. Salamanca had been founded in 1243 by Ferdinand III of Castile as a *studium generale* in the three faculties of jurisprudence, the arts and medicine. But the main stress of its activity. as was the case with all the earlier Spanish universities, was laid on the civil and the canon law. In the early part of the

15th century, however, the efforts of Martin V established a school of theology which was afterward regarded almost as an oracle by Catholic Europe. About the year 1600 the students are shown by the matriculation books to have numbered more than 5,000. According to Cervantes they were noted for their lawlessness. The earliest of the numerous colleges founded at Salamanca was that of St. Bartholomew, long noted for its ancient library and valuable collection of manuscripts.

The only Portuguese university in mediaeval times was founded at Lisbon in 1290 and had its seat alternately there and in Coimbra, until, in the year 1537, it was permanently attached to Coimbra. It had received from King Dinis a charter, the provisions of which were mainly taken from those of the charter given to Salamanca. In 1772 the university was entirely reconstituted.

MEDIAEVAL UNIVERSITIES IN CENTRAL EUROPE

Prague. — Of the mediaeval universities in central Europe, Prague, which existed as a *studium* in the 13th century, was the earliest. It mas at first frequented mainly by students from Styria and Austria, countries at that time ruled by the emperor Charles IV, who was also king of Bohemia, and at whose request Pope Clement VI, on Jan. 26, 1347, promulgated a bull authorizing the foundation of a *studium generale* in all the faculties. In the following year Charles himself issued a charter for the foundation. Charles had been a student in Paris, and the organization of his new foundation was modelled on that university, a like division into four "nations" (although with different names) constituting one of the most marked features of imitation. The numerous students — and none of the mediaeval universities attracted in its earlier history a larger concourse — were drawn from a gradually widening area, which at length included not only all parts of Germany but also England, France, Lombardy, Hungary and Poland.

Cracow.—The University of Cracow, in Poland: was founded in May 1364 by virtue of a charter given by King Casimir III the Great, but its real commencement must be considered to belong to the year 1400, when it was reconstituted. Toward the close of the 15th century the university is said to have been in high repute as a school of both astronomical and humanistic studies.

Vienna. — The Avignonese popes appear to have regarded the establishment of new faculties of theology with special jealousy; and when, in 1365, Duke Rudolph IV founded the University of Vienna. with the design of constituting it a *studium generale* in all the faculties. Urban V refused his assent to the foundation of a theological school. Because of the sudden death of Duke Rudolph, the university languished for the next 20 years, but after the accession of Duke Albert III, who may be regarded as its real founder, it acquired additional privileges.

Heidelberg. — The University of Heidelberg (the oldest of those of the German'realm) received its charter (Oct. 23, 1385) from Urban VI as a *studium generale* in all the recognized faculties save that of the civil law. It was granted at the request of the elector palatine, Rupert I. But the real founder, as he was also the organizer and teacher, of the university was Marsilius of Inghen, to whose ability and energy Heidelberg was indebted for no little of its early reputation and success. In spite of the omission of the civil law in the original charter, this was included among its faculties almost from its first creation. No mediaeval university achieved a more rapid and permanent success.

Cologne. — As a result of the labours of the Dominicans, Cologne had gained a reputation as a seat of learning long before the founding of its university; and it was through the advocacy of some leading members of the mendicant orders that, at the desire of the city council, its charter as a *studium generale* (May 21, 1385) was obtained from Urban YI. It was organized on the model of the University of Paris, as a school of theology and canon law and "any other recognized faculty," the civil law being incorporated as a faculty soon after the promulgation of the charter. In common with the other early universities of Germany—Prague, Yienna and Heidelberg — Cologne owed nothing to imperial patronage, while it would appear to have been, from the first, the object of special favour with Rome. This circumstance serves to account for its distinctly ultramontane sympathies in mediaeval times, and even far into the 16th century.

Erfurt.—Erfurt, no less noted as a centre of Franciscan than was Cologne of Dominican influence, received its charter (Sept. 16, 1379) from the antipope Clement VII, as a *studium generale* in all the faculties. Ten years later it was founded afresh by Urban VI. In the 15th century the number of its students was larger than that at any other German university — a fact attributable partly to the reputation it had acquired as a school of jurisprudence and partly to the ardour with which the nominalist and realist controversies of the time were debated in its midst; its readiness in according a hearing to novel theories caused it to be known as *novorum omnium portus*.

Leipzig.—The conditions connected with the rise of the University of Leipzig are especially noteworthy, it having been the result of the migration of almost the entire German element from the University of Prague. This element comprised: (1) Bavarians, (2) Saxons. (3) Poles (this last-named division being drawn from a wide area which included Meissen, Lusatia, Silesia and Prussia), and, being represented by three votes in the assemblies of the university, while the Bohemians possessed but one, had acquired a preponderance in the direction of affairs to which the latter could no longer submit. Religious differences, again, evoked mainly by the preaching of John Huss, further intensified the existing disagreements; and eventually, in the year 1409, King Wenceslaus, at the prayer of his Bohemian subjects, issued a decree which exactly reversed the previous distribution of votes — three votes being assigned to the Bohemian nation and only one to all the rest. The Germans took deep umbrage and seceded to Leipzig. where, a bull having been obtained from Alexander V (Sept. 9, 1409), a new *studium generale* was founded by the landgrave of Thuringia and the margraves of Meissen. The members were divided into four nations composed of natives of Meissen, Saxony, Bavaria and Poland.

Restock.-At Rostock, in the north, the dukes John and Albert of Mecklenburg conceived the design of founding a university from which the faculty of theology should be excluded. The university was accordingly founded as proposed in 1419, but in 1431 Eugenius IV instituted a faculty of theology. Six years later, the whole academic community having incurred the papal ban, was fain to migrate to Greifswald, returning, however, to Rostock in 1443, but with one important exception, that of a master of arts named Henry Rubenow, who remained to become burgomaster of the former city and succeeded in persuading Duke Wratislaw of Pommern to make it the seat of a university. Calixtus III granted a bull in 1456, but it was stipulated that the rector should be a bishop, and the professorial chairs were also made partially dependent for endowment on canonries. Greifswald thus became exposed to the full brunt of the struggle which had ensued when the endeavour to nationalize the German church was terminated by the Concordat of Vienna (1448).

Freiburg.—The universities of Freiburg, in Baden, and Tübingen, in Wiirttemberg, alike owed their foundation to the countess Matilda, by whose persuasion her husband, the archduke of Austria, known as Albrecht VI, was induced to found Freiburg in 1455, and Count Eberhard (her son by a former marriage) to found Tübingen in 1477. At Freiburg, under the supervision of its first rector, Matthew Hummel of Villingen, the numbers were soon largely augmented by migrations of students from Vienna and from Heidelberg, while its resources, which originally were chiefly an annual grant from the city council, were increased by the bestowal of canonries and prebends. Erasmus made Freiburg his residence from 1529 to 1535, during which time he may have originated the tradition of liberal learning, but in 1620, under the rule of the archduke Maximilian. the control of the humanistic studies and of the entire faculty of philosophy was handed over to the Jesuits, who also gained possession of two of the chairs of theology.

Tübingen.—The University of Tiibingen was founded in 1477 with the usual four faculties. and numbered Johann Reuchlin and Philipp Melanchthon among its teachers.

Louvain.—In the Netherlands the growing wealth and prosperity of the different states especially favoured the formation of new centres of learning. In the flourishing duchy of Brabant the University of Louvain (1426) was to a great extent controlled by the municipality; and its patronage, although ultimately attended with detrimental results, long enabled Louvain to outbid all the other universities of Europe in the munificence with which it rewarded its professors. In the course of the next century the "Belgian Athens," as styled by Justus Lipsius, ranked second only to Paris in numbers and reputation. It possessed no fewer than 28 colleges, while its active press afforded facilities to the author and the controversialist of which both Cambridge and Oxford were at that time almost destitute. It embraced all the faculties, and no degrees in Europe stood so high as guarantees of general requirements. Erasmus recorded it as a common saying that "no one could graduate at Louvain without knowledge, manners and age."

Budapest.—In Hungary, Matthias I, Hunyadi, obtained permission in 1465 to found a university where he thought best in his realm. The university at Ofen (Hungarian Buda) was founded in 1475. It had a school of law at Pressburg, the sole remains of the university there founded by Matthias in 1465.

THE PASSING OF MEDIAEVALISM

France.—The earliest 15th-century university in France was that of Aix in Provence. It had originally been nothing more than a school of theology and law, but in 1409 it was reorganized as a studium generale on the model of Paris. Its students were divided into Burgundians, Provençals and Catalans.

The University of Poitiers was instituted by Charles VII in 1431 with the design of creating a centre of learning less favourable to English interests than Paris had at that time shown itself to be. He conferred on Poitiers all the privileges collectively possessed by Paris, Toulouse, Montpellier, Angers and Orléans, and at the same time placed the university under special royal protection.

The University of Caen was founded under English auspices during the short period of the supremacy of the English arms in Normandy in the 15th century. Its charter (May 1437) was given by Eugenius IV, and the bishop of Bayeux was appointed its chancellor. After the expulsion of the English from France, it received a new charter. From this time the University of Caen was distinguished by its loyal spirit and firm resistance to ultramontane pretensions; and, although swept away at the French Revolution, it was afterward restored, owing to the sense of the services it had thus once rendered to the national cause. Other French 15th-century foundations are Bordeaux (1441), Valence (1452), Nantes (1463) and Bourges (1465).

Central and Northern Europe.—The University of Basle was opened in 1460, under the auspices of its own citizens, and Pius II (Aeneas Sylvius) granted the charter (Nov. 12, 1459). During the first' 70 years of its existence the university prospered, and its chairs were held by eminent professors. among them historical scholars such as Sebastian Brant and Jacob Wimpheling. But with the Reformation Basle became the arena of contests which menaced the very existence of the university itself, the professors being, for the most part, opposed to the new movement with which the burghers warmly sympathized. Eventually the statutes were revised, and in the latter half of the 16th century the university may be said to have attained its apogee.

The University of Ingolstadt was founded on April 7, 1459. But it was not until 1472 that the work of teaching was actually commenced there. Some long-existing prebends, founded by former dukes of Bavaria, were appropriated to the endowment. Nowhere did the Reformation meet with more stubborn resistance, and it was at Ingolstadt that the Counter Reformation commenced. In 1556 the Jesuits made their first settlement in the university.

At Trier and Mainz universities were established in the second half of the 15th century. Trier received its charter as early as 1450, but the first academical session did not commence until 1473. Sixtus IV granted the charter to Mainz (Nov. 23, 1476) at the request of Archbishop Diether, who was himself a great humanist.

Other foundations were those of Uppsala (1477) and Copenhagen (1479), which, although lying outside the political boundaries of Germany, reflected its influence. The charter for Copenhagen was given by Sixtus IV a5 early as 1475.

The university founded at Wittenberg by Maximilian I (July 6, 1502) was the first established in Germany by imperial decree. Its charter is, however, drawn up with the traditional phraseology of the pontifical bulls and is evidently not conceived in any spirit of antagonism to Rome. Wittenberg was constituted a studium generale in all the four faculties, the right to confer degrees in theology and canon law having been sanctioned by the papal legate several months before, on Feb. 2, 1502. Wittenberg was the first academic centre north of the Alps where the Latinity and antiquated methods of the scholastic era were overthrown.

Frankfurt-on-Oder received its charter in 1506.

Scotland.—The first Scottish foundation was at St. Andrews, founded in 1411 by Henry Wardlaw, bishop of that see, and modelled chiefly on the constitution of the University of Paris. It acquired all its three colleges—St. Salvator's, St. Leonard's and St. Mary's—before the Reformation. The most ancient of the universities of Scotland, with its three colleges. was thus reared in an atmosphere of mediaeval theology, and undoubtedly designed as a bulwark against heresy and schism. But "by a strange irony of fate, two of these colleges became, almost from the first, the foremost agents in working the overthrow of that Church which they were founded to defend." St. Leonard's more especially became a noted centre of intellectual life and Reformation principles.

The University of Glasgow was founded as a studium generale in 1453. Among its objects also was "the extension of the Catholic faith"; but it was to produce John Knox. It was founded on the model of Bologna, but in its customs largely imitated Louvain, whose rector at the time was a Scotsman. Though founded to "flourish in theology, canon and civil law, and in any other lawful Faculty," for long only the faculty of arts had a constitution. Throughout the 15th century this faculty flourished exceedingly.

The Cniversity of Aberdeen was founded in 1494, mainly through the efforts of Bishop William Elphinstone, who had earlier been successively dean of the faculty of arts and rector of Glasgow university. He avoided two defects in the constitutions of St. Andrews and Glasgow by providing salaries for teachers in the higher faculties and establishing a visitorial power.

The fourth Scottish university, Edinburgh, was a post-Reformation foundation.

General Aspects.—Generally speaking, the mediaeval universities were conservative. Alexander Hegius, Johan Wessel and Rodolphus Agricola carried on their work as reformers at places like Deventer, remote from university influences. That there was a considerable amount of mental activity going on in the universities themselves is not to be denied; but it was mostly of that unprofitable kind which, while giving rise to endless controversy, turned upon questions in connection with mhich the implied postulates and the terminology employed rendered all scientific investigation hopeless. At almost every university—Leipzig, Greifswald and Prague (after 1409) being the principal exceptions—the so-called Realists and Nominalists represented two great parties occupied with an internecine struggle. At Paris, because of the overwhelming strength of the theologians, the Nominalists were. indeed, under a kind of ban; but at Heidelberg they had altogether expelled their antagonists. It was much the same at Vienna and at Erfurt. At Basle, under the leadership of the eminent Johannes a Lapide. the Realists with difficulty maintained their ground. Freiburg, Tübingen and Ingolstadt, in the hope of diminishing controversy, arrived at a kind of compromise, each party having its own professor and representing a distinct "nation." At Mainz the authorities adopted a manual of logic which was essentially an embodiment of nominalistic principles.

In Italian universities. it was decided that these controversies were endless and that their effects mere pernicious. It was resolved, accordingly, to expel logic and allow its place to be filled by rhetoric, thereby effecting that important revolution in academic studies which constituted a new era in university learning and largely helped to pave the way for the Reformation. Hence the Italian universities enjoyed a fortunate immunity from dissensions such as those which distracted the centres of learning in Germany.

The professorial body in the great Italian universities attained an almost unrivalled reputation throughout Europe. For each subject of importance there were always two, and sometimes three, rival chairs and a powerful and continuous emulation was thus maintained among the teachers. "The call to a Paduan or Pisan chair was deemed the highest of all literary honours. The status of professor was, in Italy, elevated to a dignity which in other countries it has never reached; and not a few of the most illustrious teachers in the Italian seminaries were of the proudest nobility of the land. While the universities of other countries had fallen from Christian and cosmopolite to sectarian and local schools. it is the peculiar glory of the Italian that, under the enlightened liberality of their patrons, they still continued to assert their European universality. Creed and country mere, in them, no bar—the latter not even a reason of preference. Foreigners of every nation are to be found among their professors; and the most learned man in Scotland. Thomas Dempster, sought in a Pisan chair that theatre for his abilities which he could not find at home."

Spain. — To such catholicity of sentiment the Spanish universities of this period offer a complete contrast, their history being strongly modified by political and religious movements. Valencia, founded in 1501, and Seville, sanctioned by Julius II in 1505, appear both to have been regarded without mistrust at Rome. Julius had approved the foundation of the University of Santiago as early as 1504, but the bull for its creation was not granted by Clement VII until 1526. The design of establishing a university at Granada was deferred until 1531. Little, indeed, is to be learned respecting the new society until the foundation of the liberally endowed College de Sacro Monte by the archbishop of the province in 1605. Under the direction of the Jesuits the scholastic philosophy, together with a certain attention to Greek and Hebrew, became the dominant study. Gregory XIII in 1574 authorized the foundation of the University of Oviedo; but this was not opened until 1608, and then only with a faculty of law. After this time the universities in Spain shared in the general decline of the country; and. even after the expulsion of the Jesuits in 1769, no marked improvement is discernible in their schools until the second half of the 19th century.

Mention should be made, however, of the foundations in Spanish America, nhich went on for more than two centuries. They included the University of Lima, Peru (now Universidad Nacional Mayor de San Marcos and claimed as the oldest university in the new world), set up as a Dominican seminary in 1551 and secularized in 1571 with faculties in philosophy and theology; Mexico City, opened in 1553, Bogota, Colom (1572); Cuzco, Peru (1696); Havana, Cuba (1728); and Santiago, Chile (1747).

THE REFORMATION

The Reformation represents the first great boundary line in the history of European universities. Even in Roman Catholic countries its effects found expression in connection with the Counter Reformation. The influence of the humanists, and the special character which the Reformation assumed in Germany through the labours of scholars like Erasmus, Reuchlin and Melanchthon, augured well for the future. German university teaching was free from the frivolity, pedantry and scepticism which characterized so much of the corresponding culture in Italy. It gave promise of resulting at once in a critical and enlightened study of the masterpieces of classical antiquity, and in a reverent and yet rational interpretation of the Scriptures and the Fathers. The bigoted and ceaseless controversies evoked by the promulgation of Lutheran or Calvinistic doctrine dispelled, however, this prospect, and converted the universities into gloomy fortresses of sectarianism. For a century after the Reformation the history of Lutheran theology became almost identified with that of the German universities.

Marburg. — The first Protestant university was that of Marburg, founded by Philip the Magnanimous, landgrave of Hesse, May 30, 1527, and mainly built up out of the confiscation of the property of the religious orders in the Hessian capital. It rapidly became famous and attracted students from remote countries. After 1605, when, by the decree of Count Maurice, its formulary of faith was changed from Lutheran to Calvinistic, its numbers greatly declined. This dictation by the temporal power now becomes one of the most notable features in academic history in Protestant Germany.

Königsberg.—The Lutheran University of Konigsberg was founded Aug. 17, 1544, by Albert III, margrave of Brandenburg and the first duke of Prussia, and his wife Dorothea, a Danish princess. King Sigismund of Poland gave the charter (Sept. 29, 1561), and students who graduated as masters in the faculty of philosophy ranked as nobles of the Polish kingdom. When Prussia was raised to the rank of a kingdom (1701) the university was made a royal foundation, and the *collegium Fridericianum,* which was then erected, received corresponding privileges. Konigsberg will always be remembered as the university of Kant.

Jena.—The Lutheran University of Jena was opened on Feb. 2, 1558. Distinguished for its vehement assertion of Lutheran doctrine, its hostility to the teaching of Wittenberg was hardly less pronounced than that with which both centres regarded Roman Catholicism. For a long time it was chiefly noted as a school of medicine, and in the 17th and 18th centuries was in bad repute for the lawlessness of its students, among whom duelling prevailed to a scandalous extent.

Helmstedt.—The Lutheran University of Helmstedt, founded by Duke Julius (of the house of Brunswick-Wolfenbiittel), received its charter May 8, 1575, from the emperor Maximilian II. It was munificently endowed by the founder and by his son, and its *Convictorium,* or college for poor students, expended in the course of 30 years no less than 100,000 thalers, an extraordinary expenditure for an institution of such a character in those days. Distinguished by its comparatively temperate maintenance of the Lutheran tenets, it attracted a considerable concourse of students, especially from the upper classes. Until suppressed in 1809, Helmstedt enjoyed the special and powerful patronage of the dukes of Saxony.

Altdorf.—The *Gymnasium Aegidianum* of Nuremberg, founded in 1526 and moved in 1575 to Altdorf, represents the origin of the University of Altdorf. Altdorf was about the poorest university in Germany, yet long one of the most eminent. Its whole endowment never rose above £800 a year.

17TH- AND 18TH-CENTURY GERMAN FOUNDATIONS

Giessen.—The conversion of Marburg into a school of Calvinistic doctrine gave occasion to the foundation of the universities of Giessen and of Rinteln. Giessen, founded by the margrave of Hesse-Darmstadt, Louis V, as a kind of refuge for the Lutheran professors from Marburg, received its charter from the emperor Rudolph II (May 19, 1607). In 1625 the university was transferred to Marburg; in 16jo it was moved back again to Giessen.

Strasbourg.—The University of Strasbourg was founded in 1621 on the basis of an already existing academy which, under the direction of John Sturm, had attracted students from all parts of Europe and especially from Portugal, Poland, Denmark, France and England. The method of Sturm's teaching became the basis of that of the Jesuits, and, through them, of the public schools in England. In 1621 Ferdinand II conferred on this academy full privileges as a university. In 1681 Strasbourg became French. It was refounded by the emperor William I and before the close of the century numbered more than 1,100 students. At the end of the 18th century, after its reversion to Germany, it was distinguished by an intellectual activity with which the name of Goethe is connected.

Kiel.—The royal university of Kiel was founded in 1665 by Duke Christian Albrecht of Holstein (who himself assumed the office of rector), with faculties of theology, law, medicine and philosophy. After the incorporation of Schleswig-Holstein with the kingdom of Prussia it made a marked advance.

Halle and Pietism.—The year 1693 saw the foundation of the University of Halle, which has been described as the "first real modern university." It originated in a *Ritterschule* for the sons of the nobility. Leopold I granted (Oct. 19, 1693) the requisite charter. The primary object in founding a university in Halle was to create a centre for the Lutheran party; but its character, under the influence of its two most notable teachers, Christian Thomasius and A. H. Francke, soon expanded beyond the limits of this conception. Thomasius and Francke had both been driven from Leipzig because of their liberal and progressive tendencies. Thomasius was the first to set the example, soon after followed by all the universities of Germany, of lecturing in the vernacular instead of in the customary Latin. Francke, as the founder of that Pietistic school, exercised great influence. Christian Wolff, who followed Thomasius as an assertor of the new culture, was driven from Halle by the accusations of the Pietists. In 1740, however, he was recalled by Frederick II and reinstated. Throughout the whole of the 18th century Halle was the leader of academic thought and advanced theology in Protestant Germany, although sharing that leadership, after the middle of the century, with Gottingen.

Göttingen.—The University of Gottingen (named after its founder, "Georgia Augusta"), was endowed with the amplest privileges as a university by George II of England, elector of Hanover, Dec. 7, 1736. The university included all the faculties, and two of its first professors—J. L. von Mosheim, the eminent theologian from Helmstedt, and G. L. Bohmer, the no less distinguished jurist from Halle—together with Johann Gesner, the man of letters, at once established its reputation. Not least among its attractions was also its splendid library, located in an ancient monastery. The Gottingen school of history became famous. The labours of the professors at Gottingen, especially J. S. Putter, J. C. Gatterer, A. L. von Schlozer and L. T. von Spittler, combined with those of J. J. Mascov at Leipzig, did much to promote both a more catholic treatment and a wider scope. The method of appointment of professors was reformed by the chief curator, G. A. von Miinchhausen, on lines similar to those already instituted in the universities of the Netherlands by Janus Dousa.

Erlangen.—The University of Erlangen, a Lutheran centre, was founded by Frederick, margrave of Bayreuth. Its charter was granted by the emperor Charles VII in 1743. In 1791, Ansbach and Bayreuth having passed into the possession of Prussia, Erlangen also became subject to the Prussian government.

NORTHERN EUROPE

The earliest Dutch university, Leyden, founded in 1575, commemorated the successful resistance of the citizens to the Spanish. Throughout the 17th century Leyden was distinguished by its learning, the ability of its professors and the shelter it afforded to the more liberal thought associated at that period with Arminianism. Much of its early success was a result of the wise provisions and the influence of the celebrated Janus Dousa. Dousa, in fact, did for Leyden and the Dutch what Miinchhausen afterward did for Gottingen and the German universities. The appointment of the professors at Leyden was vested in three (afterward five) curators, one of whom was selected from the body of the nobles, while the other two were appointed by the states of the province, the office being held for nine years and eventually for life. With these was associated the mayor of Leyden for the time being. Leyden secured and maintained a very high reputation for scientific work. Other Dutch universities with a famous history are Franeker (1585), Harderwyk (1600), Groningen (1614) and Utrecht (1634), the last being a great resort in the 18th century for English students.

The Royal University of Uppsala, whose foundation as a *studium generale* was sanctioned by Pope Sixtus IV in 1477, despite a checkered history remained the chief centre of higher education in Sweden. In the 18th century lectures began to be delivered in Swedish, but the mediaeval division of the students into "nations" continued, as at Lund (1666), until the second quarter of the 19th.

REFORMATION AND POST-REFORMATION IN BRITAIN

Oxford and Cambridge.—The influence of the Renaissance and the teaching of Erasmus, who resided at both universities, exercised a notable effect alike at Oxford and Cambridge. The names of John Colet, William Grocyn and Thomas Linacre illustrate this influence at the former centre; those of Bishop John Fisher, Sir John Cheke and Sir Thomas Smith at the latter. The labours of Erasmus at Cambridge, as the author of a new Latin version of the New Testament, with the design of placing in the hands of students a text free from the errors of the Vulgate, were productive of important effects, and the university became a centre of Reformation doctrine several years before the writings of Luther became known in England. The foundation of Christ's college (1505) and St. John's college (1511), through the influence of Fisher with the countess of Richmond, also materially aided the general progress of learning at Cambridge. The Royal Injunctions of 1535, embodying the views and desigcs of Thomas Cromwell. mark the downfall of the old scholastic methods of study at both universities; and the foundation of Trinity cellege, Cambridge, in 1547 (partly by an amalgamation of two older societies), represents the earliest conception of such an institution in England in complete independence of Roman Catholic traditions. Trinity (1554) and St. John's (1555) at Oxford, on the other hand. founded during the reactionary reign of Mary, serve rather as examples of a transitional period.

Puritanism at Cambridge.—In the reign of Elizabeth, Cambridge became the centre of another great movement, that of the earlier Puritanism, St. John's and Queens' being the strongholds of the party led by Thomas Cartwright, Walter Travers and others. The movement continued to gather strength, and Emmanuel college. founded in 1584, owed much of its early prosperity to the fact that it was a known school of Puritan doctrine. Most of the Puritans objected to the discipline enforced by the university and ordinary college statutes, especially the wearing of the cap and the surplice and the conferring of degrees in divinity. The Anglican party, headed by such men as archbishops John Whitgift and Richard Bancroft. resorted in defense to a repressive policy, of which subscription to the Acts of Supremacy and Uniformity and the Elizabethan statutes of 1570 (investing the *caput* with larger powers and thereby creating a more oligarchical form of government) were the most notable results. Oxford, although the Puritans were there headed by Leicester, the chancellor, devised at the same time a similar scheme. the rigid discipline of which was further developed in the Laudian or Caroline statutes of 1636. It was under these respective codes—the Elizabethan statutes of 1570 and the Laudian statutes of 1636—that the two universities were governed until the introductian of new codes in 1858. The fidelity with which both universities adhered to the royal cause in the Civil War caused them to be regarded with suspicion by the Puritan party. and under the Commonwealth both Oxford and Cambridge were, for a brief period, in great danger because of the distrust. which reached its highest point among the members of the "nominated parliament" (July-December 1653), of university education generally. as tending to foster contentiousness with respect to religious belief. It was even proposed by William Dell—himself the master of Caius college—to abolish the two universities altogether, as hopelessly pledged to antiquated and obsolete methods. and to establish in their place schools for higher instruction throughout the country. They were saved, however, by the firmness of Cromwell, at that time chancellor of Oxford, and, although Aristotle and the scholastic philosophy no longer held their ground, a marked improvement was observable both in discipline and morality among the students. At Oxford, under the influence and teaching of John Wilkins, Seth Ward and John Wallis, a flourishing school of mathematics was formed.

The Cambridge Platonist Movement.—In the 17th century Cambridge became the centre of a further movement (a reflex of the influence of the Cartesian philosophy), nhich attracted for a time considerable attention. Its leaders. known as the Cambridge Platonists, among whom Henry More and Ralph Cudworth were especially conspicuous, were men of high character and great learning, although much under the influence of an ill-restrained enthusiasm and purely speculative doctrines. The spread of the Baconian philosophy, and the example of a succession of eminent scientific thinkers, among whom were Isaac Barrow, master of Trinity (1673–77), the two Lucasian professors Isaac Newton (professor 1669–1702) and his successor William Whiston (professor 1702–11), and Roger Cotes (Plumian professor 1707–16), began to render the exact sciences more and more an object of study, and the institution of the tripos examinations in the course of the first half of the 18th century established the reputation of Cambridge as a school of mathematical science. At Oxford, where the study had, in turn, declined, and where the statutable requirements with respect to lectures and exercises were suffered to fall into neglect, academic culture declined.

Edinburgh. — The "College of Edinburgh" was founded by charter of James VI, dated April 14, 1582. This made no mention of a *studium generale* or of any of the privileges associated with a university, and not until 1685 was the college referred to as a university in municipal records. But the charter gave the town council the right to provide for the teaching of all the subjects usual in a university, and from 1587 the college conferred degrees.

Trinity College, Dublin. — Trinity college, Dublin, was founded in 1591. A royal charter nominated a provost and a minimum number of three fellows and three scholars as a body corporate. The first five provosts of Trinity college were all Cambridge men, and under the influence of Archbishop Adam Loftus, the first provost, and his successors, the foundation received a strongly Puritan bias, but the policy of Laud and Wentworth was to make the college more distinctly Anglican as regards its tone and belief. At the Restoration its condition was found to be that of a well-ordered home of learning and piety, with its estates well secured and its privileges unimpaired. Under Bishop Jeremy Taylor, who succeeded to the vice-chancellorship, its progress in learning was considerable.

THE COUNTER REFORMATION

Barnberg. — The earliest university whose charter represented the Counter Reformation was that of Bamberg, founded by the prince-bishop and opened Sept. 1, 1648. At first, however, it comprised only the faculties of arts and of theology; to these were added in 1729 that of jurisprudence and in 1764 that of medicine. The university library was enriched by a collection of manuscripts from about 30 suppressed monasteries, convents and religious institutions at the time of the "secularization."

Innsbruck.—The University of Innsbruck was founded in 1672 by the emperor Leopold I. In the following century, under the patronage of the empress Maria Theresa, it made considerable progress, and received from her its ancient library and bookshelves in 1745. In 1782 the university was reduced by the emperor Joseph II from the status of a university to that of a lyceum, although retaining in the theological faculty the right of conferring degrees. In 1791 it was restored to its privileges by the emperor Leopold II.

Breslau.—The University of Breslau was founded by the emperor Leopold I in 1702. When Frederick the Great conquered Silesia in 1741, he took both the university and the Jesuits in Breslau under his protection, and when, in 1774, the order was suppressed by Clement XIV he established them as priests in the Royal Scholastic institute, at the same time giving new statutes to the university.

Jesuit Influence in France. — In no country was the influence of the Jesuits on the universities more marked than in France. The civil wars in that country during the 30 years which preceded the close of the 16th century told with disastrous effects upon the condition of the University of Paris, and with the commencement of the 17th century its collegiate life seemed at an end and its 40 colleges stood absolutely deserted. To this state of affairs the obstinate conservatism of the academic authorities contributed not a little. The Jesuits did not fail to profit by this excessive conservatism on the part of the university. and during the second half of the 16th century and the whole of the 17th they contrived to gain almost a complete monopoly of both the higher and the lower education of provincial France. Their schools rose at Toulouse and Bordeaux. at Auch, Agen, Rhodez, Périgueux, Limoges, Le Puy, Aubenas, Béziers, Tournon, in the colleges of Flanders and Lorraine, Douai and Pont-à-Mousson—places beyond the jurisdiction of the *parlement* of Paris or even of the crown of France. Their banishment from Paris itself had been by the decree of the *parlement* alone and had never been confirmed by the crown. "Lyons," says Mark Pattison, "loudly demanded a Jesuit college," and even the Huguenot duke of Lesdiguitres, almost king in Dauphiné, was prepared to erect one at Grenoble. The university was rescued from the fate which seemed to threaten it only by the excellent statutes given by Edmond Richer in 1598 and by the discerning protection extended by Henry IV.

Nevertheless, the University of Paris remained distracted throughout the 17th century by theological dissensions — in the first instance as a result of the struggle that ensued after the Jesuits had effected a footing at the Collège de Clermont, and subsequently by the strife occasioned by the teaching of the Jansenists. Toward the close of the century a certain revival took place, and a succession of illustrious names — E. Pourchot, Charles Rollin, Bénigne Grenan, Charles Coffin, Jean-Gabriel Demontempuis, J. B. L. Crevier, Charles Le Beau — appear on the roll of its teachers. But this improvement was soon interrupted by the controversies excited by the promulgation of the bull *Unigenitus* in 1713, condemning the tenets of Pasquier Quesnel. At last. in 1762, the *parlement* of Paris issued a decree (Aug. 6) placing the colleges of the Jesuits at the disposal of the university, and this was immediately followed by another for the expulsion of the order from Paris, the university being installed in possession of its vacated premises. Concurrently with this measure, both history and natural science began to be cultivated with a certain success. Then came the French Revolution.

19TH AND EARLY 20TH CENTURIES

The United Kingdom. — The Reformation marked the first great turning point in the history of the universities; the 19th century can lay good claim to having marked the second. It saw the foundation of numerous new universities, many in parts of the world previously unprovided with facilities for higher education; it saw also the reconstitution of numerous ancient universities. Neither process was the result of chance; new and reconstituted universities alike arose to meet new needs, the needs of an expanding world and an increasingly industrialized age.

Oxford and Cambridge.—In the United Kingdom of Great Britain and Ireland both processes took place. At the beginning of the 19th century Oxford and Cambridge nere "the endowed preserve of a class" (Sir Charles Grant Robertson, The *British Universities*); by the end of it the "privileges and monopoly" of this class hacl been almost completely swept away. Much of the reform came from within. hut two royal commissions, in 1858 and 1877, investigated the affairs of the universities and recornrnendetl drastic and far-reaching changes. During the century the range of studies n-as enormously extended. Exacting written examinations took the place of the often merely formal oral ceremonies. The professoriate was increased. reorganized and re-endowed, so that it became a resident, university hody.

General and uniform regulations were enforced for the selection. duties and salaries of professors. lecturers and examiners. Fellowships were thrown open to merit. The colleges were emancipated from their mediaeval statutes. invested with new constitutions and granted new legislative powers, while at the same time a proportion of their revenues was diverted to the uses of the university. A great mass of vexatious and obsolete oaths was swept away; in 1858 dissenters were admitted to matriculation and the B.A., and in 1871 all religious tests were abolished.

In 1863 noncollegiate students were admitted to Oxford and in 1869 to Cambridge. Women's colleges were also established. Girton (1869) and Newnham (1871–75) at Cambridge, Somerville (1879) and Lady Margaret Hall (1878), the latter being followed by St. Hugh'. (1886) and St. Hilda's (1893) at Oxford.

Women had to wait, however, until the 20th century before the ancient English universities would admit them to degrees.

London.—London. the first of Britain's modern universities, mas born out of religious differences, which gave it a unique and unhappy start It originated in a movement begun in 1825 by the poet Thomas Campbell. Henry (later Lord) Brougham and influential dissenters, nhose aim was to set up an institution of university status for students excluded from Oxford and Cambridge by religious belief or lack of means. In 1828 the University of London was opened. But the project brought into being a rival group, equally influential, nhich in 1829 opened King's college, London, mhose curriculum was similar except that it included instruction in "the doctrines and duties of Christianity, as the same are inculcated by the United Church of England and Ireland." The result was that neither college received a university charter. In 1836 a nonteaching body, called London university, was created, authorized to hold examinations and confer degrees, not only, it is important to note, upon students of its two incorporated colleges, University and King's, but also upon students of such other institutions in the United Kingdom and the British colonies as it might affiliate.

In 1858 the degrees of London university (except in medicine) were made available to all. Since that date London has awarded two kinds of degrees. *internal* to members of the university and *external* to anyone else passing its examinations, whether members of an educational institution or private students. This extraordinary constitution caused the University of London embarrassment for many years but later the external degrees were to prove of inestimable value in assisting university colleges in England and throughout the British Commonnealth to qualify for full university status The colleges prepare their students for the London degrees until such time as their academic standards, their teaching staff and their financial resources are sufficiently good to justify application for a university charter.

Attempt after attempt was made to reorganize the university until in 1900 it was reconstituted so that only institutions within the county of London could become recognized as "schools of the university."

Durham and Newcastle.—The London colleges were designed for students of limited means. So was the University of Durham. A residential. collegiate university. modelled on Oxford. it nas founded by act of parliament in 1832 and received its charter in 1837. It was endowed from the revenues of Durham cathedral and diocese. With it was associated in 1852, and more closely in 1870, the Newcastle College of Medicine.

In 1871 the Durham College of Physical Science was founded (in Newcastle: later called Armstrong college) and incorporated into the university. In 1908 the university was reconstituted in two divisions—Durham and Newcastle—under a single vice-chancellor but with separate teaching staffs. A further reconstitution in 1937 established a central financial control and merged the tno Nencastle colleges into King's college, Newcastle upon Tyne.

Other Provincial Universities.—Forty-four years nere to elapse before another English university was founded. but nithin that period the progenitors of at least three others were born, and before the end of the century an additional five. In 1851 Owens college, Jlanchester, was established to teach "such branches of learning and science as nere then or might hereafter be usually taught in English universities."

In 1874, at Leeds, arose the Yorkshire College of Science; in 1876 the University college. Bristol; both absorbed earlier medical schools. Within the next 20 years there were similar colleges at Birmingham, Liverpool, Nottingham. Reading and Sheffield In 1880 Owens college became the Victoria University of Manchester, in which were shortly federated the university colleges of Leeds and Liverpool.

"*Redbrick*" Universities.—The university college movement produced a rich harvest in the first decade of the 20th century. Mason college became Birmingham university in 1900. Liverpool and Leeds broke away from Manchester to obtain their own charters in 1903 and 1904, respectively The University of Sheffield followed in 1905 and that of Bristol in 1909. These five, with Manchester, established a new tradition in English university education. Each was the product of a large industrial city. endowed by its citizens (who justly claimed a share in its government) and linked closely with its occupations. Each had a strong scientific and technological side. Each catered mainly though never exclusively, for local students and was consequently nonresidential. All were completely free of religious tests; in some the teaching of religion was forbidden. In all the fees and other expenses were low. The sobriquet "Redbrick" given them later by an English writer referred primarily to their buildings but also characterized them as a homogeneous group. Reading became a university in 1926; later followed Nottingham (1948). Southampton (1952), Hull (1954), Exeter (1955) and Leicester (1957).

Scotland.—In the 19th century three royal commissions wrestled with the affairs of the Scottish universities. The first, which reported in 1830, produced no tangible results, the opposition to its proposals proving too strong. But it stimulated thought about reform and paved the way for the commission of 1558, mhose recommendations. embodied in the Universities (Scotland) act, 1858. remodelled the Scottish universities and assimilated their constitutions and conditions of graduation. The teaching and administrative functions were differentiated by the setting up at each university of a university court whose duty was to review all decisions taken by the *Senatus Academicus*. Also, each university was given a general council, which was to meet twice yearly to consider "questions affecting the well-being and prosperity of the university." The two independent degree-conferring colleges at Aberdeen, King's and Marischal, were amalgamated.

The Universities (Scotland) act. 1889, introduced further drastic changes. It set up a Scottish universities committee of the privy council, to which all ordinances and petitions from the universities had to be referred. (This procedure was abandoned 20 years later because of the delays and difficulties it caused.) It increased the membership and powers of the uni ersity courts. adding to them representatives of the senate, the general council and the municipality within which the university was situated. and vesting in them responsibility for the business management of the university property and finances. leaving the control of education and discipline only to the *senatus*. It gave statutory recognition to the Students' Representative council (which had come into being in 1884) and empowered it to petition the *senatus* or the university court about any matter affecting the students' interests. It reorganized the curriculums of all the faculties except divinity; greatly broadening them and ending the compulsion to take the "sacred six" subjects in arts (Latin. Greek. mathematics, natural philosophy, logic and moral philosophy). It reduced the period of required residence from four to three years, established a new system of honours degrees and empowered the courts to admit women to lectures and degrees in all faculties. Most of these changes were effected by the executive commission set up under the act; they took eight years to complete.

Wales.—The principality of Wales played a notable part in the university college movement and because of a strong national feeling and an earlier development of secondary education than in England, secured its university in 1893, when the university colleges of Aberystwyth (1872). Cardiff (1883) and Bangor (1885) were federated. St. David's college; Lampeter (1827), a theological college, was not included, but retained its right to confer the degrees of bachelor of arts and of divinity.

Ireland.—Religious difficulties gravely impeded university education. In 1845 three state-endowed university colleges were set up by act of parliament at Belfast, Cork and Galway, and in 1850 they were federated as the Queen's university. As no provision was made for theological teaching they were boycotted by Roman Catholics. In 1850 John Henry (later Cardinal) Newman founded a Roman Catholic university at Dublin, but this was refused the right to grant degrees. In 1879 the Queen's university was displaced by the Royal university, a nonteaching body empowered to hold examinations and grant degrees, which Catholics could take.

In 1909 university education in Ireland was reorganized. Two new universities were created: the National University of Ireland at Dublin, which incorporated the Queen's colleges at Cork and

Galway and set up a third college in Dublin; and the Queen's university at Belfast (formerly the Queen's college). Both universities nere given nominated senates with a Roman Catholic majority in Dublin and a Protestant one in Belfast. Trinity college, Dublin. was left intact. In all three universities there were to be no religious tests for teachers or students.

COMMONWEALTH OF NATIONS

India. — Though there were previously institutions of university status, the foundation of universities as such in India was the outcome of the parliamentary inquiry which preceded the confirmation of the East India company's charter in 1853, and of Sir Charles Wood's dispatch to its court of directors in 1854. In 1857 three universities — Calcutta (Jan. 24), Bombay (July 18) and Madras (Sept. 5)—were founded on the London model as examining bodies with power to affiliate. The framers of this policy did not intend the universities to have no teaching functions, but not until the 20th century did they become fully teaching institutions. Proposals made in 1865–67 for an oriental university in the Punjab resulted in the foundation of a university college at Lahore which became a university in 1882, and in 1887 Allahabad university followed. Both of these were London-model examining and affiliating bodies, though the University of the Punjab was also authorized to appoint teachers.

In 1902 a universities' commission recommended, and in 1904 an act provided. that the older universities should become teaching bodies. The conditions for affiliation were stiffened. In 1913 a government resolution proposed the establishment of residential universities at Dacca, Aligarh and Benares and the creation of new universities at Rangoon. Patna and Nagpur; but the outbreak of World War I delayed these developments.

Canada. — The history of the universities of Canada is highly complex, reflecting the varied religious and political influences in the making of the nation. All the older universities except two were founded by religious bodies, among whom the Roman Catholics, Anglicans, Presbyterians, Methodists and Baptists were prominent. Broadly speaking, these copied three models, Paris, Oxford and Edinburgh, according to the nationality of the founders. Later, after efforts, largely unsuccessful, to overcome the denominational problem by founding universities on the London style, there came the evolution of a distinctively Canadian type of federated university. Finally, the 20th century saw, in the western provinces, the foundation of fully state-provided universities.

The French Laval university, Quebec, was founded as late as 1852, but the Seminary of Quebec, from which it sprang, dates from 1633. The University of Montreal was founded in 1878 as a branch of Laval, from which it was finally separated in 1920. Other Roman Catholic foundations were Ottawa (1849) and St. Francis Xavier, Antigonish, N.S. (1853), the latter with no religious tests for entrance or degrees. Three colleges, each called King's college and each a Church of England establishment, were early founded by the immigrant American loyalists and received royal charters: at Windsor, N.S. (1802; later moved to Halifax), Toronto (1827) — later the University of Toronto — and Fredericton, N.B. (1828). which in 1859 was secularized as the University of New Brunswick. All three were modelled upon Oxford. Later Anglican foundations included the University of Bishop's College, Lennoxville, Que. (1853), and Western university (1878); the latter became nondenominational in 1908 and later changed its name to Western Ontario. The Baptists founded Acadia, Wolfville. N.S. (1838), and in 1887 amalgamated two colleges to form McMaster, now located in Hamilton, Ont. The Presbyterians founded Queen's, Kingston, Ont. (1841), modelling it on Edinburgh; it became nondenominational in 1912. The Methodists founded Mount Allison academy at Sackville, N.B., which was given a university charter in 1858 and later also became nondenominational.

The two private foundations, Dalhousie (Halifax, N.S.) and McGill (Montreal, Que.), were both from the start nonsectarian, Both were Scottish-type universities. Each had a precarious early existence; Dalhousie, though founded in 1818, did not open until 1838, and was closed again between 1843 and 1863. The reopening was made possible by the closing of various Presbyterian and Congregational colleges. In 1868 the government withdrew grants from denominational colleges, and this, with the increasing cost of maintenance, compelled them to think seriously about federation. In 1887 a scheme was approved for a university of Toronto consisting essentially of "a group of arts or divinity colleges gathered about a central university, supported and controlled by the State, the University conducting examinations, conferring degrees (except in Divinity), and giving the instruction in those branches of learning which are costly to conduct, or are taken by only a few students, or are professional in character." *(Yearbook of the Universities of the Commonwealth, 1949–50, p. 547).* This scheme became archetypal.

For nearly 20 years Toronto university was administered by a government department. In 1906 it was granted an independent board of governors, nominated by the lieutenant governor in council, and the right of nominating to academic appointments was vested in the president of the university. In 1907 Manitoba university was reconstituted on the same lines. In 1906 and 1907 provincial universities, modelled on Toronto, were founded in Alberta at Edmonton and in Saskatchewan at Saskatoon.

Australia. — The earliest Australian universities successfully combined mediaeval and modern features. Each was established by the state legislature, yet constituted a self-governing corporation. Each relied for support upon both public money and private benefactions. Each was nonresidential. nondenominational and secular, yet each made provision for including residential denominational colleges on religious foundations. Geography dictated their location in capital cities. The first to be founded was Sydney (1850), closely followed by Melbourne (1853). Each of these had, before the end of the 19th century, three colleges for men and residential accommodation for women. Adelaide was similarly established in 1874 but did not incorporate any colleges until the 20th century. When the University of Queensland was founded in 1909 it was made wholly residential, and four colleges, including one for women, were established within four years. Living at home was recognized as residence. The universities of Tasmania, Hobart (founded 1890, charter 191jj, and Western Australia, Perth (1911), had no such provision.

New Zealand. — In 1869 the University of Otago, Dunedin, was founded by provincial ordinance, with power to grant degrees in arts, law and medicine. But the next year the University of New Zealand, Wellington, a purely examining body, was established, and in 1874 Otago agreed to affiliate with it and to hold in abeyance its own right to grant degrees. Canterbury University college. Christchurch (founded 1873), also affiliated, as did later Auckland (1882) and Victoria (1897). In the early days New Zealand maintained academic standards by appointing external examiners from England.

Union of South Africa. — The development of university education in South Africa aptly illustrates the truth that universities are born to meet new needs. Higher education began with the founding in 1829 of South African college, Capetown, a proprietary institution which for 20 years had no competitors. Then within six years appeared the Diocesan college, Capetown (1849), St. Andrew's, Grahamstown (1855), and Grey college, Bloemfontein (1855). In 1858 there was established, primarily to examine candidates for public appointments, a board of examiners in literature and science, which shortly began to conduct examinations not unlike those for university degrees. This greatly stimulated the work of the colleges, and by a natural sequence the University of the Cape of Good Hope, an examining and degree-granting body, took the place of the board in 1873 Almost simultaneously the Cape parliament passed a higher education act providing for salary grants to professors at recognized colleges. This further stimulated progress and incited other college foundations, including Stellenbosch (1874), which was raised to university status in 1916. Later came the Kimberley School of Mines (1896). Pretoria University college (1908) and Natal University college (1909), all destined eventually to graduate into universities.

CONTINENTAL EUROPE

France. — On Sept. 15, 1793, the universities and colleges throughout France, together with the faculties of theology, medicine, jurisprudence and arts, had been abolished by a decree of the convention. and the whole system of national education may be said to have remained in abeyance until 1808, when Napoleon I promulgated the scheme which in many essential features obtains today. The whole system of education, primary, secondary and higher, was made subject to the control and direction of the state. France was divided into 17 districts, designated "academies," each administered by its own rector and council, but subject to the supreme authority of the minister of public instruction, and representing certain faculties which varied at different centres, in conformity with the new scheme of distribution for the entire country. The "University of France." as it was styled, became little more than an abstract term signifying collectively the various centres of professional education in their new relations to the state. While three new "academies" — those of Lille, Lyons and Rennes — were formed in 1808, many of the pre-existing centres were completely suppressed. In some cases, however, the effacement of an ancient institution was avoided by investing it with new importance, as at Grenoble; in others, the vacated premises were appropriated to new uses connected with the department, as at Avignon, Cahors and Perpignan. Each rector of an "academy" was also constituted president of a local *conseil d'enseignement*, in conjunction with which he nominated the teachers in elementary and secondary schools. The appointments were ratified by a promotion committee in Paris.

"Free Faculties." — In 1895 the government was prevailed upon to sanction the institution of certain "free faculties," as they were termed, to be placed under the direction of the bishop, depending for support upon voluntary contributions and each including a faculty of theology, the best known being those of Paris and Lille. The faculty at Marseilles was called upon to unite with the academy of Aix, its faculties being restricted to mathematics and natural science (including a medical school), while faculties of law and philosophy were fixed at Aix, which possessed also the university library. In the capital itself, the University of Paris and the École Pratique des Hautes Études carried on the work of higher instruction independently of each other — the former with faculties of Protestant theology, law, medicine. science, letters and chemistry, distributed over the Quartier Latin; the latter with schools of mathematics, natural science. history, philology and history of religions centred at the Sorbonne.

In 1896 the higher education of France was decentralized and the existing academies, consisting of isolated faculties, were converted into regional universities, while the Sorbonne. from being the University of France, became the University of Paris. The total number of universities, including that of Algiers, was 16.

Germany. — The political storms which marked the close of the 18th and the beginning of the 19th century gave the deathblow to not a few of the ancient universities of Germany. Mainz and Cologne ceased to exist in 1798, Bamberg, Dillingen and Duisburg in 1804, Rinteln and Helmstedt in 1809, Salzburg in 1810 and Erfurt in 1816. Altdorf was united to Erlangen in 1807, Frankfurt-on-Oder to Breslau in 1809 and Wittenberg to Halle in 1815. The University of Ingolstadt was first moved in 1802 to Landshut and from there, in 1826, to Munich, where it was united to the academy of sciences which had been founded in the Bavarian capital in 1759. Miinster, in Prussia, which had been constituted a university by Maximilian Frederick (elector and archbishop) in 1771, was abolished in the year 1818; but two faculties, those of theology and philosophy. continued to exist, and in 1843 it received the full privileges of a Prussian university, together with the designation of a royal foundation. Of those of the above centres which altogether ceased to exist, few were much missed or regretted, that at Mainz, which had numbered about 600 students, being the one notable exception. The others had, for the most part, fallen into a perfunctory and lifeless mode of teaching, and, with wasted or diminished revenues and declining numbers, had long ceased worthily to represent the functions of a university. Whatever loss may have attended their suppression was more than compensated by the activity and influence of the three great German universities which were born in the 19th century.

Munich, after having been completely reorganized, soon became a distinguished centre of study in all the faculties, and its numbers, allowing for the wars of 1866 and 1870, continuously increased. The eminence of its professoriate, among whom were J. J. I. von Döllinger, Justus von Liebig, Friedrich von Schelling, K. Zeuss and W. von Giesebrecht, attracted students from all parts of Europe.

The University of Berlin, known as the Royal Friedrich Wilhelm university, was founded in 1809, immediately after the peace of Tilsit, when Prussia had been reduced to the level of a third-rate power. It incorporated the famous academy of sciences. Wilhelm von Humboldt, supported by Frederick William III, adopted for it principles which not only raised it to a foremost place among the universities of Europe but also largely conduced to the regeneration of Germany. Attachment to any particular creed or school of thought was expressly repudiated in favour of complete Lehrfreiheit ("teaching freedom"). Each teacher presented freely his own views. The growth of the university was astonishing: before the end of the 19th century it had more matriculated students than any university except Vienna

The University of Bonn, founded in 1818, also by Frederick William III, became known as the Rhenish Friedrich Wilhelm university. It was the king's design to introduce into the Rhine provinces the classic literature and the newly developed scientific knowledge of Germany proper. Accordingly, he summoned to his aid the best available talent, including B. G. Niebuhr and A. W. von Schlegel, with C. F. Nasse in medicine and Georg Hermes in theology. In the last-named faculty Bonn combined the opposed schools of theological doctrine of the Evangelical (or Lutheran) and of the Roman Catholic churches.

The German universities underwent considerable changes as a result of the compulsory military service required by the law of 1867, and the events of 1870 were not unconnected with the martial spirit that had been evoked in the student world.

The Low Countries. — The settlement of Europe in 1814–15 created the "Kingdom of the Netherlands" comprising Holland and Belgium. The universities of Franeker and Harderwijk were suppressed and those of Ghent and Liege created in 1815, and a uniform constitution was given to Dutch and Belgian universities. It was provided that there should be attached to each a board of curators, consisting of five persons "distinguished by their love of literature and science and by their rank in society," to be nominated by the king. At least three had to come from the province in which the university was situated. When in 1830 Belgium was created as a separate kingdom, further changes took place there. From Louvain, the chief Catholic centre, the faculties of law, medicine and philosophy had already, in 1788, been moved to Brussels; in 1834 Brussels was constituted a free and independent university with a new fourth faculty of natural science. Having, however, no charter, it continued incapable by law of possessing property. Louvain and Brussels came to represent the two chief political parties in the realm, while the universities of Ghent and Liege recruited their students mainly from the two chief language groups, the Flemish and the Walloon. In Holland, where no such marked differences existed, the universities of Groningen, Leyden and Utrecht were in 1876 assimilated in constitution, each being administered by a consistory of five rectors with a senate composed of the professors in the respective faculties. The opening of the Free University of Amsterdam in 1880 more than repaired the loss of Franeker and Harderwijk, particularly as the progress of this new centre during its first ten years was remarkably rapid.

Scandinavia and Iceland. — The University of Christiania (now Oslo) in Norway was founded in 1811 as a state institution yet given self-government by a collegium academicum. It had at first four faculties, theology, law, medicine and philosophy; in 1860 the last was divided into the faculties of letters and science. Women gained admittance in 1882, and the first woman professor was appointed in 1912. In 1910 the Norwegian Institute of Technology was opened at Trondheim. No new universities were founded in Sweden, though institutions at Göteborg (1887) and Stockholm (1877) achieved something of university status. In Finland, the University of Abo was moved to Helsingfors (Helsinki) in 1828. In 1911 the University of Iceland was created by bringing together schools of theology (1847), medicine (1876) and law (1908). The university is probably unique in having been conducted for the first 29 years of its life in the parliament building (*Altingishus*).

Switzerland.—In Switzerland the universities shared in the conflicts handed down from the days when the Helvetic republic was first created. In 1832, Basle having joined the League of the Catholic Cantons, the Confederates divided the canton into two and agreed to raise the flourishing Hochschule, which already existed at Ziirich, to the rank of a university—a measure which may be said to mark a turning point and a new epoch in the history of higher education in the republic. The gymnasium of Berne, originally established under the teaching of Ulrich Zwingli, developed, in 1834, into a university with all the faculties. As early as 1586 Lausanne had been a noted school for the education of Protestant ministers, but it was not until 1806 that chairs of philosophy and law were established, to which those of natural science and literature were added in 1836 and, somewhat later, that of medicine. Not, however, until 1891 was Lausanne formally constituted a university. At Geneva the famous academy of the 16th and 17th centuries, long distinguished as a centre of Calvinistic teaching, became merged in 1876 in a university, where the instruction was given mainly in the French language. With this was also incorporated an earlier school of science in which H. B. de Saussure and A. P. de Candolle had once been teachers. Fribourg, founded in 1889, began with only two faculties, those of law and philosophy, to which one of theology was added in the following year. At Ziirich in 1872, and later at Geneva and Berne, women were admitted to lectures, and in 1892 were permitted to lecture.

Austria-Hungary.—The Austrian universities declined rather than advanced during the 19th century. Salzburg, founded in 1623, was suppressed in 1810. Throughout the first half of the century Vienna was in a depressed state; though its medical school attained an unrivalled reputation. its other faculties languished. Olmütz (Olomouc), founded in 1581, was closed in 1853. Lemberg. founded in 1774 by the emperor Joseph II, was in 1805 moved to Cracow, but in 1816 opened on an independent basis. In 1848 it lost by bombardment its buildings, library and natural history museum. Graz (1586) alone flourished. In 1875 Czernowitz university was founded. three years after that of Klausenburg (Cluj), the chief Magyar centre in Hungary. Zagreb, in Croatia, originally founded in 1669, was reopened in 1874.

Russia.—At the beginning of the 19th century Russia possessed only three universities: Moscow (1755), founded by the empress Elizabeth; Vilnius (1578), which was Polish; and Dorpat (Tartu) (1632), which was virtually German. Under the enlightened policy of Alexander I were founded the universities of Kharkov (1804) for New Russia, Kazan (1804) for the countries about the Volga but designed also for the populations of Finland and Siberia, and St. Petersburg (1819). Each of the foregoing six universities had a definite district assigned to it, and, as a further incentive to the pursuit of academic studies, a ukase promulgated in 1809 proclaimed that in all appointments to official posts throughout the empire the holders of university degrees would receive the first consideration. In 1835 the foundation of the St. Vladimir university of Kiev absorbed the university at Vilnius. Odessa, founded in 1865, was designed to be the university of New Russia. Although at St. Petersburg considerable attention was regularly given to the teaching of languages, especially those of Armenia, Georgia and Tartary, the general status of the Russian universities continued, throughout the greater part of the century, exceptionally low. In 1884 they were all reconstituted by the promulgation of a "universal code"; with this the statutes of the universities at Dorpat (1632) and Warsaw (1816) were essentially in agreement. The study of the Slavonic languages received a considerable stimulus, especially when, by a decree in May 1887, the use of the Russian language was made obligatory in all places of instruction throughout the Baltic provinces. During the ensuing 20 years the general influence of Dorpat rapidly spread far beyond the Baltic provinces. In 1889 the Russification of the university went far to deprive it of its claim to be considered German.

The University of Tomsk in western Siberia, founded in 1888, depended chiefly on a grant from the state, aided by private liberality.

Greece.—The University of Otho at Athens, founded by King Otho (Otto) in 1837, was modelled on the university systems of northern Germany. It originally included only four faculties, theology, jurisprudence, medicine and philosophy, to which one of applied mathematics was subsequently added. It was later renamed the National University of Athens.

Rumania, Bulgaria and Turkey.—The University of Jassy (1860) was founded by Prince Cuza of Rumania, and together with the newly founded University of Bucharest received its completed organization in 1864. Both were constituted state institutions and were represented in the senate, although not receiving any fixed revenues from the government. In the Kliment Ochridski university of Sofia (1888) in Bulgaria, faculties were established of history, philology, physics, mathematics and jurisprudence, the main object in view being the training of competent schoolteachers and lawyers and affording them the means of gaining an intelligent insight into the real wants of the native population. The University of Istanbul, founded 1453, was until the 19th century a religious school.

Mediterranean Lands.—The distracted state of Italy long prevented advance. In 1875, when the educational system was reformed, an attempt was made to assimilate the universities to the German pattern, but this policy was quickly reversed In 1890 four "free universities," Camerino. Ferrara, Perugia and Urbino, were created, and women were admitted. In Sicily the University of Palermo, founded 1779, was closed in 1805 but reopened in 1850 and became of considerable importance and size. The Sardinian universities, Cagliari (1596) and Sassari (1617) were similarly closed and reopened, but attained little eminence.

Spain.—Lifeless routine and unreasoning tradition characterized the Spanish universities until the second half of the 19th century. In 1857 the entire system of education was placed, as in France, under the control of the minister for public instruction. The kingdom was divided into ten university districts, each in the charge of a rector, and a precise plan of instruction was prescribed in which every hour had its appointed lecturer and subject. At every university philosophy, natural science, law and medicine were to be studied, but no provision was made for theology, this being transferred to the seminaries in the episcopal cities. In the same year the University of Manila in the Philippines was formally founded; it had been in existence for 250 years.

(J. B. Mu.; C. Br.; H. C. D.)

THE UNITED STATES

The origins of the universities in the U.S. are to be found in the colleges established in the colonies before the nation was formed. Nine such colleges were founded: Harvard college, 1636; College of William and Mary, 1693; Yale college, 1701; College of New Jersey, 1736; King's college, 1754; College and Academy of Philadelphia, 1755 (originated in a charity school trust created in 1740); Khode Island college, 1764; Queen's college, 1766; and Dartmouth college, 1770. In general, these institutions represented the arts course provided in the colleges of the universities of England, particularly at Cambridge and Oxford. The principal purpose of the colonial colleges was to train a class of learned men specifically ior the Christian ministry. although some of them aimed also at training a body of men in culture and knowledge for service in the state. The College and Academy of Philadelphia. in contrast with the other colleges, was founded on a broad plan of education. which included a considerable amount of mathematics, science, government and law. It established a medical department in 1765—the first in the country. Two years later King's college in New York city also opened a medical department.

From the American Revolution to the Civil War there was a spectacular increase in the number of new colleges established. During this period some of the older colleges came to be known as universities, and new institutions bearing the name were founded. The constitution of hfassachusetts adopted in 1780 refers to Harvard college as the "University at Cambridge." The College and Academy of Philadelphia, through legislative action, became the University of Pennsylvania in 1791, and in 1804 Rhode Island college was named Brown university. The names of three other colonial colleges were officially changed at later dates—Yale college to Yale university, 1887; the College of New Jersey to Princeton university, 1896; King's college to Columbia college, 1784. and to Columbia university, 191a—although all three operated as universities before these dates. Queen's college became Rutgers college in 182j and Rutgers university in 1924. The legislature of New Hampshire attempted in 1816 to take over Dartmouth college and make of it a state university, but a decision of the United States supreme court in 1819 stopped this action.

The state university, destined to become one of the important and characteristic types of U.S. higher education institutions, had its origin in the latter part of the 18th century: the University of North Carolina was provided for in the state constitution of 1776, chartered in 1789 and opened in 1795; the University of Georgia was chartered in 1785 and opened in 1801. The Indiana constitution of 1816 made it the duty of the general assembly "to provide by law for a general system of education, ascending in a regular gradation from township schools to a state university, wherein tuition shall be gratis, and equaily open to all." This statement represents the ideal of the state university—the capstone of the system of public education.

The most notable early example of the state university was the University of Virginia. which, through the influence of Thomas Jefferson, was established by legislative act in 1819 and opened in 1825. The model for the state universities, however, particularly those in the western states, was the University of Michigan, opened in 1841 and reorganized in 1850. The establishment of the state universities in the states carved out of the public lands in the west was greatly aided by grants of land from the federal government, beginning with the admission of Ohio into the union in 1803. The State University of New York, created by the legislature in 1948, was, at mid-20th century, the most recently established state university. It consisted of a number of state-owned institutions of higher education located at various places and of such new ones as might be established.

By the 1950s, all states except Pennsylvania maintained one or more state universities. Pennsylvania supports Pennsylvania State university, a privately controlled institution, and it gives also some financial assistance to several privately controlled universities, including the University of Pennsylvania. In addition, there are territorial universities. Distinguishing characteristics of the typical state university are: (1) creation and direct support by the state government; (2) control by a publicly appointed or elected board; (3) free or low tuition to students who reside in the state; and (4) provision for numerous educational services to the state in addition to instruction on the campus.

Thirteen municipal colleges and universities were established by mid-20th century: College of Charleston (S.C.); College of the City of New York, comprising four colleges; the universities of Akron, Cincinnati, Houston (district). Louisville, Omaha, Toledo and Wichita; and Washburn Municipal university of Topeka, Kan. These institutions are controlled and supported by the municipalities in which they are located.

A group of institutions which became a prominent feature of higher education in the United States are the land-grant colleges and universities. which numbered 68 in 1957. About 200 colleges for aomen had also been established by mid-century. (See WOMEN. EDUCATION OF.)

As large personal fortunes were amassed in the United States another type of university was established—that endowed by individual munificence. Among these universities (with date of original founding) were: Tulane (1834). Emory (1836), Duke (1838), Cornell (186j). Vanderbilt (1873), Johns Hopkins (1876), Stanford (1885) and Chicago (1890). Other highly endowed institutions were the Massachusetts Institute of Technology, founded in 1861 and opened in 1865; Rice institute, 1912; Carnegie Institute of Technology, 1900; and California Institute of Technology, 1891. A number of the older universities also became the recipients of large endowments, among them Columbia, Brown, Dartmouth (college), Harvard, New York, Northwestern, Pennsylvania, Princeton, Rochester. Washington, Western Reserve and Yale. A few state universities likewise acquired large endowments, some from private and some from public sources, among them California. Michigan, Minnesota, Texas, Virginia and Washington. The endowments of these 30 institutions at mid-century ranged from $24,784,000 (Brown) to $450,461,000 (Harvard), the average being $88,123,408. When the federal government was organized, some leaders of the nation desired the establishment of a national university, and subsequently numerous proposals for such an institution were placed before congress, but none was enacted into law. Some of the federal interests are served through institutions maintained by the federal government, such as the United States Military academy; other federal interests are served through certain relationships established with higher education institutions through grants-in-aid, payment for contracted services and loans for the construction of housing for students and faculty members.

Control and Organization.—Some universities are publicly controlled—by a state, a municipality or a district. Others are controlled by private organizations, which usually receive their charters from the states in which they are located. In general, each university is under direct control of a lay board, usually known as a board of trustees, although other titles, such as board of regents and board of directors, are also used. Boards of publicly controlled universities are elected by the voters of the state or the municipality which maintains the institution, or they are chosen by a governmental official or agency. In a few states all the state institutions of higher education are controlled by one board. as in Georgia and Oregon. The members of the boards of privately controlled universities elect persons to fill vacancies; such boards are known as self-perpetuating. The members of the boards that control church-related universities are, in many instances, elected by the religious organizations which maintain the institutions. For many universities the alumni elect some members of the boards of trustees. Most of the Roman Catholic institutions are controlled by the religious orders, though some are under diocesan control.

The actual administration of a university is assigned to administrative officers employed by the board of trustees. Usually the principal officer is called president or sometimes chancellor. He has a heavy responsibility and large authority in the direction and management of the institution. Among his principal assistants are vice-presidents, directors, deans and business managers. The various colleges and schools of the university are in charge of deans, who have large responsibility for such matters as selection of faculty members, leadership in development of the curriculum and improvement of the quality of instruction. Each college or school is organized in departments or divisions, or both, the division being the larger unit. In most universities the faculties have considerable control over educational policy, especially matters relating to admission requirements, organization of the curriculum and requirements for degrees; in the larger universities this control is usually delegated to a smaller group selected entirely or partly by the faculty or by instructional staff members holding certain positions. In the universities the academic year of approximately nine months usually begins in September or early October and ends the latter part of May or early June. The academic calendar is arranged on the semester plan under which the academic year is divided into two equal parts, each of which is called a semester; or it is arranged on the quarter plan under which the academic year is divided into three equal parts, providing terms or "quarters" of about three months in length. Most universities are open also for summer sessions. Some of these students in the summer sessions attend the universities during the academic year; others are teachers of elementary and secondary schools and colleges who are employed and attend only during the summer.

Educational Programs. — Admission to the university generally presupposes the completion of 12 years of elementary and secondary education or the equivalent of such education as measured by some form of entrance examination. Admission is by an examination or by a certificate which attests the satisfactory completion of an educational program in an approved secondary school. In addition to these two means of selection most institutions use also a number of others, among them psychological tests, personal interviews, and confidential information about the applicant's character and moral qualities. At the centre of the typical university in the United States is the college of arts and sciences. Students enter it upon completion of secondary education. The curriculum, which is four years long, leads to the bachelor's degree — bachelor of arts or bachelor of science. The college of arts and sciences offers a program of education for students who take all their nork in the arts and sciences, and provides a considerable amount of instruction to students who are registered in the professional schools of the university. The curriculum is usually so arranged as to require the student to obtain a general knowledge of a number of fields and more highly specialized and advanced knowledge in one or two fields.

Most of the formal professional education in the United States is acquired in the universities, where it is organized in various patterns. Much of it consists of four-year programs which students enter upon completion of secondary education and which end with attainment of the bachelor's degree. Examples are agriculture, business administration, education (preparation of teachers of elementary and secondary schools), engineering, fine arts, forestry. journalism and pharmacy. The degrees conferred for the completion of study in special fields frequently carry designation of those fields, as bachelor of education, bachelor of fine arts and bachelor of business administration; or as bachelor of science in education. bachelor of science in engineering, bachelor of science in pharmacy; or as bachelor of arts in education, bachelor of arts in business administration.

There is a tendency to lengthen programs of education for the professions. This is usually done by including, as an entrance requirement of the professional college or school, the completion of a specified amount of study in a college of liberal arts or a college of arts and sciences. As an example, three years of college work constitute a minimum for admission to the study of medicine. The medical curriculum is four years long. The educational patterns in some other fields are: dentistry, two years in college and four years in the school of dentistry; veterinary medicine. two and four; law. three and three or two and four. For admission to professional training in several fields, possession of a bachelor's degree is a prerequisite, and the professional curriculums range in length from one to three years; examples are hospital administration, public health, social work and theology. The first degrees conferred for the completion of curriculums in these professional fields are doctor of medicine, doctor of dental surgery or doctor of dental medicine, bachelor of laws, doctor of veterinary medicine, master of hospital administration (master of business administration, master of science in some schools), master of public health and doctor of public health, master of social work and bachelor of divinity.

All universities, except those that are universities in name only, provide programs of advanced study leading to graduate degrees. Such study is usually supervised by an administrative division known as a graduate school, which establishes and enforces policies and standards for advanced work. The instruction. however, is usually carried on by the regular departments of the university. In some universities the graduate work in professional studies is carried on by the professional schools independent of the graduate school. As a prerequisite for admission to graduate study a student must present a bachelor's or a first professional degree or the equivalent.

The principal purposes of graduate education are: to prepare college and university teachers; to prepare specialists in the various professions; and to prepare students to carry on research. Graduate study also prepares teachers of elementary and secondary schools for better service. Programs of graduate study consist of (1) specialized and advanced courses aimed at broadening and deepening the student's knowledge in one or a few fields and (2) independent study and research, largely original in character, intended to develop ability to do research in a particular field. The degrees conferred for graduate study are the master's degree, usually master of arts or master of science, and the degree of doctor of philosophy. The master's degree is usually obtained for one academic year of graduate work as a minimum; three or more years of study are required for the doctor of philosophy degree. Other types of doctoral degrees comparable with the doctor of philosophy are the doctor of science and the doctor of education. These degrees should not be confused with the doctor of laws (LL.D.), doctor of humane letters (L.H.D.), doctor of letters or doctor of literature (Litt.D.), doctor of divinity (D.D.) and other doctoral degrees which are conferred by colleges and universities as purely honorary distinctions.

Other Services. — Research is an important part of the work of the universities. Some of it is carried on by individual faculty members as a part of their effort to improve themselves and gain professional recognition and advancement. 4 considerable part of the research, however, is organized in projects for ahich funds are appropriated to pay the costs. The land-grant colleges and universities maintain agricultural experiment stations, and many colleges of engineering carry on research through their engineering experiment stations. Within a number of universities research institutes have been organized to promote specific types of investigations.

Research in universities is supported from university funds and from funds supplied by foundations, scholarly and professional societies, commercial concerns, state agencies, the federal government and individual donors. The financial assistance takes the form of fellowships and grants-in-aid to mature students and faculty members. and grants and contract payments to the universities. During the year 1953–54 (as an example). $372,643,000 was spent in organized research by higher education institutions.

Research in universities results in the preparation of many scholarly and scientific articles, monographs and books. To facilitate publication of such materials a number of institutions, beginning with Cornell university in 1869, established university presses. In addition to books, these presses publish a number of scholarly periodicals.

Many universities extend their educational services to persons who cannot go to the institution for regular residence instruction. These services are usually grouped under the category of extension work (see UNIVERSITY EXTENSION), which includes home-study or correspondence courses. extension classes, short courses and various minor activities. The co-operative agricultural and home economics extension work carried on by the land-grant colleges and universities is supported partly by the federal government.

Statistical Data. — The *Education Directory* for 1956–57 published by the United States office of education of the department of health, education and welfare, listed 1,886 institutions of higher education in the United States. Of this number, 228 bore the name university, but perhaps one-third of these were universities in name only and should more appropriately be called colleges.

In the fall of 1955 the enrolment in institutions of higher education was 2,720,929. Of this number 1,241,101 students were enrolled in 141 universities. (Universities, as defined by the office of education for statistical purposes. are "those institutions of large and complex organization in which several professional schools and colleges, not exclusively technical, are incorporated within the administrative framework of the institution.") The other 1,479,828 students were enrolled in smaller universities and liberal arts colleges, teachers colleges. institutes of technology, technical institutes and other institutions. The largest enrolment in one institution was 38,594; 44 universities and colleges enrolled more than 10,000 each. Graduate students comprised approximately 9% of the enrolment. The numbers of earned degrees conferred by all higher education institutions during the academic year 1954–55 were: bachelor's and first professional. 287,401; master's and second professional, 58,204; doctor's, 8,840.

The amount expended in 1953–54 by all higher education institutions for educational and general purposes, including research but not including expenditures for plant expansion and for noneducational purposes. was $2,271,296,000. At many of the institutions the expenditures ran into millions of dollars; as examples: the University of Illinois $46,946,000; The University of Chicago, $48,819,000; the University of Minnesota. $37,089,000.

The funds which the institutions of higher education received for educational and general purposes during the year 1951–52 were from the following sources: state governments, 32%; student fees, 24%; federal government, 18%; private benefactions, 8%; endowment earnings, 5%; local governments, 4%; others, 9%.

The universities, particularly the larger ones, possess extensive libraries. The book collections of 18 run to more than 1,000,000 volumes each. Some of the largest are: Harvard, 5,956,000; Yale, 4,280,000; Illinois, 2,889,000; Michigan, 2,325,000; Columbia, 2,117,000. (L. E. BH.)

SOUTH AND CENTRAL AMERICA

The achievement of independence by the Latin-American states was. in some instances at least, accompanied by measures of educational reform. Betn een 1821 and 1832 nine universities were founded or refounded and survived the many and grievous troubles which wracked the continent throughout the 19th century.

In Peru. Trujillo (1824), founded by Simón Bolivar; Arequipa, raised in 1827 from academy to university status; and Cuzco (founded 1696), uhich was in the same year transformed from an ecclesiastical to a lay foundation and made open to all, became centres of considerable intellectual activity. In Colombia the foundation of the University of Xntioquia at Medellín in 1822 nas folloned by those of Cartagena (1824) and Popayán (1827). In Argentina arose Buenos Aires (1821). and in Bolivia. La Paz (1831) and Cochabamba (1832). Round the mid-19th century there was a second cluster of foundations. The University of Montevideo in Uruguay dates from 1849. though it became important only when a medical school was added in 1876. In 1843 the University of Costa Rica was founded at San José, and in 1867 the University of Cuenca in Ecuador. In 1842 the century-old University of Havana was reorganized; its subsequent history for 60 years was unhappy. until in 1900 it was refounded with U.S. aid. In 1843 the University of Santiago in Chile (1738) was nationalized, as was also in 18j6 that of Cordoba in Argentina (1613). The closing years of the century were also marked by new foundations: La Plata (1890) in Argentina (to be reopened in 1905–08 under the auspices of the University of Philadelphia). the Catholic University of Chile in Santiago (1888), the National University of Paraguay at Asunción (1889) and the University of Guayaquil in Ecuador (1867) among others.

THE FAR EAST

China.—Until nearly the end of the 19th century public education in China consisted almost entirely of study of the classical texts. But some education on western lines had been introduced nearly half a century previously. In 1852 Roman Catholic missionaries founded a college to train Chinese as priests. Protestant missions followed suit, and Americans in particular began to found institutions of university status which were open to all. Meannhile, in 1861, the government opened two colleges. at Peking and Canton, for the study of foreign languages, and about 25 years later began to send young Chinese abroad to foreign universities. In 1902, after the Boxer rising, the government embarked on thoroughgoing educational reform and in the same year founded the National University of Peking. incorporating in it the foreign-language colleges. By 1910 an imperial university had been established, in name at least, in every one of the 18 provinces.

Japan. — On the reopening of communication with the west Japan began eagerly to absorb western learning. In 18j7 the government founded "a place for studying foreign books" and a "school for acquiring foreign medical art." To these in 1862 a college for the study of European science mas added. In 1871 a system of compulsory education was introduced, and in 1877 the Imperial University of Tokyo was founded. By 1910 three other universities (all much smaller) had been established: Kyoto (1897), Tohoku (1907) and Kyushu (1910).

WORLD WARS I AND II AND AFTER

The pears following 1914 saw a huge increase in the number of universities. Excluding the U.S.. about 250 new foundations had been recorded by the late 1950s, or rather more than one for every two universities functioning in 1914. During the same period new faculties, schools and research institutes were added in profusion at both old and modern universities. and the numbers of students and staff multiplied at an unprecedented rate. Yet the demand for admission was hardly anywhere satisfied.

It would be wrong to attribute this amazing growth solely, or even largely, to the effect of two world nars, though each proved a powerful stimulant. The growth derived from forces set in motion long before the outbreak of World War I. forces which were working themselves out in a world-wide social and economic revolution.

ASIA

China. — By far the largest increase in the number of universities took place in Asia. Including those in the U.S S.R., there were about 150 new foundations. Of these, a quarter or more took place in China. There, in 1912, a universities law was passed making the college of liberal arts and sciences the nucleus of the university. whose purpose was declared to be "to cultivate scholars and prepare men for the service of the state." By 1925 there were said to be 47 institutions of university status in China, and by 1937 (when Japan attacked China). 108. Probably fewer than half would have qualified as universities in the western sense.

Between 1937 and 1945 China wrote an immortal chapter in university history. Many of the major institutions, situated in coastal areas. were early exposed to the iull blast of invasion. Their buildings destroyed, damaged or occupied. staffs and students migrated westward, carrying with them what they could of books and equipment. More than 80 institutions are said to have thus sought security during the first year of the war; during the following seven, many universities nere compelled to move again and again. usually on foot and often across mountainous territory. They suffered terrible privations and had to pursue their studies with little or nothing even of essential materials; but they held on. Academic standards inevitably deteriorated. When hostilities ended, arrangements were made for the universities to return home, and between May and October 1946 about 60 institutions. with more than 60.000 students, nere moved back. Scarcely had this happened before the tide of war began to flow over them again. to culminate in 1949 in the complete occupation of continental China by the Communists. Within three years all universities and colleges onned or administered by foreigners had been closed or absorbed into a reorganized and nationalized system of higher education comprising some 20 universities and a large number of institutions for advanced technical education.

Japan.—Between 1920 and 1945 about 35 universities were founded in Japan. These were of three kinds: imperial; other state universities; and private. The imperial universities had several faculties, the government universities one only. The private universities, about 25 in all. were about half and half multiple- and single-faculty institutions; most of them maintained their own preparatory schools to ensure a steady flow of entrants.

During World War II the buildings of tno-thirds of the universities were destroyed or badly damaged. In 1947, following advice from a U.S. education mission, the diet passed a school education law which provided for a four-year university system after the U.S. pattern. Under this all institutions for higher education which could .satisfy the University Accreditation association (founded for the purpose) nere to be organized into about 220 "new-type" universities — jo government. 20 public and 130 private.

Indonesia. — Following the attainment of independence, there were founded the universities of Gadjah Mada in Jokjakarta (1948), the Islam university of Medan (1952) and the private North Sumatra medical university (1952).

India.——In India. follow ing the government's 1913 resolution, universities were founded at Benares (1915) and Patna (1917), the former specifically to develop Hindu culture. Almost simultaneously two universities were started in Indian states, at Mysore (1916) and Hyderabad (1919), the latter, Osmania university adopting Urdu. the official language of the state, as the medium of instruction. Between 1917 and 1919 the organization of higher education in India was examined by the government's Calcutta University commission. Little change ensued at Calcutta, but from the recommendations sprang eight new universities: the Moslem university of Aligarh (1920); Rangoon (1920); Lucknow (1921); Delhi (1922); Nagpur (1923); Andhra (1926); Agra (1927); and Annamalai (1929). During these years Bombay, Madras and Allahabad were reconstituted. During the 1930s one university was founded, at Travancore (1937), but in 1943 another succession began which produced Utkal (1943), Saugar (1946) and Rajputana (1947).

After India's attainment of independence in 1947 foundations multiplied; they included Gauhati (1948), Jammu and Kashmir (1948), Indore (Madhya Bharat, 1948), Poona (1948), Baroda (1949), Roorkee (1949), Shrimati Nathibai Damoda Thackersey Women's university (1949), Karnatak (19jo). Gujarat (19jo), Santinekatan (Visva-Bharati, founded by Rabindranath Tagore in 1921 and given university status in 1951), Bihar (1952) and Andhra State university (Sri Venkateswara, 1954). The University of the Panjab was divided in 1947 after the partition of the Punjab. The Indian Panjab university was established at Solan.

Pakistan. — On the creation in 1947 of the dominion of Pakistan, the University of Panjab (1882) became two universities: West Panjab in Pakistan and East Panjab in India. The former became the University of the Panjab. The University of Dacca (1921), previously unitary, became affiliating. The University of Sind (1947) founded just before partition, was in 1951 moved to Hyderabad. New universities mere established at Peshawar (1950), Karachi (1950) and Rajshahi, in East Pakistan (1953).

Ceylon. — In Ceylon the Cniversity college (1921) and the Medical college (1870) amalgamated to become in 1942 the University of Ceylon, which in 1952 began to move into new buildings near Kandy.

Other.;. — Following the reports of commissions sent from England, the University of Malaya was founded in 1949 by the amalgamation of Raffles college (1928) and the King Edward VII college of Medicine (1905), and university colleges were established in the West Indies (in Jamaica, 1946), Gold Coast (Achimota, 1948), Nigeria (Ibadan, 1948), East Africa (Makerere in Uganda, 1949) and the Federation of Rhodesia and Nyasaland (Salisbury. 1952). In the Sudan, Gordon college, Khartoum. was raised to university status in 1951. All these institutions were largely financed by the British government. During the years after 1914 universities were also founded in Afghanistan (1946), Java (1947), Iran (1934), the Philippines (seven between 1921 and 1948), Siam (four between 1917 and 1943).

The Hebrew University of Jerusalem, begun in 1918 and formally opened by Lord Balfour in 1925, became the world centre of Jewish culture. Bar-Ilan university, the first after the establishment of Israel in 1948, opened in 1955.

U.S.S.R.—During the revolutionary period (1917–20), many of the republics founded national universities. Between 1922 and 1932 the Russian S.F.S.R. and other republics broke up their universities into separate specialist institutes, but the sharp lowering of standards of general culture led in 1932 to a reversal of this policy. The universities were reconstituted, at first with scientific faculties only, to which between 1934 and 1948 the humanities and law were added. During World War II many universities in the west were destroyed or seriously damaged; as they were freed from German occupation they were restored. In 195j, 34 state universities and numerous institutions for advanced technical instruction were listed in the U.S.S.R.

EUROPE

Both World Wars I and II temporarily checked university development. During World War II it was German policy in all the occupied countries to transform the universities into purely nazi institutions. Everywhere the policy met with determined resistance. open or underground. The Poles formed a secret department of education and culture and organized in Warsaw a "free Polish university" nhich enabled students to study and sit for degrees. By 1943–44 this had 2,000 registered students and was providing instruction in a score of subjects. In the Netherlands, where the universities of Leyden. Amsterdam and Nijmegen were closed, 80% of the students refused to sign a declaration of compliance with nazi desires. and uent underground. In Norway the University of Oslo nas closed in 1942, when 700 students mere arrested and deported. Many escaped into Sweden, which received refugees also from Denmark. Finland and the Baltic states and organized courses and examinations for them.

There was considerable similarity between processes of recovery after World Wars I and II, though that after the latter, having to rise from far greater depths of desolation, was on a much larger and more heroic scale. First, both mars, especially the second, stimulated the desire for increased facilities for secondary and higher education. As a result, universities everyahere were overcrowded to the breaking point. Second, both wars, but again especially the second, impressed upon the nations the necessity for widespread technological and administrative proficiency; consequently there was a rapid development of specialist institutes, for both teaching and research, mainly within or attached to universities. New faculties and schools arose in equal profusion: in the applied and social sciences. agriculture, commerce and the fine arts. Third the wars emphasized the urgent need for international co-operation at university level. Cultural conventions between nations facilitated the exchange of teachers and students. This development was particularly widespread after World War II, being stimulated not least by the Fulbright agreements. International conferences, courses and summer schools proliferated, being encouraged after World War I by the League of Nations and organized by such bodies as the Institute of International Education in New York city. and after World War II by the United Nations Educational. Scientific and Cultural organization and, for example, the Association of Universities of the British Commonwealth and the British council.

After World War I. several new universities were set up in the newly established states of Czechoslovakia. Finland, Poland, Rumania, Yugoslavia and the Baltic republics; elsewhere, except in Italy under *Benito Mussolini*, only an evolutionary development took place, illustrated, for example. by the promotion of Reading (1926) in England and the foundation of Hamburg (1919) in Germany. After World War II there was a similar outcrop in the east, chiefly in Poland and Rumania, in Turkey the University of Ankara was founded (1946) and Istanbul (1944), the latter a technical university. For political reasons Berlin acquired three new universities: the British raised the famous Charlottenberg Institute of Technology to university rank (1946). the Americans founded the Free University of Berlin (1948) and the Russians the University of Potsdam (1948). The French reopened the ancient University of Mainz (1946), closed for a century and a half. Other foundations in western Europe were Nottingham (1948), Southhampton (1952), Hull (1954), Exeter (195j) and Leicester (1957) in England and Bergen (1948) in Norway, all elevations of long-established institutions. In England the experimental University College of North Staffordshire was founded in 1949 with a four-year first degree course including an initial year of general studies and less intense specialization thereafter than normally occurs in English universities.

LATIN AMERICA

Brazil. — Brazil and Mexico contributed almost half of the new universities, about 50 in number. founded in South and Central America between 1914 and the mid-1950s.. Brazil's first university, at Parana. was set up in 1912; 40 years later the country had 11. By a law passed in 1931, every university must have a law school, a medical school and either a school of engineering or philosophy.

Mexico. — The rapid growth of universities in Mexico refleeted the intensive attention given to public education after the 1910 revolution. In May of that year the ancient Royal and Pontifical University of Mexico (founded 1551) was reorganized as the National University of Mexico. In 1929 it was granted virtual autonomy and became the model for all the state universities, of which there were 11 in the mid-1950s. In 1933, the students at the state university of Guadalajara went on strike against state control and after several months forced the government to agree to found autonomous universities. Thereupon they organized the Autonomous University of Guadalajara, inducing teachers to serve without pay, until the university was recognized in May 1935. In 1943 a private women's university was founded in Mexico City providing courses in letters, law, science and special subjects.

Colombia.—In Colombia as in Mexico there was a determined effort to raise the general standard of education. A law passed in 1934 decreed that not less than 10% of the government's revenue was to be expended on education. Within the next six years four new universities had been set up, and by 1955 there were altogether ten in the country. All enjoy considerable autonomy, though all must conform to the statutes of the National university at Bogotá.

Other Countries.—Universities were also founded after 1914 in Argentina, Bolivia, Chile, Costa Rica, Ecuador, Panamá and Peru.

Cuba.—Between 1946 and 1948 Cuba increased the number of its universities from one to five: in 1946 the Catholic university, Havana, the first private university in the republic, was approved by the church; in 1947 and 1948, respectively, the universities of Oriente and Santa Clara were founded; and in 1947 the Junior college of the private Havana Business academy became an independent university.

AFRICA

Union of South Africa.—After long discussions on the replacement of examining by universities by teaching ones, the South African parliament in 1916 passed three acts whereby the University of the Cape of Good Hope became the University of South Africa, with headquarters at Pretoria; the South African college became the University of Capetown; and the Victoria college, Stellenbosch, became the University of Stellenbosch. In 1922 the University college, Johannesburg (formerly the Kimberley School of Mines), became the University of the Witwatersrand; in 1930 Transvaal University college became the University of Pretoria; and in 1948 Natal University college the University of Natal. In 1945 the Pius XII Catholic University college at Roma in Basutoland was founded, the first Roman Catholic university establishment for Negroes in the world. In the 1950s it became the government's policy to enforce *apartheid* by excluding coloured students from white universities. In 1957 a bill was approved in parliament to this end.

AUSTRALASIA

Australia.—In 1930 Canberra University college was constituted, "pending the establishment of a teaching university in Canberra." Its function was to provide courses for degrees in co-operation with one or more of the existing universities. In 1946 the commonwealth parliament passed the Australian National University act to establish at Canberra a university providing especially for postgraduate study and research. Building began in 1949. By 1952 all its four research schools (medicine, physical sciences, social sciences and Pacific studies) were at work.

In 1947 the New South Wales government set up a development council to create a university providing facilities for undergraduate, graduate and research study in technical subjects. The New South Wales University of Technology began work in March 1948 and was incorporated by the state parliament in April 1949. In 1954 the university college at Armidale, N.S.W., was detached from Sydney university to become the University of New England.

New Zealand.—In 1926 the University of New Zealand became a federal body including four constituent colleges (Otago, Canterbury, Auckland, Victoria) and two associated agricultural colleges.

UNIVERSITY COLLEGES. A characteristically British invention, university colleges are chartered institutions organized like universities and doing university work but (with two exceptions) lacking the power to grant degrees. The term was first given exact significance in 1889, when the British parliament made grants to various colleges on condition that they did work of university standard. University colleges are usually regarded as undergoing apprenticeship for promotion to university rank.

In the mid-19th century desire to promote higher education in industrial areas stimulated civic effort and private benefaction, and the unique constitution of the University of London as a body empowered to examine degree candidates anywhere provided the opportunity for university studies. If King's college, London (1829), and University college, London (1826)—originally the only institutions qualified to prepare students for London degrees—be excepted, the first university college was Owens college, Manchester, opened in 1851. It accepted students to read for London degrees. In 1880 it became a college of the newly created Victoria University of Manchester, which affiliated in 1884 Liverpool university college (founded in 1881 by the citizens of Liverpool) and in 1887 the Yorkshire college, Leeds. The federation lasted less than 20 years, all three colleges then becoming independent universities.

Growth to university college status—only to be achieved by royal charter—was in the earlier days usually by amalgamation or adaptation of earlier institutions. Mark Firth, a Sheffield steel manufacturer, founded Firth college (1879), which united in 1897 with the local medical and technical school to form University college, Sheffield. Firth's interest had been quickened by Cambridge university extension lectures held in Sheffield. The university colleges at Bristol (1876), Nottingham (1881), Reading (1892) and Exeter (1901) also originated from extension lectures. Leeds and Birmingham began as exclusively scientific institutions, the former as the Yorkshire College of Science (1874), the latter as Mason college (1880). Southampton, opened in 1862 as the Hartley institution, experienced chequered fortunes before becoming 40 years later the Hartley University college (became University of Southampton in 1952). Hull, on the other hand, came full-fledged from birth (1927) on a magnificent donation of £250,000 from T. R. Ferens. The University College of Wales, Aberystwyth, was created in 1872 by an enthusiastic national movement, and Welsh patriotism later added university colleges at Bangor and Cardiff. The three colleges were federated in 1893 as the University of Wales. In 1920 a college at Swansea was added to the university. A much earlier Welsh foundation. St. David's college, Lampeter (opened in 182j), is still outside the university though it has since 1852 been empowered to grant first degrees.

The only recognized university college having this right is the University College of North Staffordshire, near Stoke-on-Trent, founded in 1949. This college offers a four-year course. The first year is occupied by "foundation studies" surveying western civilization, society and science. Thereafter students must study at least five subjects. As this original scheme did not fit the regulations for London degrees, the college was empowered to award B.A. degrees.

By 1957 all university colleges in England had attained university status, except North Staffordshire, and their dependence on London university for their degrees ceased. In Northern Ireland, Magee University college, Londonderry (186j), is affiliated to the University of Dublin (Trinity college) for the award of degrees (although a few of its students read for those of Belfast).

The University of Ceylon (1942) spent 20 years as a university college. Canberra University college, Australia (1930), prepares students for the University of Melbourne degrees. Until 1954, when it became a university, the New England University college, at Armidale, New South Wales, was an outlier of the University of Sydney. After World War II the British government promoted six university colleges in colonial territories: Gold Coast, at Achimota (1948); Ibadan, Nigeria (1948); East Africa (Makerere college) at Kampala, Uganda (as university institution 1950); West Indies, in Jamaica (1946); Southern Rhodesia, at Salisbury (1953); and Anglo-Egyptian Sudan, at Khartoum (1951). All are in a special sponsoring relationship with the University of London, whose degrees their students take. Other autonomous colleges mainly or wholly devoted to university work but dependent upon another university for their degrees are bhe University College of Fort Hare. South Africa (1916), which prepares students for the degrees of Rhodes university, Grahamstown, S. Afr.; and Pius XII Catholic University college, Roma. Basutoland (1945), whose students take University of South Africa degrees. Both are for Africans. (H. C. D.)

United States.—In the United States, this term is used by a number of the larger universities as a name for their evening divisions for adult students. (See UNIVERSITY EXTENSION.) University colleges are typically in large cities and have varied curriculums including both degree-granting and noncredit programs. Their nearest approximation in the United Kingdom is Birkbeck college of the University of London. (H. G. RY.)

UNIVERSITY COURTS, in the English universities of Oxford and Cambridge, courts of inferior jurisdiction, administering the form and procedure of the canon lam.

At Oxford the chancellor, in 1244, acquired jurisdiction over actions of debt and actions affecting movables in which one party was a clerk; in 1275 over all personal actions in which either party was a member of the university, and in 1290 over all crimes, except homicide and mayhem. The chancellor. vice-chancellor and the vice-chancellor's deputy are justices of the peace for Oxford, Oxfordshire and Berkshire, where scholars are concerned. and so exercise jurisdiction under the Summary Jurisdiction acts. By the Oxford University act 1854, the procedure of the common Iaw was substituted for that of the canon law.

At Cambridge the chancellor enjoyed a jurisdiction similar to that of the Oxford chancellor, but limited to cases arising in the town and suburbs of the university. Previous to 1891, women of light character, who had been convicted of consorting with or soliciting members of the university *in statu pupillari,* were detained in a house of correction called the "spinning house." but in that year a conviction was held had (*ex parte Hopkins* [1891]), with the result that the clause in Elizabeth I's charter of 1561 giving power to imprison women was repealed.

See H Rashdall, *Universities of Europe in the Middle Ages (189;)*; D. S. Holdsworth, *Hist. Eng. Law* (1921). (H. H. L. B.)

UNIVERSITY EXTENSION, in its broadest meaning, includes all educational activities sponsored by an institution of higher learning for those persons (usually adults) who are not full-time students. As illustrated below, varying national practice sometimes causes the term to be given a more limited definition.

United States.—Throughout the 19th century, the many efforts by individual professors to carry knowledge to the general public were usually independent ventures not sponsored by the universities themselves. More sustained and systematic efforts did not begin until about 1885, when U.S. university leaders (most notably Herbert Baxter Adams, a historian of Johns Hopkins) became aware of the programs at Cambridge and Oxford. Several widely publicized and initially successful ventures were undertaken and soon many universities and colleges established extension committees and departments. In imitation of the English models. the early activities consisted chiefly of regular university lectures offered away from the campus. Since there was little adaptation to the needs and interests of mature students, interest soon palled; before long, many extension departments became little more than entries in university catalogues. Fortunately, however, much thought was being given to the expansion of higher education and some of the new institutional plans incorporated the idea of university extension. The most significant recognition came at The University of Chicago, whose first president, William Rainey Harper, had been an active leader in the earlier movements and in the Chautauqua institution. He included extension as an integral part of his design for the new university, incorporating provisions for off-campus centres, correspondence instruction and various other programs. In essence, the original Chicago plan represented a consolidation of the best elements of past experience. preserving it as a model for much of the widespread development which occurred later.

Soon after the beginning of the 20th century, a new interest in university extension began to be manifested, chiefly at the state institutions and most notably at the University of Wisconsin. In the same decade, Seaman Knapp and others demonstrated ways in which knowledge about scientific agriculture could be carried to farmers. The methods thus developed were incorporated into the Co-operative Extension service which, from 1914, became a distinctive function of the land-grant colleges. Somewhat later the urban universities, under both public and private auspices, began to offer educational programs for their communities. As a result of these and other influences, university extension gradually broadened in scope and function so that its services became myriad and the persons it influenced legion.

The core of extension remained the provision of group instruction. Formal lectures continued to play an important part but were supplemented by discussion groups, seminars, workshops and countiess other arrangements, both formal and informal, in which teachers or leaders worked with students. Sometimes groups mere widely scattered over a city, a state or a region, but often they were clustered together within centres. There was a marked growth of integrated programs designed to achieve goals far broader and deeper than could be accomplished in a single course.

Many other services also developed. Correspondence courses were provided in a great variety of subjects. Intensive short courses and conferences increased in number; some universities have special buildings designed to house them. Books, pamphlets, phonograph records, films and other communications materials were provided. Use of mass media (especially radio, the press and television) became widespread and some universities had film production units. Various institutions assumed other special functions such as the arrangement and judging of contests, the operation of lecture and concert bureaus, the administration of tests, the sponsorship of program planning services and the provision of assistance to communities to aid them in analyzing and solving their problems. Sometimes various methods mere combined to provide integrated services for special groups, among which are management, labour and the professions.

While university extension is an omnibus term covering all of the foregoing activities. it is sometimes used in more restricted senses: (1) Many institutions have developed special divisions to undertake this work and university extension sometimes refers only to the activities of such divisions, even though other parts of the institution may also sponsor similar activities. (2) University extension sometimes is used only in connection with those institutions of higher learning that have the word university in their titles. (3) The term occasionally refers only to large-scale and complex programs; efforts centred on a single kind of activity or organization, such as an evening college, may be excluded.

Because of these and other problems of definition and because most of the services concerned are provided for people who have reached their maturity. university adult education and continuing education mere being used in the second half of the 20th century increasingly instead of the older term university extension.

The National University Extension association is the most broadly based organization of extension workers. There are various other groupings of persons interested in special kinds of service; of these perhaps the Association of University Evening Colleges is the most active and best known.

In the United States there is no special organization of adult students corresponding to the Workers' Educational association in England. Universities in the United States usually accept full responsibility for scheduling activities and recruiting students, although sometimes they collaborate with other institutions and groups. Statistics as to the total number of persons served are largely meaningless because of the differences in length and intensity of contact of the various services. At many universities, however. the number of adults engaged in programs of instruction in the second half of the 20th century was already greater than the number of young people enrolled for full-time study on campus. The continuing increase in the scope and size of extension services seemed certain to cause fundamental changes in the conception and structure of U.S. universities.

Great Britain. — In the middle of the 19th century, the term university extension was used to designate the many current proposals to make Oxford and Cambridge more accessible to all classes of society. Included, for example, were the struggles to remove religious tests for admission and to grant entry to women. In the last quarter of the century, however, the English universities developed programs of lectures for adult audiences that aroused world-wide attention, and the term "university extension" gradually narrowed to designate only these efforts.

The first such program was established at Cambridge. James Stuart, a fellow of Trinity college, became convinced that scholars should go outside the jealously guarded walls of the universities to teach the men and women who had hitherto been denied an education. On his own initiative, he began in 1867 to offer courses on scientific subjects in northern and midland towns. Heartened by the success of his efforts and realizing the need for institutional sponsorship. he succeeded in 1873 in persuading Cambridge to accept responsibility for the provision of extension courses. The other universities soon followed this lead and, by the 1880s, extension mas flourishing in centres throughout England

The work developed on a lecture-course pattern. There were usually from 6 to 12 lectures in a series and they were delivered to audiences that averaged somewhat more than 100 persons but that were, on occasion, very much larger. The subjects principally taught were history, literature, music, economics and science. Classes for smaller groups were held after the lectures and the members of these classes were expected to do supplementary reading and to write papers. Most of the cost was met from fees or voluntary local contributions, but the universities paid part of the administrative expense.

In addition to its basic contribution of providing education for a large number of men and women, the university extension movement had other important consequences. It helped to establish higher education for women. The activities of several of the extension centres became the nuclei around which universities were developed. The program was studied by educational leaders in other parts of the world, particularly the United States, and served as a model for many similar efforts elsewhere.

The pattern of activities that was developed, however, proved to be chiefly suited to the middle class and not to the labouring people who were most in need of education. Both for this reason and because of the passing of the original leaders, the zeal and enthusiasm that had characterized the early days of the movement tended to disappear, and, by 1900, the work was settling into a rigidity of conception and form that made it less and less attractive to those concerned with adult education.

The failure of university extension to reach working-class audiences prompted Albert Mansbridge, a young clerk, to found the Workers' Educational association (W.E.A.) in 1903. His original hope was to instill new vitality into the extension movement by putting it more closely in touch with a strong and sympathetic organization of workers. In 1908, however, a new educational format, the tutorial class, was developed as a means of liberal education for adults. It is, in essence. a three-year program of close study on a single subject led by a tutor for a relatively small group of students who are expected to read extensively and to do written work. This pattern of activity became the focus of future university-W.E.A. relationships and soon achieved a dominant position in university adult education, although extension courses continued to be provided. The term extra-mural studies was used to describe both programs, and, as more and more universities developed organized units to handle the work, they were called extra-mural departments. After World War I, these departments developed rapidly and are now to be found in almost all British universities. Their work is in some measure co-ordinated by the Universities Council for Adult Education.

The tutorial course pattern has been modified in various mays, chiefly by the development of shorter courses, but its essential nature has been carefully preserved. Since new times bring new needs, the extra-mural departments at some universities, from 1945, experimented with new types of work that have been carried out under the name of extension. The old pattern of lectures to audiences continued but it was supplemented by a variety of other provisions, including diploma. certificate and study courses. These activities carried out independently of the W.E.A., were directed largely at professional people and others with a good general education. An increasing amount of work was in technologies and other subjects having a largely vocational interest.

Other **Countries.**—Elsewhere in the world, university extension has developed most fully in English-speaking countries, particularly Australia. Canada. Ghana. the Federation of the West Indies, New Zealand and the Union of South Africa. In some instances, following British practice, the term extra-mural studies is used. In every case, significant variations on the British or U.S. pattern have occurred as a result of the necessary adjustment to local conditions.

In the Scandinavian countries, adult educational programs developed in connection with several universities but with no organic relationship to them. Customarily these programs were operated and taught by university students. The popular (or people's) universities organized in some countries (notably Belgium, the German Federal Republic and the Netherlands) are not really universities at all but adult educational centres and therefore are not examples of university extension.

In the rest of the world, universities vary greatly in their provision for extension. In most of them, in the second half of the 20th century it was still related to the specific interests and concerns of individual professors or to the conduct of special programs and campaigns.

See also ADULT EDUCATION; CORRESPONDENCE INSTRUCTION.

See John R. Morton, *University Extension in the United States* (1953); Robert Peers, *Adult Education* (1958); *UNESCO, International Directory of Adult Education* (1953), *Universities in Adult Education* (1952). (C. O. H.)

UNIVERSITY PARK, a city of Dallas county, Tex., U.S., wholly surrounded by the city of Dallas (*q.v.*). University Park grew up around Southern Methodist university, chartered in 1911 and located on what was then a country knoll north of Dallas; instruction began in 1915. At first the school allowed houses around it to tie onto its artesian water supply and to the sewerage system which connected it with Dallas. By 1924 the community had outgrown these arrangements and in that year was incorporated as a city. The university's Georgian buildings occupy 150 ac. in the city's southeast quadrant. It includes a college of arts and sciences and schools of graduate studies, theology, music. law. engineering and business administration. Its downtown night college is one of the larger adult education projects in the United States. Its legal centre houses the Law Institute of the Americas. For comparative population figures *see* table in TEXAS: *Population.* (E. P. CR.)

UNRUH, FRITZ VON (1885–), German writer, was born in Coblenz of an aristocratic Prussian family. He joined the Prussian guard hut resigned his commission in 1912 when his first play *Offiziere* met with great success. His prose epic *Opfergang* (1916; English trans. *Way of Sacrifice,* 1928), which is the first written description of the battle of Verdun, expressed his revolt against militarism. His verse drama *Ein Geschlecht* (1917) dealt with passion and crime unleashed by the upheaval caused by the war; the sequel *Platz* (1920) preached a return to nature and expressionist ethics as the only cure. Unruh was regarded as one of the leaders of Expressionism. Later works include *Rosengarten* (1921), *Flügel der Nike* (1925), *Gandha* (1936), *Dcr nie verlor* (1945; English trans. *The End Is Not Yet,* 1947), *Der Heilige* (1950; English trans. *The Saint,* 1950). Unruh moved to France in 1933 and to the United States in 1940. In 1952 he returned to Germany. (A. GS.)

UNTERMYER, SAMUEL (1858–1940), U.S. lawyer, was born at Lynchburg, Va., on June 6, 1858. He was educated at the College of the City of New York and at the Columbia law school, and was admitted to the bar in 1879, practising thereafter in New York city. He was counsel in many celebrated cases covering almost every phase of corporate. civil, criminal and international law. As counsel for H. Clay Pierce he prevented the Standard Oil Co., after its dissolution in 1910, from dominating the Water-Pierce Co. In the same year he effected the merger of the Utah Copper Co. with the Boston Consolidated and the Nevada Consolidated companies. involving more than $100,000,000. In 1903 he undertook the first judicial exposure of "high finance" in connection with the failure of the U.S. Shipbuilding Co.. organized as a consolidation of the larger shipbuilding companies in the U.S. After this he conducted a number of similar exposures. In 1911 he delivered an address entitled, "Is There a Money Trust?" which led to the so-called Pujo money trust investigation by the committee on banking and currency of the house of representatives in 1912. Untermyer urged measures like the compulsory regulation of stock exchanges, reform of the criminal laws and the regulation of trusts and combinations. He took part in preparing the federal reserve bank law, the Clayton bill, the Federal Trade Commission bill and other legislation curbing trusts. He was a delegate to Democratic conventions and a strong supporter of Pres. Woodrow Wilson. who appointed him to serve on the commission which sat at Buenos Aires in 1916 to frame uniform laws for the Pan-American countries.

Untermyer acted for Gov. Alfred E. Smith in a water-power controversy over the Niagara, St. Lawrence river, Adirondack forest reserve and other hydroelectric power rights, resulting in the defeat of the grant of the water-power rights of the state to private interests. Untermyer died in Palm Springs, Calif., on March 16, 1940.

UNTERWALDEN, a canton of Switzerland, consisting of the basins of two streams, both called Aa, flowing into the Lake of Lucerne and divided into Obwalden and Nidwalden. The area of the canton is 296.4 sq.mi. Forests cover about 85 sq.mi. and glaciers occupy over 5 sq.mi. The highest point is the Titlis—10,627 ft.—south of Engelberg. As Obwalden includes this region, it is generally more mountainous than Nidwalden. The latter includes much more lake surface than Obwalden. The inhabitants are devoted to pastoral and, in a much less degree, to agricultural pursuits. In 1941 the total population was 20,110 in Obwalden and 17,346 in Nidwalden. and in 1950, 22,125 and 19.389, respectively, mainly German-speaking Catholics. The capital of Obwalden is Sarnen (pop., 1950, 6,199); and of Nidwalden. Stans (3,992).

A light railway was built from Lucerne to Briinig pass via the Sarner-Aa valley; an electric railway from Stansstad ascends the other main valley as far as Engelberg; and the mountain railways give access to the summits of Pilatus, Stanserhorn, Burgenstock and Seelisberg. Each area was organized as a single administrative district, with its own independent local institutions. In each "half" canton the legislature was composed of members elected by all male citizens of voting age.

In the church of Sachseln, on the Sarnsee were preserved the bones of the holy hermit, h'icholas Lowenbrugger (1417–87), known as Nicholas von der Flue, or "Bruder Klaus," while at Sarnen, nearby, several convents were established; the most famous of all the monasteries in the canton is the great Benedictine house of Engelberg (founded about 1120). Another site of historical interest is Stans, the birthplace of Arnold von Winkelried, the real or legendary hero of Sempach (1386).

History. — Historically, both Obwalden (save a small area in the Aargau) and Nidwalden were included in the Zurichgau. In both there were many great landowners (especially the abbey of Murbach and the Habsburgs) and few free men; while the fact that the Habsburgs were counts of the Aargau and the Zurichgau further delayed the development of political freedom. Both took part in the risings of 1245–47, and in 1247 Sarnen was threatened by the pope with excommunication for opposing its hereditary lord, the count of Habsburg. The alleged cruelties committed by the Habsburgs do not, however, appear in history until Justinger's *Chronicle,* 1420. On April 16, 1291, Rudolph, the future emperor, bought from Murbach all its estates in Unterwalden, and thus ruled this district as the chief landowner, as count and as emperor. On Aug. 1, 1291, Nidwalden (Obwalden is not named in the text of the document, though it is named on the seal appended to it) formed the "Everlasting League" with Uri and Schwyz (this being the first known case in which its common seal is used). In 1304 the two valleys were joined together. and in 1309 Henry VII confirmed to them all the liberties granted by his predecessor. This placed Unterwalden on an equal political footing with Uri and Schwyz, and as such it took part (1315) in Morgarten fight, in the renewal of the Everlasting League at Brunnen (1315), at Sempach (1386), and in driving back the Gugler or English free-booters (1375).

For physical reasons, it was difficult for Unterwalden to enlarge its territories. Yet in 1368 it acquired Alpnach and in 1378 Hergiswil. Also Obwalden shared with Uri in the conquest of the Val Leventina (1403) and in the purchase of Bellinzona (1419), as well as in the loss of both (1422). It was Nidwalden that, with Schwyz and Uri, finally won (1500) and ruled (until 1798) Bellinzona, the Riviera and the Val Blernio; while both shared in the conquests of the Aargau (1415), the Thurgau (1460) and Locarno, etc. (1512), and in the temporary occupation of the Val d' Ossola. In the Burgundian war Unterwalden, like the other Forest cantons, long hung back through jealousy of Bern but came to the rescue in time of need. In 1481 it was at Stans that the confederates nearly broke up the league for various reasons; and it was only by the intervention of the holy hermit, Nicholas von der Flüe, that peace was restored and the great federal agreement known as the compact of Stans concluded. Like the other Forest cantons, Unterwalden clung to the old faith at the time of the Reformation, being a member of the "Christliche Vereinigung" (1529) and of the Golden league (1586).

In 1798 Unterwalden resisted the Helvetic republic. but, having formed part of the short-lived Tellgau, became a district of the canton of the Waldstätten. Obwalden submitted at an early date, but Nidwalden, refusing to accept the oath of fidelity to the constitution, rose in revolt (Sept. 1798) and was only put down by the arrival of 16,000 armed men. In 1803 its independence as a canton was restored. but in 1815 the refusal of Nidwalden to accept the new constitution resulted in the transfer (1816) to Obwalden of the abbey lands of Engelberg.

UNTOUCHABLES, members of certain Indian castes which, though reckoned as Hindus, were excluded from the ordinary social and religious privileges of Hinduism. Under the constitution adopted by the Indian constituent assembly Nov. 26. 1949, "untouchability" was outlawed and persecution of untouchables made punishable by law. In Pakistan the constituent assembly accepted a similar statement in 1950.

How this caste came to be pushed out of, or never admitted within, the pale is obscure. Probably in the main they represented Dravidians of the lower orders, relegated to menial or unsavoury occupations; they must not be confused with the non-Hindu animists. the wandering and criminal tribes and the pre-Dravidians of the hills and forests. A mistaken aggregation with these latter sometimes led to their numbers being taken at 60,000,000. The population of untouchables proper seems to have been nearer 40,000,000. They are best defined as Hindus who were not allowed to enter ordinary Hindu temples and who supposedly caused pollution to ordinary Hindus either by touch or by proximity. The Brahman would not officiate at the events in life at which, in the case of other castes, his attendance was essential. The untouchables were compelled to live either in hamlets or wards of their own or in separate quarters. generally the unsanitary outskirts. of the villages. They could not use the village well, and there was always opposition to their children attending the village school. The indignities they suffered varied in different parts of India, being the worst in the south. where a fantastic code regulated the distance an untouchable must maintain from a high-caste Hindu on the public roads and the warning he must give of his approach. During their persecution, large numbers of untouchables adopted the religions of Islam or Christianity. (ME.; X.)

UPDIKE, DANIEL BERKELEY (1860–1941), U.S. printer and leader in the revival of traditional printing type faces in the United States, was born in Providence. R.I., on Feb. 24, 1860. In 1893 he established the Merrymount Press. In 1895 he revived the Scotch cut type produced by Alexander Wilson about 1835. He later acquired the 17th-century Dutch fonts of Janson and the matrices of the Mountjoy type, and he led in the revival of classical typography in the U.S. Special types, among them the Merrymount type, were designed by Bertram G. Goodhue and Herbert Horne. From 1910 to 1917 he was lecturer on printing in Harvard university. He was selected to print the Book *of Common Prayer* in the revision of 1928. His published works include: *On the Dedication* of *American Churches* (with Harold Brown; 1891); *Printing Types—Their History, Forms, and Use* (1922): In *the Day's Work* (1924). Also he edited: *A Dissertation Upon English Typographical Founders and Foundries* by Edward Rowe Mores; appendix by J. Nichols (1924), and *Notes* on *the Merrymount Press* (1934). Updike died Dec. 28, 1941.

UPHOLSTERY: *see* FURNITURE.

UPJOHN, RICHARD (1802–1878), U.S. architect and founder of the American Institute of Architects, was born in Shaftesbury, Eng., on Jan. 22, 1802. He came to America in 1829, settling first in New Bedford. Mass. (1833), and later in Boston (1834) and New York (1839). His first churches illustrate the early phase of the Gothic revival. His mature style began with Trinity church, New York (1839–46), whose significance lies in the purity of its Perpendicular Gothic style and even more in the deep liturgical chancel advocated by the Oxford movement. Thereafter, his many Episcopal churches were either Early English or Decorated in style. For poor parishes he published in *Upjohn's Rural Architecture* (1852) an unpretentious design in wood remarkable for its structural honesty and its liturgical character. He chose a modified Italian Renaissance style for secular buildings, In 1857 Upjohn founded the American Institute of Architects and served as its president until 1876. He died on Aug. 1:. 1878, in Garrison, N.Y.

See E. M. Upjohn, *Richard Upjohn, Architect and Churchman* (1939). (E. M. Us.)

UPPER AIR SOUNDINGS. In meteorology and upper-air physics, kites, aircraft, balloons and rockets are used to carry instruments aloft to put them into direct contact with the phenomena to be studied. The term soundings distinguishes these direct measurements of atmospheric phenomena from the more indirect observations made entirely with ground-based equipment.

Investigation of the upper air began in 1749 when Alexander Wilson attached a thermometer to a kite. With the development of the balloon in the late 18th century, scientific ballooning began with manned flights. Extensive application to research started in 1892 when Gustave Hermite and Georges Besançon began to use small unmanned balloons *(ballons-sondes)* carrying instruments. In 1894 Albert Rotch used large kites tethered by steel wire. but meteorological kite flying subsequently was virtually abandoned.

Between 1899 and 1902 balloon experiments led Richard Assmann and L. P. Teisserenc de Bort to the discovery of the stratosphere, and the first two decades of the 20th century saw an immense development of the balloon-sounding technique, yielding considerable information about the lowest 60,000 ft. of the atmosphere, In the period 1927–36 advances in radio techniques made possible the development of the radiosonde. This instrument, attached to a free balloon. sends radio signals that can be translated into numerical values of temperature, humidity and pressure. The results are immediately available to weather forecasters. an advantage that resulted in the adoption of the radiosonde to the practical exclusion of earlier methods, which depended on subsequent recovery of instruments dropped from balloons by parachute. During World War II and the decade immediately following, radiosonde techniques were further developed, radar was applied to wind measurements, meteorological instrumentation for aircraft was greatly advanced and the sounding rocket came into use.

Aircraft.—Aircraft are used extensively for weather reconnaissance, including hurricane patrol. Much of the data are measured and recorded automatically. The airplane aerograph used in some G.S. navy aircraft continuously presents on digital indicators ternperature, pressure. humidity and time data.

Balloons and Balloon-borne Instruments.— The usual neoprene meteorological balloons weigh from one-half to three pounds, are inflated with hydrogen or helium and carry pay loads of only a few pounds. Altitudes of 120,000 ft. can be reached, although a more representative height is about 90,000 ft. For special purposes there are giant balloons that displace hundreds of thousands or even millions of cubic feet and can carry instruments weighing hundreds of pounds to altitudes over 100,000 ft. An example is the "Skyhook" balloon, made of polyethylene plastic .001 to .002 in. thick.

The balloon-borne radiosondes are all basically the same. weigh two pounds or less and consist of a radio transmitter and antenna;

modulator; pressure, temperature and humidity-sensing elements; and battery power supply. The transmitter operates on a frequency of either 403 or 1,680 mc. and its carrier is pulsed at an audio-frequency rate determined by the electrical resistance of either the temperature or humidity-sensing element. These sensing elements. together with fixed-reference resistors, are sequentially switched into the modulator circuit. An aneroid pressure cell changes the sequencing of the sensing elements and resistors as the pressure changes, and the changes in the signal thus produced provide a means of determining the air pressure.

From the radio signal the ground equipment records the temperature and humidity as a function of time. Pressure is determined as indicated above. In the case of the simple radiosonde, the height of the balloon is estimated from the temperature, humidity and pressure data. The addition of direction-finding equipment at the ground station makes it possible to plot the position of the radiosonde transmitter and thus determine the direction and velocity of winds at various levels; such equipment is known as rawinsonde. Wind data in the upper atmosphere also may be gathered with standard radar sets or, visually, with the theodolite, a special telescope equipped with scales from which altitude and azimuth readings can be taken.

Constant-level balloons known as transosondes can be flown across oceans or uninhabited land areas to provide weather information otherwise unavailable. The balloon carries a radio transmitter which is tracked by radio direction-finding equipment. From the balloon trajectory. wind velocities and accelerations can be deduced and major air-mass features identified.

Rockets. — In the years following World War II the rocket was developed into an effective sounding vehicle. Hundreds of them were fired to study the properties of the atmosphere and the sun. on one occasion carrying equipment as high as 242 mi. Rocket sounding began in the United States in 1945 uith the WAC Corporal and continued with captured German y-2's. The Viking, Xerobee, Aerobee-Hi, Deacon. Cajun, Kike-Deacon, Nike-Cajun, Terrapin. ASP, WASP, Rockoon and Rockair were all developed in the United States specifically for research purposes. England developed the Skylark research vehicle. France the Veronique and Monica and Japan the Kappa and Sigma.

The basic air-borne rocket-sounding system consists of the rocket, electric power supply, measuring instruments, a radio telemeter, antennas. sometimes a radio-tracking transmitter and sometimes a parachute or other means of recovering equipment and records. On the ground are the firing range with its launching and tracking facilities and a telemetering receiving station.

Sounding rockets have been used extensively to study ultraviolet radiation and X-rays from the sun, ionospheric currents, low-energy cosmic rays. auroral particles, the chemical and ionic

composition of the upper atmosphere, the earth's magnetic field at high altitude and the occurrence of micrometeorites. Other phenomena which can be measured indirectly from the earth's surface are better measured with rocket-borne instruments. These include atmospheric pressures, temperatures and densities; winds; ionospheric charge densities; airglow; and auroral light.

The WASP ("Weather-Atmospheric Sounding Projectile") was designed to be launched from a 5-in. naval gun and to deliver either a metalized parachute or "chaff" (thousands of tiny strips of aluminum foil) to a point from 100,000 to 150,000 ft. above sea level. The parachute or chaff is then tracked by radar to obtain data on upper winds.

Also developed in the U.S. was a means of obtaining information on upper winds and temperatures by ejecting grenades from a flying rocket and exploding them. The measured transit times of the sound waves from the points of explosion to an array of microphones on the ground are reduced by rather complex computations to the desired data.

UPPER SIND FRONTIER, formerly the northern district of Sind, Pakistan, with administrative headquarters at Jacobabad (*q.v.*). When West Pakistan was made into one province in 1955, the district was renamed Jacobabad and became part of the Khairpur division.. Area 2.046 sq.mi.; pop. (1951) 345,080. It is watered by canals from the Indus. of which the chief are the Begari and Desert canals. Principal crops are millets, oilseeds, pulses, wheat and rice. The trade from central Asia into Sind crosses the district, bringing wool and woolen goods, fruits. carpets and horses. The district is crossed by the North-Western railway's Ruk-Jacobabad-Sibi branch (giving access northward to Quetta); and from Jacobabad a 2½-ft. gauge line runs northeast to Kashmor.

UPPER VOLTA, in French HAUTE-VOLTA, a former territory of French West Africa (*q.v.*) bounded on the west and on the north by the Sudanese Republic, on the northeast by Niger, on the southeast by Dahomey, on the south by Togo and Ghana, on the southwest by the Ivory Coast. Total area 105,839 sq.mi.; pop. (1955 est.) 3,324,969.

Volta is an immense plateau (ranging between 1,000 and 1,700 ft. above sea level) on which the Volta river (*q.v.*) has its sources. The climate and vegetation are Sudanic; there is a dry, cool season from November to February. a dry but hot season from March to May and a hot, rainy season from June to October; the vegetation consists of scrub with occasional clusters of trees.

Mossi (1,663,000) are the predominant race; they began establishing kingdoms in the area in the 14th century, the most important being that of Mogho Naba. with its centre at Ouagadougou. Other peoples, in the south and in the west. are the Bobo. the Gourounsi and the Lobi. who are far less orderly than the Mossi. There are also groups of Gourmantché, Peul, Senoufo and Marka. Overpopulation and the lack of natural resources cause a considerable number of workers to emigrate to the Ivory Coast and to Ghana. Millet is the principal food crop. peanuts and *karité* the major exports. Cattle amount to 1,300,000 head.

The Mossi country was explored by L. C. Binger in 1888; and Paul Voulet induced the kings to acknowledge a French protectorate in 1896. Cpper Volta was organized as a French colony in 1919, but dissolved in 1932. In 1947 it was reconstituted as an overseas territory of the French Union and in 1958 it became an autonomous republic within the French community. In 1960 Upper Volta became an independent republic within the French Community. The capital is Ouagadougou. (HU. DE.; X.)

UPPINGHAM, a market town and rural district in the Rutland and Stamford parliamentary division of Rutland, Eng. Pop. of civil parish (1951) 1,868. The houses, mostly of golden-brown ironstone, date from the late 16th century. The church of SS. Peter and Paul, heavily restored in 1860, contains the pulpit used by Jeremy Taylor, rector of Uppingham from 1638 to 1642. Uppingham school, founded in 1584 by Archdeacon Robert Johnson, has many houses in the town including the original school building (1584). Edward Thring (*q.v.*) in the 19th century developed the school into a public school of great educational influence.

UPPSALA or UPSALA, a city of Sweden, 41 mi. N. of Stockholm. Pop. (1960) 77,397. The name originally belonged to Old Uppsala, nearly 2 mi. N. of the present city. This Uppsala, mentioned in the 9th century, was famous for its heathen temple, which gleamed with gold. Three huge grave mounds remain there. In the same place the first cathedral of the bishops of Uppsala was erected (c. 1100). But on its destruction by fire, convenience caused removal in 1273 of the archiepiscopal see to the present city, then called Östra Aros, but later Uppsala, which became a kind of ecclesiastical capital. There the kings were crowned, after their election at the Mora Stones. 10 mi. S.E. of Uppsala.

In 1567 Eric XIV murdered in the castle five most eminent men of the kingdom, three of them belonging to the family of Sture. In 1593 was held the great synod which marks the final victory of Protestantism in Sweden; in the same year the university was restored by Charles IX. In the castle, Christina, daughter of Gustavus Adolphus, resigned her crown to Charles X in 1654. In 1702 nearly the whole city burned down.

Uppsala has water communication with Stockholm by the river Fyris and the northward arm of Lake Mälar, into which it flows. The older part of the city lies on its sloping west bank.

The university, the chief and oldest in Sweden, was founded in 1477 by Archbishop Jakob Ulfsson. The main university building, completed in 1887, lies west of the cathedral. The library building was erected in 1819–41. It is on the site of the Academia Carolina. founded by Charles IX, and is known in consequence as *Carolina Rediviva.* After 1707 the library had the right of receiving every work printed in Sweden. Among the mss. is the famous *Codex Argenteus* (6th century), a translation of the Gospels in the Gothic of Bishop Ulfilas (4th century). In the old botanic garden. Linnaeus had his residence. The new botanic garden was given by Gustavus III in 1787. The observatory was founded in 1730. The Victoria museum contains Egyptian antiquities. The Royal Society of Sciences. founded in 1710 by Archbishop Erik Benzelius, has a valuable library. Much of the revenue is drawn from the estates granted by Gustavus Adolphus in 1624. Every student must belong to a "nation" (*landskap*), of which there are 13, eaçh representing a particular part of the country and having generally its own clubhouse and fund. The students have a high reputation for singing.

The cathedral stands nobly above the town; its tall western toners with their modern copper-sheathed spires are visible for many miles. It is of simple form and mainly French in style (the first architect nas a Frenchman. Étienne de Bonneuil), modified by the use of brick as building material. Ornamentation is thus slight except at the southern portal. The church was building from 1287 to 1435. It suffered from several fires, and a thorough restoration was completed in 1893. The easternmost chapel is the fine mausoleum of Gustavus Vasa. The castle was founded in 1548 by Gustavus I. It was destroyed by fire in 1702, and only part is restored. Uppsala is a book-printing centre.

UR, a very important Sumerian site and the reputed early home of Abraham (Biblical Ur of the Chaldees). Ur lies about 140 miles south of Babylon, and about 6 miles south of the modern bed of the Euphrates, about two miles from the modern Ur junction on the Baghdad–Basra railway, in 31° N., 46° E. In ancient times the Euphrates ran west of Ur, reaching open water near Eridu. The river was diverted so that it passed by Ur in the time of Rimsin. The city also lay near the ancient junction of the Tigris with the Euphrates, when the former flowed along the Shatt al Hai. Ur lies close to the low hills which form the edge of the Arabian desert. It commanded the communications of both rivers. It was close to the sea and at the same time a convenient entrepôt for the commodities of the desert. The gradual change in the coast line and in the course of the rivers has left the ruins in the desert. Although most of the ruins of Ur as seen to-day,—and the *ziggurat* is one of the best preserved in Mesopotamia,—belong in their present form to the Neobabylonian period, recent excavations have shown that the site has been occupied from extreme antiquity. Original excavations were undertaken by Taylor in 1854. but a serious examination of the site was not made till after World War I by Hall. His work has since been ably continued by Woolley.

Amid the extensive remains of cemeteries, the most recently found graves, which lie south-east of the sacred enclosure, are the most interesting. The graves fall into three periods, and are dated provisionally by Woolley at 3500 B.C., the second series are comparable with Cemetery A at Kish, and are dated by Woolley at about three centuries later, while the third series are some centuries later, but at present are undated.

The richest graves of all belong to the earliest period. Their wealth of precious metal shows that there was a very considerable and prosperous civilization, while the settled style of the art shows that this civilization was already an old one. The graves antedate the first dynasty of Ur by 400 years, they come therefore in the period subsequent to "the flood," a period in which Sumerian historians placed two dynasties, those of Kish and Erech. For these periods and for the first dynasty of Ur they record only the names of the kings, often exaggerating the length of their reigns to an absurdly great degree. The excavations at Ur have, however, produced inscriptions of the first dynasty and these early graves show that the occupation of the lower river valley is extremely ancient, while additional confirmatory evidence of an early date has recently been found at Kish.

The great temple area at Ur is both striking and has had many archaeological results. The temenos or sacred enclosure as it exists to-day is the work of Nebuchadrezzar. The outer wall appears to have been pierced by six great gateways. On the north-east side the more northerly had a corner stone with an inscription of Bur-Sin. The southerly was restored by Cyrus, the son of Cambyses. On the south-western side the gateway opposite the ziggurat had an inscription of Nabonidus.

The ziggurat stands in the north-west corner of the sacred area. It consists of three stories. The lowest, which measures 210 × 140 × 20 ft., was built by Ur-Nammu and Shulgi and was built so well that further restoration was apparently never needed. The second stage was restored by Nabonidus. A small building crowned the third stage. This was the bedchamber of the god and goddess, not a temple as Herodotus supposed The face of the first stage was blackened, the second and third was of red stone, while the shrine on the top was encased in blue brick, the work of Nabonidus. On the north-east side there were three stairways, leading from the platform to the second stage, two ran along the face of the tower from the north and east angles respectively and met in the middle, from which point there was a third stairway, running towards the face of the tower, at right angles to the other two.

East of the ziggurat lay the great temple of E-num-mah. The ruin is of three periods, prehistoric to Neobabylonian, and of the time of Cyrus. The old Sumerian foundation wall was made of unbaked brick built on a foundation of clay which had been beaten hard. On this there were two courses of unbaked bricks of Bur-Sin. S ft 9 in thick and 8 ft. 5 in high, which had been restored at various times. On either side there is a row of rooms. The temple was laid in ruins between the time of Hammurabi and the Kassite dynasty. Nebuchadrezzar II. made a complete restoration. The old temple had no great open court, an obvious need in a great temple; for this Nebuchadrezzar made provision.

South-east of the ziggurat was a much ruined temple of Ningal. The middle cella and the side chapels lie on the north-west side of the court, and the entrance, through a great recessed doorway is on this side. On either side there were two rooms connecting with antechamber and chapels and the plan recalls the temple of Ishtar at Babylon. A roadway led from the south-east of the temple of Ningal, ending in a great double gateway which gave access to the court of a great rectangular building east of the temple. There was communication from the south corner of the temple court to this street through a pair of recessed gates. At the other end of the roadway the excavators found a recess with a door opening on to a building of the Kassite period.

Between the temple of Ningal and E-num-mah lay the shrine of

Nannar. E-dub-lal-mah. This is mentioned in an old liturgy as a temple of Ur and buildings of this name occur in other cities, such as Adab. Larsa. Lagash and Isin. The tonn itself was excavated by Woolley. It has been shon-n that the old town of Ur, as it presented itself to Abraham's view, cannot have differed much from the modern mudbrick towns of Mesopotamia.

URAL-ALTAIC LANGUAGES, a language-family consisting of two groups: (1) the Uralic group (Finno-Ugric languages [*q.v.*] and Samoyedic languages). are spoken in north-eastern Europe and northwestern Siberia; and (2) called the Altaic (Tarkic [*q.v.*], Mongolian [*q.v.*] and Tungus languages) in derivation from the mountain range of that name, are spoken over an area extending from eastern Poland to the Pacific ocean. The relationship between the two groups is disputed by some authorities.

The Phonetic System.— Almost without exception the Ural-Altaic languages recognize a law of vocalic harmony. Exceptions exist but are explained consistently with the general principle: that in any single word only vowels of the same "timbre" may appear; thus. if the radical vowel of a word be o or *u,* the vowels in the other syllables must be o, *u* or a. In other words, vowels in the same word must harmonize in method of articulation. On the other hand. if the root vowel is e or *i,* the vowels of other syllables of the same word must be prepalatals or anterior vowels (*i.e.,* articulated in the forepart of the mouth like e and i).

Thus in Finnish are the words kesi "hand," *kivi* "stone." *metsä* "forest." opposed to kala "fish," *sulka* "feathers." The same applies to Hungarian, *repülni* "to fly," *lélek* "soul." segiteni "to help." presenting vocalic contrast to *három* "three," olvadni "to melt," *savanyú* "sour."

In the Altaic languages, except Tungus, vowel harmony has developed into an actual sound harmony which has led to the formation of two opposite sound groups: velar (or postpalatal) and palatal (or prepalatal); *e.g.,* Turk. *qalɣan* "remained." *kälgän* "having come," soq- "to beat." *sök-* "to scold." Siberian-Turk. *oturɣan* "sitting. living," *ölürgän* "having killed," Razan-Tatar *qył-* "to do." *kil-* "to come." etc., Mongolian (Xalxa) *odon* "star," odon "feather," *suma* "arrow," *sümä* "temple, palace," *uxa-* "to dig." *üxä-* "to die." Sound harmony. without being general. is an important factor in the phonetic structure of Ural-Altaic languages.

Consonantal Alternation.— In any given word the consonant which ends the root syllable is subject to various mutations according to the nature of the syllable following (open or closed). It is especially characteristic of certain Uralic tongues, such as Lapp, Finnish and the Samoyedic languages. In the other languages it has not developed beyond the merest trace. Thus, in Finnish! *kukka* "flower:" but kukan (gen.) "of the flower"; *kuto-* "to weave," but *kudon* "I weave"; *repo* "fox," but *revon* (gen.) "of a fox"; onki "fishhook," but *ongen* (gen.) "of a fishhook"; *lintu* "bird," but *linnun* (< *lindun*) "of the bird." In their present fortn the consonantal alternations. so numerous and so varied in Finnish and, above all, in Lapp, give no indication of what they once were. In early times, it seems probable that at the end of the root syllable. there was an alternation of degree. in correspondence with two accentuation types—a strong one and a weak one. tt. kk. *pp.* and t. k. *p.* There was also an alternation which produced a contrast between *p. t.* k. and *β. δ.* y.; *m.* n. ŋ, and *β.* 6. *γ.*, etc. This alternation extended to groups of consonants opposing a strong mt to a weak *md, mp* to mb, *ks* to *γz.*

This alternation theory (German *Stufenwechsel*) was formulated by the Finnish linguist. E. N. Setälä. who proposed to extend it to Altaic tongues. where G. J. Ramstedt had discovered it in part; since N. N. Poppe's work it also can be considered as valid in Altaic.

Vocalic *Alternation.*—There exists also an alternation of vowels by which, according to the suffixes which a word may take, the vowel of the root syllable may be modified or changed. Thus. in Finnish. *pala* "to burn" (intrans.). and *polttā* "to burn" (trans.); in Ostyak, *n'ālәm* "tongue." and *n'ilmәm* "my tongue." These instances are rare in modern Ural-Altaic speech. and the Uralic tongues have best preserved the traces, although examples are also found in Xltaic.

The rules which determine the beginning and ending of words are that no word can begin with more than one consonant. and when a foreign word so beginning is borrowed it is simplified accordingly. The Swedish word *stor* "big." becomes *suuri* in Finnish. Elsewhere a vowel is put before the double consonant to facilitate enunciation: the Slav word *stolŭ* is in Hungarian *asztal* and the English "steam" is, in Osmanli, *istim,* etc.

The accent varies in position and quality. Most Ural-Altaic languages stress regularly the first syllable. but Turkic the last. In Samoyedic and other idioms such as Ostyak it varies.

Morphology.— In the first place. no language of the group uses prefixes; all the grammatical modifications expressed in English by prepositions (viz., to, on. of, for, etc.) are effected by means of suffixes. "I enter the house." is, in Hungarian, *belépek* a *házba* (*ház* "house"—ba, suffix meaning "into"). In a tale written in Kazan Tatar is found: ber *keše urmanγa barγan dej,* "a man went into the forest'! (*urman* "forest"—ya "into"). The majority of the grammatical relations affecting words are therefore expressed by suffixes. which differ in form from language to language, but play the same role throughout. These suffixes can be strengthened by post-positions: thus (Hungarian), egy fa alatt "under a tree" (egy "one, a," *fa* "tree," al-a-tt, locative. "under").

The possessive is formed by suffixes except in Mongolian. Hungarian *szemem* "my eye" (*szem* "eye" + *m* "my." with euphonic e); *szemed* "thine eye" (-d "thy. thine"); *szeme* "his eye" (-*e* "his"); *szemünk* "our eye" (*-ünk* "our"). Osmanli Turkish also has this form, *ev-im* "my house" (ev "house." *-im* "my"): *ev-iŋ* "thy house" (*-iŋ* "thy"); ev-i "his house" (-i "his"); *evimiz* "our house" (*-imiz* "our"). This use of the possessive suffix! which does not exist in Mongolian, varies since in Hungarian as in Turkic it is added directly to the root before other suffixes, except that of the plural, while in other tongues (Finnish. Lapp. etc.) they follow all other suffixes. Compare Hungarian a *házamban* "in my house" and Turkish (Osmanli) *ev-im-de* (Osmanli) with Finnish koda-ssa-ni (-ni "my") and Tungus (Evenki) oro-r-bo-s, plural, accusative, possessive second person singular "your (thine) reindeer."

The Uralic and Altaic languages appear to have developed their morphological system well before the time when the two groups began to separate regionally. Thus, not many suffixes can be restored throughout the family so far; *e.g.* one method of forming the plural was to suffix a *-t* to substantives, as in Mongolian and Uralic, a process of which Turkic and Tungus have conserved a few traces. But there are other essential morphological features which are common to both groups, such as suffixes of locativic and lativic cases and that of the accusative. The main characteristic of the Ural-Altaic tongues is the difficulty of distinguishing between nouns and verbs by their outward forms. The conjugation of the verb essentially consists of the possessive-suffix system of the noun and many verbal suffixes are identical in form with those which are used to construct new nouns. The adjective has no proper declension, and in the majority of the languages it is not declined at all, since no grammatical agreement exists there.

The pronouns still exhibit relics of a declension of their own, but have undergone a strong influence from that of the nouns.

In none of these languages has grammatical gender developed (in contrast to Indo-European or Hamito-Semitic).

While in most oi the Uralic languages the sentence structure is rather free and resembles, especially in the west of the area, that of Indo-European, the Altaic languages, with the exception of northern Tungus, have developed a rather rigid syntactical system requiring the sequence: subject, object. predicate. Except for conditional clauses, grammatical subordination does not exist, but co-ordinate participial or gerundial clauses are used instead. In the Altaic sentence, the governing link is always preceded by its governed, a rule which is valid also throughout the Uralic group.

Numerals.—The Ural-Altaic numeral system is decimal throughout. The names of the numbers in the different languages differ widely, because the primitive Ural-Altaic speech had not developed a proper numerical system before the dispersion.

Vocabulary. — A great many words dealing with rudimentary civilization are common to all the languages, such as most of those expressing relationship (father, mother, uncle, aunt), certain elements, animals and plants, primitive occupations and simple movement and gesture words. The comparative philology of these languages demonstrates a neolithic civilization of the type of which traces have been found in different parts of northeastern Europe and the Urals. This primitive vocabulary, the common patrimony of all the tongues, is augmented by words of very diverse origin. Altaic has borrowed much from Chinese, Indo-Iranian and Arabic languages. Uralic languages have drawn largely on Indo-European stocks and in historical times particularly from Iranian. In modern days Hungarian, Vogul, Ostyak, Cheremiss and Votyak have taken many words from Turkic. Tungus has a large percentage of Mongolian words; Osmanli Turkish has adopted much from Arabic and Persian. Mongolian and Turkic have lent to, and borrowed from, each other, and Paleo-Asiatic elements have enriched and varied the vocabularies of the Ural-Altaic languages spoken in Asia In Europe, Finnish, Lapp and Estonian have borrowed much from the Germanic, Baltic and Slavonic languages, Hungarian from Ossetian, Slavonic tongues and Germanic. The vocabularies of the Finno-Ugric and Turkic languages spoken on Soviet territory are rapidly becoming Russianized.

CLASSIFICATION

Uralic Languages

I. Finno-Ugric. **A.** Finnic: 1. Baltic sea Finnic: Suomi (or Finnish proper). Karelian. Olonecian. Ingrian, Liidic, Votic, Vepsä, Estonian. Livian; 2. Lappic (southwest, south and east dialects); 3. Volga Finnic: Cheremiss (or Mari—two dialects: Hill and Meadow Cheremiss); Mordvinian (two dialects: Erźa and Moksha). 4. Permian: Votyak (Udmurt) and Zyrian (Komi). B. Ugric: Vogul (Mańśi), and Ostyak (Xanty) on the lower Ob; and Hungarian (Magyar).

II. Samoyedic. A. North Samoyedic: 1. Yurak (Ńeńeć); 2. Tavgy (Nganasan); 3. Yenisey-Samoyedic (Eńeć). B. South Samoyedic: 1. Ostyak-Samoyedic (Selqup with many dialects); 2. Sayan-Samoyedic (Kamassinic and other languages, now Turkified by south Siberian Turkic).

Altaic Languages

I. Turkic. A. Central Asiatic: 1. Orkhon and Uighur (or Old Turkic); 2. New Uighur; 3. Chaghatai; 4. City Özbek; 5. Qyrghyz. B. Southwest group: 1. Osmanli Turkish (of Turkey and the former Ottoman empire); 2. Azarbaydjanian (with Qashqa'i); 3. Tiirkmen. C. Northwest group: 1. Qomanian (Codex Cumanicus of 1303); 2. Karaïm; 3. Kazan and west Siberian Tataric; 4. Bashkiric (Bashqort); 5. Noghay; 6. Qazaq-Qaraqalpaq. D. South Siberian Turkic (three subdivisions: Oyrot, Abaqan [Xakas] and Tuva). E. Northeast Siberian or Yakut. F. Chuvash (on the central Volga) which is a link of Turkic with Mongolian.

II. Mongolian. A. Literary Mongolian and the later east Mongolian languages (*e.g.*, Xalxa, Ordos, Tsakhar, etc.). B. West Mongolian or Ralmuck (Kalmyk, Xal'maq). C. Northern Mongolian or Buryat.

III. Tungus. A. North Tungus: 1. Northwestern or Evenki (many dialects, from the estuary of the Yenisey to the island of Sakhalin); 2. Northeastern Tungus or Lamut (in northeast Siberia); B. South Tungus: 1. Džürčen (Nü-chên); 2. Manchu; 3. Goldi (Nanay), with Olcha and Orok; 4. Udehe (Udekhe) with Orochi.

The relationships of some of these tongues are, as yet, far from being elucidated.

(A. SAU.; K. H. M.)

URAL MOUNTAINS, a mountain system which extends north to south, from the Arctic ocean to the Caspian sea and separates Europe from Asia. The Urals have been affected by a series of separate upheavals, some having a north to west strike and some a north to east. They reach their maximum altitudes along a zone stretching nearly north and south. The composite nature of the Grals is best seen at the extremities of the system, where the upheavals form a distinct chain of mountains.

The Paë-khoy or coast ridge (Samoyedic "stony ridge") is independent of the Urals proper. It has a distinct north-northwest and north-west trend, and although cut through by the Yugor strait it is continued in Vaigach island and Novaya-Zemlya. Its dome-shaped summits rise 1,000 ft.

The Obdorsk or Northern Urals begin near the head of Kara bay and extend southwest to the 64th parallel and form a distinct range, stony and craggy, sloping steeply toward the southeast and gently toward the marshes of European Russia. Its highest peaks are Khard-yues. 3,715 ft.. and Pae-yer, 4,764 ft. Sometimes the main chain has on the west two or three secondary chains, formed by sedimentary rocks, and the highest peaks of the Urals (Sablya, 5,402 ft., and Tel' pos-iz or Murai-chakhl, 5,545 ft.) occur in the south of one of these. Dense forests, chiefly fir, pine and larch, clothe the mountain slopes, but every species, except the larch, gradually disappears in the north, and the upper limit of vegetation (2,400 ft. in the south) rapidly descends to the base of the mountains near the Arctic circle, and forest vegetation disappears about 65° N. (67° in the plains).

The section between 64° and 61° N. has again a wholly distinct character. Here the main water parting is a succession of plateaus stretching in a northwesterly direction. It has broad, flat. marshy valleys, while here and there are isolated summits, mostly under 3,000 ft. (Yang-tump, 62° 43' N., 4,170 ft.). The whole region, except the mountain summits, is densely clothed with coniferous forests. This part of the range is uninhabited.

The Middle Urals, about 80 mi. broad, contain rich iron, copper and gold mines (Bogoslovsk, Goroblagodatsk and Ekaterinburg Urals). The Denezhkin Kamen in the north (4,908 ft.) and the Tara-tash in the south (2,800 ft.) mark the limits of this section. Here the orographical structure is more complicated. In the north (61st to 60th parallel) there is a succession of chains with a distinct northeastern trend. South of Kachkanar (2,890 ft.) the Urals assume the appearance of broad swellings 1,000 to 2,000 ft. in height. deeply trenched by ravines. These low plateaus have been utilized for centuries as the chief highway to Siberia. The water parting between the Russian and Siberian rivers is there not more than 1,245 ft. above sea level on the great eastward road, west of Sverdlovsk (Ekaterinburg). The valleys have a decidedly southeastern direction, as has the railway from Perm to Kurgan. The Middle Urals are densely forested. The valleys and lower slopes have a rich soil and contain large and wealthy villages. The mines also support a considerable population.

The Southern Urals (55° 30' to 51° N.) consist of three parallel chains running northeast and southwest and constitute an independent part of the Ural system. The Urals proper are a low sinuous chain hardly exceeding 2,200 to 2,800 ft. in altitude. Farther west there is a parallel chain which, although pierced by rivers, reaches 5,230 ft.; while farther west still is another series of equally high chains. The gentle slopes of the hilly tracts are dotted with woods. mostly of deciduous trees, while the hollows contain rich pasture grounds. The region is being colonized.

Farther south the main range, except when deeply trenched by the rivers, is a plateau which hardly reaches 1,500 ft. It is continued toward the Volga under the name of Obshchiy Syrt.

South of the great bend of the Ural river, quite independent ranges of hills, or flat swellings, appear (*e.g.*, Dzhaman-tau, Mugodzhar hills). A range of heights connects the Mugodzhar hills with the Ust-Urt plateau

Geology. — The Ural mountains are no more than the western edge of a broad belt of folding of which the greater part is buried beneath the Tertiary deposits of western Siberia. Throughout the greater portion of the chain a broad strip of granites. diorites, peridotites, gneisses and other crystalline rocks rises directly from the Siberian plain, and is covered toward the west by Silurian, Devonian, Carboniferous. Permian and Triassic strata, which are thronn into numerous folds parallel to the length of the chain and usually rise to much greater heights than the crystalline zone.

URALSK, a town in West Kazakh *oblast* in the Kazakh Soviet Socialist Republic. U S S R on the Ural river, where the railway crosses it. Pop. (1959) 105.000. Founded in 1775, it is a centre for grain and cattle from the Kirghiz steppe. There are flour mills and leather and gut preparing works, with iron and woolen industries: also a model farm, a museum and branches of the Russian geographical and fisheries societies. Uralsk has two cathedrals. one founded in the 18th century. the other in 1837.

URANINITE, a natural form of uranium dioxide, is an isometric mineral that occurs as crystals and granular masses or, in the pitchblende variety, as dense crusts with a botryoidal or colloform structure. It is strongly radioactive, and readily yields autoradiographs upon photographic film.

Uraninite. CO,, is a major ore of uranium. It has been obtained largely from hydrothermai vein deposits, as in the Katanga district, Republic of the Congo, at Joachimsthal and adjacent places in the Erzgebirge, Saxony. and at Great Bear lake and the Lake Athabasca district. Can The uraninite of veins usually is of the pitchblende variety. The element uranium was discovered by M. H Klaproth in 1789 in uraninite from Joachimsthal, and radium was first extracted from uraninite ore from this place by P. Curie, M. Curie and G. Bémont in 1898.

Craninite is recovered as a by-product from the conglomeratic gold ores of the Witwatersrand, U. of S Af, and it is one of the ore minerals in a rather similar deposit in the Blind river area, Ont. Important deposits of fine-grained uraninite associated with coffinite and vanadium minerals are found in sedimentary rocks, chiefly sandstones and conglomerates, as in the plateau area of Colorado, Utah, New Mexico and Arizona. The sandstone-type deposits often are extensively oxidized to carnotite, tyuyamunite and other secondary uranyl minerals, which may themselves constitute important ores.

Craninite is widespread as a well-crystallized accessory mineral in pegmatites, but such occurrences are of little or no economic interest Fine specimens are found in pegmatites at Wilberforce, Ont., the Spruce Pine district, N C.. and at Grafton Center, N.H.

.Through oxidation the composition of uraninite varies between UO_2 and about $UO_{2\ 6}$. The crystal structure of uraninite is of the calcium fluoride type, and the extra oxygen is housed interstitially. Thorium can substitute for uranium in the crystal structure and a complete solid solution series extends to thorianite, ThO_2. Some varieties contain appreciable amounts of rare-earths, particularly cerium Types with a high content of thorium and rare-earths are found principally in pegmatites. Some of them have been designated by varietal names, such as cleveite and bröggerite. Lead accumulates in uraninite as a product of the radioactive decay of the uranium and thorium present, and from a knonledge of the disintegration constants can be used to calculate the geologic age of the mineral.

Uraninite is dark gray to black in colour with a steely lustre, but becomes dark brown and dull or pitchlike accompanying chemical alteration. The hardness is $5\frac{1}{2}$ to 6. The specific gravity is 10.9 in pure UO_2, hut most natural material ranges between 6.5 and 9 0 Uraninite often alters to yellow or orange-red hydrated uranyl oxides and to greenish yellow uranyl silicates to yield pseudomorphic crystals. It is not stable under weathering conditions, and the uranium may be leached and redeposited locally as autunite, torbernite or other secondary uranyl minerals.

See Clifford Frondel, *Systematic Mineralogy of Uranium and Thorium*, U.S. Geological Survey Bulletin 1064 (1958); E. W. Heinrich, *Mineralogy and Geology of Radioactive Raw Materials* (1958).

(CL. F.)

URANIUM, a metallic element that is dense hard and nickel-white in colour. During the first 150 years uranium was known, few uses could be found for it. and it was studied chiefly because it was the heaviest element then known. Rut in 1938 Otto Hahn (*q v.*) and Fritz Strassmann discovered that the uranium nucleus undergoes fission when bombarded with neutrons, and thus offered the possibility of giving up its nuclear energy in a sustained, chain reaction One pound of uranium, it was shown later, yields as much energy as 3 000.000 lb. of coal. Economically recoverable ores usable as nuclear fuels are believed to contain many times more energy than all the known recoverable deposits of fossil fuels—coal, oil, gas. The discovery that uranium was fissionable signaled the start of one of the most intense and concentrdted studies ever made of an element.

Summaries of the findings of these studies, as well as of studies made during and prior to 1938, appear in the following sections on the history, occurrence, uses, preparation for nuclear uses and properties of uranium.

HISTORY

The element uranium was discovered in 1789 by Martin Heinrich Klaproth in the course of an examination of a pitchblende mineral originating in Saxony. To this new substance he gave the name uranium in honour of Sir William Herschel's discovery of the planet Cranus in 1781. Klaproth and tno generations of chemists nho followed him were under the impression that uranium metal itself had been prepared. In 1841, however. Eugène Melchior Péligot demonstrated that Klaproth's substance was actually the oxide UO_2; Péligot then succeeded in preparing the metal by the reduction of uranium tetrachloride with potassium. Péligot may thus be properly considered the founder of uranium chemistry.

The formulation of the periodic system by Dmitri Ivanovich Mendeléyev in 1869 directed attention to uranium as the heaviest of the elements. a position nhich was confirmed and held until the discovery of the first transuranium element in 1940. In 1896 Henri Becquerel discovered in uranium the phenomenon of radioactivity, a property that was later found in many other elements (see RADIOACTIVITY. NATURAL). This significant discovery stimulated a new and lasting interest in the previously rather obscure element. Becquerel exposed a photographic plate wrapped in black paper to the action of the beautiful fluorescent salt potassium uranyl sulfate, $K_2SO_4.UO_2SO_4.2H_2O$, and observed that a distinct impression had been produced on the plate. Further experiments indicated that metallic uranium, all uranium salts and uranium minerals (especially pitchblende) give rise to the same phenomenon. These epoch-making observations were closely followed by the discovery of radium in pitchblende (see RADIUM).

In 1934, Enrico Fermi and co-workers observed that beta activities were produced by the action of neutrons on uranium, but the full significance of this observation was not understood at the time. Then in 1938 Hahn and Strassmann showed that bombardment with neutrons caused uranium to break down into radioactive isotopes of a lighter metallic element, barium, with release of energy (*see* ATOMIC ENERGY). At a conference-in the U.S. in 1939. Fermi suggested neutrons might also be released when uranium nuclei split, and in sufficient numbers to cause the reaction to sustain itself as a chain reaction. L. Szilard and co-workers; H L. Anderson and co-workers; and F. Joliot and co-workers confirmed this possibility in 1939; later investigation showed that an average of $2\frac{1}{2}$ neutrons are released during each fission. Further study showed that the uranium fissions occurred most readily in the comparatively rare isotope U^{235}, which occurs in nature only $\frac{1}{140}$ as frequently as U^{238}. Investigators also found that neutron bombardment changes U^{238} to plutonium. nhich in turn is split by neutrons. The first self-sustaining nuclear chain reaction was conducted by Fermi at The University of Chicago on Dec 2. 1942 The chain reaction nas produced in a lattice of uranium and graphite. With the development of methods for controlling the rate of fission. the first wartime and peacetime applications of nuclear energy soon followed. The first test atomic bomb was detonated July 16, 1935, and the first bomb used in warfare was dropped Xug. 6, 1945. Atomic power for propulsion was used for the first time in a submarine (U.S.S. "Nautilus") in 1955, and one of the first full-scale nuclear power electrical generators began production at Shippingport, Pa., on Dec. 2, 1957.

OCCURRENCE

Although uranium is usually regarded as one of the rarer elements. it is actually present in the earth's crust to a considerably greater extent than such "common" elements as cadmium, bismuth, mercury, silver or iodine. The bulk of the uranium seems to be present in the upper 12–13 mi. of the lithosphere in an amount estimated to be roughly 10^{14} tons, an average content of approximately 4×10^{-6} g. per gram of rock. Concentration varies in rocks between about 0.2×10^{-6} and 25×10^{-6} g. per gram of rock. with higher values present in acid (high silica content) rocks such as granite.

Relatively minor amounts of uranium are found in the "basic" basalt rocks such as form the floors of the oceans. It is also found in very small quantities in meteorites.

Uranium is present in sea water to the extent of about $\frac{1}{2,000}$ as much as is present in an equal weight of average rock. Living matter contains uranium in amounts varying from $10^{-4}\%$ to $10^{-9}\%$ by weight, but the biological significance of the element is obscure. The fixing of uranium by algae may have played a role in the formation of certain uranium deposits. There is no simple relationship between the mean concentration of an element in the earth's crust and the probability of finding economically important deposits of that element.

In the case of uranium, numerous minerals are found in nature. It is convenient to divide uranium minerals into two broad classes, primary and secondary. Particularly important are the primary minerals uraninite (UO_2; crystalline; 45%–85% uranium), pitchblende (combined UO_2 and UO_3; amorphous, black, pitchy; variable percentage uranium), davidite (cerium. iron, titanium, vanadium, chromium, uranium oxide; black; 7%–10% uranium) and the secondary minerals carnotite, autunite and torbernite which originate from the primary minerals by weathering. Carnotite is a complex potassium uranyl vanadate ($K_2O.2U_2O_3.V_2O_5.nH_2O$; 50%–55% U_3O_8); autunite is a calcium uranyl phosphate ($CaO.2UO_3.P_2O_5.nH_2O$; 60% U_3O_8); and torbernite is a closely related copper uranyl phosphate ($CuO._2UO_3.P_2O_5\,nH_2O$; 60% U_3O_8).

Estimated reserves of U_3O_8 in the second half of the 20th century included 380.000 tons in Canada; 370.000 tons in the Union of South Africa; 225,000 tons in the U.S.; between 50.000 and 100.000 tons in France: 10.000 tons in Australia: and 7.500 tons in the Belgian Congo. Important deposits also are believed located in the Joachimsthal (Jachymov) region of Czechoslovakia and Germany and in the Freghana and other districts of the U.S.S R.

At the start of the 1960s Canada. the U.S. and the Union of South Africa lead production in that order. About 90% of Canada's reserves are located in the Blind River area of northern Ontario although most of the production has been centred in the Northwest Territories. In the U.S., reserves of uranium ores at mid-20th century were estimated by states as follows: New Mexico 55,000 000 tons: Wyoming 11,500,000 tons; Utah 5,600,000 tons; Colorado 4,400,000 tons; Arizona 1,400,000 tons. By value of ore production the top-producing states were ranked as follows: Utah, New Mexico, Colorado, Wyoming, Arizona, Washington, South Dakota, Alaska, California, Nevada and Montana. It is estimated that new deposits of uranium ore are being discovered twice as fast as the need for uranium is increasing.

The extraction of uranium from ores is complicated since most uranium ores contain a great variety of accompanying metallic elements. The ore is ground and leached with either acid or alkali; the uranium is recovered from the pregnant leach liquors by various precipitation solvent extraction or ion exchange procedures. The uranium often leaves the refinery as the oxide U_3O_8. For further purification, important in nuclear applications, the U_3O_8 may be dissolved in nitric acid to yield a solution of uranyl nitrate The uranyl nitrate can then be purified by extraction into diethyl ether.

USES

Uranium had very limited uses before its use for nuclear energy. It has been suggested for filaments of lamps. A small tube of UO_2, connected in series with the tungsten filaments of large incandescent lamps used for photography and motion pictures, tends to eliminate the sudden surge of current through the bulbs when the light is turned on, and thereby extends their life. Its compounds have been used in photography for toning and as a dye or stain in the leather and wood industries. Uranium salts are mordants for silk or wool. A little ferro-uranium has been utilized in making special steels. but its value in this connection is questionable, since such alloys may be pyrophoric if they contain 20% or more of uranium. Sodium and ammonium diuranates have been used in ceramics to produce coloured glazes. Only 0.006% is needed to give good yellow colours. By increasing the percentage, the colour may be changed to orange, brown, green or black.

Cranium carbide has been suggested as a good catalyst in making synthetic ammonia. Small quantities of uranium salts are claimed to stimulate plant growth, but large quantities are poisonous to plants.

Uranium and its chain of decay products correspond to a source of radioactive energy which has some importance and has been much studied with respect to the problem of the internal heating of the earth. Its long half life makes possible determinations of the age of the earth by measuring the amount of lead, uranium's ultimate decay product, in certain uranium-containing rocks.

By far the most important use of uranium lies in its application for nuclear (or atomic) energy. This use, in fact, so increased the value of uranium as to eliminate its use for many of the purposes mentioned above.

TABLE I.—Known Isotopes of Uranium, Natural and Artificial

Isotope	Half life	Modes of disintegration and highest energy (Mev)	Source
U^{227}	1.3 min.	α (6.8)	Th^{232} (α, 9n)
U^{228}	9.3 min.	α (∽80%) (6.67) Electron capture (∽20%)	Th^{232} (α, 8n)
U^{229}	58 min.	Electron capture (∽80%) α (20%) (6.42)	Th^{232} (α, 7n)
U^{230}	20.8 days	α (5.85)	Th^{232} (α, 6n)
U^{231}	4.2 days	Electron capture α ($5.5 \times 10^{-3}\%$) (5.45)	Th^{232} (α, 5n)
U^{232}	74 years	α (5.32)	Pa^{232} β^- decay
U^{233}	1.62×10^5 years	α (4.82)	Pa^{233} β^- decay
U^{234} (U_{II})	2.48×10^5 years	α (4.77)	Natural
U^{235} (AcU)	1.13×10^8 years	α (4.58)	Natural
U^{236}	2.39×10^7 years	α (4.50)	U^{235} (n, γ)
U^{237}	6.75 days	β^- (0.249)	U^{238} (n, 2n)
U^{238}	4.50×10^9 years	α (4.18)	Natural
U^{239} (U_1)	23.5 min.	β^- (1.21)	U^{238} (n, γ)
U^{240}	14.1 hours	β^- (0.36)	U^{239} (n, γ)

Naturally occurring uranium consists of the three isotopes of mass numbers 238, 235 and 234 with relative abundances 99.27%, 0.72% and 0.006%, respectively. The isotope U^{238} is the parent of the natural uranium ($4n + 2$) radioactive series; the isotope U^{234} is also a member of this series, and thus these two are linked by radioactive decay. The isotope U^{235} is of other origin, is the parent of the actinium ($4n + 3$) radioactive series and has a great importance because it undergoes nuclear fission with slow neutrons. It is prepared at Oak Ridge, Tenn., in nearly pure isotopic composition in substantial amounts.

The synthetic transuranium element plutonium, which is also fissile with slow neutrons, is prepared by the absorption of neutrons by the isotope U^{238}. The element with its natural isotopic composition can be used in large chain-reacting piles, where the reaction is sustained by the rare isotope U^{235}, and the synthetic element plutonium (the isotope Pu^{239}) is manufactured at the same time by transmutation of the U^{238}. The self-sustaining nuclear chain reactions may be written:

$$_{92}U^{235} + \text{neutron} \longrightarrow \text{fission products} + \text{energy} + \text{neutrons};$$

$$_{92}U^{238} + \text{neutron} \longrightarrow {}_{92}U^{239} \xrightarrow{\beta^-} {}_{93}Np^{239} \xrightarrow{\beta^-} {}_{94}Pu^{239}.$$

Smaller nuclear reactors may be built to use the pure or nearly pure isotopes U^{235} or Pu^{239} as fuels. The abundant isotope U^{238} can thus be indirectly "burned," at least in part, as nuclear fuel through the transformation to Pu^{239}, leading to a more efficient use of the uranium. A fissionable isotope such as U^{235} or Pu^{239}

gives rise to an amount of "heat energy equivalent" of about 10,000.000 kw.hr. per pound, when it completely undergoes the fission reaction.

The isotopes U^{235} and Pu^{239} can be used as the explosive ingredients for nuclear (atomic) weapons (see ATOMIC ENERGY). This possibility led in a number of countries to a certain amount of control over the mining and processing of uranium. Nuclear reactors also are used to produce highly beneficial medicines. such as the radioactive isotopes Co^{60} and I^{131}, both used in treating cancer. (G. T. SG.)

PREPARATION FOR NUCLEAR USES

The use of uranium for atomic reactor purposes involves two forms: stable UO_2 powder compacts and highly purified metal as the predominant fuel.

Oxide Treatment. — The preparation of stable UO_2 from UO_3 is customarily accomplished in a screw-type continuous reactor by contact with hydrogen at above 760° C. The powder, after cooling under a protective atmosphere, can then be stored at room temperature without reversion to U_3O_8 or UO,. Oxide components are prepared by adding an organic plasticizer. cold pressing at high pressure to pellet form and finally sintering at a very high temperature in a protective atmosphere. The final shapes are frequently ground to provide a close control of dimensions.

Metal Formation. — The preparation of uranium metal normally begins by inducing the exothermic reaction between uranium tetrafluoride and magnesium metal chips:

$$UF_4 + 2Mg \longrightarrow U + 2MgF_2 + 85 \text{ kg.cal}$$

This is carried out in a steel vessel (termed a bomb) lined with magnesium fluoride to contain the reaction and to protect the uranium from contamination. A weighed amount of uranium tetrafluoride and a measured quantity of magnesium slightly in excess of the stoichiometric requirement are thoroughly blended, then packed into the bomb which is finally topped mith a layer of magnesium fluoride and closed with a steel lid. The filled bomb is heated in an electric resistance furnace to a temperature in the range of 595° to 705° C. until the reaction occurs after an appreciable holding period. Molten uranium of high purity then separates below a layer of molten magnesium fluoride (slag) because of the large difference in their specific gravities. After cooling, the bomb is emptied of metal. slag and lining for mechanical separation.

The metallurgical efficiency of the process is influenced by three factors: the residual oxygen content of the UF_4 in the form of UO_2, UO, or UO_2F_2; the temperature at which the reaction is induced; and the quantity of magnesium metal employed. The effect of oxygen is complex since it affects both the exothermic nature of the reaction and the fluidity and melting point of the slag created. In general oxygen should be held to a minimum. Temperature has a definite bearing on economic output since low holding temperatures delay the inception of the reaction and thus prolong the process; high temperatures induce local premature reactions with insufficient heating of the charge for good liquefaction and separation of metal and slag. The optimum yield is normally achieved in the temperature range of 595° to 705° C. The best yield is also obtained when the magnesium addition is only slightly in excess of the stoichiometric amount needed; the optimum value is generally inversely related to the mass of the charge employed.

The metal and slag after discharge from the bomb are broken apart for separate processing. The slag is crushed, screened and then ground to a suitable particle size for use in new bomb liners for subsequent UF_4-Mg reactions. The metal regulus (usually called a "biscuit" in laboratory terminology and a "derby" in shop phraseology) is cleaned by pneumatic chipping and then weighed to determine the reaction yield. A proper quantity of derbies is then assembled as a charge for melting in an MgO-lined graphite crucible. Heating is carried out in *vacuo* in a high-frequency induction furnace until adequate liquefaction has been achieved. When sufficiently fluid. the metal is poured into a graphite mold coated with MgO and allowed to cool in an inert atmosphere. The ingots are then removed from the molds, ground to eliminate fins, cropped to remove impurities segregated at the top, sampled, weighed and then boxed for shipment for fabrication.

Metal Forming. — Cranium may be readily hot formed in the temperature range of 535" to 650° C. by a variety of means such as rolling. forging or extrusion. Heating to the proper temperature is usually done in molten neutral salt baths which protect the metal from oxidation. The orthorhombic structure existing in this temperature range is not particularly amenable to plastic flow, and the degree of deformation to be imposed at each step of the forming process must be held within moderate limits. After rolling or extruding to rough shape. the parts are then machined to final size with conventional machine tools. A careful use of a proper coolant is essential at this stage to avoid oxidation of the chips mith the attendant hazard of fires because of the pyrophoric characteristics of the metal.

Fuel Element Fabrication. — Atomic reactor designs for production of power have in many cases called for the use of uranium in the form of GO,. This choice of the oxide has arisen because of the advantages of three of its properties: a very high melting point, permitting pile operations at temperatures more favourable for efficient heat transfer for power generation; favourable stability of structure under irradiation. making long exposures possible; and good resistance to corrosion by uater, thereby minimizing the dangers of contaminating the cooling system with radioactive corrosion products. Fuel elements of UO_2 are usually assembled in carefully sized, close-fitting tubes of corrosion-resistant metal. The tubes are sealed and then welded in suitable clusters for reactor use.

The commonest form in which uranium metal is used in an atomic reactor is as a cylinder approximately 8 in. long and 1 in. in diameter. The cylinder is encased in an aluminum jacket to protect it from corrosion by the cooling water that flows over it in the pile to control the temperature of operation. After irradiation for a time chosen to achieve the most favourable conversion of U^{238} to Pu^{239}. the cylinder (or "slug") is discharged from the pile into a water basin where it can be handled without radiation risk to the operators. Here the slugs are assembled in suitable containers for transfer to the separations area where the plutonium is chemically extracted.

PHYSICAL AND METALLIC PROPERTIES

Uranium has the symbol U, atomic number 92 and chemical atomic weight 238.07. It occupies a position in the periodic system of the elements as the third member of a transition series, the actinide series, which includes the heaviest known elements and in which an inner electronic shell (the 5f shell) is being filled. The electronic structure of the gaseous atom has been determined to be that of the element radon plus three 5f, one 6d and two 7s electrons.

Uranium metal melts at 1,132" C., boils at 3,818' C., and has a density, calculated from X-ray data, of 19.04 g. per cubic centimetre. The metal is ductile, malleable, capable of taking a high polish and not hard enough to scratch glass. It undergoes two transitions. at 668° C. and 774° C., respectively. The crystal lattice at room temperature is orthorhombic (unit axes of crystal all at right angles to each other and all of unequal length) and can best be interpreted as having distorted hexagonal close packing; its structure is thus quite different from that of chromium, molybdenum and tungsten metals. It has not been possible to assign an unambiguous radius to uranium in the metallic state. The abnormalities of the uranium structure are reflected in various properties such as an abnormally high electrical resistivity ($32–76 \times 10^{-6}$ ohm.-cm.) of the metal at room temperature.

Metallic uranium is a highly reactive substance. It decomposes water, and in the form of powder may spontaneously inflame in air. It combines directly with oxygen at 150° to 350° C.. with chlorine at 500° C., with bromine at 650° C. and with iodine at 350° C. The metal reacts with gaseous hydrogen at 250° C. to form a hydride of the formula UH,. It reacts nith nitrogen, carbon monoxide. carbon dioxide and many other gases, uranium can therefore be used in the laboratory for the purification of gases such as the noble gases. Metallic uranium reacts with acids nith the liberation of hydrogen and the formation of compounds of U(III) and U(IV); caustic alkalies do npt act upon it. The oxidation-reduction potential for $U \rightarrow U(III)$ appears to be about 1.80 v. (on the scale in which the potential for $\frac{1}{2}H_2 \rightarrow H^+$ is taken as zero).

CHEMICAL PROPERTIES

Oxidation States of Uranium.—Uranium has the four oxidation states +3, +4, +5 and $6 and the ions in aqueous solution are usually represented by U^{+3}, U^{+4}, UO_2^+ and UO_2^{++}. The oxidation-reduction potential of uranium ions in acid solution is indicated below:

$$U \xrightarrow{+1.80\text{ v.}} U^{+3} \xrightarrow{+0.631\text{ v.}} U^{+4} \xrightarrow{-0.58\text{ v.}} UO_2^{+} \xrightarrow{-0.063\text{ v.}} UO_2^{++}$$
$$U^{+4} \xrightarrow{-0.32\text{ v.}} UO_2^{++}$$

The UO_2^+ ion is uristable in solution and undergoes disproportionation to U^{+4} and UO_2^{++}. A few solid compounds of this oxidation state U(V) are known, as, for example, UF_5 and UCl_5.

The ion U(III) forms intense red solutions in water and is oxidized by water at an appreciable rate. The rate of oxidation appears to increase with increasing ionic strength, although strong solutions are claimed to be stabilized by strong acids such as hydrochloric. Solutions of U(IV) are green: U(VI) solutions, yellow. Considerable data on the absorption spectra of the various ionic states have been obtained, and these are useful for analytical purposes.

U(IV) and U(VI) are the important oxidation states, and therefore the important chemistry of uranium may be related to the two oxides UO, and UO_3, uranium dioxide and uranium trioxide. A series of salts such as UCl_4 and $U(SO_4)_2.9H_2O$ is obtained from UO_2. The commoner uranyl salts. $UO_2(NO_3)_2.6H_2O$, UO_2Cl_2 and $UO_2SO_4.nH_2O$, in which the UO_2^{++} (uranyl ion) acts as a radical, are derived from UO_3.

The element also exhibits a formal oxidation number of U(II) in a few solid. semimetallic compounds such as UO and US. No simple ions of oxidation state U(II) are known in solution.

Uranium Oxides.—In addition to the three oxides UO_2 (brown), U_3O_8 (greenish black) and UO_3 (yellow), which have been known for a long time, there are known to exist the monoxide UO and the oxide U_2O_5. The phase relationships in the uranium-oxygen system are very complex, so that it is possible to obtain uranium "oxides" with practically any composition intermediate between UO and GO,.

Uranium trioxide exists in a number of crystal modifications. It is usually prepared by thermal decomposition of uranyl nitrate at about 300° C. The oxide U_3O_8 is formed when any uranium oxide is ignited in air at about 700° C. Uranium dioxide is usually obtained by hydrogen reduction of UO_3 at elevated temperatures (700° C.). All these oxides dissolve readily in nitric acid to give uranyl solutions. Uranium trioxide decomposes to U_3O_8 upon ignition at 500° to 700" C.; UO_2 is refractory, melting above 2.000° C.

Closely related to the oxides are the uranates and diuranates. Sodium diuranate, $Na_2U_2O_7.6H_2O$, is the uranium yellow of commerce. The simple uranates have the typical formula Na_2UO_4; this type of compound is much more difficult to prepare than the diuranates which are obtained by addition of alkali to uranyl solution. These compounds correspond to chromates and dichromates but, of course: lack the strong oxidizing properties of the latter.

Uranium peroxide, the formula of which is usuaily given as $UO_4.2H_2O$, is formed by precipitation from solutions of uranyl nitrate by hydrogen peroxide. Alkali hydroxide. hydrogen peroxide and sodium peroxide form soluble peroxyuranates, $Na_2UO_6.4H_2O$ and $Na_4UO_8.8H_2O$, when added to solutions of uranyl salts.

Uranium Nitrides and Carbides.—Three uranium carbides are known: the monocarbide, UC; the sesquicarbide. U_2C_3; and the dicarbide, UC_2. These can be prepared by direct reaction of carbon with molten uranium or by reaction of carbon monoxide with metallic uranium at elevated temperatures. The latter reaction yields a mixture of UC and UO_2.

Uranium and nitrogen form an extensive series of compounds that can be prepared by direct action of nitrogen on the metal. Uranium mononitride. UN. is the lowest nitride of uranium. If the mononitride is treated nith more nitrogen at atmospheric pressure. U_2N_3 is formed. With nitrogen under high pressure UN_2 can be prepared. but it is difficult to obtain samples of UN_2 that are completely free of UN

The carbides and nitrides of uranium are relatively inert, semimetallic compounds Uranium mononitride is stable in the absence of air to temperatures above 2 000" C.; the monocarbide is likewise refractory Both carbides and nitrides are converted to U_3O_8 by ignition in air. They are soluble with difficulty in acids.

Uranium **Hydride.**—As mentioned above, uranium metal reacts with hydrogen at 250° to 300° C to form a well-defined hydride nhich resembles the rare-earth hydrides in many respects. The formula of this substance has been shown to be $UH_{3\,00}$. Uranium hydride exists in two crystal modifications; the α form is obtained uhen the hydride is prepared at low temperatures; the β form is obtained when the temperature of formation is greater than 250° C. β-UH_3 is ferromagnetic below the Curie temperature (173° K.). The hydride undergoes decomposition nith increasing temperature: the dissociation pressure of UH_3 is one atmosphere at 436° C.

Uranium hydride is of considerable importance in the syntheses of other uranium rompounds. Since the formation of uranium hydride from massive uranium metal is accompanied by a complete disintegration of the metal to a microcrystalline ponder. and since the hydrogen can then be driven off by heating *in vacuo* to 350° to 400° C., very finely divided reactive uranium metal can be prepared. Further, the hydride itself is very reactive and can be used conveniently to prepare halides carbides nitrides etc.. of uranium at relatively moderate temperatures with the appropriate reagent.

Uranium Halides.—The halides of uranium constitute a numerous and important set of compounds. Table II lists some of the knonn uranium halides.

TABLE II.—*Halides of Uranium**

Fluorides	Melting point, ° C.	Chlorides	Melting point, ° C.	Bromides	Melting point, ° C.	Iodides	Melting point, ° C.
UF_3	(>1,140†)	UCl_3	835	UBr_3	730	UI_3	(680)
UF_4	960	UCl_4	590	UBr_4	519	UI_4	506
U_2F_9	†	UCl_5	(327)				
U_4F_{17}	†	UCl_6	179				
UF_5	(<400†)						
UF_6	64‡						

*Parentheses indicate estimated value?. †Undergoes disproportionation. In the case of UF_3, into UF_4 and U; in the case of the remaining halides, into UF_4 and UF_6 ‡Under pressure; UF_6 sublimes below its melting point.

Uranium tetrafluoride serves as a starting material for the preparation of the other fluorides. It is best prepared by hydrofluorination of uranium dioxide:

$$UO_2 + 4HF \xrightarrow{550^\circ\text{ C.}} UF_4 + 2H_2O.$$

Cranium trifluoride can be prepared by reduction of UF, with hydrogen at 1,000" C. Uranium hexafluoride. UF_6, is best obtained by direct fluorination of UF_4, although any uranium compound will yield UF_6 by reaction nith fluorine at elevated temperatures:

$$UF_4 + F_2 \xrightarrow{350^\circ\text{ C.}} UF_6.$$

The intermediate fluorides $U_2F_9(UF_{4.5})$; U_4F_{17} $(UF_{4.25})$ and UF_5 are prepared by reaction of solid UF, and gaseous UF_6 under appropriate conditions of temperature and pressure.

Uranium hexafluorirle is probably the most interesting of the uranium fluorides. Under ordinary condition.; it is a dense, white solid with a vapour pressure of about 120 mm. at room temperature. It can readily be sublimed or distilled and is by far the most volatile uranium compound known. Despite its high molecular weight, gaseous UF_6 is almost a perfect gas, and many of the properties of the vapour can be predicted from kinetic theory. Uranium hexafluoride is a strong fluorinating agent and is therefore reactive; it is sensitive to traces of moisture and must be handled by special techniques. It is used in the large scale separation of uranium isotopes by gaseous diffusion.

Uranium tetrachloride can be prepared by direct combination of chlorine with uranium metal or hydride; it can also be obtained by chlorination of uranium oxides with carbon tetrachloride, phosgene. sulfur monochloride or other powerful chlorinating agents. The trichloride is obtained by reduction of UCl_4 with hydrogen. and the higher chlorides by reaction of UCl_4 with chlorine. Uranium pentachloride disproportionates on heating to UCl_4 and UCl_6. Uranium hexachloride is a rather volatile, somewhat unstable substance. All the uranium chlorides dissolve in or react readily with water to give solutions in which the initial oxidation state of the ion corresponds to that in the solid. All the solid chlorides are sensitive to moisture and air.

The bromides and iodides of uranium are obtained either by reaction of the elements or by treatment of UH_3 with the appropriate halogen acid. The thermal stability of the halides decreases as the atomic number of the halogen increases. The uranium bromides and iodides. UBr_3, UBr_4, UI_3 and UI,, are known. A series of oxyhalides of the type UO_2F_2, $UOCl_2$, UO_2Cl_2, UO_2Br_2, etc.. is known. They are water-soluble substances which become increasingly less stable in going from fluoride to iodide.

Aqueous Systems.—As mentioned above. aqueous solutions of U(III), U(IV) and U(VI) are readily obtained. Solutions of U(III) are blood-red in appearance; hydrogen is slowly evolved with the formation of U(IV) solutions. Solutions of U(IV) are quite stable in the absence of air. As may be judged from its potential U(IV) is a strong reducing agent and is easily oxidized to uranyl by oxygen. peroxide and numerous other oxidizing agents. Uranyl solutions in turn may be reduced to U(IV) with sodium hydrosulfite, zinc or cadmium amalgam, or by electrochemical or photochemical means.

No trivalent uranium compounds can be precipitated from U(III) solutions; rapid oxidation to U(IV) compounds occurs when such procedures are attempted. Ordinarily only chloride or perchlorate solutions of U(III) are encountered, although bromide, iodide and sulfate may be obtained.

The common water-soluble salts of U(IV) are the chloride, bromide. sulfate and perchlorate. Solutions of these salts show a slight acid reaction mhich indicates a moderate degree of hydrolysis. The main absorption bands of U(IV) solutions are at 650 $m\mu$, 550 mp, 495 $m\mu$ and 430 $m\mu$. A number of different types of experiments indicate that in one molar acid the U(IV) ion is essentially U^{+4} (in the absence of complexing agents). Chloride, sulfate and bromide ions form complex ions with U(IV). Insoluble U(IV) oxalate. phosphate, fluoride, molybdate, arsenate. ferricyanide and hydroxide can be precipitated from U(IV) solutions.

Uranyl solutions are readily obtained and are more stable than those of any of the other oxidation states. Well known and extensively studied are uranyl nitrate. chloride, perchlorate, acetate, carbonate and sulfate systems. In many respects UO_2^{++} behaves like a simple doubly charged ion. Solutions of UO_2^{++} have a characteristic yellow colour and are slightly hydrolyzed. In concentrated solutions there is some evidence for the formation of polymerized ions such as $U_2O_5^{++}$.

An interesting property of uranyl nitrate solutions known since the mid-19th century is extractability with diethyl ether; uranyl nitrate hydrates are markedly soluble in ether. The addition of hydroxide. phosphate, ferricyanide, oxalate, etc., results in the precipitation of insoluble salts. The uranyl ion has. however, a strong tendency to form soluble complex ions with an excess of carbonate or oxalate ions. In general. uranyl salts of weak acids have a marked tendency to form complex ions. Characteristic is the precipitation of double salts such as sodium uranyl acetate, $NaUO_2(C_2H_3O_2)_3$, and sodium magnesium uranyl acetate, $NaMg(UO_2)_3(C_2H_3O_2)_9.9H_2O$. The latter type has considerable analytical significance. Uranyl solutions are fluorescent and undergo a great variety of photochemical reactions in the presence of organic compounds.

URANUS, Heaven. in Greek mythology. the husband of Ge and father of Cronus (q v) and other deities (see TITANS). As such he represents the generative power of the sky, which fructifies the earth with the warmth of the sun and the moisture of rain.

The Roman Caelus is simply a translation of the Greek *Ouranos,* not the name of a distinct national divinity. In art. Uranus is shown as an old, bearded man holding a robe stretched out over his head in the form of an arch,

URANUS, in astronomy, the seventh major planet in order of distance from the sun, and denoted by the symbol ♅. Ii was discovered by Sir William Herschel on March 13, 1781. although at the time he thought it was a comet. Thus on April 6 he remarked "the comet appeared perfectly sharp upon the edges and extremely well defined without the least appearance of any beard or tail." Continued observations of the new object, however, showed that it was not moving in an elongated type of orbit like most comets. About four months later A J. Lexell announced that the object was a new planet revolving in a nearly circular path at a distance from the sun of about 19 times the distance of the earth. Herschel exercised his right as discoverer by calling the planet Georgium Sidus in honour of King George III, his royal patron. The name of "The Georgian" was used in the *British Nautical Almanac* up to 1850. But the name mas unpopular outside of England, as was also that of Herschel, proposed by J. J. Lalande The name of Uranus was chosen by J. E. Bode.

Uranus is just visible to the naked eye under favourable conditions. It is not surprising therefore that a search of the records showed it had been observed many times before Herschel's discovery by astronomers who took it for a star. Thus during the opposition of 1768–69 P. C. Lemonnier had observed it eight times. These prediscovery observations were of great help in determining a reliable orbit for Uranus

The mean distance of Uranus from the sun is 19 18 times that of the earth or 1,783,700,000 mi. It completes a revolution around the sun in 84.013 years. The mean radius of the planet is 14 700 mi. or 3.72 times that of the earth (G. P. Kuiper and D. L Harris, 1951). The planet has an oblateness of $\frac{1}{14}$, so that its equatorial radius exceeds its polar radius by 1,100 mi. These dimensions of Uranus are necessarily uncertain because of its great distance. The mass of Uranus is accurately known from the motions of its satellites to be 14.54 times that of the earth. Its density is 0.28 times that of the earth or 1 56 times that of water. Surface gravity on Cranus is 1.05, practically the same as on the earth. Uranus has an albedo of 0.66, second only to that of Venus, indicating a cloud covered surface of high reflecting power.

The visual magnitude of Uranus at mean opposition is 5.44, according to the photoelectric measures H L Giclas made at the oppositions of 1950. 1951 and 1952. From a discussion of all published observations of Uranus from 1864 to 1932 W. Becker concluded that there was a well-defined variation in the brightness of the planet having a period of 8.4 years and a visual amplitude of 0.31 magnitudes. From visual observations made between 1936 and 1947 J. Ashbrook also found evidence for an eight-year period. Giclas, from his photoelectric measures of 1950–52, found no variations in brightness. Neither could he detect any short-period variations ascribable to the rotation of the planet.

Uranus when viewed through a large telescope shows a bluish-green disk slightly less than 4″ in diameter. A white central streak and some dusky bands have been noted, but no definite spots from which the rotation period could be determined. By recourse to the Doppler principle *(see* LIGHT) Percival Lowell and V. M.

Slipher, from spectroscopic observations in 1911–12, found a rotation period of 10 83 hours. Observations by J H. hloore and D. H. Menzel from 1927–30 gave a rotation period of 10 84 hours. Moore and Menzel regard this close agreement as probably fortuitous, remarking that in their opinion it may be in error by as much as half an hour.

The first visual observation of the dark bands in the spectrum of Uranus seems to have been made by A Secchi about 1870. In the last quarter of the 19th century the spectrum of Uranus was photographed by several pioneers in astronomical photography such as H. C. Vogel, Sir William Huggins, and others. A fine series of photographs of the spectra of the planets from the violet to the limit of the visual red was published in 1909 by Slipher. The spectrum of Uranus has since been extended to 8800A

The spectra of the giant planets show dark absorption bands which grow progressively stronger from Jupiter to Neptune. The bands are so strong in the spectra of Uranus and Neptune that they absorb most of the light in the yellow, orange, red and infrared regions, thus accounting for the bluish-green tint of these planets. Despite much speculation the substance producing this absorption remained unknown until 1932, when R. Wildt showed that the most prominent planetary markings occurred at the positions of bands of ammonia (NH_3) and methane (CH_4) observed in laboratory spectra Wildt's work was later confirmed and extended by A. Adel and Slipher at the Lowell observatory, Flagstaff, Ariz , and by W S. Adams and T. Dunham, Jr., at Mount Wilson observatory, near Pasadena, Calif. The bands of ammonia are prominent in the spectrum of Jupiter but much weaker in Saturn, doubtless because of the latter's lower temperature. On Uranus and Neptune with a surface temperature of about $-200°$ C. the ammonia is probably frozen out so that only methane remains.

From cosmological considerations it has long been believed that the giant planets must contain a great abundance of light elements, particularly hydrogen and helium. Cnfortunately there seemed no way of testing this idea from spectroscopic observations. The band systems of the hydrogen molecule (H_2) in the visible and ultraviolet regions have such highly excited electronic states for their lower states, that in general they cannot appear in absorption. If a source of energy were available at a temperature sufficiently high to excite these levels. it would also be high enough to dissociate these molecules, so that again no absorption could occur. Other possible atmospheric constituents of the giant planets such as nitrogen. helium, neon and argon also give no absorption markings in the observational region of the spectrum. so that the possibility of detecting their presence seemed remote indeed. Such was the outlook about 1936.

The first direct evidence for the presence of hydrogen and helium in a giant planet was obtained in 1952—not from spectroscopy as expected—but from photoelectric measures on the diminution in the light of a star as it was occulted by Jupiter (see JUPITER). These measures showed hydrogen and helium to be so abundant in the Jovian atmosphere that by comparison methane and ammonia are present only as minor constituents. Unfortunately, occultations of a suitable type are exceedingly rare events so that this method can seldom be applied.

In 1935 G. Herzberg pointed out a possible method of detecting molecular hydrogen in planetary spectra. A homonuclear molecule such as H_2 does not give a vibration-rotation spectrum since its dipole moment is zero. Rut he remarked that H_2 might possibly show a weak vibration-rotation spectrum because of its quadrupole moment A chance to try the idea occurred in 1949 when Kuiper discovered a diffuse band at 8270A in the spectra of Uranus and Neptune that could not be attributed to methane. Herzberg noted that this band fell near the position of the S(0) line of the pressure-induced 3–0 band of the quadrupole rotation-vibration spectrum of H_2. He felt that the line could no: be identified with the planetary marking because of its great width in the laboratory spectra. By reducing the temperature of the gas to $-195°$ C.. honever. the feature observed in Uranus and Neptune was satisfactorily reproduced in the laboratory. The laboratory experiments indicate conditions in the atmospheres of Uranus and Neptune corresponding to a ratio of helium to hydrogen of 3:1, a temperature of $-195"$ C. or lower, and a partial pressure of hydrogen at the bottom of the visible atmosphere of about 2 atm. The thickness of an equivalent atmosphere of uniform density mould be about 18 km. for Uranus.

Four broad lines in the spectra of Uranus and Neptune near 7500A were still unidentified in the mid-1950s. They could not be identified with silane (SiH_4) or methyl deuteride (CH_3D). Results obtained from investigation of the spectra of methyl deuteride indicated the upper limit of the ratio of deuterium to hydrogen in the atmospheres of Uranus and Neptune to be about 1:300.

Satellites of Uranus.—In Jan. 1787. Herschel detected two satellites of Uranus, now known as Titania and Oberon. In 1851–52 William Lassell at Malta, in conjunction with his assistant A. Marth. observed two satellites revolving closer to the planet than those discovered by Herschel. These mere named Ariel and Urnbriel. Lassell's telescopes were reflectors superior in light-gathering power to others of his time, and these inner satellites were not seen by other astronomers for more than 20 years. Indeed, doubts of their reality were not resolved until 1373, when they were observed with the Washington 26-in. telescope.

A fifth satellite of Uranus was discovered Feb. 16. 1948, by Kuiper on a photograph taken with the 82-in. reflector of the McDonald observatory, Mt. Locke. Tex. He appropriately named this new satellite Miranda. It revolves around Uranus in a roughly circular orbit in about the same plane as the other four satellites. Its period is 1.4 days corresponding to a distance of 77,000 mi.

The most remarkable feature about these satellites is the high inclination of their orbit planes. This amounts to 98° to the plane of the planet's orbit, and 97 8° to the ecliptic. so that the motion of the satellites is really retrograde. The result of the high inclination is that as Uranus revolves in its orbit. there are two opposite points at which the planes are presented edgewise to view, and the satellites appear to travel nearly north and south in the telescopic field. At intermediate points their orbits appear circular.

The Safellites of Uranus

Name	Distance from Uranus in miles	Sidereal period in days	Discovery
V (Miranda) . . .	77,000	1.41	Kuiper, 1948
I (Ariel) . .	119,000	2.52	Lassell, 1851
II (Umbriel) . . .	166,000	4.14	Lassell, 1851
III (Titania) . . .	273,000	8.71	Herschel, 1787
IV (Oberon) . . .	365,000	13.46	Herschel, 1787

For the irregularities in the motion of Uranus that led to the discovery of Neptune, see NEPTUNE. (R. S. RN.)

URARTU, the Assyrian name for the country later called Armenia (*q.v.*), and for its inhabitants. It is identical with the country of Ararat on one of whose mountains Noah's ark stopped, according to Genesis. the name survived in the Armenian province of Ararat and has been transferred to Mount Ararat south of the Araxes river (*see* ARARAT). Herodotus's Alarodoi are the Urartaeans nho after the immigration of the Armenians (after 600 B C.) retained or formed a distinct nation in the valley of the Araxes The inhabitants of Urartu, however, in their cuneiform inscriptions call themselves *Chaldini* ("plural").

The writing of the cuneiform inscriptions of the Urartaeans was taken from the Assyrians, but whereas Assyrian is a Semitic language. Urartaean is neither Semitic nor Indo-European. The Urartaeans or Chaldians must have immigrated from the nest into what was then to a greater part called Naïri. Apparently Sardur I, son of Lutipris, who built a fort to the west of the rock of Van. out of huge stones brought from afar, united the "Naïri-countries" under his rule after a long war against the Assyrians about the time of Assurnasirabal II, the father of Shalmaneser III. This kingdom of Naïri was replaced by the kingdom of Urartu-Chaldia. Aram, nho was the king of Urartu. was fought by Shalmaneser III (859–824 B C.), and so was his successor Sardur (Seduri II), father of King Ispuinis nho chose the rock of Van for his residence and as the holy seat of the god Chaldis. Ispuinis was the contemporary of Adadnirari IV of Assyria—son of Shalmaneser III and husband of Queen Shammuramat; *i.e.*, the historical Semiramis—whom he fought successfully, these successes enabling him to found a Chaldian colony at Musasir, west of the pass of Kelishina. A bilingual Chaldian and Assyrian inscription was erected by Ispuinis upon this occasion.

Menuas. his son, mas the mightiest and most successful of the Chaldian rulers. His greatest work is the aqueduct (the so-called Shamiramsu "river of Semiramis") more than 75 km. in length, irrigating the plain of Van and bringing drinkable water to the eastern borders of Lake Van (whose water is undrinkable), thus enabling him to found a "Menuas-city." Menuas was succeeded by Argistis I, a son, who left records of 14 years of his reign and his successful wars, on the outer walls of the set of chambers hewn into the solid rock of Van. His son Sardur III, contemporary of Assurnirari (755–745 B.C.) and of Tiglath-pileser III (745–727) of Assyria. was defeated by the latter, who destroyed the Menuas-city (735 B.C.).

Rusas I (714 B.C.), son of a Sardur, belonging to a side line of the dynasty, removed the capital to a hill called Toprakkalah in modern times, after digging an artificial lake, the outflow of which irrigated the side of the hill and the plain where he founded the Rusas-city. All this he recorded in a stela set up only a few years after the traditional date of the founding of Rome (754 B.C.). It was taken (1898–99) to the Berlin museum. Rusas I was a most energetic enemy of Sargon II of Assyria (722–705 B.C.) against whom he summoned a coalition of the states of western Asia, of which Mardukabaliddin of Babylonia (the Merodach-Baladan of the Bible) probably was one. In a bilingual stela erected over against the capital of Musasir, which had developed into a sort of independent buffer state, Rusas commemorated his feats against Assyria in re-establishing Chaldian sovereignty and the petty king Urzana in Musasir.

But in i14 the Cimmerians, breaking into the north of Urartu through the passes of the Caucasus, drove Rusas to suicide. Sargon had made a raid into Urartu and on his return had conquered Musasir. robbing its temple and overthrowing and mutilating Rusas I's stela. which, however. was later re-erected, evidently by Rusas II, the grandson of Rusas I who once more restored the power of Chaldia. Rusas II used Cimmerian mercenaries in his combats with Esarhaddon of Assyria (680–668 B.C.) and succeeded in getting rid of the bulk of the Cimmerians who went on to the west of Asia Minor. Rusas III, son of Erimenas, finished the temple of Chaldis on Toprakkalah. Sargon's sculpture of the temple of Musasir shows its front adorned with ornamented shields, a custom which the Chaldians had in common with the Cretans of Minoan times. Such shields, with inscriptions chiefly of Rusas III, were excavated in Toprakkalah. Their circular friezes are divided into semicircles upon which the animals are going in different directions so as to prevent any one appearing to stand on its head, a peculiarity only recurring on Cretan shields of the archaic period. The royal residence at Toprakkalah and the temple of Chaldis were evidently destroyed under Rusas III. The Medes must have overrun Urartu before they crossed arms with the Lydians on the Halys (May 28, 585 B.C.).

The pottery excavated at Toprakkalah, apart from other peculiar features, partly shows in red, and sometimes in black, a glazed surface which is practically equal to "bucchero." A gold medal showing a goddess of fertility and her female adorer in beaten work, has peculiarities which have left their mark in archaic Greek, especially Ionic art. A candelabrum and parts of a throne with a baldachin show a wreath of falling leaves the latter in exactly the shape in which it (the forerunner of the *kymation*) appears on the eldest Ionian or pre-Ionian capitals. The legs of the above-mentioned candelabrum and of another one preserved in Erlangen show the "zoomorphic juncture," one member of an animal coming forth out of the mouth of the same or another animal: this feature being entirely restricted to the art of the Chaldians and of the Etruscans. A bronze vessel from Toprakkalah with vertical rims has innumerable parallels in Etruscan tombs. The way the Chaldians built their walls and towers was illustrated by a model found at Toprakkalah. A striking likeness of the bison, one of the three chief races of big cattle living in Babylonia in the oldest times, in bronze stressing the beard as its special feature shows its existence in ancient Armenia in the 1st millennium B.C. Attaches or handle figures of big bronze vessels in the form of a female divinity in the winged disk of the sun are a Chaldian speciality, recurring in archaic Greek and in Etruscan art. A bronze snake, probably Tiamat, the animal of the Chaos, shows, as do numerous other pieces, a combination of different materials, the holes, for example, being partly filled mith coloured glass.

The Chaldians must have come from more western parts of Asia Minor where they were in touch with elements of Minoan culture; their culture is principally western with only minor traces of Assyrian influence; they influenced archaic Greek art in their turn, and had peculiar relations to the Etruscans which were probably based on a former relatively close proximity. When the Armenians invaded Urartu, the Chaldians withdrew into the mountains keeping up their warlike spirit and their metallurgic accomplishments. They were also called Chalybes, probably from the name of the steel which they were the first to produce. The region south of Trebizond was one of the last resorts of the Chaldians.

(C. F. L.-H.)

URAWA, the capital of Saitama prefecture, Japan, is also a residential suburb of Tokyo and the location of Saitama university. Between 1940 and 193'5 the area of the city increased from 12 sq.mi. to about 22 sq.mi. and its population from 59.700 to 143.044. Located about 50 minutes by electric rail from the heart of Tokyo, Urawa has become a densely crowded commuters' district. (C. A. MR.)

URBAN (URBANUS), the name of eight popes.

ST. URBAN I (d. 230). pope from 222 to 230, succeeded Calixtus I. His pontificate falls entirely within the reign of Alexander Severus, a time of peace for the church. No reliable information is available about his activities: the role attributed to him in the legend of St. Cecilia is a fiction of the 5th century. His feast is celebrated on May 25. (F. X. G.)

URBAN II (Odo of Lagery) (*c.* 1042–1099), pope from 1088 to 1099, was born in Châtillon-sur-Marne, France. A pupil of St. Bruno (founder of the Carthusians) at Reims and later archdeacon, Odo became monk (c. 1070), then prior! at Cluny. Called to Rome and created cardinal (1078), he served Gregory VII as legate to France and Germany. He succeeded Victor III on March 12, 1088. As pope, Urban adopted Gregory's aims. but showed keener political sense and moderation. Henry IV's refusal to abandon his antipope Guibert of Ravenna, who as Clement III still controlled Rome, blocked reconciliation. Thus exiled and despite hardship, Urban convoked councils in Italy and finally occupied Rome as Henry's power waned. By the enthusiasms evoked at two councils in 1095 (Piacenza and Clermont). Urban launched the crusade movement, which greatly enhanced papal prestige and influence. His efforts for reunion between Eastern Christians and Rome, especially at the Council of Bari (1098), had results only in Italy's Byzantine regions. Urban died on July 29, 1099. His cult was approved in 1881, and his feast day is July 29.

Setton *(ed.), A History of the Crusades,* vol. i, *The First Hundred Years* (1955).

URBAN III (Uberto Crivelli) (d. 1187). pope from 1185 to 1187. was a Milanese, created cardinal and archbishop of Milan by his predecessor, Lucius III, nhom he succeeded on Nov. 25, 1185. Urban inherited the crisis nith Frederick I. soon aggravated by the marriage in Jan. 1186 of Frederick's son Henry (VI) to Constance, Norman heiress of the kingdom of Sicily. This act confronted the papacy with the ominous prospect of the union of north and south Italy under Hohenstaufen rule, long feared as a peril to its independence. Urban died before an open rupture, and the outcome passed to his successors.

Paris, then bishop of Verdun (1253) and patriarch of Jerusalem (1255), he succeeded Alexander IV on Aug. 29, 1261. Urban IV made the fateful decision to invest Charles of Anjou. able and ambitious brother of Louis IX of France, with the Sicilian kingdom, the papal fief then ruled by the Hohenstaufen Manfred. Urban died. on Oct. 2. 1264. before Charles arrived. leaving the Angevin problem to his successors. He established the Feast of Corpus Christi (1264).

URBAN V (Guillaume de Grimoard) (1310–1370), pope from 1362 to 1370, was born in Grisac, France. of a noble family. He became a Benedictine monk, abbot and doctor of canon law, and succeeded Innocent VI on Sept. 28, 1362. As pope at Avignon he helped restore peace in Italy. and returned to Rome in 1367. Renewed strife in Rome led him to return in 1370 to Avignon, where he died on Dec. 19, 1370. A man of austere life and a patron of learning, Urban V founded new universities at Orange. Cracow and Vienna. He was beatified in 1870, and his feast is celebrated on Dec. 19.

URBAN VI (Bartolomeo Prignano) (1318–1389), pope from 1378 to 1389. was born at Naples. He was archbishop of Bari and one of the chief personages of the Curia when he nas elected pope (April 8, 1378) as the Roman populace, determined to end the French-dominated Avignon papacy, clamoured for an Italian pope. Once elected, the devout and competent official became a harsh. ill-tempered reformer. He so enraged the cardinals that they left Rome and, at Anagni, four months later, declared his election null and void On Sept 20 they elected the French cardinal Robert of Gene\-a, nho became the antipope Clement VII. Thus began a schism that lasted 40 years. Crban VI died on Oct. 15. 1389.

URBAN VII (Giambattista Castagna) (1521–1590), pope in 1590. was born in Rome of a noble Genoese family on Aug. 4. 1521. Nuncio to Spain and cardinal in 1583. he was known for his charity and piety. Elected pope on Sept. 15, 1590, he died 12 days later.

URBAN VIII (Maffeo Barberini) (1568–1644), pope from 1623 to 1644. was born in Florence. where he was baptized on April 5, 1568. Nuncio to France and cardinal in 1606. he was elected pope on Aug. 6, 1623, succeeding Gregory XI7. Urban was a cultured man of authoritarian temper. Distrusting the cardinals whom he considered subservient to the Catholic governments, he was very generous to his relatives, while keeping the reins of government in his own hands. He spent much on armaments but was unsuccessful in the war with Parma. His indecisive attitude in the Thirty Years' War has been often discussed. St. Peter's basilica was finished and consecrated during his reign. He died on July 29, 1611.

URBANA, a city of east central Illinois, U.S., 135 mi. S. by W. of Chicago; the seat of Champaign county and seat of the University of Illinois. Urbana adjoins the city of Champaign (*q.v.*). Surveyed in June 1833, five months after the creation of the county. it was one of the first towns to be laid out wholly on the prairie. The university is its chief source of employment; Urbana also has plants manufacturing scientific and technical instruments. radio: dairy products, paints! knock-down bleachers and athletic equipment and supplies. For comparative population figures see table in ILLINOIS: *Population*. (N. M. BE.)

URBAN SOCIOLOGY was one of the early specialized fields. first formally recognized in the United States, to develop within sociology. The term is a misnomer! used for purposes of brevity as a substitute for the more cumbersome titles "sociology of urban phenomena" or "sociology of urban communities." Rural sociology, its counterpart. had developed as a specialized field somewhat earlier.

The 1916 meetings of the American Sociological society were devoted to the central topic of rural sociology, but it was not until 1925 that the society similarly devoted its meetings to urban sociology.

Sociological interest in urban phenomena began to grow in the latter part of the 19th century nhen a number of important studies were undertaken in England and the United States. The classic English study of this period was the 17-volume work of Charles Booth *Life and Labour of the People in London* (1889), an empirical investigation of the state of the poor in that city. The most impressive U.S study of the period was Adna Weber's investigation of comparative urbanization, world-wide.

Systematic development of urban sociology first occurred in the department of sociology at The University of Chicago through the work of Robert E Park and Ernest TT. Burgess and their students, beginning in 1920 Viewing the city as a social laboratory for the investigation of human behaviour. they set a generation of students to investigate problems of human behaviour in the urban environment. The most systematic statement of this approach to investigation, referred to as the Chicago school of urhan sociology, is found in Robert Park's essay "The City as a Social Laboratory" (1915) and a later one by Louis Wirth, "Urbanism as a Way of Life" (1938). Scott E. W. Bedford's *Readings in Urban Sociology* (1927) and Nels Anderson ancl Edward C. Lindeman's text, *Urban* Sociology (1928), were the earliest attempts at textbook treatment.

Ways of *Viewing* Cities.—Cities are social facts of many dimensions. and they have been described and analyzed from many points of view other than the sociological. One way to define the sociological interest in cities is to examine some of the other views.

Men have moralized about cities throughout the history of urban settlement. The social philosopher treats cities (and city life) as objects of human preference, as moral entities. Cities are judged by men as good or bad, as parasitical or fecund entities. To the poet Shelley, "hell is a city much like London," while to the philosopher Aristotle, "the good life can only be lived in the city." The moralist's view of the city presupposes a set of values in terms of which the city is judged as to its desirability or undesirability as a place of human existence. The urban sociologist, on the other hand, seeks a factual description and analysis of cities and city life.

The political scientist views the city as a legal corporation or as a form of government. His concern is with development of urban forms of government, problems of governing the city and the reshaping or planning of the city through means available to government. The political scientist's view often is close to that of the moralist since he is concerned with matters of policy, of how government may deal with the problems of urban living.

Historians for the most part are interested in particular cities in history, usually the great cities, their desire being either to illuminate a historical period through the history of a city or to describe cities as history has made them.

The urban geographer and the human ecologist to some extent have shared a point of view in their study of urban phenomena. The urban geographer tends to treat the city as a focal point in the occupation and utilization of the earth by man. Interest in urban phenomena is dictated by an area viewpoint, by such questions as the location, distribution in physical space and changes in size, location and internal structure. The city is viewed in terms of the relationships between man and his territorial environment.

The interests of urban sociologists to some extent overlap all of those described above, but urban sociology has a distinct focus as well. The urban sociologist generally views the city as a form of human community in which there are particular ecological forces of integration. in which human beings acquire certain behaviour patterns as a result of association with one another and in which institutions and forms of social organization give to human life a characteristic aspect called urban. The urban sociologist. regards the city and its civilization as a distinctive kind of integration of human activity and as a major source for the initiation and control of social life in societies.

No single frame of reference or theory for the study of urban phenomena characterizes the discipline of urban sociology. There are, rather, three major approaches to the investigation of urban phenomena used in description and analysis. These are the ideal-type community approach, the urban trait-complex approach and the rural-urban continuum approach; they are sometimes combined.

Ideal-Type Community **Approach.**—The ideal type is a construct obtained by abstracting the characteristics of an object to their logical extreme and perfection. The ideal-type method is used in urban sociology to describe communities. Usually a number of characteristics describe the ideal type of urban community, but the more characteristics included in the type the less closely do empirical cases of communities approximate it. Some ideal-type approaches posit polar conceptions of communities. The G.S. anthropologist Robert Redfield considered folk and urban societies to represent polar types. He defined the folk society as a small, isolated, nonliterate, homogeneous society whose members have a strong sense of group solidarity. The opposite characteristics define the urban society.

The French sociologist Émile Durkheim regarded as polar the society based on mechanical solidarity and that based on organic solidarity. Members of the society based on mechanical solidarity are bound together by sharing common beliefs and sentiments, what he called a collective conscience. Members of the society based on organic solidarity, at the other pole, are bound together by a system of different, specialized and complementary functions. The English scholar Maine and the German sociologist Toennies utilized somewhat similar distinctions in their descriptions of forms of human community. The polar distinctions involved in their definitions are those between an intimate, traditional and settled form of human association in a village community as contrasted with a formal and deliberately contractual form of association in the urban community.

Common to all these ideal-type approaches to human community is use of the types to test hypotheses about human behaviour in a community or society. The ideal form of the community is seen as a source or cause of variation in human behaviour and organization. Redfield, for example, saw the decline in isolation and homogeneity of the community as factors in the secularization and individualization of behaviour of its members.

Trait-Complex Approach. — The trait-complex approach to study of urban communities is closely related to the ideal-type approach, the major difference being that the former uses empirical rather than logically pure attributes in defining a community. The empirical attributes are usually viewed as causally connected. For some sociologists a single variable is seen as the causal or generating variable in the trait complex. P. A. Sorokin and C. C. Zimmerman considered the single generating variable to be occupation: the agricultural occupation defines the rural community, while nonagricultural occupations define other forms of community. The occupational variable is seen in turn as generating other differences among communities. The most important of these usually considered by urban sociologists who use this approach are the size of community, density of settlement, homogeneity-heterogeneity of the population, social differentiation and stratification, mobility of the population and its system of social interaction. The problem of rural or urban sociology then is to see whether these differences between rural and urban worlds produce differences in social institutions and organizations, cultural and social processes, vital processes and the psychology of its resident population.

A related approach in urban sociology is that of investigating the extent to which concentration of population tends to give rise to the social phenomenon of the city as a way of life. The two features — concentration of population and the city as a way of life — are allowed to vary independently. The question then raised is, to what extent is the urban way of life limited to an urban population (one concentrated in physical space)? Investigators with this point of view do not see a one-to-one correlation between an urban population and an urban way of life. Concentration of population is seen as giving rise to certain features of social organization that are urban in character. But these features, once established: can be carried beyond the confines of the city so that it is possible to speak of rural populations as highly urbanized.

Rural-Urban Continuum Approach. — The third major approach in urban sociology posits a rural-urban community continuum in which there is a continuous gradation from rural to urban such that all human communities can be placed empirically at some point on the continuum. The definition of rural and urban polar ideal types of communities often implies such a continuum. A major difficulty in this approach is that while a given characteristic of a community may vary from rural to urban, all the characteristics of the community do not vary together with the same degree of urban or rural quality; thus it is difficult to place a given community empirically on a rural-urban continuum.

Factors Studied. — The factors investigated by urban sociologists are chosen from four major sets of community characteristics that define the community as (1) an ecological structure; (2) a unique demographic structure; (3) a characteristic form of social organization; and (4) characteristic forms of social relationships. Each of these characteristics of an urban community defines a focal concern of some urban sociologists.

Ecological.—The human ecologist studies the urban community from the perspective of community structure. The community is defined as the structure of relationships through which a localized population meets its daily requirements. The community in ecological theory is seen as the least reducible universe within which ecological relationships can be observed; it is the basic unit of ecological investigation. The urban ecologist studies the ways in which the urban community is differentiated and organized, particularly in its spatial organization. He is thus concerned with such problems as the segregation of persons and institutions in space, their concentration and redistribution, and he tries to account for the patterns formed: for example, residential patterns of ethnic groups, business establishments or occupation groups. At the same time ecologists are interested in the temporal organization of cities, the rhythm and tempo of an urban population. They therefore try to account for such things as the movement of persons between residence and workplace and the patterns of such movement. or the time relationship between communities. Finally ecologists are interested in accounting for the distribution of urban communities in space and for the movement of people and the organized relationships that are established among them. They are particularly interested in studying the functional relationships among urban communities and their hinterlands. the exchange relationships among them and their bases for functional specialization.

Demographic.—Closely related to the interest in ecological organization is the interest in community demographic structure, considered by some ecologists to be only an aspect of the ecological approach. The two most important community aspects investigated in this approach are size and density of settled area. The principal problem for demographic investigators is exploration of the aggregative aspects of the city, such as its population composition and its vital processes of population growth and mobility.

Socinl *Organization.*—The city often is viewed as a unique form of social organization or social system, the normative organization of the urbanized society and the structures developed for social interaction in cities then becoming the major objects of investigation. Some of the aspects of urban social organization most commonly studied include economic organization, system of social stratification, normative integration. kind and degree of social cohesion among the residents and nature of social control. Of particular concern in these investigations is what is uniquely urban about these institutional arrangements and their organization. Are they the peculiar products of urbanism?

Social Relationships.—Cities also are seen as generating characteristic forms of social relationships. Some sociologists see cities as particularly productive of anonymous and impersonal relationships. persons meeting one another in segmental or highly specialized social roles rather than as full personalities. Collective behaviour in the mass or crowd also is thought of as more distinctively urban. The urban sociologist therefore turns his attention to the kinds of social relationships developed in daily living, the role requirements of an urban dweller and the ways in which the human personality meets the requirements of urban living. Particular attention also is given to the way in which deviating behaviour is structured in the city, whether it is productive of mental illness, of organized delinquent gang warfare and organized crimes. of dissident social movements and so on.

Urban v. Rural. — Urban sociology is predicated upon the assumption that there are clearly distinguishable differences between urban and rural ways of life finding expression in different technologies, divisions of labour, social organizations and institutions, personalities and even social problems. Historically the country and the city are viewed as representing different stages of civilized life. Contemporaneously they reflect different modes of social existence. Some sociologists however question this assumption. maintaining that the proper study of sociology in this respect is the territorial organization of human groups into communities. Whether or not urban sociology will remain a field in a developing discipline is problematic. There are, however, certain problems dealt with in urban sociology to which the discipline of sociology will undoubtedly recur.

Process of Urbanization. — One of these is the general problem of population distribution and redistribution. An important aspect of population redistribution is the process of urbanization, a process of population concentration such that the ratio of urban people to the total population in a territory increases. Both the size of individual urban centres and the number of urban centres in a territory can increase without urbanization taking place, since only when a larger proportion of the inhabitants come to lire in cities is urbanization said to occur. There are four major factors nhich sociologists use to account for urban growth and urbanization Their effect has been intensified since the Industrial Revolution of the 19th century.

Agricultural Productivity. — First of these factors is that of greater productivity per agricultural worker, such that the agricultural system is capable of producing a surplus of food to supply urban populations and also to permit labour to be withdrawn from food production and used in the production of capital goods and services. Technological changes in agricultural production are of course the most important factor changing productivity per agricultural morker. The shift of labor from agricultural to nonagricultural occupations results from the greater income elasticity of demand for industrial as compared uith agricultural goods.

Factovy System. — The second major factor in the trend to urbanization is a direct consequence of the Industrial Revolution. giving rise as it did to the modern factory system and the industrial city. The invention of efficient techniques for converting energy in fuels and the derivative development of mass production made possible a large number of specialized cities with large populations within an area. Specialization in industrial production leads in fact to high interdependence not only between rural and urban peoples but also among cities; continued industrial production in almost any city depends upon continued production in many other cities.

Transportation and *Communication.*—The increased efficiency of the technology of transportation and communication is a third major factor in urbanization. Because of their specialization and their integration with both a rural and urban hinterland, cities become highly dependent upon trade. Increase in the efficiency of long-distance transportation therefore has a powerful effect in stimulating urban growth, since it makes possible increased trade through access to more and larger markets. Changes in local transport technology are also important in urban growth since they make possible the rapid intracity movement of persons and goods.

Population *Growth.*—The demographic transition accompanying the Industrial Revolution has been a fourth major factor in urban growth. The technology of sanitation and medicine brought with it sharp decrease in mortality, and since countries undergoing urbanization are characterized by high birth rates the result is a phenomenal population growth. The expanding population supplies the urban industrial labour force.

Rate *of Urbanization.*—The rate of urbanization has varied both historically and contemporaneously in different countries of the world. Prior to 1800 there were no highly urbanized countries since the cities required large rural populations for their support. From 1850 to 1900 rapid urbanization occurred in countries undergoing the Industrial Revolution, and by the middle of the 20th century the rate of urbanization was seen in many countries to be much faster than in the 19th, because of developing technology. Although highly urbanized areas are generally highly industrial areas. urbanization is not a simple function of industrialization.

Study of Community. — A second major problem area to which the discipline of sociology undoubtedly will recur is the relation of community to territorial location and its relations to the structure of social systems. The principal concern here lies with the study of persons in interaction in territorial locations. The subfields of rural and urban sociology have tended to subvert an interest in the study of community phenomena, so that a comparative community framework of inquiry did not emerge until the middle of the 20th century.

There are three major approaches to the study of community which overlap with the approaches to the field of urban sociology. These may gradually take the place of the earlier concerns with a rural and an urban sociology.

The first of these approaches is based on viewing the community as an ecological system. Ecologists assume that community structure manifests itself in a spatial and a temporal pattern. The ecologist's interest in community centres around generalizations about the structural features of communities and how these change in response to external conditions. The second major approach, which has characterized the work of social anthropologists in particular, views the community as a microcosm of the larger social system. Each community is describ'ed and analyzed in terms of all of the structural and functional features of the larger society since it is viewed as a territorial microcosm of the larger society. Each community thus is viewed as having a stratification system, a power structure: educational, religious. economic and political subsystems and so on. The community viewed as an aspect of structure of all social systems is a third major approach to community study. Populations are investigated in relation to their territorial location with special reference to the social relations that arise between them as a result of territorial location. Sociologists who follow this approach hold that a community system differs from other systems in that locality is a datum in the integration of the system.

When the field of urban sociology emerged within the discipline of sociology, it began as a perspective for viewing all aspects of social life. The city was not only a distinct way of life or form of community but a social laboratory within which all aspects of social life could be examined. With the view that the city was a social laboratory for the investigation of human behaviour. many investigations were carried out within the context of an urban community and the conclusions were thought of as referring to urban phenomena only because of the urban locus. As the field of urban sociology develops, this point of view gradually is being replaced by one based on a comparative sociology of the community.

As these changes occur, many of the problems that were first treated within an urban or rural sociological framework now have emerged as separate fields apart from the discipline of urban sociology. Among these are the fields of social stratification. industrial sociology and human ecology. With the continued emergence of new sociological fields, much of what was traditionally treated within the discipline of urban sociology no longer is rationally included within it.

URBINO, a city of Marche (Urvinum Metaurense), Italy. Pop. (1951) 6.503. It is picturesquely situated on an abrupt hill 1.480 ft. above sea level: its streets are narrow and crooked, and the town has a medieval aspect. It is dominated by the ducal palace erected by Luciano da Laurana, a Dalmatian architect, in 1465–82, for Federigo da Montefeltro (well represented in a picture by Justus of Ghent in the gallery), and regarded by the contemporaries of the founder as the ideal of a princely residence. The monumental staircase. sculptured doorways, chimneys and friezes of the interior are especially fine. Some are by Domenico Rosselli of Florence. The rich intarsia work of the duke's study is by Baccio Pontelli. In the cathedral there is a Pietà in marble by Giovanni da Bologna. Opposite the palace is the church of S. Domenico. a Gothic building with a good early Renaissance portal and a relief in the lunette by Luca della Robbia (1419). S. Francesco has a fine 14th-century portico and campanile. and a handsome portal of a chapel in the interior by Constantino Trappola (15th century). S. Bernardino, outside the town. is a plain early Renaissance structure. On the walls of the chapel of San Giovanni Rattista are frescoes by Lorenzo and Giacomo Salimbeni da San Severino (1416).

The modest house where Raphael was born and spent his boyhood forms a museum of engravings and other records of Raphael's works. A monument was erected to him in the piazza in 1897. The theatre, decorated by Girolamo Genga, is one of the earliest in Italy: in it was performed the first Italian comedy, the *Calandra* of Cardinal Bibbiena, the friend of Leo X and Raphael. The magnificent library formed by the Montefeltro and Della Rovere dukes was incorporated in the Vatican library in 1657. There is a free university founded in 1506.

The ancient town of Urvinum Metaurense takes its name from the Metaurus river. The walls can be traced. It was important in the Gothic wars, and is mentioned by Procopius. About the end of the 12th century Urbino came under the rule of the family of Montefeltro, and especially of Federigo da Montefeltro, lord of Urbino from 1444 to 1482, who was an unusually enthusiastic patron of art and literature. Federigo da Montefeltro much strengthened his position by his own marriage with Battista Sforza, and by marrying his daughter to Giovanni della Rovere, the favourite nephew of Pope Sixtus IV, who conferred upon Federigo the title of duke. Federigo's only son Guidobaldo, who succeeded his father, married in 1489 the gifted Elizabeth Gonzaga of Mantua. Guidobaldo in 1508 bequeathed his coronet to Francesco Maria della Rovere, nephew of Julius II. In 1626 the last descendant of Francesco, Francesco Maria II, abdicated in favour of Pope Urban VIII. and Urbino. with its subject towns, which included Pesaro, Fano. Fossombrone. Gubbio. Castel Durante and Cagli together with outlying small villages, about 300 in number, became incorporated in the domain of the Papal states.

During the reigns of Federigo and Guidobaldo. Urbino mas one of the foremost centres of activity in art and literature in Italy. There Piero della Francesca wrote his celebrated work on the science of perspective. Francesco di Giorgio Martini his *Trattato d' architettura* and Gicvanni Santi his poetical account of the chief artists of his time.

Throughout the 16th century the state of Urbino manufactured majolica, especially at Gubbio and Castel Durante. The finest pieces were made for the dukes. Famous citizens include the Ferrarese painter and friend of Raphael, Tirnoteo della Vite. and Bramante (*q.v.*). This city was also the birthplace of Pope Clement XI, of several cardinals of the Albani family, and of Raffaelle Fabretti. and other scholars.

URDŪ. The constitution of Pakistan (article 214) designated Urdū and the Bengali language (*q.v.*) the official languages of the state. The 1951 Pakistani census reported almost 5,500.000 persons giving Urdū as their mother tongue; the Indian census (1951) recorded 13,500,000

Like Western Hindi Urdū is an Indo-Aryan dialect of the middle and upper Gangetic Doab and the country to the north and south Cultivated by Moslems. Urdū in the course of time, depended more and more on Persian as a source of new vocabulary and idiom It is, therefore an Indian language written in Persian script with a partly Persian vocabulary and (to a lesser extent) grammar As contrasted with Hindi (*q.v*) which drew its inspiration from Sanskrit and Hindu culture. Urdū looked to Persian literature for motifs and forms and to the Islamic faith for its inspiration The two dialects in their literary stages — Urdu, with its extreme Persianization and Hindi, with its Sanskritization— are almost mutually unintelligible.

Urdū prose was little cultivated before the 18th century; in poetry Amir Khusru (d 1325), who flourished in the courts of Delhi. came first. Then poetic development nas associated with the Moslem courts of Bijapur and Golconda of the Deccan, *c.* 1575–1700. and especially with the art of Wali (1668–1744) at Delhi There the language was refined by a gradual introduction of Persian figures of speech and themes and by the adoption of models based strictly on the canons of Persian poetry At the end of the 18th century, the ebbing fortunes of the Delhi kings forced the poets who were dependent on court patronage, to seek the protection of the Nanabs of Lucknow where they flourished until the middle of the 19th century.

Urdu prose was developed in the program of instruction at the College of Fort William (Calcutta) at the beginning of the 19th century Among those who contributed to it are the famed poet Ghalib (1797–1869) and the founder of Aligarh university. Ahmed Khan (1817–98). Prem Chand (1880–1936) is the only author to have gained fame for his writings both in Hindi and in Urdū

UREA (CARBAMIDE), a colourless crystalline substance, is the chief nitrogenous end product of the metabolism of proteins (*q.v.*) in all mammals and some fishes. This material occurs not only in the urine of mammals but also in their blood, bile, milk, perspiration. aqueous humor of the eye and other body fluids, Moreover, it has been recognized in many lower forms of animal life and has been identified in certain plants and in fungi and molds. Commercially, urea is of great importance as a fertilizer and as a livestock feed supplement; large quantities are used in the production of plastics and pharmaceuticals.

In 1773 H. M. Rouelle obtained, by alcoholic extraction of the solid residue from evaporated urine, an alkaline nitrogenous substance which on bacterial fermentation yielded carbonic acid and ammonia. Subsequently Antoine F. Fourcroy and Louis N. Vauquelin (1798) prepared urea nitrate from urine, and the isolation of pure urea from this same source was first accomplished by Joseph L. Proust in 1821. Friedrich Wöhler in 1828 discovered the artificial formation of urea from ammonia and cyanic acid.

Physical and Chemical Properties. — Urea crystallizes in long rhonibic needles or short prisms having a cooling, saline taste. It is readily soluble in water. methyl alcohol and ethyl alcohol but not in ether or in hydrocarbons. It melts without decomposition at 132.7" C. (270.9" F.) and sublimes in a vacuum at temperatures just below and up to its melting point. Heating to higher temperatures causes decomposition

Crea is the diamide of carbonic acid (see AMIDES), hence the alternative name "carbamide" The chemical formula $NH_2.CO.NH_2$ originally given to urea. does not explain its behaviour under all circumstances, and many others have been proposed. The view has become generally accepted that urea is a resonance hybrid. receiving contributions from the structure given above and also from the two further structures $\overset{+}{N}H_2{=}C\bar{O}{-}NH_2$ and $\overset{+}{N}H_2{-}C\bar{O}{=}NH_2$. For reasons of convenience, however. the formula is most commonly nritten in its original form, $NH_2.CO.NH_2$. and resonance with the remaining two structures is left implicit.

The above-mentioned method of Wohler for the synthesis of urea consists essentially in the isomerization of ammonium cyanate, NH_4NCO, to urea. $NH_2.CO.NH_2$. This process, however, is a reversible one and the relative amounts of cyanate and urea depend on reaction conditions.

When urea is heated above its melting point it decomposes at first to yield ammonia. ammonium cyanate and biuret and, at higher temperatures, cyanuric acid and ammelide. At elevated temperatures under pressure melamine, ammonia and carbon dioxide are produced. When aqueous solutions of urea are boiled the compound is partially converted to ammonium cyanate, which in turn is hydrolyzed to ammonia and carbon dioxide. Heating such a solution in a sealed tube at 180° C. brings about complete decomposition.

Dilute aqueous solutions of acids and alkalis have no action on urea when cold but when heated break it down to ammonia and carbon dioxide. Strong acids yield salts, such as urea nitrate.

Although urea reacts with alcohols to form urethanes (carbamic esters) with certain glycols to produce cyclic-substituted ureas, and with many aldehydes, ketones, anhydrides and other organic compounds. its most important reactions are with formaldehyde to form methylolureas and with malonic acid derivatives to form malonylurea or barbituric acid derivatives.

Urea forms crystalline addition compounds with straight-chain aliphatic hydrocarbons containing more than six carbon atoms and with their derivatives.

The enzyme urease, obtainable from the soybean and the jack bean (*Canavalia* ensiformis). brings about the rapid hydrolysis of urea. This action serves as a convenient method for the determination of urea. Other methods sometimes used are the Kjeldahl, the hypobromite and the xanthhydrol.

Commercial Manufacture of Urea.—Many ways have been found to synthesize urea in the laboratory but only: (1) the hydrolysis of cyanamide, and (2) the reaction of ammonia and carbon dioxide, have been used industrially. Method (1) was never employed extensively and since 1936 only method (2) has been in commercial use. In this method carbon dioxide and ammonia are continuously injected into a reaction vessel maintained at temperatures up to about 200° C. and pressures up to about 5,000 lb. per square inch. Solid urea is separated from the reaction vessel effluent which contains, besides urea, water and unreacted ammonia and carbon dioxide. The commercial importance of urea increased tremendously, and by mid-20th century world production exceeded 1,000,000 tons per year.

Industrial Uses of Urea.—Urea contains 46.7% of combined nitrogen in a form which is easily and rapidly converted to ammonia in the soil; therefore, it is a much more concentrated nitrogenous fertilizer than ammonium nitrate, ammonium sulfate or sodium nitrate. Moreover, modern manufacturing methods have made it possible to deliver urea to the consumer at nearly the same cost per unit of nitrogen as the other nitrogen-containing fertilizer materials. It may be used as an ingredient in the manufacture of mixed fertilizers, applied to the land alone as a nitrogenous fertilizer or applied to plants as foliage sprays for direct feeding of the leaves by absorption. (See FERTILIZERS AND MANURES.)

By the reaction of urea with formaldehyde under carefully controlled conditions. methylene-urea fertilizers can be made which release adequate nitrogen for plant growth continuously and uniformly throughout the entire growing season. With these a full year's nitrogen supply may be safely applied at one time to turf grass, ornamentals and other long-season crops.

Although the nitrogen in urea is in nonprotein form, if urea is fed to a ruminant animal along with fermentable carbohydrate material the microorganisms in the rumen build its nitrogen into proteins which can be used by the animal through action in the lower digestive tract. Experience has shown that the grain ration fed to the animal must not contain more than 3% urea. Even so, a significant part of the protein requirement can be supplied through the use of urea. During World War II, when protein feeds were scarce, this use became important and afterward increased steadily. Urea cannot be utilized by nonruminant animals such as horses, swine and poultry.

Urea is not poisonous, or, as pharmacologists prefer to say, it is practically nontoxic. However, it has little direct use in internal medicine. Formerly it was used as a diuretic and in the treatment of certain stubborn types of suppurating infections. Urea dissolves dead tissue in which bacteria thrive, and in the resulting clean wound the living cells can successfully combat bacterial invasion so that healing proceeds rapidly.

Large amounts of urea are used by the pharmaceutical industry in the production of malonylurea and barbituric acid derivatives. Over 400 of these derivatives are known and some are commonly used as soporifics and sedatives under a variety of trade names.

The most important use of urea other than as fertilizer is in the production of urea-formaldehyde resins. (See RESINS: Synthetic Resins.) The primary reaction of formaldehyde and urea is the formation of water-soluble methylolurea. Application of heat or catalyst, or both, causes further reaction of methylolurea with itself, and a hard: insoluble, infusible resin is finally obtained. Urea-formaldehyde resins are widely used as adhesives for plywood, composition board and other materials; in molded articles; as shrink- and crease-proofing agents for cotton and rayon fabrics; for imparting wet strength to paper; in lacquers and enamels; and in the impregnation of paper and fabrics laminates, etc. Urea reacts with other aldehydes, but the resinous products obtained are not so useful as those made with formaldehyde.

Some of the many other uses for urea are as a softener for glassine paper and similar products, as a solubilizing agent for starch glues and sizes, as a textile-treating agent, as an ingredient in bindery pastes and latex paints: in the seasoning and bending of wood, as a stabilizer for certain explosives and in the refining of petroleum hydrocarbons. It is also an intermediate in the preparation of chemical compounds, pigments and insecticides.

Thiourea.—The sulfur analogue of urea. $NH_2.CS.NH_2$, is manufactured on a limited scale for employment in photography, synthetic resins, insecticides, pharmaceuticals and textile-treating agents, and as a starting material for various dyestuffs. It may be prepared: (1) by heating ammonium thiocyanate at 160°–170° C.; and (2) by the reaction of hydrogen sulfide with cyanamide. Thiourea crystallizes from water in colourless, six-sided prisms or silky needles melting at 180°–182° C.

(J. S. BY.)

UREMIA, a term coined in 1840 by Piorry and l'Heritier to designate the disease state associated with inadequate functioning of the kidneys. Etymologically, "uremia" would indicate the presence of urine in the blood, but the term is used to describe the clinical aggregate of symptoms, signs and chemical alterations associated with failure of the kidneys to perform their normal excretory function. Uremia is an imprecise term in that it does not designate any particular one of these abnormalities nor any specific combination of them. In the healthy kidney. urine is derived from blood by ultra-iiltration (removal of fat, protein and particulate elementsj followed by selective reabsorption of components of the filtrate. In addition, certain other compounds are added to the filtrate. The net result of these processes is urine, an aqueous solution of variable composition and concentration, containing organic and inorganic compounds. It is preferable not to regard urine as "waste" in the usual sense of the word, but to consider the entire complex process of urine formation as serving to regulate the composition, concentration and volume of blood and the internal aqueous environment of the body. When this function of the kidney is impaired by disease, various abnormalities in the chemical organization of body fluids result and may lead to malfunction of many organs and organ systems. The clinical manifestations of the uremic syndrome are therefore protean and variable. Practically always there is an elel-ation in the concentration of nonprotein nitrogenous constituents of blood. Other frequently occurring findings include nausea, itching, anemia, hypertension, acidosis and derangements of calcium and phosphorous metabolism.

See Stanley E. Bradley, ***The** Pathologic Physiology of Uremia in Chronic Bright's Disease (1948).* (T. N. P.)

URETHAN, the name applied to the esters of carbamic acid and more specifically to ethyl carbamate. Urethan has sedative and hypnotic properties, which were the bases for its former use in medicine. It is often used as an anesthetic in animals, acting rapidly to produce a calm sleep without depressing the physiological reflexes or the circulation. Urethan also acts on the chromosomes to produce disturbances in cell division. The principal result of this action in man and animals is a decrease in the white-cell count of the blood, which is the basis for the use of urethan in the treatment of certain forms of leukemia. It may be prepared from ethyl chlorocarbonate and ammonia, from carbamyl chloride and alcohol, by the treatment of urea with alcohol under pressure or by the action of warm alcohol on urea nitrate with the addition of sodium nitrite. It is a stable crystalline compound, readily soluble in water and melting at 49°–50° C. (V. E.)

UREY, HAROLD CLAYTON (1893–), U.S. chemist, who was awarded the 1934 Nobel prize in chemistry for his discovery of the heavy hydrogen isotope of mass two (deuterium), was born in Walkerton, Ind., April 29, 1893. After receiving his early education in rural schools, he taught in them from 1911 to 1914. He then entered Montana State university, Missoula, and received the B.S. degree in 1917, with major interests in zoology and chemistry.

After spending two years as a research chemist in industry and two years as an instructor at Montana university, he attended the University of California, Berkeley, where he was granted, the Ph.D. degree in chemistry in 1923. He was next an American-Scandinavian foundation fellow with Niels Bohr at Copenhagen, Den. (1923–24), associate in chemistry at Johns Hopkins university (1924–29), Baltimore, Md., and a member of the department of chemistry at Columbia university (1929–45). In 1945 he joined the newly formed Institute for Nuclear Studies and the department of chemistry of The University of Chicago.

After his discovery of deuterium, Urey worked out procedures for the separation of heavy isotopes of carbon, oxygen, nitrogen and sulfur. During World War II he was director of research of the Substitute Alloy Materials laboratories, Columbia university, which became a part of the Manhattan Engineers District program for the development of the atomic bomb. Urey's group provided the fundamental information for the separation of the fissionable isotope, uranium-235, from the more abundant isotope, uranium-238, by gaseous diffusion, and investigated methods for the concentration of the heavy isotope of hydrogen and for the separation of the boron isotopes. After the war he developed methods for measuring temperatures as they existed in oceans of past geological ages and also a theory for the origin of the earth, particularly its chemical aspects *(The Planets,* 1952). (W. C. J.; X.)

URFA, the chief town of a *vilayet* of the same name in southeastern Turkey, lies at the northwestern corner of the well-watered, fertile plain of Haran, controlling a historical road from Anatolia to northern Mesopotamia. Pop. (1955) 48,013. A limestone hill! on which stand the ruins of the ancient citadel, overlooks the modern town which lies spread out below. It is the centre of a rich agricultural area and a market for animal products (especially butter and wool) and wheat.

The town has a history of great antiquity, extending perhaps to the first part of the 2nd millennium B.C., and was named Edessa by the Macedonian conquerors. Through the centuries it suffered many changes of ownership, including occupation by the Crusaders in 1098, and saw many armies pass along the east-west road in victory or defeat until it was finally annexed to the Ottoman empire in 1637.

The *vilayet* of Urfa is bounded on the south by Syria, on the west by the upper reaches of the Euphrates, and is separated from Diyarbakir *vilayet* on the east by Karaca Dag (6,295 ft.). It consists mainly of a barren limestone plateau with scanty water resources. The climate is dry and the summers hot (average July temperature in the town 90° F.). Pop. (1955) 347,712; area 7,502 sq.mi. Its chief economic activity is stockraising, though agriculture is important in the irrigated Haran plain. The main exports are butter and wool. The other principal towns are Birecik, Siverek and Hilvan. (For ancient and medieval history *see* EDESSA; OSROENE.) (N. Tu.; S. Er.; E. Tu.)

URFE, HONORE D', MARQUIS DE VALBROMEY, COMTE DE CHÂTEAUNEUF (1568–1625), French novelist and miscellaneous writer, was born at Marseilles on Feb. 11, 1568, and was educated at the Collège de Tsarnon. A partisan of the league, he was taken prisoner in 1595, and, though soon set at liberty, he was again captured and imprisoned. During his imprisonment he read Ronsard, Petrarch and above all the *Diana enamorada* of George de Montemayor and Tasso's *Aminta.* Here, too, he wrote the *Epîtres morales* (1598). Honoré's brother Anne, comte d'Urfé, had married in 1571 Diane de Châteaumorand, but the marriage was annulled in 1598 by Clement VIII. Anne d'Urfé was ordained to the priesthood in 1603, and died in 1621 dean of Montbrison. Diane had a great fortune, and to avoid the alienation of the money from the D'Urfé family, Honoré married her in 1600. This marriage also proved unhappy; D'Urfé spent most of his time separated from his wife at the court of Savoy.

In Savoy he conceived the plan of his novel *Astrke,* the scene of which is laid on the banks of the Lignon in his native province of Forez. It is a leisurely romance in which the loves of Céladon and Astrée are told with digressions. Some episodes suggest the adventures of Henry IV. The two first parts of *Astrée* appeared in 1610, the third in 1619, and in 1627 the fourth part was edited and a fifth added by D'Urfé's secretary Balthazar Baro. *Astrde* set the 'fashion temporarily in the drama as in romance, and no tragedy was complete without elaborate discussions on love in the manner of Céladon and Astrée. D'Urfé also wrote two poems, *La Sireine* (1611) and *Sylvanire* (1625). He died from injuries received by a fall from his horse at Villafranca on June 1, 1625, during a campaign against the Spaniards.

URGA: *see* ULAN BATOR.

URI, one of the cantons of central Switzerland. The name is popularly derived from *urochs* or *auerochs* (wild bull), a bull's head having been borne for ages as the arms of the region.

The total area is 415 sq.mi., of which only approximately half (the lowest proportion in the confederation) is reckoned as "productive" (forests covering 48 sq.mi.), while $7\frac{1}{2}$ sq.mi. are occupied by a part of the Lake of Lucerne and more than 20% of the unproductive area is covered with glaciers. The highest summit in the Uri is the Damma Stock (11,909 ft.), north of the Furka pass. Little of the land is capable of further cultivation, for Uri is composed of the torrent section of the upper Reuss, draining, with its tributaries, steep-sided valleys. The chief railway is the main St. Gotthard line. Near Wassen are the remarkable looped and spiral tunnels. There is also an electric railway from Altdorf to its port, Flüelen. Communication is largely by the excellently planned roads which lead to the mountain passes; these give access to the cantons lying east and south; *e.g.,* Glarus (the Klausen pass, 6,391 ft.), the Grisons (Oberalp pass, 6,706 ft.), the Valais (Furka pass, 7,976 ft.).

In 1950 the aggregate population was 28,556 (69 to 1 sq.mi.). Of the 1930 population of 22,968, 22,249 were German-speaking, 594 Italian-speaking and 62 French-speaking, while 21,674 were Catholics, 1,251 Protestants and 2 were Jews. After 1814 Uri was administered by the bishop of Coire; previously all the canton except Andermatt (Urseren) was in the diocese of Constance. The capital and largest town is Altdorf (pop. 6,576 in 1950), indissolubly connected with the legend of William Tell (*q.v.*).

Uri was organized as an administrative district containing 20 communes. The legislature until 1928 was a primitive democratic assembly (*Landsgemeinde*) composed of all male citizens of 20 years of age and over. This assembly had met, uninterruptedly, since 1309, usually once annually, near Altdorf. The procedure was controlled by many antique ceremonies. After 1928 there was an elected legislature of 49 members. *(See* SWITZERLAND: *Government.)*

History.—Uri is first mentioned in 732 as the place of banishment of Eto, the abbot of Reichenau, by the duke of Alamannia. In 853 it was given by Louis the German to the nunnery (*Frauenmünster*) at Zürich which he had just founded, and of which his daughter. Hildegard, was the first abbess. As early as 1243 Uri had a common seal, and in the confirmation of its privileges (1274) granted by Rudolf of Habsburg mention is made of its "headman" (Amman) and of the "commune" (*universitas*).

It took part, with Schwyz and Unterwalden, in founding the "Everlasting league" (*q.v.*) on Aug. 1, 1291, defending its liberty in the fight of Morgarten (1315) and renewing the League of the Three at Brunnen (1315). It took part in the victory of Sempach (1386), and (1512) the conquest of Lugano. At the Reformation Uri clung to the old faith.

In 1798, on the formation of the Helvetic republic, Uri became part of the huge canton of the Waldstatten and lost all its Italian possessions. In 1803 Uri became an independent canton again, with Ursern. but without the Val Leventina. It tried hard to bring back the old state of things in 1814–15, and opposed all attempts at reform, joining the League of Sarnen in 1832 to maintain the pact of 181j. opposing the proposed revision of the pact, and being one of the members of the Sonderbund in 1845. (See SWITZERLAND: History.)

URIBURU, JOSÉ EVARISTO (1831–1914), Argentine statesman and president, was born in Salta on Nov. 19, 1831, into a family prominent in the war of independence against Spain. After taking his doctor's degree in jurisprudence in 1854, he entered public life. He served in various political positions and held important diplomatic posts in several South American countries. He became minister to Chile in 1883, and in that post he helped mediate the dispute at the end of the War of the Pacific, which Chile had waged against Bolivia and Peru. In 1892 Uriburu was elected vice-president of Argentina; he succeeded to the presidency after Luis Sáenz Peña resigned on Jan. 23. 1895. During Uriburu's term he reorganized the armed forces and made reforms in public finance so that Argentina could resume payment on the public debt. He continued peaceful relations with Chile during the serious boundary dispute with that country. He retired from the presidency in 1898. but served as interim president in 1903. He was senator in the national congress from 1901 to 1910. He died in Buenos Aires on Oct. 23, 1914. His son JosC Evaristo Uriburu (1880–19j6), historian and diplomat. served as minister (1921–27) and ambassador (1927–31) to Great Britain.

URIBURU, JOSÉ FRANCISCO (1868–1932), Argentine army officer and political leader, a nephew of Pres. JosC Evaristo Uriburu (*q.v.*), was born in Salta on July 20, 1868. He graduated from the military college of Argentina in 1888, and spent more than 40 years in army service. He served as military attaché in Madrid. London and Berlin; in 1902 he was a member of the Argentine-Chilean boundary commission. Uriburu retired from the army in 1929. In 1930 during the economic depression he led an army revolt against the Radical leader, Pres. Hipólito Irigoyen. Uriburu became provisional president on Sept. 8, 1930, and set up a government dominated by the wealthy and conservative classes. After governing by decree for a year he permitted new elections to be held on Nov. 8. 1931; he refused to seek election but he made it plain that he would never permit the Irigoyen wing of the Radical party to return to power. The successful candidate was Gen, Agustin P. Justo. who had participated in the military coup of 1930, and who had the support of the government in the election. After the inauguration of Justo on Feb. 20, 1932, Uriburu went to Paris to seek medical treatment. He died in Paris on April 29. 1932.

URIC ACID, in organic chemistry, an acid which is one of the penultimate products of the tissue-waste in the human body. (See PURINES.)

While the bulk of the nitrogen of the albuminoids is excreted by kidneys and bladder as urea (*q.v.*), a small portion of it stops at the uric acid stage. Human urine contains only a fraction of a per cent of the acid, chiefly as sodium salt; an abundance of uric acid is met with in the excrement of serpents and birds, in which it is the principal nitrogenous product of tissue waste. Pure uric acid. $C_5H_4N_4O_3$, forms a snow-white microcrystalline powder devoid of smell or taste.

URICONIUM (more correctly VIROCONIUM or VRICONIUM), chief town, as proved by an inscription, of the Cornovii, now Wroxeter on the Severn, j mi. E. of Shrewsbury. At first perhaps (47–65) it was a Roman legionary fortress, held by the 14th and 20th legions against the Welsh hill tribes. When the garrison was removed, it became a flourishing town with public baths (excavated 1859–61), town hall and market (excavated 1924–27).

Studies*, xii, 252, xiv, 226, xv, 228, xvi, 224, xvii (1923–27); *Classical Review*, pp. 146 *et seq.* (1924), p. 10 *seq.* (1928).

URIM AND THUMMIM (Heb. *'ūrim*, tummim), means employed by the Hebrews in divination, but their identity and use are obscure. In I Sam. xxviii. 3–6, they are listed with dreams and prophets as a means of divine communication. From I Sam. xiv, 41 (Greek text), it would appear that lots were cast by their means. Hence the common explanation of them as stones or sacred dice. Ex. xxviii, 30, and Lev. viii, 8, make it clear that they were put in the "breastplate of judgment," and were not the precious stones attached to it as some, including Josephus, have conjectured. Others, basing on the root meanings of the words, would interpret them as symbols of abstract ideas, "revelation and truth" (Greek text), "perfection and doctrine" (Latin), and similarly Philo, the Talmud, etc. Others have sought, unsuccessfully, association with Egyptian deities, Ra and Tme, or with the Babylonian god Marduk's "tablets of destiny."

It is probable, however, that the solution lies elsewhere. The initial letter of 'urim is '(aleph), the first letter of the Hebrew alphabet, and that of Tummim, the tav, the final letter. Hebrew letters were used also for numbers and " 'urim and Tummim" could have been the expression for the 22 letters, odd and even. more particularly when used as numbers. The terms have, indeed, survived in the root elements of the Greek 'arithmos, "number," derivation otherwise unknown. The letters of the alphabet were thus put into the "breastplate of judgment" and would be affected by the Shekinah (*q.v.*), which rested on the high priest. The high priest would extract letters to be treated either as numbers, odd or even. or as alphabetic letters to form words.

According to rabbinic tradition. the 'urim and Tummim were among the five things lacking in the Second Temple.

See articles in Bible dictionaries by various scholars; also articles by W. Muss-Arnolt and L. Blau in *The Jewish Encyclopedia*, 12 vol. (1901–16), and particularly that by E. Kautzsch in *The New Schaff-Herzog Encyclopedia of Religious Knowledge*, 12 vol. (1908–12).

(E. Ro.)

URINARY SYSTEM. The urinary system in adult man, as in other mammals, consists of the two kidneys, the two ureters, the urinary bladder and the urethra.

The kidneys are the organs wherein the excretory fluid, the urine, is manufactured (see EXCRETION [KIDNEY]). The production of urine is continuous, so that it is constantly flowing from each kidney into its effluent duct, the ureter. The ureters transport urine into a single commodious expansile receptacle, the urinary bladder, where the urine is stored. In the process of voiding (micturition. urination), the bladder empties itself by a series of interrelated activities largely under voluntary control, and the emptying process results in rapid transport of urine from the bladder through a passageway to the exterior of the body. This final pathway, which in the male is also intimately related to the reproductive system. is known as the urethra.

Kidneys. — The kidneys are two firm reddish-brown organs with a characteristic "kidney bean" shape. Each measures four to five inches in length, two to three inches in breadth and about one inch in thickness. The combined weight of the two kidneys in relation to body weight in humans is about 1 to 240; hence, the two weigh less than a pound. They lie on either side of the spine behind most of the other abdominal organs. The right kidney is located somewhat lower than is the left, as if to accommodate the great bulk of the liver, which monopolizes the right upper quadrant of abdominal space. Both kidneys extend upward high enough to overlap with the lowest ribs, and each is capped by another important organ, the adrenal gland. The kidney is surrounded by a considerable padding of fatty connective tissue which cushions it from the body wall behind and the intestines in front. It is indented at its medial

FIG. 1.— SECTION OF KIDNEY SHOWING PARENCHYMA

margin (the hilum), which faces somewhat forward because of the sloping declivity of the posterior body wall. The organ is provided with a thin tough fibrous capsule which continues inwardly at the hilum and outlines within a potential space called the renal sinus. The fibrous capsule thereby forms a ringlike mouth at the hilum and an expanded sac inside.

Traversing the ringlike mouth and the renal sinus are the renal artery, the renal vein and the ureter. As a rule, the vein lies in front, the artery intermediate and the ureter behind and below. The ureter is expanded within the renal sinus as the renal pelvis, which in turn sprouts smaller conduits, the renal calyxes. These structures are illustrated in fig. 1, which shows how the calyxes are attached to the kidney substance. Each minor calyx fits around the apex of a pyramidal structure, the renal pyramid, which carries kidney ducts to it. Each pyramid, in turn, is the site of joining of many smaller kidney ducts which ultimately converge upon its apex (the papilla) to deliver urine into the calyxes and pelvis. The pyramids are separated from each other and from the exterior of the kidney by tissue which contains the beginning of the urinary pathway. The pathway commences at the glomerulus, which is a tuft of anastomosing arterial capillaries; each glomerulus is associated with the first part of a duct system. Although the glomeruli are located outside the pyramids (in the "cortical zone" and "cortical column" of fig. 1), their ductile continuities ultimately become incorporated into the pyramidal substance and lead successively to the calyxes, the pelvis and finally to the ureter.

Ureter, Bladder and Urethra. — The ureter or duct of the kidney begins at the hilum, descends on the back wall of the abdominal cavity, passes over the pelvic brim and opens into the urinary bladder. It is about one foot long and has a thick contractile wall. It varies considerably in calibre at different points throughout its extent. At its termination the ureter passes obliquely through the bladder wall so that, as the bladder fills, this terminal part tends to close.

The urinary bladder is a musculomembranous bag situated in the pelvic cavity. It lies in front of the rectum, from which it is separated in the female by the uterus. The bladder is capable of considerable distention, although usually it is emptied periodically when its volume reaches ten ounces or so. In distention the bladder wall may rise above the pelvic brim and become pressed against the front wall of the abdomen. In the interior of the bladder is a triangular area (the trigone) the two upper angles of which represent the openings of the ureters, while its lower mid-line angle presents the exit into the urethra. The urethral exit is kept closed by the action of a circular muscular valve except during the process of voiding. The bladder is emptied by contraction of the muscles of its wall and the relaxation of this circular valve. Physiologically the process of voiding is a somewhat complicated one involving the integration of several activities co-ordinated by the nervous system.

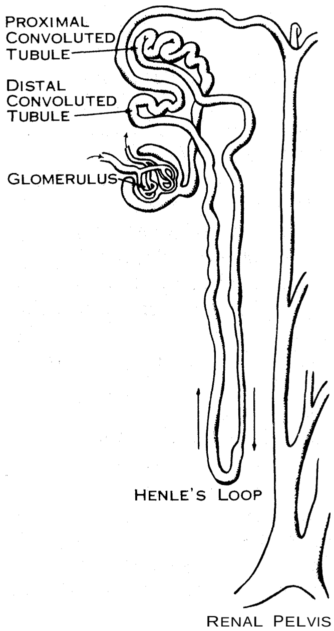
The urethra of the male consists of three parts, the first of which passes through the prostate gland and receives ducts from the testes (the ejaculatory ducts). This part lies above the pelvic floor (pelvic diaphragm). The second part of the urethra passes through the pelvic diaphragm and the third part traverses the length of the penis. In the male, then, the structure of the urethra is such that it serves as a final common pathway both for the urine and the reproductive secretions. The urethra in the female is much shorter than in the male. being about $1\frac{1}{2}$ in. in length and corresponding to that part of the male urethra which is above the point of entrance of the ejaculatory ducts. The female urethra also passes through the pelvic diaphragm and opens into the vestibule of the vagina, which latter receives the vaginal canal into its posterior aspect.

Embryology.—The development of the urinary system is a story of great fascination, since not one but three sets of kidneys are elaborated in each man's life history. These three sets correspond to three kidney types found at successive levels in the vertebrate hierarchy and hence are regarded as recapitulations of the evolutionary history of this organ. The first kidney to develop, the pronephros (head kidney), represents the adult kidney in primitive vertebrates such as the lamprey and hag. In bony fishes and amphibians a pronephros also develops, but it is superseded by a second organ, the mesonephros (middle kidney). Reptiles, birds and mammals have still a third kidney, the metanephros (hind kidney); but the older kidneys still spring up in the course of individual development in a remarkable series of events. which combines growth, regression and transformation, related not only to the development of the permanent kidney itself but to other parts of the body.

In man the pronephros appears very early in embryonic life and disappears quickly; its existence as a functional organ seems doubtful. It consists of a series of tubules connecting the embryonic body cavity (coelom) to a duct. Although the tubules fade away almost as soon as they are formed, the duct is more sturdy and extends downward to receive the tubules of the second kidney and, indeed, to become the mesonephric duct proper.

The mesonephros or middle kidney becomes a well-defined structure in the prenatal human and is related importantly both to the final kidney and to the reproductive system, particularly in the male. The mesonephric duct empties into the cloaca, the common lower terminus of the urogenital and digestive systems, which in turn is split into a front part, the urogenital sinus, and a back part which forms the lower digestive tract. In the partitioning of the cloaca, the mesonephric ducts retain their connections with the front part, and thus remain in contact with the lower part of the urogenital system, rather than with the digestive system.

The metanephros begins as an outgrowth from the lower part of the mesonephric duct. This diverticulum grows and divides to become the ureter, pelvis, calyxes and collecting ducts of the kidney. The rest of the kidney (intrinsic blood vessels including the glomeruli, the upper tubules) develops from a mass of embryonal connective tissue which concentrates about the end of the outgrowing ureter and its sprouts. The tubules which differentiate from this connective-tissue mass during development form the upper part or beginning of the urinary pathway. In fig. 2 these are labeled "proximal convoluted tubule." "Henle's loop" and "distal convoluted tubule." In order for the urine, which is largely formed in this upper part of the urinary system, to flow into the lower part, it is necessary for the upper tubules to make connection with the outgrowing sprouts from the ureter. This union takes place in the upper part of the pyramids or in the extensions of the pyramids toward the kidney surface, so that millions of tiny canals are developed, each leading from a single glomerulus to larger and lower parts. Once the collecting ducts are reached, the system begins to converge until the ureter finally emerges as the single common duct for each kidney.



FROM "UROLOGY," VOL. I, EDITED BY MEREDITH CAMPBELL, 1954; BY COURTESY OF W. B. SAUNDERS CO.

FIG. 2.— DIAGRAM OF A NEPHRON

As the human kidney develops, it is distinctly lobulated, each lobe representing tissue related by drainage into a single pyramid. Certain mammalian kidneys have only a single pyramid, and hence are not lobulated.

In other mammals such as the

cattle, the bears, the seals and the whale, the fetal lobulation persists throughout life.

In man fetal lobulation is largely effaced in the process of growth and maturation, and it is usually not recognizable or becomes very indistinct in the adult.

For a while in mammalian development the ureter empties into the mesonephric duct from which it arises, and this arrangement persists in reptiles. Later on the ureters and mesonephric ducts become separated, as is the case in birds. Finally, mammals take an extra step, in that the upper part of the urogenital sinus develops into the bladder and the lower part into the urethra. In this process of differentiation the ureters establish their final continuity with the hladdcr and the mesonephric ducts become associated with the urethra.

The fate of the mesonephric ducts differs in the two sexes. In the male each duct becomes associated in its upper part with the testis. Below, the ducts retain their connection with the urethra. In consequence, the male urethra is capable of transporting urine from the bladder and sexual secretions from the testes, a dual function which is explained by its embryological history. By contrast with the sequence of events in the male subject is the behaviour of the mesonephric duct in females. Here the mesonephric duct is not appropriated by the reproductive system, but regresses almost completely, being represented in the adult only as a series of vestigial structures. The female generative tract owes much of its final form to another pair of ducts, the paramesonephric ducts. These tubes are present in both sexes in early embryonic life. They fail to develop in males, but continue to flourish in females to become the uterine tubes, the uterus and part of the vaginal canal. Like the mesonephric ducts, the paramesonephric ducts contact the urogenital sinus. Above their point of entry, the sinus differentiates into bladder and urethra; below, it becomes the vestibule of the vagina. Again, the adult relationships (urethra and vaginal canal communicating with a common lower vestibule) are explained by the developmental history of the organism. For the functions of the urinary system, and its diseases, see BLADDER AND PROSTATE, DISEASES OF; EXCRETION (KIDNEY); KIDNEY, DISEASES OF; UROLOGY.

URMIA (URUMIA), renamed Rizaiyeh, a city in the province of W. Azerbaijan in Iran, on a plain at an elevation of 4,400 ft., in 37° 34′ N., and 45° 4′ E., 1jj mi. around the lake by road via Marand and Khoi from Tabriz. The population in 1956 was 67,580, being mainly Turkish, with Armenian and Assyrian (Nestorian) minorities. The plain of Urmia is fertile. By means of irrigation cultivation, especially of fruits and tobacco, reached a high standard.

In World War I there was a wholesale exodus of Christians —said to have reached 59,000—in July 1918, during the Turkish advance after the Russian debacle; and, in the same year, there were massacres by the Turks and Kurds of two-thirds of those who remained. In 1919, the remnant of 600 Christians was transferred to Tabriz, but some survivors were repatriated by the Iranian government.

URMIA (URUMIA), **LAKE OF,** in northwestern Iran, between 37° 10′ and 38° 20′ N. and between 45° 10′ and 46° E., which takes its name (Pers. *Deryacheh i* Urmia, Turk. *Urmi göl*) from the town of Urmia, situated near its western shore, but is also known as the Deryache-yi Shahi and Shahi göl.

The limits of the lake vary much, the length (north to south) from 80 to 90 mi., the width (east to west) from 23 to 31 being greater in the season of high water in spring when the snows melt.

The mean depth of the lake is 16 ft., and its greatest depth probably does not exceed 49 feet. The lake has exhibited extraordinary changes of level, either due to a movement of the earth's crust or merely to an increase of rainfall as compared with evaporation. De Morgan gave an area of 4,000 and 6,000 sq.km. (1,544 and 2,31; sq.mi.) for low and high water respectively.

In the south is a cluster of about 50 rocky islands, the largest of which, Koyun daghi, *i.e.*, "Sheep-mountain," is 3 to 4 mi. long and has a spring of sweet water near which a few people graze their goats and sheep.

All the other islands are uninhabited. The lake is about three-fifths as salt as the Dead sea—far too salt to permit of any life, except of lower organisms.

By the U.S.S.R. treaty with Iran, of 1921, the railway from Tabriz to Julfa and branch line from Sofian to Lake Urmia and all the properties pertaining to navigation on the lake—formerly a Russian concession—were gratuitously transferred to Iran. From the port of Sharaf-Khaneh on the eastern shore of the lake a fleet of motor boats of 20–160 h.p. is operated in conjunction with the railway. The service is weekly. The lake is also navigated by clumsy craft with round bows and flat sterns carrying enormous sails. *(See* URMIA.)

URMSTON, an urban district in the Stretford parliamentary division of Lancashire, Eng., 6 mi. S.W. of Manchester. Area 7.5 sq.mi. Pop. (1951) 39,237. The district, largely residential, comprises the three townships of Urmston, the administrative, shopping and transport centre, Flixton, and Davyhulme, in the northern part of which is the Trafford Park industrial estate. Flixton house, dating from the 17th century, is used as an assembly hall and communal centre, and at Urmston a covered swimming pool was built in 1932 and a large civic hall in 1947. The district is bounded by the river Mersey on the south and the Manchester Ship canal on the west and north. Its industries, nearly all in Trafford Park, include the production of commercial and household goods, asbestos roofing sheets, pipes, railway wheels and axles and soap. There, too, large imports of heavy oil are dealt with.

URODELE, a term used for tail-bearing amphibians, salamanders and allies, belonging to the order Urodela. Some authorities prefer the later terms caudate and order Caudata. *See* CAUDATA; AMPHIBIA.

UROLOGY. Urology is the branch of medicine, chiefly surgical, that deals with diseases of two systems, the urinary tract of both sexes and the male genital tract. These genitourinary organs are the pair of adrenal glands, kidneys, ureters, bladder, urethra, penis, prostate, seminal vesicles, testes, *vas deferens* and other scrotal contents.

The specialty of urology has passed through a remarkable period characterized by invention of diagnostic and therapeutic instruments and standardization of surgical technique. For example, a cystoscope which uses a right-angle optical system can be inserted in the urethra and the inside of the hladder visualized without performing surgery. The foroblique lens system of the panrndoscope is employed to observe the entire lining of the urethra. Transurethral use of the foroblique telescope in a resectoscope permits excision of certain hladder tumours or benign enlargement of the prostate. Many bladder stones are crushed into small pieces by the transurethral use of a lithotrite and then washed out of the bladder. Instruments are available for transurethral extraction of small stones in the lower ureter. All these instruments obviate the need for major lower abdominal surgerj-. While cystoscopy is being performed, fine hollow tubes (catheters) can be inserted up the ureters to the kidneys and urine collected for study of individual renal function. As these catheters are radiopaque, an X-ray film will demonstrate not only the renal outlines but also the catheters in the ureters. If a solution containing an iodized organic compound is instilled into each kidney and an X-ray taken, the entire lining of the kidneys can be visualized (retrograde pyelography). If X-rays are taken at specific time intervals following intravenous injection of a similar compound, renal form and function can be determined without cystoscopy. X-ray films taken after presacral air insufflation can often demonstrate adrenal tumours. Through the scientific precision of these and other instruments and methods, urologic diagnosis has achieved a high degree of accuracy.

Urologic investigation necessary to determine diagnosis and plan of treatment often consists of the following: history and physical examination, urinalysis, cystoscopy and retrograde pyelograms or intravenous pyelograms and tests of renal function. Infection can be determined by microscopic examination of the urinary sediment (urinalysis) for an increase in the normal number of white blood cells; by demonstration of glitter cells or double refractile fat bodies in the urinary sediment; by Gram stain of the sediment for demonstration of nonspecific bacteria, or by Ziehl-Neelsen stain, culture or guinea pig inoculation to reveal tuberculosis bacilli. Various types of urine culture enable identification of particular organisms. A specialized staining technique (Papanicolaou) can sometimes detect malignancy of the kidney. bladder or prostate by staining exfoliated cancer cells in the urine. Detection of urinary sugar can lead to the diagnosis of diabetes mellitus. Albumin indicates renal disease but may be associated with infection of kidney, bladder or prostate, with genitourinary tumours or with functional conditions. Waxy, granular or hyaline casts in the urinary sediment may be the only sign of serious renal disease. An increase in the normal number of red blood cells may have the same significance or may stimulate an investigation for tuberculosis or tumour. Certain other studies of the urine and blood afford remarkably accurate methods for determination of kidney damage or failure.

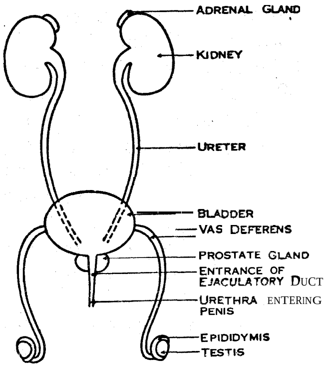

FIG. 1.— MALE GENITOURINARY SYSTEM, ANTERIOR VIEW

The functions of the kidney are (1) to filter the plasma through the glomeruli; (2) to maintain normal acid-base balance of body fluids by conserving base in the tubules; and (3) to regulate body fluids by reabsorption of water and other compounds. The kidney filters or excretes 40 to 50 g. of solids, such as urea, ammonia, uric acid: creatinine, chloride, sodium, phosphorus, potassium and calcium, per litre of urine. The filtrate formed by the glomeruli amounts to 150 to zoo 1. (about 180 qt.) per 24 hours. All this fluid volume would be urinated each day were it not for the fact that the renal tubules reabsorb about 99% of it. Urochrome is the normal urinary pigment. Function tests of glomeruli or tubules are often of great value in diagnosing urologic disease, assessing degree of renal damage and determining whether or not surgical intervention is possible or would be of help to the patient. Methods to determine renal insufficiency are based on retention of nonprotein nitrogenous waste products in the blood, evaluation of rate of excretion of these products and measurement of failure of the renal tubule to dilute or concentrate or reabsorb water.

When kidney disease becomes overwhelming, death ensues from uraemia. Uraemia is characterized most often by an increase in serum concentration of nonprotein nitrogenous waste products (urea, uric acid, creatinine); increased concentration of serum potassium: which can produce fatal cardiac disease; an increased serum phosphorus and a decreased calcium, which can produce tetany; an increase in serum chloride; acidosis; anaemia; normal, decreased (oliguric) or absent (anuric) urinary output, depending on the type of renal disease producing the uraemia.

UROLOGIC DISEASES

Congenital and Other Anomalies. — Most urologic anomalies consist in absence, underdevelopment, incomplete or complete duplication or abnormalities of position. The majority of anomalies produce no signs or symptoms and require no treatment. If symptoms are caused by urologic anomalies, it is usually because of obstruction to the conduction of urine. This in turn may produce infection and possibly stone formation proximal to the obstruction, and often requires surgical correction. A few of these abnormalities such as absence of both kidneys (but not one), are incompatible with life. In other conditions the obstruction may cause such severe destruction to the kidneys that death from uraemia ensues. Still other conditions, such as polycystic kidneys or bilateral renal hypoplasia, may be fatal to the patient by their very nature or natural course.

Kidney. — A hypoplastic or infantile kidney may be associated with hypertension (high blood pressure). Horseshoe kidneys are the commonest form of fused kidneys and consist in union of the lower pole of the kidney with its opposite mate. Surgical separation of the kidneys or partial or complete unilateral nephrectomy may be necessary. An ectopic or misplaced kidney may be found anywhere from below the location of the normal kidney to within the pelvis resting just behind the bladder. Nephroptosis is abnormal mobility of the kidney; it seldom requires treatment. Polycystic renal disease is bilateral and fatal, as the enlarging cysts destroy renal tissue and the patient dies from uraemia. It may produce hypertension.

Ureter.—Congenital ureteral obstruction can occur at the ureteropelvic junction and if untreated may destroy the kidney. Treatment consists of surgical removal of the obstruction and plastic ureteral procedures. If severe hydronephrosis exists, nephrectomy may be indicated. Ureterocele is caused by a defective union of ureter to bladder. If not treated it may produce renal damage. Treatment consists of fulguration of the ureterocele.

Bladder. — Exstrophy consists of failure of union of the anterior wall of the bladder and abdominal wall over it, with exposure and extroversion of the posterior wall of the bladder and ureter. If untreated, about 70% of those suffering from it die from renal disease before reaching 20 years of age. Treatment should be early and consists of excision of the bladder and anastomosis of ureters to the large bowel. Patent urachus represents the remains of the embryonic allantois at the dome of the bladder. It may become infected, abscessed, develop a calculus, tumour, perforation or urinary fistula and is cured hy surgical excision.

Urethra and Penis. — Phimosis exists when the opening in the redundant foreskin is too small to permit the prepuce to be drawn back over the glans. When the phimotic prepuce has been retracted in back of the glans penis and cannot be replaced, it is termed paraphimosis. Immediate reduction of paraphimosis is necessary. Treatment for both conditions is circumcision. Failure to have circumcision performed during infancy is considered an important factor in development of penile cancer. Congenital urethra1 valves can cause obstruction, abnormalities in urination, residual urine and even death from uraemia. Surgical excision of the valves should be performed. Hypospadias is caused by failure of the distal portion of the male urethra to close. As a consequcnce, voiding occurs through an opening which can be at any point throughout the length of the urethra. Surgical treatment consists of correction of chordee (angulation of the penis) and construction of a urethra from the meatus to the tip of the penis.

Hermaphroditism is another anomaly; true forms of this condition are rare, as a person of one sex usually has some features of the other sex. Treatment, if any. is directed at determination of the predominant sex. and surgical creation of structures most like that gender with excision of organs and structures of the opposite sex.

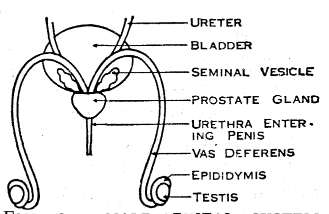

FIG 2.— MALE GENITAL SYSTEM, POSTERIOR VIEW

Testis.—Cryptorchism consists of a failure of descent of one or both testes from the retroperitoneal or inguinal areas into the scrotum. Administration of gonadotrophic hormone or, if this is unsuccessful, surgical relocation of the testes should be employed before age six, for at this time injury to the seminiferous tubules by temperature variant begins which may produce sterility. The condition rarely causes impotency. Congenital hydrocele is an accumulation of fluid around the testis usually associated with a hernia. Excision of the hydrocele sac is carried out at the time of herniorraphy.

Injuries. — Serious traumatic injuries to the genitourinary system are not common. A highly protected anatomical position (kidney, ureter, bladder, prostate) or extreme mobility (penis, scrotal contents) acts to lessen any trauma. Penetrating wounds, crush injuries or blows account lor most cases. The two most important complications are bleeding and extravasation or leakage of urine from its normal channel into the surrounding tissues. Bright red blood in the urine (haematuria) after an injury to the flank or back indicates renal injury. While surgery is seldom necessary, in rare instances excision of the kidney (nephrectomy) may be a lifesaving procedure.

Injury to the lower abdomen or perineum may cause rupture of the bladder or urethra with extravasation of urine. If extravasation caused by rupture of the bladder is not diagnosed and urinary drainage of the tissues is delayed for 48 hours, the condition is often fatal. Rupture of the bladder is usually characterized by inability to urinate. Passage of a urethral catheter to the bladder reveals no urine or a small amount of bloody urine. After injection into the bladder of a sterile radiopaque solution, anterior and oblique X-ray exposures will reveal the solution outside the bladder. Surgical exploration of the bladder and peritoneal cavity with insertion of drains is a mandatory immediate procedure.

Urethral ruptures require the insertion of a catheter into the urethra and bladder. where it is left indwelling by means of a small inflatable bag on its tip (Foley catheter). If there is oedema or swelling, indicative of a haematoma or collection of blood in the tissues of the perineum, scrotum or penis. and it is impossible to insert a catheter into the urethra to the bladder. open surgery should be performed immediately.

Urinary Tract Obstruction.—Obstruction to the outflow of urine may he present anywhere from the kidney to the tip of the urethra. Narrowing of a renal infundibulum may produce dilatation of its calyx; ureteropelvic obstruction can lead to hydronephrosis; ureteral stricture or ureterocele can produce ureteral dilatation and hydronephrosis; bladder neck obstruction of any type can cause bilateral hydronephrosis and, if severe, death from uraemia; the same may be said of urethral stricture or even of a narrow urethral meatus. If the obstruction is diagnosed in time and relieved by urinary tract drainage. much of the renal insufficiency may be reversible. The effects of obstruction may be infection, stone formation and renal damage.

The commonest obstructions are median bar or benign prostatic hypertrophy and urethral stricture. Approximately 60% of men over 50 years of age have benign enlargement of the prostate gland in the form of an encapsulated adenoma, but only about 35% of these men require surgery. The prostate surrounds the urethra at the outlet of the bladder. With enlargement, this benign tumour compresses the urethra and can produce alteration in voiding characteristics. urinary retention or renal damage. Rectal examination reveals the enlarged prostate gland. Excision of the prostatic adenoma is performed by one of four methods of "prostatectomy": suprapubic, retropubic or perineal for large adenomas, and transurethral resection for small, hypertrophied glands. The operative mortality is between 1% and 2%. Ligation of the vas *deferens* is performed. which greatly reduces the incidence of acute infection of the epididymis. Postoperatively these patients have complete urinary control and potency.

Crethral stricture may occur occasionally after prostatectomy or after severe chronic urethral infection or trauma. Gentle insertion of curved metal instruments (sounds) in the urethra establishes diagnosis and dilates the stricture.

Turnours.—Kidney.—Renal cancer of children is named Wilms's tumour, embryonal carcinosarcoma or embryoma. There is seldom haematuria or pain, but the tumour attains large size. Best results are obtained by nephrectomy and postoperative irradiation therapy. Cure rate ranges from 14% to 58%. Renal cancers of adult life may be divided into tumours of the parenchyma or renal tissue itself and tumours of the pelvis and calyces. Parenchymal tumours (hypernephroma, clear cell or Grawitz' tumour and medullary carcinoma) comprise about 90% of adult renal tumours. Haematuria is the most constant sign, but this often occurs after the development of distant metastases or spread. If no distant metastases are present, treatment consists of excision of the kidney with its surrounding fatty covering. Neoplasms of the renal pelvis or calyces comprise about 10% of adult kidney cancers. They are usually either papillary or squamous cell neoplasms. Papillary lesions tend to involve or reappear in the ureter; therefore, the ureter and cuff of the bladder as well as the kidney are excised. Cure rate is in the range of 15% to 20%.

Bladder.—Bladder tumours produce haematuria and symptoms of bladder irritation. They may be classified in three groups: Papillary tumours are benign lesions, but they eventually become malignant and are therefore resected by high-frequency electrodesiccation. Papillary carcinoma and sessile tumours are true cancers, which must be treated by (1) transurethral resection with a resectoscope and fulguration of the base; (2) implantation of radon seeds; (3) excision by open operation of the segment of the bladder containing the lesion; or (4) removal of the entire bladder (cystectomy) and anastomosis of the ureters to the large bowel or skin. Far-advanced bladder cancers can produce death from uraemia or haematuria.

Prostate Gland.—Adenocarcinoma of the prostate arises in the posterior lobe in more than 90% of cases. Early prostatic cancer presents no signs or symptoms and is detected only by the presence of a prostatic nodule on rectal examination. Treatment consists of excision of the entire prostate and seminal vesicles. Postoperatively about 5% of patients have some loss of urinary control, and nearly all are impotent. The operation offers a 38%–50% cure rate.

If the patient presents X-ray evidence of spread, or metastases, or an increase in either serum acid or alkaline phosphatase, radical surgery does not cure him; palliative endocrine therapy often lessens pain and prolongs life. Growth of the prostate is dependent on androgen, or male hormone, produced by the testes. The antiandrogenic control of prostatic cancer consists of removal of the testes (orchiectomy) and administration of female hormone (estrogen). Activity of advanced prostatic cancer may be determined by the concentrations of serum acid and alkaline phosphatase.

Testis.—The common testis cancers are teratoma, seminoma, embryonal carcinoma, chorioepithelioma and terato carcinoma. Testis cancer usually becomes apparent as a painless mass during the period of greatest endocrine activity (ages 15–35 years). Chorioepithelioma may produce gonadotrophic hormone that may be measured in the urine, and patients may have gynaecomastia. In addition to orchiectomy, lymphadenectomy should probably be used for all but chorioepithelioma and seminoma. The cure rate for chorioepithelioma is practically zero, and seminoma is sensitive to irradiation therapy and offers an excellent prognosis.

Infection.—Infection of the urinary tract is a common condition most often caused by obstruction, atony or a focus of infection from a distant organ, This infection may spread to other organs of the urinary tract; for example, a renal infection (pyelonephritis) may produce a secondary bladder infection (cystitis). Successful treatment of any urinary tract infection depends on search for and removal of the cause and on prolonged administration of the specific drug in doses sufficient to produce a high tissue level concentration.

Urine culture and sensitivity studies will determine not only the organism but also the specific drug necessary for treatment. Eighty per cent of these infections are due to Gram-negative bacteria and are treated successfully with one of the sulfonamide drugs such as gantrisin, elkosin or thiosulfil. Resistant organisms may require use of other compounds: Aerobacter *aerogenes* is frequently sensitive to achromycin (tetracycline). *Pseudomonas* aeruginosa (pyocyaneus) is often cured with terramycin (oxytetracycline). *Proteus vulgaris* responds well to furadantin. *Escher*ichia coli is best treated with either oxytetracycline or tetracycline. Sensitivity studies may indicate use of chloramphenicol (chloromycetin), streptomycin or erythromycin or methenamine (mandelamine) niandelate. Gram-positive organisms are ireated with either penicillin or sulfonamides. Mixed infections may be treated by a combination of antibiotic or chemotherapeutic drugs.

Pyelonephritis can be of an acute or chronic type. The acute type is often associated with high fever, chills, nausea and vomiting and back pain. Treatment with antibiotic drugs routinely effects a dramatic cure. Chronic pyelonephritis produces a much milder degree of the above signs and symptoms and is most difficult to cure as the aetiology is often obscure. If inadequately treated, some patients with chronic pyelonephritis develop fatal hypertension.

Renal tuberculosis is frequently characterized by gross or microscopic haematuria or symptoms of a secondary cystitis. This is a disease caused by tuberculosis infection elsewhere in the body, although the focus can be identified clinically in only 25% of patients. It is treated by nephrectomy. In cases of small unilateral lesions or bilateral involvement, treatment consists of streptomycin, isonicotinic acid hydrazide and para-aminosalicylic acid.

Cystitis is a bladder infection, usually of women or children, producing symptoms of vesical irritation. It can be caused by pyelonephritis, obstruction at the bladder neck, bladder calculus, cystocele, vaginal discharge, infected Fallopian tube, teeth, appendix or tonsils or other focus of infection.

Epididymitis is usually secondary to an infection originating in the prostate gland. It is usually nonspecific and characterized by fever, pain, swelling and tenderness of the epididymis. Administration of antibiotic drugs, elevation of the scrotum and bed rest are used as standard treatment. Tuberculosis of the epididymis can originate from renal tuberculosis or prostatitis. While surgical excision is commonly practised, use of streptomycin, isonicotinic acid hydrazide and para-aminosalicylic acid have been recommended.

Calculus Disease.—Normally, urinary colloids tend to hold urinary crystalloids in solution and prevent stone formation. A stone is formed by a nucleus composed of a mass of epithelial cells, pus cells, protein aggregate, bacteria, etc., and surrounded by many layers of organic and inorganic material. Stones are sometimes composed of a pure compound such as uric acid or cystine; others have a mixed composition such as calcium phosphate, calcium urate or calcium oxalate.

The cause of urolithiasis in humans is not well understood. Calculi can form as a result of the following conditions: urinary tract obstruction, increased activity of the parathyroid glands (hyperparathyroidism), gout, certain types of urea-splitting infections of the kidneys, prolonged immobilization as in paraplegia, defective cystine metabolism and hypercalcaemia. It is not possible to demonstrate these "known" causes of stone formation in more than 15% of patients with calculus disease. About 50% of patients with urolithiasis have infection of the urine. Fortunately, more than 90% of stones can be visualized by X-ray films.

Stones may form in the renal parenchyma (nephrocalcinosis) or renal calyx or pelvis. If a stone develops in either of the latter locations it can enter the ureter or can remain in the kidney. If it remains intrarenal it may increase in size to a remarkable degree and completely destroy the kidney without producing any marked symptomatology, or it may remain the same size. Most stones in the ureter pass into the bladder without operative intervention. Passage of a ureteral calculus may become arrested at the ureteropelvic junction, in the lower third of the ureter or at the ureterovesical junction. Because of this obstruction it may produce severe renal colic. renal damage or marked pyelonephritis. Any or all of these findings can indicate the need for surgical removal of the stone. Calculi in the lower third of the ureter can be removed frequently by plastic, nylon or metal snarelike instruments manipulated transurethrally through a cystoscope.

About 8% of patients with stones develop recurrences. In order to decrease the recurrence rate of calculi, the cause (if determined) should be removed, infection controlled and fluid intake increased. Patients with cystine or uric acid stones should be given alkalinizing agents. The use of acid or alkaline or other special diets to prevent the recurrence of calculi has proved unsatisfactory.

Most bladder calculi originate from the kidney. When a calculus passes down the ureter (4 mm. in diameter) to the bladder, it usually is expelled through the urethra (9 mm. in diameter) at once. If it remains in the bladder it can increase greatly in size over a short period of time. Small bladder calculi may be crushed transurethrally with a lithotrite and then washed out of the bladder. Large bladder calculi are usually removed by open surgery. I'atients with prostatic calculi always have infection of the prostate. It is not known whether this infection is primary or secondary to the calculi.

Infertility and Impotency.—In most cases of sterility both male and female partners should be studied. Sterility in the male may be due to loss of erections (impotency); inability to direct the ejaculate to the proper location, as in some patients with hypospadias or after bladder neck surgery; obstructive lesions preventing exit of the spermatozoa from the ejaculatory ducts into the urethra. as in chronic prostatitis or bilateral epididymitis; and qualitative or quantitative deficiencies of the spermatozoa.

The cause of impotency in more than 95% of patients is psychoneurosis. Neurogenic causes, such as disease or injury of the central nervous system or local peripheral nerves, injury to the body of the penis or absence of the testes may produce this condition. A few men with fatigue or debility can fail to have erections.

The most frequent cause of sterility is a decrease in the quality or quantity of the spermatozoa. A total of about 60,000,000–80,000,000 spermatozoa is considered at the very lower limit of normal consistent with ability to procreate, provided all other characteristics are normal. Minor (10%) abnormalities of morphology or form of the spermatozoa are not considered of as serious importance as decreased motility. Any or all of these abnormalities may be caused by seminiferous tubular immaturity, mumps, trauma or thermal injury (cryptorchism). Frequently such damage is of unexplained aetiology.

See M. Campbell (ed.), Urology, 3 vol. (1954); F. H. Colby, Essential Urology, 2nd ed. (1953). (RR. B.)

URQUHART, SIR THOMAS (1611–1660?), Scottish author. translator and polymath whose works are marked by originality of both language and method. was born in 1611, the eldest son of Sir Thomas Urquhart of Cromarty. After studying at King's college, Aberdeen, he traveled in France, Italy and Spain. He was back in Scotland in time to fight against the Covenanters at Turriff (1639), and was knighted by Charles I in 1641. His strong royalist convictions led him to join the army of Charles II in 1651, and he was taken prisoner at the battle of Worcester and incarcerated in the Tower of London and at Windsor. His imprisonment mas fairly nominal: Cromwell allowed his release on parole and after 1653 he appears to have been at liberty. At any rate he died abroad, traditionally "in a fit of excessive laughter, on being informed by his servant that the King was restored" in 1660.

Urquhart's earliest production. *Epigrams: Divine and Moral* (1641). was an undistinguished collection of verses, which gave no hint of what was to come. In 1645 he published *The Trissotetras*, an almost impenetrably obscure treatise on trigonometry, paying tribute to the recently invented logarithms of his fellow countryman John Napier, but couched in a fantastic verbal symbolism whose would-be mnemonic value is far less assimilable than the normal mathematical terms. This was followed in 1652 by "ΠΑΝΤΟΧΡΟΝΟΧΑΝΟΝ," a highly imaginative demonstration of the pedigree of the Urquharts of Cromarty, traced back to Adam "surnamed the Protoplast." Also in 1652 appeared a more important work, "ΕΚΣΚΥΒΑΛΑΥΡΟΝ," an unclassifiable compound of personal, historical and patriotic reminiscence and exhortation; containing his deservedly famous account of the life of James ("the Admirable") Crichton (1560–85?). *Logopandecteision* (1653) was subtitled "An Introduction to the Universal Language," but the ostensible subject is overlaid by a series of autobiographical and apologetic digressions of great interest and some historical value. These are, as Urquhart says. "bookes, on subjects never hitherto thought upon by any," and the style he develops is equally idiosyncratic: rich, full, inventive; polysyllabic but vigorous; pedantic and eccentric yet capable of presenting sharp description and sharper comment.

Urquhart found the perfect medium for his "literate and compleat elucubrations" in translating the *Works of Mr. Francis Rabelais* (books i–ii, 1653: book iii, 1693). Though he is not always accurate. and though he frequently amplifies the original, Urquhart produced in this work a classic of translation and one of the most vivid examples of 17th-century English prose. (Although Urquhart was Scottish. he used very few Scottish words.) His linguistic exuberance and his sympathy with the free spirit of Rabelais combined to make this the established version in English.

Urquhart's *Works,* excluding the translation of Rabelais, were edited by G. Maitland for the Maitland club (1834); *Selections* were edited by J. Purves for the Saltire society (1942); Urquhart's Rabelais was edited with an introduction by C. Whibley (1900).

URQUIZA, JUSTO JOSÉ DE (1800–1870), Argentine rancher and provincial *caudillo,* or military-political leader, who conquered the powerful dictator Juan Manuel de Rosas (*q.v.*) and laid the constitutional foundations of modern Argentina, was born in the province of Entre Rios on March 19, 1800. Urquiza became its governor in 1842, as an ally of the Buenos Aires dictator Rosas. In 1851 he turned against Rosas, mainly for economic reasons, raised the latter's siege of Montevideo and defeated him in the battle of Caseros (Feb. 1852). Urquiza called a convention which wrote the enduring constitution of 1853 and was elected president for the term 1854–60. Buenos Aires, determined to lead the nation. seceded from the new confederation and under Gov. Bartolomé Mitre defeated Urquiza and the confederation forces at Pavón (1861). Urquiza then retired to his lands. He was assassinated on April 11, 1870, by the agents of López Jordán, an ambitious local *caudillo.* (T. F. McG.)

URSA MAJOR (THE GREAT BEAR), in astronomy, a constellation of the northern hemisphere, supposed to be referred to in the Old Testament (Job ix, 9; xxxviii, 22), and mentioned by Homer, Ἄρκτος θ', ἣν καὶ ἅμαξαν ἐπίκλησιν καλέουσι (*Il.*, 18, 487). The Greeks identified this constellation with the nymph Callisto (*q.v.*), placed in the heavens by Zeus in the form of a bear together with her son Arcas as "bear warder," or Arcturus (*q.v.*); they named it Arctos, the she-bear, Helice, from its turning round the polestar. The Romans knew the constellation as Arctos or Ursa; the Arabs termed the quadrilateral formed by the four stars α, β, γ, δ, Na'sh, a bier, whence it is sometimes known as Feretrum Majus. The Arabic name should probably be identified with the Hebrew name 'Ash and 'Ayish in the book of Job (*see* G. Schiaparelli, *Astronomy* in *the Old Testament,* 1905). Ptolemy catalogues eight stars. Of these, the seven brightest (six stars: α, β, γ, ϵ, ζ and η, are of the second magnitude and δ is of the third magnitude) constitute one of the most characteristic figures in the northern sky; they have received various names—Septentriones, the Wagon, Plow, Dipper and Charles's Wain (a corruption of "churl's wain," or peasant's cart). With the Hindus these seven stars represented the seven Rishis. The stars α and β are called the pointers, since they point to the polestar. Five stars of the Plow form an associated group with common proper motion; but α (the upper pointer) and η (the last star of the tail) have no connection with the others. Stars in other parts of the sky have been found to belong to the same cluster; in particular Sirius is a stray member of it.

URSA MINOR (THE LITTLE BEAR), in astronomy, a constellation of the northern hemisphere, mentioned by Thales (7th century B.C.). By the Greeks it was sometimes named Cynosura (Gr. κυνός, dog's; οὐρά, tail)! alleging this to be one of the dogs of Callisto, who became Ursa Major. The Phoenicians named it Phoenice. or the Phoenician constellation, possibly in allusion to the fact that the brightest star; Polaris, being situated very close to the north pole. is of incalculable service to navigators. Polaris, a second magnitude star, was in 1937 distant $1°\ 2'$ from the celestial pole. It is a Cepheid variable with very small light range.

URSINS, MARIE ANNE DE LA TRÉMOILLE, PRINCESSE DES (1642–1722), lady of the Spanish court, daughter of the duke of Noirmontier and Renée Julie Aubri. After the death of her second husband, Flavio Orsini, duke of Bracciano. she assumed the title of Princess des Ursins, a corruption of Orsini, and for her unofficial services in securing Neapolitans and Spaniards of rank at Rome as French partisans in view of the approaching death of Charles II of Spain, she was rewarded in 1699 by a pension. When Philip. duke of Anjou. grandson of the French king. was declared heir by the will of Charles II, the princess took an active part in arranging his marriage with a daughter of the duke of Savoy. Appointed *camarera mayor* by quiet diplomacy and the help of Madame de Maintenon. she accompanied the young queen to Spain in 1701. Till 1714 she was the most powerful person in the country. She was expected to look after French interests in the palace and to manage the Spanish nobles. But she wisely held that the young king should rely on his Spanish subjects and was in frequent conflict with the French ambassadors. Recalled in 1704, she still had the support of Madame de Maintenon, and her own tact placated Louis XIV. In 1705 she returned to Spain with practically the power to name her own ministry. During the War of the Spanish Succession she was the real head of the Bourbon party. She was so far from offending the nation that when Louis XIV threatened in 1709 to desert his grandson she dismissed all Frenchmen from the court. On the death of the queen, acting by advice of Alberoni, she arranged a marriage for the king with Elizabeth Farnese of Parma. She was rudely disillusioned in her hopes of governing the new queen as she had done the old. Driven from Elizabeth's presence with insult, at Quadraque. whither she had gone to meet her, she was sent out of Spain without being allowed to change her court dress. After a short stay in France, Madame des Ursins went to Rome. where she died on Dec. 5, 1722.

See F. Combes, *La Princesse des Ursins . . .* (1858); *Lettres inédites de Mme. de Maintenon et de . . . la Princesse des Ursins* (1826; Eng. trans., 1827): *Lettres inédites de la princesse des Ursins* (1859); C. Hill, *Story of the Princess des Ursins in Spain* (1905).

URSULA, SAINT, legendary leader of 11,000 virgin martyrs believed to have suffered at Cologne. The story rests on a 4th- or 5th-century inscription stating that an ancient basilica had been restored on the site where some holy virgins had been martyred. These are mentioned again in an 8th- or 9th-century sermon, their number now having increased to several thousand who are reported to have suffered under the emperor Maximian. A later form of the legend names Ursula, a British princess, as their leader, who was said to have gone to Rome accompanied by 11.000 virgins and to have been killed together with them by the Huns on her return from the pilgrimage. The discovery in 1106 of an ancient Roman burial ground at Cologne believed to contain the remains of the martyrs was the occasion of additional legends, which were further embellished by revelations of the visionary Elizabeth of Schonau.

Ursula is remembered especially as the patron of the Ursuline nuns. Her feast day is Oct. 21.

See M. Tout. "The Legend of St. Ursula and the Eleven Thousand Virgins," in *Historical Essays by Members of the Owens College Manchester,* pp. 17–56 (1902). (H. C. G.)

URSULINES, a religious order founded at Brescia by Angela Merici (1470–1540) in November 1535, primarily for the education of girls and the care of the sick and needy. It was approved in 1544 by Paul III, and in 1572 Gregory XIII declared it a religious order under the rule of St. hugustine. In the following century it was encouraged by St. Francis of Sales and the Ursulines in Canada did valuable work among the French and Indian:.

URTICACEAE (nettle family), a family of flowering plants belonging to the order Urticales. There are 41 genera, with about 480 species, mainly tropical, though several species such as the common stinging nettle (*Urtica dioica*) are widely distributed and occur in large numbers in temperate climates. Six genera, *Urtica, Parietaria, Boehmeria, Hesperocnide, Laportea* and *Pilea,* are represented in North America, with about 15 native species. *Urtica* and *Parietaria* are also found in the British Isles.

The plants are generally herbs or somewhat shrubby, rarely, as in some tropical genera, forming a bush or tree. The simple, often serrated leaves have sometimes an alternate sometimes an opposite arrangement and usually, with the exception of *Parietaria,* bear stipules. Stinging hairs often occur on the stem and leaves. The bast fibres of the stem are generally long and firmly attached end to end, and hence of great value for textile use. Thus in ramie (*q.v.*) (*Boehmeria nivea*) a single fibre may reach nearly nine inches in length, and in stinging nettle as much as three inches. *Maoutia* and *Urtica* have also been used as sources of fibre.

The small inconspicuous regular flowers are arranged in definite (cymose) inflorescences often crowded into headlike clusters.

They are unisexual and monoecious or dioecious. The four or five green perianth leaves (or sepals) are free or more or less united; the male flowers contain as many stamens, opposite the sepals. The flowers are adapted for wind pollination. The female flower contains one carpel bearing one style with a brushlike stigma and containing a single erect ovule. The fruit is dry and one-seeded; it is often enclosed within the persistent perianth.

The family is divided, according to Engler, into two main classes: (1) the Urereae with stinging hairs, including the genera *Urtica*, *Urera*, *Laportea:* (2) others, without stinging hairs. *See* also NETTLE; PELLITORY.

COMMON NETTLE (URTICA DIOICA)

URTICARIA: *see* HIVES.

URUAPÁN (URUAPÁN DEL PROGRESO), a town of Mexico in the state of Michoacán, about 270 mi. W. of the federal capital. Pop. (1950) 31,409. Uruapán, Tarascan for "where the flowers abound," was founded in 1533. It is famous for its colourful lacquer ware and handicrafts produced by the Tarascan Indians. Tourists have been attracted there by its healthful climate and the many picturesque sights in Uruapán and the surrounding countryside, including the volcano Paricutin, which appeared in 1943. (R. B. McCK.)

URUBAMBA, a river in southern Peru, rises in the Nudo de Vilcanota on the border between Cuzco and Puno departments, and flows for about 450 mi. to its junction with the Apurimac (*q.v.*) to form the Ucayali. Its upper part: where it passes Sicuani, Urcos and Urubamba, is densely settled by Indian farmers. Below Urubamba, in the Gorge of Torontoy, the river plunges from 11,000 ft. to 8,000 ft. in 20 mi. The Inca ruins of Machu Picchu overlook the lower Urubamba. The deeply cut valley bottom around Quillabamba is sparsely populated. (P. E. J.)

URUGUAIANA, a river port on the left bank of the Uruguay river in the state of Rio Grande do Sul, Brazil, is located opposite the Argentine town of Paso de los Libres. The two towns are connected by a bridge which was completed in 1945. Uruguaiana is about 350 mi. W. of Pôrto Alegre, with which it is connected by rail. The Gruguay river is 2 mi. wide and 154 ft. above sea level at this point. It is navigable for shallow-draft river boats only for short distances between the numerous rapids that interrupt its course. Uruguaiana is a livestock centre and has meat-processing plants. Its factories produce candles, soap, tanned leather goods, perfumes and tobacco products. The former spelling was Uruguayana. Pop. (1950) 32,639. (P E. J.)

URUGUAY (officially the Rephblica Oriental del Uruguay, and still locally called the Banda Oriental, the "eastern shore" of the Uruguay river), the smallest (area 72,152 sq.mi.) independent state in South America. It lies between Brazil on the north and the estuary of the Rio de la Plata on the south, extending from the Uruguay river to the Atlantic coast. It has a seaboard of about 120 mi., a shore line on the Plata of 235 mi. and one of 270 mi. along the Uruguay.

This article is divided into the following sections:

There are also short articles on the departments and more important cities.

I. PHYSICAL GEOGRAPHY

Geology. — The eastern and southern half of Uruguay is a low hilly land, with a subsoil of weathered ancient schist and granite, through which protude low ridges of less weathered rocks. In central and north-central Uruguay a basement of ancient schist is overlain by nearly horizontal Permian beds. which form a low plateau. The northwestern portion is occupied by a southward extension of the Paraná plateau of southern Brazil. This plateau is formed of horizontal beds of Triassic red sandstone of continental origin, in places faulted and capped by sheets of Triassic basalt. The plains of Uruguay are covered with Pleistocene deposits of sand and clay like those found on the pampas of Argentina and with alluvial beds.

Physiography. — The southeastern part of the country consists of low rolling hills, a southward extension of the Brazilian highlands. The coast line is fringed with tidal lakes and sand dunes: the banks of the two rivers are low, unbroken stretches of level land. The northwestern section of the republic presents greater variety of relief, with occasional ridges and low plateaus, alternating with broad valleys. a southward extension of southern Brazil. None of the hills and plateaus of Uruguay exceeds 2,000 ft. in elevation.

There are no large rivers entirely within Uruguayan territory. The Negro, the largest stream; is navigable only in its lower part. No other streams are navigable except for vessels of light draught. The Santa Lucía, Queguay and Cebollati are the other principal watercourses. The Uruguay river, along the border, is navigable for steamers of 14-ft. draught from its mouth to Paysandú, and above that point for smaller vessels to the falls at Salto, 200 mi. in all. *(See* also PLATA, RÍO DE LA.)

Climate. — Uruguay has a truly temperate climate. The average temperature for the summer months of January and February being about 71° F. and that of the coldest month, July, being 50°. Frost is almost unknown. The weather of both summer and winter is marked by great variability from day to day, a result of the passing of cyclonic storm centres. Brusque wind shifts are common, the hot northerly wind sometimes being followed immediately by the chill pampero from the southwest and bringing a sudden drop in temperature. These changes give a middle latitude character to the climate of Uruguay.

There are no decided rainy and dry seasons. A rainfall maximum is reached in the autumn (April and May), not in the winter months as is often supposed. Winter rains are most frequent but autumn rains are heaviest. The mean annual precipitation is about 35 in., decreasing with distance from the sea, but everywhere well distributed throughout the year. In summer there are frequent thunderstorms. Fogs are common from May to Oct., but seldom last all day on land.

Vegetation. — Uruguay is mostly covered with tall rich prairie grass. There are more trees, however, both native and introduced, than on the pampas, but these are found chiefly in narrow ribbons along the bottom lands of the watercourses. The principal species are the ombú, alder. aloe, poplar, acacia, willow and eucalyptus. The *montes,* by which are understood plantations as well as native thickets, produce, among other useful wood, the algarrobo, the guayabo, the quebracho and the urunday. Indigenous palms grow in the valleys of the Sierra de San José Ignacio, as also to some extent in the departments of Lavalleja, Maldonado and Paysandh. The myrtle, rosemary, mimosa and the scarlet-flowered ceibo are common.

The valleys within the hills are fragrant with verbena and aromatic shrubs. The prairies are gay with the scarlet and white verbenas and other brilliant wild flowers.

Animal Life. — As in most of the inhabited parts of the world, the wild animals have largely disappeared. Even the rhea (the American ostrich) is now seldom seen, except in a semidomesticated state. Pumas and jaguars are found on the wooded islets and banks of the larger rivers and along the northern frontier. The fox, deer, wildcat, the carpincho. or water hog. and a few small rodents nearly complete the list of native quadrupeds. A little armadillo. the mulita, is the living representative of the extinct giants, *mylodon* and megatherium. whose fossils are found over the pampa. There are a few specimens of the vulture, a native crow (lean, tall and ruffed) and many partridges and quails. Parakeets are plentiful in the *montes* and the lagoons swarm with waterfowl. The most esteemed is the *pato real,* a large duck A characteristic sight on the prairies is that of the tiny burrowing owl, sitting on top of every little eminence. Large flocks of the lapwing, terutero, are common, with their habit of warnıng other game of the approach of danger. Of birds of bright plumage, the humming bird and cardinal — the scarlet, the yellow and the white—are the most attractive, while white herons are frequently seen in swampy lands. The scorpion is rare. but large and venomous spiders are common.

The principal reptiles are a lizard, a tortoise, the *vibora de la cruz* (a dangerous viper, so called from marks like a cross on its head) and the rattlesnake in Maldonado and the stony lands of Minas. Along the upper waters of the Uruguay river the cayman (alligator) is not uncommon. Seals are found on small islands oil the southeast coast, particularly Lobos Island, which so gets its name.

II. GEOGRAPHICAL REGIONS

Uruguay is the most coherent of all the states of Latin America. Not only is the whole of the national territory effectively occupied, but also there is little contrast between the different parts of the country. When Uruguay became independent in 1828 its national territory was so uniformly occupied that only very minor geographical regions could have been distinguished. The "no-man's land" along the eastern shore of the Uruguay river was neither wholly Spanish nor wholly Portuguese. The land was then used almost exclusively for the grazing of herds of scrubby cattle on the unfenced range, and there were few permanent settlements outside of Montevideo and Colonia, and the villages along the Uruguay.

After independence, Uruguay received a small influx of immigrants, chiefly from Italy and Spain. This was a time when Argentina nas torn by civil strife, and settlement on the Pampas was not yet attractive. The newcomers entered Uruguay through Montevideo and settled in a zone along the Plata and Uruguay rivers. After 1852, the European immigrants to the Plata region preferred to go to Argentina. As a result the agricultural zone in southern Uruguay remained static, because, unlike in Argentina, livestock grazing, and the cultivation of crops remained in separate geographic areas. Southward toward Montevideo, there was in the early 1940s a notably sharp boundary between the pastoral region to the north and the agricultural region to the south at the town of Florida, only 50 mi. N. of the capital. However, since the mid-1940s there has been a great increase in the area devoted to agriculture. The sharp boundary between the two regions disappeared. Crops are more important than pasture as far north as Durazno, more than 100 mi. N. of Montevideo: and the crop zone has also extended northward along the Uruguay river as far as Salto.

The grazing of animals in the pastoral region is no longer on the unfenced range. Barbed wire, first introduced to Uruguay during the 1870s, is used throughout the interior to separate one pasture from another, and to border the highways and animal driveways. Planted pasture grasses have replaced the native grasses, and the carrying capacity is very high — about one animal unit per acre. There are many large ranches or *estancias,* some more than 25,000 ac., in the pastoral region. Sheep are more significant than cattle in the northwest, especially on the relatively dry low plateaus on diabase and red sandstone. Cattle are of major importance south of the Negro river.

The agricultural zone, on the other hand, has little land devoted to pasture. The chief crop is wheat, but there are important areas also of flax (for linseed), oats, barley and grapes. In the 1940s the government began to support agricultural prices and encourage agricultural expansion. The acreage in wheat more than doubled between 1950 and 1955, but the acreage of flax (an export crop) declined. Other crops that have increased in acreage include rice. maize, fruit orchards and vineyards. There are large acreages of sunflowers, the cheapest source of cooking oil, in the northeast of Uruguay, as well as in the southern part of the country.

Montevideo is the largest urban centre, in which there is the chief concentration of manufacturing. Industries were also established at Fray Bentos, Salto (*qq.v.*) and Paysandú along the Uruguay. A hydroelectric station on the Negro river provides power. (P. E. J.)

III. HISTORY

The area was explored by Juan Díaz de Solís (*q.v.*), who sailed into the Rio de la Plata in 1516; other early explorers were Ferdinand Magellan and Sebastian Cabot. Little was done with it since there was no mineral wealth and the local Charrúa Indians were fierce nomads. The latter were eventually pacified by Jesuit and Franciscan missionaries. The Banda Oriental del Uruguay (the east bank of the Uruguay river), as it was called, became a tremendous unfenced pasture where wild cattle practically roamed at will and where bands of cattle skinners made periodic forays. In 1680, the Portuguese moved down from Brazil and established Novo Colonia do Sacramento on the Río de la Plata opposite Buenos Aires. To counteract Portuguese influence, the Spanish set up San Felipe de Montevideo in 1726 as a garrison town, and drove the Portuguese back (*see* MONTEVIDEO). This exemplified the colonial period, which was marked by a prolonged struggle between the Spaniards of Argentina and the Portuguese of Brazil.

Independence. — Uruguay, one of the last areas colonized in South America, was swept into the general Latin American fight for independence. The brief British occupation (Feb. 3–Sept. 9, 1807) of Montevideo under Sir Home Papham during the Napoleonic mars (since Spain was an ally of France) brought new ideas. The city's first newspaper, La *Estrella del Sur,* was published by the invaders. Buenos Aires' declaration of independence in 1810 spurred José Gervasio Artigas, leader of the gauchos (*q.v.*), the cowboys of the Uruguayan interior, to besiege the Spanish garrison in Montevideo in 1811. Artigas became caught up in the struggle between Buenos Aires and the interior for leadership in emergent Argentina. After nine years of heroic effort, during which an Uruguayan national conciousness developed, Artigas, considered Uruguay's national hero, was forced into exile in Paraguay.

The Banda Oriental was in turn occupied by Portuguese, Brazilian and Argentine troops. Its separate existence is due in part to Uruguayan resistance, reactivated in 1825 by Juan Antonio Lavalleja and his *Treinta* y *Tres* .(band of 33) who organized an army with Argentinian-help and defeated the Brazilians at Ituzaingó, Feb. 20, 1827, in larger part. to the inability of either Argentina or Brazil to annex the area and, lastly, to British mediation which suggested the establishment of Uruguay as an independent buffer state. Uruguayan independence was proclaimed by a treaty between Brazil and Argentina signed at Rio de Janeiro Aug. 27, 1828.

On July 18, 1830, Uruguayan leaders duly promulgated a unitarian (centralist) constitution and almost immediately chaos developed The names of Fructuoso Rivera and Manuel Oribe crystallized the history of the era which was wretchedly confused by civil strife. Both were lieutenants of Artigas, both had gaucho armies! both were presidents of Uruguay, Rivera the first, Oribe the second. They soon broke with each other and their gaucho followers wore the ribbons that were to mean so much for so long, the *Colorado* (red) of Rivera: the *Blanco* (white) of Oribe. It was impossible to contain the fight within Gruguay, since both Argentina and Brazil still had designs on the area or, at least, wanted friendly governments in Montevideo. By 1843 Oribe, supported by Juan Manuel de Rosas, dictator of Argentina was besieging Rivera in iliontevideo. France and England, anxious to break Rosas, supported the defenders of Montevideo. This mas the Great War, the siege of Montevideo. the New Troy as Alexander Dumas called it. Giuseppe Garibaldi, the Italian patriot and his legion of red shirts were among the defenders of the city. It lasted nine years, with relatively little fighting, but it dug deep into Uruguayan consciousness, and party affiliation, Colorado or the Blanco, became a family, even a religious matter.

The siege was lifted in 1851, the first event of a chain which led to Rosas' fall in Argentina, and new hope filled Uruguay. The educated classes, the so-called *doctores,* hoped to do away with *caudillos* (personalist leaders) and the two traditional parties—they failed. The period from 1852 to 1872 was, if anything. more disastrous than the earlier one. Argentina was settling by force the long standing struggle for internal supremacy between Buenos Aires and the interior. Uruguay, as an area of intrigue and a theatre of war, could not escape. Brazil made countermoves; alternative presidents of Uruguay, both Colorado and Blanco, sought support from their more powerful neighbours. Venancio Flores, Rivera's successor as Colorado *caudillo,* was able to get both Brazilian and Argentine support in 1865 and firmly established the Colorados in control. Uruguayan participation in the victorious Brazil-Argentine war against Paraguay 1865–70 was the price exacted. The end of the Paraguayan war coincided with the settlement of Argentina's internal problems. Thereafter, Uruguay was increasingly able to avoid intervention by its neighbours in its affairs.

The 40-year period following independence had taken a terrible toll in livestock consumed by revolutionary armies, in ranches destroyed, in government projects which had to be abandoned. A huge public debt further complicated political life. Once more the new *doctores,* now doctrinaire liberals with degrees from the University of Montevideo, tried to end the traditional parties. And they failed. as had their predecessors. Their failure produced the advent of militarism: government by professional army officers. First Col. Lorenzo Latorre in 1875. then Gen Máximo Santos, next Gen. Máximo Tajes who served from 1886 to 1890. Latorre used assassination, coercion and exile as weapons. His iron rule broke the power of the interior *caudillos* and secured the power of central government.

The military peace encouraged ranchers to import blooded breeding stock and to fence their *estancias,* this marked the beginning of modern ranching in Uruguay. Railroads, financed mostly by British capital under profit guarantee by the Uruguayan government, started communications between Montevideo and the interior. Modern public utilities, again financed from abroad, began transforming Montevideo. A system of free public education was established. Trickles of immigrants began entering the country. The gaucho. however, suffered privations as he was not needed on fenced ranches.

Military government became increasingly corrupt and unpopular. Both political parties, Colorado and Blanco, were maturing, developing permanent organizations and programs. The country was changing, prosperity and optimism were in the air. General Tajes recognized this and supported a civilian, Julio Herrera y Obes, as his successor. Herrera y Obes the shrewdest of the new liberals proceeded to break the power of the military. He disappointed the Blancos, or Nationalists as they were now called, by governing as a Colorado partisan and alienated one Colorado wing by his fraudulent manipulation of elections. He had to face the economic crash of 1890, brought on by a speculative building boom, but he did re-establish civilian government in Uruguay.

Jose Batlle y Ordóñez.—Civilian government was not enough: nationalists wanted to participate in government, dissident Colorado wanted free elections. The successor to Herrera y Obes was confronted with Natidnalist revolution and Colorado indifference. His assassination in 1897 brought a rapid political realignment. The Nationalists, in exchange for control of six of Uruguay's 19 departments, supported the new government as did the once dissident Colorado wing, one of whom, José Batlle y Ordóñez (*q.v.*), managed to get himself elected president for the period 1903–1907 by the narrowest of margins.

Batlle's first difficulty was with the Nationalists who felt defrauded at his election and who revolted in 1904. The revolt was suppressed, after eight bloody months and Batlle became a Colorado hero, for having defeated the greatest threat to that party's domination since Flores had elevated it to power in 1865. He proposed to use his authority to transform armed politics to electoral-politics. The 1904 civil war was the last serious armed uprising in Uruguayan history.

The ensuing peace enabled ranchers and businessmen, cautious since the 1890 crash, to invest in livestock and new enterprises. Refrigerated packing plants went into operation. Trade was increased and tax receipts rose providing the government with regular budget surpluses, and making large-scale public works possible. Batlle initiated a reform program. Innovations included government ownership of banks, businesses and utilities, which would provide cheap services and replace foreign corporations; introduction of labour legislation, the eight-hour day and old-age pensions, to benefit the previously neglected working classes; educational expansion; divorce and paternity legislation to raise moral standards and weaken Catholic influence. Batlle envisaged a progressive land tax which ultimately would end the unearned increment and put land to use.

Despite his political acuteness—he was the only Uruguayan president elected to a second term, 1911–15—Batlle faced increasing difficulty in carrying out his program. Even his closest supporters balked at his favourite political solution, which he advanced to end presidential omnipotence, namely the substitution of a plural executive (collegiate government) for the presidency of the republic. His second term was hectic, his party split. In 1916 his plan for a nine man executive was put to a vote. For the first time the secret ballot was used and the total Nationalist-dissident Colorado vote exceeded the pro-government vote. A compromise constitutional solution was worked out. The 1917 constitution established a nine man council of administration composed of six members of the majority party and three of the minority. The president of the republic controlled the ministries of war, police and foreign affairs.

1916 to Date.—From 1916. Uruguay has had recurrent political problems. Splits within both traditional parties, furthered by proportional representation, made it difficult to secure legislative majorities for the enactment of advanced progressive legislation. Elections became increasingly important, but government jobs were baits used to attract voters. The result was to expand the bureaucracy excessively by increasing the number of workers in government-run enterprises, which no longer ran at a profit. Urbanization, Montevideo especially, grew, for ranches could not use many hands.

Livestock production did not keep pace with the rising urban consumption, less meat was exported, and the state of the Uruguayan economy increasingly depended on the rise and fall of world wool prices.

In the 1920s the political and economic problems were apparent. Batlle formed the Batllista party within the Colorado party and remained Uruguay's dominant political figure until his death in 1929. The delicate political situation, made worse by Batlle's death and complicated by the economic depression of the 1930s, caused Pres. Gabriel Terra (*q.v.*) to overthrow the 1917 constitution and govern as dictator in 1933. This bloodless revolution from the top shamed Uruguayans who considered it an affront to their hard won electoral democracy. Even Terra's successor and close relative Gen. Alfredo Baldomir shared this view and overthrew, in turn, Terra's 1934 constitution. From 1946 to 1958 the Batllista party won every election. In 1951 it was successful in reforming the constitution and establishing a plural executive. A nine man council of administration, six from the majority party, three from the minority, governs Uruguay.

On Nov. 30, 1958, after 93 years of Colorado government, the Nationalists were elected by an overwhelming majority. They won in Montevideo and 17 other departments, only the border department of Artigas remained Colorado. Various causes explain this reversal. Internal Colorado Batllista splits weakened the governing party. The public lost patience with notoriously bloated and inefficient government operations. Export volume and wool prices fell. The Colorado government's attempts to control inflation and restore prosperity failed. Voters turned to the Nationalists who proposed to accomplish these ends through a program of modified austerity.

On March 1, 1959, without turmoil, the historic rotation of parties took place. Shortly thereafter on April 8, 1959, Luis Alberto de Herrera, principal Nationalist *caudillo* since the 1920s, died. The already difficult economic situation was dealt a further blow by one of the worst flood disasters in Uruguayan history. Yet, the sometimes criticized plural executive was an excellent cushion for political transition, especially because it provided for three Colorado minority members. This ability peacefully to rotate parties after almost a century of one party rule, in the midst of flood, death, political complications and economic adversity is striking proof of the maturity of Uruguayan democracy.

Uruguay. a small country with democratic leanings and powerful neighbours, has traditionally stood for collective security at peace conferences. the League of Nations, the United Nations and in the Pan-American movement. It declared war on Germany and Japan on Feb. 15. 1945. The election of José A. Mora, an Uruguayan, as secretary-general of the Organization of American States indicated the respect accorded Uruguay as Latin America's voice of conscience. Democratic sympathies and a desire for a counterweight to her big neighbours have also made Uruguay a traditional friend of the United States. In the mid-1950s this friendship was dampened by Uruguayan displeasure at U.S. economic policy which Uruguay considered extremely damaging to its exports. Changes in U.S. policy following the visits of Vice-Pres. Richard Nixon (April 1958) and President Eisenhower (March 1960), and U.S. assistance during the April 1959 Uruguayan floods helped strengthen friendly relations. (M. I V.)

IV. POPULATION

Number and Distribution. — The last official population census in Gruguay was taken in 1908. Therefore any current estimates of the number of inhabitants. the growth of population or the manner in which the population is distributed among the departments may be subject to a large margin of error. It also means that Uruguay is not included in the countries for which the United Nations supplies comprehensive information on the composition or characteristics of the population Under these circumstances it is inevitable that the figures secured from different sources will vary greatly. Estimates of the total number of inhabitants in Uruguay given in the *Demographic Yearbook* of the United Nations place the population at 1,479.000 in 1920, 2.155,000 in 1940. 2,407,000 in 1950, 2 615,000 in 1955 and 2 679,000 in 1958. Other sources indicate that the nation's population was about 1.870.000, 2,050,000, and 2,175,000 in 1940, 1950. and 1955, respectively. If one accepts the estimates presented by the United Nations there was a density of about 36 persons per square mile; the annual population increase after 1955 averaged about 30 000, the rate of growth was 1 7%, the birth rate 18 per 1 000 population and the death rate 7. The lower estimates, on the other hand, would mean a population density in 1955 of 30 per square mile, an annual increment since then of about 25,000, a rate of growth of 1.2% per annum. a birth rate of 21 per 1,000 population, and a death rate of about 9.

Uruguay's population is highly concentrated in its capital, Montevideo (*q.v.*), which by 1958 probably had approximately 1.000.000 inhabitants. Almost one-half of the nation's people live either in this city or in Montevideo department. The remaining inhabitants are distributed among the 18 departments into which the country is divided, of which Canelones and Salto are the most populous. Other leading cities, with populations between 35,000 and 50,000, are Mercedes, Salto, Paysandú, Minas, Melo, Florida and Rocha.

Area and Population

	Area* (in sq.mi)	
TOTAL	68,369	2,800,921
DEPARTMENTS		
Artigas	4,682	70,426
Canelones	1,735	224,446
Cerro Largo	5,317	118,947
Colonia	2,378	149,386
Durazno	4,710	110,729
Flores	1,982	41,081
Florida	3,985	117,387
Lavalleja	3,936	128,918
Maldonado	1,824	76,480
Montevideo	208	853,649
Paysandú	5,474	101,012
Río Negro	3,655	57,403
Rivera	3,511	100,863
Rocha	4,252	96,070
Salto	5,546	123,003
San José	1,912	106,789
Soriano	3,414	110,939
Tacuarembó	6,105	132,473
Treinta y Tres	3,743	80,923

*Adjusted subsequent to 1950: 72,152 sq.mi.; no subdivision data available.

Composition. — The population of Uruguay is predominantly of the white race most of its people being the descendants of immigrants from Spain, Italy and other European countries who arrived during the 19th and 20th centuries. The native American Indian population of the republic is now extinct. and less than 5% of the present inhabitants exhibit Indian physical features to any noticeable extent. The yellow races of Asia are practically unrepresented There are a few Negroes and mulattoes in the population. but probably not more than 10,000 of the former and 50.000 of the latter.

Due to the lack of any modern population census. the age distribution of Uruguay's people is not known nith any degree of certainty. The best estimates indicate 'that persons less than 15 years of age make up no more than 30% of the total, the lowest figures for any of the Latin American countries. Persons aged 15 to 64, inclusive, probably constitute about 65% and those of 65 and over at least 5% of the population. The figure for the aged is the highest in Latin America; and this proportion seems likely to increase, due to the low death rate, the comparatively low birth rate, and the fact that the immigrants who come in such large numbers during the first quarter of the 20th century are now in or approaching the retirement ages.

Comprehensive and recent statistical data on the religious affiliations of Uruguay's people are lacking, but general observation is sufficient to indicate that the majority profess the Roman Catholic faith. State and church are separated and there is complete freedom of worship.

Spanish is the official language and also that spoken in the home by the overwhelming majority of the nation's families. In the villages and towns along the Brazilian border, however, in common usage many Portuguese words and phrases are mixed with the Spanish.

Growth of Population.— —The two early censuses of Uruguay's population that were made indicated a population of 915.647 in 1900 and 1,042,686 in 1908. Hence. for this period the rate of population increase was about 1.5% per annum. with irnmigation contributing significantly to the annual growth. For later decades, however, it is difficult to determine the extent to which immigration has contributed to the population increase since the data are very involved. Uruguay was the first South American country to legalize divorce and by mid-20th century Montevideo and its satellites became temporary places of residence for thousands of divorce seekers from across the Rio Plata in Argentina, and from other parts of the continent. Such short-term immigation beclouds statistics. Nevertheless, almost all the growth of population during the 1940s and 1950s was probably due to the excess of births over deaths.

If the birth rate is actually about 18 per 1,000 population and the death rate 7, as estimated by the statisticians of the United Nations. then the annual rate of increase should be about 1 5%; or if the birth rate is 21 and the death rate 9. as estimated elsewhere the increase is only 1.2% annually. In either case, in comparison with rates of population growth in other Latin American countries. that in Uruguay is relatively low. (T. L. SH.)

V. ADMINISTRATION AND SOCIAL CONDITIONS

Government. — From March 1952, when the offices of president and vice-president were abolished, Uruguay was governed by a nine-man national council elected for a four-year term, six members of which belong to the majority party and three to the leading minority party All nine were given equal power. The presidency of the council, responsible for domestic and foreign policy, rotates annually among the four highest majority-party members on the ballot, and for protocol purposes the president of the council serves as president of the republic. The legislative branch consists of a senate of 30 members and a chamber of deputies of 93, elected for four years, the political parties having proportional representation. This general assembly was given power to override the council by a two-thirds vote. It also elects a supreme court of five judges for a ten-year term. The death penalty was abolished in 190i and replaced by long term penal servitude.

Living and Working Conditions.—With 1953 figured as 100, the cost of living had risen to 314 by 1960. The gross national product was computed at U.S. $382 per person. Approximately 875,300 Uruguayans were gainfully employed. The strength of the labour movement is reflected by the number of workers (approximately, 200,000) who were members of internationally affiliated trade unions in the late 1950s.

Welfare Services.—Since the first administration of Pres. José Batlle y Ordóñez (1903–1907) Uruguay—often called the "Switzerland of South America"—has played a leading role in the development of social security. Uruguay's comprehensive program includes extensive provisions for unemployment insurance, compensation for injuries to workmen, family allowances, and aid to the aged and indigent. With respect to problems of health and sanitation, Uruguay is among the most fortunately situated of the Latin-American countries. In 1959 the infant mortality rate was 87.1 per 1,000 births; there were 860 people per physician and 2,156 people per dentist in the country; 5.9 hospital beds existed for every 1,000 Uruguayans; and the daily per capita calorie consumption stood at 2,810. Long a South American pioneer in international co-operation, Uruguay participates in the technical assistance programs of the United States, the Organization of American States, and the United Nations.

Education.—Uruguay made marked progress in education after the reforms of 1877 instigated by José Pedro Varela, who urged that education be free, compulsory, co-educational and under secular control. This progress was reflected in the high literacy rate (about 80%). From 1934 there was a compulsory attendance law, though it was not rigidly enforced. In the late 1950s there were approximately 1,800 primary schools with 250,000 pupils and 7,000 teachers, and 200 secondary schools with 50,000 pupils and 4,500 teachers.

The University of Montevideo (founded 1849) has an enrollment of more than 10,000. It has ten faculties, including a distinguished medical school which draws students from many South American countries. There is also a privately supported Institute of Higher Studies devoted to scientific research. Vocational training is given by the Technical university which organizes and controls a number of industrial and night schools.

Defense.—The army, composed of volunteers enlisting for 1 year or 2 years, comprised (1955) 9 regiments of cavalry, 6 of engineers, 5 each of infantry and artillery and a tank regiment. There is a small navy and an air force of about 200 planes. With a reserve trained every year under the compulsory military training law, it was estimated in the 1950s that about 120,000 troops could be mobilized in case of war. (G. I. B.)

VI. THE ECONOMY

The foundation of Uruguay's economy was said to have been laid in 1603 when a farseeing governor of Paraguay, Hernando Arias de Saavedra. having observed the fertility of the empty southern pastures, shipped about 100 head of cattle and 100 horses and mares downstream from Asunción. These animals were landed on the Uruguayan river bank, where they were left to run wild and multiply. Later in the century the herds were so abundant that they attracted gauchos from Buenos Aires, who crossed the Rio de la Plata and began a trade in hides. The gauchos were nomads, with no desire to settle, but gradually merchants from Buenos Aires established themselves on the Uruguayan side of the estuary. As more and more cattlemen arrived boundaries had to be fixed, and thus there came into existence the great estancias that are still characteristic of the country.

The relatively high standard of living enjoyed in and around Montevideo is closely related to the earnings from pastoral and agricultural exports; prosperity is somewhat precarious because these primary products are subject to sudden fluctuations in world demand and prices. To reduce the nation's dependence on external trade, successive governments have encouraged the development of domestic industry by means of protective tariffs, import controls, exemption of machinery from import duties and preferential exchange rates. But as there are no local sources of petroleum, coal or iron, and no heavy industries, Uruguay is obliged to import most of its fuel and industrial raw materials and all of its vehicles and industrial machinery. These essential supplies have to be paid for with the produce of the ranches and farms and the income derived from foreign tourists.

Nevertheless, the economic crisis which afflicted the republic in the late 1950s was not entirely the result of the deterioration in world prices for primary products. The financing of the "welfare state" imposed heavy burdens on the producers; and the government's agrarian and exchange policies were often designed to gratify the consumer, *i.e.,* the majority of voters, rather than to remove, by necessarily unpopular measures, the causes of inflation and of the decline in the value of the national currency.

Livestock and Agriculture.—The whole of the available land in Uruguay is in use for grazing or agriculture and production can therefore be increased only by technical improvements in breeding and cultivation. In general, such improvement has been slow.

High wool prices during and after World War II encouraged sheep breeding, and the Korean war further stimulated this activity. In the late 1950s there were about 23,000.000 sheep on the pastures. and even when prices dropped wool continued to be the greatest source of foreign exchange; the number of beef cattle dropped to about 7,000,000 head. Domestic consumption of meat increased with the growth in the population, but cattle breeders were discouraged by government price restrictions; moreover, the official policy of subsidizing the production of nheat caused much good grazing land to be transferred to agriculture. It became more profitable to dispose of cattle on the black market, or to smuggle them over the frontier into Brazil, than to sell them to the meat-packing plants. The latter therefore received insufficient supplies and the meat export trade suffered accordingly. The original object of the government's policy of subsidizing wheat production was to ensure that the nation should become self-sufficient in that grain. In practice, however, the inducement proved to be so attractive that too much wheat was planted. The cost of the subsidy. moreover, was a serious burden on the national budget, especially as the Uruguayans continued to resist the introduction of income tax. Other crops include flax, maize, oats and barley. Fruits grown are oranges, lemons, peaches, grapes (sufficient for the local wine industry), pears and apples.

Power and Industry.—The state operates a large number of public corporations. It controls electricity and the refining of imported petroleum; it manufactures alcohol and cement; it directs a meat-packing plant and the processing of fish; and it controls the railways (purchased from their British o ners at the end of World War 11), the principal banking institutions and insurance.

As the low, rolling countryside of Uruguay is not generally suited to hydroelectric development, most of the electric installations were formerly dependent on imported coal or oil; but two hydroelectric plants were built on the Negro river.

The processing of food and other products of the land is the basic form of industry. The subsidized wool-combing industry has added to the country's exports. Consumer goods manufactured locally (mainly in the neighbourhood of Montevideo) include textiles, tires and other rubber goods, shoes and many household appliances.

Foreign Trade.—In the late 1950s wool exports amounted to at least 50% of the national total, while meat and by-products varied from 10% to 20%. Hides, skins and wheat were the other principal items. The chief markets were the Netherlands, the United Kingdom, the United States. western Germany and Brazil. During the same period the principal imports were raw materials for industry, vehicles, machinery and fuels. The chief suppliers were the United States, Brazil, the United Kingdom, German Federal Republic and Belgium-Luxembourg. In spite of strict import controls the balance of payments during the 1950s was usually unfavourable.

Transportation.—Uruguay has more than 3.000 mi. of paved highways (including the Pan-American highway), among the best in South America, which radiate from Montevideo This city is also the rail hub of the country, and the main airport at Carrasco, 13 mi. outside. is served by local and international airlines.

URUGUAYANA: *see* URUGUAIANA.

URUGUAY RIVER, forms with its tributaries the second major river system of the Rio de la Plata estuary. It rises on the coastal range of south Brazil and flows west and southwest for 1.000 mi. along the Brazil-Argentina and Uruguay-Argentina borders to join the Paraná river.' *See* PLATA. RÍO DE LA.

URUMCHI (TI-HUA, WU-LU-MU-CH'I), capital and Chinese garrison centre for. Sinkiang, (*q.v.*), commanding strategic routes through the Tien Shan as well as the highway and rail routes along the north flank of this range leading from China to Soviet central Asia. Its 1953 population was about 140,700, predominantly Chinese, but also including considerable Uighur, Khazak, Tungkan, and Manchu minorities. It shares the steppe climate of the Dzungarian basin but depends upon impounded irrigation water from the Crumchi river for its oasis farmlands. The town is a trading centre for the steppe nomads and also has numerous small industries based on nearby coal, iron and copper ore deposits. A thermal and a small hydroelectric plant supply power for industries making cotton textiles. electric light bulbs, cement. chemicals. flour and for motor vehicle repair. A small iron and steel plant was enlarged in the late 1950s. It is the seat of Sinkiang Medical college and has institutes of Russian languages, minorities and agriculture. (H. J. Ws.)

USBEGS. The Usbegs form the ruling clan in Bokhara, Khiva and Kokand, occupying there a very similar position to that of the Osmanli in Turkey. They are also found in Samarkand and in some parts of Syr Daria and Ferghana, in nhich latter place the Kipchak also live. and should probably be classified as Sarts. They are a mixed people. closely allied to the Mongols, and are in a transition from a nomad to a sedentary life.

USHAK or USAK, a town of Turkey, in the Kutaiah (Kütahya) vilayet, connected nith Smyrna and Konia by rail. Pop. (1955) 23 366. It is noted for its heavy pile carpets, *khali*, known as "Turkey carpets." There the Turkish army captured the Greek commander in chief, Gen. Trikoupis. Sept. 2. 1922

USHANT (Fr. *Ouessant*), a rocky, reef-fringed island lying $11\frac{1}{2}$ mi, offthe mainland of northnestern France (Brittany). Pop. (1954) 2.071. Cshant, has a maximum east-west length of 5 mi. and a north-south width of 2 mi. Maximum elevation. 1jo ft. Most of the coast is cliffed or high; only on the southeast at Lampoul, the major village, is access easy. The population is dominantly engaged in fishing. Garden crops are cultivated and sheep are pastured.

USHAS, in Vedic Hindu mythology goddess of the dawn (from the same root as Lat. *Aurora* and Gr. 'H ώς). Celebrated in some 20 hymns of the *Rig-Veda*, Ushas is its most graceful creation. Borne on a car drawn by ruddy kine, the sun is her lover. She rises resplendent . . . showing her charms—ever shortening the lives of men she reveals their paths and bestows new life . . . she opens the doors of darkness as the cows their stalls.

USHER or USSHER, **JAMES** (1581–1656), Irish divine and archbishop, was born in the parish of St. Nicholas, Dublin, on Jan. 4. 1581. He was sent to a school in Dublin opened by two political agents of James VI of Scotland. nho sought to secure a party for James in Ireland in the event of the queen's death.

In 1594 Usher matriculated at the newly founded university of Dublin. whose charter had just been obtained by his uncle, Henry Usher, archbishop of Xrmagh. He graduated M.A. in 1600, became a fellow of Trinity college, and was ordained in 1601. In 1607 he became regius professor of divinity and also chancellor of St. Patrick's cathedral. Dublin. In 1613 he published his first printed work, though not his first literary composition—*Gravissimae Quaestionis de Christianarum Ecclesiarum, . . . Historic Explicatio*, wherein he took up the history of the Western Church from the point where John Jewel had left off in his *Apology for the Church of England*, and carried it on from the 6th till past the middle of the 13th century.

James nominated him archbishop of Armagh in 1625. As archbishop he discountenanced (1629) Bishop William Bedell's proposal to revive the Irish language in the service; he shared in drafting (1634) the code of canons of the Irish Church, and defeated the attempt to make the Irish Church conform exactly to the doctrinal standards of the English. In 1640 he paid another visit to England on one of his usual scholarly errands, meaning to return when it was accomplished. But the Great Rebellion of 1641 prevented his return. Usher pleaded in vain with Charles I not to abandon Strafford. By way of compensation for the loss of his Irish property he received the temporalities of the vacant see of Carlisle. In 1643 he declined a seat in the Assembly of Divines at Westminster. He quitted Oxford in 1645 and went into Wales, where he remained till 1646, when he returned to London, and was in 1647 elected preacher to the Society of Lincoln's Inn, an office which he continued to hold until near his death.

In 1648 Usher conferred with Charles I in the Isle of Wight, on the abortive negotiations with parliament on the question of episcopacy. In 1650–54 he published the work which was long accounted his most important production, the *Annales Veteris et Novi Testantenti*, in which he propounded a now disproved scheme of biblical chronology, whose dates were inserted by some unknown authority in the margin of reference editions of the Authorized Version. In 1655 Usher published his last work, *De Graeca LXX Interpretum Versione Syntagma*. He died on March 20, 1656, in Lady Peterborough's house at Reigate, and was buried in Westminster abbey.

Usher's works are very numerous, and were first collected by C. R. Elrington and J. H. Todd (Dublin, 1847–64) in 17 vol. See *Life* by Carr (1895); W. B. Wright, *The Ussher Memoirs* (1889).

USK, THOMAS (d. 1388), the author of *The Testament of Love*, a prose work formerly attributed to Geoffrey Chaucer, was born in London, Eng. In 1897 Henry Bradley interpreted the acrostic comprised of the initial letters of its chapters—"Margarete of virtw, have merci on thin Usk"—as a statement of authorship. Thomas Usk was clerk of the closet to John of Northampton when he was mayor of London, 1381–83. In 1384 Usk was put in prison, but he was released on promising to bring charges against Northampton, who had been arrested for treason. Usk freely produced evidence which sent Northampton to prison. Usk fell aith the king in the successful rebellion led by the duke of Gloucester, the king's uncle, in 1387.

Tried for treason in 1388. Usk was condemned to death. At his execution, March 4. 1388, he was first hanged and then beheaded by 30 blows with a sword.

The *Testament of Love*, which includes passages similar to the translations of Boethius by Chaucer, is a work of almost 60.000 words. It portrays the author in prison as he has interviews with an apparition in the form of a beautiful lady called Love. Excessively tedious, its obscurity and dullness was demonstrated by the fact that successive editors did not discover that the leaves of the original manuscript had been shuffled and the body of the treatise misarranged. No manuscript of the work was preserved; it was first printed by William Thynne in his edition of *Chaucer* (1532). In 189; Walter William Skeat, with cancelled sheets to cover the unlucky mistake referred to above. issued a revised and annotated text in his *Chaucerian and other Pieces*.

USK, a small market town and urban district in the Monmouth parliamentary division of Monmouthshire, Eng., on the river Usk, 11 mi. S.N.E. of Newport by road. Pop. (1951) 1.609. Area 1 sq.mi. It xas a Roman fort, *Burrium*, and there are ruins of a castle built by the Clares in defense of the Welsh marches. The castle was taken by Simon de Montfort in 126j and suffered under Owen Glendower. The church of St. Mary perpetuates a Benedictine nunnery founded by Richard de Clare in 1236.

USK, a river of Wales and England, 70 mi. long, flowing to the Bristol channel. The source is on the north flank of Carmarthen Van, a summit of the Brecon beacons; the course passes Brecon, Crickhowell, Abergavenny, Usk and Caerleon. The river is noted for its salmon and trout fishing. Newport (*q.v.*), Monmouthshire, lies on its estuary.

USTI NAD LABEM (AUSSIG A. D. ELBE), a town in a region of the same name, Czechoslovakia, in a highland district at the confluence of the Bela and the Elbe, is an important Elbe port. Pop. (1950) 56,920. The town was ceded to Germany in 1938 by the pact of Munich, and reverted to Czechoslovakia after World War II.

USURY, the charging of interest in excess of that allowed by law for a loan of money or for the extension of the maturity of a debt. In early English law, usury meant compensation for the use of money regardless of amount.

The laws against usury are of ancient origin. Early lams of China and India prohibited usury. The Mosaic law limited the exaction of interest; the Roman law proscribed or regulated such charges. In England during the middle ages the practice of charging interest was maligned by the church and outlawed by the state. But the credit requirements of modern commerce caused removal of these restrictions in England and elsewhere. While the exaction of oppressive interest is not illegal under the common law of England or the Gnited States, a public policy which protects debtors from overreaching lenders has been implemented by the statute lam of both countries. In England the Moneylenders acts of 1900 and 1927 constituted a code providing for registration of moneylenders, governing the form of their contracts, limiting rates of interest and providing for the reopening by the court of moneylending transactions.

The state usury statutes in the U.S. impose a wide variety of limitations. Typically, they establish a maximum rate of interest which may be charged on loans. Some provide that contracts which require payment in excess of the lawful rate are void. These laws permit the borrower to avoid payment of principal as well as interest. Other statutes affect only the lender's right to recover interest in excess of the legal rate. Some usury laws protect natural persons but not corporations; others permit certain lenders to charge higher rates because they assume greater risks. In general, these statutes reflect a policy to protect borrowers without crippling the lenders and lending institutions.

See also MONEY-LENDING. (R. M. A.)

UTAH, which took its name from the Ute Indians, is a mountain-desert state in the western part of the United States. It is bordered on the north by Idaho and Wyoming, on the east by Colorado, on the south by Arizona and on the west by Nevada. The 45th state admitted to the union (in 1896), it is the 11th largest, about 345 mi. long and 269 mi. wide, with an area of 84,916 sq.mi., of which 2.577 sq mi. is water surface. Its people call themselves Utahns (not Utahans). Commemorative of incidents in pioneer history, the state flower is the sego lily and the state bird the sea gull; the state tree is the blue spruce. The capital is Salt Lake City.

PHYSICAL GEOGRAPHY

Physical Features. — Utah (situated between approximately latitude 37° and 42° N. and longitude 109° 3' and 114° 3' W.) is divided into three major physiographic areas, the Colorado plateau province, embracing most of the eastern half of the state and including the drainage basins of the Green, Colorado, San Judn and Virgin rivers with their tributaries; the Basin and Range province, better known as the Great basin, of which the western third of the state forms a part; and the northern Rocky mountains province, the northeastern sixth of the state, primarily consisting of the Wasatch and Uinta mountains (see also COLORADO RIVER; GREAT BASIN, THE).

More generally, Utah is divided into two Iargely arid regions by the rain-catching high mountains and plateaus which comprise the eastern rim of the Great basin. East of that divide lies the brilliantly coloured, fantastically eroded country which makes Utah a geological and scenic marvel, with deeply incised canyons, natural bridges and arches, and towers and turrets of every description. West of the divide lies the long chain of valleys collectively known as the Wasatch oasis, once covered by the 19,000 sq mi. Pleistocene Lake Bonneville, of which Ctah lake is a freshwater remnant and Great Salt lake, Sevier lake and Little Salt lake are saline remnants. Deposits laid down in the prehistoric lake created fan-shaped deltas at canyon mouths where all the principal Utah cities have been built and where most of the irrigable land is found. In the southwest, the warm valley of the Virgin gives Utah a subtropical region locally called Dixie.

Altitudes range from the 13,498 ft. of Kings peak, in the Uintas, to an approximate 2,100 ft. in the southwest corner, where Beaverdam wash flows into Arizona. The average elevation is 6,100 ft., but about 90% of the population is estimated to live at altitudes between 4,250 and 4,650 ft.

Climate. — Precipitation varies from less than 5 in. annually west of Great Salt lake to more than 40 in. in the Wasatch mountains. In general the climate is temperate, variations occurring, of course, relative to latitude and altitude. Seasons are well marked; low relative humidity minimizes the range in temperature, which may vary from 100' F. in summer to zero or below in winter. The highest recorded temperature is 116°, the lowest −50°. As a rule, the weather is sunny and pleasant.

Soils. — The aridity that has limited Utah's agricultural development has at the same time conserved the minerals in the soil. Some soils are 60% limestone and may never require additional lime. Elsewhere, the weathering of mountains that contain extensive phosphate deposits has produced soils with half again the amount of phosphorus found generally in the earth's crust. Excessive irrigation has damaged some soils by flushing out the plant foods or by bringing alkali salts to the surface; and precipitation of minerals by saline lakes has poisoned surrounding soils. Most farming is done on the sloping surface of lacustrine soils laid down in old Lake Bonneville, which are fertile, well-drained and advantageously situated for irrigation.

Vegetation. — Over 4,000 species of plants are found in Utah, reflecting six climatic plant zones, from the Lower Sonoran in the Virgin valley to the Arctic above the timber line on the higher peaks. Plants that grow in the warm southwestern deserts include creosote bush, screwpod mesquite, cactus and sword plant, and the Joshua tree. Juniper and sagebrush grow in all parts of the state, the latter denoting fertile, nonalkaline soils. Shad scale, saltbush and greasewood thrive in the alkaline desert areas. In the mountains grow many species of spruce, fir and pine. along with nurturing aspens. Cottonwoods characteristically mark out the courses of creeks; other common native trees are the big-tooth maple, red birch, mountain alder, box elder and such shrubs as scrub oak, dwarf maple, chokecherry, serviceberry, hawthorn and willow. Numerous beautiful wild flowers vary from prickly pear to columbine, sego lily to Indian paintbrush. Less agreeable are poison ivy, poison oak and stinging nettle. Native grasses, extending up into alpine meadows, are the basis of the state's grazing industry.

Animal Life. — Mule deer, brown bear, pronghorn antelope and cougar are the sole large animals that have maintained themselves in Utah. Bison, elk. grizzly bears and timber wolves became extinct, but the first two have been reintroduced. Infrequently, a moose nanders down from the north. Coyotes, bobcats and lynxes, like cougars, are hunted as predators. Fur-bearing animals include the weasel muskrat. beaver. badger, skunk, marten, fox and ringtailed cat. Among the rodents are jack rabbits, cottontails, snowshoes, pygmy and rock rabbits, prairie dogs, tree and ground squirrels, marmots, rats and field mice, and porcupines. Migratory waterfowl include many species of ducks and geese. Principal upland game birds are sage hens, pine hens, ruffed grouse and quail, and the introduced hybrid ring-necked pheasants. The golden eagle is the largest predatory bird; hawks and owls are numerous, as are magpies, and crows and vultures occasionally are seen. Songbirds include larks, blackbirds. finches, water ouzels and commoner birds. On bird refuges in Great Salt lake live great blue herons, white pelicans and sea gulls. To native trout, whitefish, suckers. chubs, minnows and other common fish have been added other species of trout, carp, catfish, bass, yellow perch and grayling. Reptiles and amphibians include rattlesnakes. gopher snakes! water racers. garter snakes, toads. frogs. salamanders, desert tortoises and lizards (among which the poisonous Gila monster is rare). A brine shrimp is one of the few life forms that can survive in Great Salt lake.

Parks, Monuments and Recreation. — Utah at mid-20th century had two national parks. Bryce Canyon and Zion; eight national monuments, Arches. Capitol Reef, Cedar Breaks. Dinosaur. Hovenweep. Natural Bridges. Rainbow Bridge and Timpanogos Cave: and the Golden Spike National Historic site. An expanding state park system initially included Camp Floyd near Fairfield. Dixie State park near St. George. the Old State house at Fillmore and the Pioneer monument at Salt Lake City. The High Uintas Wilderness area, like Utah's nine national forests. provide:, fishing. hunting. hiking. riding and packing and skiing. The Wasatch mountains adjacent to Salt Lake City and Ogden offer winter sports facilities.

River-running down the Green. Colorado and San Juan attracted enthusiasts prior to World War II. and the building of new multipurpose dams on those rivers at mid-century further stimulated boating in regions once inaccessible.

HISTORY

The Indians who occupied Utah when white chroniclers entered the region were principally of Shoshonean stock—Utes occupying the mountainous eastern half of the state, southern Paiutes living in the arid valleys of southwestern Utah and western Shoshone dwelling in the yet more arid reaches of northwestern Utah. Northern Shoshone and Bannocks occasionally ranged into northern Utah from present Idaho and Wyoming; and in the basin of the San Juan river lived the Navahos. an Athapascan people. All these Indians had a hunting and gathering culture, but some Pahvant Utes, Paiutes and Navahos practised simple agriculture. raising corn and pumpkins by rude irrigation. (See also NAVAHO; PAIUTE; SHOSHONE: UTE.)

Exploration. — The chasms and naked aridity of the Colorado plateau region rebuffed the earliest venturers to approach the Utah country, and not until 1776 was the first Spanish penetration made. Two Franciscan friars. Silvestre Vélez de Escalante and Francisco Xtanasio Dominguez, seeking a route from Santa Fe to missions newly established on the California coast. explored up through Colorado. then proceeded west across Green river above present Jensen and on through the Cinta basin to Utah valley. Impressed by its natural advantages. the priests recommended colonization of the valley. They turned south to the Sevier and Virgin rivers. and, finally. having abandoned the effort to reach Monterey, journeyed back to Santa Fe.

Spain (and after 1821. Mexico) never found the resources to establish a new colonial frontier. and only obscure Indian traders entered Utah from New Mexico for nearly half a century. The advance of the fur frontier into the interior nest. however, brought British trapper.; under Michael Bourdon into northern Utah in 1819, and between 1824 and 1527 the Utah country was fully explored by trapping parties—Americans coming northwest from Taos and southwest from South pass. while British trappers came south from western Montana. Great Salt lake was discovered and named at this time, and in 1826–27 Jedediah Smith, while making the pioneer overland journey from the Missouri river to California. became the first man to traverse Utah from north to south and from west to east. Of 16 annual rendezvous of the fur trade, the hrst four were held in Utah. 1825–28.

Tiear-round settlement by white men began in 1837–38. when Xntoine Robidoux established a trading post in the Uinta basin. originally near the mouth of White river but soon moved to present Whiterocks. His "Ft. Uintah" was abandoned in 1845, the year before Miles Goodyear established "Ft. Buenaventura" on the site of Ogden. the initial white settlement in the valley of the Great Salt lake. Goodyear sold out to the Mormons in 1847.

Meanwhile, between 1829 and 1831, a cars\-an route known as the Spanish trail was worked out between Santa Fe and Los Angeles; traversing southern and central Utah, it was used till 1849. In 1841 the Bartleson party, called the first overland emigrants to California, took wagons through northern Utah en route to their destination. John Charles Frémont, with a government exploring expedition, reconnoitered northern Utah in 1843, also visiting Frémont Island in Great Salt lake. Returning from California in 1844, he rode up through Utah as far as Utah valley before turning east. Frémont came back with another exploring expedition in 1845, pioneering south of Great Salt lake and across the Salt desert a new route made notorious as the Hastings Cutoff by California emigrants who used it in 1846. En route to the scene of their frightful starvation in the Sierra Nevada. the Donner-Reed party, among these 1846 emigrants, cut through the Wasatch mountains a route made a permanent road by the hlormon pioneers in 1847.

Settlement and Territorial Period. — The vanguard of the westward-moving Mormons reached the site of Salt Lake City between July 21 and 24. 1847, and under Brigham Young began establishing a commonwealth. Utah was then Mexican territory, but by the treaty of Guadalupe Hidalgo it came under U.S. sovereignty in 1848. From their ecclesiastical government the Mormons evolved a provisional state of Deseret (a Book of Mormon word, meaning "honeybee" and signifying industry) and in 1849 sought admission to the union. Deseret would have extended from the Rocky mountains to the Sierra Nevada, including a portion of the southern California seacoast, thus embracing not only present Utah and Nevada but also large parts of California, Oregon, Idaho, Wyoming, Colorado, New Mexico and Arizona. By the compromise act oi Sept. 9, 1850. however, congress created Utah territory, n-hich within Utah's present north and south boundaries extended from the Rockies to the eastern line of California. These initial boundaries were reduced by the creation of Colorado, Nevada and Wyoming between 1861 and 1868.

As soon as the Mormons were firmly established in Utah. Brigham \-oung began colonizing all the fertile valleys north and south of Salt Lake City. wherever streams permitted irrigation. This was a planned economy of a type and on a scale no other state had seen. and it gave Utah a culture differing from that of all other western states, a mixture of New England and the west. Salt Lake City from the time of its founding has been the Mormon world capital and. except for a brief period during the 1850s, the political capital of Utah. Other principal cities which developed early were Ogden, Provo and Logan (*qq.v.*).

Utah had a turbulent territorial history. Almost constant friction between U.S. officials and Mormon authorities led to the "Utah war" of 1857–58, when federal troops were sent to put down "rebellion." Although they were withdrawn on the outbreak of the American Civil War, California-Nevada volunteers under Col. Patrick Edward Connor took their place in 1862, garrisoning Ft. Douglas above Salt Lake City. These soldiers prospected widely, and their placer gold strike in Bingham canyon opened up Utah's mining economy. until then deliberately neglected by the Mormon leaders, who feared its possibly destructive impact on Mormon society. Meanwhile, comniunications were improved with mail service to California and the east. dramatized by the pony express (*q.v.*). Completion of the Pacific railroad at Promontory in 1869 induced the Mormons to build a connecting line from Ogden to Salt Lake City. followed by other roads north and south. which gave further impetus to the mining industry. These Mormon-built railroads. for the most part, were taken over later by the Denver and Rio Grande Western, which entered Utah from Colorado in 1882, or by the railroad completed to Los Angeles in 1905, now incorporated into the Union Pacific system.

Brigham Young's view that it was cheaper to feed the Indians than to fight them militated against widespread Indian wars, though there were periods of Ute hostility, the Walker War of 1853–54 and the Black Hawk War of 1865–68. The Utes were eventually placed on a reservation in the Uinta basin, Paiutes and Shoshone on smaller reservations; much later. lands south of the San Juan river were incorporated into the Navaho reservation.

After 1870 internal strains developed in the Mormon church between liberal and conservative elements, in part because of the evolution away from a basically agricultural economy, Simultaneously an influx of gentile (non-Mormon) elements brought political strife between Liberal and People's parties, continuing until the early 1890s. Both were factors in Utah's complex political relations with the federal government, which from 1862 began to search for ways and means to break down the tightly knit Mormon hegemony, viewed as incompatible with the American political system.

Statehood. — Five vain efforts to achieve statehood were made after 1849. Constitutional conventions of 1856, 1862, 1872, 1882 and 1887 accomplished nothing in the face of the determination of the federal government to force abolition of polygamy, which became the symbol of the supremacy of U.S. law over the Mormon way of life. The road to statehood opened only after the Mormons lost conclusive battles in the U.S. supreme court over damaging antipolygamy laws of 1882 and 1887. The church publicly surrendered in 1890 when the president, Wilford Woodruff, issued a manifesto declaring his intention to submit to the law and to use his influence to cause other church members to do likewise. In 1895 a new constitution was drafted, and on Jan. 4, 1896, the proclamation of statehood was signed by Pres. Grover Cleveland.

With the coming of statehood, the old social hostilities in Utah began to die out concurrent with the integration of the Mormons into U.S. society. Sharing in three wars, a far-reaching depression and a markedly expanding economy made Utah a part of the nation as it had not been before, bur the state's culture continued to be distinctive, of as much interest to modern visitors as the scenic splendors of its former badlands. Politically Utah became a two-party state when Mormon and anti-Mormon parties disbanded in anticipation of statehood. Until the era of the New Deal, representation in congress was usually mixed, and the state had governors from both parties. From 1932 to 1950 the Democrats were the dominant power, but the Republicans by the latter date had made such gains as to restore the state to its original balanced political complexion.

World War II brought important economic gains, including a vastly expanded steel industry, followed by major oil developments and a perceptible industrialization. This was reflected in renewed population gains and increased effortto develop the state's agricultural potential. Federal reclamation in Utah, supplementing the irrigation works of pioneer times, effectively began with the Strawberry reservoir project of 1912–16, which pioneered in diverting irrigation waters from one Utah watershed to another. Vastly greater projects were authorized during the 1950s, including the Weber basin and Central Utah projects, and the spectacular multipurpose dams at Flaming gorge and in Glen canyon, to conserve the waters of the upper Colorado river basin. From these extraordinary developments Utah could anticipate more water, more usable land, more power, more trade and varied new recreational facilities.

GOVERNMENT

The Utah constitution was formed by a convention at Salt Lake City, March 4–8, 1895, was ratified on Nov. 5 and came into effect when Utah was admitted to the union. One provision, irrevocable without the consent of the U.S. government, guarantees religious freedom, forbids sectarian control of public schools, prohibits polygamy and defines the relation of the state to the public lands. The constitution grants equal civil, political and religious rights to males and females alike, prohibits any law restricting freedom of the press or the establishment of religious sects, and forbids imprisonment for debt unless the debtor absconds. The right of suffrage is conferred on all U.S. citizens who have lived in Utah a year, in the county four months and in the precinct 60 days, but only those who have paid a property tax the year before may vote in elections levying special taxes creating indebtedness or increasing the state rate of taxation.

Executive. — The principal executive officials are the governor, secretary of state, state auditor, treasurer, attornt v general and superintendent of public instruction. The governor has the right of veto, but may be overruled through repassage of a bill by a two-thirds majority in both houses of the legislature. The board of pardons is made up of the governor, justices of the supreme court and attorney general. The board of examiners consists of the governor, secretary of state and attorney general.

Legislative.-- he legislative power is vested in a senate and a house of representatives, and in the legal voters, who have the power of initiating legislation and of referendum on all laws not passed by a two-thirds vote of both houses. A legislator must be a citizen of the United States, at least 25 years old, a qualified voter in the district from which he comes and a resident of Utah for three years and of his district for one year. Regular sessions of the legislature are held in odd-numbered years. Representatives are elected for two years, senators for four. The number of senators must not exceed 30, and there must be at least twice as many representatives as senators.

Judiciary. — The judicial power is vested in the senate sitting as a court of impeachment, and in a state supreme court, district courts, city courts, justices of the peace and other courts inferior to the supreme court, as established by law.

Local Government. — The basic local government is that of the county, functioning by statutory delegation of power from the legislature. The legislative and governing authority is an administrative tribunal, the board of county commissioners. Elected officers include (in addition to the three commissioners) a treasurer, sheriff, clerk, auditor, recorder, attorney, surveyor and assessor, who carry out administrative, recording, judicial, law enforcement, financial, election, educational, welfare, health, roads and agricultural functions. Cities and towns may be organized from parts of counties by municipal incorporation. According to population, Utah municipalities are divided into three classes. Cities of the first class, with population exceeding 90,000, are governed by a mayor and four commissioners. Cities of the second class, with population between 15,000 and 90,000, elect a mayor and two commissioners. Smaller cities elect a mayor and five councilmen; and towns are governed by a board of trustees consisting of a president and four trustees. The office of city auditor is elective for the first two classes, city treasurer for the third. State lam also permits the city council and board of trustees of any city or town to appoint a qualified person as city manager. Within a more restricted sphere, the powers and duties of municipal governments parallel those of county governments.

Finance. — Gross state revenue of the late 1950s was about double what it had been a decade earlier, reflecting both the expanding economy and the development of new sources of revenue. The sales tax, instituted in 1935, contributed almost one-third of all tax revenue. Other sources were income and mine occupation levies and proceeds from corporation, franchise, motor fuel, cigarette, beer and similar taxes. Licences and fees came chiefly from educational sources, reflecting the growth of the institutions of higher learning. Liquor income originated in the state monopoly of liquor sales. Federal grants-in-aid encompassed roads, public health and welfare and education, also including sizable miscellaneous grants.

Educational disbursements, amounting to almost one-third of total expenditures, were allotted to local school districts for equalization of educational opportunity, to universities and to junior colleges.

Expenditures and revenue had increased together, but between 1939 and 1955 the state retired its bonded indebtedness and became free of debt.

POPULATION

The population of Utah in 1850 was 11,380; in 1880, 143,963; in 1910, 373,351; in 1940, 550,310; in 1950, 688,862; and in 1960, 890,627. The population per square mile in 1960 was 10.5, as compared with 8.1 in 1950 and 6.7 in 1940 and with 49.6 in the U.S. in 1960. Such figures, however, do not take into account the concentration of most of Utah's population in a small area; close to three-fourths of the total population lives in the valleys extending 50 mi. north and south of Salt Lake City, one-fourth in Salt Lake City alone.

The 1960 census found that 561,546 or 63.1% of the population

*Populations are reported as constituted at date of each census.
Note: Dash indicates place did not exist during reported census, or data not available.

been for the people to live in compact towns and farm outlying areas. The state has three standard metropolitan statistical areas, which are Ogden, Provo-Orem and Salt Lake City. These areas had a total population of 600,770 or 67.5% of the total population of the state in 1960.

More than 70% of the state population belongs to the Church of Jesus Christ of Latter-day Saints.

EDUCATION

Public Schools. — Thirty weeks' annual school attendance is compulsory for Utah children aged from 6 to 18 years, though' local school boards may make exceptions after the age of 16. The state's 40 public school districts must make a stated financial effort in support of their schools, after which equalization aid is provided. As shown by the 1960 census, a larger proportion of children go to school in Utah than in most states. They also rank higher in level of grades completed; in the late 1950s it was found that 58% of the population over age 25 had completed high school, as compared with 20% nationally. The state has made a consistently superior effort in support of its schools, one-third of the state revenue being expended for this purpose and an estimated 7% of personal income.

Higher Education. — The University of Utah at Salt Lake City, chartered in 1850 as the University of Deseret, underwent a great expansion, particularly of its graduate schools, after World War II. and by the late 1950s it had about 10,500 regularly registered students annually. Governed by a 15-member state board of regents, the university comprises schools and colleges of letters and science, social work (graduate), business, education, engineering, law, medicine, mine and mineral industries, nursing and pharmacy.

Utah State university at Logan, chartered in 1888 as Utah Agricultural college, has 4,600 students. and includes colleges of engineering and forestry. Branches are the College of Southern Utah (1897) at Cedar City and Snou (1888) at Ephraim. Weber college at Ogden. founded in 1889, enrolls 3,150. Smaller state colleges are Carbon (1938) at Price and Dixie (1911) at St. George.

Brigham Young university at Provo, maintained by the Mormon church, matched the gronth of the University of Utah with an enrollment in the late 1950s of 10,400. The Mormon church also operates religious institutes near the state colleges. Westminster college (1875), operated by three Protestant denominations but nonsectarian, is in Salt Lake City. Smaller colleges are maintained by the Roman Catholic Church in Salt Lake City, Ogden and Price.

HEALTH, WELFARE AND CORRECTIONS

Public health and welfare are supervised by the state board of health. Unemployment insurance, old-age assistance and other social legislation conform to the federal Social Security act of 1935, but industrial accident insurance was provided for by law in 1917, and legislation governing hazardous occupations and hours for women and children is as old as statehood. Penal and charitable institutions operated by the state include a prison in Salt Lake county; an industrial school for delinquent boys and girls at Ogden; a school for the deaf and blind at Ogden; a training school for mentally incapacitated children at American Fork; a hospital for the insane at Provo; and a tuberculosis sanatorium at Ogden. Many private hospitals are operated by religious denominations.

THE ECONOMY

Three basic industries, manufacturing, mining and agriculture, backed up a fourth equivalent "industry," national defense, and by supporting industries — in which tourist trade and the exploitation of Utah's recreational potential bulk increasingly large — by the late 1950s had emerged as the foundations of the state's economy. Other major elements of the economy are wholesale and retail trade; government exclysive of defense; service and miscellaneous; transportation, communications and utilities; construction; and finance, insurance and real estate. Government — federal, state and local — is the largest employer; the seven large installations operated by the U.S. department of defense alone (chiefly in the Salt Lake City periphery) pay annual wages of about $100,000,000.

Agriculture. — Topography, climate, type of soil and, above all, lack of water have limited Utah's agricultural development. Although nearly 90% of the land, including the high mountains with their multiple-use national forests, is put to use, 87% must be utilized for grazing. Only 4% is used for crop production. and only two-thirds of that for irrigation farming, which explains Utah's low rank among the agricultural states (41st in the late 1950s) and the keen interest taken in reclamation projects under development in the Colorado river basin Income from farm marketing throughout the 1950s was stable, at about $150,000,000 annually. Almost 75% of farm income comes from livestock and livestock products (dairying, poultry. beef and lamb's wool), the rest from field crops (wheat, barley and other grains, dry beans, hay, alfalfa, potatoes and sugar beets), fruit (cherries, apples, peaches, apricots, berries and melons) and canning crops (tomatoes, peas and corn).

Mining. — Thanks in large part to the great opencut Utah Copper mine at Bingham, Utah continued as an important mining state after most of its early mines were exhausted, and through the 1950s, among the western states, ranked first or second in production of uranium, second in copper, gold and silver, third in lead and sixth in zinc. Almost 70% of mineral production is in the form of metallic minerals, 40% from copper alone, but iron mines in southwestern Utah after the 1940s gave the state fourth rank in iron, and, together nith coal from the extensive beds in Emery and Carbon counties, provided the base for a vigorous new steel industry. Petroleum recovery on a large scale began in eastern Utah in 1948; ten years later, with more than 35 oil pools discovered estimates of proved reserves ran from 2,000,000,000 to 3,000 000.000 bbl. Four counties, Duchesne, Grand. San Juan and Uintah produce all of Utah's oil. Utah's known reserves of uranium ore (estimated at 5 700,000 tons in the late 1950s) place the state third among the states in reserves of this mineral and first in richness of ore. Many other metallic and nonmetallic minerals give weight to the mining economy.

Manufacturing. — Manufacturing assumed its dominance in the Utah economy during and after World War II, rising in value from $87,000,000in 1939 to $450,000,000 in 1957, with over 1,000 manufacturing firms. About 40% of total employment is associated with the smelting, refining, processing and fabricating of metals and minerals, while another 25% is connected with food processing. Printing and publishing, stone, clay and glass products, petroleum and coal products, chemicals, lumber and wood products and apparel are also important. Yew manufactures associated with defense include microwave and electronic transmitting tubes, ram-jet engines and solid-propellant rocket engines. A minor but interesting development was increased use of Utah's magnificent scenery by motion-picture makers.

Transportation and Communications.—On May 10, 1869, the transcontinental railway was completed when the Union Pacific and Central Pacific were united by the golden spike at Promontory. The Union Pacific has remained the dominant Utah railroad, having taken over many locally built roads as well as the Los Angeles & Salt Lake, and being connected with the Southern Pacific at Ogden. The Denver and Rio Grande Western at Salt Lake City has a similar California outlet in the Western Pacific. Federal. state and local governments by the early 1960s had constructed nearly 32,000 mi. of streets and roads in Utah, including six major U.S. highways, which served about 400,000 vehicles licensed in the state. More than 60 airports scattered over the state mainly served private aircraft, but major facilities were the expanding commercial airport at Salt Lake City and the Hill air force base near Ogden.

Five daily newspapers were published in Utah in the late 1950s, and about 55 weeklies or biweeklies. The Church of Jesus Christ of Latter-day Saints, which operates its own publishing plant, issues several monthly publications. Five television stations were operating, and numerous radio stations.

BIBLIOGRAPHY.—General bibliographical essays may be found in Dale L. Morgan, *The Great Salt Lake* (1947), and in Leonard J. Arrington, *Great Basin Kingdom* (1958). A classified bibliography appears in Utah Writer's Project, W.P.A., *Utah: a Guide to the State* (1941). General histories include H. H. Bancroft, *History of Utah* (1889); O. F. Whitney, *History of Utah*, 4 vol. (1892–1904); Noble Warrum, *Utah Since Statehood*, 3 vol. (1919); A. L. Neff, *History of Utah, 1847 to 1869* (1910); Wain Sutton, *Utah: a Centennial History*, 3 vol. (1919). The period to 1890 is covered in an economic history by L. J. Arrington and sociologically by Nels Anderson, *Desert Saints* (1912). *See* also Charles P. Schleicher and G. H. Durham, *Utah: the State and Its Government* (1943). General descriptive works, in addition to *Utah: a Guide to the State*, include G. W. James, *Utah, the Land of Blossoming Valleys* (1922); Wallace Stegner, *Mormon Country* (1942); Maurine Whipple, *This Is the Place: Utah* (1945).

Current statistics on production, employment, industry, etc., may be obtained from the pertinent state departments; the principal figures, together with the current history, are summarized annually in the *Britannica Book of the Year*, American edition. (D. L. M.)

UTAMARO KITAGAWA (1754–1806), Japanese painter and print designer, one of the best known of the designers of colour prints. was born at Kawayoye in 1754. His landscape paintings and drawings of insects are highly regarded by Japanese critics, but his fame among Europeans will always rest on his designs for colour prints, the subjects of which are almost entirely women—professional beauties and the like. Utamaro's colour prints are distinguished by an extreme grace of line and colour, and his composition is superb.

Even in his lifetime Utamaro achieved enormous popularity. His work had a considerable reputation with the Dutch who visited Nagasaki, and it was imported into Europe before the end of the 18th century. (E. F. S.; X.)

UTE, a Shoshonean-speaking group of Indians of western Colorado and eastern Utah, whose name was given to the latter state. When Father Silvestre Vélez de Escalante traversed their territory in 1776, the Ute had no horses and lived in small family clusters subsisting by food collecting. At that time. there was no clear distinction between the Ute and the southern Paiute, both of whom speak the Ute-Chemehuevi branch of Shoshonean. After acquiring horses in the early 19th century, however, the Ute of western Colorado and later of northern Utah, became organized in loose bands of hunters. As the area became settled by Europeans, these bands became predators on livestock. In the southern regions of Utah, Nevada and California, however, the Ute-Chemehuevi remained afoot and became known as southern Paiute.

After the Indian wars, most of the Colorado Ute were settled on a reservation in southwestern Colorado, while those of Utah were placed on the Uintah reservation. where most of them remain today. They numbered about 1,000 in Colorado and 2,660 in Utah in the second half of the 20th century.

UTICA, a city of ancient Africa, 15½ mi. N.W. of Carthage. Agathocles easily captured it in 310. After the destruction of Carthage it received, the rank of a *civitas libera* with an accession territory. After the battle of Thapsus in 46 Cato shut himself up in Utica for the final struggle against Caesar. and there committed suicide. Utica was captured by Gaiseric and the Vandals in 439, reconquered by the Byzantines in 534 and finally! in 698, it fell into the hands of the Arabs and was depopulated.

UTICA, a city of central New York, C.S.. the seat of Oneida county and a central city of the Utica-Rome standard metropolitan statistical area (Herkimer and Oneida counties). Situated on the Mohawk river in the upper Mohawk valley, 90 mi. N.W. of Albany, Utica is on the main line of the New York Central railroad, the State Barge canal and the New York thruway. Its county airport is the home port of Mohawk Airlines.

Rich in early American history, the area was the country of the Iroquois federation. specifically the tribes of the Mohawks and Oneidas. French Jesuit missionaries were the first white men to enter the valley after Champlain and Hudson sailed to its edge. They were followed by Protestant missionaries, the most distinguished of whom was perhaps Samuel Kirkland, who in 1793 founded Hamilton Oneida academy, for Indians, in the territory later named after him as the Town of Kirkland. (Hamilton college. for men, developed from this academy.) The first settlers were Dutch and Palatinate Germans. followed by New Englanders. Among the many pioneers the most distinguished was Peter Smith (1768–1837), later a partner of John Jacob Astor. and father of Gerrit Smith (*q.v.*), born there in 1797. The area was the scene of many battles between Indians. French. Dutch and English interests; the most famous action was the battle of Oriskany (9 mi. W. of Utica), during the American Revolution, in which Gen. Nicholas Herkimer's continental troops stopped the advance of the British through the valley. A monument marks the spot.

Utica was incorporated as a village in 1798 (its name was drawn from a hat) and as a city in 1832. It stands at the centre of an east-west chain of the communities of Little Falls. Herkimer, Ilion. Mohawk. Frankfort, Rome and Sherrill (the last founded by the Oneida Community, a Utopian society which became known for its manufacture of silverware). The population of Utica was 100,410 in 1960. a loss of 1.1% since 1950; that of the standard metropolitan statistical area was 330,771, an increase of 16.4%. There are in the population Welsh. German. Irish, Italian and Polish elements. the descendants of immigrants who followed the original settlers.

Utica has always been an important transportation and textile centre. It became more diversified in the second part of the 20th century with the replacement of textiles by metals and machinery manufacture, and important government facilities.

Two new coeducational institutions were founded in 1946 in Utica. The Mohawk Valley Technical institute is a county-state junior college. Utica college of Syracuse university is a four-year college of arts and sciences. In addition to Hamilton college, mentioned above. there is also an art gallery and school of painting, the Munson-Williams-Proctor institute. The state Masonic home is located there.

Utica has a planning board to guide its physical development and its satellite villages are following this lead. The city has an excellent system of large parks supplemented by other recreational facilities. Its location in the heart of many fine state parks, including the immense Adirondack park, makes it a favoured spot for every kind of outdoor sport. (V. C. C.)

UTILITARIANISM, the ethical theory that holds that an action is right if it achieves the greatest good of the greatest number of people.

The "greatest good" or, more precisely, the "greatest happiness" first appears as a formula for a moral standard in Richard Cumberland's De *Legibus naturae* (1672) where its authority is derived from God, Whose basic law it is. This theological version was further developed by John Gay, Abraham Tucker and William Paley.

It was with Jeremy Bentham, however, that the term "utilitarian" originated and the theory became well known and influential. Bentham first took it up as a criterion for distinguishing good from bad laws, and his use of it was throughout practical and political rather than theoretical. He defended utilitarianism as a moral theory in *Principles of Morals and Legislation* (1789) and in *Deontology* (published posthumously. 1834). He held that the only object a man ever pursues as an end is happiness. that is, pleasure and the absence of pain (hence his theory is sometimes called hedonistic or eudaemonistic utilitarianism). To explain how an individual, whose sole pursuit is his own pleasure, can have a duty to pursue the general happiness, he invoked certain "sanctions": if I do not take account of the pleasures and pains of others, I shall be arrested (the political sanction) or ostracized (the moral or social sanction) or punished hereafter (the theological sanction). To call a motive good merely means that it usually brings good consequences and is therefore approved merely as a means. *(See* BENTHAM, JEREMY.)

J. S. Mill in *Utilitarianism* (1863) provided the theory with its classic expression but at the same time imported into it elements inconsistent with its hedonistic (or pleasure) basis: for example, the assertions that some pleasures are higher or nobler than others and that ends other than pleasure, such as virtue or knowledge, can be desired for their own sake. The last important "happiness-utilitarian" was Henry Sidgwick. In his *Methods of Ethics* (1874) he explicitly rejected the psychological hedonism on which Bentham and Mill had based their arguments and presented a very full defense of the "greatest happiness principle" as the only fundamental principle of morals. *(See* MILL, JOHN STUART.)

G. E. Moore in *Principia Ethica* (1903) rejected the view that happiness is the only thing good as an end. Knowledge, aesthetic enjoyment and personal affection all contribute elements of intrinsic value to the *summum bonum.* But, in *Ethics* (1912), he defended the principle that an act is right if it achieves the greatest good of the greatest number. His version of the theory is therefore sometimes called agathistic or ideal utilitarianism to distinguish it from the hedonistic or eudaemonistic utilitarianism of his predecessors. Moore also recognizes that. besides judging actions as right or wrong (on the utilitarian criterion), we also judge them by reference to their motives and intentions as praiseworthy or blameworthy; he treats this as an independent type of judgment and does not attempt to treat motives merely as means to an end, as the earlier utilitarians did.

Moore is clear that it is the rightness of a particular act which is determined by the utilitarian criterion. Mill and Sidgwick sometimes show traces of an alternative view. On this view. it might sometimes be right to do an act which did not produce the best possible consequences. because this act was required by a rule (of justice, or of gratitude. or of truthfulness). These rules mould then be justified by their general utilitarian value. But this more plausible view is neither fully worked out by them nor is it distinguished from the simpler view characteristic of Moore.

Utilitarianism owes its permanent attractiveness to its apparent ability to combine two incompatible positions. If my only possible aim is my own happiness. then benefits to others are relevant only so far as it pays me to achieve them. If I can aim at the good of mankind as an ultimate end, then it is false that my only aim is my own happiness. *See* ETHICS; ETHICS; HISTORY OF; *see* also Index references under "Utilitarianism" in vol. 24.

UTILITY. In economics the utility of a good is not conceived to be its usefulness, as judged by any objective standard. but its importance to a consumer. Capacity to excite desire rather than to yield benefits or bestow happiness is the measure of a good's utility, in this technical sense, and only as the conduct of life is completely rational and guided by adequate foresight are the two capacities the same.

The law or principle of diminishing utility, which serves in economics as a logical foundation for the laws of demand, is merely a general statement respecting an obvious aspect of the way in which men apportion their time and their means. Summarized, it is that progressively diminishing importance is attached by a consumer to successive additional increments of a good. Diminishing utility has two aspects: absolute and relative. One suit of clothes is more important than a second, and a second is more important than a third. It is more important that in a cold climate one should have enough coal to keep one room warm during the winter than that a second, a third or a fourth room should be heated. It cannot be said, however, that all luxuries, and particularly such as minister to the "desire for distinction," have different uses which can be ranked in an order of diminishing importance.

Marginal utility is the utility of the last increment (not necessarily last in point of time) which the consumer thinks worth acquiring. *See* also ECONOMICS and VALUE. (A. Yo.)

UTMAN KHEL, a Pathan tribe who occupy the hills to the north of Peshawar in West Pakistan. They claim to be descendants of Baba Utman, who accompanied Mahmud of Ghazni in his expedition into India in 997. The Utman Khel are a tall, stout and fair people, but in dress and general customs follow the neighbouring peoples of Bajour.

UTO-AZTECAN FAMILY, perhaps the most numerous and important stock of North American Indians. named after a representative northern and southern tribe, extended in a long irregular tract, broken only in 'Arizona. from ldaho to Tabasco. Mex., and beyond as far as Panama in scattered populational islets. The bond of union was linguistic and geographic rather than racial or cultural.

In customs there was little common to the lowly northern tribes and the more advanced ones of southern Mexico.

See INDIAN, NORTH AMERICAN. (A. L. K.; X.)

UTOPIA, an ideal commonwealth whose inhabitants exist under perfect conditions. Hence "utopian" is used to denote a visionary reform, which fails to recognize defects in human nature. The word first occurs in Sir Thomas More's *Utopia,* published in Latin as *De optimo reipublicae statu, deque nova insula Utopia* (Louvain, 1516). It was compounded by More (*q.v.*) from the Greek *οὐ,* not! and *τόπος*, a place, nowhere.

The idea of a utopia is, even in literature, far older than More's romance; it appears in the *Timaeus* of Plato and is fully developed in his *Republic.* The idealized description of Sparta in Plutarch's life of Lycurgus belongs to the same class of literary utopias. A similar idea occurs in the Greek. and the mediaeval Norse, Celtic and Arab legends which describe an earthly paradise in the western or Atlantic ocean *(see* ATLANTIS). Few of these survived after the explorations of Columbus, Vasco da Gama and others in the 15th century; but in literature More's *Utopia* set a new fashion: the imaginary voyager arrives at the ideal state.

In the writings of Thomas Hobbes. Sir Robert Filmer and Jean Jacques Rousseau an ideal state of society is described. In Francis Bacon's *New Atlantis* (1624–29) science is the key to universal happiness; Tommaso Campanella's *Civitas Solis* (1623), which portrays a communistic society, was largely inspired by Plato's *Republic;* James Harrington's *Oceana* (1656), which had a profound influence upon political thought in America, is a treatise rather than a romance and is founded on the ideas that property, especially in land, is the basis of political power, and that the executive should only be controlled for a short period by the same man or men. With these may be compared the Christian utopias, J. V. Andreae's *Christianopolis* and S. Golt's *Nova Solyma* (1648). Bernard de Mandeville's *Fable of the Bees* is unique in that it describes the downfall of an ideal commonwealth.

Other utopias are the "Voyage en Salente" in Fénelon's *Tilemaque* (1699), Vairasse's *Histoire des Sevarambes* (1716); Mercier's *L'An 2440* (1742); James Burgh's *Account of the Cessares* (1764); J. B. Say's *Olbie* (1800); Étienne Cabet's *Voyage en Icarie* (1848); Bulwer Lytton's The *Coming Race* (1871); Samuel Butler's *Erewhon* (1872) and *Erewhon Revisited* (1901); Edward Bellamy's *Looking Backward* (1888); William Morris' *News from Nowhere* (1890); H. G. Wells's *Anticipations* (1901), *A Modern*

Utopia (1905) and *New Worlds for Old* (1908). Many utopias, like the *Fable of the Bees* and *Erewhon,* are satires. Others were based on socialistic ideals; among these may be mentioned *Freiland, ein soziales Zukunftsbild* (1890) and *Reise nach Freiland* (1893), by the Austrian Theodor Hertzka (b. Budapest, 1845), portraying a commune in central Africa.

UTRECHT, the smallest Netherlands province, has the Zuider Zee washing its very short northern frontier. Its area is 511 sq.mi., and with a population of 650.304 (1957 est.) it ranks third in the list of most densely populated provinces. This is also the position which it occupied at the beginning of the 20th century, but between 1900 and 1930 its average density increased from 470 per square mile to 773 per square mile. Utrecht city (*q.v.*) had (1957 est.) 249,324 (mun.) inhabitants (fourth in the country) and Amersfoort 66.403 (mun.). The other settlements are relatively small. The province falls entirely within the Rhine delta. The southern limit of the Scandinavian ice passed diagonally through the province from northwest to southeast in the vicinity of Ctrecht city, and the western part of the province consists of clay lands and, in the northwest, of low fen.

The sand and gravel eastern region is covered with bare heaths and patches of woods, and the occupations of the scanty population are chiefly those of buckwheat cultivation and peat digging. Amersfoort is the only large town there, but along the western edge of this tract there is a row of thriving villages. such as Amerongen, Driebergen. Doorn and Zeist.

The southern area is picturesque with more extensive woodlands and has long been popular for country seats: Zeist provided a hunting box for William III, and Doorn a retreat for former Kaiser Wilhelm II. Veenendaal, on the southeastern border. became a market for the local beekeeping industry, and Amersfoort, one of the chief seats of the Old Catholics, a thriving garrison town with a variety of crops, including tobacco, growing on the sandy hills in its neighbourhood. It retained the Koppelpoort gateway spanning the Eem, probably the finest and least altered medieval entry to any town in the Netherlands. Within the town the old ramparts were laid out as leafy promenades. Baarn, farther downstream, is a popular summer resort for Amsterdam citizens, and on the east side of the Eem are the typical peaceful fishing villages of Bunschoten and Spakenburg.

At Maarsen, near Utrecht, was built Zuylen castle. Rhenen was once the seat of an independent lordship, though afterward joined to the bishopric of Utrecht. The ancient church was provided with a fine tower (1492–1531). Wijk-by-Duurstede, originally a Roman settlement, was of considerable commercial importance as early as the time of Charlemagne but decayed as a result of Norman raids in the 10th century. The tower of the ruined castle of the bishops of Utrecht still stood in modern times.

Ecclesiastical History.—The province represents the bulk of the ancient see, founded in 722 by St. Willibrord. The bishopric was weak compared with Holland, Gelderland and Brabant, and the middle ages saw local wars. Holland's growth in the 14th century forced Gelderland and Brabant to relinquish their claims over the see. Later, in the 15th century, its supremacy passed to the dukes of Burgundy and, still later, to the emperor Charles V. Notwithstanding the elevation of Utrecht to an archbishopric (1559), it was one of the seven provinces on the Protestant side which signed the union of Utrecht (1579) against Spain. The chapter of the see was secularized and the power of the members of the five ecclesiastic colleges was severely curtailed.

Under the vicariate of De la Torre (1651), trouble began with Rome, which claimed the right of appointing successors. In 1702 Codde, the nominee of the Dutch secular clergy, was accused by the Jesuits of Jansenism (*q.v.*). Although innocent, he was deposed, and his chief opponent, De Kock, was appointed in his stead. De Kock was expelled from the country by the states-general and the Church of Utrecht was without a head.

In 1713 the French government enforced the bull *Unigenitus,* and many refugee priests entered Holland, including Dominique Varlet who settled in Amsterdam in 1720. Steenoven, in 1723, was elected archbishop by the chapter of Utrecht and his subsequent consecration by Varlet led to a general excommunication by the pope. The Jansenist Church of Holland was continued as an independent body accepting the general councils, but rejecting *inter alia* the Vatican council and the infallibility of the pope. Two suffragan sees were created: Haarlem (1742), Deventer (1757); and though, in the next century, the church lost membership, yet it later attracted numbers of the less rigid Roman Catholics. At first the Jansenist church of Utrecht established close relations with the Old Catholic movement in Germany, but it subsequently strongly disapproved the departures of the German members from Catholic tradition. The Jansenists refused to recognize the validity of Anglican orders, and in 1908 a singular offshoot of the Church of Utrecht was established in England when Gerard Gul (Jansenist archbishop of Utrecht) consecrated Arnold Harris Mathew bishop of the Old Catholics in England. Meanwhile, in 1851, in Holland itself the Roman Catholic hierarchy had been restored, with Utrecht as the archiepiscopal see.

For general statistics see HOLLAND.

UTRECHT, the capital of the province of the same name, lies in the centre of the Netherlands, on the Kromme Rijn (winding Rhine), the Leyden Rhine. the Vecht and the Amsterdam-Rhine canal, 19 mi. S.S.E. of Amsterdam. Area 19.8 sq.mi. Pop. (1957 est.) 249,324.

Utrecht is well known for its university, the Industries fair and as a junction of railways, waterways and highways. It is a picturesque old town, especially in the centre. Unique in the whole of western Europe are the Oude Gracht and the Nieuwe Gracht (sunken canals) with their wharves and deep cellars, formerly used by merchants for storage. The Dom tower, in Gothic style. is about 360 ft. high and has two chapels and a fine chime of bells. Formerly this tower was connected with the Dom church opposite, but the nave of the church (1254–1517) collapsed during a hurricane in 1674 and was never rebuilt. The transept, the choir and two chapels remained and are still in good condition. The chapter room (1409), connected to the church by a beautiful Gothic cloister, is now used by the State university as its main hall. Other churches are Janskerk (1040), Pieterskerk (1048) with a beautiful Romanesque crypt, Nicolaikerk (1131), Jacobikerk (1173), Buurkerk (10th-century), Geertekerk (1260) and St. Catharijnekerk (1468) which is now owned by the Roman Catholic archbishopric. Paushuize (Pope's house) was built for the only pope of Dutch blood, Adrian VI, about 1520; it is now the residence of the queen's governor for the province of Utrecht. In the 19th century and later, modern residential districts have arisen, with fine parks, as well as the Town hall (1830), office buildings and the Municipal theatre (1941). The Maliebaan (1636) is the loveliest promenade in the Netherlands. The old ramparts along the moats were replaced by parks and pleasure grounds in the 19th century.

The Utrecht State university (1636) is the largest of the Dutch state universities. The university library, partly housed in the palace built for King Louis Napoleon, contains about 300,000 vol. Utrecht has a great many special schools for architecture, mechanical technology and electrical engineering, typography, engineering, horticulture, textiles, etc. There are a municipal symphony orchestra, a modern theatre and a number of museums including the Central museum (pictures, sculpture, historical costumes, period style rooms, archaeological finds); the Archiepiscopal museum (medieval art); the Dutch Railway museum; the Netherlands Gold, Silver and Clock museum; the Museum of New Religious Art; the Old Catholic museum; the State Forestry museum; and the Acoustical museum.

Communications and Industry.—Utrecht is connected with other towns in the Netherlands and abroad by means of railways, highways and water. The Amsterdam-Rhine canal, running beside the town, is one of the busiest west European waterways.

Utrecht has a great many industries, such as the construction of bridges and wagons, iron and steel foundries, aluminum, clothing, furniture, foodstuffs, typographical and chemical industries, etc. Many of the products are exported. There are big vegetable and fruit markets and the cattle market is one of the largest in the country. The state mint is in the city as well as banking, credit and insurance businesses.

Industries Fair.—The Royal Dutch Industries fair, founded in 1916. is an important international commercial event. General international fairs are held in spring and in autumn. The so-called professional fairs are held in the Industries fair buildings, situated in Vredenburg (1921–38), Bernhard hall (1953), Margriet hall (1954). Juliana hall (1956) and Merwede hall (1958).

History.—Utrecht is a city of great antiquity. It was first mentioned by Roman writers as Trajectum. Its present name derives from "Uut" (downstream) and "Trecht" (ford). In 48 B.C. the Romans built a fortress called Albiobola. which was part of a belt of fortifications along the northern frontier of the Roman empire. Around this fortress arose a settlement from which Utrecht originated. Albiobola existed up to the 3rd century A.D. Later the Franks built, on the site of the fortifications, a church dedicated to St. Martin, which was probably the first Christian church in the northern Netherlands. Early efforts made to propagate Christianity from this church were in vain. but after A.D. 690 the Frankish king Pepin (Pippin), who had just defeated the Frisians. allowed the Anglo-Saxon Bishop Willibrord to establish his see there. Willibrord became the archbishop of the Frisians and, starting from Utrecht, converted to Christianity most of the northern Netherlands. Under the bishop of Utrecht the city became an important temporal as well as ecclesiastical power and a centre of trade and industry. Its greatest prosperity was in the 11th.and 12th centuries. Toward the end of the 13th century trade declined, partly because of political disturbance and partly because of the rise of other towns, such as Amsterdam and Dordrecht; but industry, mainly cloth weaving, held its ground and for centuries provided a living for many of Utrecht's citizens.

In the middle ages Utrecht remained the most powerful and important town in the northern Netherlands. The citizens opposed the temporal power of the bishops and it mas the guilds particularly that led the way in this struggle. As early as 1304 an urban council was created. In 1528 the bishop of Utrecht, Henry of Bavaria, renounced his temporal rights in favour of Charles V of Spain. Spanish domination prevailed up to 1577, when the women of Utrecht, led by Katrijn van Leemput, an ensign's wife, scaled the fortress of Vredenburg. built by Charles V. and started to pull it down. After that time Utrecht supported the cause of the prince of Orange. Partly as a reaction to Spanish occupation Utrecht became a firm stronghold of Calvinism and remained so for many centuries. A treaty to drive out the Spanish soldiers was concluded in 1579 and signed by seven provinces. This treaty, known as the union of Utrecht (although Utrecht had hardly any say in the matter), exercised great influence on the history of the Netherlands and may be regarded as the foundation of the later kingdom of the Netherlands.

In 1713 Utrecht witnessed the conclusion of the treaty of Utrecht, which ended the War of the Spanish Succession. In 1807 Napoleon's brother Louis Napoleon. king of Holland (1806–10), made up his mind to make it his residence, but the course of history decided differently. Utrecht gradually became an ordinary provincial town. Thanks to its central position in the Netherlands and to the numerous big institution. and enterprises settled there. Utrecht developed and flourished in the 20th century. It is the seat of the provincial government, of a Roman Catholic archbishopric, of the Old Catholics, of the county court and is a centre for congresses and meetings. (J. C. J.)

UTRECHT, TREATY OF, the general name given to the important series of treaties which in 1713 and 1714 concluded the War of the Spanish Succession (*q.v.*).

The congress opened on Jan. 29. 1712. But it was not until July 10, 1712, that Ring Philip of Spain signed a renunciation of his rights to the succession of the crown of France. Then, England and France having concluded a truce, the pace was quickened and the main treaties were signed on April 11, 1713.

By the treaty between England and France. Louis XIV recognized the Protestant succession in England and undertook to give no further aid to the Stuarts. France ceded to England, Newfoundland. Nova Scotia or Acadia. the island of St. Kitts or St. Christopher. and the Hudson's bay territory. and promised to demolish the fortifications of Dunkirk.

The treaty between France and the United Provinces was mainly concerned uith securing the barrier of fortresses. These arrangements were somewhat complicated and to a large extent provisional, as Austria and Bavaria, two countries deeply interested in the fate of the Netherlands, had not yet assented to the terms of peace. By a commercial treaty concluded on the same day, France gave the Dutch privileges similar to those enjoyed by England. Other treaties concluded at the same time were between France and Savoy, France and Prussia, and France and Portugal. By the first the duke of Savoy regained Savoy and Nice, and France undertook to obtain for him the island of Sicily and the title of king. By the second Prussia secured some small additions of territory, including part of Gelderland and Neuchâtel; in return France definitely and finally obtained the principality of Orange. The treaty between France and Portugal mainly concerned the Portuguese settlements in Brazil, her claim to these being recognized by France.

Other treaties were signed at Utrecht between Spain and the allies, Philip now concluding these as the recognized king of Spain. On July 13, 1713, a treaty was signed between England and Spain, which embodied certain commercial arrangements previously made between the two countries. Spain ceded to England Gibraltar and Minorca, and promised to give up Sicily to Savoy. She gave also to England the monopoly for 30 years of the lucrative slave trade uith Spanish America, hitherto enjoyed by France: this was the famous Asiento treaty. The peace between Spain and the United Provinces was signed on June 26, 1714, but the conclusion of that between Spain and Portugal was delayed until the following February. The former was concerned mainly with commercial matters, Spain giving the United Provinces most-favoured-nation treatment.

The treaty of Ctrecht also provided compensation for the Emperor Charles VI as soon as he surrendered his claim to Spain. He was to receive Naples and Milan, and also the Spanish Netherlands, henceforward known as the Austrian Netherlands.

But the general pacification was still incomplete, as France and the empire continued at war. It was not long, however, before Charles VI realized that without allies he was no match for France.

Accordingly, his representative, Prince Eugène, met the French marshal Villars at Rastatt in Nov. 1713, and here peace was made on March 7, 1714, Charles VI concluding the treaty without waiting for the assent of the states of the empire. This consent, however, was necessary, and a little later the representatives of some of the princes of the empire met those of France at Baden, where, on Sept. 7, 1714, the treaty of Baden, the last of the treaties included in the general peace of Utrecht, was signed. This dealt entirely with the question of the frontier between France and the empire, which was restored as it was before the war except that France gained Landau.

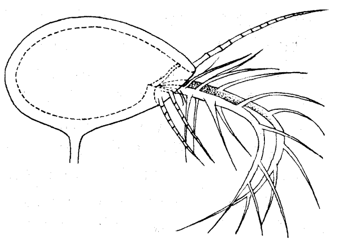
One other important matter was dealt with at Utrecht. A second barrier treaty between England and the United Provinces was signed on Jan. 30, 1713, and a third treaty signed at Antwerp on Nov. 1;, 1715 clinched the matter. Seven fortresses were to be garrisoned by a total of 35,000 men, three-fifths of the cost being borne by the imperial government and the remainder by the United Provinces.

The treaties were bitterly assailed by the Whigs, and after the accession of George I four of its Tory authors, Bolingbroke, Oxford, Ormonde and Strafford, were impeached for concluding it, the charges brought against them being that they had corresponded with the queen's enemies and had betrayed the honour and interests of their own country.

BIBLIOGRAPHY.—The text of the treaty of Utrecht is published as the *Actes, mémoires et autres pièces authentiques concernant la paix d'Utrecht* (Utrecht, 1714–15); and by C. W. von Koch and F. Scholl in the *Histoire abrégée des traités* (1817–18). As far as it concerns the party politics of England, there is much about the peace in Dean Swift's works. *See* also C. Giraud, *La Paix d'Utrecht* (1847); I S. Leadam *Political History* of *England 1702–1760* (1909); A. W. Ward in the *Cambridge Modern History*, vol. v (1908), and the *State Trials* for the proceedings against the impeached English ministers. But perhaps the most valuable work on the whole peace is O Weber's *Der Friede von Ctrecht. Verhandlungen zwischen England, Frankreich,*

dem Kaiser und den Generalstaaten 1710–1713 (Gotha, 1891).

UTRICULARIA, a genus of the bladderwort family (Lentibulariaceae) containing about 250 species of carnivorous fresh-water and land plants. Closely related are the genera *Biovularia* (two species) and *Polypompholix* (probably four species). They are commonly called bladderworts because of their numerous small hollow traps, first regarded as bladders and thought. erroneously, to serve for floating the plant. Since land forms also have "bladders." this view was obviously open to question, and was shown to be false. *Utricularia* species live in various environments; some are aquatic, some are terrestrial and some are intermediate. growing either in water or on wet soil. The aquatic plants live either submersed in or floating upon usually still, fresh waters, though two species are known which live attached to stones or other firm surfaces in rapidly running streams. In the latter the traps are, literally, streamlined, and are thus adapted to moving water. The land forms grow recumbent upon wet soils, usually of quartz, sand, mud or moss. In jungles, a few species grow upon moist foliage; one or two species grow in the water held by the leaf rosettes of certain epiphytic bromeliads (related to the pineapple) in South America.



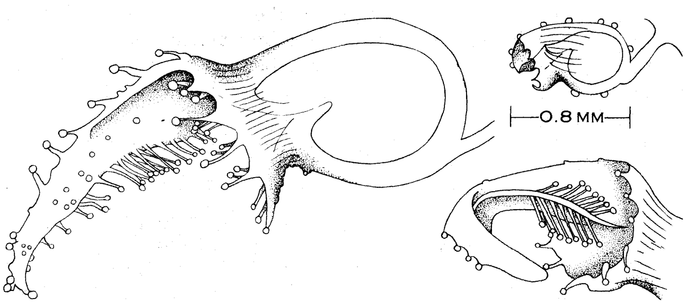
FROM LLOYD, "THE CARNIVOROUS PLANTS" (CHRONICA BOTANICA CO.)

FIG. 1.—UTRICULARIA GIBBA SHOWING SIDE VIEW OF A TRAP

These plants are of world-wide distribution, ranging longitudinally from Greenland to south Africa, North America has about a dozen species including a number of land forms (*e.g., U. subulata*). Europe has about four species, all of which are submersed or partly submersed forms. The largest. common to both hemispheres in the temperate regions, is U. *vulgaris.* Floating in quiet waters, this attains a length of three feet or more, with several branches and with finely dissected leaves bearing numerous traps, two to three millimetres long, which serve to catch minute animals, such as water fleas (Crustacea), larvae of flies, including mosquitoes, small spiderlike creatures, etc. The prey serves as a source for nitrogenous food. and probably for salts of various kinds. Minute algae (*e.g., Euglena)* often are found living apparently happily within the traps, subsisting on the readily available food source.

A few land forms are of considerable stature, as U. *globulariaefolia* of Trinidad and *U. renifolia,* with large showy flowers, of the Organ mountains of Brazil. The latter is showy enough to be grown in greenhouses, where it is usually segregated with the orchids, less for its superficial resemblance than for its similar requirements of high humidity and temperature. But the vast majority of land forms are small and inconspicuous save for their flowers, which, though often small, are quite readily seen. The larger, though having small vegetative parts, have tall inflorescences, the flower stalks in U. *cornuta* being a foot high. The smaller, except for their showy, small flowers, are inconspicuous among the mosses: etc., in which they grow. Still others are almost microscopic in size.

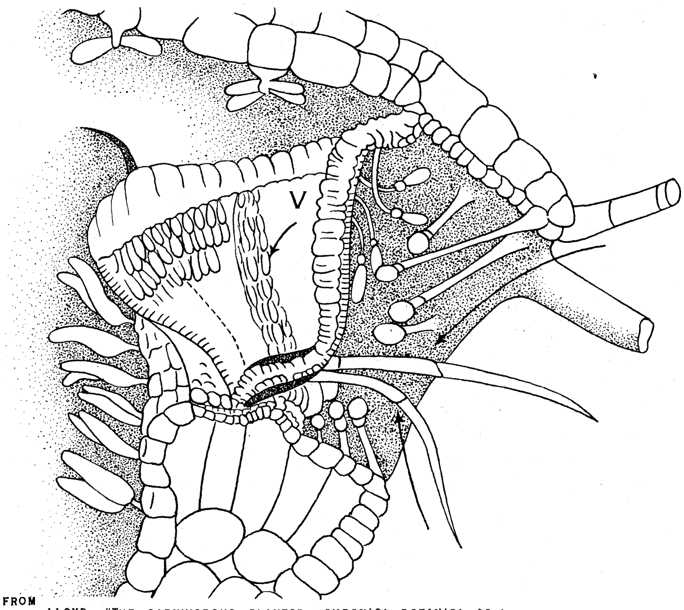
Plant Structure.— The plant body consists of a more or less horizontal stem (a stolon) bearing simple or divided leaves placed in a variety of relations, not following any obvious rule. A peculiar and significant feature, noted by Karl Goebel. is that the leaves face away from the apex of the stolon which bears them, the reverse of the usual condition. Correlated with this is the occurrence of the axial bud in a correspondingly reversed position.



FROM LLOYD, "THE CARNIVOROUS PLANTS" (CHRONICA BOTANICA CO)

FIG. 2.—UTRICULARIA ROSEA WITH A FUNNEL-SHAPED ENTRANCE AND KNIFELIKE ROSTRUM

In *Utricularia* the calyx has two members, a dorsal and a ventral one. In *Polypompholix* there are two additional. in lateral positions. The corolla is entire and of the personate type, two lipped, with the mouth closed by a palate and provided with a spur from the lower portion. The spur is very large in *U. menziesii* and vestigial in *U. minor,* and is represented by a wide, cuplike expansion in U. *cymbantha.* The spur is a nectary, but nectar glands occur also in the bowl-shaped condition. The colour of the corolla may be white, very often yellow, pale blue to purple, and in one species brilliant crimson, variously marked on the palate with other colours. Reproduction is by means of seeds, by winter or resting buds and by adventitious growth from various parts, as from leaf buds. The inflorescence is a raceme, and in some floating kinds is held up in position by means of a whorl of floats, which are leaves in which the midrib is much inflated, as in the American *U. stellata.* Expansions of the stolons lead to the formation of tubers. which, containing sap and starch, can serve to resist drying during adverse periods and act as reproductive structures.



FROM LLOYD, "THE CARNIVOROUS PLANTS" (CHRONICA BOTANICA CO.)

FIG. 3.—UTRICULARIA GIBBA

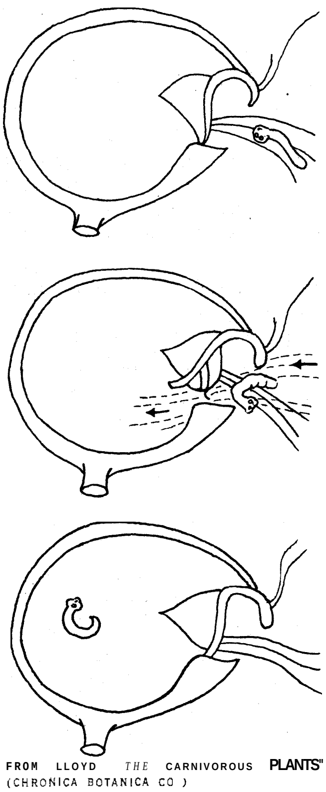
Diagram of the entrance in longitudinal section. The outer surface of the door and the sides of the entrance bear mucilage glands. The arrows point at the tripping bristles and indicate the direction of the prey's approach. V indicates velum

Mechanism of Capture.—The most noteworthy feature of the three genera considered here is the occurrence of traps, usually, but incorrectly, called bladders. From the time of Darwin and Ferdinand Cohn (1875) until that of Frank Brocher (1911), these structures were thought to be passive traps, consisting of a hollow, bladderlike sac guarded by a curved, flexible door or valve. This, it was interpreted, would be pushed in by an intrusive animal of a suitable size, and permit easy entrance; but since the valve is a check valve, permitting movement in only one direction, the animal remained captive, balked of escape by a now resisting wall. This account was shown to be quite inadequate by Brocher, a Swiss entomologist, who during a study of mosquitoes and *Utricularia* in relation to each other. discovered that, when a larva is caught, the sides of the trap, normally impressed and concave, were then definitely expanded. This could be explained only as being the result of an inflow of water, and that the prey was washed into the trap thereby. This indicated that the valve or door was fixed in a position of unstable equilibrium which was upset by impact of the prey on certain bristles, four in number, projecting from the door surface. This was later confirmed (by E. M. Merl and T. Czaja), and it was shown also that the action could be repeated, 14 repetitions of the action having been counted. This could be explained only when it was discovered that the wall of the trap constantly excretes water from the inside of the trap to the outside and that the door is so postured that it can resist the relatively increased water pressure on the outside.

Later it was found that the door posture of itself is insufficient to render it watertight, which it must be to allow the maintenance of reduced water pressure on the inside. It was then found that, in addition to the door, there is a second valve, the "velum." which consists of a membrane attached to the valve seat on which the door edge rests, applied against the lower zone of the door in such manner as to prevent the inleakage of water under it. as can readily occur at the side reaches of the door edge (F. E. Lloyd). The valve seat, called by Darwin the "collsr," is a stout, curved weal of tissue, lined with a soft cellular lining, the cells of which'supply the velum by exfoliation of their cuticles, which remain attached to each other and to the front edge of the collar. After action, the valve or door reseats itself on the upper surface of the collar, and the velum folds upward over the door edge. The trap is then sealed, and, after sufficient excretion of the inner water, mill again react.

In order to set the trap into action, the door is provided with a trigger mechanism In *U. vulgaris* and the like, this consists of four to six stout, curved bristles which, when disturbed by the impact of prey, bend, and, in doing so, twist slightly the edge of the door, releasing it from its delicate equilibrium and allowing the external water pressure to push it in, carrying the prey uith it. The inward swing of the door is followed, as the pressure of the insurging water decreases, by a return to approximately the original posture. the whole occupying about $\frac{1}{35}$ second The walls of the trap are now more or less bulging, due to the greater contained volume of water. The trap is now in the relaxed state. The set state is reached in 15 to 30 minutes *(U vulgaris),* during which time the door changes its posture somewhat, because of the now increased uater pressure, and is again ready for repetition. As the result of somewhat different mechanical conditions in the traps of many species, the change in posture of the door from the relaxed to the set state is very marked and readily observed (U. *capensis; Polypompholix)*

The expulsion of water from the inside to the outside of the trap through the walls demands a mechanism, and this is found in two sets of trichomes. one on each surface. uhose capital cells are bare of cuticle. These are. on the inside. the quadrifid and bifid hairs, as Charles Darwin called them, and on the outside hairs with rounded or elongated capitals. Since the rest of the wall surfaces are covered with cuticle, this seems to be the only reasonable conclusion. The quadrifid hairs are numerous in *U vulgaris,* and few, but relatively much larger, in small traps such as those of *U. subulata*

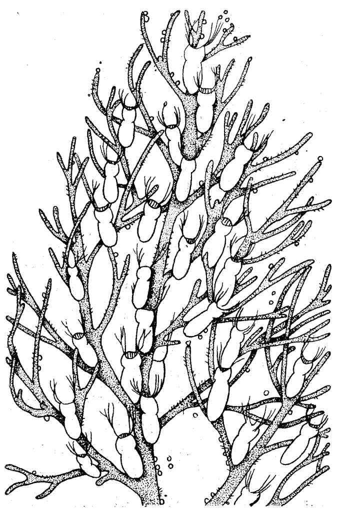


FROM LLOYD *THE* CARNIVOROUS PLANTS" (CHRONICA BOTANICA CO)

FIG 4 —UTRICULARIA GIBBA SHOWING THREE STAGES IN CAPTURE OF PREY

Door being sprung by larva (top); door opening (centre); larva caught and door again closed (bottom)

The trigger mechanism is widely different in various species. but is always composed of trichomes of various shapes and dispositions. Aside from these, the remaining appendages of the trap consist of variously shaped and disposed emergencies, ranging from branching arms to extensive wings. In *U. vulgaris* there are two curved arms extending from the upper corners of the entrance. Between them on the edge of the entrance stand several delicate, long bristles, with similar ones, about four. in an oblique row extending along the "cheek" of the mouth. These form a sort of guiding funnel leading to the mouth, and hence to encounter with the trigger bristles. In various species the upper edge of the entrance may be strongly developed into a single, or a bifurcate rostrum, armed with large glandular trichomes. The single rostrum may be broad and rounded, or may have the shape of a knife blade. Again, a rostrum may arise from the lower edge of the entrance and extend far forward and upward, as in the American *U. purpurea.* In Australian species the rostrum may be much branched and in such case the trap bears two ventral wings extending obliquely toward the entrance and acting as guides thereto. Again, the whole margin of the entrance map be draun out to form a deep funnel lined with radiating rows of glandular hairs. which it has been suspected secrete. beside mucilage, some substance or substances attractive to prey. thus acting as a lure. Convincing evidence is, however, lacking.



FROM LLOYD THE CARNIVOROUS PLANTS (CHRONIC4 BOTANICA CO)

FIG 5 —UTRICULARIA VULGARIS LEAF SEEN FROM BELOW

The genus *Polypompholix* has traps which have thick and massive walls, three in number, so that the trap is triangular in section. The entrance is blocked in front by a swelling of the stalk, so that approach to it must be made from the sides. Wings and rows of bristling hairs serve to guide the prey appropriately These plants are all found in central south and southwestern Australia.

Biovularia has two species, one in Cuba and one in South America. They are characterized by the possession of only two ovules, in contrast to the 100 or more of *Utricularia.* Certain species of Africa, because of the fact that only three ovules occur, have been regarded as belonging in *Biovularia,* but the traps are like those of *Utricularia.* Those of *Biovularia* have six tripping bristles set at about the middle point of the door instead of near the lower edge, as in *Utricularia.*

It is not satisfactorily determined whether the dissolution of captured organisms in the traps is the result purely of secreted enzymes, of bacterial action, or both. Much of the difficulty of deciding the question arises from the small size of the traps.

See F E Lloyd. *The Carnzvorous Plants* (1942) (F. E. L)

UTRILLO, MAURICE (1883–1955), French painter, noted for his scenes of Montmartre, was born in Paris on Dec 2j, 1883, the natural son of the model and artist, Suzanne Valadon (1865–1938). His father was not known, and he uas given a name by the Spanish art critic. Miguel Utrillo. Utrillo had no instruction as an artist apart from that given by his mother, who herself was untutored. When, as an adolescent, Maurice became an alcoholic, his mother encouraged him to take up painting as therapy. Despite frequent relapses into alcoholism, painting became Utrillo's obsession. and he produced thousands of oils, as well as a few drawings and lithographs. In 1924, to keep her son permanently away from the bars of Montmartre. Suzanne Valadon moved with him to a château near Lyons. In 193j the artist married a widow. Lucie Pauwels (Lucie Valore), herself a Sunday painter, and settled in Le Vésinet. a fashionable suburb of Paris

Though Utrillo was initially attracted by the Impressionist paintings of Camille Pissarro and Alfred Sisley, he had neither aesthetic concepts nor artistic preferences, nishing only to reproduce what he saw, as faithfully as possible. Shy and withdrawn, he painted very few portraits: except for a number of flower pieces, the bulk of his compositions are devoted to the old. deteriorating houses and streets of Montmartre. its windmills (no longer existing ı. and its cafés and amusement places. Trips to Brittany and Corsica also yielded a few paintings.

His best work is that of his "white period" (*c.* 1908–14), so called from the lavish use of zinc white. In heavy. rich pigment he built up aging. cracked walls. often covered with large inscriptions. These freshly conceived and freely brushed oils brought him fame and a great fortune. In 1929, he was made a chevalier of the Legion of Honour. In his later years, his painting. largely based upon picture postcards. declined sharply in originality and vigour. He died at Le Vésinet on Sov. 5, 1955.

UTTAR PRADESH, a state in the republic of India. Area 113.423 sq.mi. Pop. (1951) 63.215.742. During the period of British rule the state was known as the North-Western Provinces until 1902: as the United Provinces of Xgra and Oudh from 1502 to 1937. and thereafter as the United Provinces. The title Uttar Pradesh was introduced at the time oi the declaration of the republic of India in 1950.

The state includes the former states of Rampur, Tehri-Garhwal and Benares. It is bounded on the north and northeast by Tibet and Nepal and comprises the whole of the upper part of the Gangetic basin, from the Himalaya and the Punjab border to the T'indhyan plateau and the ricelands of Bihar, an area roughly corresponding to the Hindustan of the old Moslem chroniclers. To this it adds the great semicircular tract. watered by the Gogra and the Gumti, which was formerly the kingdom of Oudh. The capital is Lucknow (pop. [1951] 444,711).

The population is larger than that of any other state of the republic. In the census of 1941, 83.3% of the population were Hindus and 15.3% Moslems. In 1951, 85% were Hindus and 14.3% Moslems. which shows that the movement of population caused by partition did not greatly affect the general distribution by religion in this state. The number of displaced persons in Uttar Pradesh was 475,822 in 1951. Hindustani or Urdu and Hindi (eastern and western) are the chief languages.

Physical Aspects.—At one end the state rises into the Himalaya and includes. at one extreme, some of the grandest of the peaks which look out upon upper Asia. At the other extreme. where it borders on central India, it has a fringe of rough, broken and picturesque country. Apart from these, however. it is a level and somewhat monotonous expanse, well-drained. closely cultivated and studded with villages. the number of which (nearly 105,000) far exceeds that in any other state. Many of them. standing high on the dehris of older sites. have the air of fortified places; and the fine mango groves which often adjoin them redeem the bareness of the surrounding plain.

The flora of the forests is rich and varied. The sal tree yields the most important timber. 'The hard wood of the *shisham* is also valuable. and several other timber trees afford materials for furniture or roofing shingle. Among the scattered jungles in various parts of the state. the mahua tree is prized alike for its edible flowers. its fruits and its timber. The fauna comprises most of the animals and birds common to the Gangetic plain; but the wild elephant is now practically unknown. except when a stray specimen loses its way at the foot of the hills. Tigers are found in any numbers only in the *tarai* (swampy lowland belt near the Himalaya). Leopards haunt the canebrakes and thickets along the banks of the rivers; and nilgai and antelopes abound. Game birds consist of teal and wild duck, snipe. jungle fowl and peacock.

The Ganges and its great affluents. the Jumna, the Ramganga and the Gogra. rise in the Himalaya and meet n·ithin the state. In addition there are the secondary streams: the Kalinadi and the Hindan flow through the Doab; the Chambal intersects the trans-Jumna tract. In Bundelkhand the principal streams are the Betwa and the Ken. The Ramganga, rising in Garhwal. pursues a tortuous course through Rohilkhand: the Gumti flows past Lucknow and Jaunpur to join the Ganges and the trans-Gogra region is divided into two nearly equal parts by the Rapti. These rivers are constantly modifying the adjacent lands.

Climate.—The climate as a whole is hot and dry. The Himalayan districts of course are cool and have a much greater rainfall than the plains. They are succeeded by a broad submontane belt. the *tarai*, which bears the reputation of being the rnost unhealthy in all India: in many parts only the acclimatized aborigines can withstand its deadly malaria. The plain country is generally warm and dry. the heat becoming more oppressive as the general level of the country sinks ton·ard Allahabad and Benares (Banaras). or among the hills of Bundelkhand. The rainfall varies from 30 to 44 in. in the plains. increasing gradually toward the Himalaya. The temperature in the hot season ranges from 86° to 115° F. and even higher in the shade.

Minerals and Agriculture.—Because of the loamy nature of the soil. few minerals of any kind are found; and the chief underground product is the abundant nodular limestone (*kankar*) which is used ior road making. Iron and coal exist in the southern hills but not in paying quantities. and there are traces of old iron-workings in the lower Himalaya. The course of tillage comprises two principal harvests: the *kharif*, or autumn crops. sown in July and reaped in October or November: and the *rabi*, or spring crops. sown in October or November and reaped in March or April. The great agricultural staple is wheat, but millets, rice, barley and pulses are also largely cultivated. Speaking broadly. rice and oilseeds predominate in the eastern and sub-Himalayan districts, millets and cotton in Bundelkhand and n·heat in the greater part of the Gangetic plain. Sugar cane, condiments and tobacco are locally important; and a little tea is grown in the submontane districts of Almora Garhwal and Dehra Dun.

Irrigation.—The Doab is intersected by canals drawn from the great rivers. The major productive works are the Upper and Lower Ganges, the Eastern Jumna and the Xgra canals. The greatest work in the state and one of the greatest irrigation works in the world, is the Upper Ganges canal, which is taken from the river where it leaves the hills. some 2 mi. above Hardwar. In the first 20 mi. of its course this gigantic canal crosses four great torrents. which bring down immense volumes of water in the rainy season. The total length of the main canal is 213 mi., navigable throughout and designed to irrigate 1,500,000 ac. The Lower Ganges canal is taken from the river at Narora. 149 mi. below Hardwar. After crossing four great drainage lines. it cuts into the Cawnpore and 7 mi. lower down into the Etawah branches of the Upper Ganges canal. These branches are below the point of intersection. part of the Lower Ganges canal system. The irrigating capacity of this canal is 1,250,000 ac. The Sarda canal, opened in 1928 to carry the waters of the Sarda into Oudh. was extended in 1941, making the total length of its main canals and branches 7,236 mi.. one of the longest systems of its kind in the world, the area irrigated being more than 1,200,000 ac. (including 200.000 ac. of sugar cane).

Land Tenure.—Under British rule the system of land tenure was not uniform. In the Benares division. the land revenue was permanently fixed in 1795, on the principles that had been previously adopted in Bengali and there a special class of tenants, as well as the landlords, enjoyed a privileged status. Throughout the rest of the province of Agra temporary settlements were in force, usually for a term of 30 years, the revenue being assessed at one-half the "assets" or estimated rental value. The settlement was made with the landholders or zamindars, who were frequently a group of persons holding distinct shares in the land and might be themselves petty cultivators. The privileged tenants were those possessing "occupancy" rights, defined by statute. All other tenants were merely tenants-at-will. In Oudh. after the convulsion of the Indian mutiny, all rights in land were confiscated at a stroke; and the new system adopted was in the nature of grants to the talukdars, or great landlords, who were declared to possess permanent, heritable and transferable rights. with the special privilege of alienation, either in lifetime or by will, notwithstanding the limits imposed by Hindu or Mohammedan law.

On July 1. 1952. an act of 1951 abolishing zamindari took effect. Compensation (eight times the annual income) went to 2,000,000 zamindars at a cost of £112.500,000, the 12,000,000 tenants holding their 60,200,000 ac. (83.3% of the total agricultural land) directly from the state.

Manufactures and Trade. — The principal manufactures are those of sugar. metal and coarse cotton cloth. Ornamental metalwork is made at Benares. Among the factories are the Elgin and Muir cotton mills at Cawnpore, the Cawnpore wool mill, tanneries and leather factories: the Shahjahanpur rum distillery and the breweries at Mussoorie and Xaini Tal. There are also iron and brass foundries. lac factories and oil mills. Agra is a shoemaking centre, and glass bangles are made in large quantities at Firozabad and exported to all parts of India.

The export trade is chiefly confined to agricultural produce. The principal staples include wheat, oilseeds, raw cotton, sugar, molasses, timber and forest produce, dry stuffs, ghee and tobacco. The imports consist mainly of English piece goods, metalwork, manufactured wares, salt and European goods. The chief centres of trade are Cawnpore, Allahabad, Agra, Mirzapur, Benares, Meerut and Moradabad.

Railways. — The state is well supplied with railways. The main lines of the Northern and North-Eastern traverse it from end to end connecting with \Vest Bengal on the one side and the Punjab on the other and linking up with the Central railway line at Allahabad. Agra and Cawnpore.

Besides this broad-gauge system, there is also a metre-gauge connection which serves the whole of the submontane tract and projects into \Vest Bengal. while it also joins with the Western railway at Rluttra. The trade of the state thus has access to the sea at Bombay and Calcutta.

Administration. — Under British rule the United Provinces were under the direction of a governor with an executive council and ministers. The legislature had 118 members, to whom the ministers were responsible. After the transfer of power the legislature remained until 1952, when elections were held under the new Indian constitution. The assembly then had 430 members with a legislative council of 72 members. The first governor after the transfer of power was the poetess politician, hlrs. Sarojini Naidu, who died during her term of office on March 2, 1949.

The state has 51 districts; each under a collector and magistrate (called also deputy commissioner in Oudh and Kumaon). The supreme judicial tribunals are the high courts at Xllahabad, with jurisdiction over the part of the state that was formerly Agra, and the chief court at Lucknow with jurisdiction over Oudh.

(E. HD.; S. GL.; X.)

UXBRIDGE, a market town and municipal (19jj) and parliamentary borough of Middlesex, Eng., 1j mi. W. of London by road and linked with London by the Metropolitan and underground railways. Pop. (1951) oi old urban district, 55,960. Area 16 sq.mi. Uxbridge does not appear in Domesday Book, but as early as 1139 it is mentioned in a deed of that time as Oxbridge. It was the scene of negotiations between commissioners of Charles I and parliament for peace terms in 1645. Part of the Treaty house in which they took place still remains. The Grand Junction canal forms the western boundary of the borough and on its banks are sawmills and wharves. In Uxbridge are engineering works (making cash collection and control machines, transport ticket machines, centrifugal pumps, generators, instruments. tools. etc.), brickworks, a brewery, horticultural nurseries! etc. Uxbridge is well known for the R.A.F. depot, from the control room of which the battle of Britain was directed.

UXMAL, the ruins of an 'ancient Mayan capital city of the New empire about 50 mi. S. of Merida, in Yucatan, Mex.: in 89° 42' W. and 20° 18' N. It was one of those frontier Mayan cities that did not rise to prominence until shortly before A.D. 1000 when the League of Mayapan was formed with three cities, Mayapan, Chichen-Itza and Uxmal, dominant in "the New empire" of the Mayas. With the earlier fall of the Old empire in Guatemala and southern Mexico the Itza established themselves at Chichen ("The Mouths of the Wells"), the Cocom made hlayapan their capital, and the Tutul Xiu. a kindred tribe. settled at Uxmal. The period subsequent to the formation of the League of Mayapan constitutes the golden age of the New empire of the Mayas, when peace and plenty provided favourable opportunity for the development of tradq and religion and science and art, particularly architecture.

Great stone temples and colonnades elaborately carved and ornamented rose in every city; religion flourished; the sciences. especially astronomy and mathematics, mere fostered; and a renaissance of culture held sway for over two centuries. The buildings of this period at Uxmal surpassed those of the other cities in their grandeur and elegance. When the New empire crumbled under internal dissension and the conquest of the Aztec-Toltec imperialists from central Mexico, about the middle of the 1jth century, Uxmal succumbed with the rest, and it is reasonably certain that only vagrant tribes lingered about the old ruins at the time of the Spanish conquest.

The region of the Uxmal ruins, like most of Yucatan, is a dry grass savanna, in places rather heavily wooded as about Uxmal. The relief is negligible. the terrain for the most part being as level as a floor, though a range of low hills lies between Uxmal and Ticul, the railway station about 20 mi. eastward. The water supply of the city was furnished by "cenotes," or wells, within the city, or by pools some distance to the west, now partly filled up and vanished, but in the rainy season so marshy as to be the breeding places of myriad mosquitoes that spread malaria. fever and disease. It may have been some of the mosquito-borne pestilences that destroyed the Mayan civilization.

The main ruins occupy an area not much over 160 ac., but outlying remnants indicate a residential district much larger, for which the central group, massive and extremely impressive, merely constituted the religious and civic nucleus. The stone used in the structures is the pale, yellowish and reddish-gray limestone, obscurely marbled, which was probably obtained not far from the city, though the quarry has not yet been definitely located. The body of the walls and the framework of the temples is generally of fragmental stone set in a whitish mortar of excellent composition made of lime burned in the neighbourhood. The facings and ornaments are all cut exquisitely yet daringly, and in view of the fact that the Mayan artisans laboured without metal tools. the excellence of their work is amazing. The faces and edges are graved and hewn with perfect precision and the joints are in many cases so perfect as to conceal the mortar. Much plastering was done, and nearly all surfaces, and apparently even the intricate details of moldings and sculptures, were smoothed painstakingly by white plaster and finished in many colours.

The walls are massive. averaging 3 ft. in thickness, but in some ruins 9 ft., approximately vertical on the exterior to the full height, and to the spring of the arch inside. Few recesses or projections disturb the smoothness of the exterior walls, but elaborate ornamentation relieves the monotony. Rigid moldings divide the walls into upper and lower zones. the latter faced with smooth stone except for a narrow band of design near the base, and the former, a development of the entablature, compositely graven and bordered by a heavy band of moldings at the top. The shoe-shaped coping stones held the level cement roof. The corners of the buildings were square or rounded. No windows or other openings admitted air or light (or mosquitoes). The doorways, confined to the lower panel of the wall, were simply constructed and of medium to large size. The jambs mere faced with cut stone and the longer lintels were of sapote wood dressed squares.

The buildings were generally long and rectangular with one, or more usually two, ranges of rooms; and as a rule these buildings were arranged in groups of four forming a quadrangle. None of the buildings was over one story in height, and nearly all were built on terraces or pyramids of varied ground plan and profile The rooms were high and spacious. with vaulted ceilings formed of the usual wedge-shaped arch built from horizontally laid stones corbeled and beveled with the slope. Stairways nere numerous. wide, steep and well built of cut stone.

Five principal buildings or groups of structures were the pyramid temple of the magician crowning a majestic pyramid 80 ft. high and 240 by 180 ft. at the base; the Nunnery quadrangle composed of four large rectangular buildings enclosing a court. all on a terrace 300 ft. square and 1j ft. above the level of the plain, and all divided into numerous small rooms probably occupied by the priesthood; the governor's palace, an imposing structure set upon a triple terrace, and said to be the most important single unit of' its kind in America: the House of the Turtles. a smaller structure distinguished by a frieze of sculptured turtles on the molding, and the House of the Pigeons, a quadrsngle like the Nunnery quadrangle, of which one building carries a peculiar roof-comb of colossal size perforated by hundreds of openings which make it appear like a great dovecot, and nhich may have been occupied by statues like the roof-combs of Palenque. Besides these a number of smaller or less important ruins or groups of ruins dot the locality and help to create a scene of ancient power, prosperity and culture, probably unsurpassed in Yucatán and certainly rivaled only by Mayapan and Chichen-Itza

UZ, a land, the scene of the story of the book of Job. Its precise location is uncertain, but the name in the Old Testament appears to be associated nith three districts.

1. Northern Mesopotamia, a district to which Uz, son of Aram, is commonly referred (Gen x, 23).

2 Damascus and the country lying to the south of it. Josephus (*Antiq.,* i, 6. 4), commenting on Gen. x, 23, remarks that Uz founded Trachonitis and Damascus.

3. Edom. In Gen. xxxvi, 28, Uz appears in the genealogy of Seir in the land of Edom, and in Lam. iv, 21, Uz stands as a parallel to Edom.

The suggestion has been made that if the name is so widespread. the explanation may be that it is tribal rather than territorial. The transcription of the name in the Greek version suggests the Arabic Audh, a well-known deity, and might well be a tribal designation. Lam. iv, 21, appears to be the sole passage, which gives a clear indication of locality, and it is emphatic for Edom. (E. Ro.)

UZBEKISTAN. A soviet socialist republic of west central Asia, which in 1924 was carved out of the former Turkestan Autonomous Soviet Socialist Republic. It is bounded on the northwest and the north by Kazakhstan; its share of the Fergana (Ferghana; *q.v.*) valley is surrounded on the north. east and south by Kirghizia; its southeastern neighbour is Tajikistan, and on the south it is bounded by Afghanistan and Turkmenistan.

Physical Geography. — Uzbekistan extends from the westerly spurs of the Tien-shan, which enclose the Fergana valley, and from the Afghan frontier along the Amu Darya (Oxus), northwestward across the Kyzyl Kum ("Red Sands") to include the Kara-Kalpak autonomous republic around the lower Amu Darya and the southern and western shores of the Aral sea. Much of the area is thus desert. The Ust Urt plateau, a tableland rising 600–900 ft. above sea level, approaches the Aral sea (about 170 ft.) on the west in an abrupt slope. The Aral sea, rarely more than 60 ft. deep, is rich in sulfates.

For about 300 mi. between the Xral and the mountain foothills stretches the Kyzyl Kum, an area of sands stabilized by vegetation, providing sparse grazing, and with few patches of true dune sand. It lies generally below 600 ft.. but in places hills of Palaeozoic rocks stand above it. The only permanent river in the Uzbek portion of the Kyzyl Kum is the lower Amu Darya. Its former tributary the Zeravshan no longer manages to join it. The Amu spreads much debris in a wide flood plain over which it flows in constantly changing braided channels. Drawing its main supplies of water from melting snows, the river shows a marked contrast in volume between summer and winter. Its true delta begins at Nukus, but some water is diverted along the old Kunya Darya channel (*see* TURKMENISTAN) to maintain the Khiva oasis.

Southward rises a belt of dry loess plains which, with a number of alluvial fans. fringes the foothills. The remainder of the republic is a close association of mountain spur and valley. In the north the Chatkal range, southeast of Tashkent, feeds the Chirchik and Angren rivers which water the oasis round that city before joining the Syr Darya. Southward the range drops to the tectonic trough of the Fergana valley, which measures about zoo mi. by 70 mi. Loess-covered alluvial gravel cones descend from the surrounding slopes, while the floor is occupied by loess, sands and the Syr Darya flood plain, at an altitude of up to 1,500 ft. Many of the streams upon which life in the basin depends descend from the Alai and its westerly continuation, the Turkestan ranges, to the south, but. south of these again, their drainage and that of the Zeravshan and Hissar ranges is toward the Amu Darya.

The mineral wealth of Uzbekistan lies almost entirely in the mountainous south. Petroleum is found in the Fergana valley and near Termez on the Afghan frontier, zinc, coal and copper in the Angren valley, salt and sulfur in Fergana. antimony at Kassansai north of Fergana, and tungsten and molybdenum at Lyangar in the Nura-Tau, a continuation of the Zeravshan range.

In a country of such varied relief it is not easy to generalize about the climate, beyond saying that it is everywhere continental. Winters are cold. the January mean in the lowlands being about 28° F., while the summers are very hot (July mean often above 80°). Mountain basins suffering intense cold on their floors in winter, because of temperature inversion: in summer become ovenlike. Rainfall is slight in the lowlands, three to four inches falling mainly in spring in the Amu Darya delta. In the mountains the total may reach 24 in., coming chiefly in summer. Local winds are of significance. Thus the valleys and foothills may be warmed in winter by foehn winds descending from the Tien-shan. In the south. Termez receives a cold dusty wind, the *afganets,* on as many as 70 days in the year, blowing out from the central Asiatic high pressure area in winter and spring.

In the Ust Urt and Kyzyl Kum the vegetation varies from sparse semidesert to true desert. An ephemeral cover of grasses and sedges flourishes with the coming of the spring rains, but soon withers in the scorching summer sun. The *juzgun* shrub (*Calligonum*) and the ahite *saxaul* characterize sandy areas, and in saline clayey areas black *saxaul, boyalych* shrub (*Salsola arbuscula*), *biyurgun* (*Anabasis salsa*) and *Artemesza* can tolerate the conditions. The steppe and the loessic piedmont plains bear an ephemeral cover of blue grasses and sedges. Along the banks of the rivers there develops the *tugay* belt of saline meadows and forest in which poplars (*P. diversifolia* and *P. pruinosa*) are the main trees. with tamarisk, small willows and Russian olive. With increasing altitude the grasses improve until at about 4,000 ft. there are permanent meadows and tree junipers. succeeded by deciduous forest of walnut, maple, apricot, etc., above which alpine meadows and, in places, conifers occur.

Of the extensive fauna, lizards, jerboas, *sulsiks* and other sand-adapted types live in the desert, as also hyena. jackal and more rarely mild ass and antelope. The Turkestan tiger is found in the *tugny* forests of the Amu delta. In the mountains, wild goat, mountain sheep, leopard and cheetah are noteworthy.

(B. L. C. J.)

HISTORY

Uzbekistan's history must be considered with that of the whole of Turkestan or Turkistan; *i.e.,* a country inhabited by the Turkic peoples (*q.v.*) and stretching from the Caspian sea on the west to the Tien-shan on the east and from a line embracing the Aral sea and Lake Balkash in the north to Kapet Dagh and the Hindu Kush chains in the south. The history of this area, sometimes described as the Turanian basin. is essentially the history of human settlements in the valleys of the two great rivers, Syr Darya (Jaxartes, Saihun) and Amu Darya (Oxus, Jaihun), of nomadic invasions and also of changes in the courses of the main rivers.

Crossroads of Dead Empires. — The original population of Turkestan was probably Iranian, and the southern part, the satrapies of Sogdiana and Bactria, belonged to the Persian empire. These two provinces were also part of the empire of Alexander of Macedon. Soon after his death they became a Bactrian kingdom which in the 2nd century B.C. suffered an invasion from the east of a people described by Chinese sources as Yue-chi and Hiung-nu.

At the end of the 7th century and the beginning of the 8th century an Arab army under Emir Kotaiba ibn Muslim conquered Khorezm (Khiva; *q.v.*) and Sogdiana (Bukhara; *q.v.*). Under the Abbasid caliphs of Baghdad the Persian influence became dominant in the oasis cities of Transoxiana. About 874 the country was conquered by the Persian Samanid dynasty from Balkh. In 999 a Turkic Karakhanid dynasty, the first to embrace Islam, supplanted the Samanids in Samarkand and Bukhara. The new rulers even pushed south of the Amu Darya, but they were stopped by Mahmud of Ghazni and thenceforward that river became the dividing line between Iran and Turan. At the beginning of the 11th century the Seljuk Turks passed through Transoxiana and appointed a hereditary governor at Khorezm, while leaving the Karakhanids at Samarkand. In 1141 yet another dynasty appeared in Transoxiana. the Kara Kitai from north China, who were not converted to Islam, although later some of them became Christian (Nestorian). Under the Seljuk shahs Khorezm remained a Moslem outpost.

The Mongol invasion of Jenghiz Khan in 1219–20 brought destruction and great ethnic changes among the population. After Jenghiz' death in 1227 most of Turkestan was ruled by his son Chagatai (or Jagatai). Yet the conquerors became assimilated and adopted the Turkic language, also known as Chagatai. Timur or Tamerlane. who seized power in Transoxiana about 1370 and created another short-lived empire, with Samarkand as capital, was a Turkicized Mongol.

At the beginning of the 16th century Turkestan was conquered by another wave of Turkic nomads, the Uzbeks (Usbegs), whose name derived from Uzbek Khan, a chief of the Golden Horde, who died in 1340. The term Uzbek was used in the 15th century to indicate Moslem as opposed to shamanistic Turkic *ulus* or tribes. The Uzbek leader Mohammed esh-Shaibani forced Baber, the Timurid ruler, to abandon the Fergana valley and enter India.

The Shaibanid dynasty ruled from Bukhara for a century. Abdullah Khan, its last representative (d. 1597), united Khorezm with Bukhara. After his death another branch of the Shaibanids assumed power and ruled from Gurganj (later renamed Urghench). but, because of the change in the course of the Amu Darya (*c.* 1573). their capital had to be moved to Khiva. Bukhara recovered its independence in 1599 first under the Ashtarkhanids and from 1753 under the Manghyts, both Gzbek houses. In the 18th century Kokand (*q.v.*) made itself independent from the emirate of Bukhara. but was soon subject to China, which had conquered eastern Turkestan, called Sinkiang ("New Dominion"). The khanate of Khiva became in 1688 a vassal of Persia. but recovered its independence in 1747. While the Uzbek emirs and khans ruled central Turkestan, the wide steppes in the north were the homeland of the Kazakhs. In the west. between the Caspian and Aral seas, north of Kapet Dagh, lived the nomadic Turkmens. In the east, in the valleys of the Tien-shan, dwelled the Kirghiz, and in the southeast, in the highlands north of the Hindu Kush, was the homeland of the Persian-speaking Tajiks.

Russian Conquest. — Eighteenth-century Turkestan presented a picture of economic decay and political anarchy. Khiva and Bukhara were protected by desert from the growing Russian empire. In 1714–17 Peter the Great sent a military expedition against Khiva. This was a disaster, but, as a result, three small fortresses, including Krasnovodsk, were built on the eastern Caspian coast. In the mid-18th century the Russians established a chain of fortresses along the Cral (Yaik) river, Orenburg (later Chkalov) being the most important. In western Siberia a military frontier stretched to Omsk on the Irtysh and up that river to Semipalatinsk.

In 1853 Xk-Mechet ("White Mosque," renamed Perovsk, later Kzyl Orda), on the Syr Darya, was conquered by the Russians, and the following year the fortress of Vernoye (later Alma-Ata) was established. On June 29, 1865, Tashkent, then a city of about 200,000 inhabitants, was taken by Gen. M. G. Chernyayev. Alim Kul. the khan of Kokand, was wounded in the battle and died soon afterward. On July 29. 1867, Gen. C. P. Kaufmann, a German Balt, was appointed governor general of Turkestan with headquarters in Tashkent. On May 14, 1868. he captured Samarkand. On July 5 Mozaffar ed-Din, emir of Bukhara, signed a treaty making his country a Russian vassal state uith much-reduced territory. Khiva mas conquered by Gen. N. N. Golovachev, and on Aug. 24, 1873, Khan Mohammed Rakhim Kuli had to become a vassal of Russia. Furthermore. all his possessions east of the Amu Darya were annexed to the Turkestan governor-generalship. The khanate of Kokand was suppressed and on March 3, 1876, became the Fergana province.

On the eve of World War I Khiva and Bukhara were enclaves within a Russian Turkestan divided into five provinces or *oblasti*. Together with the four steppe provinces in the north (latter-day Kazakhstan). Russian central Asia, according to the 1897 census, had a total population of 9,922,000. In 1914 this population was estimated at 13,579,000. According to the 1939 census the total population in an almost identical area was 16,356,177. The tsarist government did not attempt to Russify the indigenous Turkic or Tajik populations, preferring to keep them backward and illiterate. Military conscription was not applied to them, and rioting broke out when, on Aug. 7, 1916, their conscription was ordered.

Turkestan Divided Into Soviet Republics. — The revolution of March 1917 created a confused situation in the area. In Tashkent there was a Turkestan committee of the provisional government; a Communist-controlled council of workers', soldiers' and peasants' deputies; also a Moslem Turkic movement, Shuro-i-Islamiya, and a Young-Turkestan or Jaddidi (Renovation) party. The last-named party claimed full political autonomy for Turkestan and the abolition of the emirate of Bukhara and the khanate of Khiva. After the Communist *coup* d'dtat in Petrograd, the council of people's commissars on Nov. 24 (Dec. 7), 1917, published an appeal to "all toiling Moslems in Russia and in the east" proclaiming their right to build their national life "freely and unhindered." In response, the Moslem and Jaddidi organizations in Dec. 1917 convoked a national congress in Kokand which appointed a provisional government headed by Mustafa Chokayev (or Chokaioglu; 1890–1941) and resolved to elect a constituent assembly to decide whether Turkestan should remain within a Russian federal state or proclaim its independence. The Tashkent Communists in Feb. 1918 sent a force against the Kokand government, which collapsed.

At that time Turkestan was cut off from Russia because Adm. A. V. Kolchak's army was in possession of Orenburg. In the spring of 1919 a Red army group defeated Kolchak and in September its commander, M. V. Frunze. arrived in Tashkent with V. V. Kuibyshev as political commissar. The Communists were still much too weak in Turkestan to proclaim the country part of Soviet Russia. Faizullah Khojayev organized a Young Bukhara movement, which on Sept. 14, 1920, proclaimed the dethronement of Emir Mir Alim, who fled to Afghanistan. Bukhara was made a soviet people's republic. In Khiva Khan Asfendiar Bahadur was assassinated in 1917 and was succeeded by his son, while a Turkmen revolutionary leader. Junaid Khan, assumed power. In 1920 the Tashkent Communist government declared war on Junaid. who took to flight, and Khiva became another soviet people's republic. In Oct. 1921 Enver Pasha, the former leader of the Young Turks, appeared in Bukhara and assumed command of the Basmachi movement. (*Basmach* means "bandit" in Turkic. but for anti-Soviet nationalists it had become identical with "patriot.") In Aug. 1922 he was forced to retreat into Tajikistan and died on

Aug. 4, in a battle near Baljuvan. According to the official Soviet sources the Basmachi rebellion had ended in 1924, hut its chief, Ibrahim Beg Lakai. mas not captured and shot until 1931. Munavar Kary, the Jaddidi leader was executed in the same year.

Birth of Uzbekistan.— Khiva concluded a treaty of alliance with the Russian S.F.S.R. in Sept. 1920 and Bukhara followed suit in March 1921. Theoretically, a Turkestan Autonomous Soviet Socialist Republic had existed since May 1, 1918; in 1920 this "Turkrepublic." as it was called. was proclaimed part of the R.S.F.S.R. In 1923, however, J. V. Stalin stated that as Turkestan was "the most important Soviet republic from the point of view of revolutionizing the east," the time had come to transform it accordingly. On Sept. 18, 1924, the Uzbek and Turkmen peoples were authorized to form soviet socialist republics of their own, and the Kazakhs, Kirghiz and Tajiks to form autonomous soviet socialist republics. On Oct. 27, 1924, the Uzbek and Turkmen S.S.R. were officially constituted and the former was formally accepted on Jan. 1j. 192j. as a member of the U.S.S.R. Tajikistan was an autonomous soviet republic within Uzbekistan until Dec. 5, 1929, when it became a soviet socialist republic. On Dec. j. 1936, Uzbekistan was territorially increased by incorporating into it the Kara-Kalpak A.S.S.R. (*q.v.*), which had belonged to Kazakhstan until 1930 and afterward had come under direct control of the R.S.F.S.R. In Oct. 1952 the Uzbek Communist party had 142,355 members, including 25.416 candidates. Khojayev. who in 1924 became the first chairman of the council of ministers, and Akmal Ikramov. the first secretary-general of the Uzbek Communist party. were shot on March 13, 1938, for pan-Turkic tendencies.

Population.— The republic's area is 157.876 sq.mi. Its total population (within the 1936 boundaries) was 6,282,450 in 1939. and 8,105,572 in 1959. The area of the Kara-Kalpak A.S.S.R. is 63,938 sq.mi. and its population was estimated in 1959 to be 510,101. The total number of Uzbeks in the U.S.S.R. was 3,954,701 in 1926 (3,012,900 or 66% in their own republic) and 4,844,021 in 1939. No percentages of the national composition of the population in 1939 were given, but the Uzbek supreme soviet of 400 members. elected on Feb. 16, 1947, included 249 Uzbeks (62%).

The first capital of Uzbekistan was Samarkand, but the atmosphere there was considered too nationally Uzbek, and the capital was moved to the more cosmopolitan city of Tashkent. This city's population grew from 323,613 in 1926 to 911,930 in 1959, the increase being mainly to the advantage of the Russians; the town council elected in 1950 included 51% Uzbeks and 37% Russians. The population of other cities was as follows (1939; 1959 in parentheses): Samarkand 134.346 (195,000); Kokand 81.665 (105,000); Andizhan 83.691 (129,000); Namangan 77.351 (122,000); Bukhara 50,382 169,000). The Uzbeks are Sunni Moslems.

Education.— Before 1914 about 97% of the Uzbek population was illiterate. but by 1939 the proportion was only 32.2%. In 1951 there mere approximately 5,000 schools in the republic with 1,300,000 pupils; there were 36 institutions of higher education, including the Tashkent (Russian) and Samarkand (Uzbek) universities, with a total of 32,000 students. An Uzbek Academy of Sciences was founded in 1943.

Economy.— Uzbekistan is important as a cotton-growing country. While in 1913 its production amounted to 516,000 metric tons, in 1939 it was 1,600,000 tons. 60% of the total Soviet production. This policy made Uzbekistan depend on Russia for food supply. Before 1914 the country had no textile mills; one cotton mill was inaugurated at Fergana in 1930 and another at Tashkent in 193j; a silk mill operated at Marghelan. In 1950 there were more than 150 large and small textile enterprises. In 1944 an iron and steel plant was inaugurated at Begovat, receiving coking coal from Angren; opened in 1940, the Angren coal mine produced 100,000 tons in 1945. At Chirchik and Farkhad big hydroelectric power stations mere established; while in 1913 the country's electricity capacity amounted to 3,000 kw., in 1945 it was 180,000 kw. Chirchik. a new town, had also a large nitrogen plant. 4 superphosphate plant was inaugurated in 1946 at Kokand. The Great Fergana canal. built in 1939–40, is 205 mi. long, 27–33 yd. wide and 4.4 yd. deep; it irrigates an area of 1,675,000 ac.

UZÈS, a town of southern France standing on a height above the Alzon. Pop. (1954) 4,136. Uzès, the seat of an episcopal see from the 5th century to 1790, has a cathedral flanked by a 12th-century round tower of five stories. The Duché preserves a 12th-century donjon; the main building, flanked by a Gothic chapel, is Renaissance in style.

UZICE (now Titovo Uzice), the capital of the Uzice district. Yugos, Pop. (1961) 20.069. Uzice (meaning "the narrow places") is built in a narrow, lonely glen, 1,385 ft. above sea level, on a stream spanned by two mediaeval stone bridges. Though poor. it has a well-built school, in the entrance to which is a Roman altar stone. and also a girls' school where weaving is taught. The surrounding heights produce excellent tobacco, and there are linen and cotton mills. Commerce is retarded by the bad roads.

In the 13th century Uzice was the seat of St. Sava, the first archbishop and patron saint of Serbia.

UZZIAH, more correctly called Azariah. was seated on the throne of Judah in succession to his father Amaziah by popular choice at the age of 16 (II Kings xiv. 21 et *seq.*; xv. 1–7). The records assign to him a reign of 52 years, covering roughly the first part of the 8th century B.C., but during part of this time his son Jotham, who succeeded him c. 740 B.C., acted as regent, because Uzziah had become a leper. He was for several years contemporary with Jeroboam II of Israel; and both kingdoms flourished. Uzziah repaired the walls of Jerusalem and recovered and rebuilt the port of Elath on the Gulf of Aqaba. The account of his military reorganization and successful campaigns in II Chronicles xxvi is probably not without historic basis. The chronicler explains his leprosy as a punishment for infringing priestly prerogatives. A certain Azriau of Yaudi appears in the inscriptions as leading a combination against Tiglath Pileser III *c.* 739. It has been contended that the reference is to Xzariah of Judah. Despite the striking coincidence of names, it seems probable that the leader was king of Y'di, a small independent kingdom mentioned in the Aramaic inscriptions found at Zenjirli. (W. L. W.)

V THE history of this letter is identical with that of *U,* from which it was not differentiated till the 15th to 17th century. The letter passed out of Latin having a majuscule pointed form V and a minuscule rounded form u and doing duty for two sounds. the high rounded voael (English *oo*) and the voiced labial spirant (English *v*). The consonantal sound was that most usually occurring when the letter was initial, in which position the majuscule form V would most generally be used. Thus the pointed form V became identified with the consonant, the rounded form with the vowel. A minuscule v and a majuscule *U* were then adapted as required. (B.F.C.A.; J.W.P.)

VAAL, a river of South Africa, chief affluent of the Orange (*q.v.*). It rises at an elevation of over 5,000 ft. above the sea in the Drakenberg mountains, of the Transvaal, about 170 mi. in a direct line west of Delagoa bay. It flows in a general S.W. direction, with a markedly winding course, across the plateau of inner South Africa, joining the Orange in 29" 3' S., 23° 36' E. The river valley is 500 mi. long, the length of the river being 750 mi.

The first considerable tributary is the Klip (80 mi. long), which rises in the Drakenberg and flows N.W., its junction with the Vaal being in 27° S., 29" 6' E., 12 mi. S.W. of Standerton. From this point to the eastern frontier of the Cape, the Vaal forms the boundary between the Orange Free State and the Transvaal. The river is usually shallow and is fordable at many places, known as *drifts.* But after the heavy summer rains the stream attains a depth of 30 or more feet. At such times the banks, which are lined with willows and in places very steep, are inundated. As a rule little water is added to the Vaal by its tributaries. On the north the basin of the Vaal is contracted by the Witwatersrand and the Magaliesberg ranges, and its tributaries are few.

The Mooi rises in the Witwatersrand west of the Klip and, after running almost due S. 7j mi., unites with the main stream about go mi. below Vereeniging. In its course through Griqualand West, the Vaal flows in a wide rocky channel, with banks 30 ft. high, through an alluvial plain rendered famous in 1867–70 by the discovery of diamonds in the bed of the river and along its banks. The diamonds are washed out by the water and found amid debris of all kinds, frequently embedded in immense boulders. The last affluent of the Vaal, the Riet river, rises in the Beyers Bergen S.E. of Reddersburg and flows N.W. 200 mi. through Orange Free State, being joined, a mile or two within the Cape frontier, by the Modder river (190 mi.), which rises in the same district as the Riet but takes a more northerly course. The united Riet-Modder joins the Vaal 18 mi. above the Orange confluence.

The name Vaal is a partial translation by the Dutch settlers of the Hottentot name of the river—Kai Gariep, properly Garib (yellow water) which refers to the clayey colour of the stream. The Transvaal is so named because the first white immigrants reached the country from the south by crossing the Vaal.

VAALPENS (dusty-bellies), a little-known nomadic people of South Africa, who lived in small groups in the Zoutpansberg and Waterberg districts of the Transvaal, especially along the Magalakwane river. The Vaalpens were so called by the Boers from the dusty look of their bodies, due, it is said, to their habit of crawling along the ground when stalking game. But their true colour was black. In height the men averaged about 4 ft., *i.e.,* somewhat less than the shortest Bushmen. The Vaalpens lived entirely by hunting and trapping game. and dwelt in holes, caves or rock shelters. They wore capes of skins, and procured the few implements they needed in exchange for skins, ivory or ostrich feathers. Their speech was full of clicks.

VACARESCU, the name, according to tradition, of one of the oldest noble families in Walachia. The first member of historical importance was IANACHE (b. 1654), the grand treasurer of Walachia, who was killed with his master, Prince Brancovan in Constantinople, 1714. His grandson through his son Stephan, also called IANACHE (or "Enakitza the Ban," 1720–1796?), started a line of Rumanian scholars and poets; he was the author of the first known Rumanian grammar in the vernacular, printed in 1787. While in exile in Nicopolis he wrote the contemporary history of the Turkish empire in two volumes (1740–99). He was also the first to attempt Rumanian versification. Greater as a poet was his son ALECU (Alexander), who died as a prisoner in Constantinople in 1798. In 1796 a collection of his poems appeared in Rumania. His brother Nikolaes (d. 1830) also wrote some poems, but they remained in ms. until 1860, when they were published.

By far the greatest member of the Vacarescu family in the male line was IANCU (1786–1863), the son of Alexander. An ardent patriot, he sided with the national movement in 1821, and assisted in establishing the Rumanian theatre, translating many books and plays from German and French into Rumanian, notably the *Britannicus* of Corneille, a literary event of no small importance at the time. He inaugurated modern Rumanian poetry. In 1830 appeared his first volume of verse. He died in 1863. A niece of Alexander was the gifted writer ELENA VACARESCU (Hélène Vacaresco) (1866–1947), maid-of-honour to the queen of Rumania, and Rumanian delegate to the League of Nations, who inherited the talent of her family and enriched Rumanian literature with her *Bard of the Dimbovitza,* and other poems and novels in Rumanian and in French, including *Chants d'Aurore,* which was crowned by the French academy; *L'Âme Sereine,* and *Rumanian Ballads,* which obtained the Prix Jules Favre at the French academy. (M. G.)

VACARIUS (1120–1200?), Italian scholar of civil and canon law, the first known teacher of Roman law in England, was of the school of Bologna, though of a later generation than the hearers of Irnerius. He was taken to Canterbury, possibly by Thomas Becket, together with a supply of books upon the civil law, to act as counsel (*causidicus*) to Archbishop Theobald in his struggle, which ended successfully in 1146, to obtain the transfer of the legateship from the bishop of Winchester to himself. Vacarius is next heard of as lecturing somewhere in England in 1149, to "crowds of rich and poor," and as preparing, for the use of the latter, a compendium in nine books of the *Digest* and *Codex* of Justinian, "sufficient," it was said, "if thoroughly mastered, to solve all legal questions commonly debated in the schools." It became a leading textbook in the nascent university of Oxford, where, perhaps by' 1149, perhaps not until 1169, Vacarius mas teaching; and its popular description as the *Liber pauperum* gave rise to the nickname *pauperistae* applied to Oxford students of law. Nearly complete manuscripts of this work remained in existence, notably in the cathedral libraries at Worcester and Prague and in the town library at Bruges. Fragments of it were also preserved in the Bodleian library and in several college libraries at Oxford. Another manuscript was found in the British museum, London, in 1959.

The new learning mas not destined to make its way without opposition. King Stephen silenced Vacarius and ordered the destruction of the books of civil and canon law that had been imported by Theobald. The edict to this effect, however, seems not to have been in force after the death of its royal author in 1154, since John of Salisbury wrote, *eo magis virtus legis invaluit quo eam amplius nitebatur impietas infirmare* ("the value of the law was strengthened in proportion as wickedness tried to weaken it"). In any case. Vacarius was soon called to practical work, as legal adviser and ecclesiastical judge in the northern province, by his old friend and colleague at Canterbury, Roger de Pont l'Évêque, after the promotion of the latter to the archbishopric of York in 1154. Thenceforth the name of "magister Vacarius" is of frequent occurrence in papal letters and the chronicles of the period, as acting in these capacities. He was rewarded with a prebend in the collegiate church of secular canons at Southwell, half of which he was allowed in 1191 to cede to his "nephew" Reginald. He is last heard of in 1198, as commissioned. together with the prior of Thurgarton, by Pope Innocent III to carry into execution in the north of England a letter with reference to the crusade. Of two works attributed to the second half of Vacarius' life, the *Summa de assumpto homine,* on Christ's humanity, is of a theological character and the *Summa de matrimonio* is a legal argument to the effect that the essential fact in marriage is neither, as Gratian maintained, the *copula* ("consummation") nor, as Peter Lombard, consent by *verba* de *praesenti* ("pledge from the present party"), but mutual *traditio* ("surrender").

BIBLIOGRAPHY.—*The Liber Pauperum of Vacarius, ed.* by F. de Zulueta (1927), contains a life and a bibliography. *See* also Ilarino da Milano, *L'eresia* di *Ugo Speroni nella confutazione del maestra Vacario* (1945). (J. F. LR.)

VACCINATION, strictly speaking, is the implanting of the living virus of cowpox in a person to protect him against smallpox. The procedure was introduced to supersede "inoculation," the artificial implanting of smallpox virus, in order to protect against smallpox acquired in the natural way. The inoculated smallpox commonly gave only a sparse general eruption of pocks, with a fatality rate much lower than that of the natural smallpox, which otherwise was a hazard to be expected by everyone in the 18th century.

Edward Jenner (*q.v.*) in his original publications of 1798–1800 did not use the term "vaccination" but spoke of "inoculation for the cow-pox." In devising a Latin term for this disease, previously without medical description, he called it *Variolae* (plural noun meaning "smallpocks" j *vaccinae* (adjective meaning "of the cow," from Lat. *vacca*, "a cow"). From this Latin of Jenner's the French in 1800 coined the term "vaccination," half in derision, for the implantation of cowpox. To the French and to those versed in Latin. "vaccination" would mean "en-cowing." "Vaccine." an adjective meaning "of the cow," then "of the cowpox," later became a noun meaning the material used for vaccination.

Jennerian vaccination against smallpox was the first and for nearly a century the only successful immunizing procedure against any disease, other than by inoculation with, or exposure to, the real disease itself.

In 1881 Louis Pasteur demonstrated immunization against anthrax by the injection of a comparatively harmless attenuated culture of the bacillus causing that disease. He then used the terms "vaccine" and "vaccination" for prophylactic inoculation in general as homage, he said, "to the merit and to the immense services rendered by one of the greatest of Englishmen, Jenner." Four years later Pasteur developed rabies vaccine. His work led to wide extension of immunizing methods against many diseases with correspondingly widened meanings of the terms "vaccination" and "vaccine," applying them to the use not only of living but also of dead material.

The present article deals with vaccination in its original and stricter sense; that is, vaccination against smallpox. This is still approximately the most perfect method of immunization against any disease, judged by the security and duration of protection in proportion to its inconvenience.

Jenner, trusting too much to the stories of the country people in his neighbourhood, believed that the cowpox, and perhaps the smallpox, originated in an infection of the heels of horses. The evidence accumulated, however, that the natural occurrences of cowpox started from the hands of milkers afflicted with smallpcx when the latter disease was widely prevalent. The infection was disseminated through dairy herds by other milkers on whose hands it took the changed form of cowpox. Strains of good cowpox virus were artificially started, chiefly in Germany, by transfer of smallpox virus to the cow, more readily through other animals, such as the monkey or the rabbit, first. Such strains propagated from smallpox virus were called variola vaccine.

Smallpox virus is not so easily transmitted to lower animals as is vaccine (cowpox) virus. The different establishments preparing vaccine virus have had the habit, when their particular strain showed signs of weakening, of reinforcing it with strains of virus from other establishments. Thus the strains can hardly be traced back to any one particular source. Jenner himself lost strain after strain, using new ones from time to time derived from natural cowpox found in dairy herds or their milkers. The remarkable fact is that his descriptions and pictures of the day-to-day appearance of the vaccinated arm, and the descriptions and pictures of the most careful observers since his publication, have coincided exactly with the appearance of arms vaccinated with good strains of modern vaccine virus, particularly the rapid spread of the area of redness surrounding the vesicle after the seventh day in a previously unimmunized person. This is different from the appearance after any other sort of inoculation, and such an inoculation has always given protection against smallpox anywhere in the world. Even the obsolete inoculation with smallpox virus itself produced a different course of events as to the inoculated arm, besides later giving rise to an eruption of pustules over the other areas of the body.

Originally the virus was carried from arm to arm, the vaccinated persons being told to return on the seventh day so that the contents of the clear vesicles at that time could be transferred to the arms of the next set to be vaccinated. Crusts of the dried vesicles, or vesicle contents dried on quills or threads or ivory points, were also used. Later, strains of vaccine virus were carried back to the cow for one or more passages in an attempt to make them stronger. This was called "retrovaccination." By the early years of the 20th century nearly all vaccine virus was propagated on calves (carabao in the far east), suspended in glycerine solution and distributed in hermetically sealed capillary tubes. Occasional passage through other species, such as the rabbit, appears to aid in maintaining the purity and the potency of the virus. In Spain rabbit-brain virus was used instead of calf virus, and many essays have been made to substitute growth in the chick embryo (fertilized egg) for growth on the bovine skin. A theoretical objection to such procedures—not without some confirmation in experience—is that the virus should not be adapted to deep proliferation in the layers of body tissue; human vaccination is safest from disagreeable results when it is as superficial as possible. Dried virus has also been used, and, though inconvenient and expensive to dilute unless many are to be vaccinated at one time. it has served a useful purpose where prolonged transportation to warm climates is necessary. The greatest advance in the prevention of smallpox in the 20th century was the cold storage of the vaccine virus (below freezing) up to the time of use.

Need.—Increased global travel, the presence of virulent strains of the disease in various parts of the world (*see* also SMALLPOX OR VARIOLA), its great contagiousness and the fact that no population is sufficiently vaccinated to be proof against a smallpox epidemic are sufficient reasons for keeping up vaccination in spite of the remarkable decline in smallpox cases. Vaccinations regularly carried out are preferable to emergency vaccination of a population at risk. All foreign travelers in both directions need the successful application of fully potent vaccine before undertaking the journey

Efficacy and Time of **Vaccination.**—Jenner was misled into thinking that one successful vaccination gave lifelong protection. It is possible that the continual exposure to smallpox to which people were subject in his day tended to keep up the immunity initiated by cowpox. Vaccination every five years is a safe general rule, but for nurses physicians and hospital attendants constantly in danger of exposure, and for foreign travelers in similar danger, once a year is safer. There is always the danger that the tube of vaccine used may not have been constantly refrigerated; this explains accounts of smallpox after recent vaccination **A** case of smallpox within two years after a successful vaccination is extremely rare even though exposure is ample, and such a case of the disease is mild. There are great differences between individuals in the firmness of holding onto immunity toward smallpox. just as there are toward other infections. **A** not inconsiderable proportion of a population might be protected against smallpox for life by one vaccination, though they would lose their immunity to vaccinia (cowpox) more readily. Long after complete protection subsides, a former vaccination modifies the severity of an attack of smallpox.

There are great advantages in having the first vaccination performed during the early months of life. Infantile vaccination, if properly performed and cared for, is milder than a later first vaccination, usually giving rise to no inconvenience whatever; it makes the subsequent vaccinations, if decades are not allowed to pass without revaccination, much milder affairs. Protection is gained not only against smallpox but also against accidental vaccination from the arm of a playmate or associate; and the scar of such an early vaccination becomes much less noticeable than if the first vaccination is performed later. The first spring of a child's life is probably the most favourable time for vaccination.

Disadvantages — The former and cruder methods of preparing the vaccine and performing the inoculations, together with the stern measures with which compulsory vaccination was enforced, naturally aroused opposition. One cannot expect something for nothing, and the remarkable protection which vaccination bestows is bound to entail a slight risk, at least of inconvenience. With proper vaccine, procedure and care, the risk is negligible compared to the advantage to the community and the individual. Clean technique, with a small adequate inoculation in only the most superficial layers of the skin, on an arm which is kept dry and cool, covered by no dressing except the loose clean sleeve of the child's garment, ensures for the great majority of vaccinations a perfectly satisfactory course. No practical cleansing can remove all the bacteria from the skin, however, and occasionally, especially in leg vaccinations, the vesicle may become purulent on this account and the drying process be delayed or even require attention. Eruptions soon after the maximum reaction are seen at times but disappear rapidly without treatment. Tetanus following vaccination formerly occurred once in a while, but later was entirely prevented by proper technique and particularly by allowing the vesicle of vaccination to dry naturally without dressing, shield or bandage. Authentic cases of demyelination encephalomyelitis have been reported after vaccinations as after other inoculations or infectiocs, but never where the above precautions were followed and the first vaccination was performed in early infancy.

Course. — In a first vaccination on a ch ld with good vaccine and good technique, nothing is usually seen until the third day, when a papule (pimple) appears at the site. The central part of this papule soon develops into a vesicle (that is, contains fluid) and is surrounded by a narrow red zone. It is the behaviour of this red zone which constitutes the characteristic and important detail in the course of the reaction. While the vesicle is enlarging at the rate of about a millimetre a day in diameter, the red zone remains of moderate size until about the 7th day, when it rapidly begins to enlarge, reaching its greatest diameter between the 8th and the 14th day after vaccination, then disappears as rapidly. The vesicle meanwhile continues to enlarge slowly, but before the height of the reaction is reached starts drying from the centre, forming a dark crust (scab) which drops off about three weeks after vaccination, leaving a clean pink scar which becomes white in about a year. A day or two of fever is often observed without particular relation to the course of the reaction. Care should be taken (as in bathing) to keep moisture away from the vesicle and crust until the latter comes off. The reaction above described is called primary vaccinia.

In more than half the revaccinations performed with fully potent vaccine on a group of people who had their previous vaccinations 10 to 40 years before, the appearance of the arm on successive days will be somewhat similar to that described in the preceding paragraph except that the course will be accelerated to give the greatest diameter of the red zone between 72 hours and seven days after vaccination: usually the spread and subsidence of the redness is more gradual than in vaccinia. Such a reaction is called vaccinoid and indicates partial protection against smallpox.

In what may be called the early reaction of vaccination the broadest redness occurs within 72 hours after vaccination and there may or may not be a visicle. One is not justified in saying that this indicates previous complete immunity against smallpox unless full potency of the vaccine can be assured; the history of the cold storage and the results with that batch of vaccine are seldom sufficiently known. Practically an exact counterpart of the early reaction or even one simulating the vaccinoid reaction may be given on a person with little or no immunity when vaccine of less than full potency is used.

If observation is thorough, every adequately performed vaccination with potent vaccine will be found to give a reaction which can be classified in one of the above categories: vaccinia, vaccinoid or early reaction.

VACCINE THERAPY. Vaccine therapy results in the induction of a state of active immunity in an individual, either for the purpose of preventing the development of a specific infectious disease, or in some cases as a means of treatment of an already established infection. The actively immune state is induced in the person or animal being immunized by the introduction into the body of a vaccine cornposed of suspensions of living or dead microorganisms of a specific kind, or of some of their metabolic products.

These substances in the vaccine stimulate the body cells to modify normal globulin molecules so that they acquire a very high degree of specificity against the disease-producing microorganisms or their products from which the vaccine was originally prepared.

The altered globulin molecules or antibodies, as they are called, are the immune substances in the blood, and distributed throughout the body. which combat the subsequent invasion of the microorganisms. or help control the multiplication and spread of infectious agents already established in the body.

The principle of using a less virulent, or attenuated, microorganism to induce active immunity for protection against a particular disease originated in the orient. In ancient times the crusts from lesions of very mild cases of smallpox, containing the weaker virus, were applied in one of several ways to the skin or nasal mucous membranes of persons who wished protection against a severe case of smallpox. The Turks accomplished the same purpose by scratching the crusts from lesions of mild smallpox into the arm of the person to be immunized. This procedure, known as variolation, was introduced into England by Lady Mary Wortley Montagu (1689–1762). The practice was not free from risk, and some persons developed a virulent generalized case of smallpox and died.

To Edward Jenner, a British country physician, goes the credit for his discovery, reported in 1798, that infectious material (vaccinia virus) from lesions of cowpox (vaccinia) could be inoculated artificially into the skin of man, and thus induce immunity against smallpox. Hence the terms vaccination and vaccine were originally used only in relation to immunization against smallpox with vaccinia virus. Louis Pasteur and others later applied the same principles to the prophylaxis of other virus, bacterial and rickettsial infections. Consequently, the term vaccine Lame to be used in a broader sense, including suspensions of living attenuated or dead infectious agents, emulsions of their cellular constituents and solutions of their altered metabolic products (toxoids). Sir Aimroth Wright extended the principles of active immunization to include not only the prevention but also the treatment of infectious diseases. Regardless of whether the desired result of active immunization is the prophylaxis or therapy of a particular infectious disease, the procedures of vaccine preparation and immunization are essentially the same. The person to be immunized is usually inoculated with the vaccine by intradermal, subcutaneous or intramuscular injections at regular, specified intervals. The degree of immunity resulting from the administration of a vaccine is quite variable; it depends on several factors including the antigenic potency of the preparation, the dosages given, the time interval between injections and the degree of ability of the person to produce antibodies when properly stimulated.

Early successes in the development and use of vaccines in the prevention of smallpox, anthrax and rabies encouraged attempts to develop actively immunizing agents for many other diseases. Effective vaccines were also developed for active immunization against typhoid and paratyphoid fevers, cholera, plague, tuberculosis, undulant fever, whooping cough, tularaemia, chronic staphylococcal and streptococcal infections, diphtheria, tetanus, influenza, yellow fever, Japanese B encephalitis. Russian tick-borne encephalitis. St. Louis encephalitis, equine encephalomyelitis, Rocky mountain spotted fever, typhus and against several important diseases of animals.

A true evaluation of the efficacy of vaccine prophylaxis is exceedingly difficult to obtain for many diseases. It may be readily understood that it is often impossible to arrange experiments involving sufficient numbers of individuals in the inoculated and uninoculated or "control" groups to assure statistically significant analyses of the results. This is particularly difficult in diseases which have relatively brief incubation periods, or in which exposure to the disease is irregular and unpredictable, such as those diseases which do not ordinarily occur in epidemic form in the population. At mid-20th century, adequate statistical data concerning the effectiveness in humans of some of the virus vaccines was still lacking, although protection tests in experimentally infected animals indicated their probable value. The difficulty in correctly evaluating the effectiveness of vaccines is even greater when they are employed in the treatment of individuals already suffering from an established infection. Such cases must be judged separately; other therapeutic measures and the possibility of coincidence must be seriously considered when attempting to form a correct estimate of the value of vaccine therapy. In many diseases, such as typhoid and paratyphoid fevers, there is overwhelming evidence for the high degree of protection established by vaccination; in other diseases there is evidence of definite value from vaccination, even though it may not always be protective, as in whooping cough; in still others, the results of vaccination are equivocal. However, there is no question concerning the importance of specific active immunization.

Types of Vaccines. — There are two main types of vaccines — stock or heterogenous, and autogenous. Stock vaccines are prepared from microorganisms previously isolated irom persons having a particular infectious disease. After identification of the causative agents, they are cultivated or stored in the laboratory. Since bacteria of the same species may exhibit biological variations and minor differences in antigenic structure, stock vaccines may be composed of several different strains of the same species, thereby rendering the vaccine polyvalent. Treatment with such polyvalent stock vaccines is of distinct value particularly in certain chronic infections. Stock vaccines must of necessity be used only in an attempt to immunize the normal individual prior to exposure to infection by the corresponding infectious agent.

Autogenous vaccines are prepared irom the actual microorganism isolated from the particular patient being treated. Such preparations are definitely superior to even polyvalent stock vaccines in the treatment of chronic infections, such as sinusitis or pyoderma, since the resulting antibodies developed are entirely specific for the particular agent causing the disease. For the prevention of tetanus and diphtheria, diseases in which the chief symptoms and pathology result primarily from effects of the bacterial toxins in the body, the modified toxins, or toxoids as they are called, comprise the vaccine, and stimulate the production of immunity which is antitoxic rather than antibacterial.

Preparation of Vaccines. — Bacterial vaccines, whether stock or autogenous, are prepared in a manner somewhat as follows: the selected microorganism is grown, usually on a solid culture medium under conditions which are optimum for maximum growth. The resulting bacteria are suspended in a sterile physiological solution of sodium chloride, washed by centrifugation and resuspended in more of the sterile saline solution. If the vaccine is to be composed of intact bacterial cells, the microorganisms are usually killed, either by heating in a water bath at 60° C. for one hour or by the addition of some chemical. The number of bacteria per unit volume of suspension is determined by any of several ways: by density determinations, by chemical analyses or by direct or proportional microscopic counts. The bacterial suspension is then adjusted to the desired standard by either dilution or concentration, as the need may be, and cultured to ensure its sterility. The standardized sterile vaccine is stored in sterile glass vials or ampuls and is ready for use. If the vaccine is to be composed of fragments of bacterial protoplasm, rather than of the intact bacteria themselves, the bacteria are killed by disrupting the cells, after their concentration is standardized, either by repeated rapid freezing and thawing of the suspension, by grinding in a ball mill, by ultra-violet irradiation or by ultrasonic vibrations. The resultant mixture of bacterial antigens is tested for sterility to ensure its noninfectivity, and a preservative, such as phenol, is added in proper concentration.

Virus and rickettsial vaccines are prepared in a manner somewhat similar to the above, except that these microorganisms must be cultivated in the presence of living animal cells. Ernest Goodpasture's development in 1931 of the embryonated hen's egg as a culture medium for many viruses and rickettsiae provided the opportunity for producing vaccines of many of these infectious agents.

Salk Poliomyelitis Vaccine. — Later developments in the field of tissue and cell cultivation *in vitro* made possible the demonstration in 1949 by John F. Enders, Frederick Robbins and Thomas H. Weller that all three types of viruses which cause poliomyelitis (infantile paralysis) could be grown in test-tube cultures of a variety of living human and monkey cells of non-neural origin. This contribution, which won for its developers the Nobel prize for medicine and physiology in 1954, coupled with the discovery in 1952 that poliomyelitis viruses circulate in the blood during the preparalytic phase of the infection, suggested the feasibility of a vaccine to stimulate active immunity to poliomyelitis.

Jonas E. Salk and his associates prepared a poliomyelitis vaccine by growing all three types of virus in cultures of living cells from the kidneys of rhesus monkeys imported from Pakistan and India. The viruses were separated irom kidney tissue, killed by formalin, and standardized for both potency and safety. In 1954 a large scale field test of effectiveness of the Salk poliomyelitis vaccine was conducted in nearly 2,000,000 children in epidemic areas of the United States. This evaluation of the vaccine revealed in 1955 that: (1) its greatest effect was in the prevention of the most fatal form (bulbospinal) of the disease; (2) it was from 60% to 70% effective against disease caused by type I viruses; and (3) it was 90% or more effective against the disease caused by viruses of types II and III. Developments in production and administration of Salk vaccine indicated even greater future effectiveness. The vaccine is given intramuscularly in a series of tao injections separated by an interval of two to four weeks, followed by a third injection seven months later.

The successful adaptation by the pharmaceutical industry of tissue culture methods to the enormous scale required for virus vaccine production made likely future developments of vaccines against the infectious diseases still to be brought under control.

VACCINIUM, a genus of shrubs of the heath family (Ericaceae, *q.v.*), comprising about 130 species found widely throughout the northern hemisphere and extending to Madagascar and the Andes. They are erect or creeping shrubs, with deciduous or evergreen leaves. The small flowers bear much resemblance to those of the true heaths *(Erica),* from which they ditier in having the ovary inferior. The fleshy, often delicious, berries are usually edible.

In North America about 40 species occur, more abundant in the northern and mountainous parts of the continent. In the eastern states and adjacent Canada several species, commonly known as blueberry (*q.v.*), are prized for their fruits. In northern Canada the red whortleberry, commonly called mountain cranberry, is gathered for cooking purposes. V. *macrocarpon,* the American cranberry, is extensively cultivated. Several species occur in the Rocky mountain region and about ten are found in the Pacific states, the latter including V. *occidentale,* the western blueberry; V. *parvifolium,* the red bilberry; and V. *ovatum,* the California blueberry.

Four species occur in Great Britain: V. *myrtillus,* the bilberry, blaeberry or whortleberry; V. *uliginosum,* the bog bilberry; V. *vitis-idaea,* the red whortleberry or cowberry; and V. *oxycoccos,* the cranberry (*q.v.*), all of which are found widely distributed throughout large areas in Europe. Asia and North America, being especially abundant in cool northern and mountainous regions.

VACUUM, empty space; specifically, an enclosed space devoid of matter. Physically, the condition of complete absence of matter is never realized; even the most nearly perfect vacuum contains gas or vapour in a state of great rarefaction — how great may be realized by considering that the lowest practicably attainable pressure in a tight vessel is of the order of 10^{-7} mm. of mercury, whereas atmospheric pressure is about 0.75×10^3 mm.—the height of the mercury column in a barometer. The ratio of these pressures is about 1.3×10^{-10}; in round numbers, therefore the pressure in the vessel, as well as the number of molecules of gas in it, has been reduced by a factor of 10,000,000,000. In each cubic centimetre of gas at normal atmospheric pressure there are 2.7×10^{19} molecules. Reducing the pressure to the practicable limit therefore reduces the number of molecules by a factor of, say, 10^{10}, leaving behind 2.7×10^9 molecules, or roughly 3,000,000,000, in each cubic centimetre of space within the vessel. Whereas at atmospheric pressure the mean free path (average distance covered between collisions) of a molecule in air is about 9.5×10^{-6} cm., this becomes 14 m. at the low pressure mentioned.

During the years between the World Wars I and II, and particularly during the prodigious scientific and technological efforts in the United States and Great Britain brought forth by the exigencies of World War II, great strides were made in the application of high-vacuum technology to many problems and situations, both in the laboratory and the factory, in fields of great diversity in pure and applied science.

It is general knowledge that Thomas A. Edison's incandescent electric lamp required that its glass envelope or bulb be "pumped out" to prevent its carbon filament from uniting with the oxygen of the air and chemically burning out. The commercial needs of rapidly exhausting the air from light bulbs resulted in improvements in methods of pumping. The "Edison effect"—forerunner of the Fleming valve, the Deforest audion, and the multitude of modern electronic tubes—was discovered because it had become possible by 1883 to pump the air out of a lamp bulb to the point where a current through the residual gas could be detected. The rapid growth of the radio industry, accompanying the development of broadcasting methods and of means for broadcast reception, which occurred in the decade beginning about 1920, could not have occurred without the concomitant development of techniques for exhausting the radio valves, or vacuum tubes, to the requisite high vacuum by methods that were technically and economically feasible.

Metallurgical processes by which such rare metals as tantalum and tungsten are produced in pure state from their ores depend for their success on high-vacuum furnaces in which the vacuum can be rapidly produced and readily maintained while the metallic bars, at white heat, are giving off great quantities of gas. Practically all optical instruments used in World War II were greatly improved in their ability to transmit light by having the optical surfaces of their lenses and prisms coated or "bloomed" with a hard, transparent mineral layer a few molecules thick, to reduce the reflection and therefore loss of light at these surfaces. The coating process is carried on in a high vacuum: and its development to commercial practicability comprises many highly ingenious procedures. In the optical field also, the best first-surface mirrors are produced by a vacuum distillation process, in which the metal is vaporized by electric heat and caused to condense on the glass surface from which light is to be reflected. The mirrors of practically all astronomical reflecting telescopes are now prepared by evaporation and condensation of metal—usually aluminum—in a high vacuum.

The production of vitamin A from fish-liver oil, by fractional distillation in a high-vacuum still, is now a highly successful commercial process; but this is only a single example of a well-developed technology in the fields of nutrition and pharmacology yielding useful and valuable and sometimes unexpected returns. High-vacuum technology plays an essential role in the production, in commercial quantities, of penicillin, and in the rapid dehydration of blood plasma and serums.

In the basic science laboratories, particularly those of physicists, the availability of apparatus for the rapid production of high vacuum has profoundly influenced the success of many researches, It has, in fact, been the *sine qua non* of soine of the most fundamental experiments in electronics, nuclear physics and X-rays. Without high vacuum there would be neither radio broadcasting nor radio reception; and without it, television could not have been developed. For it is only in high vacuum that the electrons may be given off and controlled to make tubes and circuits possible in which a weak signal may be amplified ten-millionfold and more; and it is in high vacuum that light may cause useful emission of electrons from a photosensitive surface which constitutes the heart of the television transmitter. The cathode-ray oscillograph, one form of which is essential to the production of a visible image in a television receiver, likewise depends on high vacuum. The cathode-ray oscillograph may be said to have saved England, for it is one of the essential components of radar. The cyclotron, the betatron, the electron microscope, the mass spectrograph—all are useful, practicable instruments because of high vacuum. The separation of U-235, the fissionable atom of uranium, from its isotopes of atomic weights 234 and 238, was accomplished in high vacuum, in a magnetic field, by applying the principle of the mass spectrograph.

These examples from industry and the research laboratory have been cited to show the importance of vacuum, and particularly of modern high-vacuum technology. The requirements of the innumerable situations in which high vacuum is an essential factor have given rise to a modern technology that may be designated "high-vacuum engineering." This comprises a knowledge of the means for producing high vacuum, namely, the several kinds of vacuum pumps, formerly called air pumps; the means for measuring vacuum—the several kinds of manoineters or vacuum gauges; and the unusual methods and artifices that must be employed in order that a vacuum system—consisting of the pump or pumps, the vessels or containers being exhausted, the measuring and controlling devices and the tube-lines connecting all together properly—may function most effectively. These several aspects of production and measurememt of high vacuum and the management and control of vacuum systems will be discussed in this article.

Rotary Oil-Sealed Pumps.—About 1920 the reciprocating-piston vacuum pump was displaced by the rotary mechanical types. Some ten years earlier the Gaede *Kapselpumpe* had appeared. It was characterized by a cylindrical rotating member, or rotor, eccentrically mounted within a cylindrical housing, or stator, of somewhat larger diameter (fig. 1). The rotor A contained tno diametrically opposite slides, S and S', bearing against the inner surface of the stator B under spring pressure and centrifugal action. Air in the space V_d ahead of the slide S′ is swept out through an exhaust port, as the volume of the space decreases; whereas, behind the slide S the volume increases, causing air to enter through an intake port from the vessel being exhausted. Air in the space V betueen the two slides. at the pressure of that in the vessel being exhausted, is compressed. as soon as slide S′ has passed the exhaust port and V has become V_d, to atmospheric pressure. and is expelled through the valve E to atmosphere. Small clearance and an oil film at C keep the compressed gas in V_d from entering V_i. Many rotary pumps of various specific designs but employing the same principle have appeared and are in common use in shops and laboratories. The Gaede rotary *Kapselpumpe* was designed to serve as a primary or forepump (Ger.: *Vorpumpe)* in series with the Gaede rotary mercury pump with which high vacuum could be slowly produced. More recent designs of rotary pumps have been used in large numbers as torepumps with the mercury vapour diffusion or condensation pumps, and with the oil-vapour pumps of this type.

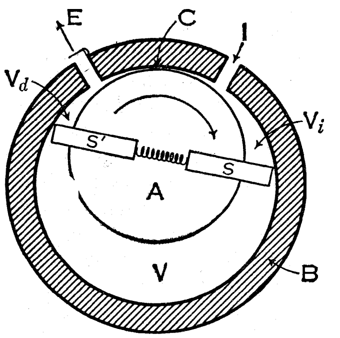

FIG. I.—SECTION OF THE GAEDE "KAPSELPUMPE"
I, intake of pump from vessel to be evacuated; E, exhaust; A, rotor; S′, S, slides; B, stator; V_d, volume of exhaust air; V_i, volume of intake air; V, volume of air at pressure of that in vessel being exhausted; C, seal between stator and rotor

The type of rotary pump, which was responsible for displacing the reciprocating air pump from laboratories generally, is a series known as "Hyvac"—with displacements ranging from about 170 cc. to 17,000 cc. per second. These represent the first rotary, oil-sealed pumps capable of producing a vacuum — with exclusion of vapour from the system — of better than 0.001 mm. of mercury. In principle this type differs from the pump of fig. 2 in having its rotor eccentrically mounted on a shaft, and in having a single vane in the stator to separate the high-pressure from the low-pressure side.

In fig. 2 Rotor **A** is eccentrically mounted on a shaft concentric with the cylindrical cavity of stator B. At C the surface of the rotor is ground, for a short distance, on a radius almost equal to that of the stator cavity, to provide sealing contact over a finite area rather than along a cylindrical element, or line. The slide S is maintained in contact with the rotor by spring pressure. The intake is at D, the exhaust port at E; the latter is provided with a ball valve. With rotation as indicated, the space V_i increases and V_d decreases at each cycle from the instant of passage of the sealing area C beyond the slide S. In its practical embodiment, this pump may consist of two pumping units in series. They are arranged side by side, separated by a common wall, ground plane-parallel, through which a hole is drilled that constitutes both the exhaust port of the high-vacuum unit and the intake port of the forepump unit. While the space V_d in the former is decreasing, it is expelling the air into the space V_i of the latter. Thus the air in the space V_d of the high-vacuum unit is not compressed appreciably. As a result, leakage into the high-vacuum side is minimized. In illustration of the effectiveness of such an arrangement, a single-stage pump of this type produces a vacuum of about 0.05 mm., whereas the two-stage pump produces about 0 0005 mm., two orders of magnitude better.

Pumps Utilizing Liquid Mercury. — In the second half of the 19th century various types of mercury pump were introduced, which were used in all the early experiments on the discharge of electricity through gases at low pressure. The principle of all these pumps is to connect the receiver with a Torricellian vacuum created by the pump; the equalization of pressure will then bring part of the air in the receiver into the Torricellian space. The receiver which is being exhausted is then cut off from the vacuous space, and the vacuum re-created. This process can be carried out in various nays. The simplest and earliest form of apparatus is that described by Heinrich Geissler in 1862. This consists simply of a vessel connected by a flexible tube to an open reservoir of mercury; the vessel can by means of a two-way stopcock be connected either with the outside air or with the space to be exhausted. The stopcock being turned so as to give passage to the air, the reservoir is raised until the vessel is full of mercury; the stopcock is then turned so that the vessel is cut off from the air and connected to the space to be exhausted, and the reservoir is lowered. This tends to create a Torricellian vacuum in the vessel, into which the air from the space being exhausted rushes. The cycle can be repeated as often as desired, the fraction of air removed each time depending upon the relative volumes of space to be exhausted and the vessel.

A type of pump possessing many advantages over the Geissler pump was devised by August Töpler; it avoids all stopcocks, the connections and disconnections being made by the mercury itself. An improved form of Topler pump is shown in fig. 3, from which the working of the pump can easily be understood. V is a cylindrical vessel connected by the tube S to the space to be exhausted. M is a mercury reservoir which must be of somewhat greater capacity than V. When the mercury levels are as in fig. 3, V contains gas at the same pressure as S. The reservoir M is then raised; the mercury rises in the tube Z, cutting off V from S, and fills the vessel V, driving the gas from it down the tube T. The gas being thus expelled, M is lowered again, and the vacuous space V is once more in connection with S. The process is repeated as often as may be required. A valve at C, consisting of a glass float, the top of which is ground to fit on a seating at O, serves to prevent the mercury ever passing over into the vessel S, while the inclined position of the cylindrical vessel V has, among other advantages, that of lessening the shock of the rising mercury against the top of the vessel. Pumps of the Topler type were widely used for producing a vacuum in the researches of the first ten years or so of the 20th century, but were then gradually superseded by rotary and other types. Pumping uith them was a tedious business. By mid-20th century they were used only when it was desired to collect the gases which were being pumped out, a purpose for which they are excellently adapted.

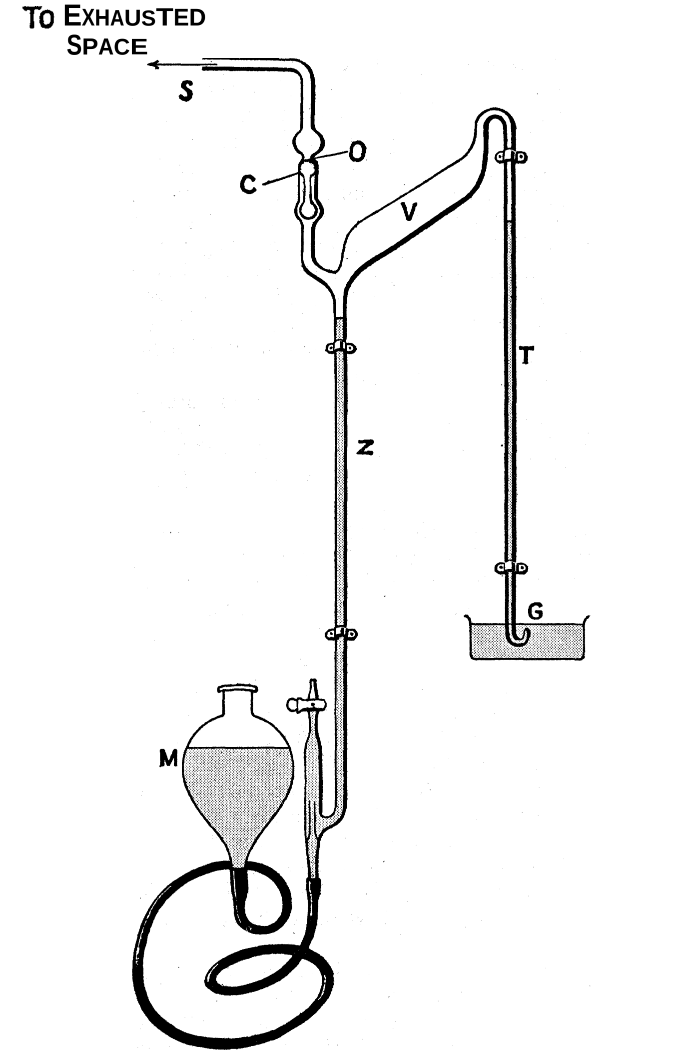

FIG. 3.— THE TÖPLER MERCURY PUMP
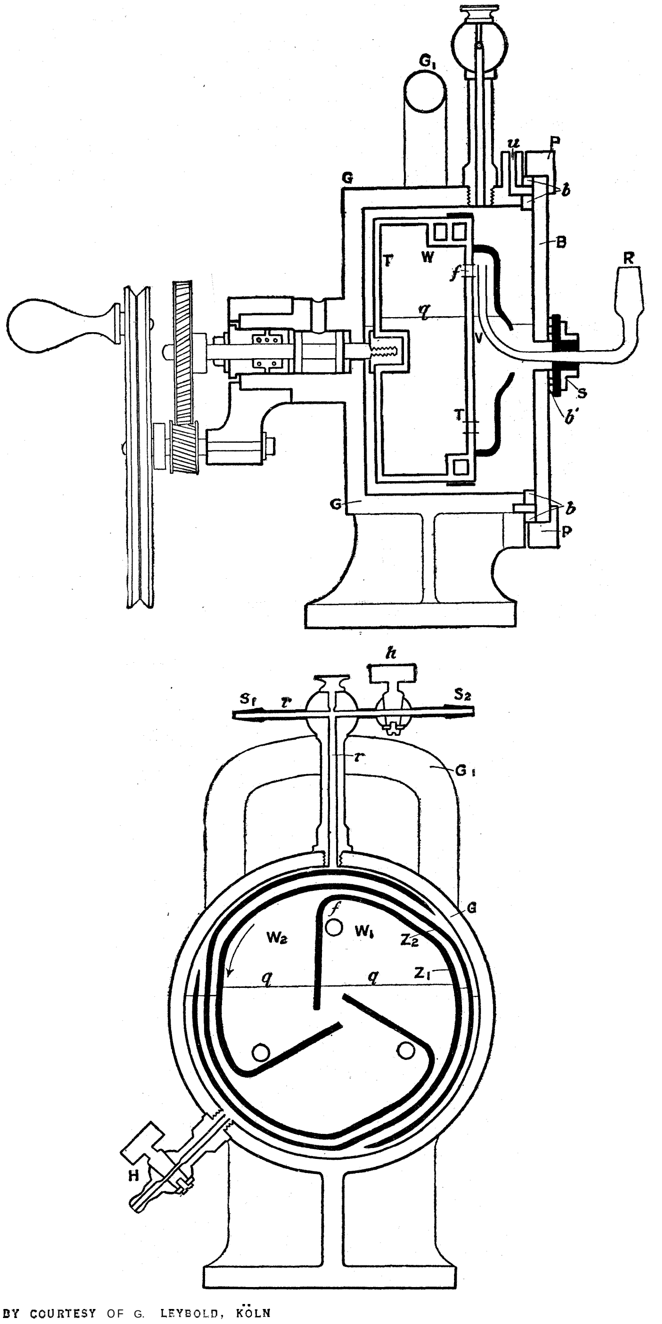
When the reservoir M is lifted the mercury rises into the vessel V, and expels the gas down tube T. C is a float valve, seating at O, which cuts off the exhausted space

To avoid the tedious raising and lowering of the reservoir, a process which may have to be carried out for an hour or two to obtain the desired vacuum, automatic mercury pumps were devised. The earliest was that of Herman Sprengel, which consists essentially of a narrow tube down which mercury flows in a succession of drops, filling the bore of the tube, from a reservoir; the top of the tube is connected to the space S to be exhausted. If the tube is of barometric height the pressure at the top will be zero, air will pass into it from S, and will be carried down as bubbles by the mercury and discharged into a collecting vessel or into the air, as desired. This type of pump was much improved by Gimingham in 1877, and in this form used by Sir William Crookes in his extensive investigations on electrical discharges in vacuum tubes. These pumps were not strictly automatic, in that the reservoir gradually emptied and had to be refilled by hand. Devices were introduced by which the reservoir could be kept automatically refilled; a typical pump of this kind was that of G. W. A. Kahlbaum (1894), in which the flow of mercury was maintained by the help of a water-operated filter pump of ordinary type. The Sprengel type of pump, which came to be extensively used, like the widely known Topler type, was the subject of many modifications.

A revolution in high-vacuum technique was brought about in 1905 when Gaede introduced his rotary mercury pump. In principle the pump, which is illustrated in fig. 4, is something like a gas meter run in reverse. It consists of a porcelain drum W, rotating on an axis A, mounted in an iron vessel GG, the front of which is closed by a glass plate B, as shown in the upper figure. The drum is divided into two parts by a vertical wall T, the portion on the right of this wall enclosing a space V which communicates through the tube R with the vessel to be evacuated. The portion to the left of the wall is divided into three compartments by walls of the shape shown in the lower figure. The pump is filled with mercury up to the level qq. When the drum rotates in the direction of the arrow the compartment W_1, which communicates with V by the hole f, is filled with gas from the receiver, while the gas in the compartment W_2, drawn from the receiver just before, is displaced by the mercury and ultimately passes into the space between the revolving drum and the casing. The action is continuous. It is, however, clearly necessary that the pressure prevailing in the space between drum and casing shall not exceed a few millimetres or so of mercury; the pump must therefore be run in connection with a suitable forepump, which first reduces the pressure to a value at which the rotary mercury pump can be put in operation, and subsequently removes, as long as necessary, the gases displaced by the mercury pump. The forepump is connected to the tube S_2, the other branch S_1 being connected to a rough mercury gauge.



BY COURTESY OF G. LEYBOLD, KÖLN

FIG. 4.—GAEDE'S ROTARY MERCURY PUMP

As the drum W rotates, the air is displaced from the chamber W_2 into the space between drums and casing G, and is drawn frcm the receiver into the chamber W, through opening f. The chamber W, moves into the position of chamber W_2, and the process is repeated

With mercury pumps of this type a pressure as low as 10^{-5} mm., as measured with the McLeod gauge, can be attained. There is, however, always the pressure of the mercury vapour itself, amounting to about 0.001 mm. at ordinary room temperature, unless special precautions are taken to trap the vapour between pump and receiver. Moreover, the pump cannot deal with condensable vapours, such as water vapour, for the decrease of volume of the chamber during the expulsion of the gas leads to condensation of the saturated vapour in the drum. The pump requires about 40 lb. of mercury. It has, however, the advantage that it can be stopped without detriment to the vacuum already attained, nhich cannot be done with other types of pump to be described. The speed is about 100 cc. per second over a wide range, an exceedingly slow rate as compared with modern pumps.

Aspirators **and Ejectors.**—When water flows through a pipe with a constricted section, the pressure in the region of higher velocity, at the narrow section. is lower than it is in the larger sections of the pipe. Because of the reduced pressure, air or other gas may be drawn into the stream through an opening in the pipe at the reduced section. This simple application of Bernoulli's principle is the basis for the water aspirator. a form of air pump usually attached to a water tap, and operated by opening the cock. A side arm, with the opening into the section at reduced pressure, provides means for connection of the receiver to be exhausted. A well-designed aspirator is rapid and produces a pressure of between 1 j mm. and 25 mm., depending on the temperature of the water, the attainable limit being the vapour pressure of the water. This simplest of air pumps is useful for many operations in the laboratory that do not demand high vacuum, but it is not adapted to serving as a forepump for condensation and diffusion pumps (see PUMP).

In principle the steam ejector resembles the water aspirator, except that the operating fluid is steam. The gas being pumped is drawn into the high-speed jet of steam. Such an ejector, operating into atmospheric pressure, may produce a pressure of the order of 50 mm. to 100 mm. To produce lower pressure by the same means, two ejectors may be used in series, with a resultant pressure of about a j mm. to 50 mm. Still lower pressure is thus attainable by adding another ejector to the series, usually with a condenser interposed between the second and third ejector. This condenses the working steam from the ejectors operating at loner pressures. With three ejectors, a pressure of 0.1 mm. has been achieved; with five in series, a pressure of 0.03 mm. has been reached. This is sufficiently low for many industrial uses.

If the steam ejector worked on exactly the same principle as the water pump, the lowest pressure obtainable would be that in equilibrium with steam at room temperature. or 1; mm. to 20 mm. Hg. That much loner pressures are obtainable is evidence that all the molecules of steam in the high-vacuum jet have been given a velocity so far in excess of their normal thermal velocity that few can return into the evacuated space.

Ejectors employing steam or oil vapour are employed as forepumps and booster pumps in modern vacuum systems.

Mercury Diffusion and Condensation Pumps.--In 1915

Gaede once again appeared with an idea for making the processes developed on the basis of the kinetic theory of gases work toward the production of a high vacuum. The scheme of operation of his diffusion pump may be understood by reference to fig. 5. A stream of mercury vapour passes upward in a tube which has a side branch closed with a porous plug or narrow slit through which gases may diffuse. The branch connects a vessel containing air at reduced pressure. The pressure of the mercury vapour may be of the order of 1 mm., corresponding to the temperature at which evaporation occurs. Some of the vapour diffuses through the barrier into the space containing air and this, in greater part, condenses; at the same time, air diffuses in the opposite direction, where the molecules are entrained in the blast of vapour. The rates of diffusion in opposite directions depend on the respective molecular weights, the mean size of the capillary passages in the diffusion barrier, and the partial pressures on opposite sides of the barrier of the two gaseous mediums. Thus the diffusion of the air into the vapour stream will continue so long as there is air in the vessel connected to the side arm, and theoretically approaches a perfect vacuum. Although the mercury continues to diffuse in the opposite direction, its vapour pressure on the right of the barrier remains low, corresponding to the low temperature of its surroundings, namely that of the cooling jacket surrounding the exhaust tube.

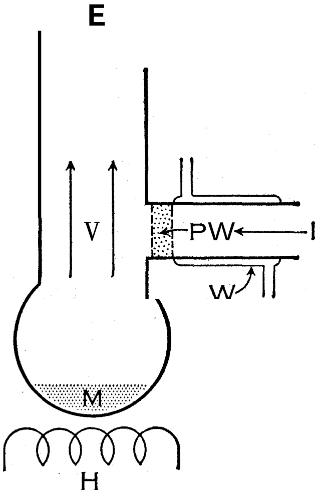


FIG. 5.—GAEDE DIFFUSION PUMP
I, intake; E, exhaust; P, diffusion barrier: W, water cooling jacket; V, mercury-vapour stream; M, mercury; H, heater

Because of the manner in which diffusion takes place in a gas, the porous plug or Gaede's equivalent of it, a narrow slit, is not necessary. In Gaede's original pump, the blast of mercury vapour was made to pass a narrow slit through which the air diffused into the stream of vapour. According to his reasoning. the greatest speed of pumping was attained when the width of the slit was of the same order as the mean free path of the air molecules. The mercury vapour diffusing through the slit was immediately condensed on a cooled surface opposite the slit. Although the pump produced a vacuum higher than had theretofore been attained, its speed was slower than that of the Gaede rotary mercury pump.

By eliminating the slit and arranging for cooling of inner wall surfaces in such a manner that the mercury vapour could not diffuse back into the vessel being exhausted, or prevent the air from diffusing rapidly into the stream of vapour, Irving Langmuir greatly increased the speed of exhaust and rendered the pump less subject to variations in performance with changes in temperature of the boiler. Langmuir reasoned that the mercury molecules could readily be prevented from diffusing in the direction opposite that of the air molecules by cooling the walls of the tube at a point just beyond the tube through which the: air is diffusing into the vapour stream. Thus. the air molecules are rapidly carried away from their outlet, the vapour is rapidly condensed, and the temperature in the vicinity of the outlet is maintained so low that practically no mercury is re-evaporated in this region. Because of the dependence upon condensation of the mercury vapour for proper functioning, Langmuir designated this type as a condensation pump, as distinguished from Gaede's diffusion pump. However, both types depend upon both diffusion and condensation for operation. Gaede's has a restricted area through which diffusion takes place, uhereas Langmuir's has a large area. Modern refinements in condensation pumps have given them extremely high pumping speeds, speeds limited only by the physical dimensions that are practicable in specific cases.

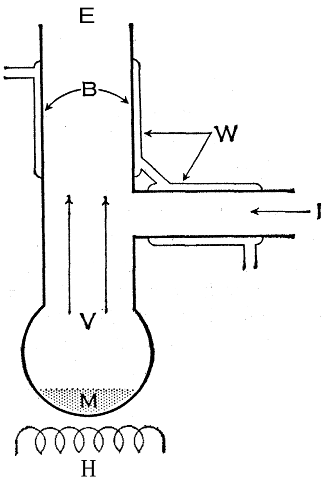

FIG. 6 —LANGMUIR CONDENSATION PUMP

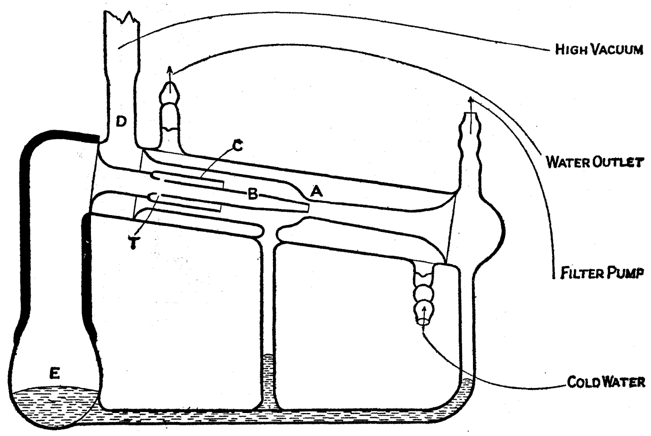
Mercury Vapour Pumps.—Two- and three-stage mercury vapour pumps, in which the stages are arranged in series, so that the high pressure side of one is the low pressure side of another, are made for rapid work. Since at very low pressure the mercury vapour stream loses its jet form, the stream in a diffusion pump exerts no action such as the steam jet does in an ordinary injector. However, at higher pressures the Bernoulli effect comes into operation, and is utilized in the preliminary stage or stages of a multiple stage pump, where, because of the higher pressure, the diffusion principle is less effective. One of the early two-stage mercury vapour pumps as designed and built by Dunoyer mhich will work against a forepressure of 25 mm. or 30 mm. is illustrated in fig. 7. The first mercury jet A acts like the steam injector, and is forced into a conical diffuser which is connected to the forepump. This first jet lowers the pressure in B, into which an annular stream of vapour is sent from the sleeve C. This jet still further diminishes the pressure in D, which is joined to the system requiring evacuation. The annular jet is formed by vapour which gets into C by the small holes T, the remainder of the vapour going on to form the jet at A. The high vacuum in D is created by diffusion and condensation in the same way as in the Langmuir pump.



FROM DUNOYER, "VACUUM PRACTICE" (BELL)
FIG. 7.— A TWO-STAGE MERCURY VAPOUR PUMP. DESIGNED BY DUNOYER

Oil Vapour Pumps.—For many years mercury was the only pumping fluid used in diffusion and condensation pumps. Beginning about 1929 C. R. Burch in England and K. C. D. Hickman in the United States prepared some organic oils uhich proved to be useful as pumping fluids. Some of these have extremely low vapour pressures, a property which was exploited to obtain lower pressures. The principles underlying mercury vapour pumps are also basic to oil vapour pumps. Recognizing that oils contain components which, because of their different vapour pressures, boil at slightly different temperatures, Hickman developed the fractionating pump. Two of the first practicable fractionating pumps are shown in Pl. I, figs. 2 and 4. The two-stage fractionating pump seen in Pl. I, fig. 4 is made of glass and is capable of producing a vacuum of the order of 10^{-7} mm. in a closed system. This is made possible by a design which by application of known principles of distillation and condensation controls the passage of oil and oil vapour through multiple boilers. After the unit has run for a short time, the extreme volatiles have been distilled into the alembics of the vertical tube. The condensed oil from the jets returns to the first boiler (boiler under the vertical tube) where the highest relative temperature is maintained. The more volatile constituents in the oil are vaporized and stream from the jet. The material of lower vapour pressure passes through the connecting tube to the second boiler. The second stage produces better vacuum at high speeds because the oil which reaches it has been rectified in the first stage; *i.e.,* fractions of higher vapour pressure have been eliminated. The small boiler at the end of the pump serves as a still in which the dark-coloured nonvolatile residue collects while the more active components are distilled and returned to the other two boilers by the overhead glass tubes leading to these boilers. The addition of another boiler and jet as seen in Pl. I, fig. 2 broadens further the use of the principle of fractionation and realizes the ultimate possibilities of oils as pumping fluids.

A metal fractionating oil pump is illustrated in Pl. I. fig. 3, and in fig. 8. This pump is not so efficient in fractionating the oil as is the horizontal glass pump described above but it does afford considerable self-conditioning of the pumping medium, is robust, compact and capable of reaching pressures of 10^{-6} mm. and lower. This design of pump may be built in different sizes resulting in a series of pumps with a wide range of pumping speeds.

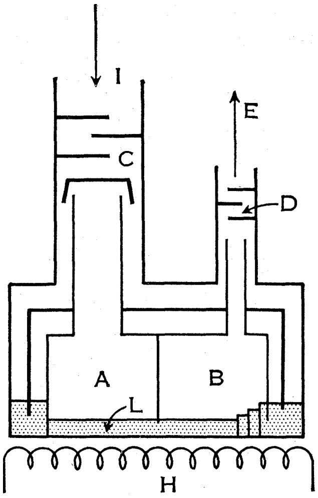


FIG. 8.—SECTION OF AN ALL METAL, TWO-STAGE, FRACTIONATING PUMP

I, intake; E, exhaust; C, high vacuum section; D, forevacuum section; A, high vacuum boiler; B, forevacuum boiler; L, pumping fluid; H, heater

The boiler of this pump is divided into two sections, A and B in fig. 8. The high vacuum section C has an umbrella jet and the forepressure section D has an upright jet. There are baffles in each section above these jets to provide cool areas for oil vapours to condense on and be returned to the boilers. The two stacks of this pump may be either air-cooled or water-cooled. The stacks in Pl. I, fig. 3 are air-cooled; external fins enlarge the cooling surface. In the forepressure boiler B there are small dams making the oil pass over a longer path enabling the more volatile constituents to evaporate in this boiler and allowing the less volatile constituents to get over to the high-vacuum boiler which serves the high-vacuum jet.

Similar to the multijet mercury diffusion pumps, oil diffusion pumps may be made as nonfractionating one-, two- or three-jet types. However, most oil pumps are designed to produce some partial fractionation of the oil, since the employment of this principle always results in a more efficient pump. In a three-stage oil diffusion pump, as shown in Pl. II. fig. 3, the condensed vapour enters the circular boiler from the outside edge. The chimney is common to the three jets. supplying the jets with vapour in a manner similar to the mercury vapour condensation pump previously described. There is built into the forepressure arm a series of alembics for collecting the highest volatile substances and preventing their return to the pumping fluid. In another type of upright, three-jet oil diffusion pump, there are three separate concentric chimneys for the three jets. The outside chimney feeds the lowest vacuum jet and the inside, the highest. The condensed vapour enters from the outside edge into the boiler and on its passage to the centre chimney the higher volatiles are boiled off into the higher vacuum jets. This results in a semifractionation of the oil.

The pumping speeds of mercury vapour and oil vapour pumps range from 1 l. per second up to many thousands of litres per second at 10^{-4} mm. and under proper conditions will attain an ultimate pressure of 10^{-7} mm.

Booster Pumps.—With the development of the oil diffusion pump, certain limitations in its use were soon discovered. Although higher speeds at lower pressures mere obtainable because of improved pump construction and lower vapour pressure of the oils, it was noted that the pressures into which the oil diffusion pump would satisfactorily discharge the gases were comparatively lower. Another may of stating the same thing is that the forepressure breakdown, or pressure into which or against which the oil diffusion pump would operate, was low. This resulted in low speeds in the regions of pressure between the optimum working pressure for the mechanical pump and the optimum forepressure for the high speed diffusion pump. To overcome this difficulty it was necessary to develop another type of pump which would discharge into a region of comparatively high forepressure. These pumps are known as "booster pumps" (Pl. II, figs. 1, 2 and 4). They operate on the diffusion-condensation and jet ejector principles and will maintain a low pressure into which a high-speed diffusion pump may exhaust.

Measurement of Low Pressures.—Vacuum Gauges.—Pressures down to a few millimetres of mercury can be measured by an ordinary mercury manometer, consisting of a U-tube having one side closed at its upper end and filled with mercury. When the other branch is connected to the vessel in which the pressure is to be measured the difference of level in the two branches, which may be read with vernier attachments or with a cathetometer, indicates the excess pressure in the vessel above the Torricellian vacuum in the closed branch. Such manometers are commonly used for rough readings, since, in the vacuum range of 1 mm. and less, this small difference in levels cannot be measured with great accuracy. A more sensitive mercury manometer is one in which the two mercury surfaces are kept precisely in contact with fine vertical pointers. The difference of pressure is measured by the angle through which it is necessary to tilt the manometer in order to restore the level when it is disturbed by the presence of gas on one side. This gauge has been used to measure pressures from 1.5 mm. to 0.001 mm. Another way of measuring very small displacements of the mercury surface in a U-tube manometer is by means of a little float on the surface supporting one end of a lever carrying a small mirror; the tilt of the mirror is measured by a lamp and scale.

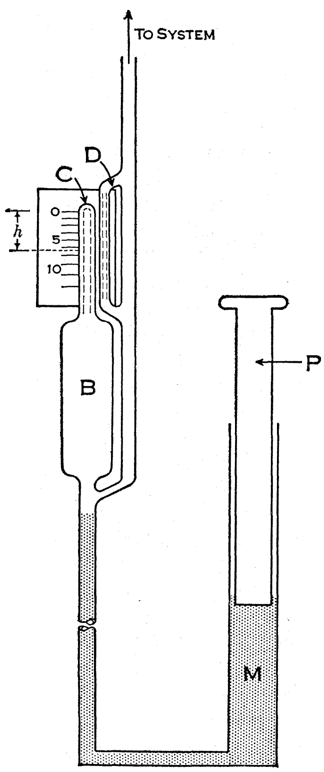

FIG. 9.— MCLEOD GAUGE

B, bulb; C, D, capillary; P, plunger; M, mercury

The first successful special device for measuring pressure too low to be accurately measured by the ordinary U-tube manometer was the gauge invented by McLeod in 1874, and known by his name. It consists in principle of a bulb B, some 250 cc. in capacity, provided with a fine calibrated vertical capillary C, fig. 9. The mercury surface can be adjusted to any desired height by the device of a mercury reservoir with displacement plunger P connected to the apparatus. The bulb B is connected to the space in which the pressure is to be measured. The mercury surface is raised, cutting off a known volume of gas, at very low pressure, in B, and then forcing it into the capillary C. The pressure which the amount of gas present exerts in this confined space is then observed. To avoid error due to capillarity in measuring the pressure a side-tube D is provided of exactly the same bore as C, and the difference of levels h in C and D measured. The level in D is opposite the top of the capillary C. Assuming Boyle's law, and knowing the volume of the bulb B and of the graduated tube C, the original pressure in B, which is the pressure required, may be calculated from $p=ah^2/V$, where p is the pressure of the gas in mm., a is the cross section of the capillary C, h is the head of mercury which is compressing the gas (difference of level in C and D) and V is the combined volume of the bulb B and the capillary C.

The McLeod gauge was by mid-20th century the standard instrument for the accurate measurement of pressures down to 10^{-6} mm. with certain gases and proper precautions. Many other types of gauges are calibrated using this gauge as the standard of reference. The accuracy of the gauge depends upon the closeness with which the gas in question obeys Boyle's law, perfect compliance with which is assumed in the deduction of the equation for the pressure. The gauge cannot be used with condensable vapours, such as those of water or ammonia, which tend to liquefy on the walls; even with carbon dioxide the readings are not reliable. With such gases as hydrogen and nitrogen, on the other hand, the gauge works down to its limit of pressure measurement.

Since McLeod gauges cannot be used with such gases as chlorine, which are chemically very active and attack mercury, various types of membrane manometer have had to be devised. Very thin spiral glass tubes, working on the principle of the Bourdon gauge used for steam pressures, have been used for such gases, the displacement of the end of the spiral being measured with mirror and scale. Such gauges are not sensitive to pressures less than about 0.1 mm. The mechanical deformation of a very thin metal or glass membrane has been used to measure small pressures. One side of the membrane is exposed to the gas or vapour, while on the other side the vessel is evacuated by a high-vacuum pump. The very small movements produced are measured by an interference method, and results have been obtained down to 0.001 mm., but the instrument is difficult to manipulate.

The exceedingly low pressures produced by modern techniques have led to the construction of a whole class of new manometers, depending for their operation on the behaviour of gases at low pressures; *i.e.*, the behaviour of gases when the mean free path of the molecule is comparable with the linear dimension of the vessel. The thermal conductivity and the viscosity are properties which are independent of the pressure so long as the mean free path is small, but change rapidly with the pressure when the pressure is very low, becoming proportional to the pressure below a certain value of pressure, depending upon the nature of the gas and the dimensions of the vessel. Again, at low pressures, the radiometer effect manifests itself; that is, there is a mechanical repulsion between a warm surface and an opposing colder surface when gases at low pressure lie between them. Further. with simple forms of triode vacuum tubes, as long as (1) the pressure is low enough for the electrons to have a free path greater than the distance between the hot wire and the surrounding grid and (2) the potential fall accelerating the electrons which is well above the ionization potential of the gas, the ionization produced between the grid and the surrounding cylinder is proportional to the pressure. All these effects have been utilized in the construction of special low-pressure gauges.

Two types of viscosity gauges may be mentioned. In one, devised by Langmuir and Dushman, a very light horizontal disk of mica hangs suspended by a quartz fibre directly above a second horizontal disk. This second disk is carried on a vertical shaft which can be set in rapid rotation by a rotating magnetic field outside the glass vessel. The drag of the rotating disk on the suspended disk, which is proportional to the speed of rotation and to the pressure of the gas between the disks, is measured with the aid of a mirror attached to the suspended disk. The effective viscosity depends not only upon the pressure but also upon the nature of the gas, so that the gauge requires special calibration. Because of secondary effects this gauge is not reliable at extremely low pressures, and on account of the lack of proportionality between drag and pressure it cannot be used at pressures above 0.02 mm. Hg. The gauge has not found wide use.

A much simpler form of viscosity gauge, developed by Langrnuir, consists merely of a vertical quartz fibre, rigidly fastened at the upper end to the top of the vessel. When the vessel is tapped, the fibre is set in vibration, the amplitude of which decreases at a rate determined by the pressure of the residual gas in the vessel. The gauge can be used down to pressures of 10^{-4} mm. Hg.

The Pirani gauge is based on the physical principle that the thermal conductivity of a gas is related to its pressure by the approximate relation, $K = C \times p$, for pressure below values where the thickness of the gas layer is of the order of the mean free path. K is the thermal conductivity of the gas, p its pressure and C is a constant. The thermal conductivity is indirectly measured by ascertaining the change with pressure in the resistance of a hot filament in the vacuum chamber. As the pressure about the filament alters, so the speed at which heat is conducted away from the filament changes. The heat is conducted away from the filament by molecules of gas colliding with the filament and, in turn, colliding with cooler surrounding surfaces. The more of these collisions (higher pressures) the greater the cooling effect on the filament and hence the lower resulting temperature of the filament. The change in temperature effects a change in the resistance. These resistance changes are measured by a Wheatstone bridge arrangement, fig. 10. The filament used should be of a metal with as high a variation in resistance with temperature as possible; tungsten and platinum wire and a "thermistor" unit are satisfactory in this respect.

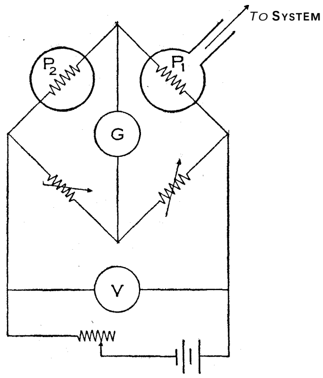

FIG. 10 —PIRANI GAUGE

In fig. 10, P_1 is the gauge filament which is enclosed by a housing attached to the vacuum System, P_2 is an identical filament whose housing has been evacuated to an extremely low pressure. The instrument has to be calibrated against a McLeod gauge.

The total pressure is indicated by the gauge; *i.e.*, it shows the pressures of condensable gases and vapours, for example, water vapour. Unfortunately the heat loss of the filament is determined by the nature of the gas molecule and so the gauge can be accurately calibrated for only one particular gas. It is very important, therefore, to avoid the introduction of water or other vapour when measuring air pressures. However, despite this fault it has the virtue that it will indicate the presence of unsuspected vapours which the McLeod gauge would completely fail to reveal. The other advantage is the ability to indicate the pressure instantaneously and continuously.

The useful range of the Pirani gauge is from 10^{-1} mm. to 10^{-4} mm. This gauge is widely used.

Another conductivity gauge is the thermocouple gauge, which, in operation, closely resembles the Pirani gauge, and is subject to the same operating conditions. It differs from the Pirani gauge in its utilization of thermoelectromotive force in place of change of electrical resistance as the actuating means. A thermoelectric junction of small dissimilar wires, fig. 11, is supported inside a glass bulb. A small heating element, spot-welded to the junction, is also supported inside this same glass bulb. The bulb is joined to the system in which the pressure is to be measured. A current of the order of 0–100 milliamperes is passed through the heating element. The thermoelectric current developed is measured by a sensitive meter. Since the temperature attained by the junction depends on the conductivity, and hence on the pressure, the surrounding gas pressure is indicated in terms of meter deflection, and the scale of the meter may be calibrated in pressure units if desired. The useful range of the gauge is between 10^{-1} mm. and 10^{-4} mm.

The ionization gauge, fig. 12, in its usual form is similar to a three-element vacuum tube. The electrons from a heated filament are accelerated toward a collecting electrode which may be either the grid or the plate of the tube. The positive ions formed through bombardment of gas molecules by this electron stream are collected on the third electrode; *i.e.*, on the plate if the electron current is collected on the grid. The positive ion current varies with the pressure in the region of the grid and plate.

In fig. 12 the grid is the electrode which collects the electron current. The grid is positive with respect to the filament and nega-

tive with respect to the plate. Some of the electrons after receiving energy caused by the voltage drop between the filament and the grid pass through the grid openings into the region between the grid and the plate. In this region the electrons bombard gas molecules and produce positive ions which migrate to the plate. The equivalent current is read on the microammeter.

In a second arrangement the plate is positive with respect to the filament and the grid is negative. The negative plate arrangement is the more sensitive method but the procedure when using the negative grid is the easier.

The electron or filament emission current is about 10 milliamperes whereas the ionization current is about 50 microamperes. Below 10^{-4} mm. the pressure is directly proportional to ionization current. With the emission of 10 milliamperes the plate voltage needs to be about -20 v. and the grid voltage of the order of

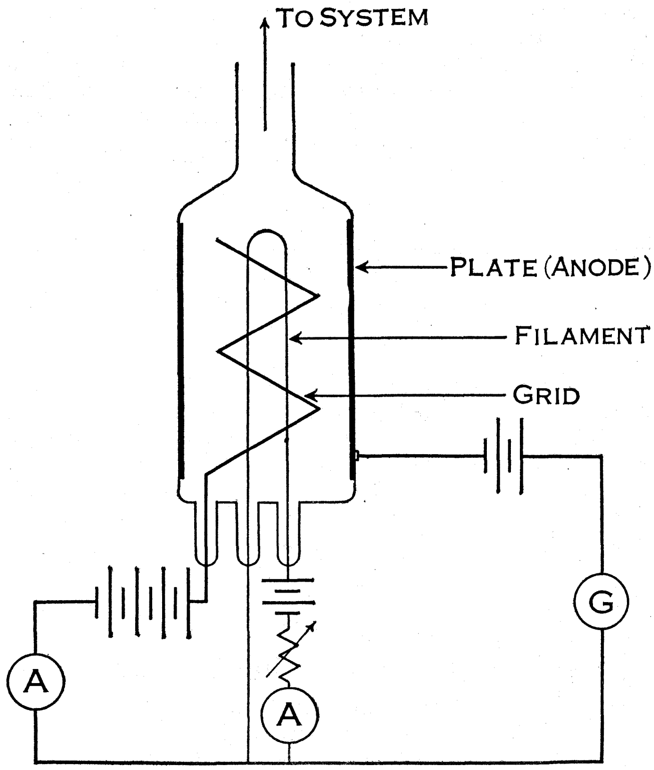

FIG. 12.— IONIZATION GAUGE

200 v. For given pressure, anode voltage and anode current, the ionization current is proportional to the number of free electrons in the gas. Thus the gauge is selective and needs to be calibrated for each gas used. The lowest pressures attained, of the order of 10^{-8} mm., have been measured with an ionization gauge. The extremely low limit of pressure capable of being measured with it is the great advantage of the gauge. The two principal disadvantages of the gauge are its low maximum pressure reading, and the fact that it needs calibration for each gas used. By the same token, for accuracy of reading, vapours must be excluded. Because of possible oxidation of the hot tungsten filament the gauge should not be operated above 10^{-3} mm.

Calibration is done by means of the McLeod gauge. Great care needs to be taken to ensure purity of gas and equality of pressure throughout the system during this calibration.

The cold-cathode ionization gauge, fig. 13, uses a cathode glow-

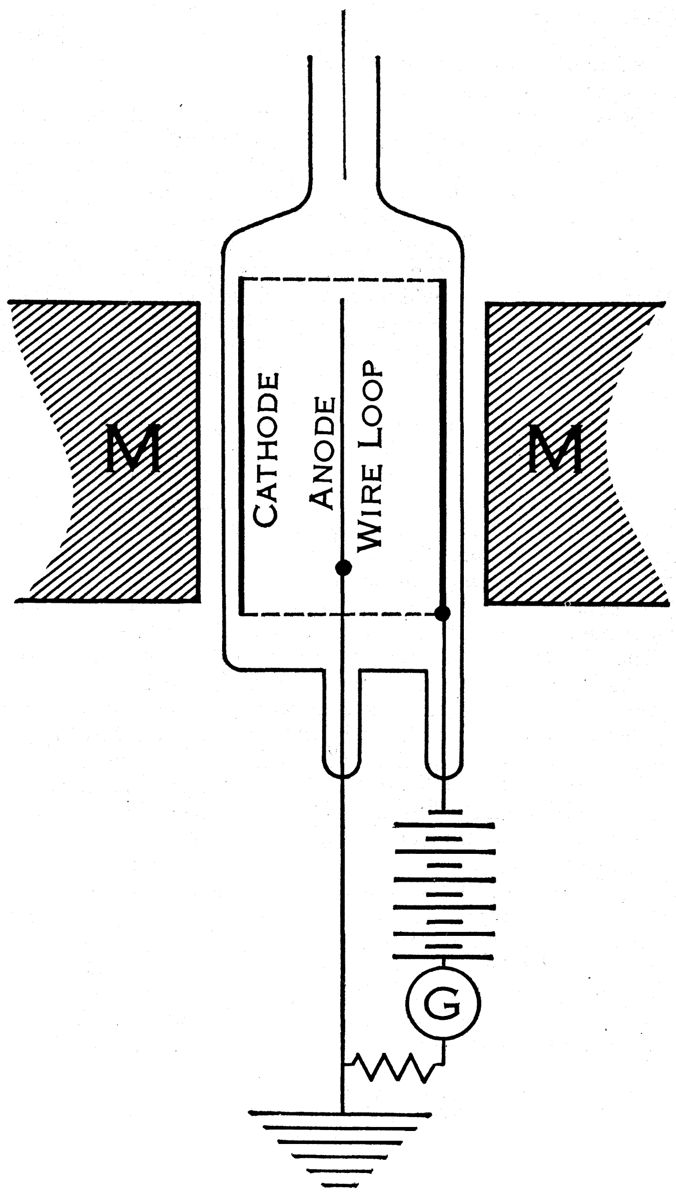

FIG. 13.— DISCHARGE IONIZATION GAUGE

discharge as the means for ionizing the gases in the envelope of the gauge tube. A permanent magnet is used in some designs of cold-cathode gauges to increase the length of the electron-molecule collision path. The electrons ejected from the surface of the cathode by the high potential gradient at the cathode ionize the gas in the gauge envelope. The electrons resulting from this ionization are either collected by the anode and the resulting cathode-anode current measured by a sensitive meter or the electrons produce further ionization which results in more electrons. The additional electrons are collected by the anode and the total electron current measured. There is a proportionality between number of gas molecules and electron current produced by ionization.

In some designs of the cold-cathode gauge the electron paths from cathode to anode are made several hundred times longer than the direct path by applying a magnetic field across the tube causing the electrons to move in a spiralling or sinuous path. Increasing the travel of the electron will, in proportion, increase the probability of an electron ionizing the molecules of the residual gas, and so an ionization current is obtained several times greater than would prevail if the electrons travelled in straight lines from cathode to anode impelled by the electric field only. Since the cold-cathode gauge does not depend upon a hot tungsten filament for its operation it may be used at higher pressures than the hot-filament ionization gauge. Also, it cannot measure extremely low pressures. The range of the cold-cathode ionization gauge is from 0.0001 mm. to 0.03 mm. Opening the gauge to atmospheric pressure does not harm it.

Fig. 13 shows the electrode and circuit arrangement for the cold-cathode ionization gauge with magnetic field. The anode and cathode are shown in their relative positions. Magnet M maintains a strong magnetic field. The voltage across the tube is of the order of 2,000 v. D.C. and the magnetizing field around 400 oersteds. The cathode is made of zirconium, thorium or other material giving a copious supply of electrons under the "cold" discharge. The gauge should be calibrated against a McLeod gauge for each gas used. This gauge coupled with the Pirani or thermocouple gauge makes a very useful combination because the two cover the range from a few millimetres to approximately 10^{-4} mm. pressure.

A third type of ionization gauge, in many ways like the cold-cathode gauge, is the alpha-ion gauge. Ionization of the gas molecules in the gauge is accomplished by the alpha particles which are discharged at constant rate by a radium source. The radium is sealed into the gauge housing. The range of this gauge is from 0.001 mm. to 10 mm. It extends to higher pressure ranges than the cold-cathode gauge and also is not damaged by opening to atmospheric pressure. Calibration of the cold-cathode and alpha-ion gauge is made using a McLeod gauge as the reference.

The Knudsen gauge provides continuous readings from 10^{-3} mm. to 10^{-7} mm. It is an absolute gauge and needs no calibration against a McLeod. The gauge consists of an aluminum vane suspended from a fine tungsten wire within a metal casing, fig. 14. The deflection of the vane is measured by an optical system in which a beam of light is reflected onto a translucent scale from a small mirror attached to the vane. Two electric heaters are located parallel with the vane on opposite sides near the edges. so that gas molecules accelerated by the heaters strike the vane, causing it to rotate. The amount of rotation is proportional to the pressure, other conditions remaining constant, and the distance between the vane and heaters being small in comparison to the mean free path of the molecules at the existing pressure. The damping magnets eliminate erratic movement of the vane caused by normal vibration without appreciably affecting its sensitivity.

The equation for calibration of the Knudsen gauge is given by

$$P=\left(\frac{2\pi^2 I}{rAt^2}\right)\left(\frac{D}{d}\right)\left[\frac{1}{\left(\frac{T_1}{T}\right)^{\frac{1}{2}}-1}\right]$$

If T_1 and T are fairly high temperatures on the absolute scale, and if their difference is small,

$$P=\left(\frac{4\pi^2 ID}{rAt^2 d}\right)\left(\frac{T}{T_1-T}\right)\text{dynes per square centimetre}$$

where: I = moment of inertia of moving vane
r = mean radius of moving vane
$2A$ = total area of the vane opposite heaters
t = period of oscillation of the vane
D = scale deflection
d = scale distance

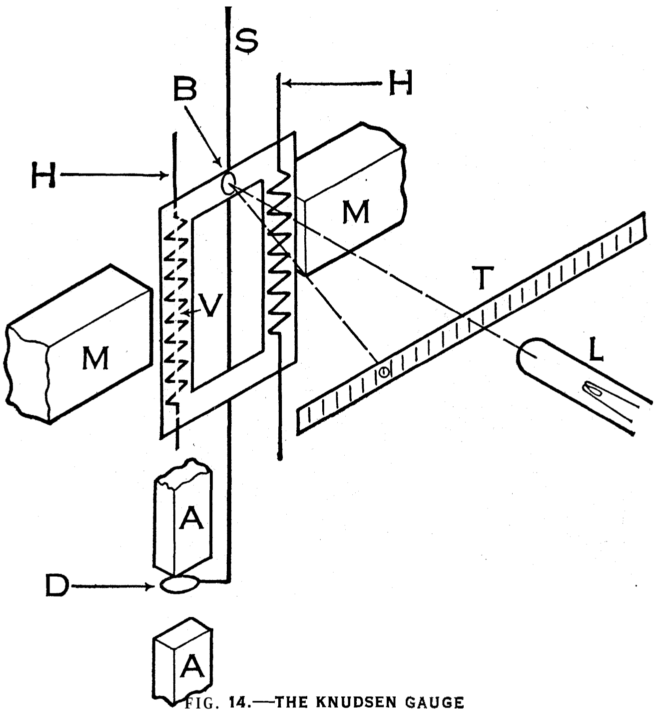

FIG. 14.—THE KNUDSEN GAUGE

S, tungsten wire; H, heater; A, internal damping magnet; B, mirror; D, damping vane; M, external damping magnet; V, impact vane; L, lamp; T, scale

T = absolute temperature of residual gas in gauge
T_1 = absolute temperature of heating elements H.

Since all these quantities can be measured directly, it follows that the device can be used as an absolute manometer, without the necessity of calibrating against any other gauge. It is also evident that the indications of this gauge must be independent of the gas to be measured.

Pumping Speed.—In the preceding discussion three principal types of vacuum pumps—the oil-sealed mechanical pump, the diffusion pump and the booster pump—have been described. Usually some combination of two of these pumps is needed and there are occasions where all three types together constitute the pumping unit for the vacuum system.

One important characteristic of any pump is its pumping speed. The speed of exhaust of a closed vessel may be measured at constant pressure, and defined as the volume of gas pumped from the vessel at that pressure in unit time. Expressed mathematically

$$S_1=-\frac{dV}{dt}$$

where S_1 is the pumping speed and dV is the small change of volume in the short time dt. By applying Boyle's law for a perfect gas this definition may be written as

$$\frac{dp}{dt}=-\frac{S_1}{V}p$$

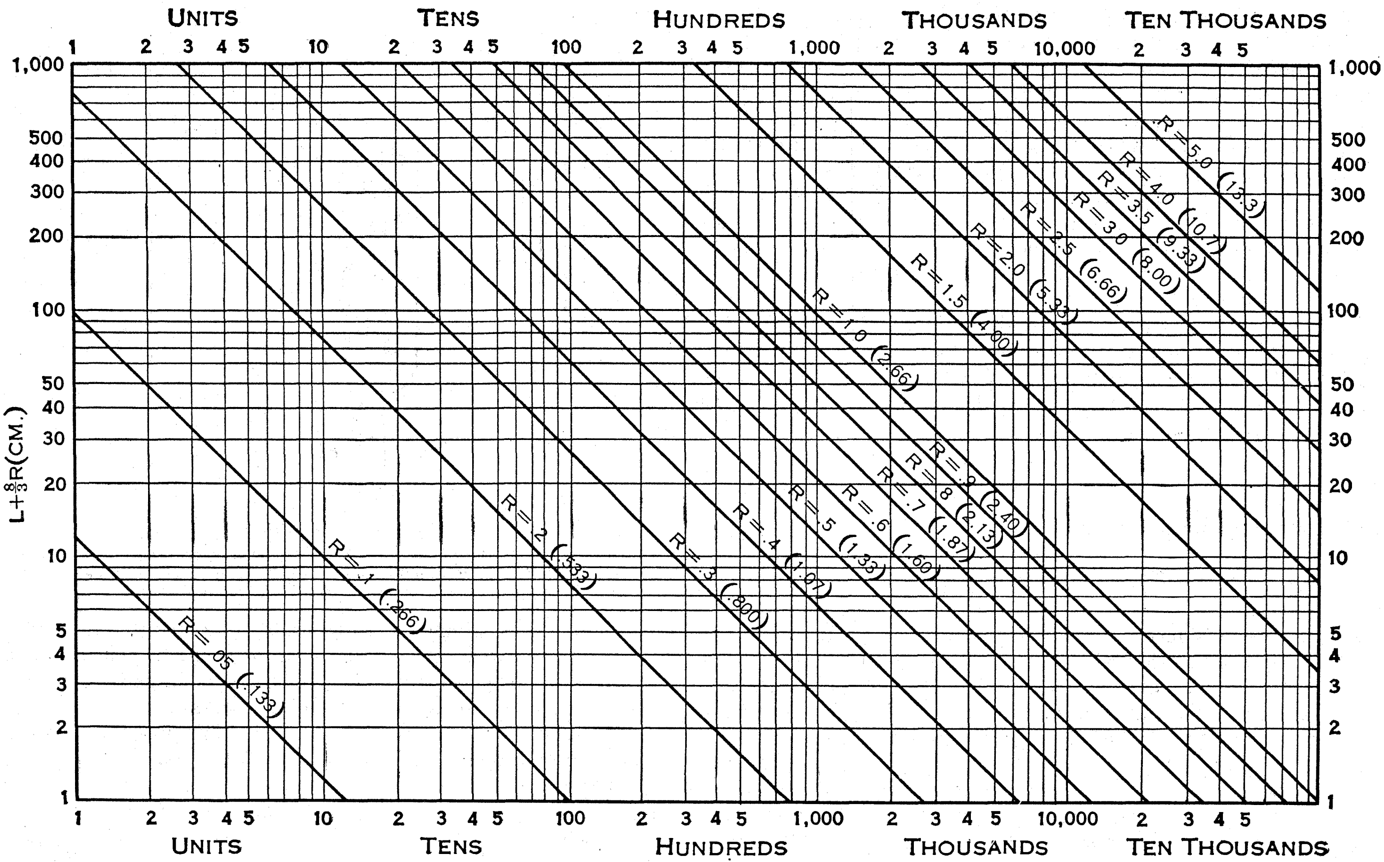
where p is the instantaneous pressure at the time t in a closed volume V being exhausted by a pump having a speed S_1. In 1913 Gaede published some of his work with vacuum pumps, which indicates that he originated the concept of pumping speed. In 1916 Langmuir introduced the concept of limiting pressure p_0 for a pump which modifies the Gaede equation by substitution of $(p-p_0)$ for p. The equation above then becomes

$$\frac{dp}{dt}=-\frac{S_1}{V}(p-p_0)$$

The solution of this modified equation is

$$t_2-t_1=\frac{2.3V}{S_1}[\log_{10}(p_1-p_0)-\log_{10}(p_2-p_0)]$$

where t_2-t_1 is the time required to reduce the pressure in the volume V from p_1 to p_2 using a pump of speed S. It should be noted that the vessel being evacuated is connected directly to the intake of the pump. Pump speed S_1 is the pumping speed



BY COURTESY OF CENTRAL SCIENTIFIC COMPANY

FIG. 15.— CHART OF CONDUCTANCE OF CONNECTING TUBES FOR AIR AT LOW PRESSURE

at the pump intake.

Usually a connection of some length is required between the pump and the vacuum chamber. Under such circumstances the pump speed S_1 is not the controlling factor. In making "pump-pown" calculations, particularly if pressures below 10^{-2} mm. are involved, the speed of evacuation S rather than pump speed S_1 determines the period of cyclic operations.

When the pump is operating in the high-vacuum range, the flow of gas through a tube is substantially molecular in character. The hydrodynamic component of gas flow, being proportional to pressure, becomes relatively unimportant. In other words, at extremely low pressures the gas removed from the system is largely confined to those molecules which, because of their thermal kinetic energy, happen to wander into the low pressure region created by the pump, and by the action of the pump become trapped and prevented from again entering the chamber being evacuated.

From experiments over a large range of pressures with different gases, Knudsen in 1909 derived the following semiempirical relation which holds at all pressures.

$$Q=\left[aP+Z\frac{(1+\alpha P)}{(1+\beta P)}\right](p_1-p_2)$$

Where $a=\frac{\mathbf{a}R^4}{8\mu L}$ (coefficient of hydrodynamic flow—Poiseuille's constant)

$Z=\frac{\sqrt{2\pi}}{\rho'}\frac{4}{3}\frac{R^3}{L}$ (coefficient of molecular flow)

$\alpha=\frac{2\sqrt{\rho'}R}{\mu}$

$\beta=\frac{2.47\sqrt{\rho'}R}{\mu}$

where Q = volume of gas, measured at pressure P, which flows per second through the tube

p_1-p_2 = difference in pressure at the two ends of the tube

$P=\frac{p_1-p_2}{2}$ = average pressure

R = radius of tube

L = length of tube

μ = coefficient of viscosity of the gas

$\rho'=\frac{p}{P}$ where p = density of the gas

ρ' is a function only of the kind of gas and the temperature.

For ordinary pressures this equation assumes the form commonly known as Poiseuille's law,

$$Q=\frac{\pi R^4}{8\mu L}P(p_1-p_2)$$

while at extremely low pressures it becomes

$$(1)\quad Q=\left[\frac{\sqrt{2\pi}}{\rho'}\frac{4}{3}\frac{R^3}{L}\right](p_1-p_2)$$

The quantity enclosed by brackets in the above equation is a factor applying only in the case where one is considering the quantity of gas, Q, flowing per second through a tube of length L and radius R with a difference of pressure at the ends of p_1-p_2. Effects of the various end conditions that may be applied to the tube have not been considered. Hence where we have a tube of length L and radius R connecting two vessels at low pressures, the quantity of gas Q flowing per second from the vessel at pressure p_1 through the tube into a second vessel at pressure p_2 is given by

$$(2)\quad Q=\left[\frac{4}{3}\left(\frac{\sqrt{2\pi}}{\rho'}\right)\left(\frac{1}{\frac{L}{R^3}+\frac{8}{3R^2}}\right)\right](p_1-p_2)$$

It will be observed that the form of the last two equations is similar to Ohm's law, where Q is similar to a current, (p_1-p_2)

similar to a potential drop and the bracketed term similar to a conductance. It must be remembered that the bracketed term in the equation (1) considers only the gas flowing through a tube, neglecting end effects. For a long tube this is sufficiently accurate in most cases. The bracketed term in equation (2) is for the case of a tube terminating at a thin mall, the circular opening in the wall being of the same diameter as that of the tube. This expression for the conductance has been used in plotting the curves shown in fig. 15. Other types of end configurations would introduce other correction factors into these equations. For different gases the value of the conductance varies as the reciprocal of the square root of p'.

Some of the references given in the bibliography give further discussion to the problem of flow of gases in pipes at low pressures.

The system speed of evacuation S is related to the speed of the pump S_1 and the conductance of the connecting tubing Z by the following relationship:

$$\frac{1}{S}=\frac{1}{Z}+\frac{1}{S_1}$$

On rearranging the terms,

$$S=Z\left[\frac{S_1}{Z+S_1}\right]=S_1\left[\frac{Z}{Z+S_1}\right]$$

These expressions have important significance. The fractional term in either expression is less than 1. Consequently, the speed of evacuation S can never be greater than the conductance Z nor can it be greater than the speed of the pump S_1. The second expression suggests that the speed of evacuation approaches the speed of the pump only when Z is very large in comparison with S_1. This expression shows that the performance of a high-speed pump may be seriously impaired by the use of ill-chosen connections. For a well-designed pipe line, pumping speed (speed of evacuation) S in a system should not be much less than 80% of the speed S_1 at the intake of the pump.

When several lengths of tubes of different diameters are connected in series between the pump and exhaust chamber the conductance Z for the combination is given by

$$\frac{1}{Z}=\frac{1}{b_1}+\frac{1}{b_2}+\frac{1}{b_3}+\ \dots\ +\frac{1}{b_n}$$

where b_1, b_2, etc. are the respective conductances of the tubes.

Traps or Condensers.—A trap is an obstruction placed in a vacuum system for the purpose of collecting solid particles, liquids, vapours or gases. If vapours are involved, the trap must be cooled. The cooling may be done by mechanical refrigeration, by a mixture of solid carbon dioxide (dry ice) and alcohol or acetone, or by liquid air. Typical traps are shown in fig. 16. Certain "permanent" gases may be removed by using a trap of activated charcoal cooled with liquid air.

The conductance of a trap in the vacuum system may be quite important. Hence traps are preferably constructed with large passages to avoid undesirable reduction in pumping speed.

Refrigerated glass traps are commonly used between a McLeod gauge and the vacuum system to prevent contamination of the mercury and the glass parts of the gauge and to prevent diffusion into the vacuum system of mercury vapours from the gauge. Such a trap is also frequently used between the pump and the vacuum system, either to trap vapours which might contaminate the pumping fluids, or to prevent passage of oil vapours from the pump into the vacuum system.

MANAGEMENT OF THE VACUUM SYSTEM

In industrial use, high vacuum is considered to begin in the range of pressures corresponding to 1 mm. Probably this would not be considered high vacuum by the experimental or resedrch man working in the laboratory where pressures of the order of 10^{-6} mm. are obtained. Attainment of a good vacuum requires thoughtful selection of equipment, care in assembly and manipulation of the apparatus.

The elements of a vacuum system have been discussed in the preceding sections. They consist of forepump, diffusion pump, cold traps, valves, plumbing, gauges and the apparatus or equipment to be evacuated. A number of factors must be considered in selecting a pumping system. The choice will be largely influenced by the arrangement of the equipment, the volume of the vacuum chamber, the quantity of gas to be handled at low pressures and the importance of time in cyclic operations. One consideration that is generally common to various arrangements is the speed of the forepump. This is directly related to the speed of the diffusion pump and the ratio of pressures at the discharge and intake of the diffusion pump. On the assumption that a particular diffusion pump has a speed of 100 l. per second at 10^{-6} mm. and that the pump operates satisfactorily at a fore-pressure of 10^{-2} mm., the ratio of pressures is 1 to 10,000. This means that a forepump capable of handling 0.0001 of 100 l. per second or 0.01 l. per second is theoretically sufficient for the job. This suggests that a relatively low-speed forepump would be sufficient. However, there are usually other factors that must be considered.

Fluids used in diffusion pumps often deteriorate if their temperatures are elevated when in contact with air at pressures of 0.1 mm. and above. Unless appropriate steps are taken. this means that a certain amount of time is lost in heating and cooling the boiler in a cyclic operation. To avoid this loss of time, various techniques are used. In some instances, two parallel pumping systems are installed. One consists of a high-speed forepump either directly connected or connected through a cold trap to the vacuum chamber and a second independent connection in which a relatively small forepump backs a diffusion pump. During the preliminary pumping period or when air is admitted to the vacuum chamber the intake to the diffusion pump is closed but all the pumps are permitted to opcrate, In operation the high-speed forepump withdraws the air from the chamber to the low millimetre range after which the diffusion pump is opened to the system so that the reduction in pressure continues without interruption. In another arrangement only one forepump is used. More vacuum valves are required because the high-speed forepump is first connected to the vacuum chamber and later placed in series with the diffusion pump.

Valves and plumbing must be free from leaks and of high conductance. The question of system speed (speed of evacuation) has been discussed and the methods for calculating conductance outlined. As part of the steady improvement in vacuum techniques, by which the lower limit of pressure has been pushed steadily downnard, it became increasingly important to detect and locate even the microscopic leak in the walls of the vessels, connecting tubes, junctions of parts, all of which constitute the barrier betn een a region of high vacuum and one of atmospheric pressure. The final vacuum attained in a system is an equilibrium condition between pumping speed, on the one hand, and the rate of leak into or evolution of gas within the system, on the other.

Various methods of leak detection have been employed. With the rapid advances in vacuum techniques made during World War II many new methods were developed. Older methods employ the Tesla coil, discharge tube, Pirani and ionization gauges. Newer methods make use of the differential Pirani gauge and the mass spectrometer. Oddly enough, the most sensitive method is also the most rapid; *i.e.* the mass spectrometer method.

Vacuum systems are constructed from glass and metal. Depending upon the conditions a system may be either all glass or all metal. Glass can be easily cleaned and welded at junctions. It has high electrical insulating quality, may be baked out and sealed off to give a more or less permanent vacuum. Metal systems are made from steel or brass. The parts may be machined and fitted together with rubber gaskets or soft-soldered, silver-soldered or brazed. Glass or metal vacuum valves can be fitted permanently or with tapered joints, into the system.

Where the highest degree of vacuum is desired considerable outgassing of glass and metal parts must be done. Outgassing removes gases adsorbed to the surface of glass and metal. Prolonged heating of glass at 150° C. to 200° C. in vacuum removes most of the gases adsorbed on the surface, metals strongly heated in a vacuum give off adsorbed gases as well as absorbed gases and gas arising from the decomposition of oxides near the surface. Metal parts within the evacuated chamber are outgassed by heating to a high temperature with high frequency induced currents. When an apparatus has been reduced to its lowest pressure by continued pumping and heating and is sealed off from the system, the pressure may be further lowered by a getter. Getters remove gases by chemically combining with them and by absorbing them.

Further detailed information on procedures in the management of high vacuum systems will be found in the references given in the bibliography.

HIGH-VACUUM COMMERCIAL APPLICATIONS

High vacuum as employed in industry generally falls within two ranges of pressures:

(a) 1 to 1000 μ (1 μ = 0.001 mm. Hg.),

(b) 10^{-8} mm. to 10^{-3} mm. Hg.

The extremely low pressures are found almost exclusively in the electronics industry, while pressures in the micron range find applications throughout the chemical and metallurgical fields. By undertaking processes under an appropriate range of gas pressures, one or more of the following advantages may be gained: (1) oxidation is prevented, (2) distillation temperature is reduced, (3) absorbed and adsorbed gases may be removed, (4) dehydration may be performed at low temperatures, (j) gaseous ionization may be prevented or controlled, (6) thermal conduction of gases may be reduced, (7) radiant energy absorption may be reduced.

Vacuum Metallurgy.—The use of free air pressures below 100 μ has found many applications in the production, purification and treatment of metals.

Thermal Reduction.—Metal oxides may be reduced under vacuum and distilled from the hot reaction zone in highly purified form. Magnesium has been commercially produced from calcined dolomitic limestone by the following reaction:

$$2(MgO.CaO) + \tfrac{1}{6}FeSi_6 \xrightleftharpoons{2{,}150^\circ\ F.} 2Mg\uparrow + (CaO)_2.SiO_2 + \tfrac{1}{6}Fe\ .$$

With appropriate reducing agents other metals such as calcium, lithium, barium, caesium, rubidium, sodium, and potassium may be produced in pure form from their salts.

Distillation of Metals.—Through the use of pressures of 1 to 100 μ the lower melting metals (magnesium, zinc, lead, tin, cadmium, lithium, barium, etc.) may be purified by distillation. Impure magnesium as formed by the carbothermic process has thus been distilled in vertical electrically heated retorts, of several-ton capacity. Separations of lighter melting metals by fractional distillation (*i.e.,* zinc and tin or zinc and aluminum) has also been accomplished.

Vacuum Sintering.—This technique is employed chiefly in the production of tungsten, molybdenum, tantalum and columbium. Bars of the pressed powdered metal are electrically heated in vacuum and after sintering, rolled to size.

Heat Treatment.—Through the use of a vacuum furnace, dies, tools, etc., may be heat-treated without the usual oxidation, the vacuum serving as a true neutral atmosphere.

Vacuum Melting.—Dissolved gases may be removed by maintaining metals above their melting point at low pressure. Gas-free metals, particularly copper and iron, are useful in the electronics industry for the fabrication of parts sealed in vacuum. Copper so treated has greatly increased ductility and improved thermal and electrical conductivity. Highly reactive metals like titanium have been melted and cast at air pressures of 10 μ.

Vacuum Dehydration.—Vacuum evaporation is commonly used in the chemical industry for the removal of water or other solvents from many products. By the use of extremely low air pressures (*i.e.,* less than 10 μ) moisture can be rapidly removed from heat-sensitive materials.

Three pumping methods are normally employed for the removal of water vapour at low temperatures: steam ejectors, refrigerated condensers and chemical absorption systems. In the case of steam ejectors, partial air pressures below 50 μ are feasible on a commercial scale and very large volumes of water vapour may be handled at slightly higher pressures. In other systems, the free air is removed with steam ejectors or mechanical pumps, alone or in combination with oil diffusion pumps. The water vapour is then (a) condensed or (b) absorbed. Free air pressures as low as 1 to 10 μ are possible and under such conditions moisture can be removed at temperatures in the product as low as −75° C.

The possibility of low-temperature drying has been applied for many years to the preservation of biological products on a small scale. It was only after recent advances in vacuum engineering that low-temperature high-vacuum dehydration was applied on a commercial scale.

Blood Plasma.—In order to prevent changes in composition, and to preserve a so-called lyophilic structure capable of rapid rehydration, blood plasma is vacuum dried from the frozen state.

Biologicals, *etc.*—Low-temperature drying has also been applied to penicillin, sera, vaccines, bacteria, nerves, etc.; through the use of the very low temperatures made possible by high vacuum, cellular structure may be preserved throughout the drying cycle and the biological properties maintained after reconstitution even though the product in dried form is stored for long periods.

Foods.—The vacuum dehydration of food products had, by 1951, offered one of the most promising solutions to the production of a high-quality product. The original structure may be maintained, flavour and colour are relatively unimpaired. and sufficiently low moisture content may be produced (0.5% to 1%) to ensure a satisfactory storage life. Because of the relatively high costs involved, vacuum dehydration at air pressures in the micron range has been applied to such relatively expensive materials as orange juice and soluble coffee. The vacuum process for producing a 4:1 concentrate of frozen orange juice had by 1950 become a $100,000,000 a year business. Vacuum drum driers operating at moderate vacuums (10 mm. to 50 mm.) are used for a variety of products such as tomato paste, soups, coffee, etc.

Vacuum Evaporation.—Through the use of pressures below 10^{-4} mm., a variety of metals and salts may be evaporated and their vapours subsequently condensed on a surface.

Low-Reflection Coatings.—So-called low-reflection coatings are produced by evaporating magnesium fluoride, or material of comparable refractive index, in a vacuum system and depositing the vapour to a controlled thickness (one-quarter of a wave length) on a lens or other optical surface.

Reflecting Surfaces.—This same technique may be used to produce front surface mirrors on glass, plastics or other material. Aluminum is commonly employed and evaporated from a heated tungsten filament. Chromium, gold: rhodium, silver, etc., are also used for special applications.

Decorative *Coatings.*—For decorative purposes, plastic sheeting and cloth may be continuously coated with metals by vacuum evaporation. In the case of plastic and paper sheeting, the metal-coated product is used for the manufacture of electrical condensers. Gold leaf may also be made in this manner, by stripping the metal foil after applying to a thin surface.

Other Coatings.—There are many applications for electrically conducting coatings. Piezo quartz crystals are coated with silver in order to improve frequency characteristics and stability. Conducting layers can also be applied to plastic insulated wave guides, quartz fibre suspensions for instruments, etc.

Vacuum **Sputtering.**—Vacuum sputtering involves coating (usually of nonconductors) by means of a gas discharge at 1 mm. to 0.01 mm. The surface to be coated is placed near the Crookes dark space and a cathode formed of the material to be sputtered.

Vacuum Distillation.—At low pressures the boiling point or distillation temperature of all chemical products is materially reduced. In most commercial processes, pressures of 25 mm. to 100 mm. are sufficient. This range is economically attained on a large scale with conventional steam ejectors and the fractionation of petroleum oils is one of the largest operations under such conditions.

High *Vacuum* Distillation.—Through the use of noncondensible gas pressures below 50 microns and vapour paths of low impedance, between evaporating and condensing surface, the distillation point of many high boiling products—waxes, higher alcohols; esters—is sufficiently reduced to permit purification with some fractionation without undue decomposition.

Molecular Distillation.—If the residual gas pressure is reduced to less than 10^{-3} mm. Hg., a point will be reached where any further reduction has substantially no effect on the rate of distillation. If at these pressures the distance between distilling and condensing surface is small and unimpeded, so-called molecular distillation takes place. By such a technique many materials of high molecular weight may be distilled, which otherwise could be handled only with excessive decomposition, if at all.

Commercially, this method has been successfully applied to the production of vitamin concentrates, by direct distillation of vitamin-bearing oils.

Electronics.—The electronics industry has long been concerned with the production of extremely low pressures. With the exception of large continuously pumped systems used with high-voltage X-ray tubes, large magnetrons, etc., high vacuum must be maintained in a closed space for long periods of time. Pressures as low as 10^{-8} mm. to 10^{-5} mm. Hg. are required for many electronic devices, the lowest being necessary to prevent formation of positive ions as in cathode ray and other tubes employing high-voltage electrons. Most electronic devices are now evacuated with oil diffusion pumps. In some cases (*e.g.,* receiving tubes), residual gases are absorbed with "getters" such as barium, magnesium or other reactive metals.

Vacuum Impregnation.—High-vacuum techniques are commonly used as an aid to impregnation processes. Products to be treated are usually placed in a vacuum chamber and the pressure reduced to something less than 1 mm. The chamber is subsequently filled with the impregnation medium which in turn displaces the entire volume previously exhausted. This method of processing finds wide application in the electrical industry where it is a common practice to vacuum impregnate condensers, coils, transformers, cables, etc., with waxes, resins, oils or other materials of appropriate insulating characteristics.

Miscellaneous.—Industries of a wide variety employ high vacuum in one or more stages of product manufacture. In the manufacture of refrigerators it is necessary to remove all traces of water from the entire compressor system, including the small valves, pipes and fittings. This is accomplished by vacuum treatment at pressures of 10 to 200 μ.

A similar procedure is employed in the manufacture of bellows-type barometers and vapour operated thermometers. In the latter case, proper calibration can be achieved only with the complete removal of both condensible and noncondensible gases prior to filling with the operating fluid. (R. S. ME.)

Other applications of vacuum techniques formed the basis for such new industries as the production of citrus juice concentrates. Diffusion pumps of huge size have been employed in the metallurgical industries and the television industry. The low cost of television receivers would be impossible without the routine production of high vacuum by methods which were formerly considered a sophisticated laboratory art. The huge particle accelerators, such as the cyclotrons, the synchro-cyclotrons, the cosmotrons and the linear accelerators: all depend on diffusion pumps having speeds of tens of thousands of litres per second. (P. E. K.)

The manufacture of all vacuum bottles of course depends upon the maintenance of pressures below 10 μ for thermal insulation. Vacuum spectrographs permit industry to carry on spectrographic research and production control operations in the ultra-violet regions of the spectrum. (R. S. ME.)

VACUUM BRAKE, a form of brake utilizing the force exerted on a piston by the pressure of the atmosphere. As long as a vacuum is maintained in the system the brake blocks are kept off the wheels.

However, when air is admitted it presses against one side of the piston and applies the blocks. See BRAKE: *Motorcar* Brakes; *Railroad* Brakes.

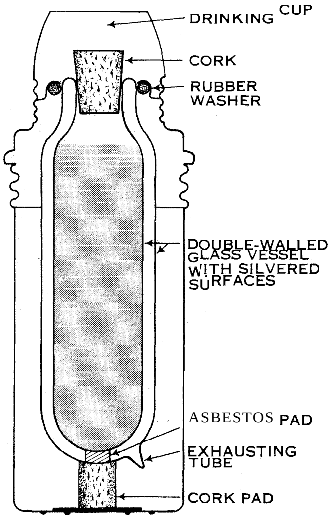
VACUUM CLEANER. An appliance for extracting and removing dust from fabrics, such as carpets, upholstered seats, cushions. etc.. by suction only or by suction and a motor driven brush, designed for the primary purpose of carrying out this operation without the necessity of displacing the articles to be cleansed from the positions which they normally occupy when in use.

It is also used to remove dust from such surfaces as those of floors, shelves, walls, etc. It was so named by H. C. Booth, who made and patented a successful appliance in 1901.

A vacuum cleaner consists essentially of an air suction pump, or exhauster, connected by a pipe or tube or directly to a nozzle having an orifice which is passed over the material being cleansed, the surrounding lip of the orifice being kept in close contact with the material. An air filter which cleanses the air either before or after its entry into the exhauster serves at the same time as a chamber, or receptacle, for collecting the dust, which can be removed therefrom conveniently and without dispersal. In the domestic floor or stick types, this receptacle is often of cloth in the shape of a bag. Tank or cylinder cleaners use other types of receptacles.

In operation, suction from the air exhauster causes air to rush violently into the nozzle through the interstices of the fabric being cleansed and to carry away with it the imprisoned dust. See HOME EQUIPMENT.

(H. C. Bo.; X.)



VACUUM FLASK. EVACUATED SPACE RETARDS TRANSMISSION OF HEAT TO OR FROM CONTAINER

VACUUM DISTILLATION: see DISTILLATION.

VACUUM FLASK, a glass vessel with double walls, the space between which is evacuated. The only junction of the walls is at the neck of the vessel. It is also known as a Dewar vessel after its inventor Sir James Dewar (*q.v.*); Thermos flask is a proprietary name applied to a form protected by a metal casing.

It was invented in the first place to preserve liquefied gases (see LOW-TEJLPERATURE PHYSICS) by preventing the transference of heat from the surroundings to the liquid. The evacuated space between the glass walls is practically a nonconductor of heat, and radiation is reduced to a minimum by silvering the glass. The chief path by which heat can be communicated to the interior of the inner vessel is at the junction of the walls at the vessel's neck, which is consequently made as small as possible. This thermal isolation applies equally to heat, a hot liquid remaining at a high temperature for several hours. Where the flask is subjected to rough usage, metal has been substituted for glass. but the latter is the more efficient material.

VACUUM PUMP: see VACUUM.

VACUUM TUBE: see ELECTRON TUBE.

VACZ or VAC (Ger. WAITZEN), a town in Pest *Megye* (county). Hungary. 20 mi. N. of Budapest on the left bank of an arm of the Danube at the foot of the Cserhát mountains, where the river takes its southward course.

On the hills around the town are large vineyards and viticulture is an important industry. There are also distilleries and textile, soap and shoe factories. The town is the see of a bishop and has an 18th century cathedral and episcopal palace. Vacz has numerous architectural remains as well as a museum of the Roman and medieval relics in which the district is so rich. Pop. (1957 est.) 23,000 (mun.).

VAGA, PERINO DEL (PIETRO BUONACCORSI) (1500–1547), a painter of the Roman school, was born near Florence on June 28, 1500. Perino was first apprenticed to a druggist, but soon came under tutelage of a mediocre painter, Andrea da Ceri, and, when 11 years of age, of Ridolfo Ghirlandajo. The painter, Vaga from Toscanella, undertook to settle the boy in Rome, but first set him to work in Toscanella. Perino, when he at last reached Rome. was poor, and with no clear prospect beyond journeynork for trading decorators He was eventually entrusted with some of the subordinate work undertaken by Raphael in the Vatican.

He assisted Giovanni da Udine in the stucco and arabesque decorations of the *logge* of the Vatican, and executed some of those small scriptural subjects which go by the name of "Raphael's Bible" — Raphael himself furnishing the designs. Perino's examples are: "Abraham About to Sacrifice Isaac." "Jacob Wrestling With the Angel," "Joseph and His Brethren," the "Hebrews Crossing the Jordan," the "Fall and Capture of Jericho," "Joshua Commanding the Sun to Stand Still," the "Birth of Christ," "His Baptism" and the "Last Supper."

Vaga also painted, after Raphael's drawings, the figures of the planets on the ceiling of the great hall of the Appartamenti Borgia.

After Raphael's death in 1520 he executed several works independently in Rome, in the churches of S. Marcello and Trinità de Monti. He then returned to Florence. where his work was much appreciated. On his return to Rome in 1523 he associated himself with Giulio Romano and Penni, whose sister he married. After the sack of Rome in 1527 he settled in Genoa, where he was employed in decorating the Doria palace. He ornamented the palace and frescoed historical and mythological subjects in the apartments, fanciful and graceful arabesque work, sculptural and architectural details. Among the principal works are. the "War Between the Gods and Giants," "Horatius Cocles Defending the Bridge" and the "Fortitude of Mutius Scaevola." He also did some work in Pisa in the *duomo* and elsewhere. Finally he returned to Rome, where Paul III allowed him a regular salary. He worked in the Sala della Segnatura (Vatican) on the monochrome decoration of the basement, to replace Fra Giovanni's woodwork decoration which had been destroyed in the sack of 1527; he was engaged in the decoration of the Sala Reale, begun by Paul III, when his health gave way, and he died on Oct. 19, 1547. Vaga is buried in the Pantheon. (W. M. R.)

VAGRANCY. Since the establishment of settled government in England people wandering from their usual habitations, without visible means of support or socially approved reasons for their movements, have been classed as vagrants. Such persons have been subjected to a series of repressive statutes since the 7th century. though the reasons for their official condemnation have varied. In medieval England the masterless man was a potential criminal. By the 14th century, when declining population had given a scarcity value to labour, escaping serfs or landless labourers, absconding from their communities, were regarded as a threat to the traditional social order. Tudor rulers considered vagrancy as politically dangerous. By the 17th and 18th centuries vagrants had become a social nuisance and an economic liability.

Every kind of punishment has been used to eliminate vagrants. In 1360 fugitive labourers could be branded. The act of 1495 committed vagrants to the stocks for three days on a diet of bread and water. In 1530 they were to be whipped and sent home. A statute of 1547 condemned them to slavery for a year for a first offense, for life for a second and to a felon's death for a third. Three years later this act was repealed and whipping, henceforth the usual punishment, was revived. The act of 1597 ordered vagrants to be whipped until their backs were bloody, then returned to their birthplace. last place of residence or to the house of correction. This act remained the basis of the vagrancy laws until 1714, when it was amended to secure greater efficiency.

In 1744 vagrants were classified as (1) idle and disorderly persons, (2) rogues and vagabonds and (3) incorrigible rogues.

By the 17th century the administration of these laws had become slack, even though to secure stricter execution, rewards were given to constables for apprehending vagrants and the expense of removal was borne by the county (1690). Gradually floggings became less frequent. Though forbidden to do so magistrates gave passes to vagrants without previous punishment as the easiest way of getting rid of them, or regular vagrant contractors undertook for a fixed sum to move them to their place of settlement. It was this breakdown in the vagrancy laws that led to the appointment of a select committee in 1821 to inquire into the problem.

The report of the committee was followed by the repeal of existing legislation and by a new act of 1824, which left vagrancy offenders liable to punishment as idle and disorderly persons. as rogues and vagabonds or as incorrigible rogues. (D. ML.)

Ten years later the reform of the poor law in 1834 modified the general institutional background. The poor lam commissioners recognized in 1837 that all cases of destitution should be relieved irrespective of the fact that applicants might belong to distant parishes. Five years later, by act of parliament. they were ordered to require vagrants to work in return for food and lodging. In 1848 when the poor law board took the place of the poor law commission it urged uniformity in treatment of vagrants, refusal of relief to able-bodied men not actually destitute, and employment of police officers as assistant relieving officers for vagrants.

Poor law reform and growing economic prosperity greatly reduced vagrancy. A small number of vagrants continued to seek temporary work and shelter. To deal with the problem, more casual wards were provided by workhouses! and more private lodginghouses were designed for vagrants. The growth of social legislation in the 20th century further modified the approach to vagrancy. The setting up of labour exchanges in 1909, the provision of unemployment insurance from 1911 onward. the growth of national assistance after 1934 and the welfare policy put into effect by such measures as the National Insurance act of 1946 and the National Assistance act of 1948, reduced vagrancy to manageable proportions.

Twentieth-century trends can be traced back to the departmental committee on vagrancy, 1906, which suggested that the control of casual wards should be transferred to the police with a view to securing uniform treatment throughout the country. By the 1930s it was often necessary for vagrants to apply for tickets at police stations before they could sleep in casual wards. although the police had no final control. By then in many parts of the country vagrancy committees had been set up for counties or larger areas, while in London the Metropolitan Asylums board had unified the London wards, made them cleaner and more efficient and introduced greater uniformity in administration.

Just as the poor law as a whole, however, retained a deterrent element until 1946, so the care of vagrants was influenced by stringent moral considerations. The casual poor relief order, 1925, for example, while requiring poor law authorities to provide for vagrants "a decent and proper provision for sleeping, for the drying and disinfection of clothes, and for personal cleanliness" added that "every opportunity should be afforded to a casual to alter his mode of life, especially if he is an elderly man, by entering the institution." Guardians were told to insure that "children should not be allowed to grow up to a life of vagrancy." The Local Government act, 1929, which transferred responsibility for vagrants from the guardians to the county councils and county boroughs, did not change policy.

In 1935 a new act stated that no unemployed person should be described as a vagrant unless he had been directed to a reasonably accessible place of shelter and failed to apply for or refused accommodation. It also insisted on the criterion of persistence in relation to "wandering abroad."

The National Assistance act (1948) changed both terminology and procedures. The term casual ward was replaced by reception centre, and it became the duty of the National Assistance board, with the support of local authorities, to make provision for "persons without a settled way of life." In the well-managed reception centre the casual was to receive a bath, a clean bed and food. In return he had to do some housework. He was to be urged to stay at the centre until work was found and to be interviewed by social workers who would examine his background. problems and qualifications. Old and ill casuals were to be transferred to hospitals or to rehabilitation centres maintained by voluntary organizations.

The number of vagrants decreased, although by mid-century a hard core still remained. In 1905 there were 9,768; in 1932 at the height of the economic depression. 16,911; in 1949 the post-1945 peak of 2,617. Most of the vagrants were men. nearly two-thirds of them under 50, and a high proportion of them without family responsibilities. Investigation of the conticued causes of vagrancy was becoming associated with psychological inquiry more than with an analysis of prevailing economic conditions. (See also POOR LAW; SOCIAL SECURITY; SOCIAL SERVICE.)

BIBLIOGRAPHY.—There is no modern study of the history of vagrancy. *See* C. J. Ribton-Turner, *History of Vagrants and Vagrancy* (London, 1887); W. H. Dawson, *The Vagrancy Problem* (London, 1910); the Vagrancy acts of 1824, 1935 and the National Assistance act, 1948. (A. BRI.)

Vagrancy in the United States.—Statutes had been passed by the legislatures of about. 40 states by the mid-rqjos to codify and extend the English definitions of vagrancy. Different types of personal condition by "being" certain types of person are included. Almost all of these laws define vagrancy to include living in idleness without any visible means of support; nearly half of them also include being a common prostitute. Other conditions frequently covered include persons who are common drunkards or common gamblers, keepers of gambling houses or keepers of houses of prostitution, associates of knovin thieves and wanton, dissolute or lascivious persons. Many laws also include persons guilty of specific acts of wandering, loitering or begging.

Vagrancy is usually a misdemeanour punishable by a small fine or a jail sentence of a few months. In most states there is no right to trial by jury, since vagrancy was not historically one of the "crimes" for which common constitutional provisions guarantee a jury trial. Conviction of vagrancy based upon personal condition ordinarily requires evidence of a series of acts showing the existence of the forbidden condition. Proof of a bad reputation alone is not enough. Since the crime is committed wherever the defendant may be found, it may be proved by acts evidencing it committed in another jurisdiction. Reformation by the defendant before trial is generally held a bar to conviction.

Vagrancy prosecutions constitute an important method of crime prevention. This is because the overt acts required to prove vagrancy frequently also show an intent to commit offenses in the future. Known criminals may be harassed hy vagrancy prosecutions until they move on, or may be held temporarily during a period of emergency. Drunkards and other derelicts also may be picked up on vagrancy charges, and given a night's lodging in jail and a chance to become sober out of harm's way.

When members of the criminal classes are believed to be involved in some serious crime it is often possible to arrest them legally for vagrancy. This legalizes incidental searches and permits the defendants to be held for a sufficient time to secure evidence of guilt of the serious crime through fingerprint checks and police line-ups for identification. Even if the evidence of the other crime remains too weak for successful prosecution. some punishment may be meted out by pressing the original vagrancy charge.

Prior to the middle 1930s, occasionally it was claimed that vagrancy prosecutions were used against strikers and other labour agitators. The breadth and vagueness of the definition of the crime gave the police an unusually wide discretion in its use. Vagrancy prosecutions were not much used in connection with labour disputes after 1935.

So-called "gangster acts" were passed in several states. imposing drastic penalties on vagrants where the additional element of association with others for criminal purposes could be proved. A New Jersey law of 1935 provided up to 20 years' imprisonment for any person with a prior criminal record, not engaged in any lawful occupation, who was "known to be a member of any gang consisting of two or more persons."

In 1939 the Supreme Court of the United States held this New Jersey law to be "so vague, indefinite and uncertain that it must be condemned as repugnant to the due process clause of the Fourteenth Amendment." (*Lanzetta* v. New Jersey, 306 U.S. reports 451 at 458.) The decision that this law was unconstitutional put an end to the attempt to use such gangster acts in the war on organized crime. This decision did not, however, lessen the effectiveness of vagrancy prosecutions against small-time criminals, persons suspected of serious crime acd potential offenders.

See Forrest *W*. Lacey, "Vagrancy end Other Crimes of Personal Condition," *Harvard Law Review*, vol. 66, p. 1203 (1953). (L. HL.)

VAI (or VEI), a Mandingo-speaking Negro tribe (Mandé-fu subgroup), about 40.000 in number, inhabiting the Pujehun district of Sierra Leone and the neighbouring part of Liberia. They are remarkable for the use of a syllabic script of more than 160 signs invented in the first half of the 19th century by Momolu Doalu Bukere (d. 1850), and unrelated to any other script.

See A. Klingenheben, "The Vai Script," *Ajrica*, vol. vi, pp. 158–171 (London, 1933). (W. B. FC.)

VAIDA-VOEVOD, ALEXANDRE (1871–1950), Rumanian statesman, mas born at Olpret, Transylvania, in 1871. He studied medicine in Vienna and practised for many years at Karlsbad (Karlovy Vary). At the age of 28 he joined the National Rumanian party of Transylvania and from 1906–18 sat in the Hungarian parliament at Budapest, where he waged a permanent fight in defense of the Rumanians in Transylvania. On the collapse of the Central Powers in the autumn of 1918. Vaida-Voevod was instructed by the newly formed "Rumanian National committee," to voice their claims in the Hungarian parliament. Invoking the right of self-determination he denied the right of the Hungarian government to speak in the name of the Rumanians of Transylvania and claimed that the latter should have their own representative at the peace conference. Soon after. the Rumanian National committee took administrative control of Transylvania and delegated Vaida-Voevod to represent the Rumanians of Transylvania and the Banat at the peace conference in Paris.

In 1919 Vaida-Voevod was appointed prime minister and minister for foreign affairs of Rumania and in the latter capacity went to Paris and London early in the following year to negotiate with the French and British governments the recognition of the union of Bessarabia with Rumania. This he succeeded in doing in March 1920 when the rights of Rumania over Bessarabia were recognized by the Supreme Economic council. and afterward ratified by the Treaty of London (Oct. 28, 1920). Vaida-Voevod resigned in the same year and afterward sat in parliament as one of the lenders of the National Rumanian party. from which he later resigned. He was prime minister again from Aug. to Oct.

1932, and from Jan. to Nov. 1933. He died March 19, 1950.

VAIL, THEODORE NEWTON (1845–1920), U.S. businessman, twice president of the American Telegraph and Telephone company, was born in Carrol county, Ohio, July 16, 1845. He began his career as a telegraph operator for the Union Pacific railroad and rose to general superintendent in 1875. In 1878 he became general manager of the American Bell Telegraph company and in 1885 the first president of the newly organized American Telephone and Telegraph company. He resigned two years later because of ill-health.

In 1907 he was re-elected president and upon resigning again in 1919 became chairman of the board. He died in Baltimore, Md., on April 16, 1920.

See A. B. Paine, *Theodore N. Vail, A Biography* (1929).

(J. R. Lt.)

VAILLANT, EDOUARD MARIE (1840–1915), French politician, was born in Vierzon, Cher, on Jan. 28, 1840. He studied science, residing in Heidelberg, Tubingen and Vienna. On his return to Paris he took part in the republic and socialist battle against the Second Empire, becoming a disciple and friend of Louis Blanqui. On March 18, 1871, he took part in the Commune insurrection, and, on the 26th, was elected a member of the Commune. He was a delegate on the executive commission, and his work for public instruction displays his revolutionary audacity and his scientific knowledge.

After the defeat of the Commune he fled to England and became associated with Karl Marx. But, after having been a member of the general committee of the First International, after having participated in 1872 in the congress at The Hague, he induced his friends to abandon this association because it seemed to him to be insufficiently revolutionary. He founded "The Revolutionary Commune" which published the manifesto in which these disciples of Blanqui declared themselves to be atheists, republicans, communists, revolutionaries and partisans of class conflict.

Condemned to death by the war council in 1872, Vaillant only returned to France in 1880 under amnesty. He was a founder of the Socialist Revolutionary party, and in 1884, he became a municipal councillor of Paris, becoming deputy in 1893. Under his direction, the Blanquist party made itself noticeable among the other socialist parties. In Boulangisme (1889), he separated from other blanquists, who, through nationalism, were inclined to accept a plebiscitary dictator.

In 1899, and again in 1905, Vaillant made himself the apostle of socialist unity in France. When in 1905, all the socialist parties united, he became a very close friend of Auguste Jaurbs, and secured with him the majority in all socialist congresses until 1914. He advocated the eight-hour day, security and hygiene for workers, remedies against stoppage of work, and a struggle against war.

In Aug. 1914 Vaillant considered that France was attacked and that it was the duty of the socialists to defend it as in 1870 and 1871. He resumed the formulas of Blanquist socialism and declared himself unreservedly in favour of national defense.

VAILLANT, GEORGE CLAPP (1901–1945), U.S archaeologist, an authority on the ancient civilizations of middle America. nas born on April 5. 1901, in Boston, Mass. Educated at Harvard (Ph D., 1927), his first archaeological field work was undertaken in Arizona for the university's Peabody museum. Later he nent on expeditions to Pecos. N.M., Yucatan and Egypt. While affiliated nith New York's American Museum of Natural History (1927–41), where he became curator of Mexican archaeology, he undertook major excavations in the valley of Mexico, identifying and describing the successive stages that gave rise to the higher civilizations culminating in the Aztec empire His lively and authoritative account. *The* Aztecs of *Mexico* (1944), became a classic.

At the museum he reinstalled collections from Central America and Mexico, skillfully emphasizing their artistic values. He taught at New York and Columbia universities and was director of the university museum of the University of Pennsylvania from 1941 until his death. His relations with Mexican scholars furthered international scientific collaboration. In this, as well as in his research, he was aided by his wife, Suzanna Beck. During World War II he served as cultural officer for the U.S. foreign service in Peru.

Vaillant died May 13, 1945 in Valley Forge, Pa. (A. V. K.)

VAISESHIKA, one of the six schools of thought to which Indian philosophers adhered in the centuries following the Epic period See INDIAN PHILOSOPHY: The Six Systems.

VAISHNAVITES (Bengal). Chaitanya, the founder of the great Vaishnava sect of Bengal, was the son of a high-caste Brahman of Nadiya, the famous Bengal seat of Sanskrit learning, where he was born in 1485, two years after the birth of Martin Luther, the German reformer. Having married in due time, and a second time after the death of his first wife, he lived as a householder (grihastha) till the age of 24, when he renounced his family ties and set out as a religious mendicant (vairagin), visiting during the next six years the principal places of pilgrimage in northern India, and preaching with remarkable success his doctrine of Bhakti, or passionate devotion to Krishna, as the supreme deity.

He subsequently made over to his principal disciples the task of consolidating his community, and passed the last 12 years of his life at Puri in Orissa, the great centre of the worship of Vishnu as Jagannatha, or "lord of the world," which he remodelled in accordance with his doctrine, causing the mystic songs of Jayadeva to be recited before the images in the morning and evening as part of the daily service; and seeking to humanize divine adoration by bringing it into accord with the experience of human love. To this end, music, dancing, singing parties (sankirtan), theatricals—in short anything calculated to produce the desired impression—would prove welcome to him.

His doctrine of Bhakti distinguishes five grades of devotional feeling in the Bhaktas. or faithful adherents: viz., (*santi*) calm contemplation of the deity; (dasye) active servitude; (sakhya) friendship or personal regard; (vatsalya) tender affection as between parents and children; (madhurya) love or passionate attachment, like that which the Gopis felt for Krishna. Chaitanya promoted the celebration on an imposing scale of the great Puri festival of the Rathayatra, or car procession, in the month of Ashadha, when, amidst multitudes of pilgrims, the image of Krishna, together with those of his brother Balarama and his sister Subhadra, is drawn along, in a huge car, by the devotees. This festival was, and is, attended by people from all parts of India, without distinction of caste or sex. All classes, even Mohammedans, were admitted by Chaitanya as members of his sect. The ordinary form of worship is very simple, consisting mainly of the constant repetition of names of Krishna, or Krishna and Radha, which of itself is considered sufficient to ensure future bliss. The partaking of flesh food and spirituous liquor is strictly prohibited. By the followers of this sect, also, an extravagant degree of reverence is habitually paid to their gurus or spiritual heads. Indeed, Chaitanya himself, as well as his immediate disciples, have come to be regarded as complete or partial incarnations of the deity to whom adoration is due, as to Krishna himself; and their modern successors, the Gosains, share to the fullest extent in the devout attentions of the worshippers. Chaitanya's movement was directed against the vile practices of the Saktas (see SAKTISM) then very prevalent in Bengal, but his own doctrine of divine, though all too human, love was by no means free from corruptive tendencies. While in Chaitanya's creed, Krishna, in his relations to Radha, remains at least theoretically the chief partner, an almost inevitable step was taken by some minor sects in attaching the greater importance to the female element, and in this way making Krishna's love for his mistress the guiding sentiment.

VALAIS, a canton of south Switzerland. The region is the old' *Vallis Poenina* (Upper Rhône valley). The former spelling, Vallais, was officially replaced in the early 19th century by Valais.

The modern canton includes the entire basin above St. Maurice, but below this point it consists of the western part only; its lower limits are in the Lake of Geneva. The total area is 2,020.7 sq.mi. (exceeded only by the Grisons and Berne), of which, however, only 55.9% is reckoned as productive; forests cover 282.6 sq.mi.

and vineyards 12.2 sq.mi. Its unproductive area includes the most considerable stretch of glaciers in Switzerland (c. 375 sq.mi.), together with about 5 sq.mi. of lakes. Poor as the canton is, it would be poorer were it not for its excellent wines—the area under vineyards is second only to Vaud (*q.v.*) and is increasing—and for its well-organized tourist traffic. Hotels have been built in nearly every tributary glen, and on the majority of the high pastures. The striking beauty of the scenery of its high glens, and the accessibility (see below) of the most characteristic features, have made the canton unusually popular, chiefly with summer visitors. The Upper Rhône occupies a northeast to southwest gorgelike trench from Gletsch to Brig; below this the valley widens and runs east to west to Leuk; onward it resumes its original course, ever widening until Martigny is reached, where the remarkably sharp bend carries the feature to the northwest; between St. Maurice and the lake is the only low land in the canton. The lowest commune is St. Gingolph (1,266 ft. alt.). The loftiest point is the Dufourspitze summit (15,200 ft.) of Monte Rosa, but the highest mountain wholly within the canton is the Dom (14,942 ft.). (See SWITZERLAND: Physical Geography.)

The chief railway line (about 75 mi.) through the canton is from St. Gingolph, on the Lake of Geneva, to Brig, at the north mouth of the Simplon tunnel (1895–1905—12¼ mi. long); from St. Maurice onward it forms part of the main through line from Lausanne toward Milan. There are also several mountain railways; *e.g.*, from Visp up to Zermatt (thence a branch up to the Gornergrat), from Vernayaz (near Martigny) past Salvan toward Chamonix, and from Leuk to Leukerbad, near the Gemmi pass and noted for its mineral springs. A new tunnel (1906–12) beneath the Lotschen pass, connects Kandersteg, in the Bernese Oberland, with Brig, thus opening up a new direct route from Paris to Italy, via Berne. The lofty alpine barriers of Valais are, as a rule, accessible only by footpaths or mule paths, but there are excellent roads over the Great St. Bernard pass (8,094 ft.) and the Simplon pass (6,591 ft.) to Italy, while at the head of the Rhône valley other excellently engineered roads give access to Uri over the Furka pass (7,992 ft.) and to Berne over the Grimsel pass (7,100 ft.).

In general, the boundaries of the canton run along the summit ridges of the surrounding mountains, but from an early date it has held a valuable part of the southern slope of the Simplon pass to below Gondo, as well as the rich Alpine pastures on the northern slopes between the Gemmi pass (7,641 ft.) and Schwarenbach.

The total population by the census of 1950 was 159,178; in 1930 it was 136,394, of whom 88,498 were French-speaking, 44,275 were German-speaking and 3,269 were Italian-speaking. The Italians decreased in number during the 20th century. The linguistic frontier has shown much oscillation; at present the inhabitants above Leuk generally speak a dialect of German, while below Leuk a Savoyard patois (French dialect) is the prevailing tongue. In general, the history of Valais (from 1810 to 1814 the French department of the Simplon) is a struggle between French and German elements. It is one of the last three admissions to the confederation. In 1930 there were 130,801 Catholics, 4,662 Protestants and 48 Jews.

The canton forms the 4th-century diocese of Sion (created *c.* 580) and has St. Théodule as its patron saint. Since 1513 its bishop has had no superior except the pope. Valais contains the three famous religious houses (all now held by Austin canons) of St. Maurice, of the Great St. Bernard, and of the Simplon. The abbey of St. Maurice (4th century and the oldest Christian foundation among the Alps) has, since 1128, belonged to the Augustinians. Since 1840 its abbot has borne the title of bishop of Bethlehem in partibus.

Good wines, especially muscat and vin du glacier, are produced in the canton, but the chief activity of the main valley below Brig is agriculture, rendered rather precarious in former days by extensive Rhône inundations. In the higher valleys the inhabitants are employed in pastoral occupations. The number of mountain pastures is greater, and they are better stocked in the more congenial Lower Valais than in Upper Valais (the line of division passing near Leuk). The capital is Sion (pop. 10,904). The canton has no large towns. The average density of the population in 1950, 79 per sq.mi., was but little above that of Uri (*q.v.*). Of the larger settlements, Monthey (5,608)—near St. Maurice—with an electric railway up the Val d'Illiez to Champéry, and Brig (3,854) are the most important. Naters, near the latter town, has a prosperous colony of Italian workmen.

Valais is divided into 13 administrative districts, which comprise 170 communes. The cantonal constitution was entirely remodelled in 1907. The legislature (grand conseil) is composed of 119 members elected by the people in the proportion of one for every 1,100 Swiss residents. The executive (*conseil d'état*) is composed of five members. Both councils hold office for four years. The obligatory referendum prevails for all laws and financial resolutions passed by the grand conseil, while 4.000 electors (6,000 in the case of a revision of the cantonal constitution) have the right of initiative as to legislative projects; the latter initiative dates back to 1848. The canton provides two members of the federal *Ständerat* and six members of the federal Nationalrat, elected by a popular vote. The principles of proportional representation are employed in communal elections.

History.—The Vallis Poenina was won by the Romans after a great fight at Octodurus (Martigny) in 57 B.C., and was so thoroughly Romanized that the Celtic aboriginal inhabitants and the Teutonic Burgundian invaders (5th century) became Romance-speaking peoples. Valais formed part of the kingdom of Transjurane Burgundy (888), which fell to the empire in 1032, and later of the duchy of Burgundia Minor, which was held from the emperors by the house of Zahringen (extinct 1218). In 999 Rudolph III of Burgundy gave all temporal rights and privileges to the bishop of Sion, who was later styled "praefect and count of the Valais." About the middle of the 13th century independent communities or tithings (*dizains* or Zehnten) were growing up, these, though seven in number, taking their name most probably from a very ancient division of the bishop's manors for administrative and judicial purposes. In the same century the upper part of the valley was colonized by Germans from Hasli (Bern), who Teutonized it, though many Romance local names still remain. In 1354 the liberties of several of the seven tithings (Sion, Sierre, Leuk, Raron, Visp, Brieg and Conches) were confirmed by the emperor Charles IV. A little later the influence of Savoy became predominant, and the count secured to his family the bishopric of Sion, of which he was already the suzerain. His progress was resisted by the tithings, which in 1375–76 crushed the power of the house of La Tour-Châtillon, and in 1388 utterly defeated the forces of the bishop, the count and the nobles at Visp, this being a victory of the Teutonic over the Romance element in the land.

From 1384 the Morge stream (a little below Sion) was recognized as the boundary between Savoyard or Lower Valais and episcopal or Upper Valais. In 1416–17 the Zehnten of the upper valley made an alliance with Lucerne, Uri and Unterwalden, with a view partly to the conquest of the Val d'Ossola, which was finally lost in 1422, and partly to the successful crushing of the power of the lords of Raron (1420). By the election of Walther von Supersax of Conches as bishop in 1457 the Teutonic element finally won the supremacy. On the outbreak of the Burgundian War, the bishop of Sion and the tithings made a treaty with Bern. In November of the same year (1475) they seized all Savoyard or Lower Valais up to Martigny, and in 1476 (March), after the victory of Grandson, won St. Maurice, Evian, Thonon and Monthey. The last three districts were given up in 1477, but won again in 1536, though finally by the treaty of Thonon in 1569 Monthey, Val d'Illiez and Bouveret alone were permanently annexed to the Valais, these conquests being maintained with the help of their old allies, Uri, Schwyz and Untermalden. These districts (or Lower Valais) were ruled as subject lands by the bishop and tithings of Upper Valais. In 1790–91 Lower Valais rose in revolt; but it was not finally freed till 1798, when the whole of Valais became one of the cantons of the Helvetic republic. Such prolonged resistance, however, was offered to French rule that in 1802 Bonaparte declared Valais an independent state under the name of the "Rhodanic Republic." In 1810, for strategic reasons, he incorporated it with France as the "department of the Simplon," and it was not freed till the Austrians came in 1813. In 1815 a local assembly was created, in which each of the seven tithings of Upper, and each of the six of Lower Valais elected four members, the bishop being given four votes. This constitution was approved by the federal Swiss diet, and the Valais was received as a full member of the Swiss confederation. By the constitution of 1839, the local assembly was to be elected according to population (1 member for every 1,000 inhabitants), and the bishop was given a seat instead of his four votes, while the clergy elected one deputy. By the 1844 constitution the clergy elected a second deputy. In 1844 there was civil war, and the Valais became a member of the Sonderbund. It was the last canton to submit in the Sonderbund War (1847) By the constitution of 1848 all ecclesiastical exemptions from taxation were swept away, and the bishop lost his seat in the assembly. New constitutions were framed in 1852, 1875 and 1907. (See SWITZERLAND: History.)

VALDEMAR I, king of Denmark (1131–1182), the son of Canute Lavard and the Russian princess Ingeborg, was born a week after his father's murder, and was brought up in the religious and relatively enlightened household of Asser Rig, whose sons Absalon and Esbjorn Snare, or "the Swift," were his playmates. On the death of King Eric Lam in 1147 Valdemar came fonvard as one of the three pretenders to the Danish crown, Jutland falling to his portion (compact of Roskilde [1157]). Narrowly escaping assassination at a banquet a few days later, at the hands of his rival, King Sweyn III, he succeeded only with the utmost difficulty in escaping to Jutland, but on Oct. 23 utterly routed Sweyn at the great battle of Grathe Heath, near Viborg, Sweyn perishing in his flight from the field.

Valdemar had no longer a competitor. He was the sole male survivor of the ancient royal line; his valour and ability were universally recognized, and in Absalon, elected bishop of Roskilde in 1158, he possessed a minister of equal genius and patriotism. The first efforts of the new monarch were directed against the Wendish pirates who infested the Baltic and made not merely the political but even the commercial development of the Danish state impossible. What the Northmen were to the western powers in the 8th and 9th centuries the Wends were to the Scandinavian lands in the 11th and 12th centuries. At the beginning of the reign of Valdemar the whole of the Danish eastern coast lay wasted and depopulated. Arkona, the chief sanctuary, and Garz, the political capital of the Wends, in the island of Riigen, were captured in 1169 by a great expedition under the command of Valdemar and Absalon; the hideous colossal idol of Rugievit was chopped into firewood for the Danish caldrons, and the Wends were christened at the point of the sword.

This triumph was only obtained, however, after a fierce struggle of ten years, in which the Danes were much hampered by the uncertain and selfish co-operation of their German allies, chief among whom was Henry the Lion, duke of Saxony and Bavaria, who appropriated the lion's share of the spoil. For at the beginning of his reign Valdemar leaned largely upon the Germans and even went the length, against the advice of Absalon, of acknowledging the overlordship of the emperor Frederick Barbarossa at the diet of Dôle, 1162. Very different was Valdemar's second conference with Barbarossa, on the banks of the Eider in 1182, when the two monarchs met as equals in the presence of their respective armies and a double marriage was arranged between two of Valdemar's daughters and two of the emperor's sons.

The only serious domestic trouble during Valdemar's reign was the rebellion of the Scanian provinces, which objected to the establishment of a strong monarchy inimical to local pretensions and disturbances, and especially to the heavy taxes and tithes necessary to support the new reign of law and order. The rising was ultimately suppressed by Absalon at the battle of Dysiaa, 1181. In the following year King Valdemar died.

VALDEMAR II, king of Denmark (1170–1241), was the second son of Valdemar I and brother of Canute VI, whom he succeeded on Nov. 12, 1202. Already during his brother's lifetime, as duke of Schleswig, Valdemar had successfully defended Denmark against German aggression. In 1201 he assumed the offensive, conquered Holstein, together with Hamburg, and compelled Count Henry of Schwerin to acknowledge the overlordship of the Danish crown. Immediately after his coronation, he hastened to his newly won territories, and was acknowledged lord of Northalbingia (the district lying between the Eider and the Elbe) at Liibeck, Otto IV, then in difficulties, voluntarily relinquishing all German territory north of the Elbe to Valdemar, who in return recognized Otto as German emperor. Thus the three bishoprics of Liibeck, Ratzeburg and Schwerin, which hitherto had been fief of the Reich, now passed under Danish suzerainty. In 1208, when the emperor Otto felt more secure upon his unstable throne, he would have attempted the recovery of the lost German territory but for the interposition of Pope Innocent III, who threatened to excommunicate any German prince who should attack Valdemar, the equally pious and astute Danish king having undertaken. at the bidding of the holy see, to lead a crusade against the heathen Estonians. Valdemar's position was further strengthened by the accession of Frederick II, who formally renounced all the German lands north of the Elbe and Elde, as well as the Wendish lands on the Baltic, in favour of Valdemar.

Valdemar henceforth turned to the extension of the Danish empire over the eastern Baltic shores. There, however, he had already been forestalled by German colonists established in Gotland and at Riga. In 1206 Valdemar, urged by Archbishop Anders Suneson, had occupied the Isle of Oesel on the Estonian coast. In 1210 Valdemar led a second expedition eastward, this time directed against heathen Prussia and Samland, the chief result of which was the subjection of Mestwin, duke of Pomerania, the leading chieftain in those parts.

In 1218 the German Bishop Albert of Riga was driven to appeal for assistance to King Valdemar. Valdemar cheerfully undertook a new crusade "for the honour of the Blessed Virgin and the remission of my own sins." In 1218 he set sail for Estonia with one of the largest fleets ever seen in northern waters, including a Wendish contingent led by Prince Vitslav. Landing at Lyndantse (the modern Reval) in north Estonia, Valdemar at once received the submission of the inhabitants, but three days later was treacherously attacked in his camp and only saved from utter destruction by his own personal valour and the descent from heaven, at the critical moment, of a red banner with a white cross on it, the Dannebrog (Danes' Cloth), heard of for the first time, and which henceforth was to precede the Danish armies to victory till its capture by the Ditmarshers, three hundred years later. This victory was followed by the foundation of Reval and the occupation of Harrien and Wirland, the northern districts of Estonia, by the Danes.

King Valdemar II was then, after the king of England, the most powerful potentate in the north of Europe. The southwestern Baltic was a Danish sea, and Danish territory extended from the Elbe to Lake Peipus. But this scattered and heterogeneous empire required a large standing army and a strong central government to hold it together. It is doubtful whether even the genius of Valdemar would have proved equal to such a stupendous task. He never had the opportunity of attempting it. In May 1223 he was seized at midnight in his tent on the isle of Lyo, where he had gone to hunt, by his vassal and guest Count Henry of Schwerin, and conveyed with his son and many other valuable hostages to the inaccessible castle of Dannenberg-on-Elbe. In this dungeon he languished for two and a half years, and despite all the efforts of Pope Honorius III on his behalf, he was ultimately forced to pay a heavy ransom and surrender Northalbingia and all his Wendish conquests except Riigen.

On his release he tried to retrieve his position by force, but was defeated at Bornhoved (July 22, 1227), which deserves a place among the decisive battles of history, for it destroyed at once and for ever the Danish dominion of the Baltic and established the independence of Lübeck, to the immense detriment in the future of all the Scandinavian states. On the other hand Valdemar, by prudent diplomacy, contrived to retain the greater portion of Danish Estonia (compact of Stensby, 1238). With rare resignation Valdemar devoted the remainder of his life to the great work of domestic reform. His noblest achievement in this respect is the codification of the Danish laws known as the *Jydske Lov* (Jutland Code), which he lived to see completed a few days before his death at Vordingborg on March 21, 1241. Valdemar was twice married, his first consort being Dragomir (Dagmar) of Bohemia, his second Berengaria of Portugal. All his four sons, Valdemar, Eric, Abel and Christopher, became kings of Denmark.

See *Danmarks Riges Historie*, vol. i, pp. 736–849 (Copenhagen, 1897–1905). (R. N. B.; X.)

VALDEMAR IV, king of Denmark (*c.* 1320–1375), was the youngest son of Christopher II of Denmark. Valdemar was brought up at the court of the German emperor Louis of Bavaria during those miserable years when Denmark was partitioned among Holstein counts and German Ritter, while Scania, the breadbasket of the monarchy, sought deliverance from anarchy under the protection of Magnus of Sweden. Even the Hansa towns, the hereditary enemies of Denmark, regarded the situation with disquietude. "One would gladly have seen a single king in Denmark if only for peace sake," says the contemporary Lubeck chronicle, "for peace was not to be had either at sea or on land." The assassination at Randers of the detested Holstein tyrant Count Gerhard III (1340), who for nine years had held Jutland and Funen and dominated the rest of Denmark, first opened Valdemar's way to the throne, and on midsummer day 1340 he was elected king at a *Lartdsting* held at Viborg, after consenting to espouse Helveg, the sister of his most important confederate, Valdemar, duke of Schleswig.

Valdemar could not have been more than 20 when he became the nominal king of Denmark, though, as a matter of fact, his territory was limited to the northernmost county of Jutland. His precocious maturity is strikingly evident from the first. An energy which never slackened, a doggedness which no adversity could crush, a fiery ambition coupled with the coolest calculation, and a diplomatic unscrupulousness which looked always to the end and never to the means, these were the salient qualities of the reconstructor of the dismembered Danish state. First Valdemar aimed at the recovery of Zealand, which was actually partitioned among a score of Holstein mortgagees who ruled their portions despotically from their strong castles and sucked the people dry. The oppressed clergy and peasantry regarded Valdemar as their natural deliverer; but the work of redemption proved painfully slow.

In Nov. 1343 Valdemar obtained the town and castle of Copenhagen from King hlagnus Smek of Sweden by reconfirming in still more stringent terms the previous surrender of the rich Scanian provinces, and by the end of the following year he had recovered the whole of North Zealand. In 1347 the remainder of Zealand was redeemed, and the southern islands, Laaland, Falster and Mon, also fell into the king's hands. By this time, too, the whole of Jutland (except the province of Ribe) had fallen to him, county by county, as their respective holders mere paid off. In 1349 at the *Landsting* of Ringsted, Valdemar proudly rendered an account of his stewardship to the estates of Zealand, and the bishop of Roskilde congratulated him on having so miraculously delivered his people from foreign thraldom. In Aug. 1346, he prudently rid himself of the distant and useless province of Estonia by selling it very advantageously.

In north German politics Valdemar interfered to protect his brother-in-law the Margrave Louis of Brandenburg against the lords of Mecklenburg and the dukes of Pomerania, with such success that the emperor Charles IV, at the conference of Bautzen, was reconciled to the Brandenburger and allowed Valdemar an annual charge of 16,000 silver marks on the city of Lubeck (1349). Some years later Valdemar even contemplated a descent on England in alliance with the French king John, but the chronic state of rebellion in western Denmark, fomented by the discontented Jutish magnates, lasted with short intervals from 1350 to 1360 and compelled Valdemar to renounce this fantastic design. But he proved more than a match for his domestic rebels, especially after his great victory at Brobjaerg in Funen (1357). Finally, the compact of Kalundborg restored peace to the kingdom.

Valdemar now turned his eyes to the "kingdom of Scania." Valdemar had indeed pledged it solemnly and irrevocably to King Magnus of Sweden, who had held it for 20 years; but profiting by the difficulties of Magnus with his Norwegian subjects, after skilfully securing his own position by negotiations with Albert of Mecklenburg and the Hanseatic league, Valdemar suddenly and irresistibly invaded Scania, and by the end of 1361 all the old Danish lands, except North Holland, were recovered.

By the recovery of Scania Valdemar had become the lord of the great herring-fishery market held every autumn from St. Bartholomew's day (Aug. 24) to St. Denis' day (Oct. 9) on the hammer-shaped peninsula projecting from the southwest corner of Scania containing the towns of Skanor and Falsterbo. This flourishing industry, which fully occupied 40,000 boats and 300,000 fishers assembled from all parts of Europe to catch and salt the favourite Lenten fare of the whole Continent, was the property of the Danish crown, and the innumerable tolls and taxes imposed by the king on the frequenters of the market was one of his most certain and lucrative sources of revenue. Foreign chapmen eagerly competed for special privileges of Skanor and Falsterbo, and the Hanseatic merchants in particular aimed at obtaining a monopoly there. But Valdemar was by no means disposed to submit to their dictation, and political conjunctures brought about actual hostilities between Valdemar and the Hansa, or at least that portion of it known as the Wendish towns[1], whose commercial interests lay principally in the Baltic.

From time immemorial the Isle of Gotland had been the staple of the Baltic trade, and its capital, Visby, whose burgesses were more than half German, the commercial intermediary between east and west, was the wealthiest city in northern Europe. In July 1361 Valdemar set sail from Denmark at the head of a great fleet, defeated a peasant army before Visby, and a few days later the burgesses of Visby made a breach in their walls through which the Danish monarch passed in triumph. The conquest of Gotland at once led to a war between Valdemar and Sweden allied with the Hanseatic towns; but in the spring of 1362 Valdemar repulsed from the fortress of Helsingborg a large Hanseatic fleet provided with "shooting engines" (cannon) and commanded by Johan Wittenburg, the burgomaster of Lubeck. In Sweden proper he was equally successful, and the general pacification which ensued in April 1365, very greatly in his favour, was cemented by the marriage of his daughter Margaret with Haakon VI of Norway.

Valdemar was now at the height of his power. Every political rival had been quelled. With the papal see, since his visit to Avignon in 1364, he had been on the best of terms. His ecclesiastic patronage was immense, and throughout the land he had planted strong castles surely held by the royal bailiffs. But in the winter of 1367–68 a hostile league against him of all his neighbours threatened to destroy the fruits of a long and strenuous lifetime. The impulse came from the Hansa. At a *Hansetag* held at Cologne on Nov. 11, 1367, three groups of the towns, 70 in number, concerted to attack Denmark, and in Jan. 1368 Valdemar's numerous domestic enemies, especially the Jutlanders and the Holstein counts, acceded to the league, with the object of partitioning the realm among them.

And now an astounding and still inexplicable thing happened. At Easter-tide 1368, on the very eve of this general attack, Valdemar departed for three years to Germany, leaving his realm in the capable hands of the earl-marshal Henning Podbusk. Valdemar's skilful diplomacy, reinforced by golden arguments, did indeed induce the dukes of Brunswick, Brandenburg and Pomerania to attack the confederates in the rear; but fortune was persistently unfriendly to the Danish king, and peace was finally concluded with the towns by Podbusk and the Danish council of state at the congress of Stralsund, 1370. The con-

[1] Rostock, Greifswald, Wismar and Stralsund.

ditions of peace were naturally humiliating for Valdemar, though ultimately he contrived to render illusory many of the inordinate privileges he was obliged to concede. He was also able, shortly before his death on Oct. 24, 1375, to recover the greater part of Holstein from the rebels. (R. N. B.)

VALDÉS, JUAN DE (c. 1500–1541), Spanish religious writer, was born about 1500 at Cuenca. He has been confused with his twin brother Alfonso (Latin secretary of state from 1524; d. 1532 at Vienna). Juan probably studied at the University of Alcalá. In fear of the Spanish Inquisition he left Spain for Naples in 1530. In 1531 he moved to Rome, where his criticisms of papal policy were condoned.

From the autumn of 1533 Valdés made Naples his permanent residence, his name being Italianized as Valdesso and Val d'Esso. Valdés' house was the centre of a literary and religious circle; his conversations and writings (circulated in manuscript) stimulated the desire for a spiritual reformation of the church. His first production at Naples was a philological treatise, *Diálogo de la lengua* (1535). His works entitle him to a foremost place among Spanish prose writers. His friends urged him to seek distinction as a humanist, but his bent was toward problems of biblical interpretation in their bearing on the devout life.

Vermigli (Peter Martyr) and Marcantonio Flaminio were leading spirits in his coterie. On Bernardino Ochino, for whose sermons he furnished themes, his influence was great. Pietro Carnesecchi, who had known Valdés at Rome as "a modest and well-bred courtier," found him at Naples (1540) "wholly intent upon the study of Holy Scripture," translating portions into Spanish from Hebrew and Greek, with comments and introductions. Valdés died at Naples in May 1541, and his death scattered his band of associates. Some of Valdés' writings ivere published by degrees, in Italian translations. They combine a delicate vein of semimystical spirituality with the personal charm attributed to their author in all contemporary notices. Juan Llorente traces in Valdés the influence of Johannes Tauler; any such influence must have been at secondhand. The *Aviso* on the interpretation of Scripture, based on Tauler, was probably the work of Alphonso.

The suggestion that Valdés was unsound on the Trinity was first made in 1567 and was adopted by Sand (1684), Robert Wallace (1850) and other anti-Trinitarian writers, and is countenanced by Pierre Bayle. But Valdés never treats of the Trinity, reserving it as a topic for advanced Christians; yet he explicitly affirms the consubstantiality of the Son, whom he unites in doxologies with the Father and the Holy Spirit. Practical theology interested him more than speculative, his aim being the promotion of a healthy and personal piety.

Valdés' writings include *Diálogo de la lengua* (written, 1533; first printed, 1737); *Qual Maniera si devrebbe tenere a informare . . . gli figliuoli de Christiani delle Cose della Religione* (before 1545; Eng. trans., 1882); *Trataditos* (1881; Eng. trans., 1882); *Aliabeto Cristiano* (nritten about 1537; Eng. trans, 1861); *Cento e dieci divine considerazioni* (all copies of the original edition suppressed by the Spanish Inquisition; Eng. trans, 1638, 1865); *Comentario breve . . . sobre la epistola de San Pablo a los Romanos* (1556; Eng. trans, 1883); *Cowentario breve . . . sobre la primera epistola de San Pablo a los Corintios*, no 8 (1557); *El Evangelio de San Mateo* (1881; Eng. trans, 1883).

See B. Wiffen's *Life* of Valdés prefixed to Betts's translation of the *Considerations* (1865); E. Boehmer, *Spanish Reformers of Two Centuries* (1874), *Lives of J. and A. de Valde's* (1882). (*A.* Go.; X.)

VALDÉS LEAL, JUAN DE (1622–1690). Spanish painter and etcher, an unaccomplished draftsman but a subtle and original colourist who added a new note to Spanish painting, was baptized at Seville, May 4, 1622. His father Fernando de Nisa was Portuguese, his mother was Sevillian. He nas influenced first by Bartolomé Esteban Murillo; both artists were officers of the Academy of Draning, Seville. In 1653 Valdés Leal painted six scenes on the life of St. Clara for the convent in Carmona and in 1657. at Seville. a series on St. Jerome and the nuns and monks of Jerome's order. Perhaps his finest altarpiece was that done for the monastery of the Carmelitas Calzados at Córdoba (1658). As an etcher he was especially distinguished. His few portraits reveal skill in that branch of the arts. Paintings of many heads of martyred saints gained him the title of "the painter of the dead," and his *vanitas* motifs are unequaled in Spanish art. "The Hieroglyphs of the End of Our Days" (1672), two paintings on macabre subjects, done for the Hospital de la Caridad, Seville, are considered his masterpieces. His life was spent at Cordoba and Seville except for a brief journey to Madrid. He died at Seville on Oct. 14, 1690.

VALDEZ, a town of Alaska, U S, farthest north all-$ear-open port in North America, on Prince William sound, about 370 mi. S. of Fairbanks. Selected in 1898 by the U.S war department as a base for exploration. it became the site of a military post, Ft. Liscum, where troops were stationed until 1922. The route of a military telegraph line from Valdez to the settlements of Eagle and Fairbanks became a trail, a wagon road and eventually the principal highway, known as the Richardson highway, open all year between the coast and the interior. Valdez thus became an important port of entry for shipments to Fairbanks, Anchorage and other cities. Gold and copper mining, fish canning and fur farming are important. Pop. (1960) about 600. (J. E. Cl.)

VALDNIA, a province of southern Chile where agriculture, lumbering and tourism flourish. It was one of the eight provinces created in 1826 but modifications have reduced its area, the latest occurring in 1943 when Osorno province (*q.v.*) was created. Valdivia's 8,083 sq mi. area includes coastal range, central valley and cordilleran landscapes. The central valley. its rolling eastern margin, and the westward extending lowlands of the Valdivia and Bueno river systems are agricultural; eastern and western uplands are forested. Vacationist attractions include the Valdivia estuary, and the lakes (Calafquén, Panguipulli. Riñihue, Ranco, Puyehue) and mountains of the east (notably volcanoes Choshuenco and Puyehue). Trout fishing, as in much of southern Chile, is remarkably good. Temperature extremes are moderate but the wmters are very met.

Pop (1952) 232.647. About 45% of the gainfully employed are engaged in agriculture and lumbering. Meat. wheat. lumber, milk, potatoes and fruit are the major products. Valdivia's lumber production is of major importance in Chile and its beef and dairy are also significant. Much of local industry is concerned with processing farm and forest products for domestic consumption but iron and steel smelting (Corral), foundry and metal fabrication, and seafood preserving (Valdivia) have been important. Stimulating all these phases of economic gron th have been German colonizers and their descendants. The first families settled near La Unión in 1846. Government-supported immigration, begun in 1850, developed clusters of Germans in Valdivia (q v.) and on farm land in the vicinity, and near La Unibn and Osorno (*q.v.*). Valdivia, pop. (1952) 45.203, is the provincial and departmental seat; La Unión (9,830) and Río Bueno (6,259) are departmental capitals. All are served by the longitudinal rail system that links Santiago uith Puerto hlontt. (J. T.)

VALDIVIA, a city in southern Chile with important manufacturing, lumbering, commercial and recreation functions, and the capital of Valdivia province (*q.v.*), was founded in 1552 by Pedro de Valdivia. It is located on the Valdivia river, about 12 mi. from the sea. Although a strategically significant outpost to colonial Spanish South America, Valdivia did not flourish until after the mid-19th century when German settlers introduced capital, vigour and fresh skills into local economic life. Pop. (1952) 45.203. Its commercial and administrative heart, on the river's south bank, is flanked by residential districts, railroad shops and factories (foodstuffs, metal fabricating, lumber products, boat yards). Linked to the city by two bridges is a north-bank industrial neighbourhood, the university, airport and fairgrounds. Construction in the 20th century employs modern design and materials but the preponderance of frame and corrugated metal buildings gives an interesting pioneer-city appearance. Almost all of Valdivia's important maritime trade is barged to or from Corral's anchorage. Both the city and the outport were severely damaged during the earthquakes that shook south-central Chile early in 1960.

The Valdivia-Corral area is a popular summer resort; the city is a gateway to Chile's lake district. (J. T.)

VALDOSTA, a city of southern Georgia. U.S., 120 mi. N.W. of Jacksonville, Fla.; the seat of Lowndes county. The area produces well over half of the nation's naval stores of turpentine. Agricultural products include tobacco, cotton, watermelons, peanuts and vegetables; factories in the city produce feed, fertilizer, textiles. and wood and metal products. Cattle raising is the predominant livestock industry.

Valdosta nas settled in 1859. George M. Troup. governor of Georgia, 1823–27, had chosen the name of the Italian province Valle d Aosta ("vale of beauty") for his estate and when the town was incorporated in 1860 the name was adopted in modified form. Chartered as a city in 1901, it established a council-manager form of government in 1958. The chief educational institution is Valdosta State college. a division of the University of Georgia (see GEORGIA: *Education*). Moody air force base, 10 mi. N. of the city, was established in 1941 and reactivated in 1951. Hunting is popular among sportsmen and the 80 lakes in the region provide fishing and uater sports. For comparative population figures see table in GEORGIA: *Population*. (S. B. K.)

VALENCE, a town of France, is on the Rhône Pop (1954) 36,659. Valentia was the capital of the Segalauni, and the seat of a celebrated school before the Roman conquest. a colony under Augustus, and an important tonn of Viennensis Prima under Valentinian The bishopric of Valence dates probably from the 4th century. Valence nas ravaged by the Alani and other barbarians, and fell successively under the power of the Burgundians the Franks. the sovereigns of Arles, the emperors of Germany, the dukes of Valentinois, the counts of Toulouse and its own bishops. The citizens put themselves under the protection of the dauphin, and in 1456 had their rights and privileges confirmed by Louis XI, the bishops recognizing the suzerainty of the dauphin. Valence became the capital of the Protestants of the province in 1563. The toun was fortified by Francis I. It had become the seat of a university in the 15th century, but the revocation of the Edict of Nantes crippled the town's prosperity.

VALENCE (or VALENCY), in chemistry, is the property of an element that determines the number of other atoms with which an atom of the element can combine. The property is not a simple one; the effort to obtain a clear understanding of the nature of valence led to the dissociation of the concept into several new concepts—of ionic valence, covalence, oxidation number, coordination number, metallic valence—corresponding to different modes of interaction of atoms. Some chemists have felt that the word valence might well be allowed to drop into disuse, in favour of these more precise terms. In practice, however, valence continues to be used as a general expression of the combining capacities of the elements or as a synonym for one or another of the more precise terms.

When, toward the middle of the 19th century, the relative weights of atoms and molecules became accurately known, especially through the reintroduction by Stanislao Cannizzaro in 1858 of Amedeo Avogadro's principle (1811) of the relation between the molecular weight and the density of a gas, it became clear that the number of atoms with which a given atom could combine varied with the nature of that atom: that, for example, a fluorine atom could combine with one hydrogen atom, an oxygen atom with two, a nitrogen atom with three and a carbon atom with four, forming the compounds HF, H_2O, H_3N and H_4C. These characteristic combining capacities were shown to extend to more complicated compounds: two of the four hydrogen atoms in methane, CH,, could be replaced by one oxygen atom, or all four by two, or three by one nitrogen atom, as in H_2CO, CO_2, HCN. Thus, it appeared that every atom could combine with or replace a definite number of other atoms of a specified kind, and hydrogen, since it was the lightest atom arid mas never found to combine with more than one atom of another element, was selected as the standard. The term valence, introduced in 1868, is used to express both the power of combination in general, and its numerical value.

As the examination of the valence of elements was extended there was much dispute as to whether or not it was constant in value for any one element. It soon became evident that the valence of many elements is variable: for a time it was maintained that the variations were always by two units, so that elements could be divided into those of odd and those of even valence; but before long it was recognized that, although this is true of many elements, there are others whose valence must vary by single units at a time.

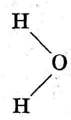
The discovery of the periodic classification of the elements by Dmitri Mendeléyev and Lothar Meyer (1864–69) brought to light a new regularity in the valences of the elements (see PERIODIC LAW). Mendeléyev pointed out that all the elements of a periodic group have the same principal valences, and that these change in value by one unit in passing from one group to the next. In particular, the highest valence of an element, as shown in its oxide, is equal to the ordinal number of the group to which it belongs. On the other hand, the valence in the hydrides seems to rise with that in the oxides from 1 to 4, and then to fall by steps of one unit to unity again.

Earlier Theories—All discussions of valence in the 19th century were handicapped by the absence of any satisfactory theory of its cause. J. J. Berzelius, in the earlier part of the century, had assumed atoms to be electrically charged, and to be held together in the molecule by the attraction of opposite charges. This view was supported by the phenomenon of electrolysis, as investigated especially by Sir Humphry Davy and Michael Faraday. Its validity as a general theory of valence was. however, destroyed about 1840 by the discovery that under some conditions "electropositive" atoms could be replaced by "electronegative" atoms without any fundamental modification of the properties of the molecule: thus, part of the hydrogen in acetic acid can be replaced by chlorine, and the product resembles the original acid in many ways, and obviously must have a similar structure. The attempts of Berzelius to stretch his theory to explain such phenomena led to its falling into discredit, and it was in part replaced by what ultimately became the theory of structural chemistry.

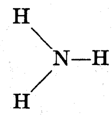
In this new theory no assumptions were made as to the nature of the forces connecting the atoms in a molecule, and hence no opposition in character between the atoms was required. Every atom was regarded as having a certain number of units of combining power, and every atomic link as involving the utilization of one of these units by each of the atoms concerned. Double and triple links, in which each of two atoms used up two or three of these units in combining with one another, were also recognized. The valence of an atom in the numerical sense was the number of such units that it possessed. On paper, the links were represented by lines, giving such formulas as

Hydrogen

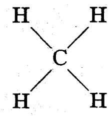
Hydrogen fluoride



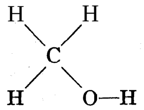
Water



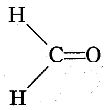
Ammonia



Methane



Methyl alcohol



Formaldehyde

Carbon dioxide

Hydrogen cyanide

This theory had an astounding success in its application to organic chemistry. It was found possible to determine from the reactions of a substance the order in which the constituent atoms are linked in the molecule and thus to assign to the vast hordes of organic compounds "structural formulas" that account for their existence and to a large extent also for their properties. For a discussion of further extensions of this theory, which made it possible to determine the approximate relative positions in space of the various atoms and groups in a molecule, see STEREOCHEMISTRY. The electrical theory again became prominent in and after 1887, with the rise of the Svante Arrhenius theory of salt solutions, which showed that a solution of a salt in water contains oppositely charged ions (a solution of sodium chloride, for example, contains positive sodium and negative chlorine ions) that have to a great extent the properties of free molecules.

(N. V. S.; L. C. P.)

Werner's Co-ordination Theory.—A new concept in chemistry was developed in 1893 by Alfred Werner. It had been recognized that many metallic salts have the power of combining with other salts or with water or ammonia or other molecules. The compounds formed in this way had not been fitted into any theory of valence, however, and their existence had been attributed to the action of weak residual forces, inferior to the forces of true valence. By the study of an immense number of these compounds, Werner showed that their compositions and properties could be systematized on the basis of a new assumption. This assumption, which was later completely verified by X-ray investigations of the structure of complex crystals (R. W. G. Wyckoff and R. G. Dickinson. 1920), is that a metal atom has the power of combining with a definite number (usually 4 or 6) of other atoms. ions or molecules, and "co-ordinating" them into a definite geometrical arrangement about itself. Werner was able to present sound evidence) consisting mainly' of the existence of isomers, to support his proposal that most complexes with "co-ordination number" 6, such as the hexachloroplatinate ion, $[PtCl_6]^{2-}$, and the cobaltic hexammine ion, $[Co(NH_3)_6]^{3+}$, have an octahedral configuration, the six attached groups being arranged at the corners of a regular octahedron about the central atom. He also showed that some complexes with co-ordination number 4 have a tetrahedral configuration (such as $[Zn(NH_3)_4]^{2+}$) and some have a square, planar configuration ($[PtCl_4]^{2-}$ and other complexes of bivalent palladium and platinum). General acceptance of Werner's co-ordination theory came in 1911, after his prediction and the experimental verification of the existence of the optical isomerism of some octahedral co-ordination complexes. See CO-ORDINATION COMPOUNDS; STEREOCHEMISTRY.

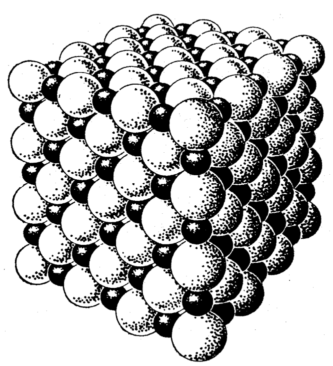
The Development of the Electronic Theory of Valence.—The modern electronic theory provides a detailed and thoroughly sound explanation of valence and chemical combination in terms of the electrostatic forces operating between electrons and atomic nuclei. The first great step in the development of this theory was made by G. N. Lewis (1916): the identification of the valence bond of organic chemistry with a pair of electrons held jointly by two atoms, and serving to hold them together. Lewis also discussed the relation between the electronic structure of atoms and the valence of elements, including their power to form ions. In the same year, the electronic structure of ions was discussed by W. Kossel; and after the development of the detailed electronic theory of the periodic system of the elements (see PERIODIC LAW) further progress in the formulation of the electronic theory of valence was rapidly made through the efforts of I. Langmuir. N. V Sidgwick and many other chemists.

Within two years after the development of quantum mechanics (*q.v.*) by W. Heisenberg, E. Schrodinger and P. A. M. Dirac, the fundamental nature of the shared-electron-pair chemical bond was elucidated by the quantum-mechanical treatment of the hydrogen molecule, carried out by W. Heitler and F. London in 1927. During the next few years many workers contributed to the application of quantum mechanics to the problem of chemical combination and valence, and rapid progress was made in the discovery of the principles determining the formation of shared-electron-pair bonds, the relation of the nature of bonds to the character of bond orbitals and the significance of quantum-mechanical resonance to molecular structure. As a result of this progress. and the great progress that has been made in the determination of the detailed atomic structures of molecules and crystals by methods of spectroscopy and the diffraction of X-rays and electrons, the theory of chemical valence is no longer a discussion of empirical rules but is in large part a precise discussion of electronic structures and interatomic forces firmly based on the modern knowledge of electrons and atomic nuclei and their interactions.

Ionic Valence.—Molten sodium chloride is a good conductor of electricity. This molten salt consists of monatomic ions (positive sodium ions, Na^+, and negative chloride ions. Cl^-) in a moderately compact aggregate in which because of thermal agitation. each ion is free to move slowly around. Under the influence of the applied electrical field the sodium ions move toward the negative electrode and the chloride ions toaard the positive electrode. and this motion of the ions carries the electric current through the region between the electrodes.

A sodium ion is a sodium atom that has lost one electron, and has thus acquired an electric charge $+e$ (or $+1$, with use of the magnitude of the electronic charge as unity). Since sodium is one greater in atomic number than neon, the sodium ion contains the same number of electrons as the neon atom. The chloride ion is a chlorine atom that has gained one electron, and has thus assumed a negative charge $-e$ (or -1) and the same number of electrons as argon. It is not accidental that these ions have the same electron numbers as the noble (inert) gases neon and argon. The noble gases are shown by their extreme chemical inertness to have especially stable electronic structures. This stability is shown by the fact that the ionization energy (the energy required to remove one electron from the atom: $X \rightarrow X^+ + e^-$) is greater for the noble gases than for any other atoms. Similarly, the electron affinity (the energy liberated in picking up an additional electron, according to the reaction $X + e^- \rightarrow X^-$) is smaller for the noble-gas atoms than for other atoms. An atom with an atomic number near that of a noble gas tends to achieve the noble-gas structure by the loss or gain of electrons. One electron of a neutral sodium atom is loosely held and can be removed by a rather small amount of work; the ionization energy of the sodium atom is small. The chlorine atom has the power of adding an electron. When metallic sodium and gaseous chlorine react, an electron is transferred from each sodium atom to a chlorine atom, forming the ions Na^+ and Cl^-. Sodium chloride is an aggregate of these ions. The necessity of electrical neutrality requires that the substance contain equal numbers of singly charged cations and singly charged anions—hence, its formula is Na^+Cl^- (usually NaCl); only a minute excess of ions of one sign would cause the sample of salt to have a high electrical potential.

The coulomb forces between the ions cause each ion to attract neighbouring ions of opposite sign, and to tend to co-ordinate them about itself. This leads to a stable spatial arrangement, shown by the sodium chloride crystal (see figure), in which each ion has 6 nearest neighbours of the opposite sign and 12 neighbours of the same sign at a distance $\sqrt{2}$ larger. The total coulomb energy for this arrangement is found by summation over pairs of ions to be $-1.7476\frac{e^2}{R}$ per Na^+Cl^- ion pair, in which R is the distance between the centre of one ion and the centre of one of its six nearest neighbours. The crystal is hence stabilized by this coulomb attraction by an energy quantity 75% greater than the coulomb energy of a positive and a negative charge the distance R apart. This coulomb energy of the crystal is large: it amounts to -205 kg.cal. per mole for sodium chloride and is large enough (with the help of the electron affinity of chlorine) to provide the energy to sublime sodium metal to separate atoms, to ionize these atoms and to dissociate chlorine molecules into chlorine atoms, all with 98 kg.cal. per mole to spare—evolved as the heat of formation of sodium chloride from the elements.



BY COURTESY OF LINUS PAULING

THE ATOMIC ARRANGEMENT IN THE SODIUM CHLORIDE CRYSTAL: SMALL SPHERES ARE SODIUM IONS; LARGE SPHERES. CHLORIDE IONS

The forces of attraction of ions of opposite charge are called "ionic valence forces," and the charge of an ion is called its "ionic valence." Sodium and the other alkali metals, with atomic numbers one greater than the noble gases, tend to form ionic compounds in which they have ionic valence 1+ (are "unipositive"). Chlorine and the other halogens form compounds in which they have ionic valence 1− (are "uninegative"). The alkaline-earth metals lose two electrons per atom to form the bipositive ions Be^{2+}, Mg^{2+}, Ca^{2+}, Sr^{2+}, Ba^{2+} and Ra^{2+}, in compounds such as $Ca^{2+}Cl^{-}_{2}$, $Ca^{2+}O^{2-}$, etc. The elements of Group VI of the periodic table may be formed into binegative ions O^{2-}, S^{2-}, Se^{2-} and Te^{2-}.

The metals of Groups Ib and IIb (*see* PERIODIC LAW) tend to form cations (Cu^{+}, Ag^{+}, Zn^{2+}, Cd^{2+}, Hg^{2+}) in which they have ten electrons more than a noble gas. The transition elements also form cations with other electron numbers. Usually these ions are bipositive or terpositive: the electron affinity of electronegative elements and the stabilizing effect of interionic attraction seem to be sufficient to remove two or three electrons from a transition atom, but not more. Examples of stable ions are Cr^{3+}, Mn^{2+}, Fe^{2+}, Fe^{3+}, Co^{2+}, Ni^{2+} and Cu^{2+}. The rare-earth metals usually form terpositive ions; a few, such as cerium, also form quadripositive ions, and a few others, such as europium, form bipositive ions.

Covalence.—Another kind of valence of great importance is "covalence," which results from the sharing of two electrons by two atoms. The bond that consists of a pair of shared electrons is called a "covalent bond"; it is essentially the bond of the organic chemist, represented by a dash in structural formulas, such as

$$\begin{array}{ccccccc} & & H & & H & & \\ & & | & & | & & \\ H & - & C & - & C & - & O-H \\ & & | & & | & & \\ & & H & & H & & \end{array} \quad \text{for ethyl alcohol.}$$

Whereas in an ionic compound the individual ions retain some independence of one another, and under certain conditions (as in the molten salt or in solution in a solvent of high dielectric constant) can move about rather freely, the atoms that are bonded together by covalent bonds are held tightly to one another and form a rather rigid molecule.

The simplest example of a covalent molecule is the hydrogen molecule, H_2, for which the structure H:H or H—H can be written. This molecule has been found by experiment to be rigid, with the equilibrium internuclear distance 0.740 Å.; the frequency of nuclear vibration 4,318 cm.$^{-1}$ (corresponding to a large restoring force to the equilibrium configuration); and the energy of dissociation of the molecule in its normal state into atoms 102,700 cal. per mole. The quantum-mechanical treatment of this molecule, carried out by Heitler and London and relined by H. M. James and A. S. Coolidge. has given complete agreement with these experimental values, leaving no doubt that the chemical bond in this molecule is the shared-electron-pair bond postulated by Lewis and formulated mathematically by the theory of quantum mechanics.

The rules that determine the formation and properties of covalent bonds may be stated as follows: A covalent bond between two atoms consists of two electrons (with opposed spins—see ELECTRON) occupying one orbital for each atom. The strength of the bond is determined by the stability of the atomic orbitals and also by their nature, a good bond orbital of an atom being a stable orbital that extends in the direction of the atom with which the bond is formed.

The requirement of stability of bond orbitals (as well as of atomic orbitals occupied by electron pairs not shared with other atoms) causes the covalence of atoms to be related to certain stable electronic configurations, especially those of the noble gases. Since an atomic orbital can be occupied by either an unshared electron pair or a shared electron pair, a noble-gas configuration can be achieved by an atom by the formation of covalent bonds as well as by the transfer of electrons (ionic valence). The normal covalences 4, 3, 2 and 1, respectively, for carbon, nitrogen, oxygen and fluorine correspond to the achievement of the neon structure by the sharing of electrons:

$$\begin{array}{c} H \\ H{:}\ddot{C}{:}H \\ H \end{array} \qquad \begin{array}{c} H \\ {:}\ddot{N}{:}H \\ H \end{array} \qquad \begin{array}{c} H \\ {:}\ddot{O}{:}H \\ \end{array} \qquad {:}\ddot{F}{:}H$$

A double bond between two atoms involves two electron pairs and two orbitals for each atom, as in ethylene,

$$\begin{array}{ccc} H & & H \\ & C{::}C & \\ H & & H \end{array}.$$

A triple bond involves three electron pairs and three orbitals for each atom, as in hydrogen cyanide (H:C:::N:). In each of these molecules the hydrogen atom achieves the helium configuration by forming one shared pair, and the carbon and nitrogen atoms achieve the neon configuration. An atom may form covalent bonds in number different from the normal number and complete its stable electronic configuration by the transfer of electrons. An example is nitrogen in the ammonium ion,

$$\left[\begin{array}{c} H \\ H\ {:}\ddot{N}{:}H \\ \ddot{H} \end{array}\right]^{+}$$

When uncertainty arises as to the most satisfactory electronic structure for a molecule, the question may usually be resolved by assigning to a molecule a hybrid structure, corresponding to resonance among the likely alternative structures (*see* RESONANCE, THEORY OF). Thus, hydrogen chloride may be assigned the structure {$H^{+}Cl^{-}$, H—$\ddot{C}l$:}, a hybrid of the structure involving an extreme ionic bond and that involving a normal covalent bond; nitrous oxide may be assigned the structure {:N=N=O:, :N≡N—O:}, a hybrid of the two most reasonable valence-bond structures. Some progress has been made in the rough quantitative assignment of hybrid structures, with use of experimental values of energy of formation, interatomic distances and other molecular properties.

For some purposes it is convenient to make use of the concept of formal charge. The formal charge of an atom is the electrical charge that the atom would have if it retained all its unshared electrons and one-half the electrons that it shares with atoms to which it is bonded. For example! in the ammonium ion, with the structure shown above, the formal charge of the hydrogen atoms is 0, and that of the nitrogen atom is +1.

Co-ordination Number.—The "co-ordination number" of an atom is the number of atoms, ions or molecules that the atom holds as its nearest neighbours in a complex or a crystal. Thus, the metal atom has co-ordination number 8 in the Werner co-ordination complexes $[Mo(CN)_8]^{4-}$ and $[Sr(H_2O)_8]^{2+}$; 7 in the complex $[ZrF_7]^{3-}$; 6 in the complexes $[SnCl_6]^{2-}$, $[PtBr_6]^{2-}$, $[FeF_6]^{3-}$; $[Co(NH_3)_6]^{3+}$ and $[Al(H_2O)_6]^{3+}$; 4 in the complexes $[Zn(CN)_4]^{2-}$, $[Cu(CN)_4]^{3-}$, $[Ni(CN)_4]^{4-}$, $[Ni(CN)_4]^{2-}$, $[Be(H_2O)_4]^{2+}$, $[BF_4]^{-}$ and $[Pt(CN)_4]^{2-}$, and 2 in the complexes $[Ag(NH_3)_2]^{+}$, $[AuCl_2]^{-}$ and $[HgCl_2]$.

The forces which hold the atoms together in these complexes, and which lead to the observed co-ordination numbers. are of different kinds. The bonds to the highly electronegative fluorine atoms in the fluoride complexes are essentially ionic, and the increase in co-ordination number, with fluoride ion, from 4 to 6 to 7 for B^{3+}, Fe^{3+} and Zr^{4+} is the result mainly of the increase in size of the cation, which permits a successively larger number of fluoride ions F^{-} to be packed about the central ion. The influence of the relative size of the co-ordinated molecule and the central ion is important in hydrated cations. in which the co-ordinating bond is mainly the electrostatic attraction of the central cation and the negative end (oxygen atom) of the water molecule.

In many Werner complexes—including those formed by the cyanide ion, thr nitrite ion or nitro group, the thiocyanate ion, the halide ions (other than fluoride), the ammonia molecule and the carbon monoxide molecule—the bonds between the attached atom or group and the central atom are essentially covalent, and the co-ordination number is determined by the nature of the bond orbitals of the central atom. Thus. Zn^{2+} and Cu^{+} have their five 3d orbitals occupied by unshared pairs of electrons, leaving as stable orbitals suited to bond formation the one 4s and the three 4p orbitals These can hybridize to form four bond orbitals directed toward the corners of a regular tetrahedron; accordingly, these ions form cyanide complexes $[Zn(CN)_4]^{2-}$ and $[Cu(CN)_4]^{3-}$, with co-ordination number 4 and the tetrahedral configuration.

The neutral nickel atom similarly forms tetrahedral complexes $[Ni(CN)_4]^{4-}$ and $[Ni(CO)_4]$. However. the bipositive nickel ion Ni^{2+}, behaves differently It may use one 3d orbital for bond formation: this orbital can hybridize with the 4s orbital and two 4p orbitals to form four bond orbitals directed toward the four corners of a square that is coplanar with the central ion. It was discovered by Werner that bivalent palladium and platinum form these square planar complexes, and this configuration has been verified for the covalent complexes of bivalent nickel also.

The octahedral covalent complexes, such as the ferrocyanide ion, $[Fe(CN)_6]^{4-}$, involve six covalent bond orbitals formed by hybridization of two 3d orbitals with the 4s and 4p orbitals.

Some heavy-metal atoms tend to assume co-ordination number 2 and to form two oppositely directed covalent bonds. Examples of such linear complexes are: $[:N{\equiv}C{-}Cu{-}C{\equiv}N]^{-}$, $[N{\equiv}C{-}Ag{-}C{\equiv}N.]^{-}$, $[Cl{-}Au{-}Cl]^{-}$. $[Cl{-}Hg{-}Cl]$.

Oxidation Number.—After the concepts of ionic valence and covalence had been introduced. and detailed electronic structures of molecules began to be written, it was recognized that a simple representation of the oxidation states of elements in a compound is needed, especially as an aid in balancing equations for oxidation-reduction reactions. The "oxidation number" came into use for this purpose.

The oxidation number of an element in a substance is the electrical charge assigned to the atoms of fhe element according to certain rules. These rules are simple, but are not completely unambiguous, and their application requires some chemical insight. The rules, as generally accepted, are the following:

1 The oxidation number of a monatomic ion in an ionic substance is equal to its electrical charge.

2. The oxidation number of atoms in an elementary substance is zero.

3 In a covalent compound of known structure, the oxidation number of each atom is the charge remaining on the atom when each shared electron pair is assigned completely to the more electronegative of the two atoms sharing it (*see* PERIODIC LAW). A pair shared by two atoms of the same element is usually split between them.

4 The oxidation number of one element in a compound of uncertain structure may be calculated from a reasonable assignment of oxidation numbers to the other elements in the compound.

For example, in the permanganate ion, MnO_4^{-}, oxygen is assigned its usual oxidation number -2; manganese, hence, has oxidation number $7. In acidic solution this ion can be reduced to manganous ion, Mn^{2+}, by a suitable reducing agent. Hydrogen peroxide can serve as the reducing agent for this purpose. The oxidation number of oxygen in hydrogen peroxide, H_2O_2, is -1, that of hydrogen being $+1$, and on oxidation of hydrogen peroxide free oxygen is formed, with increase in oxidation number of oxygen from -1 to 0. Hence, two manganese atoms can oxidize ten oxygen atoms and the equation for the oxidation of hydrogen peroxide by permanganate ion in acidic solution is easily written. $2MnO_4^{-} + 5H_2O_2 + 6H^{+} \rightarrow 2Mn^{++} + 5O_2 + 8H_2O$.

The word valence when used in the field of inorganic chemistry ordinarily refers to the state of oxidation of an element as expressed by its oxidation number, whereas in organic chemistry it ordinarily refers to the covalence of the element.

The Hydrogen Bond.—A structural feature that has an important effect on the properties of many substances is the "hydrogen bond" A hydrogen atom bonded to an electronegative atom can attract another electronegative atom and form with it a weak bond (with bond energy 5 or 10 kg cal per mole). This bond is not a second covalent bond—hydrogen, with only one stable orbital, can form only one covalent bond—but is the result of the attraction of the residual positive charge of the hydrogen atom bonded to one electronegative atom for an unshared electron pair of the other atom.

The strongest hydrogen bonds are formed by fluorine ($[FHF]^{-}$, polymers of HF). The hydrogen bonds formed by water molecules are responsible for the surprisingly high melting point of ice and boiling point of water, for the existence of a maximum density of water and for the expansion of water on freezing (*see* ICE). Many special properties of inorganic and organic molecules. such as the dimerization of fatty acids, are caused by hydrogen-bond formation.

Metallic Valence.—The nature of the valence forces operating in metals, and especially in intermetallic compounds, had not been completely elucidated by the early 1960s. It seems certain. however, that metals and intermetallic compounds can be described as aggregates of metal cations bound together by valence electrons, which have considerable freedom of motion through the specimen, and it is reasonable to call the number of electrons of an atom that help to bind the metallic crystal together the "metallic valence" of the atom.

It is likely that the metallic valence of the alkali metals is 1, and that that of the alkaline-earth metals is 2. Values for the transition metals are uncertain, but their strength and hardness suggest values increasing from 3 for scandium to about 6 for chromium and succeeding elements, and then decreasing for copper and zinc. The magnetic properties of the rare-earth metals provide evidence that the metallic valence is 3 for all the rare-earth metals except europium and ytterbium, for which it is 2; the paramagnetic susceptibility of these two metals is the same as for their bivalent salts. whereas for the other rare-earth metals it is the same as for their tervalent salts.

Some progress has been made in systematizing the often complex formulas of intsrmetallic compounds such as y-brass, Cu_5Zn_8, and the compounds $Cu_{31}Sn_8$, Cu_9Al_4, Fe_5Zn_{21}, etc., which are related to it (*see* ALLOYS). It was pointed out (by A. Westgren and W. Hume-Rothery) that if the valences 1, 2, 3 and 4 are assigned to Cu. Zn, Ga and Sn, respectively, the formulas Cu_5Zn_8, Cu_9Ga_4 and $Cu_{31}Sn_8$ all correspond to the same ratio, $\frac{21}{13}$, of valence electrons to atoms; and a quantum-mechanical theory of the stability of these alloys in terms of electron waves was developed by H. Jones. An equivalent theory was formulated (by L. Pauling) with the use of another set of metallic valences, originally deduced from the ferromagnetic properties of the transition metals. These valences (5.44, 4.44, 3.44 and 2.44 for Cu, Zn, Ga and Sn, respectively) also lead to a constant value, $62\frac{7}{13}$, for the ratio of valence electrons to atoms in the y-alloys. with the formulas given above. Further progress toward a penetrating understanding of the nature of metals was needed before a firm choice between the metallic valences 1 and 5.44 for copper (and similar pairs of values for other transition elements) could be justified.

It is clear that valence does not play as great a part in determining the compositions of intermetallic compounds as it does for salts and organic compounds. Among the other factors of significan'ce for intermetallic compounds the relative sizes of atoms of different kinds is of greatest importance; many intermetallic compounds have compositions corresponding to modes of filling space with atoms of different sizes in such a way as to give each atom the maximum number of neighbours.

From the consideration of interatomic distances V. M. Goldschmidt was led to conclude that the metallic bond is closely related to the covalent bond. Gsually the number of neighbours of an atom in a metal or alloy is greater than its metallic valence, and the covalent bonds formed by the atom are considered to resonate among the interatomic positions.

VALENCIA, a maritime province of eastern Spain. Pop. (1960 est.) 1,440,761. Area. 4,156 sq.mi. When the ancient kingdom of Valencia was incorporated into Aragon in 1238, it included the provinces of Castellón de la Plana (*q.v.*) and Alicante. It was bounded on the north by Catalonia, west by Aragon and New Castile, and south by Murcia.

The inhabitants are of very mixed origin. because of the successive occupation of the country by Iberians. Greeks. Carthaginians, Romans. Visigoths and Moors. Their dialect resembles Catalan but is softer, and contains a larger percentage of Arabic words.

The elaborate irrigation works and the system of intensive agriculture which have rendered the *huertas* or gardens of Valencia celebrated were initiated by the Moors as were the Elche date groves, the Alicante vineyards and the Valencia orange plantations.

With the decline of the caliphate of Cordova early in the 11th century, Valencia became an independent kingdom which passed successively into the power of the Almoravides and Almohades.

In 1609, 200,000 Moriscos, or Moors who outwardly professed Christianity, were banished from the country. In 1833 Valencia was divided into the three provinces already named

The coast is skirted by considerable stretches of sand dune, and by a series of these the lagoon called the Albufera de Valencia is separated irom the Mediterranean. The principal rivers are the Guadalaviar or Turia and the Júcar (*q.v.*). Irrigation disputes are settled by the peasants' Tribunal de las Aguas.

The *vegas* ("cultivated plains") have an exceptionally fine, almost subtropical climate. In their low-lying portions rice is the favourite crop; elsewhere wheat, maize and all kinds of iruit; the mulberry is cultivated for silk; and wine and oil are produced. Esparto grass is grown in the less fertile areas. The fishing industry is considerable, and there are manufactures of silk, carpets and tapestry, woolen, hemp and linen fabrics, glass, pottery and leather; there are also iron foundries, distilleries, cooperages and oil refineries. The coast railway from Barcelona traverses the province.

Besides Valencia, the capital and principal seaport, some of the more important towns of the province are Sagunto, Alcira, Sueca, Játiva, Gandia, Carcagenta and Cullera. Other towns (mun. pops.) are Algemesi (17,789), Catarroja (11,296). Oliva (13,472), Liria (9,327), Tabernes de Valldigna (12,212) and Torrente (16,123).

VALENCIA, a town of Spain and the capital of the province of the same name. is situated on both banks of the river Turia, near the eastern coast, 3 mi. from the Mediterranean. The city has a temperate climate with mild winters. Pop. (1960 est.) 571,452.

All around the city stretches the Huerta de Valencia. a fertile plain with groves of oranges, lemons and mulberries. At the mouth of the Turia is the port of Villanueva del Grao, accessible by road and rail from Valencia. and along the coast are small villages and beautiful beaches. Separated from the sea by a narrow, pine-forested belt of land and 7 mi. S. of Valencia is the Albufera, Spain's biggest lake. Until 1871 Valencia was enclosed by a Roman wall rebuilt in 1356 by Pedro IV; two gateways, the Serranos and Cuarte towers; remain.

At the heart of the city, Caudillo square lies a little to the north of the northern station and the bull ring. On opposite sides of the square are the main post office and the town hall, which houses the municipal museum. The baroque-style building of the flower market is in the Caudillo square. A little farther to the north. the Plaza del Mercado is the site of the central market; with more than 1,000 market stalls, this is one of the biggest in Europe. St. John's church in the same square is typical of many Valencian baroque buildings and has frescoes by A. Palomino in the vault. The most beautiful building on the Plaza del Mercado, however, and classified as a national monument, is La Lonja. a Gothic building which was the silk exchange in the 15th century.

To the northeast stands,the cathedral called La Seo. This building. in various styles. was begun in 1262; the campanile (el hliguelete). an isolated octagonal Gothic tower, is 152 ft. in height. The cathedral has rich treasures including examples of 15th-century sculpture and a collection of paintings by Don Sebastián Llanos. Fernando Yáñez de la Almedina, Juan de Juanes (Vicente Juan Macip), Orente, and two large canvases by Goya. What is traditionally believed to be the chalice used at the Last Supper is the most precious treasure of the cathedral and has been kept there since the 15th century. In the vicinity of the cathedral stand the archbishop's palace, the basilica of the Virgin of the Desamparados and the palace of the Generalidad, with its fine Renaissance paneled ceilings.

To the east lies the Cruz de los Caldas, a circular plaza almost surrounded by gardens, one of which extends to the riverbank. The palace of justice, a neoclassic building of the 18th century erected originally as a customhouse, is to the south. Several roads radiate from the Cruz de Ios Caldas; of these, three lead directly to bridges over the river and one, the Calle de la Nave, leads to the Gniversity of Valencia and to the church and college of Corpus Christi which are close by. The university, which has a magnificent library including a valuable collection of manuscripts, was iounded about 1500. The Patriarca museum, which has some beautiful 15th-century Brussels tapestries and one of the finest collections of paintings in the city, is housed in the Royal College of Corpus Christi.

There are beautiful private gardens in the city as well as the public gardens of Yiveros, Moniortc, la Alameda, la Glorieta and Parterre. The Alameda is where the July fair and the iamous battle of the flowers are held. The botanic gardens on the river bank to the west were the first in Spain. Valencia is famous for its many colouriul festivals; the *fallas*, when bonfires are lit, takes place in March, and the procession of the Virgin of the Desamparados, during which flowers are thrown along the route, in May.

Communications **and Industry.**—Valencia is a centre of road anti rail communications for eastern Spain. Regular sea services operate between the town and other ports on the mainland and also between i'alencia and the Balearic Islands. There is an airport at hlanises, $7\frac{1}{2}$ mi. W. of the city. The industries of Valencia are many and varied, but the principal manufacture is silk for which the city has been famous from the 15th century. Other fabrics including linen and rayon are made. In addition to the big shipyards, Valencia has several heavy industries for the manuiacture of machinery and railway equipment; there are chemical and printing works. Fruit, rice and vegetables produced in the region are processed. Typically Spanish articles, such as fans and lace, are made for export, but Valencia is more particularly famous for its coloured tiles.

History.—The earliest mention of Valencia (I'alentia) is by Livy who states that the consul Decimus Junius Brutus settled the soldiers of Viriathus there in 138 B.C. Valencia sided with Quintus Sertorius. the Roman general, in his war against Pompey but was partially destroyed by Pompey in 75 B.C. It seems to have recovered speedily irom this setback for it was prosperous again under Augustus and was mentioned by Pliny as being a colony in the region of the Edetani. Yalencia was taken by the Yisigoths in A.D. 413. Three hundred years later (714) it was captured by the Moors and in 1021 it became the seat of the newly established independent Moorish kingdom oi Valencia which extended from Almería to the Ehro estuary. From 1089 until the final capitulation of the city in 1094 the kingdom was being fought for by the Cid (*q.v.*) who eventually secured it irom the Almoravides. It remained in the hands of the Cid, after whom the city is sometimes called Yalencia del Cid. He died there in 1099. The Moors recovered possession of the city in 1101. In 1238 James I of Aragon added Valencia to his dominions. In 1479 the kingdom of Valencia together with the thrones of Aragon, Catalonia and Majorca passed to Ferdinand II. son oi John II. king of Castile.

A long period of peace followed during which the city developed rapidly and the arts prospered. The first Spanish printing press is said to have been set up there in 1474 and during the next two centuries the city was the seat of the Valencian school of painting. In the War of the Spanish Succession the city took a stand in favour of the archduke Charles of Austria. It was captured by the French in 1812 and held till 1813. During the Spanish civil war Valencia was made the loyalist capital in Nov. 1936, but was captured by the nationalists in 1939. Industries have increased in number and importance during the 20th century. A mark oi the city's prosperity is the annual holding of an international samples fair during the first two weeks oi May.

VALENCIA, a city of Venezuela and capital of the state of Carabobo. is situated in a large basin between parallel ranges of the Central highlands. Lying at an elevation of 1.600 ft. above sea level, it has a generally pleasant and healthy climate. with an average temperature of 76° F. Valencia was founded in 1555. At the beginning of the war of independence the city was made the capital of Venezuela; it served as capital again in 1830 and in 1858 but each time the seat of national government returned to Caracas. The city came into its own only after 1910, following the eradication of malaria. It is strategically located as a converging point of highways for the states of Yaracuy, Falcón, Lara, Zulia. Cojedes, Portuguesa, Aragua, Barinas. and the Federal District. Accordingly, it has become one of the country's leading industrial centres. Despite much modern construction Valencia still retains the features of a Spanish city. Through the centuries it has survived sacking, fires, earthquakes, epidemics and economic upheavals. Valencia is the centre of the country's most developed agricultural region and of its cattle business.

Not far from the city is the 100 sq.mi. Lake Valencia, a shallow lake bordered by a marshy lacustrine plain which provides fattening pastures for cattle from the Llanos. Pop. (1961) 161,313. (L. WE.)

VALENCIA or VALENTIA, an island in County Kerry. Ire., forming the southern horn of Dingle bay. It is 7 mi. long and 3 mi. broad. with hills to the west and north. The channel separating it from the mainland forms a fine natural harbour with narrow entrances and a depth of about 40 ft. at low tide. A ferry connects Knightstown on the island with the railway terminus on the mainland. The harbour is used only by fishing boats. Peasant farming and fishing are the main occupations. An important meteorological station is maintained on the island and it is the terminus for transatlantic cables. Pop. (1956) 971. (T. HER.)

VALENCIENNES, a town of northern France. Population (1954) 42,214. Valenciennes is said to owe its name and foundation to one of the three Roman emperors named Yalentinian. In the middle ages it was the seat of a countship which in the 11th century was united to that of Hainaut. In the 16th century Valenciennes became the stronghold of Protestantism in Hainaut, but was conquered by the Spaniards. In 1656 the Spaniards under the prince of Condé made a successful defense against the French under Vicomte de Turenne; but. in 1677 Louis XIV took the town and Vauban constructed the citadel. Valenciennes, which then became the capital of Hainaut, has since always belonged to France. In 1793, after 43 days' bombardment, the garrison surrendered to the allied forces. In 181j it defended itself successfully.

The Scheldt there divides into two branches, one of which flows through the town, while the other, canalized and forming a port, skirts it on the west. The Tour de la Dodenne (13th and 15th centuries) and the citadel (17th century) are the chief remains of the old fortifications. The town hall is early 17th century, with a 19th-century façade. The museum contains a good collection of paintings. Valenciennes is the centre of the rich Anzin coal field. There are important ioundries, forges, rolling mills, wireworks and machine shops. There is also an extensive sugar-beet cultivation, with attendant sugarworks and distilleries, and glass, starch, chemicals and soap are produced. Hosiery, trimmings and handkerchiefs are manuiactured and cotton weaving and printing are carried on, though little of the iamous lace is now made.

VALENCY: see VALENCE.

VALENS, East Roman emperor from 364 to 378, owed his elevation in the 36th year of his age to his brother, Valentinian. who chose him to be his associate in the empire. Valens had been attached to Julian's bodyguard. but he did not inherit the military ability of his father. Gratian of Pannonia. A revolt headed by Procopius in the second year of his reign was quelled by the ability of his generals. In the year 366 Valens at one stroke reduced the taxes of the empire by one-fourth, a very popular measure. though one of questionable policy in the' face of the threatening attitude of the Goths on the lower Danube. Before venturing on a campaign against them, Valens received baptism from Eudoxus, the Arian bishop of Constantinople. After some small successes over the Goths. won by his generals (367–369), Valens concluded a peace with them. which lasted six years, on a general understanding that the Danube was to be the boundary betn-een Goths and Romans. On his return to Constantinople in 369–370 Valens began to persecute his orthodox and Catholic subjects, but he lacked the energy to carry out his edicts.

In the years 371 to 377 Valens was in Asia Minor, most of the time at the Syrian Antioch. Though anxious to avoid an Eastern war, because of danger nearer home from the Goths, he was compelled to take the field against Shapur II. Valens crossed the Euphrates in 373, and drove back the king of Persia to the iarther bank of the Tigris. But the Roman success n-as by no means decisive, and no definite understanding as to boundaries was come to with Persia. Valens returned to Antioch, where in the winter of 373–374 he instituted a persecution of magicians. Between 374 and 377 we read of grievous complaints of injustice and extortion perpetrated under legal forms. Although preparations were made for following up the war with Persia and securing the frontier, a truce was patched up, rather to the disadvantage of the empire, Armenia and the adjacent country being half conquered and annesed by Shapur. The armies of Rome, in fact, were wanted in another quarter. The Huns, of whom me now hear for the first time. were beginning in 376 to press the Goths from the north, and the latter asked leave of the emperor to cross the Danube into Roman territory. This they were allowed to do, on the condition that they came unarmed, and their children were transported to Asia as hostages. The conditions, however, were not observed by the imperial generals. Accordingly, the enraged Goths, under their chief Fritigern, streamed across the Balkans into Thrace and the country round Adrianople, plundering, burning and slaughtering as they went. They were driven back for a time, but returned in the spring of 378 in greater force! with a contingent of Huns and Alans and penetrated to the neighbourhood of Adrianople. Valens left Constantinople in May 378 with a strong and well-officered army. Without awaiting the arrival of his nephew Gratian, emperor of the West, who had just won a great victory over the Alamanni, Valens attacked the enemy at once. The battle, which was fought on confined ground in a valley, was decided by a cavalry charge of the Alans and Sarmatians, which threw the Roman infantry into confusion and hemmed it in so closely that the men could scarcely draw their swords. The slaughter, which completely destroyed the Roman army, was one of the greatest recorded in antiquity. Valens perished either on the field or, as some said, in a cottage fired by the enemy. From the battle of Adrianople the Goths permanently established themselves south of the Danube.

VALENTIN, LE (JEAN DE BOULOGNE) (1594–1632), French painter. who settled in Rome as a young man and became one of the followers of Caravaggio, was born at Coulommiers in 1594. The works of the Caravaggesque artists were very popular with private collectors during the first two decades of the 17th century, but Yalentin was one of the few who continued the manner in Rome after 1620. when the Bolognese and full baroque styles came into favour. He chose to exploit the more obvious aspects of Caravaggio's style and subject matter; that is to say, the picaresque figures, the scenes of gaming, feasting and violence, the strong, dramatic lighting with its heavy shadows and the coarse realism. But he lacked Caravaggio's depth of feeling and his economy and concentration. as well as his range of subject matter.

Like other Caravaggesque painters, Valentin worked exclusively in oil colours on canvas. never in fresco. He rarely painted pictures for churches. so that most of his output is now in museums or in private hands. He died in Rome on Aug. 20, 1632.

See H. Voss, *Die Malerei des Barock in Rom* (1924); R. Longhi; "Apropos de Valentin," *Revue des Arts,* 8:58–66 (1958). (M. W. L. K.)

VALENTINE, SAINT. The feast of St. Valentine on Feb. 14 seems to be intended to commemorate two saints of the same name. According to legend, one was a Roman priest who suffered martyrdom during the persecution of the emperor Claudius and was buried on the Flaminian way, and the other a bishop of Interamna (Terni), who was martyred apparently also in Rome, and whose relics were later translated to Terni.

In their present form the acts of both martyrdoms are legendary, but they seem to be based on a historical foundation. It is possible that they may actually be different developments of the same original account and refer only to one person. St. Yalentine's day as a lovers' festival, the choice of a valentine and the modern development of sending valentine cards has no relation to the saint or to any incident in his life. These customs seem rather to be connected either with the pagan Roman festival of the Lupercalia which took place in the middle of February, or with the spring season in general.

See E. M. Fusciardi, *Vita di S. Valentino* (1936). (H. C. G.)

VALENTINIAN I, Roman emperor of the West from A.D. 364 to 375, was born at Cibalis, in Pannonia. He had been an officer of the guard under Julian and Jovian, and had risen high in the imperial service. He was chosen emperor in his forty-third year by the officers of the army at Nicaea in Bithynia in 364, and shortly afterwards named his brother Valens (*q.v.*) colleague with him in the empire. As emperor of the West, Valentinian took Italy, Illyricum, Spain, the Gauls, Britain and Africa, leaving to Valens the eastern half of the Balkan Peninsula, Greece, Egypt, Syria and Asia Minor as far as Persia. During the short reign of Valentinian there were wars in Africa, in Germany and in Britain, and Rome came into collision with the Burgundians, Saxons and Alamanni. The emperor's chief work was guarding the frontiers and establishing military positions. Milan was at first his headquarters for settling the affairs of northern Italy; next year (365) he was at Paris, and then at Reims, to direct the operations of his generals against the Alamanni who were driven back to the German bank of the Rhine, and checked for a while by a chain of military posts and fortresses. At the close of 367, however, they suddenly crossed the Rhine, and sacked Moguntiacum (Mainz). Valentinian attacked them at Solicinium (Sulz in the Neckar valley or Schwetzingen) with a large army, and defeated them with considerable loss on his own part. (Later, in 374, he made peace with their king, Macrianus.) The next three years he spent at Trier, which he chiefly made his headquarters, organizing the defence of the Rhine frontier.

During his reign the coasts of Gaul were harassed by the Saxon pirates, with whom the Picts and Scots of northern Britain joined hands, and ravaged the island from the wall of Antoninus to the shores of Kent. In 368 Theodosius was sent to drive back the invaders; in this he was completely successful, and established a new British province, called Valentia. In Africa the Moorish prince, Firmus, raised the standard of revolt against Count Romanus, the military governor. The services of Theodosius were again requisitioned. He landed in Africa with a small band of veterans, and Firmus, to avoid being taken prisoner, committed suicide. In 374 the Quadi, a German tribe in what is now Moravia and Hungary, resenting the erection of Roman forts to the north of the Danube, and further exasperated by the treacherous murder of their king, Gabinius, crossed the river and laid waste the province of Pannonia. The emperor, in April of the following year, entered Illyricum with a powerful army, but during an audience to an embassy from the Quadi at Brigetio on the Danube (near Pressburg) died in a fit of apoplexy.

Valentinian's general administration seems to have been thoroughly honest and able, in some respects beneficent. If he was hard and exacting in the matter of taxes, he spent them in the defence and improvement of his dominions. Though himself a plain and almost illiterate soldier, he was a founder of schools, and he also provided medical attendance for the poor of Rome, by appointing a physician for each of the fourteen districts of the city. He was an orthodox Catholic, but he permitted absolute religious freedom to all his subjects. The great blot on his memory is his cruelty, which at times was frightful.

VALENTINIAN II., son of the above, an infant of four in 375 with his half-brother Gratian (*q.v.*) a lad of about seventeen, became the emperors of the West. They made Milan their home; and the empire was nominally divided between them, Gratian taking the trans-Alpine provinces, whilst Italy, Illyricum in part, and Africa were to be under the rule of Valentinian, or rather of his mother, Justina. In 387 Magnus Maximus (*q.v.*), who had in 383 overthrown Gratian and made himself master of the northern provinces, crossed the Alps and threatened Milan. The emperor and his mother fled to Theodosius, the emperor of the East. Valentinian was restored in 388 by Theodosius. Four years later he was murdered at Vienne in Gaul, probably at the instigation of his Frankish general Arbogast.

VALENTINIAN III., emperor of the West from 425 to 455, the son of Constantius and Placidia. He was only six years of age when he ascended the throne, and during his minority the conduct of affairs was in the hands of his mother. His reign is marked by the dismemberment of the Western Empire; the conquest of the province of Africa by the Vandals in 439; the loss of great portions of Spain and Gaul, in which the barbarians had established themselves; and the ravaging of Sicily and of the western coasts of the Mediterranean by the fleets of Genseric. As a set-off against these calamities there was the great victory of Aetius over Attila in 451 near Châlons, and his successful campaigns against the Visigoths in southern Gaul (426, 429, 436), and against various invaders on the Rhine and Danube (428–31). Ravenna was Valentinian's usual residence; but he fled to Rome on the approach of Attila, who ravaged North Italy in 452. In 454 Aetius was treacherously murdered by Valentinian. Next year, however, the emperor himself was assassinated by two of the barbarian followers of Aëtius. He was self-indulgent, incompetent, and vindictive.

VALENTINO, RUDOLPH (RODOLPHO ALFONZO RAFFAELO PIERRE FILIBERT GUGLIELMI DI VALENTINA D'ANTONGUOLLA) (1895–1926), motion-picture actor, was born in Italy on May 6, 1895. He went to the United States in 1913 and worked there for a time as a landscape gardener and dishwasher, later becoming established as a professional dancer in vaudeville. In 1918 he went to Hollynood, where he played small parts in films but with little success. Through the intervention of June Mathis, scenario writer, he was given the role of Julio in *The Four Horsemen of the Apocalypse* (1921). He immediately became a star. Darkly handsome in appearance, he received enormous acclaim for his romantic portrayals. As Frederick Lewis Allen commented (in *Only Yesterday*, New York: Harper & Brothers, 1931), "With his sideburns and his passionate air, [Valentino] ... set the standard for masculine sex appeal."

His films included *The Sheik* (1921), *Blood and Sand* (1922), *The Young Rajah* (1922), *Moran of the Lady Letty* (1922), *Monsieur Beaucaire* (1924), *A Sainted Devil* (1924), *Cobra* (1925), *The Eagle* (1925) and *The Son of the Sheik* (1926).

Valentino died in New York city, on Aug. 23, 1926; his lying in state, managed by skillful press agents, attracted an 11-block-long crowd. (M. S. BY.)

VALENTINUS (d. 827) was pope for about 40 days in Aug. and Sept. 827, between Eugenius II and Gregory IV. A Roman by birth, he had become archdeacon under Paschal I, and was beloved for his goodness. Nothing is known of his pontificate.

VALENTINUS and **THE VALENTINIANS.** Valentinus, the most prominent leader of the Gnostic movement, was born, according to Epiphanius (*Haer.* 31, 2), near the coast in Lower Egypt, and was brought up and educated in Alexandria. Valentinus came to Rome (c. 135–160) during the episcopate of Hyginus, flourished under Pius and stayed till the time of Anicetus. According to Irenaeus iii. 3, 4, Polycarp, during his sojourn in Rome under the episcopate of Anicetus, converted a few adherents of the Valentinian sect. Tertullian (*Adv. Valentin.* cap. 4) declares that Valentinus came to Rome as an adherent of the orthodox Church, and was a candidate for the bishopric of Rome, but he abandoned the Church because a confessor was preferred to him for this office. The credibility of this statement may be questioned. Great uncertainty attaches to the residence of Valentinus in Cyprus, recorded by Epiphanius (*loc. cit.*), who places it after his stay in Rome, adding that it was here that he definitely accomplished his secession from the Church. But it seems to be clear that Valentinus did not, like Marcion, break with the Church from the very beginning, but endeavoured to maintain his standing within it.

Justin's *Syntagma*, which treats of Valentinus, is unfortunately lost. Irenaeus, *Adversus Haereses*, i. 11, 1–3, as in every other article where named, has preserved what is obviously an older document, possibly from Justin, dealing with Valentinus's own teaching and that of two of his disciples. The sketch which he gives is the best guide for the original form of Valentinianism. For Valentinus himself we have also to consider the fragments of his writings preserved by Clement of Alexandria. The best edition of and commentary on them is Hilgenfeld's *Ketzergeschichte des Urchristentums* (pp. 293–307). Irenaeus also gives a detailed account of the two chief schools following Valentinus, the school of Ptolemaeus (i. 1–10), and Marcus and the Marcosians (i. 13–21). For his account of the Ptolemaeans, Irenaeus seems to have used various writings and expositions of the school, especially prominent being a collection of Scripture proofs which may have once had a separate literary existence (i. 1, 3; 3, 1–5 [6]; 8, 2–4). To this is appended in a somewhat disconnected fashion a commentary on the prologue to the fourth Gospel (i. 8, 5). Irenaeus himself twice prefaces his remarks by saying he is indebted to other authorities for his exposition (i. 2, 3–4; 7, 2–5). *Excerpta ex Theodoto* which are to be found in the works of Clement and may be looked upon as a collection made by the author with a view to the unfinished eighth book of his *Stromateis*. The lost *Syntagma* of Hippolytus, which can be partially reconstructed from Philaster (*Haereses*) and from pseudo-Tertullian (*Adversus Valentini anos*), seems to furnish us with valuable information as to the earlier doctrines of the sect; and in his second treatise against heretics, the so-called *Philosophumena* (6, 29 *seq.*), Hippolytus gives a homogeneous and continuous exposition of a later Valentinian system, possibly connected with the school of Ptolemaeus. Important, too, are Hippolytus' references to an Italic and an Anatolian branch of the Valentinian sect (6, 35). Tertullian gives at the beginning of his treatise against the Valentinians a few separate notices of the life and disciples of Valentinus, but his further argument is closely dependent upon Irenaeus' exposition of the Ptolemaean system, which he embellishes in his usual fashion with bitterly sarcastic comments. Epiphanius deals with Valentinus and his school in sections 31–36 of his work. He has preserved a valuable letter of Ptolemaeus to Flora, which is of the highest importance for the understanding of Gnosticism.

Valentinus is the only one of the Gnostics who had a whole series of disciples who are known by name—indeed, in the accounts of the Church Fathers his own system and views are almost entirely obscured by the accounts of those of his disciples. The most important disciples are the two dealt with at length by Irenaeus, Ptolemaeus and Marcus, who both seem to have had a numerous following. Also, there was Herakleon, of whose commentary on the gospel of St. John extensive fragments are preserved by Origen. Ptolemaeus and Herakleon are counted by Hippolytus (6, 35) among the Italic branch of Valentinianism. There was also the Anatolian branch, as representative of which Hippolytus mentions Axionicus, who is also referred to by Tertullian as having actually been taught in Antioch. The *Excerpta ex Theodoto* in Clement are also, according to the superscription, fragments from the Anatolian Gnosticism. It is, however, an error when Hippolytus speaks of Bardesanes as representative of this branch, for he had an entirely distinct position. Valentinianism was based on primitive gnosticism (*q.v.*), with the doctrines of which Valentinus may have become acquainted in Egypt. The mother goddess stands at the centre of the system. The main doctrines are outlined below.

(1) Valentinus has a system of thirty aeons, but the quite shadowy plurality of ten and twelve aeons (the *Dekas* and the *Dodekas)* of the Valentinian system we may at once set aside as mere fantastical accretions. We have left only a group of eight celestial beings, the so-called Ogdoas, and of these eight figures four again are peculiar to this system.

(2) The first pair of aeons, *Bythos* and *Sige,* is an original innovation of the Valentinian school, and clearly betrays a monistic tendency. According to Irenaeus's account of the "Gnostics" (i. 29), their theory was that *Sophia* casts herself into the primal substratum of matter *(Bythos)* to be found outside the celestial world of aeons. But in the Valentinian system matter is not originally and irretrievably separated from the higher celestial world, but the latter originally exists for itself alone; the fall or disturbance is accomplished within the celestial world, and the material world first comes into existence through the fall.

(3) There remain a double pair of aeons, the Father and Truth, the *Anthropos* and the *Ekklesia.* With the celestial Primal Man—of whom the myth originally relates that he has sunk into matter and then raised himself up from it again—is associated the community of the faithful and the redeemed, who are to share the same fate with him.

(4) In the true Valentinian system the so-called *Christos* is the son of the fallen Aeon, who is thus conceived as an individual. *Sophia,* who in a frenzy of love had sought to draw near to the unattainable *Bythos,* brings forth, through her longing for that higher being, an aeon who is higher and purer than herself, and at once rises into the celestial worlds. Among the Gnostics of Irenaeus we find a kindred conception, but with a slight difference. Here *Christos* and *Sophia* appear as brother and sister, *Christos* representing the higher and *Sophia* the lower element. In the enigmatic figure of *Christos* we again find hidden the original conception of the Primal Man, who sinks down into matter but rises again. (In the later Valentinian systems this origin of the *Christos* is entirely obscured, and Christ, together with the Holy Spirit, becomes a later offspring of the celestial world of aeons; this may be looked upon as an approximation to the Christian dogma)

(5) A figure entirely peculiar to Valentinian Gnosticism is that of *Horos* (the Limiter). The name is perhaps an echo of the Egyptian *Horus.* The peculiar task of *Horos* is to separate the fallen aeons from the upper world of aeons. He becomes a kind of world-creative power, who in this capacity helps to construct an ordered world out of *Sophia* and her passions. He is also called, curiously enough, *Stauros* (cross), and we frequently meet with references to the figure of *Stauros.* But we must not be in too great a hurry to assume that this is a Christian figure. A Platonic conception may have been at work here. The cross can also stand for the wondrous aeon on whom depends the ordering and life of the world, and thus *Horos-Stauros* appears here as the first redeemer of *Sophia* from her passions, and as the orderer of the creation of the world which now begins. The figure of *Horos-Stauros* was often assimilated to that of the Christian Redeemer.

(6) The dualism of the two separate worlds of light and darkness was thus overcome. This derivation of the material world from the passions of the fallen *Sophia* is, however, affected by an older theory according to which the son of *Sophia,* whom she forms on the model of the *Christos* who has disappeared in the higher heavens, becomes the *Demiourgos,* who with his angels now appears as the real world-creative power. These two conceptions had now to be combined at all costs. And it is interesting to observe here what efforts were made to give the *Demiourgos* a better position. According to the older conception, he was an imperfect, ignorant, half-evil and malicious offspring of his mother, who has already been deprived of any particle of light (Irenaeus i. *29,* 30). In the Valentinian systems he appears as the fruit of *Sophia's* repentance and conversion. He is no longer called *Jaldabaoth,* but has been assigned the better name, drawn from the philosophy of Plato, of *Demiourgos.* The *Demiourgos* of the Gnostic corresponded to the God of the Old Testament, which again suggests a compromise with the Christian faith

(7) With the doctrine of the creation of the world is connected the subject of the creation of man. We fortunately know, from a fragment preserved by Clement, that Valentinus here preserved the old Gnostic myth practically unaltered in his system. According to it, the world-creating angels—not one, but many—create man, but the seed of the spirit comes into their creature without their knowledge, by the agency of a higher celestial aeon, and they are then terrified by the faculty of speech by which their creature rises above them, and try to destroy him. A definite Valentinian idea is here added in that of the threefold nature of man, who is represented as at once spiritual, psychical and material. In accordance with this there also arise three classes of men, the *pneumatici,* the *psychici* and the *hylici* (ὕλη, matter). All the other Gnostic systems recognize only a dual division, the children of light and the children of darkness. That the Valentinians should have placed the *psychici* between the *pneumatici* and *hylici* signifies a certain recognition of the Christian Church and its adherents who are not treated as outcasts.

(8) At the centre of the whole Valentinian system naturally stands the idea of redemption, and so we find here developed particularly clearly the myth of the heavenly marriage already known from Irenaeus i. 30 to be Gnostic. Redemption is essentially accomplished through the union of the heavenly *Soter* with the fallen *Sophia.* This myth of the redeemer is of significance for the practical piety of the Valentinian Gnostics. It is the chief idea of their pious practices mystically to repeat the experience of this celestial union of the *Soter* with *Sophia.* In this respect, consequently, the myth underwent yet wider development. Just as the *Soter* is the bridegroom of *Sophia,* so the heavenly angels, who sometimes appear as the sons of the *Soter* and *Sophia,* sometimes as the escort of the *Soter,* are the males betrothed to the souls of the Gnostics, which are looked upon as feminine. Thus every Gnostic had his angel standing in the presence of God, and the object of a pious life was to bring about and experience this inner union with the celestial abstract personage. This leads us straight to the sacramental ideas of this branch of Gnosticism.

(9) With this celestial *Soter* of the Valentinians and the redemption of *Sophia* is connected the figure of Jesus of Nazareth and the historical redemption connected with his name. The *Soter,* the bridegroom of Sophia, and the earthly Jesus answer to each other as in some way identical. Here again we recognize the artificial compromise between Gnosticism and Christianity.

(10) The Valentinians laid down that even the Redeemer has a threefold nature; from his mother, Sophia, he derived his

nature as a *pneumaticos,* in the world of the Demiourgos he was united with the Christos, and finally a wonderful bodily nature was formed for him from celestial elements, which was yet not of earthly material. As such he was miraculously born of the Virgin. The compromises with the Catholic Church are here obvious. Also, there was the idea that upon this Jesus, so constituted, yet another celestial nature, the Christos or the Soter, has descended at his baptism.

The first survey of these confused speculations, these myths gathered together and preserved from the ancient world, this marshalling together of the most varied traditions, and above all, these artificial attempts at compromise, makes us inclined to doubt whether it was possible for any true piety to coexist with all this. Yet such piety existed; indeed we have here a set of regular mystics. It is not, indeed, a purely spiritual and mystical piety, but a mysticism much distorted and over-grown with sacramental additions and a mysterious cult. But all this is not without an inner value and an attractive atmosphere. In a letter in Clement ii. 20, 114, Valentinus sets forth that the soul of man is like an inn, which is inhabited by many evil spirits. "But when the Father, who alone is good, looks down and around him, then the soul is hallowed and lies in full light, and so he who has such a heart as this is to be called happy, for he shall behold God."

But with this mysticism is connected the mystery and cult of the sacrament. The lofty spirituality of the Gnostic degenerates over and over again into a distinctly material and sensual attitude, in which all kinds of efforts are made actually to assimilate to oneself the divine through external means.

The chief sacrament of the Valentinians seems to have been that of the bridal chamber. Just as the apostle Paul represented his Christianity as a living, dying and rising again with Christ, so the first concern of the pious Valentinian was the experience of the divine marriage feast of Sophia. As Sophia was united with the Soter, her bridegroom, so the faithful would experience a union with their angel in heaven. Through a fortunate chance, a liturgical formula which was used at this sacrament appears to be preserved. It runs: "I will confer my favour upon thee, for the father of all sees thine angel ever before his face . . . we must now become as one; receive now this grace from me and through me; deck thyself as a bride who awaits her bridegroom, that thou mayest become as I am, and I as thou art. Let the seed of light descend into thy bridal chamber; receive the bridegroom and give place to him, and open thine arms to embrace him. Behold, grace has descended upon thee."

Besides this the Gnostics already practised baptism, using the same form in all essentials as that of the Christian Church. The name given to baptism was *apolytrosis* (liberation). In one of the formulae occur the words: "I would enjoy thy name, Saviour of Truth" The concluding formula of the baptismal ceremony is: "Peace over all upon whom the Name rests" (Irenaeus i. 21, 3). This name pronounced at baptism over the faithful has above all the significance that the name will protect the soul in its ascent through the heavens, conduct it safely through all hostile powers to the lower heavens, and procure it access to Horos, who frightens back the lower souls by his magic word.

Here and there a reaction took place against the absurdity of this sacramental superstition. Thus Irenaeus (i. 21, 4) tells us of certain Gnostics who would admit no external holy practices as efficacious. A pure piety breathes in the words of the Gnostics preserved in *excerpta ex Theodofo,* 78, 2: "But not baptism alone sets us free, but knowledge *(gnosis)*: who we were, what we have become, where we were, whither we have sunk, whither we hasten, whence we are redeemed, what is birth and what rebirth."

We have seen that Valentinian Gnosticism affected the nearest approach of all the Gnostic sects to the Catholic Church. Valentinus's own life indicates that he for a long time sought to remain within the official Church, and had at first no idea of founding a community of his own.

And yet this reconciliation of Gnosticism was a fruitless and henceforward a purposeless undertaking. Oriental dualism and wildly intemperate Oriental mythology had grown into so radical and essential a part of Gnosticism that they could not be separated from it to make way for a purer and more spiritual view of religion. And at a time when the prevailing tendency of Christianity was a struggle out of the darkness of Oriental mythology and eschatology into clearness, and an effort towards union with the lucid simplicity of the Hellenic spirit, these Gnostics, for all their efforts, and even the most noble of them, had come too late. They are not the men of a forward movement, but they are, and remain, in spite of all clearer insight, the rear-guard of piety.

See Bibliography to article GNOSTICISM.

VALENZUELA, FERNANDO DE (1636–1692), Spanish royal favourite, was born at Naples where he was baptized on Jan. 17, 1636. He gained influence at the Spanish court by his marriage with a lady in waiting to Mariana, Philip IV's second wife. When he was appointed introducer of ambassadors (Oct. 12, 1671), it became notorious that whoever had a petition to present must apply to him. He became popularly known as the *duende*, the fairy or brownie of the palace, and was believed to be the lover of the queen. Dismissed (1675) from court by intrigue, he was made marquis of Villa Sierra by the queen and ambassador to Venice. He exchanged the embassy for the governorship of Granada, organized a counterintrigue and returned to court. The queen-regent appointed him prime minister and made him a grandee, to the profound indignation of the other grandees. At the palace revolution of Jan. 1678, Valenzuela fled to the Escorial, was captured, degraded from the grandeeship, exiled to the Philippines and his property confiscated. He died in Mexico on Feb. 7, 1692.

See *Documentos inditos para la historia de España,* vol. lxvii *(1842 et seq.).*

VALERA Y ALCALA GALIANO, JUAN (1824–1905), Spanish novelist, entered diplomacy in 1847 and became unpaid attaché to the Spanish embassy at Naples under the famous duke de Rivas. He held various other diplomatic posts until 1858 when he returned to Spain and entered the House of Deputies, taking his place with the Liberal opposition. On the flight of Isabella II. in 1868 he was elected deputy for Montilla in the province of Cordova, became under-secretary of state for foreign affairs, and was one of the deputation who offered the crown to Amadeus of Savoy in the Pitti Palace at Florence. Though he always called himself a Moderate Liberal, Valera invariably voted for what are considered Radical measures in Spain, and a speech delivered by him in Feb. 1863 against the temporal power of the pope created a profound sensation. However, though a member of the revolutionary party, he steadily opposed organic constitutional changes, and therefore he retired from public life during the period of republican government. After the Bourbon restoration he acted as minister at Lisbon (1881–83), at Washington (1885), at Brussels (1886) and as ambassador at Vienna (1893–95), retiring from the diplomatic service on March 5, 1896. During his last ten years he took no active part in politics.

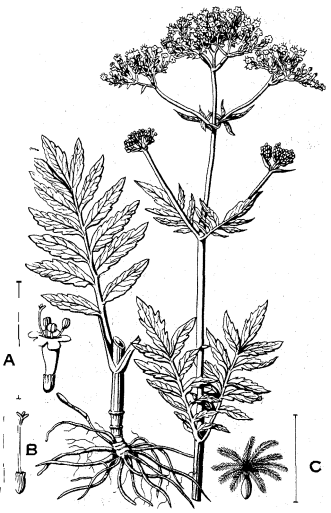
Valera's *Poesias* (1858) are imitative exercises rather than original poetry. His criticism in the *Estudios criticos sobre literatura* (1864), in the *Disertaciones* y *juicios literarios* (1878) and in the *Nuevos estudios criticos* (1888) show penetration and taste, but also an excessive amiability. He said a hundred incisive, wise, witty, subtle and suggestive things concerning the mysticism of St. Theresa, the art of novel-writing, *Faust*, the Inquisition, *Don Quixote,* Shakespeare, the psychology of love in literature; but, to do himself justice, it was an almost indispensable condition that he should deal with the past. In the presence of a living author Valera was disarmed

When in his 50th year, he published *Pepita Jiménez* (1874) a recital of the fall of Luis de Vargas, a seminarist who conceived himself to be a mystic and a potential saint, and whose aspirations dissolve at the first contact with reality. It is easy to point out blemishes: the story is not well constructed, and it has pauses during which the writer's fantasy plays at pleasure over a hundred subjects not very germane to the matter; but its characters are as real as any in fiction, the love story is told with the most refined subtlety and malicious truth, while page upon page is written in such Spanish as would do credit to the best writers of the 16th and 17th centuries. A second novel, *Las ilusiones del Doctor Faustino* (1875), was received with marked disfavour, and has the faults of over-refinement and of cruelty; yet in keen analysis and in humour it surpasses *Pepita Jiménez.* The *Comendador Mendoza* (1877) is more pathetic and of a profounder significance; and if *Doña Luz* (1879) repeats the situation and the general idea already used in *Pepita Jiménez* it strikes a deeper and more tragic note, which came as a surprise to those familiar only with the lighter side of Valera's genius. Besides these elaborate psychological studies, Valera issued a volume of *Cuentos* (1887), some of these short tales and dialogues being marvels of art and of insight.

At the close of the 19th century Valera was recognized as the most eminent man of letters in Spain. He had not Pereda's force nor his energetic realism; he had not the copious invention nor the reforming purpose of Pérez Galdós; yet he was as realistic as the former and as innovating as the latter. And. for all his cosmopolitan spirit, he fortunately remained intensely and incorrigibly Spanish. His aristocratic scepticism, his strange elusiveness, his incomparable charm are his own; his humour, his flashing irony, his urbanity are eminently the gifts of his land and race. He is by no means an impersonal artist; in almost every story there is at least one character who talks and thinks and subtilizes and refines as Valera himself wrote in his most brilliant essays. This may be a fault in art; but, if so, it is a fault which many great artists have committed. (J. F.-K.)

VALERIAN, common name of any of the genus *Valeriana,* herbaceous perennial plants of the family Valerianaceae, widely distributed in temperate regions of North America, Europe and Asia. The genus comprises about 175 species. native to Europe or Asia; two species, *Valeriana officianalis* and *V. dioica,* are indigenous to Britain. Common valerian (*V. officianalis*), or garden heliotrope, is cultivated in the United States! Britain and western Europe for the medicinal uses of the root, which acts as a sedative and carminative.

The valerians have opposite leaves and small, very fragrant flowers! usually white or reddish, and arranged in terminal cymes. The limb of the calyx is remarkable for being at first inrolled and afterward expanding in the form of a feathery pappus which aids in the dissemination of the fruit. The dried root or rhizome consists of a short, central, erect portion, about the thickness of the little finger, surrounded by numerous rootlets about 0.1 in. in diameter, the whole being of a dull brown colour. When first taken from the ground it has no distinctive smell, but on drying it acquires a powerful odour of valeric acid.



VALERIAN (VALERIANA OFFICINALIS) ONE-THIRD NATURAL SIZE
(A) Flower; (B) flower after removal of corolla; (C) fruit crowned by the feathery pappus (A,B, & C enlarged)

This odour, which is now regarded as offensive, was in the 16th century considered to be fragrant, the root being placed among clothes as a perfume. just as V. *celtica* and other species are still used in the east.

The ornamental Jupiter's beard or red valerian of gardens is *Centranthus ruber,* also belonging to the Valerianaceae; but Greek valerian or Jacob's-ladder is *Polemonium caeruleum,* belonging to the family Polemoniaceae. and introduced from Eurasia to the northeastern C.S. and southern Canada. Cats are fond or' the smell of this plant. as they are of the true valerian. and will frequently roll on the plant and injure it. Valerian thrives in a rich, loamy, moist soil.

The chief constituent of valerian is a volatile oil, which is present in the dried root to the extent of 1% to 2% and is responsible for its medicinal properties.

The oil is of complex composition, containing valeric (valerianic), formic and acetic acids combined with terpene; the alcohol known as borneol; and pinene.

VALERIANUS, PUBLIUS LICINIUS, Roman emperor from A.D. 253 to 260. He was of noble family, and in 238 was *princeps senatus.* In 251, when Decius revived the censorship with practically supreme civil authority, Valerian filled the post. Gallus, the successor of Decius, summoned him from the upper Rhine in 253 when threatened by the rebellion of Acmilianus. The soldiers, however, proclaimed Valerian emperor, and marching slowly towards Rome he found both his rivals dead, slain by their own soldiers. Trouble on the frontiers east and west was complicated by something near national bankruptcy. Valerian left his son, Gallienus, in charge of the wars in Europe; and took the offensive against the Goths, recaptured Antioch and marched to relieve Edessa.

He was defeated and taken prisoner, and disappears from history (258).

VALERIUS FLACCUS, GAIUS (fl. 1st century A.D.), Latin epic poet, was the author of an *Argonautica.* Very little is known of his life, but he must have died about A.D. 90 since he is mentioned by Quintilian who says of him in his *Institutio oratoria,* published between 93 and 95, that his recent death was a great loss. Valerius' own reference to the Jewish war of Titus shows that he was writing after A.D. 70, and as he also mentions the eruption of Vesuvius he must have been alive after A.D. 79.

The *Argonautica* is the only work of his that survives. It is an epic poem in hexameter verse, and is dedicated to the emperor Vespasian. It describes the famous voyage of the ship "Argo" in which Jason and other heroes sailed to Colchis to bring back the golden fleece to Thessaly. The first four books deal with the adventures of the Argonauts on their voyage, the story of the Lemnian women, the battle at Cyzicus, the loss of Hylas and departure of Hercules, and others. In the fifth book they arrive at Colchis and Jason meets Medea. She falls in love with him and helps him to sow the dragon's teeth and steal the fleece. He then takes her off with him on the "Argo." Soon after this the poem breaks off abruptly. in the eighth book.

Valerius clearly borrowed material from the *Argonautica* of the Alexandrian poet Apollonius Rhodius (fl. *c.* 200 B.C.); and for his style and treatment he was deeply indebted to Virgil, though his Medea is a much gentler and less passionate figure than Dido. His work is free from some of the vices of Silver Latin epic poetry, such as display of erudition and exaggerated rhetoric, and the great 17th-century scholar, Nikolaes Heinsius, admired it. To the modern reader it seems less poetic than the best of Statius and less powerful than the best of Lucan, but it is a good narrative, in simple and direct language, which shows distinct dramatic talent.

The *Argonautica* was unknown until the first four and a half books were discovered by Poggio at St. Gall in 1417. The first edition was published in 1474. Later editions include P. Langen in *Berliner Studien fur klassische Philologie,* new series, vol. 1 (1896–97), and O. Kramer in the Teubner series (1913).

See W. C. Summers, *A Study of the Argonautica of Valerius Flaccus* (1894); J. W. Duff, *A Literary History of Rome in the Silver Age,* pp. 433–451 (1927). (An. K.)

VALERIUS MAXIMUS (fl. *c.* A.D. 20), was the Latin author of a book of historical anecdotes. His family was poor, and he owed everything to Sextus Pompeius (consul A.D. 14, and proconsul of Asia), a kind of minor Maecenas, whom he accompanied to the east *c.* A.D. 27. His book, *Factorum et dictorum memorabilium libri ix* ("Nine Books of Memorable Deeds and Sayings," *c.* A.D. 31), was intended for use in the schools of rhetoric. The anecdotes are drawn chiefly from Roman history, but include extracts from the annals of other peoples, principally the Greeks. The arrangement is loose and irregular, the style turgid, artificial and showy, but Valerius can sometimes produce an effective and well-placed pointed expression, an ingenious transition or a clever piece of fancy. In spite of its contradictions and errors this varied collection proved very popular, especially in the middle ages. There is an edition in the Teubner series with two later epitomes (the second surviving incomplete) by C. Kempf (1888) and an English translation by S. Speed (1678).

It is not easy to determine Valerius' sources. He made considerable use of Cicero. He also used Pompeius Trogus, Livy, an earlier historian and probably Varro. It has not been proved that he used Sallust or Caesar. Valerius was a champion of Caesarism, and reproduced the general feeling of the empire that the Romans of his day were inferior to their ancestors but greatly superior to the rest of the world.

See J. W. Duff, 4 Literary History of Rome in the Silver Age, pp 65–81 (1927); R. Helm in Pauly-Wissowa, Real-Encyclopadie der classischen Altertumswissenschaft, 2nd series, vol. 8, col 90–116 (1955). (G. B. A. F.)

VALÉRY, PAUL (1871–1945), French poet, was born at Cette on Oct. 30, 1871. He first became known as the author of several apocalyptic poems of remarkable beauty and form, which appeared in such reviews as *L'Ermitage,* Le Centuure, etc., and were issued later in a collection entitled Album de Vers *anciens* (1920). From 1900 to 1917 Valéry lived in strict retirement and published nothing. During this period, however, his ideas matured, and he accumulated material later given to the public in Cahier *B,* Rhumbs and *Analecta.* It was not until 1917 that he published his first great poem La Jeune Parque, dedicated to André Gide. Then came Aurore (1917), Le *Cimitière marin* (1920), La *Platane, L'Ebauche* d'un Serpent, etc., which appeared in a collection entitled Les *Charmes* (1922).

Valéry also wrote critical essays (on Stendhal, Poe, etc.) and philosophical treatises (Introduction *à* la mdthode de *Léonard* de *Vinci, Soirée* avec *M. Teste*) of which some were collected under the title *Variétés* (1924), *Eupalinos* and *Ame et la Danse* (1923), two Platonic dialogues.

Valéry initiated a new movement in French poetry. Influenced by Mallarmé, especially in his sense of verbal music, he believed with the symbolists that pure poetry must have value in itself apart from any reference to the accidents of being. Interested in philosophy and mathematics, he was a poet-mathematician trying to set his subtle analysis to music.

Valéry was a member of the Académie française from 1926. He died July 20, 1945, at Paris.

VALHALLA (Old Norse VALHÖLL), in Norse mythology was the hall of slain warriors, who lived there blissfully under the leadership of the god Odin. Valhalla is depicted as a splendid palace, roofed with shields, where the warriors feast on the flesh of a boar slaughtered dally and made whole again each evening. They drink liquor which flows from the udders of a goat, and their sport is to fight one another every day.

Thus they will live until the Ragnarök (Doomsday), when they will march out the 640 doors of the palace to fight at the side of Odin against the giants. When heroes fall in battle it is said that Odin needs them to strengthen his forces for the Ragnarok.

Early Norse poets frequently allude to Valhalla and its splendors, but it is improbable that the belief in it was ever widespread among the common people. (G. T.-P.)

VALKYRIES, generally represented in Northern mythology as divine maidens who, sent by Odin, ride through the air to determine the course of battles and to select brave warriors for Valhalla (*q.v.*).

Beings with the same name (*waelcyrgean*) were in England associated with witches.

VALLA, LORENZO (LAURENTIUS) (c. 1407–1457), Italian humanist, was born at Rome about 1406, his father, Luca delle Vallea, being an advocate. He was educated at Rome, became a priest in 1431, and wandered from one university to another lecturing. About 1437 he became private secretary to Alphonso V of Aragon, who ever afterwards protected him, and later helped him to open a school at Naples. Valla by now had achieved a great reputation by the De Voluptate and the *De Elegantiis* Linguae Latinae. The first is a remarkable dialogue presenting in turn the Stoic, Epicurean and Christian ethical systems. Christianity is allowed to prevail, but Epicurus is very favourably treated. The De Elegantiis is a scientific analysis of the rules of Latin grammar and style. In 1440 appeared his famous exposure of the Donation of Constantine (*q.v.*), followed by other attacks on spurious documents. He was compelled to appear before an inquisitory tribunal composed of his enemies, and he escaped only by the special intervention of Alphonso. He was not, however, silenced; he ridiculed the Latin of the Vulgate and accused St. Augustine of heresy. In 1446 he visited Rome, but in this city also his enemies were numerous and powerful, and he saved his life only by flying in disguise to Barcelona, whence he returned to Naples. After the death of Eugenius IV in 1447 he went again to Rome, where he was welcomed by the new pope, Nicholas V, who made him an apostolic secretary, and this entrance of Valla into the Roman Curia has been justly called "the triumph of humanism over orthodoxy and tradition." Valla also enjoyed the favour of Pope Calixtus III. His most famous dispute was with Poggio (*q.v.*). He died in Rome on Aug. 1, 1457.

Over Valla's private life, the most obscene language was employed. He appears as a vain, jealous and quarrelsome man, but an elegant humanist, an acute critic and a venomous writer, who had committed himself to a violent polemic against the temporal power of Rome. In him posterity honours the man who initiated a bold criticism, which he applied to language, to historical documents and to ethical opinions. Luther had a high opinion of him, and Cardinal Bellarmine calls him *praecursor Lutheri,* while Sir Richard Jebb says that his *De Elegantiis* "marked the highest level that had yet been reached in the critical study of Latin."

Collected, but not quite complete, editions of Valla's works were published at Basle in 1540 and at Venice in 1592 *seq.,* and De *Elegantiis* was reprinted nearly 60 times between 1471 and 1536. For detailed accounts of Valla's life and work see G. Voigt, Die *Wiederbelebung* des *classischen* Alterthunzs (1880–81); J. A. Symonds, *Renaissance in Italy* (1897–99), G. Mancini, *Vita di* Lorenzo Valla (Florence, 1891); M. von Wolff, Lorenzo Valla (Leipzig, 1893); J. Burckhardt, Kultur der Renazssance (1860); J. Vahlen, *Laurentius* Valla (1870); L. Pastor, Geschichte der Papste, Band ii. Eng. trans. by F. I. Antrobus (1892); the article in Herzog-Hauck's *Realencyklopadze,* Band xx (Leipzig, 1908); J. E. Sandys, Hzst. of Class. Schol. ii. (1908), pp. 66–70; and V. Rossi, *Il* Quattrocento, 2nd ed. (1933).

VALLADOLID, an inland province of Spain, one of the eight into which Old Castile was divided in 1833. Population (1950 census) 348,185; area, 3,155 sq.mi.

The province belongs to the basin of the river Duero (Douro). It is for the most part flat and exceedingly fertile, the only part that can be called hilly being in the northwest, where the low Montes de Torozos occur. Valladolid shares with the Tierra de Campos in Palencia the title of granary of the Peninsula.

Besides wheat, maize, barley and oats, the province produces hemp, flax, various fruits, red and white wine, oil and madder. Honey, wax and silk are also produced. The woollen fabrics of Valladolid were once highly esteemed, but this industry later greatly declined, although in the larger towns there are still linen and cloth factories, besides iron foundries, tanneries, saw-mills and flour-mills. Trade is facilitated by the Canal de Castilla, connecting Valladolid, on the Pisuerga, with Alar del Rey, in Palencia. Valladolid is traversed from north to south by the railway from Madrid to France. Apart from the capital Valladolid (*q.v.*), Medina del Campo (13,242) is the only large town. The province was captured by nationalist troops in 1936, during the early stages of the civil war of 1936–39.

VALLADOLID, the capital of the Spanish province of Valladolid, 2,228 ft. above sea-level, at the confluence of the river Pisuerga with the Esgueva Pop. (1950) 115,157.

Valladolid is sometimes identified with the ancient Pintia of Ptolemy. Its Roman origin is uncertain. The present name is undoubtedly Moorish. Valladolid was recovered from the Moors in the 10th century, but is first named by Sancho II of León in 1072. The cortes of Castile frequently met here in the following centuries. and in the beginning of the 15th century John II made it his principal residence. After the removal of the capital to Madrid by Philip II in 1560 it began rapidly to decay. Columbus died

(1506) and Philip II was born (1527) at Valladolid. The cathedral was begun in 1585 by Juan de Herrera in the Renaissance style. The interior contains pictures by Luca Giordano (1632–1705) and the celebrated silver monstrance wrought by Juan de Arphe. Other buildings are the church of Santa Maria la Antigua (1200); the church of San Pablo (1286); San Gregorio (15th century); and San Benito (end of the 14th century). The Plateresque college of Santa Cruz, built by Enrique de Egas in 1479–92, contains three pictures by Rubens, and some remarkable wooden statues by Alonso Berruguete (d 1561), Gregorio Hernández (1566–1636) and others. The university, originally founded at Palencia early in the 13th century, was transferred to Valladolid before 1250. The house in which Cervantes lived (1603–06) has been preserved. Manufactures include textiles, pottery, gold and silver work, flour, wine, beer, chocolate, leather and ironware.

VALLANDIGHAM, CLEMENT LAIRD (1820–1871), U.S. politician who was exiled for his opposition to the American Civil War, was born in New Lisbon, O., on July 29, 1820. He attended Jefferson college, Canonsburg, Pa., but left before graduating. He then studied law and was admitted to the bar in Ohio in 1842. He soon turned to politics and was elected to the Ohio house of representatives in 1845. From 1857 to 1863 he was in the U.S. house of representatives, where he was noted for his strong opposition to the principles and policies of the new Republican party. He became a leader of the midwestern Democrats or "copperheads." who were opposed to the prosecution of the Civil War for the benefit of eastern interests. He bitterly attacked the Lincoln administration, charging that it was destroying the constitution and would end by destroying civil liberty in the north. In 1863 he made vigorous speeches in Ohio against the war and the administration, and for these he was arrested by the military authorities, tried by a military commission in Cincinnati and sentenced to imprisonment. President Lincoln commuted his sentence to banishment, and Vallandigham was sent into the Confederate lines, whence he made his way to Canada. His case was appealed to the U.S. supreme court, which decided in Ex *parte Vallandigham* (1 Wallace 243) that it had no jurisdiction. While in exile he received the Democratic nomination for governor of Ohio, but was defeated. In 1864, in spite of the order for his banishment, he returned to Ohio and took active part in the campaign of that year. He wrote part of the national Democratic platform in which the war, as carried on by the Lincoln administration, was denounced as a failure. After the war he criticized the reconstruction policy of the Republicans as unconstitutional and tyrannical, but in 1870, seeing the uselessness of further opposition, he advised his party to accept the situation and adopt a "new departure" emphasizing financial issues. Vallandigham was an able lawyer and a popular politician. He died in Lebanon, O., on June 17, 1871, after accidentally shooting himself with a firearm that was an exhibit in a murder trial.

See F. L. Klement, *Copperheads in the Middle West* (1960); H. S. Merrill, *Bourbon Democracy of the Middle West* (1953).

(W. B. HE.)

VALLE, PIETRO DELLA (1586–1652), Italian traveler in the east, was born on April 11, 1586, in the family palace built by Cardinal Andrea. He served against the Moors of Barbary, but also became a member of the Roman academy of the Umoristi, and acquired some reputation as a versifier and rhetorician. Sailing from Venice in 1614, he reached Constantinople, where he remained for more than a year. In Sept. 1615 he sailed for Alexandria. From Alexandria he went on to Cairo, and, after an excursion to Mount Sinai, left Cairo for the holy land in March 1616. Having visited the holy sites, he journeyed by Damascus to Aleppo, and thence to Baghdad, where he married a Syrian Christian named Maani. He now desired to visit Persia; but, as that country was then at war with Turkey, he had to leave Baghdad by stealth in Jan. 1617. Accompanied by his wife he joined Shah Abbas in a campaign in northern Persia, in the summer of 1618. On his return to Isfahan he began to think of returning by India; but the state of his health, and the war between Persia and the Portuguese at Ormuz, created difficulties.

In Oct. 1621 he started from Isfahan, visited Persepolis and Shiraz, went on to the coast and in Jan. 1623 found passage for Surat. In India he remained till Nov. 1624, his headquarters being Surat and Goa. He was at Muscat in Jan. 1625, and at Basra in March. In May he started by the desert route for Aleppo, and took ship at Alexandretta. Touching at Cyprus, he reached Rome on March 28, 1626. He died at Rome on April 21, 1652.

VALLE, a small department in southern Honduras, bordering the Gulf of Fonseca and El Salvador. Pop. (1961) 80,924, of which 77% was rural. Population is evenly distributed within the department. Nacaome, the departmental capital, pop. (1961) 3,715, is on the Inter-American highway and is connected by Inter-Ocean highway with Tegucigalpa. Amapala, a port on Tigre Island, handles nearly as much cargo as Puerto Cortés. Most of the department consists of coastal and low alluvial plains. About 55% of the land is used for farms; 28% is cultivated and 20% is in pasture. Important products are cotton, swine, cattle, sesame, corn and beans. (C. F. J.)

VALLE D'AOSTA, the upper basin of the Dora Baltea river, from its source near Mont Blanc to just above Ivrea. Geographically and historically part of Piedmont, it formed from 1948 an autonomous region within the Republic of Italy. Pop. (1961) 99,754. Area 1,260 sq mi. Through it runs the important highway from the Po valley to the Great and Little St. Bernard passes. The capital and episcopal see is Aosta (anc. Augusta Praetoria Salassorum), 1,920 ft. above sea level and 80 mi. N N W. by rail (48 mi direct) from Turin, at the junction of the two Alpine routes. Pop. (1957 est.) 28,446 (commune). It was the birthplace of Saint Anselm (1033–1109), archbishop of Canterbury. The valley is economically important for its dairy products and as a tourist centre, and has valuable hydroelectric resources. The local dialect has strong Franco-Provençal affinities.

Originally the territory of the Salassi (a Celtic tribe), the valley was annexed and Aosta, the capital, was founded in 25 B.C. After the fall of the western Roman empire Valle D'Aosta passed through many hands until in the 11th century it came into, and thereafter remained in, the hands of the house of Savoy. Aosta has preserved the walls, two gates and the street-plan of its Roman predecessor, as well as a fine triumphal arch in honour of Augustus, the vaulted substructures of a large rectangular temple-precinct, one complete wall of the theatre, and elements of the amphitheatre and public baths. The plan, a strict rectangle of 792 by 625 yd., bisected longitudinally by the main valley road and crossed at right angles by another road, is laid out on a basis of 64 equal *insulae* and is an outstanding example of Roman formal city planning. Of later monuments the cathedral is notable for its treasury and 12th-century floor mosaics, and the church of St. Orso for its Romanesque cloisters and Gothic choir stalls. A feature of the valley is its magnificent series of medieval castles.

BIBLIOGRAPHY.—P. Toesca, *Aosta* (1911); P. Barocelli, *Augusta Praetoria* (Forma Italiae xi, i, 1948); J. B. Ward-Perkins, *Town Planning Review,* vol. xxvi, pp. 127–154 (1955). (J. B. W.-P.)

VALLE DEL CAUCA, a department of the republic of Colombia that encompasses the flat-floored valley of the upper Cauca river (elevation 3,100–3,300 ft.). Area 7,888 sq.mi. Pop. (1961 est.) 1,743,320. The department is a leading producer of sugar, rice, tobacco and coffee. Buenaventura (*q.v.*) on the Pacific ocean, connected with the capital city of Cali (*q.v.*) by both rail and highway, has become a leading port of the country. Through it moves the major portion of Colombia's coffee exports. The ambitious Cauca Valley Development project, a 20-year plan, was modeled on the Tennessee river project in the U.S. (Js. J. P.)

VALLE-INCLÁN, RAMÓN DEL (1866–1936), Spanish novelist, dramatist and poet, outstanding as a stylist, was born at Villanueva de Arosa (Pontevedra), on Oct. 28, 1866. After a childhood and youth in Galicia and a sojourn in Mexico in 1892, he settled in Madrid, where he became renowned for his colourful personality. Coming under French "decadent" and Symbolist influences, he was early preoccupied with style. His first notable work, *Sonata de otoño* (1902), is the story of a latter-day Don Juan, the marquis of Bradomin, told in evocative, cadenced prose of great beauty. Bradomin, also the protagonist of three more *Sonatas* (1903–1905; Eng. trans. of all four, 1924), remains one of the memorable characters of Spanish literature. In other works Valle-Inclán developed a style rich in popular as well as literary elements, as in the prose *Comedias bárbaras* (*Aguila de blasón,* 1907; *Romance de Zobos,* 1908; *Cara de plata,* 1923'1. about the patriarchal Don Juan Manuel de Montenegro and his brood of wild sons. Later, with a growing social and political consciousness, Valle-Inclán wrote plays, novels and verse in a tone of burlesque tragedy and a style superbly adapted to his grotesque, satirical, Goyalike vision, calling the new genre *esperpento* ("an ugly, ridiculous person or thing"). In this vein are his last novels, *Tivano Banderas* (1926; Eng. trans. 1929), with its vivid portrayal of a Latin-American despot, and the unfinished series. El *ruedo ibérico: La corte de los milagros* (1927), *Viva mi dueño* (1928) and the posthumous *Baza de espadas* (1958), dealing with the political degradation of 19th-century Spain. Valle-Inclán died at Santiago de Compostela on Jan. 5, 1936.

(W. L. Fi.)

VALLEJO, a city of Solano county, Calif., U.S., on San Pablo bay at the mouth of the Napa river north of the Carquinez straits, is at the head of deep water with a 35-ft. channel to San Francisco, 25 mi. S.W. Vallejo is within the San Francisco-Oakland standard metropolitan statistical area; *see* SAN FRANCISCO. Its population in 1960 was 60,877; for comparative population figures *see* table in CALIFORNIA: *Population.*

It was named for the Mexican soldier and pioneer, Gen. Mariano Guadalupe Vallejo, who explored the area in 1830. In Jan. 1851. a few months after California's admission to the United States. Generai Vallejo offered the legislature 156 ac. of land for a state capital on San Pablo bay. Although the offer was accepted and the legislature moved from San Jose. Vallejo served as the state capital for only seven days in Jan. 1852 and for a month in 1853. The establishment of the Mare Island naval shipyard in 1854 permitted the town to survive and prosper.

The rapid growth of Vallejo's population and economy after 1940 was due largely to varied military operations in the area, of which the most important continued to be Mare Island. Important civilian industries include flour milling and meat packing. The city is the economic hub of the agriculturally rich Solano county, noted for its production of sheep and wool, field crops such as tomatoes and sugar beets, and a large variety of fruit and nut crops. The public school system of the city includes a junior college. Vallejo is the home of the California Maritime academy, a special institute conferring the bachelor's degree based on an accelerated program. (M. H. Mo.)

VALLÈS, JULES (1832–1885), French journalist and author, was born at Puys, France, on June 10, 1832. Coming to Paris, he joined the staff of the *Figaro* and became a constant contributor to the other leading journals. He was in Paris during the siege of 1870 and after the capitulation was a member of the Commune and founded *Le Cri du Peuple.* He took a conspicuous part in the fighting in the Paris streets but finally made his escape to London, whence he contributed anonymously to the French press. In 1878 he began in the *Siècle* the serial publication of his principal work, *Jacques Vingtras,* a long autobiographical romance. He died in Paris on Feb. 14. 1885.

VALLETTA or VALETTA, the capital of Malta (since 1570), was built after the great siege of 1565 and named after the grand master Jean Parisot de La Valette who had led the knights of the Order of the Hospital of St. John of Jerusalem to victory against the Turks; it is a major British naval and air base. The nucleus of the city is built on the promontory of Mt. Sceberras that runs like a tongue into the middle of a bay which it thus divides into two harbours, Grand harbour to the east and Marsamuscetto (Marsamxett) to the west; these are subdivided again into creeks by three smaller peninsulas. On two of these peninsulas on the east side of Grand harbour; and at their bases, are built the aggregate of towns called the Three Cities—Vittoriosa, Cospicua and Senglea. On the main promontory, with Valletta. is the suburb Floriana and, on the extremity of this promontory, Fort St. Elmo. The suburb Sliema lies on the western point which encloses Marsamuscetto harbour; Fort Ricasoli is on the eastern point, enclosing Grand harbour. Pop. excluding suburbs (1957) 18,202.

The most interesting building in the town is St. John's co-cathedral, formerly the conventual church of the Order of St. John, but now equal in rank with the bishop's cathedral in Notabile (hence its title of co-cathedral). It was designed by the Maltese architect Girolamo Cassar and built by the grand master Jean Lévesque de la Cassière between 1573 and 1577. In 1661 Mattia Preti (1613–99) was invited from Rome to Malta to decorate the ceiling of the church; he also painted some of the altarpieces for the side chapels. Though the church was despoiled by Napoleon, it still contains many art treasures such as the magnificent set of Flemish tapestries executed by Judocus de Vos from Preti's designs and presented to the church by the grand master Ramon Perellos in 1697. Other important buildings by Cassar are the palace of the grand masters (1573–77), now shared by the British governor and the Maltese legislative assembly and containing the armoury of the Order of St. John; the Auberge d'Aragon, now the seat of the prime minister; and the Auberge de Provence, now a national museum. Of the other *auberges* (lodges of the knights of Malta) by Cassar those of France and Auvergne were destroyed during World War II. The Auberge de Castille. originally built by Cassar, was completely remodeled in the 18th century by Domenico Cachia; it is used for military offices, clubrooms and other purposes. The Royal Malta library (containing 300.000 volumes and 1,450 manuscripts) was constructed by Stafano Ittar at the end of the 18th century. The Royal University of Malta, in St. Paul street, was founded by the grand master Emmanuel Pinto in 1769. After the British occupation of Malta in 1799, Valletta became a naval and military station of the first importance. The naval dockyards, arsenal and provisions stores occupy the shores of the two main creeks within Grand harbour. The large transit trade and the local trade of the island is also centred in the city. Valletta has no industries but it is the shopping town. All the main government departments are there and it is the administrative centre of Malta and Gozo. Transport is by bus, taxi or the local horse-drawn vehicle called the *karrozzin.* Valletta was the principal objective of bombing raids on Malta by German aircraft, which commenced on June 11, 1940, and continued for nearly three years on a scale unequaled elsewhere in the world. *See* also MALTA. (*P.* J. Ni.)

VALLEYFIELD (SALABERRY-DE-), a city in Beauharnois county. Que., Can.. 25 mi. S.W. of Montreal, at the eastern end of Lake St. Francis—a widening of the St. Lawrence river—and at head of the Beauharnois canal section of the St. Lawrence seaway. Pop. (1956) 23,584. of which 90% are French-speaking. It is the seat of a Roman Catholic bishopric and serves as an administrative and cultural centre for the surrounding agricultural areas. Industry has been attracted to the area because of available hydroelectric power and a large labour force. Important products are cotton and silk yarns, paper, bronze, drugs, canned goods and wood products. (W. F. Ss.)

VALLEY FORGE, an area about 20 mi. N.W. of Philadelphia, Pa., U.S., where the American Revolutionary army of about 11,000 men under George Washington spent the winter of 1777–78. Their sufferings there from cold, starvation and sickness hallowed the historic site for Americans. The troops wintered in log huts and received little food or clothing. On Dec. 23, 1777, Washington wrote: "We have this day no less than 2,873 men in camp unfit for duty because they are barefooted and otherwise naked. . . . Numbers are still obliged to sit all night by fires." There were many desertions and occasional symptoms of mutiny, but for the most part the soldiers bore their sufferings with heroic fortitude. In Feb. 1778 the winter encampment became the first training camp of any United States armed forces. Under the drillmaster. Baron Frederick von Steuben (*q.v.*) the army was reorganized, and left Valley Forge June 19, 1778, an efficient fighting unit. Of the original encampment 2,033 ac. are owned, maintained and preserved by the commonwealth of Pennsylvania and known nationally as Valley Forge park. Washington headquarters, Varnum quarters, commissary quarters and much of the military works used by the Continental army was restored. The ruins of the valley forge, an iron plant which gave name to the area and which the British burned in Sept. 1777, have been excavated. Statues of Anthony Wayne and Von Steuben and the National Memorial arch, erected as a tribute to all the men, are outstanding monuments.

The locations of troop units from each of the 13 original colonies are indicated by granite markers. One memorial to Washington is the magnificent Washington Memorial chapel with its carillon of 49 bells. (G. S. J.)

VALLEY OF TEN THOUSAND SMOKES, a volcanic region in Alaska, which came into being at the time of the eruption of Mt. Katmai on the Alaskan peninsula on June 6, 1912. An ancient trail led through the valley, so that it was well known to have been rich in plant and animal life, a favourite hunting ground of the natives. One of the first events in the Katmai eruption was the bursting forth of a new volcano, Novarupta, in the floor of one arm of the valley. Probably from this vent, and other smaller ones, issued the great flow of incandescent sand which filled the floor of the valley, 17 mi. in length and 4 mi. in width, utterly consuming everything in its path until it reached the lower end of the valley, where the trees were merely turned to charcoal. At the time of its discovery not ten thousand but millions of jets of steam were issuing from the floor of the valley from vents ranging in size from a tiny crack to pits or craters 150 ft. in diameter. In temperature they ranged up to 1,200° F., hot enough to melt zinc and to set ablaze a stick held in the steam. Immediately following the hot sand flow Mt. Katmai 'exploded. Its three-peaked snow-covered crown was blown to bits, leaving a crater 3 mi. wide, containing a lake 3,700 ft. below the crater rim. Kodiak Island, 100 mi. away. was covered with a blanket of volcanic ash a foot deep. Acid rains fell in Cordova, 360 mi. distant, while the fumes tarnished brass in Victoria, B.C., 1,500 mi. away. The haze was noted in Virginia and at the bureau of standards in Washington, D.C. The dust from Katmai thrown into the higher layers of atmosphere robbed the north temperate zone of 10% of the sun's heat in the summer of 1912. Because Katmai is located in a region almost uninhabited, not a human being lost his life, though this eruption nas one of the largest ever known.

The Valley of Ten Thousand Smokes and its neighbouring wonders mere discovered by Robert F. Griggs, director of the National Geographic society's expeditions of 1915–16–17–18–19, This region proved to be so stupendous a volcanic laboratory as well as so rich in scenic value that in Sept. 1918 Pres. Woodrow Wilson set aside the whole district, comprising 2,697,590 ac., as the Katmai National monument. (L. T. G.)

VALLEY STREAM, a village of New York, U.S., in Nassau county, about 16 mi. from Manhattan, is the first suburban community outside of the political limits of New York city on the south shore of Long Island. The village was first settled in 1647 on open, flat, farm country. It was incorporated in 1925.

Valley Stream is almost entirely suburban in character; between 60% and 70% of its working population commutes to New York city. After World War II its population steadily increased until practically no land was available for new housing. The community has long been regarded as an ideal suburban residence because of its convenience to Manhattan and also to Long Island's beaches and recreational facilities. For comparative population figures see table in NEW YORK: Population. (WI. M. D.)

VALLOMBROSA, a summer resort of Tuscany, Italy, in the province of Florence, reached by road (9 mi.) from the station of Saint Ellero (which is 16 mi. S.E. of Florence) and 328 ft. above sea level, on the northwest slope of the Prato Magno chain. The former monastery was suppressed in 1866. A number of hotels have been built. Similar summer resorts are situated among the woods above the Casentino or upper valley of the Arno to the east, such as Camaldoli, Badia di Prataglia, etc. Camaldoli was the original headquarters of the Camaldulensian order, now partly occupied by a hotel. Five hours' journey to the south of the last on foot and 7½ mi. to the east of Bibbiena by road is the monastery of La Verna, 3,660 ft. above sea level, founded by St. Francis in 1215 on an isolated limestone peak. There he received the stigmata in 1224. The small Church of the Angels, erected by him, and the Chiesa Maggiore (begun in 1348) contain some fine terracotta reliefs by the Della Robbia family.

VALLOMBROSIANS, an order of monks under the Benedictine rule, founded by St. John Gualbert, who, about 1030, withdrew to Vallombrosa, a shady dale on the side of a mountain in the Apennines, 10 mi. from Florence, and for several years led a completely solitary life. Disciples, however, gathered around him, and he formed them into an order in which the cenobitical and the eremitical lives should be combined. The Benedictine rule was the basis of the life; but every element of Benedictine life was eliminated that could interrupt the attention of the mind to God—even manual labour.

The Vallombrosians spread in Italy and France, but they never had more than 60 houses.

VALMY, a small village on the main road between Verdun and Paris, just west of Ste. Menehould, famous for the French victory of Sept. 20, 1792. Pop. (1954) 255. Eastward of Valmy lies, roughly north and south, the long barrier of the forest of Argonne. Dumouriez. with the belated assistance of Kellermann, was attempting to hold this in September against the advance of the duke of Brunswick's German troops. The duke's forces broke through to the north by a pass known as the Cross in the Woods. In great haste, on the 19th, Dumouriez was able to withdraw under the cover of darkness the forces guarding the northern portions of the Argonne, which would otherwise have been cut off, and to complete his junction with Kellermann. By the morning of Sept. 20 his army was on the flank of Brunswick's advance and was facing toward Paris, with its back to the Argonne.

As soon as the heavy mist lifted on the morning of Sept. 20, the duke commenced an attack on the French by heavy artillery preparation. The French artillery was the sole important arm which had not been disorganized, and was able to reply effectively to the Prussian cannonade. Early in the afternoon, however, the Prussian guns did tremendous damage by a lucky shot which blew up the French ammunition reserves. A German mercenary brigade in the French service broke, and Brunswick decided the moment had come for an attack, and gave the signal.

The Prussians advanced en *échelon* under a severe fire, but steadily, about two-thirds of the intervening distance. The shaky ranks of the French were rallied by Kellermann, and were more or less prepared to meet the attack, when the Prussians hesitated, and, still apparently without disorder, retreated to their original position. Some mystery surrounds this, the central event of the battle: it seems probable that the Prussian advance was impeded by unsuspected thick mud at the foot of the hill, as well as by the accurate French gunnery—the support of their own guns necessarily ceasing as they approached the French lines. The cannonade continued till nightfall. Brunswick, having failed to defeat his enemy, realized that his position was strategically untenable and retreated.

See FRENCH REVOLUTIONARY WARS.

VALQIS, COUNTS AND DUKES OF. The French countship of Valois (*pagus Vadensis*) takes its name from Vez (Lat. Vadum), its early capital, a town in the *département* of the Oise. From the 10th to the 12th century it was owned by the counts of Vermandois and of Vexin; but on the death of Eleanor, sister and heiress of Count Raoul V (d. 1167), it was united to the crown by King Philip Augustus. Soon detached from the royal domain, Valois was the property of Blanche of Castile, uidow of Louis VIII, from 1240 to 1252, and of Jean Tristan, a younger son of Louis IX, from 1268 to 1270. In 1285 Philip III gave the county to his son Charles (d. 1325), whose son and successor, Philip, count of Valois, became king of France as Philip VI in 1328. Sixteen years later Valois was granted to Philip's son, Philip, duke of Orléans; then passing with the duchy of Orléans in 1392 to Louis (d. 1407), a son of Charles V, it was erected into a duchy in 1406 and remained the property of the dukes of Orléans until Duke Louis became king of France as Louis XII in 1498, when it was united with the royal domain. After this the duchy of Valois was held by Jeanne, countess of Taillebourg (d. 1520), from 1516 to 1517, and by Marie, countess of Vendôme, from 1530 until her death in 1546; it was given to Catherine de Medici, the widow of Henry II, in 1562, and in 1582 to her daughter, Margaret of Valois, the wife of Henry of Navarre. In 1630 Louis XIII granted Valois to his brother Gaston, duke of Orléans, and the duchy formed part of the lands and titles of the dukes of Orléans until the Revolution.

The house of Valois, a branch of the great Capetian family, is thus descended from Charles, a son of Philip III, and has been divided into several lines, three of which have reigned in France. These are: (1) the direct line (reigned 1328–1498) beginning with Philip VI; (2) the Orléans branch (reigned 1498–1515), descended from Louis, duke of Orléans, a son of Charles V; (3) the Angoulême branch (reigned 1515–89), descendants of John, another son of the same duke.

VALOIS, anciently a district of Picardy, part of the government of the Ile-de-France, bounded on the north by Soissonnais, on the east by Champagne, on the south by the Ile-de-France proper, and on the west by Beauvaisis. It included the towns of Crépy (capital), Morienval, Pierrefonds, Compiègne, Verberie, Pont-Sainte-Maxence, Senlis, Chantilly, Villers-Cotterets. Under the Roman domination it belonged to the Suessiones but it is now a small area in the departments of the Oise and the Aisne.

At first governed by its own independent counts, Valois in 1214 was joined to the kingdom of France by Philip Augustus. It has given its name to three lines of the second branch of the Capetian kings. See VALOIS, COUNTS AND DUKES OF.

VALPARAISO, coastal range province of central Chile, the smallest (1.860 sq.mi.) and second most populated. Pop. (1960) 613,405. The province is administered from the city of Valparaíso (*q.v.*). Adjacent is Viña del Mar, a luxurious beach resort. The province embraces the lower Aconcagua basin and such westward draining lowlands as the Limache and Casablanca valleys. Dairy pastures, the vine. orchard, truck and grain crops are common to all lowlands. Near Limache (pop. [1960] 27,563 [mun.]), Quillota (41.910 [mun.]) and La Calera 121,750 [mun.]) farming is most intensive. The province, second to Santiago in industrial development, produces over 15% (in value) of Chile's manufactured goods. Leading manufactures are food and tobacco products, textiles, chemicals, cement and clothing. The Concón petroleum refinery and Quintero and Viiia del Mar tank farms are Chile's most important. All-year roads and highways and an electrified railway link the urban centres with each other and with Santiago. La Calera and Llay-Llay, respectively, are junctions for the railway to north Chile and the trans-Andean railway route. A branch of the Valparaíso-Santiago railway serves Quintero. Quintero, Maitencillo, Algarrobo and El Quisco are popular coast resorts. The Juan Fernández Islands (*q.v.*) and Easter Island (*q.v.*) are administered from Valparaiso province. (J. T.)

VALPARAÍSO, the second city and first seaport of Chile. capital of the province of the same name, lies on the south side of a broad open bay of the Pacific, 115 mi. N W. by rail of Santiago. Pop. (1960) 259,241 (mun.). The city stands on the slopes of a great semicircular spur of the coastal plateau which ends in the rocky peninsula of Punta Xngeles. This point affords good shelter to the bay from southerly and westerly storms, but leaves it open to those from the north.

The commercial quarter with its port works, warehouses, banks, shopping centre and railway to Santiago occupies reclaimed land adjacent to the crescent-shaped bay, as do the administrative buildings grouped around Plaza Sotomayor. The cathedral, parks, boulevards, theatres, cafes and a few surviving colonial building;, notably the church of La Matriz, are also concentrated in the lower part of the city, of which other principal streets are Calle Esmeraldas and Avenida Pedro Montt. The naval academy buildings and residential quarters are located on the steep slopes and valleys of encircling hills, many of the poorer dwellings occupying the highest parts. Funicular railways, elevators, steps and zigzag roads connect the upper and lower city. The population grew relatively slowly in the middle decades of the 20th century, for the tourist resort of Viña del Mar, adjacent to Valparaiso on the west, increasingly acted as a residential suburb.

Communications.— The state railways connect the city with Santiago by electrified line, and by steam lines nith all the important cities and ports of Chile from Pisagua in the north to Puerto Montt in the south. Valparaiso is the western terminus of the Transandine railway, and thus has direct overland connection with Buenos Aires. Good highways run to the resort towns north and south and to the capital. Internal airlines link the city with other parts of Chile.

Commerce and **Industry.**—Valparaíso is pre-eminently commercial and industrial. There are foundries, and factories producing chemicals, textiles, sugar, paints, clothing, leather goods and vegetable oils. About 60% of Chilean imports enter the country through the port, and although its exports are but 5% by value of the Chilean total, its significance in internal maritime communications is paramount, 1,000,000 tons of shipping using the port annually. It is a terminal and major port of call for several international shipping lines, and its dock facilities, sheltered by a great breakwater, 3,000 ft. long, are modern, well-equipped and capable of accommodating the largest liners afloat.

History.—Valparaíso was founded in 1536 by Juan de Saavedra, who named it after his birthplace near Cuenca in Spain. In 1578 it was captured by Sir Francis Drake, in 1596 by Sir John Hawkins, and in 1600 it was sacked by the Dutch under Oliver van Noort. The port and town were of little note during the colonial period, for free commercial intercourse with the colony was forbidden. In 1819, near the end of its war of independence. its population barely reached 5.000. The relaxation and final breaking of the Spanish mercantile monopoly. the birth of the Chilean navy and its supremacy along the Pacific coast of South America, and the linking of Yalparaiso with Europe by steamship services were powerful factors in the transformation of the little town into a great port. Other factors were British investment in the commerce of the new republic, the function of Valparaiso as a refueling and provisioning port for those coming from Europe via Magellan's strait to the gold fields of California, and the governmental support provided, particularly by Diego Portales, in the 1830–40 period. This expansion mas checked in 1866 by a bombardment by the Spanish fleet which demolished a large part of the town. It was also partially sacked during the civil war of 1891 when congressional troops entered the city after their victory over President Balmaceda's forces. In 1906 an earthquake, the worst Yalparaiso ever experienced, destroyed much of the city but permitted its rebuilding in its present modern form. From ashes and debris streets were widened and paved; better business premises arose and a modern water supply and sewerage system were provided.

The growth of Santiago and the centralization of commerce in the capital have caused many businesses to move from Valparaíso, and the city has thus declined relatively in importance. It retains, however, a marked individuality and character reminiscent of older European ports; and the influence of its strong British connections is still evident. (G. J. B.)

VALTELLINA (Ger. VELTLIN; the name comes from the former capital, Teglio). properly the name of the upper valley of Adda, in north Italy. Historically, it also comprises the Italian Liro or San Giacomo valley, now the province of Sondrio.

Today the whole valley belongs to Italy, except the side valley of Poschiavo (Puschlav), which belongs to the Swiss canton of the Grisons (Graubiinden). The chief town is Sondrio (pop. [1957 est.] 16.471 (commune]). Near Bormio there are some frequented mineral springs (sulfur and lime), known in Pliny's time.

The highest points in the ranges enclosing the valley are the Piz Zupo (13,117 ft.) in the Bernina group and the Gran Zebrù (Konigsspitze) (12,661 ft.) in the Ortler district; the Monte della Disgrazia (12,067 ft.) is the highest peak comprised entirely within the water basin of the valley. Four well-marked Alpine passes are traversed by good roads—the Stelvio pass (9,052 ft.) from Bormio to Spondigna in the Adige valley; the Bernina pass (7.316 ft.) from Tirano to Samaden in the Upper Engadine; and the Aprica pass (3,875 ft.) from Tirano'to the Val Camonica and the Lake of Iseo; while from near the top of the Stelvio a fourth road leads over the Umbrail pass (8,209 ft., the highest in Switzerland) to the Swiss valley of Münster, which is reached at the village of Santa Maria.

The population is wholly Italian-speaking and Roman Catholic, the valley being in the diocese of Como. The shrine of the Madonna of Tirano (founded 1520) attracts large numbers of pilgrims. The valley, particularly in its lower portion, is extremely fertile; and of late years vigorous measures have been taken to prevent the damage caused by the frequent inundations of the Adda. Chestnuts, vines, mulberry trees and fig trees abound; and there are many picturesquely situated churches, castles and villages. The chief articles exported are wine and honey. Large quantities of honey are annually sent abroad. The Valtellina has now become important for its hydroelectric plants.

History.—After the defeat of the Lombards (774) the Valtellina was given (775) by Charlemagne to the abbey of St. Denis near Paris, which never seems to have exercised its rights. In 824 Lothair I., confirming an earlier donation (803) made by Charlemagne, gave the churches of Poschiavo and Bormio to the bishop of Como. Bormio was in 1205 won by the men of Como, who in 1006 had received one-half of Valtellina from the emperor, and by 1214 they were masters of the entire valley. They retained Bormio till 1300, when it freed itself; but in 1336 it belonged to the bishop of Chur. In 1335 the Visconti of Milan became lords of Como, and therefore of Valtellina. As early as 1360 the men of Rhaetia made incursions into Valtellina on the pretext that it had formed part of ancient Rhaetia. This idea was confirmed in 1404, when, in return for kind treatment received during his exile, Mastino Visconti (son of Barnabò) gave to the bishop of Chur his share of the Milanese, including Poschiavo, Bormio and Valtellina. Relying on this donation, the men of the Three Leagues of Rhaetia (best known by the name of Graubiinden) invaded the valley in 1486–87, Poschiavo becoming in 1486 permanently a member (not a subject land) of the Gotteshausbund. In 1512 Chiavenna, Bormio and Valtellina were also seized and harshly ruled. Mastino Visconti's donation was solemnly confirmed in 1516 by the emperor Maximilian I. In 1530 the bishop of Chur was forced to sell to the Three Leagues his title to these two districts. At the time of the Reformation Poschiavo became Protestant. The other two districts clung to the old faith and came under the influence of Carlo Borromeo. Valtellina was extremely important to the Habsburgs as affording the direct route between their possessions of the Milanese and Tirol. Hence a great struggle took place between Austria and Spain on one side and France and Venice on the other. The religious conflicts in Graubdnden led to reprisals in the "subject land" of Valtellina. In 1620 (July 19–Aug. 4) the Spanish and Catholic faction (headed by the Planta family) massacred from 350 to 600 Protestants in the valley, according to different accounts (*Veltliner* Mord or *Sacro Macello*). For the next 20 years the valley was the scene of great strife, being held by the Spaniards (1621–23, 1629–31, 1637–39), by the French (1624–27, 1635–37) and by the pope (1623, 1627). At length Georg Jenatsch, a former pastor, who had been the active and unscrupulous leader of the Protestant party, became a Catholic (1635) in order to free the land from the French by aid of the Spaniards (1637), who finally (1639) gave it back to its old masters on condition that the Protestants were excluded from the valley. In this way the local struggles of Valtellina came to be mixed up with the Thirty Years' War. In 1797 Bormio and Valtellina were annexed to the Cisalpine republic, in 1805 to the Napoleonic kingdom of Italy and in 1815 (despite the remonstrances of the Rhetian leagues) to the kingdom of Lombardo-Venetia, held by the emperor of Austria. In 1859 they became, like the rest of Lombardy, part of the kingdom of united Italy. Poschiavo followed the fortunes of the "Gotteshausbund." It became (after 1798) part of the canton Rhetia of the Helvetic republic, and in 1803 of the canton of the Graubiinden or Grisons, which was then first received a full member of the Swiss Confederation. (See SWITZERLAND.)

VALUATION. In English law a valuation may be said to be an opinion of the value of goods or of an interest in land or in land and buildings. Valuations, particularly of land or of land and buildings, can be made for various purposes. including sale, purchase, mortgage, insurance, compensation of different kinds and for purposes of taxation including rating, income tax and death duties. The opinion may be of capital or of rental value and the valuer's opinion of the same interest in a property may vary according to the purpose of his valuation, because of the statutory provisions under which the valuation is made or because of considerations which in the valuer's opinion are involved.

The usual methods of valuation employed include: (1) direct comparison of capital value between the property to be valued and other similar properties, either as entities or by means of a suitable unit; for example, farm land is often valued at so many pounds per acre; (2) cost of construction of buildings; (3) profits, in the case of certain types of business premises; for example, licensed premises; (4) residual basis, usually applied to properties upon which it is necessary to expend capital in carrying out improvements in order to realize the full potentialities of the property; (5) investment basis, which consists of applying a rate of interest to an actual or to an estimated income to arrive at capital value. In connection with the last method, valuers often employ various tables of compound interest.

Where a contract has been made for the sale of property at a valuation, a valuation made in accordance with its terms will be conclusive as between the parties, in the absence of fraud, collusion or mistake. Where there has been an agreement to sell goods on the terms that the price is to be fixed by the valuation of a third party and such third party cannot or does not make spch valuation, the agreement is voided; but if the goods or any part thereof have been delivered to and appropriated by the buyer, he must pay a reasonable price therefor. Where the third party is prevented from making the valuation by the fault of the seller or buyer. the party not in fault may maintain an action for damages against the party in fault. Where the fixing of a value by valuers is not of the essence of an agreement, but is wholly subsidiary to it, the courts will, if justice requires it, ascertain the value in order to carry the agreement into effect. In a case nhere an agreement had been entered into for the sale of a house at a fixed price and of the fixtures and furniture therein at a valuation by a person named by both parties, and he was refused permission by the vendor to enter the premises for that purpose, the vendor was ordered to allow the entry. A valuer is liable to the person who has employed him for the consequences of negligence or want of due care on his part, but to that person only and not to any other. If his services are thereby rendered worthless he will not be able to recover anything by way of remuneration. He is not, as a rule, liable for a mistaken opinion of value. (*See* AUCTIONS AND AUCTIONEERS; ESTATE AND HOUSE AGENTS.) (X.)

UNITED STATES

Valuation under U.S. law has assumed great importance particularly in three fields: taxation, corporate reorganization and public utility rate regulation. This discussion does not encompass valuation problems presented in the guise of damages for injury to person or property or for property taken. which arise frequently in damage suits, eminent domain cases and under insurance policies. (See COMPENSATION; DAMAGES; TORT; etc.)

Although essentially the same terms, value, market value and fair value, recur in various branches of the law, valuation methods and the results reached vary markedly with the circumstances and purposes of the valuation. While the traditional legal definition of value—the price at which property would change hands between a willing seller and a willing buyer with neither under compulsion to act—is regularly repeated by the courts, it contributes little to the solution of valuation problems. Realistic valuation requires a recognition that value is a term which is not, in Justice Oliver Wendell Holmes's words, "a crystal transparent and unchanged" but instead "the skin of a living thought and may vary greatly according to the circumstances and the time in which it is used" (Towne v. Eisner, 245 U.S. 418, 425, 38 S. Ct. 158, 62 L. Ed. 372, 376 [1918]).

Taxation.—The constitutions or statutes of most states require real property, and in some states personal property, to be assessed, for tax purposes, at full value, cash value, fair value or by a similar standard. While the terms used by the statute vary, there is no discernible difference in assessments made by reason of the particular language used. Three principal methods of valuing real property are used in administering property tax statutes: (1) analysis of market data, with particular emphasis on current sales and bids and offers affecting the property being valued and comparable property; (2) consideration of cost of reproduction of the property, reduced by accrued depreciation; and (3) capitalization of the earnings of the property. Evidence of sales prices of comparable property, made on an arm's length basis by vendor and vendee not labouring under undue pressure to sell or to buy is ordinarily the best evidence of value. Indeed this is the very essence of the value being sought. Such evidence is rarely available, for the sales each year are comparatively few in relation to the vast number of properties required to be assessed. Because the very definition of value assumes a free and steady market, it has been suggested that just as in income tax cases where the statutes typically tax the receipt of property at its market value, no tax should be imposed where no market exists. Such a rule would exempt from property taxation large blocks of property and in depressed times would play havoc with state and local tax revenues. It is, accordingly, well established that the terms value, full value and cash value, or other ad valorem statutory phrases are not synonymous with market value. A whole host of cases arising during the depression of the 1930s produced judicial decisions (and in some cases statutory modifications) requiring properties to be valued by reference to a nonexistent normal market. Where evidence of sales does not exist, bona fide offers to buy and sell may be used. In dealing with such evidence, a major obstacle lies in establishing that the properties sold or bid or offered are in fact comparable in character, location and other qualities.

The capitalized earnings method lends itself best to the appraisal of commercial rental property and apartment houses. It is based on the premise that future income capabilities determine the present value of the property. Actually the future income, the prediction of which is a hazardous undertaking, is normally ascertained by reference to past earnings, and the capitalization rate is determined by reference to the expected return from real estate in the community. Many difficulties arise in determining the net income from the property, once gross rents have been ascertained. Depreciation, adequacy of the use of and improvements in the property, the appropriate capitalization rate and other factors give rise to much controversy in using the earnings method.

The courts have placed a good deal of reliance on reproduction cost, less depreciation, particularly where market price data are unavailable, as a method of valuation in property tax cases. In some states, assessed values of improvements may not exceed reproduction cost, less depreciation, on the theory that no buyer would in ordinary circumstances pay more than the replacement value of the property. The techniques of estimating replacement costs have greatly advanced in the 20th century. Elaborate tables giving the cost per cubic foot of erecting buildings of various types have been prepared and are published in assessors' manuals; they are kept up-to-date by price indexes and current market costs. Depreciation is typically determined on a straight line basis, and obsolescence must also be taken into account.

In practice, it is seldom possible for the assessor to find adequate sales data, or to determine the replacement cost or to compute the capitalized income for more than a small proportion of the properties to be assessed. Consequently, the practical solution adopted by assessors is to utilize a comparative mass appraisal approach derived from the three methods of valuation. By the use of sales and income data, various types of land are reduced to front or square footage rates for standard parcels. These standard units become the base for valuing land. adjusted for special features, such as corners, depth, terrain and so forth. Similarly, various types of buildings are reduced to standard unit cubic footage costs for each classification of improvement; once a structure is assigned to a particular classification, replacement cost new is determined and adjustment is made for depreciation.

In the second half of the 20th century there was a growing recognition that assessment methods had failed to achieve equality among property owners, both because of inadequacies in the assessing staffs and the dislocatians in values produced by wide price fluctuations, rapid and large scale movements of population and industry and new technological developments in construction. A 1957 study made by the Assessment Advisory committee of the New York State Board of Equalization and Assessment found that over half the sample parcels of properties studied in cities were assessed at more than 25% above or below the average for the assessment roll, and that about one-third the properties in towns and villages showed at least a 25% variation from the over-all level. While extensive revisions have been made in assessment methods and procedures, including the making of periodic reassessments of property, improvement in the calibre and training of assessing personnel and vesting of greater control and supervision of assessments in state equalization or taxing boards, significant developments have been taking place in the courts to achieve greater equality among property owners. The extent of judicial review of ad valorem assessments varies markedly among the states. Thus, in some states — California, Illinois and Texas are among them — assessed valuations will not be set aside by the courts unless they are "arbitrary," "capricious," or are so excessive as to be "constructively fraudulent" or involve "an error of law." In such states taxpayers are virtually denied judicial relief from overassessment or inequality in assessment except in the most flagrant cases, or the application of methods or rules of assessment regarded as erroneous by the courts. These courts proceed on the theory that the assessing function has been vested in the assessor and that his judgment as to valuation, erroneous though it may be, is not subject to judicial review unless tainted by fraud, caprice or error of law. In other states, among them Alabama. Iowa, New York and Pennsylvania, the courts have gone to the opposite extreme, allowing a very broad scope for judicial review. While these courts pay lip service to the rule that the action of the assessor is prima facie correct, once the taxpayer introduces valuation testimony attacking the assessments, the courts essentially take over the assessment function and make their own determinations as to assessed values. The result of this approach is not only a usurpation of an executive function by the courts, but it has also produced an unending flow of property tax litigation to clog the courts. Thus, in New York city alone about 10,000 property tax cases per year were filed.

The scope of judicial review should depend on the character of the administrative review. If the taxpayer is given a fair hearing to review the action of the assessor before a competent, impartial and independent review board, the courts ought to be limited to considering problems of laws, errors of method and impropriety in procedure. However, if the administrative review is a perfunctory, rubber-stamp type of hearing conducted by the taxing agency itself or by other personnel in the executive branch of the government, then there is considerable justification for broad judicial review.

An intermediate view of the place of judicial review in property tax assessments has been adopted by the courts of other states, notably, Massachusetts and Ohio. In those states, the courts respect the valuations made by the assessing officers, without paying the slavish deference accorded to their action in states such as California, Illinois and Texas. Only "errors of law" are reviewable, but the absence of substantial evidence to support the assessor's action is regarded as an error of law. Here the courts are following the principles of judicial review of action of administrative officers which have been developed in the law generally.

A virtual revolution in property tax assessments took place in several states as a result of a series of landmark decisions by the highest state courts in New Jersey dealing with inequality of assessment, a requirement emphasized by the mandate embodied in all but two or three state constitutions that assessments must be equal and uniform. It is notorious that despite statutory requirements of full value assessments, few taxing authorities seek even to approximate full value. The key, therefore, to an equitable distribution of property taxes is equality of treatment of various property owners. Effective relief from inequality in assessment was, however, barred by the rule long followed in New Jersey and other states, that so long as a taxpayer could not show that his property was assessed at more than its full value, he could not have his assessment reduced in the courts, despite a showing that other properties were assessed at a lower percentage of full value than his property. Although the United States supreme court had held as early as 1923 in the landmark case of *Sioux City Bridge Co.* v. *Dakota county* (260 U.S. 441 [1923]) that such a rule violated the taxpayer's federal constitutional right to equal protection of the laws, a number of state courts continued to deny reductions in the complaining taxpayer's assessment and to offer him instead the expensive and impracticable procedure of starting proceedings to have all other assessments brought up to the level of his assessment. Such decisions helped perpetuate the single most striking characteristic feature of U.S. ad valorem taxation, namely, that the statutory mandate to tax all property at uniform full value has been consistently ignored for at least many decades. When a group of taxpayers in Essex county, New Jersey, indignantly challenged an upward reassessment of a selected group of properties, while property in the county generally remained at the old level, the New Jersey court in 1954 held that the property owners were entitled to have their assessments reduced (*Baldwin Construction Co.* v. *Essex County Board of Taxation*, 16 N.J. 329, 108 A. 2d 598 [1954]). This decision initiated a development in the New Jersey courts which resulted in holding that assessments at anything less than full value are illegal (*Switz* v. *Township of Middletown*, 23 N.J. 580, 130 A. 2d 15 [1957]). This was a highly salutary development, for so long as assessors flout the legal requirement of assessing all properties at full value (or at a lower fixed statutory percentage), inequalities and unfairnesses will be rife. Legislation was introduced in New Jersey, and was in force in some other states, requiring assessment at a fixed percentage for all properties but at values less than 100%. Whether substantial uniformity and equality would be achieved under such legislation was uncertain.

Intangibles present a host of troublesome valuation problems in death and income taxation. The statutory standard is typically fair market value. Securities traded on stock exchanges or other public markets are ordinarily valued by reference to market quotations. However, where a large block of securities is involved, the courts have generally accepted so-called blockage valuation. Here testimony of experts as to the price which can be obtained for the block of stock being valued and the costs of marketing the stock typically result in lower valuations than market quotations involving small blocks.

The valuation of a substantial business, with its fixed and current assets and its tangibles and intangibles, is a considerable undertaking. Many states are confronted with the even more difficult task of determining, particularly for purposes of property taxes on public utilities and capital stock taxes on corporations generally, the value of a portion of a business which is conducted in more than one state. Under the federal constitution a state may ordinarily tax only the portion of the corporation's business or assets located within its borders. Apportionment formulas have been developed which admittedly do not accurately measure the value of the portion of the corporation's assets, business or capital stock employed in the state but which are acceptable handy tools for solving an extraordinarily difficult valuation problem. The most nidely used formula for apportioning the assets (or the net or gross income where that is the base of the tax) of an interstate business among the states is the so-called Massachusetts formula, which averages the ratios of (1) the value of real property and tangible personal property within the state to the total wherever located; (2) business receipts from business done in the state to total business receipts; and (3) payroll within the state to total payroll. Because the United States supreme court has sustained virtually every apportionment formula which has been challenged before it—and properly so under the federal constitution—the multistate business is at times subject to a myriad of formulas which sometimes produce aggregate valuations exceeding the total value of the enterprise.

Corporate Reorganization.—In corporate reorganizations which stem from insolvency, or in the case of solvent corporations reorganized under the Public Utility Holding Company act of 1935 or other regulatory statutes, valuation is required to establish (1) the extent and nature of the securities which can soundly be issued by the reorganized company on the basis of its assets; and (2) the degree to which existing security holders are entitled to participate in the reorganized enterprise. In contrast with valuations in other areas in which the courts lean heavily on asset values and on past earnings, the law in insolvency reorganizations has developed toward acceptance of the principle that values are determined primarily by reference to estimated future normal earning power, giving weight to past earnings adjusted to reflect actual and expected changes in conditions. These earnings are capitalized at the rates at which the market for securities of comparable enterprises reflects the capitalization of the earnings of those enterprises. Asset values are ordinarily significant only where they exceed the earnings valuation, in which case liquidation of the enterprise is indicated.

An important doctrinal development took place in reorganizations under the Public Utility Holding Company act which affected the results. In administering the act, the Securities and Exchange commission (SEC) utilized the investment-value doctrine under which the claims of securities surrendered were determined by "the value of the securities on the basis of a going business and not as though a liquidation were taking place" (15 SEC Ann. Rep. 124 [1949]; *Electric Bond and Share Co.*, 21 SEC 191, 197, 210, 21 SEC 309. 21 SEC 457, enforcement granted S D N.Y. [1945]; compare *Otis & Co.* v. *SEC*, 323 U.S. 624 [1945], *SEC* v. *Central Illinois Securities Corp.*, 338 U.S. 96 [1949]). The bundle of rights embodied in the surrendered security determined the scope or magnitude of the claim, not as it stated obligations to be fulfilled, but only to the extent that these obligations were in fact reflected by the value of the business as a going concern. The effect of the application of this doctrine was to entitle security holders to receive at times less and at other times more than the contractual liquidation value of the claim. Nevertheless, because most holding companies' reorganizations were carried out in the 1940s and 1950s, when the national economy was expanding rapidly and the utility industry in particular experienced a phenomenal growth, in point of fact, frequently the new securities issued turned out to have a market value far in excess of the apparent investment value of the old securities surrendered. At the same time, participation and values were preserved for common stock and other junior securities.

The investment value doctrine is held by the supreme court, as well as by the Securities and Exchange commission, to be inapplicable to bankruptcies, cases under chapter X of the Bankruptcy act and other insolvency reorganizations, where the courts deal with enterprises that have failed. In such circumstances, under the so-called absolute priority principle, the security holder is entitled to measure his claim by liquidation standards. Nevertheless, even in insolvency cases, this does not mean that he is entitled to the immediate cash liquidation value of his claim, but only to a security that will, within a reasonable time, sell at prices equivalent to the claims they replace. In actual operation. however, the market prices of securities issued under this rule particularly in railroad insolvency reorganizations, often failed to reach the claims of senior security holders within a few years after the reorganization. These results reflect weaknesses in applying the doctrine and excessive optimism in determining value, as well as an unarticulated effort to prevent the wiping out of junior claims. While the wisdom of applying liquidation standards and the propriety of sticking to the absolute priority rule in insolvency reorganizations has long been the subject of dispute in the literature, the differences in the nature, origin and objectives of insolvency reorganizations as compared with Public Utility Holding Company act reorganizations justify the rejection of the investment company doctrine in the former type of cases.

In mergers and similar combinations of corporations, dissenting stockholders are generally entitled to be paid the value of their stock Unlike insolvency reorganizations and reorganizations under the aegis of regulatory commissions, primary weight has been placed on market quotations of the stock being appraised, and in some states consideration is also given to past earnings and asset valuations. In only a few jurisdictions do stockholders receive liquidating value (*i.e.*, asset value), when it can be established that such value exceeds the amounts determined by reference to market quotations, capitalization of past earnings or other methods employed.

Public Utility Valuations.—The United States constitution, as interpreted by the courts. requires the states and the federal government. in regulating rates of public utilities, to permit a reasonable return on the property dedicated to the public service. In 1898, in the momentous case of *Smyth* v *Antes,* the supreme court held that utilities nere entitled to a reasonable return on the fair value of their properties and that in ascertaining fair value the original cost of construction, the cost of reproduction and the amount and market values of the utility's stocks and bonds were to be taken into account. The first two decades of the 20th century witnessed a struggle in which utilities typically sought to have their properties valued by reference to original cost to protect their historical investments, while state rate commissions found it advantageous to give greater weight to cost of reproduction (in both cases with adjustments for depreciation). With the sharply rising costs of production brought on by World War I the tables were largely turned, and the utilities sought values measured by reproduction costs; they succeeded by the middle 1920s in obtaining reversals by the supreme court of decisions of state regulatory commissions for failure to give adequate weight to reproduction costs. Justice Louis Brandeis dissented from these holdings and advanced the theory that the rate base should be determined by the "amount prudently invested" in the property dedicated to public service. In the 1940s the supreme court largely abandoned the role of safeguarding to utilities a fair return on the present value of the properties, took the position that the valuation function belongs to regulatory agencies and limited its review of rate orders to a determination as to whether "reasonable rates" had been allowed. While the contours of the conception "reasonable rates" had not yet been rounded out in the second half of the 20th century, it was clear that the revenues must be sufficient to enable the utility to meet its operating expenses and interest and dividend requirements and to maintain proper credit and market standing.

Valuation for utility rate purposes was thus lodged essentially in the administrative agencies. Each of the valuation methods available to such agencies has its defects and shortcomings. The use of original cost often involves proof of costs incurred many decades previously, with records that are inadequate or that have been destroyed or lost; padded costs and unwarranted expenditures must be squeezed out. Reproduction costs involve estimates and speculation as to costs of labour, materials and money; and every major fluctuation in costs requires a revised valuation. The prudent investment theory eliminates some of the defects of original cost and reproduction cost valuations, but, as is true in other fields. valuation by a single yardstick or by formula seldom produces acceptable results. A consideration of all these methods appears to be required, but the soundness of the judgment of value to be reached will depend on the expert knowledge, the integrity and the economic predilections of the valuers, for public utility valuations have their roots in the political and social attitudes of the day; it is not surprising, therefore, that utility valuations tend to fluctuate with the temper of the times. VALUE. In economics the value of a good is measured by the quantity of other goods for which it will exchange. As this depends on the relative prices of the goods in question, the phrase "the theory of value" has come to be applied by economists to that branch of their science which is concerned with the forces governing the relative prices of different goods and services. Changes in the price of any particular good are measured by comparing its money price with that of another good or with an index number measuring prices in general. The price of a good may be influenced by a number of transient factors; *e.g.,* by good or bad harvests (in the case of agricultural products), by changes in fashion or by temporary gluts or shortages arising because producers have misjudged the extent of demand. These factors have been regarded as causing fluctuations about a normal price determined by more fundamental forces, and the study of these fundamental determinants of economic value has always occupied a large part of the attention of economists.

One of the oldest theories on this matter is the labour theory of value. Adam Smith said that "Labour alone, therefore, never varying in its own value, is alone the ultimate and real standard by which the value of all commodities can at all times be estimated and compared"; though he goes on to say that account must be taken of the rent of land and of the profits of "stock" or capital. The theory was presented in its purest form by David Ricardo. He showed that the rent of land was not a causal factor in value, since the value of a good had to be high enough to cover its cost of production on the worst land in use, which would be earning no rent. He regarded capital as stored-up labour and assumed that the proportion of capital to labour was roughly the same for all goods. He was thus able to ignore interest on capital and to maintain that the normal prices of goods tended to be proportional to the amount of labour required to produce them.

The labour theory was taken up by Karl Marx and a number of socialist writers, but it is unsatisfactory in several ways: it does not deal adequately with differences between various types of labour; it eliminates interest on capital only by means of an arbitrary and unreal assumption; and it affords no recognition of the part played by organization and by risk bearing in the productive process. In seeking a way out of these difficulties, some writers, including John Stuart Mill, turned to a cost-of-production theory of value, asserting that normal prices tended to be proportional to the costs of production.

A good can obviously have no value (and so will not be produced) unless someone has a use for it. Smith, Ricardo and Mill had all distinguished between value in use and value in exchange, but they did not carry the idea of value in use very far. During the second half of the 19th century, however, it was raised to a central position in value theory as a result of the writings of W. S. Jevons, of Carl Menger and of M E. L. Walras. They showed that, other things being equal, the utility per unit of a good declines with an increase in a consumer's rate of purchases. A rational consumer will adjust his purchases so that the utility that he gets from the last unit bought is just equal to that which he could get by spending his money in some other way. The utility of this last unit, which is only just worth buying, is known as the marginal utility of a good, and it follows from this reasoning that the prices of different goods will tend to be proportional to their marginal utilities.

The synthesis of the cost-of-production and marginal-utility theories owes much to the work of Alfred Marshall. Marshall distinguished between four "agents of production": land, labour, capital and organization. He accepted and extended the Ricardian view of rent but maintained that the normal reward of the other three factors must be-included in cost of production. The "normal" reward, in this sense, would be that which was necessary to maintain a given supply of a factor engaged in the production of a particular good. being neither high enough to attract additional supplies from other industries. nor low enough to cause factors to be lost to other industries. Marshall analyzed the way in ahich cost of production varied with changes in the rate of output and developed the concept of marginal cost. analogous to that of marginal utility. He was thus able to show that, given time for adjustments to take place. a change in either the demand for or the cost of production of a good would lead to a change in its rate of production such as to keep both marginal cost and marginal utility equa! to price. Hence. he says, "We might as reasonably dispute whether it is the upper or the under blade of a pair of scissors that cuts a piece of paper as whether value is governed by utility or cost of production ··

Since the cost of production of any good depends on the prices of the factors of production, any theory of value which uses cost of production must study factor prices as well as goods prices. Factor prices, like goods prices. are determined by supply and demand. but the supply of many factors is determined by forces outside the scope of economics (*e.g.,* by the size of the working-age population). When the supply of a good or a factor is given, its price must be such that the given supply will just satisfy the demand. This led later writers to give demand (determined by utility) a rather more prominent place in the theory of value than Marshall had given it.

The price which must be paid for a factor used in the production of any one good depends partly on the demand for that factor for the production of other goods. This, in turn. depends on the demand for those goods and on the cost of other factors used in their production. Hence no one price can be strictly determined except in relation to all others, and the logical extension of the marginal-utility and cost-of-production theories is the "general equilibrium" analysis, used by most modern value theorists. in which these relationships are all expressed as mathematical functions from which relative prices can be determined by the solution of a number of simultaneous equations.

Marshall generally assumed a state of free and perfect competition, though he discussed monopoly briefly as a special case. There are. however, many types of market structure intermediate between pure competition and simple monopoly. A market may be imperfect because people are prevented from buying from the cheapest seller. whether through ignorance or by prejudice or costs of transport. An industry may be dominated not by a single monopolist but by a few large firms: or competition may be deliberately restricted either by actual agreement or by tacit understanding between firms. Much of the work in value theory after Marshall's death was devoted to one or other of these situations.

Another controversial change was that which by the middle of the 20th century had come about in the treatment of marginal utility While some economists still maintained that marginal utility is intrinsically measurable and that it can actually be measured in some situations (though not in all) by the amount of money that a consumer is prepared to pay for a marginal unit of a good. others, asserting that the cardinal measurement of utility is impossible, adopted a system in which the consumer is supposed to have only an ordinal scale on which various combinations of goods can be ranked in order of preference; the consumer is then supposed to choose the combination of goods which gives him the maximum utility attainable in any given situation, but no attempt is made to measure utility. Yet other economists rejected the idea of utility altogether and attempted to reconstruct a theory of demand on purely behaviourist lines, simply assuming that the consumer makes a series of consistent choices but without saying anything of what lies behind them.

These changes made value theory in some ways more realistic; but they rohhed it of some of its generality and took economists further than ever from the acceptance of any absolute standard of value. Value came to be equated with relative price, and the word price to displace the word value in much of the contemporary literature.

VALUE, THEORY OF. Until comparatively recently there was no general theory of value. Value has long been a fundamental notion of political economy, and various theories of its nature have been developed, but it was not until the 19th century that it came to be universally recognized as one of the great philosophical topics. Its discovery has been held by some to be "the greatest philosophical achievement of the 19th century," and its development as a special field of psychological and philosophical study has gone so far that a special name has been created for it. namely "axiology."

The development of such a theory requires the consideration of the following problems: (1) What is the nature of values (definition)> (2) What are the fundamental values and how are they to be classified? (3) How may we determine the relative values of things and what is the ultimate standard of value? (4) Are values merely subjective. satisfying merely subjective desires, or are they objective, in some sense other than objects of desire, and giving some law or norm to desire? (5) What is the relation of values to things or of value to existence and reality>

History of the Value Notion. — A brief sketch of the history of the idea of value in philosophy will help to make clear the meaning of these problems. The Greeks did not have the term value as now understood, but in the light of subsequent developments it may be seen that they had the notion and were aware of these problems. Plato conceived the good or value as the culmination of the world of ideas and the constructive principle of the world which organizes all its forms or laws. Aristotle. in proposing to view all things teleologically and to make the relation of a thing to its end or value essential to its very being, affirmed not only the objective reality of value qualities but also their supremacy over all the other attributes of things. Neither Plato nor Aristotle developed this line of reflection fully, nor did succeeding philosophers investigate the subtle and perplexing problems involved in it. Plato himself called this the most difficult question of all science. Nevertheless, the general principle enunciated by Greek philosophy continued to be the rule throughout the middle ages, and the objectivity of value the key to all thinking.

The modern developments of the subject proceed directly from Immanuel Kant, who here, as elsewhere, represents a crisis in philosophic thought The classical conception of the objectivity of the good or value had been abandoned by empirical thought. If the "secondary" qualities. such as colour. taste, sound, etc., are made dependent upon the percipient subject. all the more must the "tertiary" qualities such as beauty. goodness, etc , be made dependent upon human desire and feeling. This extrusion of all values from the objective world seemed to Kant to be the necessary consequence of the assumptions of "science." But he could not accept it as the whole story of values. By a well-known line of reasoning which cannot be repeated here. he restored their objectivity in a new form. Though not "existent" in the same sense as physical things their reality must be postulated and acknowledged if life and action are to be possible They have. in his terms, "validity" and "practical reality." With this an entirely new line of thought was set in motion, raising new problems of fact and value. value and validity, value and existence. A large part of modern axiology or general theory of value has developed under the inspiration of neo-Kantianism. But it is to R. H Lotze (1817–81) more than any other man perhaps except Nietzsche that the popularity of the term value is attributable, and certainly he more than any other is responsible for the prevalence of the idea of value as an ultimate notion in philosophy Albrecht Ritschl (1822–89), Lotze's theological colleague at Göttingen made the value notion central in the discussions of religion and theology and furnished modernist tendencies in theology with a large part of their inspiration and much of their terminology. He agrees with Kant that the objects of religion are objects of faith as distinct from knowledge in the scientific sense, but he develops much further the notion that they are matters of value judgment as distinct from theoretical judgment, although equally capable of certainty and validity. It is mainly to Ritschl that is due the current distinction between judgments of value and judgments of fact and the subordination of judgments of fact to judgments of value. From Ritschl's position it was easy to pass to that of W. Windelband (1848–1915). who, together with H. Rickert and Hugo Mdnsterberg (1863–1916), developed the neo-Kantian axiology to which reference has been made.

The chief stimulus to the development of the general theory of value as a distinct field of psychological and philosophical study came, honever, from the work of **A.** Meinong (1853–1920) and C. von Ehrenfels (1859–1932). A fresh analysis of value in the economic sense had been undertaken by the Austrian economists Eugen Bohm von Bawerk and Friedrich von Wieser which resulted, among other things, in raising many problems of psychological and even philosophical importance. Under their influence, Meinong and Ehrenfels investigated values other than economic, and first undertook a systematic study of the entire field of value. The more philosophical developments of the subject were largely the work of Meinong. Starting with the psychological concept of the economists, he gradually came to the view of values as objective and independent of their being experienced. At this point the problems of the two modern movements described tended to coalesce. No history of value theory would, however, be complete that did not note the influence of Nietzsche, with his "transvaluation of all values," and the pragmatic movement in philosophy. for which knowledge is subordinated to practice and truth becomes a form of value.

Nature of Value.- he fundamental problem of a general theory of value is the question of the nature of all determinations of value; in other words. of so defining it as to include all the forms of value. The immediate and natural answer to this question is to say that value is a determination or quality of an object which involves *any sort* of *appreciation or interest.* Such appreciation, however, involves feeling and ultimately desires or tendencies underlying the feeling. Therefore value *is* the feeling. Value and feeling of value are the same thing. This is the psychological notion of value, and the theory of value developed on this basis is the psychological theory of value. For many this seems to tell the whole story The economic theory of value made its first scientific steps by abandoning the notion of value, whether in use or exchange, as an objective quality inherent in the thing, and conceiving it as the function of the relation of the object to satisfaction of desire. Following this lead. the general theory of value was in the first place a psychological theory of value. Even in economic theory, however, it is realized that this is only part of the story. Back of desire and feeling lie certain biological tendencies or instincts presupposed by the desire and its satisfaction. So that value becomes. in the words of Orestano, "a biological phenomenon appearing in psychological form." A theory of value that shall be not merely a theory of *price* must relate the *instrumental* values of economics to life. Unless we consider these tendencies merely in their aspect of determinants of price, we must have a quite different notion of value to include them. If this is true of the limited field of economic goods or values, it is all the more true of the *intrinsic* values which a more general theory of value recognizes. Psychological theories of value thus tend to become biological theories in the broader sense of the term. Value is defined in terms of survival and enhancement of life. and the biological tendencies are graded according to some standard of value-for-life. It is at this point, however, that the specifically philosophical theories of value arise. We wish to explain and ultimately validate these values by carrying them back to life. But in this it is already assumed that life and its continuance have value. If values get their significance from their teleological relation to life and its enhancement, then surely life must get its significance from "absolute" values which it embodies; otherwise life and its relative values lose all genuine meaning. From a more ultimate point of view a knowledge of value is presupposed in any concept of a valuable life. As the result of reflections of this type, two main positions have emerged in the general philosophical theory of value. Either value is conceived of as a "logically primitive" concept. and therefore as ultimately indefinable, as are certain other ultimate concepts in philosophy, or else it is conceived of as function of the coherent organization of life or experience as a whole.

It may be said without hesitation that value theory is today predominantly philosophical rather than psychological. This does not mean, however, that the psychological study of the processes of valuation is not an important part of the general theory. The psychological question is what goes on in consciousness when we value, and while an answer to this question will neither tell us what value ultimately is, nor afford us a standard of value which will enable us to form a system or scale of values, it nevertheless throws light on many questions. The most important contributions here are, perhaps, the studies of the mutations or transvaluations of values. The popular interest aroused by Nietzsche in his *Genealogy of Morals* found a scientific echo in the study of the phenomena, causes and laws of the mutations of values. A notable feature of modern value theory is the interpretation of history as a value science, or part of a philosophy of values.

Classes and Standards of Value.—It is generally admitted that distinct species of value exist, although there is no complete agreement as to what they are or how they are to be classified. It is clear, however, that there are sciences which deal with values, and special sciences have been developed to deal uith special classes of value. Thus economic value has long been recognized as a fundamental notion of political economy, which ever since Adam Smith divided it into value in use and value in exchange has been defined thus. the former as the utility of objects for human purposes and the latter the power to induce or compel persons to pay other valuables for the use of them. That ethics also deals with values is generally agreed, although there is dispute as to just what these values are and how they are related. It is now generally recognized that ethical value is not identical with pleasure or happiness, although pleasure is one of the values. Aesthetic values are also generally, although not universally, admitted, many pragmatists holding that, since valuation is always judgmental. and the aesthetic "has no logical function, it must be denied the name of value " From the philosophical standpoint, the most important group of values distinguished is perhaps the logical or theoretical values. Several schools of thought hold that logic is the science of cognitive values and that truth is a positive and error a negative value Indeed this view is quite generally implied, although it is not always explicitly avowed. "Religious values" are quite commonly talked about, although whether they constitute a special group or represent rather a fusion of, or a reaction to, the other values is a matter of dispute. It may be argued that they do not constitute a distinct class, because there is no specific biological tendency or instinct to which they correspond, or that they represent merely the reaction on the fate of the other values in the universe. But the tendency to recognize the value of the "holy" as a distinct type, as developed by the neo-Kantians. is very strong: it found expression in a much-read book, *The* Holy, by Rudolf Otto. Some writers speak of distinct classes of social and political values, but the general tendency, perhaps, is to view these as subforms of the ethical.

Despite such differences of opinion, incidental to any developing theory, there is substantial agreement as to the existence of these five outstanding classes of values. There is, unfortunately, not the same consensus regarding their relations; *i.e.*, the ordering of these values in a system or in a scale of relative value and importance There are in general three accepted ways of classifying them. There is the psychological, which, assuming values to be the functions of interests or desire, divides them according to modes of this interest and tends to become ultimately biological and genetic, the outstanding classes being connected with some fundamental "instinct" or tendency. A more historical mode of classification accepts as units those values, or groups of values, which have acquired an institutional form, such as economic, moral. cognitive, political, aesthetic, religious. A third, which has been called the axiological, accepts in the main the trinity or tetrad of the good, the beautiful and the true, to which it adds the higher unity of God. Such classifications or systems of value all have their uses, but it is generally felt that the first two are not sufficient. A large body of opinion, accepting the axiological classification, holds that while the economic values are clearly instrumental and relative to the others, the other groups are intrinsic and absolute, and as such ultimately co-ordinate. Others hold that they may be put in relations of subordination in a comprehensive scale of values. There are, however, some things that may be said with a certain degree of assurance. The ethical, aesthetic and logical values are self-sufficient and co-ordinate in the sense that they are irreducible the one to the other. All attempts at such reduction, whether. for instance, of the aesthetic to the ethical, of the ethical to the logical or of the logical to the ethical, have proved unsatisfactory. On the other hand, it seems clear that they are all intimately related. No intrinsic value can stand alone. This is equally true whether we consider the question from the standpoint of the realization of values in the individual life or from the more objective point of view of their logical relations. It is impossible to define any one type of value alone or apart from the others. The ancient view that values are subsumable under the heads of goodness, beauty and truth, "a threefold cord, not lightly broken," is in general strengthened rather than weakened by modern value theory.

The idea that these ultimate values are co-ordinate in the sense described does not, however, as might at first appear, exclude the notion of an ultimate standard of value in the light of which some hierarchical principle or scale of value might be developed and the classes-of values be subordinated to each other. On the general question of the commensurability of value as such. there is a large measure of agreement. For the opinion. held by a fen, that they are incommensurable. there is indeed something to be said. It may be objected that an economic satisfaction and an aesthetic experience are of such different inner qualitative content that it is absurd to compare them with each other. The fact remains that we do actually compare them constantly. Not only do we compare values within the same class. as when we choose one economic good rather than another; but we also choose between types and classes. The standpoint of the incommensurability of values can be admitted only in the sense that the different values cannot he expressed in quantitative units and measured in this sense. But there are few that hold this idea at the present day. For the merely psychological or biological theories, the standard of value is found in such conceptions as intensity of feeling. the strength of the desire, or ultimately in the importance for life of the biological tendencies presupposed. For the more philosophical theories, on the other hand, that recognize the limitations of these notions of value, a different conception of the ultimate standard is also necessary. In general such a standard is found in the notion of *inclusiveness*, in some functional conception such as the totality of life or experience, that value being highest which contributes most to the coherent functioning and organization of experience as a whole. Such a standard may be formulated in terms that seem to avoid metaphysical implications, but in general it may he said that the highness or lowness of an experience of value is held to be determined by its metaphysical content. From this point of view a very common table or scale of values is that which puts the economic values as the lowest and the religious (in the broadest sense) as the highest. the ethical, the logical and the aesthetic being arranged in various ways in between. The standard here employed is, in the last analysis. some form of the principle of inclusiveness, the different values being arranged either in accord with the degree of integration of our interests or tendencies, or in accord with the range of the metaphysical content to which they correspond.

Logical or Theoretical Values — Validity. — Theinclusion of logical or theoretical values in the general theory of value is undoubtedly the main reason for the outstanding place which axiology has in modern thought. Such an inclusion obviously involves a radical revision of our entire notion of values and of the relation of value to fact and truth. It is pointed out by the value philosophers that for an ultimate analysis, logic is also a science of values. The pragmatists insist that theoretical values "presuppose purposes, selections. choices," and that "judgments are acts which do not differ in kind from those which are openly practical." The neo-Kantian axiologists point out that the desire for truth and rationality, the demand for logical consistency or validity, is itself a craving for what *ought to be,* and that here too we are moved by an ideal and directed by a norm, as surely as in the realms of ethical and aesthetic values. In either case validity becomes a form of value and logical rules instruments of the will to truth. The development of this notion involves difficult problems which cannot be gone into here. Whether the "value" of truth is relative or absolute; whether truth is the ultimate value upon which all the others in some way depend, or merely subordinate and instrumental to the other values. or. finally, in some way co-ordinate with them—all these are debated questions which, as we have seen. in turn affect the problems both of classification and order of values. In any case, the notion of validity as a form of value brought about in many quarters a radical revision of the notion of the relation of value to fact and truth. Against purely intellectualistic views it is contended not only that every statement of fact is ultimately an evaluation but also that the logical impulse ought not to have the primacy over the other demands of our nature, and that no philosophical system can he adequate which fails to do justice to all our values. Philosophic system tends to become, from this point of view, a system of values. or at least to presuppose such a system.

Value and **Reality.**—Whatever differences of opinion there may be among the various theories of value, there is substantial agreement that values are not subjective in the sense that they are merely matters of opinion and exist only for the persons who appreciate or feel them. Even for the psychological-biological theory. while they are dependent upon interest (desire and feeling), they are independent of judgment and opinion. The "objectivity" thus universally accorded values is indeed given different meanings, but in any case it is generally agreed that values cannot be denied existence or reality in any world that can exist for man. They must, it would seem, exist in several senses.

Values "exist" in the sense that they are operative and effective in and on human minds and in human action, and find embodiment in the objective institutions of society. They are "real" in the sense that they are valid, that is they claim to be true ideals as opposed to false ideals or fictions. They must, however, be real in a still more ultimate sense (metaphysical), in that they are part of the nature of things, and not something merely added to existences. For values to be real in either of the first two senses they must be real in the third. For both must be so related to real existence that they constitute the key to the nature of the real. Otherwise they become false ideals and futile fictions. The question of just how values may be said to exist (to be part of the nature of things) is a difficult and debated question that cannot be gone into here. It is possible, however, to state a general proposition to which almost all theories of value would subscribe. Values are not mere subjective incidents, more or less gratuitously superadded to fact, but are inherent in the structure of reality. Reality in its fullness contains and exhibits values. and they can be extruded from it only by a process of abstraction that is relative to restricted purposes (of special sciences) and that is never quite successful. This reinstatement of the objective reality of values (in its essentials the Greek notion) is attributable partly to developments within value theory itself and partly to a larger movement in philosophy as a whole. In any case, it is now widely felt that in the answer to the problems of value is to he found the key to the philosophical interpretation of reality as a whole.

BIBLIOGRAPHY.—The literature of the subject is extensive and scattered, some of the most important contributions being found in articles and journals and in general works in philosophy. Among the works in English expressly devoted to the theory of values are W. M. Urban, *Valuation, Its Nature and Laws* (London, 1890, etc.); and R. B. Perry, *General Theory of Value* (New York, 1926). Refs. to the more extensive liter. will be found in W. M. Urban. "Value Theory and Aesthetics." *Monist* (Oct. 1926). Important works in general philosophy in which the value notion is central are G. E. Moore, *Principia Ethica* (Cambridge, 1903); Hugo Munsterberg, *Eternal Values* (London, Cambridge, Mass.. 1909); B. Rosanquet. *The Principle of Individuality and Value* (London, 1912) and *Value and Destiny of the Individual* (London, 1913) (rep. the idealistic point of view); S. Alexander, *Spare, Time and Deity* (London, 1920) (rep. the realistic and naturalistic point of view); and W. R. Sorley, *Moral Values and the Idea of God,* 3rd ed. (Cambridge, 1924). The Ger. and Fr. lit. is even more extensive. Among those of historical importance are C. V. Ehrenfels. *System der Werttheorie* (Leipzig, 1897–98); A. Meinong, *Zur Grundlegung der allgemeinen Werttheorie* (Graz, 1923); G. Simmel. *Philosophie dcs Geldes* (Leipzig, 1900); H. Rickert, *System der Philosophie* (Tübingen, 1921); W. Stern, *Wertphilosophie* (Leipzig, 1924); C. Berpuer, *La Notion de valeur* (1908); C. Bouglé, *L'Evolution des valeurs* (1922). (W. M. U.)

VALVE (MECHANICAL), a device used to control the flow of some fluid (liquid, gas or vapour) in a line of pipe. The word preceding the term valve may indicate the type of valve or the purpose for which the valve is used; for example, the term gate valve indicates a type of valve, whereas the term relief valve indicates the purpose of the valve. The size of a valve, in inches

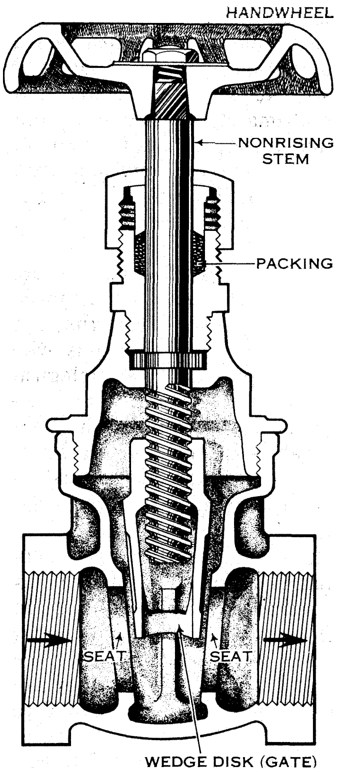

FIG. 1.—SCHEMATIC DIAGRAM OF GATE VALVE. FULLY OPENED

or feet, is the nominal size of the pipe in which the valve is installed.

Common types of simple control valves are the gate valve, globe valve, needle valve and butterfly valve. As illustrated in fig. 1, fluid flows through a gate valve in a straight line; this path minimizes resistance to flow. A gatelike disk, actuated by a stem (with screw threads) and a handwheel, moves up and down at right angles to the flow direction; the wedge gate seats against two seat faces to shut off the flow. The gate valve is suited for starting and stopping flow, but it is not ideal for regulating or throttling flom. It is best applied for services in which the valve is kept fully closed or fully opened.

Fig. 2 illustrates a globe valve, so-called because of the globular form of the valve body or casing. The globe valve is somewhat similar in action to that of the gate valve.

Horzever, it may have a tapered plug, a ball, a plug with a 45° seat or a disk in the upper movable section which fits a corresponding seat in the lower part of the fixed valve body. The disk is moved up and down by the valve stem (with screw threads) and a handwheel. The fluid must change direction in flowing through a globe valve and thus the resistance to flow is increased, but this construction permits better regulation or throttling of the flow. The valve disk and seat usually can be replaced or repaired quickly and conveniently.

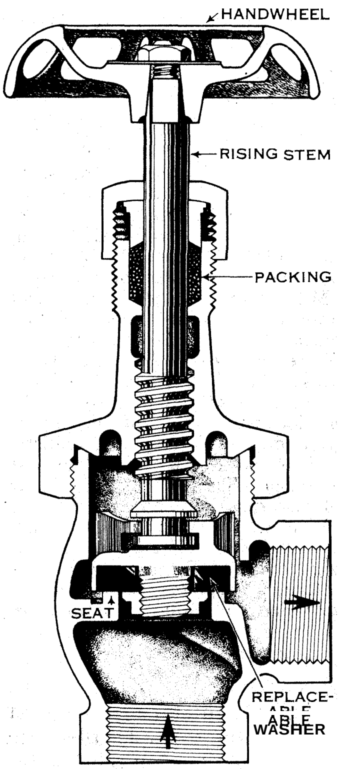

FIG. 2.—SCHEMATIC DIAGRAM OF BALL VALVE. CLOSED

The structure surrounding the valve stem is sometimes called a bonnet. Packing is placed in the upper part of the bonnet, around the stem, in order to prevent leakage of fluid past the stem. In some valves, called diaphragm valves, a circular diaphragm is installed to seal the bonnet without packing. The outer edge of the diaphragm is fastened to the bonnet, and the stem passes through a leakproof joint at its centre.

Fig. 3 shows a needle valve, in which there is a long tapered or conical piece or needle in place of a gate or disk. There is a tapered or conical seat in the valve body to mate with the movable needle. The needle is moved up and down by the valve stem (with screw threads) and handwheel, permitting a very gradual opening and closing of the passage. The volume of liquid flowing through the valve is controlled by the clearance between the needle and the seat. Fig. 3 also illustrates the design of the angle valve, in which the inlet opening is turned 90° from the outlet opening. When used in making a 90° turn in a pipeline, an angle valve reduces the number of joints and the labour in assembly. It also gives less resistance to flow than the combination of elbow and straight-run valve that it replaces.

FIG. 3.—SCHEMATIC DIAGRAM OF ANGLE NEEDLE VALVE

Fig. 4 shows the operation of a butterfly valve, which is essentially a circular disk, pivoted along one diameter. The damper used in stovepipes and warm-air heating systems is of this type, and butterfly valves also are used in the intake systems of automobile engines.

On hydraulic turbine installations, such valves may be 12 ft. or more in diameter.

Check valves are installed to prevent reversal of flow in piping, and they are available in several types. In each type, flom in one direction keeps the valve open, whereas reversal of flow or gravity, or both, closes the valve automatically. Fig. 5 shows a swing check valve; fluid moves through this valve in approximately a straight line from left to right. A swing disk, pivoted at its upper side, is held open by the flom; however, if the flow reverses, the weight of the disk and the movement of the fluid force the disk to seat on the valve seat. In the lift check valve, the construction is similar to that of the globe valve (except that there is no valve stem or handwheel), with the flow coming from under the valve disk and lifting it up. If the flow reverses, the fluid and weight of the valve disk block the reverse flow. In the gravity ball check valve, a ball rests on a spherical seat in the valve body. Flow in the upward direction lifts the ball off the seat; flow in the downward direction is blocked by the ball resting on its seat, A spring may be used to assure positive seating of the ball.

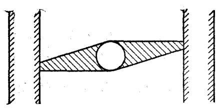

FIG. 4.—DIAGRAM OF BUTTERFLY VALVE

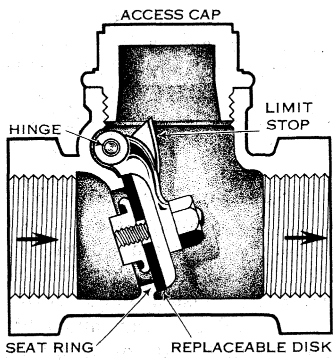

FIG. 5.—SCHEMATIC DIAGRAM OF SWING CHECK VALVE. CLOSED TO PREVENT REVERSE FLOW

Fig. 6 illustrates a cock. In the body is a tapered or conical seat; a conical plug with a hole fits into this seat. By turning the plug. the hole in it is lined up with the pipe or turned so that the pipe passage is blocked.

Pressure-reducing valves are used to lower the pressure in a particular section of a piping system. Fig. 7 illustrates such a valve, which has a cylindrical body holding a fixed valve seat; a valve disk (at one end of the stem) can move toward or away from the valve seat. The outlet pressure acts on the upper side of the movable piston, while a spring (which may be adjustable) acts on the lower side of the piston. The position of the piston, therefore, depends on the net effect of the spring force and the force of the outlet pressure. The piston, in turn, moves the valve disk upward as the outlet pressure is reduced (thus increasing the outlet pressure), or downward as the outlet pressure is increased (thus reducing the outlet pressure). In one type of valve, the piston is replaced by a circular diaphragm, fixed at its outer edge to the valve body and at its

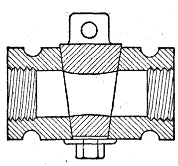

FIG. 6.—DIAGRAM OF COCK, SIMPLE FORM OF ROTARY VALVE

FIG. 7.— SCHEMATIC DIAGRAM OF PRESSURE-REDUCING VALVE

inner edge to the valve stem.

In hydraulic power and control systems, the spool or piston valve is common. This consists of a cylindrical spool arrangement sliding inside a cylindrical bore. In the valve shown in fig. 8, fluid enters port A; port C is covered, but port B is not; thus, fluid passes from port A through the valve body and out port B. Various arrangements of ports and spools can be devised to achieve different types of flow control. (See POWER TRANSMISSION: Hydraulic Power Transmission.)

Boilers and other mechanical equipment subject to possible damage by excessive pressures are normally equipped with safety

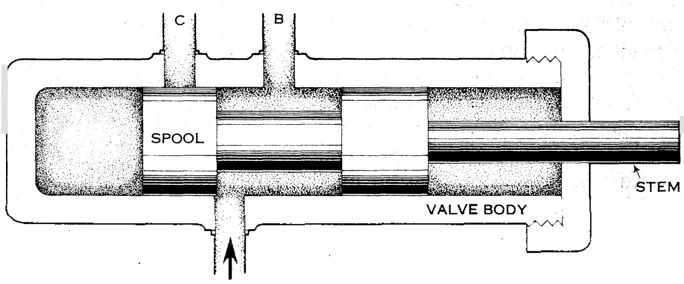

FIG. 8.— DIAGRAM OF PISTON OR SPOOL VALVE. (*See* TEXT)

or relief valves. These valves can be loaded with a spring so that they open automatically when the pressure exceeds a certain value. (R. C. BR.)

VALVE, ELECTRON: *see* ELECTRON TUBE.

VAMPIRE, a term originally applied to bloodsucking ghosts, later transferred to blood-eating bats inhabiting South America and north to southern Mexico.

In its original meaning a vampire is supposed to be the soul of a dead man which quits the dead body at night to suck the blood of living persons. Hence, nhen the grave is opened, the corpse is found to be fresh. To put a stop to his ravages the commonest method is to drive a stake through the body. The belief in vampires is still prevalent among Slavonic peoples. (*See* also DEMON.)

The blood-eating bats comprise two genera (*Desmodus,* the best knonn, and Diphylla) from the forest of tropical America. Their attacks upon men and warm-blooded animals, generally while asleep or at rest, were noticed by writers in the 19th century, but for many years the bats themselves were not identified and the large fruit-eating *Glossophaga* soricana and the carnivorous *Vampyrus* spectrum were mistaken for the true blood-eating species. *Desmodus rotundus* is the most abundant species; it is a small bat, about 3 in. in length, with reddish-brown fur and peculiar teeth adapted to its mode of feeding. They are said to be able to pierce the skin and lap up blood with the tongue without awakening their victim. Diphylla *ecaudata* is less abundant, being confined to Brazil, and differs in the details of the teeth. Since the vampire bats, like some others, carry rabies and other diseases. the bite can be dangerous.

VAN, the chief town of an il of the same name in Asiatic Turkey; altitude 5,400 ft. Pop (1960) 22 018 It is situated about a mile from the eastern shore of Lake Van. and built along the south side of the citadel rock, an isolated rocky ridge 1.300 yd long, rising 360 ft. out of a plain which extends up to the sharply defined rocky mass of the Varak range. 8 mi. distant. On the gently sloping ground east of the citadel are the gardens, covering an area of 5 by 3 mi. and containing several suburbs and detached houses, along central avenues fringed with trees, and having channels of running water by the sides for irrigation.

The town itself is a poor place with flat-roofed mud houses, narrow winding streets, and surrounded by a ruinous mud wall; but it still contains the business quarter, the government offices and the principal bazaars. Water comes from *karez* or underground channels and streams from Varak. fed from the Sikhe lake. an ancient reservoir which preserves the snow waters on the summit of the mountain. For the southern quarter there is the Shemiram canal. also of very ancient construction, which derives its supply from a large spring 19 mi. distant. near Meshingird. The climate is generally healthful, extremely cold in minter, with 2 to 3 ft. of snow from December to March, nhile the summer heat is not excessive. The Persian trade of Van has declined; European goods. with which the bazaars are fairly well supplied, come from Trebizond through Erzerum. There is a fair local trade in wheat and agricultural produce. as well as sheep and cattle, wool, hides and furs for export.

The cuneiform inscriptions of Van are very numerous, the town having been the capital of the Vannic kingdom of the Assyrian period (see URARTU).

In the 6th century B C. Van passed into the hands of the Persians, and shortly before it fell to Alexander the Great it was rebuilt. according to Armenian historians. by a native prince called Van. In 149 B.C. Valarsaces or Vagharshag, the first Armenian king of the Arsacidae, rebuilt the town, and a colony of Jews was settled in it by Tigranes (94–56 B.C.). In the middle of the 4th century A.D. it was taken by Sapor (Shapur) II, and became the capital of an autonomous province of the Sassanian empire, until it fell into the hands of the Arabs (c. 640), under whom it regained its autonomy. About 908 the governor of Van or Vaspuragan was crowned king by the caliph Moktadir. and in 1021 his descendant Senekherim was persuaded by Basil II to exchange his kingdom for the viceroyalty of the Sebasteian theme. After having formed part of the possessions of the Seljuks, Mongols, Tatars and Persians, Van passed in 1514, after the defeat of Shah Ismail by Selim I at the battle of Kalderan, to the Osmanlis, who did not occupy the town until 1543. In 1636 it nas taken by the Persians, but soon recovered. In 1845 the town was held for a time by the Kurd chief Khan Mahmud.

The *il* of VAN lies along the Iranian frontier between the *ils* of Bayazid and Hekkiari Pop (1960) 211.362 The mineral wealth of the *il* is brlieved to be great.

LAKE VAN, called Arsissa Palus and also Thospitis from its Armenian names, is roughly rectangular, 78 mi. long nith an area of 1,453 sq mi. It stands about 5.643 ft. above sea level. It is without an outlet, and its greatest depth is along the southern shore. It has constant steady fluctuations, rising and falling about eight feet in a periodic movement of five years. In the middle of the 19th century a sudden rise submerged several places on the banks, including Arjish Kale, and the naters did not subside. The northeastern arm is much shallower than the rest. The water is bitter and undrinkable. being largely impregnated with carbonate and sulfate of soda with some borax. The salts are evaporated in pans, and called perek, being sold for washing purposes. There is, however, good water along the coast from springs and streams.

The lake has been navigated from the earliest times, and sailing boats, carrying about 20 tons burden, now ply it, chiefly with wheat and firewood. Severe storms make navigation dangerous in winter. The southern shore is fringed by a steep range of mountains, with several thriving villages along the coast. The hills have been almost denuded of trees. At the southeastern corner is the island of Akhtamar with its ancient church, erected (c. 928) by Gagig, first king of the Ardzrunian dynasty. The catholicos of Akhtamar was one of the highest offices in the Armenian church, and dated from 1113. Large numbers of darekh, a kind of herring, exist in the lake, and are caught in nets from boats or when they enter the shallow lagoons in the spring and summer.

VANADINITE, a mineral consisting of a lead chloride vanadate, is a source of vanadium for the manufacture of vanadium steel. It occurs as crystals, which are usually six-sided prisms terminated by the basal planes, often skeletal and sometimes rounded; they may also be compact, globular or in crusts. The colour is usually brown to yellow, but crystals from Arizona are brilliant red. The hardness is 3. The formula is $Pb_5Cl(VO_4)_3$. It crystallizes in the hexagonal system, and is isomorphous with pyromorphite and mimetite (*qq.v.*). Because of isomorphous replacement of vanadium by phosphorus and arsenic, the specific gravity varies from 6.6 to 7.2. A variety containing much arsenic is called endlichite. Vanadinite is a secondary mineral, forming in the oxidized zones of lead deposits. It occurs in the Urals, Carinthia, Morocco, southwest Africa. Northern Rhodesia, Mexico, Argentina and New Mexico and Arizona. (L. S. RL.)

VANADIUM is a metallic element whose most important use is as an alloy to improve certain qualities of steel and cast iron. For example, vanadium is used in making high-speed tool steel, high-strength structural steel and wear-resistant cast iron. The following article discusses the history, occurrence, extraction, production, physical properties, chemical properties, uses and analysis of vanadium in that order.

History.—Andrés Manuel del Rio (1801) reported the discovery of a new element in vanadinite from Zimapán, Mex., which he named erythronium because of the red colour acquired by its salts on heating. On re-examination a few years later he concluded that he was mistaken and that the brown ore from Zimapán was merely a basic lead chromate. For a quarter of a century no more was heard of the new element erythronium. In 1830 N. G. Sefstrom became interested in an extremely soft iron obtained from Taberg, Swed., iron ore and on examination discovered in the ore, as well as in the wrought iron and slag. a new element which he named vanadium, from Vanadis, the Scandinavian goddess of beauty and youth—a name suggested by the beautiful colours of its compounds in solution. A short time before this, F. Wöhler had undertaken a re-examination of the vanadinite ore from Zimapán and found (1830) that the new element, surmised and abandoned by Del Rio, was identical with the vanadium of Sefstrom. Because of illness contracted as a consequence of poisoning by hydrogen fluoride vapour, Wöhler failed to report his findings and thus did not receive credit for the discovery of the new element. J. J. Berzelius (1831) prepared a number of compounds of vanadium and concluded that the element belonged in the same family as chromium and molybdenum.

H. E. Roscoe then showed (1867–70) that Berzelius was in error in this conclusion since the substance, which Berzelius had assumed to be the free metal, was really the oxide, VO, and that therefore most of the compounds studied by Berzelius had contained oxygen. Roscoe established the position of vanadium in the fifth group (subgroup V) of the periodic system by showing that it forms a number of compounds analogous in composition to those of phosphorus and also that a number of vanadates are isomorphous with the corresponding phosphates. Roscoe (1869) was the first to obtain metallic vanadium, 95.8% pure, by reduction of vanadous chloride, VCl_2, with hydrogen. Metallic vanadium has been one of the metals most difficult to isolate in highly pure state because of the great stability of its lowest oxide, its nitride and its carbide. J. W. Marden and M. N. Rich (1927) succeeded in obtaining metallic vanadium, 99.7% pure, by heating a mixture of vanadium pentoxide, calcium metal and calcium chloride for one hour at 900° to 950° C. At mid-20th century pure vanadium was being produced in limited quantities.

Occurrence.—Vanadium is widely distributed in various minerals. coal and petroleum. Although it is estimated to comprise betneen 0.02% and 0.03% of the earth's crust, ores of commercial value occur in only a few places. The principal commercial ores are patronite, roscoelite, vanadinite and carnotite. Patronite, not a well-defined mineral, occurs in coal deposits at Mina Ragra, Peru (elevation 16,000 ft.). It is essentially a sulfide of vanadium, is associated with free sulfur and iron pyrites, and contains 10% or more of vanadium. On preliminary roasting the vanadium content is increased to 20% with almost complete elimination of sulfur. These deposits have been materially depleted. Roscoelite, $K_2(Mg,Fe)(Al,V)_4Si_{12}O_{32}.4H_2O$, one of the micas, occurs in Colorado and other western states. This mineral and carnotite, $K_2O.2U_2O_3.V_2O_5.3H_2O$ (Utah and Colorado), are the ore types which heretofore have been the source of most of the domestic U.S. vanadium. Vanadinite, $PbCl_2.3Pb_3(VO_4)_2$, with arsenic and phosphorus replacing vanadium in some cases, occurs in Arizona, New Mexico, southwest Africa and Northern Rhodesia (also in the Crals, Mexico, Spain and Argentina). Potential vanadium reserves in extensive phosphate beds of the Wyoming-Utah area were disclosed as a result of studies begun by the U.S. geological survey in 1939. Results of laboratory and field work indicated the possibility of obtaining both vanadium pentoxide and phosphate fertilizer at costs not greatly different from those for other ores. Vanadium-bearing magnetite mined in northern New Tork contains an average of 0.6% V_2O_5. Generally, vanadium-poor iron ores can be used in steelmaking processes directly. Vanadium is a common constituent of coals, asphalts, bitumens and oil. Flue dust from smokestacks and boilers of ships burning certain Venezuelan and Mexican oils contains 12% to 15% V_2O_5 and has become a commercial source of vanadium.

Extraction.—The methods of extraction vary widely depending on the nature and richness of the ore and the value of the by-products (such as uranium and radium from carnotite). The difficulties encountered are connected with the separation of the vanadium from uranium, aluminum, iron and silica. The methods fall into two general types: (1) acid extraction, in which soluble pervanadyl compounds, $(VO_2)_2SO_4$ or VO_2Cl, are formed; and (2) alkali extraction, in which soluble alkali vanadates, $NaVO_3$ and Na_3VO_4, are produced. Crude vanadium pentoxide may be obtained from the acid leach by evaporation and ignition. Or the acid leach may be nearly neutralized, other constituents precipitated and the resulting solution treated with excess sodium carbonate (soda ash), thereby converting the vanadium to soluble vanadates. The precipitate containing iron, aluminum and calcium is discarded and the vanadium is then precipitated as ferrous vanadate on addition of ferrous sulfate to the neutralized solution. From an alkaline leach, vanadium may be precipitated as ammonium metavanadate on addition of excess ammonium chloride; as ferrous vanadate or as hydrated vanadium pentoxide by proper acidification. Although wet processes are more common, dry processes involving initial fusion with sodium carbonate are used.

Various modifications of these more general procedures were developed.

Production of Vanadium and Its Alloys.—Four methods of preparing vanadium metal are known, but production of the pure metal on a tonnage basis had not been accomplished by 1960. The four methods, listed below, generally involve chemical reduction. (1) A reaction known as the alumino-thermic process has been used to produce vanadium of 98% purity. 'The reaction mixture that has been used contains vanadium pentoxide, aluminum and sodium carbonate in the proportions of 150, 60 and 18 g. respectively. (2) Reduction of vanadium pentoxide (V_2O_5) with calcium metal is the most popular method of producing vanadium metal. In this method a calcium chloride ($CaCl_2$) flux is often used, and the reaction is carried out in a constant volume steel bomb. Sample proportions of 175 g. of V_2O_5 and 300 g. each of Ca and $CaCl_2$ are reacted at 900° C.; massive pieces of metal can be produced. This method is capable of producing 99.7% purity metal with satisfactory ductility if the oxygen content is kept below 0.05% by weight. Commercial vanadium has a typical purity of 0.05% carbon, 0.07% oxygen, 0.003% hydrogen and 0 08% nitrogen. (3) Thermal decomposition of vanadium di-iodide has produced ductile metal. This method is similar in principle to the methods used for the production of zirconium or titanium but suffers because of the low vapour pressure of vanadium di-iodide. Temperatures of 900° to 1,000" C. are generally employed (4) Hydrogen reduction of chlorides at temperatures near 1,000" C. is another way of producing ductile vanadium. Nitrogen-free hydrogen should also be used in order to prevent the formation of vanadium nitride during the reduction process. Care must be taken to anneal the final metal of approximately 99.9% purity in vacuum since hydrogen tends to embrittle the metal.

Alloying of vanadium or remelting of stock is carried out by arc-melting the metals in an argon atmosphere in a water-cooled copper mold with a tungsten tipped electrode. Ceramic crucibles cannot be used because vanadium reduces or dissolves stable oxides. carbides and borides. For alloys containing 50 atomic per cent vanadium or less the use of thoria-lined recrystallized alumina crucibles has been reported as satisfactory. Hot working vanadium and vanadium-rich alloys is a questionable operation, but it is possible to roll, swage and extrude alloys by jacketing them in mild steel. In this way atmospheric contamination is prevented, and the mild steel jacket can be pickled off in hydrochloric acid. After such pickling, vanadium is likely to be embrittled with hydrogen, and vacuum annealing is called for. Since vanadium sheets one-quarter of an inch thick can be cold rolled to 0.001 in. sheets without intermediate annealing, the amount of strain hardening is very small. Cold worked vanadium can be recrystallized at approximately 800° C.

Physical Properties. — Vanadium, whose symbol is V, has the atomic number 23 and an atomic weight of 50.95.

Vanadium metal has a bright silver-white colour and does not tarnish readily. Compared with other metals at their respective melting points it is one of the least volatile (melting point, 1,950" C.). Its density (cold-worked) is 6.0 g. per millilitre at 22° C. as determined from X-ray data obtained with the powdered metal. Since cold-working increases the density, this value is somewhat higher than that usually given (approximately 5.9).

When heated in the presence of hydrogen, vanadium becomes very brittle. Malleability may be restored by heating in a vacuum. Other physical properties of the metal are:

Boiling point, 3,600" C.
Specific gravity, 5.87 at 15° C.
Index of reiraction, 3.03.
Specific resistance at 20° C., 26 × 10^{-6} ohm-centimetre.
Temperature coefficient of resistance, R, between 20° and 150" C. is given by the relation $R = R_o(1 + at)$, in which a = 0.0028.
Specific heat between 20" and 100" C.. 0.120 cal. per gram per C°.
Specific heat oi fusion, 8.0 cal. per gram:
Estimated heat of sublimation at 25° C., 121.9 Kcal. per gram atom.
Ionization potential of gaseous atoms, 6.71 v.
Crystal structure, body centred cubic system, a, = 3.0258 Å
Radius of ion, V^{+5}, in crystals, 0.59 × 10^{-8} cm. (0.59 Å)
Coefficient of linear thermal expansion, 200°–1,000° C., 9.7 × 10^{-6}/° C.
Recrystallization temperature for 70% cold-rolled sheet, 700"–800" C.

Vanadium alloys with a large number of elements including aluminum, cobalt, copper, iron, manganese, molybdenum, nickel, platinum. tin and silicon. It is infinitesimally soluble in mercury.

Naturally occurring vanadium consists of two isotopes (mass numbers 50 and 51). Four artificial radioactive isotopes have been produced with mass numbers 47, 48, 49 and 52 and half-lives of 33 min.. 16 days, 600 days and 3.74 min. respectively.

Metallic vanadium may be cold-worked into wire and other forms. It resembles tantalum in these respects and also in its crystal form, which belongs to the body-centred cubic system.

Chemical Properties; Compounds. — Vanadium is the first member of subgroup V of the periodic system, which also includes niobium and tantalum in order of increasing atomic weight. Like its congeners in the subgroup, vanadium may be described as seminoble. When heated with oxygen, nitrogen, carbon and sulfur it forms the oxides V_2O_3, VO, VO_2 and V_2O_5; the nitride VN; the carbides, VC and V_4C_3, and the sulfides, VS_2 and V_2S_5. The three metals of subgroup V form compounds in which their maximum oxidation state (valence) is plus five. The other oxidation states possessed by vanadium in its compounds are two, three or four. Vanadium dissolves in nitric acid and is oxidized by other moderate oxidizing agents in acid solution. It is not dissolved by hydrochloric or dilute sulfuric acid even though its oxidation by hydrogen ion in these acid solutions is thermodynamically possible. Fusion of vanadium with alkalies produces soluble vanadates and hydrogen.

The basicity of the hydrogen-oxygen compounds of vanadium varies with the oxidation state. In the two lower oxidation states. two and three, these compounds are basic; in oxidation states four and five they are amphoteric, being much more basic than acidic in state four and more acidic than basic in state five. The formulas. names and colours of the ions of vanadium in the different oxidation states in acid and basic solutions, respectively, are given in the following table:

Oxidation state	Acid solution	Basic solution
+2	V^{++}, vanadous, lavender	—
+3	V^{+++}, vanadic, lavender-blue	—
+4	VO^{++}, vanadyl, blue	$V_4O_9^{--}$, vanadite, brown
+5	$V(OH)_4^{+}$, $V(OH)_3^{++}$, $V(OH)_2^{+++}$ tetra-, tri-, di-hydroxypervanadyl, greenish-yellow	$V_3O_9^{---}$, metavanadate, colourless VO_4^{---}, orthovanadate, colourless $V_2O_7^{----}$, divanadate, colourless

The molal electromotive forces at 25° C. and the half-cell reactions involving various oxidation states of vanadium in acid solution are as follows:

$$V = V^{++}\ 2e^- \qquad +1.18\ v\ \text{(estimated)}$$
$$V^{++} = V^{+++} + e^- \qquad +0.255\ v$$
$$V^{+++} + H_2O = VO^{++} + 2H^+ + e^- \qquad -0361\ v$$
$$VO^{++} + 3H_2O = V(OH)_4^+ + 2H^+ + e^- \qquad -1.00\ v$$

As these values indicate, pentavalent vanadium in acid solution may be reduced to the tetravalent state, VO^{++}, by mild reducing agents such as iodine, ferrous ion, sulfur dioxide and mercury (in sulfuric acid). Stronger reducing agents cause further reductions, e g., iron, magnesium and stannous tin give trivalent vanadium. V^{+++}, and zinc and cadmium give the vanadous state.

Intermetallic compounds have been identified in a number of binary and ternary metallurgical systems. In the iron-vanadium (Fe-V) system only a single intermediate phase corresponding to FeV but having a range of vanadium content between 30% and 60% has been reported. The solubility of carbon in austenite is increased by vanadium additions to iron-carbon alloys; however, in steels iron carbide (Fe_3C) and V_4C_3 are precipitated separately and not as complex double carbides. The existence of a spinel FeV_2O_4 has been reported.

Uses. — Vanadium metal. as such, has small commercial use and is therefore produced in very limited quantity. Ductile vanadium, 99.8% pure, was made available in 1950 About 90% of the vanadium used is consumed as ferrovanadium in the manufacture of tool steels, engineering steels, high-strength structural steels, non-aging rimming steels and special wear-resistant cast irons. (See VANADIUM STEEL.) A satisfactory ferrovanadium alloy must contain 30% to 40% of vanadium and not more than 0.5% carbon, 1.0% silicon, 2.0% aluminum, 0.1% phosphorus and 0.1% sulfur. In steel fabrication, vanadium functions in three ways: it (1) increases the strength and durability by partially dissolving in the ferrite; (2) produces a finer and more uniform grain size and minimizes the tendency to grain growth during heat treatment; and (3) forms very stable carbides that add to the strength and hardness and show little tendency to segregate or to form large masses at elevated temperatures. Quantities of vanadium for 0.15% to 0.25% are sufficient. Although vanadium is a powerful deoxidizer, it is too expensive to be used in steels for this purpose alone. High-speed tool steel contains 0.50% to 2.50% vanadium along with about 0.70% carbon, 0.20% silicon, 18.0% tungsten, 0.25% manganese and 4.0% chromium. Vanadium steels date from the discovery of the Peruvian deposits in 1905. Certain alloys of vanadium with other metals, such as copper and aluminum, have found industrial uses.

The largest uses of vanadium pentoxide and ammonium metavanadate at mid-20th century were as catalysts, in colouring glass and ceramic glazes, for driers in paints and inks and for laboratory research. After 1927 the use of vanadium catalysts in the contact process for manufacturing sulfuric acid revolutionized this industry. These catalysts are not susceptible to poisoning as are platinum catalysts and compare favourably with the best platinum catalysts in their effectiveness. The active agent is vanadium pentoxide or sodium metavanadate. The catalytic action is attributed to the alternate oxidation and reduction of the vanadium between the tri- and pentavalent states. Vanadium pentoxide and vanadates are likewise efficient catalysts for the oxidation by oxygen of a large number of organic substances. Among the more important of such oxidations are the following: naphthalene to phthalic anhydride, benzene to maleic acid, aniline to aniline black, toluene to benzaldehyde and benzoic acid, anthracene to anthraquinone and methyl alcohol to formaldehyde.

Analytical. — Qualitatively the presence of vanadium pentoxide in a mixture of oxides may be shown by the violet-red colour of ammonium thiovanadate, $(NH_4)_3VS_4$, which is produced on treating the solution of the oxides in hydrofluoric acid with excess ammonium sulfide. The presence of pentavalent vanadium in acid solution — present as $V(OH)_4^+$ — may be shown by the red colour produced on addition of hydrogen peroxide. The intensity of this red colour has been used in the quantitative determination of vanadium.

Gravimetric procedures depend upon the weight of vanadium pentoxide, the formation of which has been indicated under methods of extraction. Two of the simpler volumetric methods of determining vanadium are based on (1) reduction of pentavalent vanadium in hot acid solutions to the tetravalent state (vanadyl) with sulfur dioxide, removal of excess sulfur dioxide and titration of the hot solution with standard potassium permanganate solution; and (2) reduction of pentavalent vanadium in acid solution to the tetravalent state with iodide ion in the absence of oxygen, and titration with standard sodium thiosulfate solution. See also Index references under "Vanadium" in the Index volume.

VANADIUM **STEEL.** The advantages inherent in adding vanadium to steel first became a matter of industrial knowledge at the end of the 19th century. Widespread use of alloy steels after World War I reflected on vanadium, which came to be used for many types of steels both alone and in association with other alloying elements.

Vanadium and iron are mutually soluble in the liquid state in all proportions but form a compound containing 48% vanadium below 1,250" C. In steels, vanadium principally strengthens the matrix. if both vanadium and carbon are kept very low. But as either of them is proportionally increased, vanadium will be increasingly present as a very hard and stable carbide.

Vanadium has essentially two effects upon the steel: it refines the grain of the steel matrix, and it increases strength and hardness by forming free carbides. Fine grain is developed in the steel by the action of small, dispersed vanadium carbides possibly with assistance from other vanadium compounds formed in the steel. Vanadium steels retain their fine grain over the full range of heat treating temperatures. These features are applied in the production of heavy castings and forgings. In special cases, namely, for easier machining and also for maximum high temperature strength, the fine grain of vanadium steels can be coarsened by holding them above normal quenching or annealing temperatures. The grain grows, as the carbides increasingly dissolve in the austenite. Fine grain returns with renewed heat-treating in the quenching or annealing range.

Vanadium is added to constructional steels to improve elastic properties, toughness and yield to tensile strength ratios. Medium carbon steels containing 0.6% to 1.0% manganese and 0.1% to 0.2% vanadium are used for heavy railroad equipment, namely, connecting rods, driving axles and crank pins; a similar steel with 1.23% to 1.75% manganese serves under more severe conditions. This type of steel with low carbon and 1.0% to 1.25% manganese is used for rivets and bolts and as plate in marine and other transportation equipment. Numerous products such as gears, camshafts, springs, shafting, ball bearings and wearing plates are made from a low-vanadium analysis with chromium and carbon in the ranges of 0.4% to 1.2% and 0.4% to 1.0%, respectively, according to application. For very heavy forgings, such as turbine rotors, complex vanadium steels are specified, principally nickel-vanadium, nickel-molybdenum-vanadium, nickel-chromium-vanadium types.

Additions of the metal to steel are usually made with ferrovanadium containing between 35% and 80% vanadium. Since the metal is chemically very active, the steel is first deoxidized. Where cheaper deoxidizers have a deleterious effect, the metal is employed to combine with both oxygen and nitrogen. However, in so-called nonaging rimming steels, vanadium combines with nitrogen while permitting a mild rimming action (reaction of iron oxides with carbon prior to solidification, causing development of carbon monoxide and permitting a better yield of metal from the ingot), thus combining the advantages of rimming steel with the nonaging characteristics of "killed" steels (which do not contain any oxides free to react with carbon and do not materially change their properties in time — do not age).

Tool steels. either the carbon-vanadium or more complex low-alloy types, are produced in large variety, usually with not more than 0.25% vanadium. These steels generally ensure controlled shallow hardening, and this feature is applied in the heat treatment of tools designed to have a hard exterior and a tough core. Also, in tools of varying cross section the surface of the heaviest part can be fully hardened without danger of grain coarsening in the lightest. When the vanadium content is increased to about 0.5%, the depth of hardening can be finely adjusted by raising the quenching temperature to take more or less vanadium-rich carbide into solution.

The greater stability of the vanadium carbides permits higher tempering temperatures and thus improves shock resistance combined with a relatively high hardness. It also allows higher cutting-edge operating temperatures, leading to better performance at high speeds or wear resistance at greater pressures or higher temperatures in forming operations.

In these carbon and low-alloy tool steels, vanadium ranges between 0.1% and 1.3% and is used to develop optimum properties in virtually all types ranging from razor and knife blades, taps and dies, chisels, lathe tools and milling cutters to drop-forging, die casting and extrusion dies. In high-speed tool steels, which are used for all types of heavy-duty cutting. drilling, forging, extruding, etc., the great hardness of the vanadium carbides is utilized to the fullest possible extent. Among these steels a type designated as 18–4–1 (tungsten-chromium-vanadium) was outstanding for many years. During the 1940s and 1950s a lower tungsten, 6–6–4–2, tungsten-molybdenum-chromium-vanadium composition came to the fore along with a 9–4–2, molybdenum-chromium-vanadium analysis with or without 2% tungsten.

Carbon in high-speed steels generally ranges between 0.65% and 0.85% but is lower where severe impact loads apply. Later developments tended toward higher wear resistance and also greater hardness by raising carbon and vanadium contents which may lie between 1 5% and 4.0%, and between 4% and 12%, respectively.

In vanadium-bearing high-temperature steels, special properties are frequently produced by heat treatments to dissolve practically all the carbide Steels for power-generating units often contain carbon, vanadium, molybdenum and chromium with sometimes tungsten all at a medium alloy level. An excellent performance record has been established by a 1% chromium, 1% molybdenum, 0.25% vanadium tube steel in steam power service up to 1,100° F.

Vanadium-bearing cast steels and cast irons generally contain *0.05%* to *0.20%* vanadium with one or more of *0.50%* to 1.50% chromium. 0.15% to *0.35%* molybdenum (with occasionally higher molybdenum in iron) and normal *(0.7%)* or high *(1.0%* to *1 75%)* manganese in steel. Vanadium limits the growth of dendrites in the solidification of steel castings; in cast irons it helps to produce a uniiorm distribution of graphite in the form of moderate-size flakes In steel castings vanadium is included to engender improved impact resistance and to raise the ratio of the yield strength to the ultimate tensile strength; in cast irons the stability and hardness of vanadium carbides increase wear resistance and strength. (C. M. C.)

VAN ALLEN RADIATION BELTS. In May *1958,* J. A. Van Allen interpreted the response of a Geiger counter he had installed in the first U.S. artificial satellite. Explorer I, as an indication of an intense belt of particulate radiation surrounding the earth. Subsequent experiments by Van Allen and others, undertaken with other satellites and space probes, confirmed this discovery, established many properties of the radiation and revealed that there are two huge zones of trapped charged particles encircling the earth. The trapped particles in these Van Allen radiation belts, as the zones soon came to be called, were found to be protons and electrons. The Van Allen belts, especially the outer one, play an important role in a number of geophysical phenomena such as auroras. geomagnetic storms (i e., large disturbances in the earth's magnetic field), airglow and atmospheric heating. Studies of the belts have revealed much concerning the intensity of cosmic rays (*q.v.*) in interplanetary space.

Particle Motion in Earth's Magnetic Field.—An analysis of the motion of charged particles in the earth's magnetic field will explain how these belts can contain such an extraordinary flux of high-speed particles. Consider a particle of charge e, velocity **v** and momentum **p** that is moving at an angle a relative to the direction of a magnetic field of uniform flux density B. The magnetic force on the particle is perpendicular to both of the vectors **B** and **v** (or **p**). Hence the magnitude of the velocity and of its component along the direction of **B** remain constant, while the component of velocity normal to B is continually modified in direction by the force. The resulting motion of the particle is along a spiral with pitch angle equal to a. Equating the magnetic force, Bev sin a. to the centripetal force $mv^2 \sin^2 \alpha/\rho$ required for the circular motion normal to B shows that p, the radius of the spiral, is equal to $p \sin \alpha/Be$.

For the high-energy cosmic rays that are not stored in the Van Allen belts, the radius of gyration, p, is comparable with or greater than that of the earth; hence the change of the magnetic field along the paths of these particles is very important. Indeed. as they approach the earth from interplanetary space, these high-energy cosmic rays execute in most cases less than one revolution about the lines of force of the earth's field. But the particles found in the Van Allen zones have comparatively low momentum and their radii of gyration are so small compared with the distance from the centre of the earth that to a first approximation their motion is a tight spiral about the lines of force, as though the particles were moving in a uniform field.

The gas density at the altitudes where these particles are found is so low that atomic collisions are very rare, and the particles can travel for distances hundreds of times the diameter of the earth without experiencing deflections other than those due to the earth's magnetism.

The magnetic field of the earth at high altitudes is approximately that of a dipole (*i.e.*, a short bar magnet) of strength $M = 8.1 \times 10^{25}$) gauss-cubic centimetre, displaced *342* km. from the centre of the earth toward latitude 6.5° north, longitude 162° east and tilted 11.5° relative to the geographic axis in the plane of the meridian 69° west of Greenwich (see GEOMAGNETISM). It is convenient to describe the field in terms of co-ordinates centred on the dipole instead of on the geographic centre of the earth. The dipole field has a northward component, $B_\lambda = M \cos \lambda/r^3$, and a radial component, $B_r = -2\ M \sin \lambda/r^3$, where λ is the geomagnetic latitude and r the distance from the centre. The lines of force are represented by the family of curves $r = r_0 \cos^2 \lambda$, where r_0 is the radius at which a line crosses the magnetic equator. The strength of the field varies along a line of force according to $B = (M/r_0{}^3) \sec^6 \lambda\ (1 + 3 \sin^2 \lambda)^{\frac{1}{2}}$. Near the surface of the earth the true field is more complicated, but the dipole approximation is adequate for the present discussion.

As a charged particle follows its spiral path northward or southward from the equator along the lines of force, the particle approaches closer to the atmosphere, since the radius of a line of force decreases according to $r = r_0 \cos^2 \lambda$. For instance, particles that cross the equator at an altitude of $3\ R_e$ (R_e being the radius of the earth, about *6,470* km.) would strike the earth at a latitude of about ± 60°.

However, as the spiral proceeds northward or southward the field lines do not remain parallel, but converge. In a convergent field the force, which remains perpendicular to the field lines, has a component along the axis of the spiral. decelerating this component of motion and making the pitch of the spiral grow steeper according to $\sin^2\alpha = (B/B_0) \sin^2\alpha_0 = \sec^6\lambda\ (1 + 3 \sin^2\lambda)^{\frac{1}{2}} \sin^2\alpha_0$, where α_0 is the pitch and B_0 is the field strength where the spiral crosses the equator. Somewhere between the equator and the latitude where the spiral would enter the atmosphere, the condition $\sin^2\alpha = 1$ is reached for those particles having a sufficient pitch angle at the equator. At such latitudes, the particles are reflected in their north–south motion and retrace their paths to a similar latitude in the opposite hemisphere, where they are reflected again. Particles traveling along paths with smaller pitch angles enter the atmosphere and are absorbed.

Thus. a magnetic-dipole field constitutes a trap or "magnetic bottle" for charged particles moving in a vacuum, confining many of the particles between certain limits of latitude and altitude. If the field is static and no scattering by atomic collisions occurs, particles trapped in the field cannot get out. and particles capable of entering the region from outside cannot get trapped in it.

The spiral motion, viewed along the axis, is not quite circular, because at the points of lowest altitude the field strength, and hence the curvature, is slightly greater than at the points of highest altitude. **As** a result, the particles drift in longitude at a rate given by

$$\frac{\text{drift velocity}}{\text{total transverse velocity}} = \frac{3}{2}\ \frac{\text{radius of spiral}}{\text{distance from magnetic center}}$$

The positive particles (protons) drift from east to west and the negative particles (electrons) from west to east, in either case generating a westward electric current. Consider a typical trapped electron of *20* Kev energy at a distance of $4\ R_e$ from the centre and having a pitch angle of 30° at the equator. The radius of gyration is about ½ km. and the particle executes *14,000* oscillations per second. Meanwhile it travels north and south bet een reflection points at latitudes of ±33° about once a second, and drifts eastward around the earth about once a day. Although the drift velocity is slow. the number of particles in the Van Allen zones is so large that they constitute a ring current exceeding a million amperes. This causes an appreciable modification in the earth's magnetic field—as much as the normal dipole field itself at a distance of about $10\ R_e$. The field due to the ring current reduces the total field inside the ring and adds to the field outside.

Magnetometer measurements in Soviet and American space vehicles have verified the existence of such ring currents. The location and strength of the principal current appear to be variable: that found by Soviet workers in *1959* was at *3* to $4\ R_e$, while that found by the U.S. satellite Explorer VI six months later, and by the space probe Pioneer V in *1960* (a current of about *5* million amperes), occupied a toroidal volume between radii of 7 and 13 R_e.

Proton Distribution.— Two kinds of particles, protons and electrons, are trapped in abundance around the earth, the protons being much less numerous but individually more energetic than the electrons. The protons are found only in the innermost radiation belt, which has a kidney-shaped cross-sectional contour about 2.000 km. in radial thickness, tapering off rapidly in intensity at latitudes in excess of 30". Because of the eccentricity of the magnetic dipole with respect to the earth's centre, the altitude of the equatorial lower edge of this belt varies from 400 km. on one side of the earth to 1,200 km. on the other. The lower edge occurs at altitudes where the magnetic field is equally strong on all sides of the earth.

The peak intensity of the protons with energy exceeding 40 Mev is about 20,000 particles per second crossing a sphere of 1 cm.^{2} area in all directions—10,000 times the intensity of cosmic rays in interplanetary space in 1959. The spectrum of these protons is rather hard, the number with kinetic energy above E being approximately proportional to $E^{-1.8}$, at least up to 700 Mev. Thus, many of the protons can traverse shields of lead several inches thick.

The average energy of the trapped protons decreases with distance from the earth. This variation in the spectrum, as well as the absence of protons in the outer reaches of the earth's field, are explained by the fact that the magnetic bottle is quite "leaky" unless the radius of gyration of the particle is very small compared with the distance from the centre of the field. The magnetic field strength decreases with the cube of this distance; hence the maximum momentum of containable protons decreases as the square of the distance, and the kinetic energy decreases as the fourth power. Protons of very low energy would probably be found at distances of several earth radii, were it not for the presence of a rare atmosphere of neutral hydrogen there. When a proton of energy that is small compared with an Mev passes near a neutral hydrogen atom, the proton is likely to capture the electron from the neutral atom. Thereupon the faster moving particle escapes, since it is no longer deflected by the magnetic field; and the remaining, nearly stationary proton is soon neutralized by combining with a free electron from the surrounding plasma (ionized gas).

This restriction of the proton belt to low altitudes also explains its confinement between low latitudes. The lines of force which cross the equator at altitudes less than one earth radius all meet the top of the atmosphere at latitudes less than 44°, and those that cross the equator at 1 km. altitude meet the atmosphere at about 20°. The particles having pitch angles at the equator large enough to lead to reflection points above the atmosphere are the only ones that can be stored; the others plunge into the atmosphere and are absorbed.

Electron Distribution.— The trapped electrons are subject to the same limitations on momentum as the protons, but because they are 1,837 times lighter, the electrons have much higher velocity and kinetic energy than protons of the same momentum; furthermore, electrons are not lost by a neutralization process, as are the low-energy protons. This explains the occurrence of many low-energy trapped electrons, which are distributed over a much broader region of space than is the proton belt.

Many electrons of moderately high energy, extending up to at least several Mev and capable of making very penetrating X-rays when they strike a space vehicle, exist along with the protons in the inner radiation belt; and electrons of energy in the Kev region are trapped as far out as 14 R_e. Here the lines of force of the earth's field merge with those in interplanetary space, and at larger radii no particles can be confined because the field lines do not connect with the earth.

With instruments sensitive to electrons of energy above 20 Kev. the maximum recorded flux is about 10^{11} particles per second crossing one square centimetre in all directions. This intensity was found near the equator at a height of between 2 and 3 R_e above the surface. The energy spectrum of these particles was found to be very steep, less than 1 in 1,000 having energy above 200 Kev. There is indirect evidence from the association of this band of radiation with the aurora borealis that the number of electrons continues to increase with decreasing energy below the threshold of the above-mentioned instruments, reaching at least 10^{13} per square centimetre per second at 4 or 5 Kev. (By direct detection of the particles with more sensitive instruments that were carried aboard rockets fired into auroral arcs, it was found that the major part of the auroral light is caused by electrons of energy of this order of magnitude.)

The distribution of the electrons in space is complex and also varies with time. With rockets fired outward from the earth at the equator, it was found that the intensity rises sharply at altitudes above 1 km., reaches a maximum at 1 to 1.5 R_e from the surface, decreases, then increases again to the principal maximum at 2.5 to 3 R_e. The decrease beyond this maximum is irregular, and at distances between 7 and 13 R_e large variations were found in small intervals of time or space, indicating strong bunching or waves of electrons. Magnetometers also detected sharp-crested waves in the magnetic field, supporting the picture of this outer region as being strongly disturbed by the impact of streams of plasma from the sun. Beyond about 14 R_e no trapped particles are found—there is only the normal flux of high-energy cosmic rays.

Thus, over the equator the electrons are distributed in a broad and highly structured belt extending from about 1 km. above the earth's surface to 90,000 km., with a peak intensity at about 20,000 km. The north-south spiral paths of these electrons converge as the paths approach the earth at high northern and southern latitudes, mostly between 50° and 70°. Hence the outer radiation zone has a cross section resembling a crescent, with horns reaching down toward the earth in the auroral zones.

Argus Experiments.— The theories of the motion of particles in the exosphere (*i.e.*, the outermost layer of the atmosphere) were put to test in Aug. and Sept. 1958 by the Argus experiments, in which three nuclear explosions were set off in rockets at high altitude over the South Atlantic. The explosions released large numbers of beta ray electrons into the altitude region of the "slot"; *i.e.*, the space between the inner and outer radiation zones where there is ordinarily a minimum density of particles. The electrons spiraled back and forth between northern and southern latitudes as predicted, causing artificial auroras and atmospheric electrical disturbances. The particles having paths of sufficient pitch angle to be reflected before entering the atmosphere were detected with instruments in an artificial satellite; these particles were found to circle about the earth as expected, and to remain trapped for at least two weeks. Solar emissions then caused a disturbance in the earth's field which apparently precipitated the loss of the remaining artificial radiation.

Injection Processes.—As long as the earth's field is undisturbed, purely magnetic deflections can neither make particles escape from the trapped orbits nor conduct any particles into them. The static field merely acts as a bank: deposits and withdrawals require other mechanisms.

Neutron Albedo.—One mechanism of injection is neutron albedo; *i.e.*, the high-energy cosmic rays of galactic origin colliding with atoms in the atmosphere produce secondary neutrons, some of which are ejected backward and leave the atmosphere. These neutrons have been measured outside the atmosphere and found to number about one per square centimetre per second, as predicted from earlier measurements inside the atmosphere. Neutrons have a natural half life of 12 min., and as they travel through the radiation zones at speeds on the order of 30.000 km./sec. some of them (a small proportion) decay into protons and electrons. The calculated energies of particles produced by this mechanism fit the observations in the inner radiation belt. However, both the neutron flux and decay probability are so small that, to account for the number of particles in this zone. the mean storage time has to be on the order of 10 years. In 1963 it was not yet clear whether the various loss mechanisms (atomic scattering into orbits that lead into the atmosphere. neutralization by charge exchange and perturbations of the earth's field by solar disturbances) would permit such long storage.

It is clear that this injection mechanism does not supply the particles in the outer zone, since the electrons there are much more transient, and their spectrum does not fit that of the beta rays arising from decay of albedo neutrons.

Solar Plasma Streams.—Following solar flares, both the content and spatial distribution of particles in the outer zone are observed to undergo major changes. The initial phase, occurring about a day after the flare (when the emitted plasma stream first reaches the earth), is a decrease in the stored radiation; this is often associated with a visible aurora. Apparently the stream of ionized gas disturbs the earth's field in such a way that many of the stored particles are released into the atmosphere at latitudes between 50° and 70°, causing auroras, atmospheric heating and expansion, enhanced ionization and consequent changes in radio transmission. These effects are accompanied by measurable alterations in the magnetic field at the surface of the earth (*i.e.*, a geomagnetic storm) and by major changes in the ring current and the magnetic field in the outer radiation zone. The second phase, occurring in the next few days, involves a gradual recovery of the inner magnetic field and, simultaneously, a build-up of the radiation in the outer zone to a level much higher than the value preceding the disturbance. It appears that the solar stream leaves behind many charged particles and excites violent magnetohydrodynamic oscillations in the exosphere. These oscillations expend themselves gradually in accelerating the electrons to energies above the threshold for detection.

In such an event, the radiation density has been observed to accumulate to the point where the energy per unit volume in the radiation was as much as in the quiescent magnetic field; the field cannot hold a larger amount of energy. Following such an injection process, the particle density dies down comparatively slowly as particles are gradually scattered out of the trapped orbits, until another solar flare causes a repetition of the sequence of events.

The details of the above process were not well established in 1963, but it was clear that the electron acceleration occurs in the earth's field after the arrival of the solar streams, because space rockets did not encounter such dense concentrations of energetic electrons far from the earth.

It was suspected that a process of the same type might be more important than neutron albedo in supplying the particles of the inner band; however, the field close to the earth is too strong to be greatly affected by the solar streams, and the changes in content of the inner radiation belt, produced in geomagnetic storms, were too small to permit a test of this supposition by 1963.

See also SPACE EXPLORATION. (K. GN.)

VANBRUGH, SIR JOHN (1664–1726), British dramatist and architect, was born in the parish of St. Kicolas Acons in the City of London, and christened on Jan. 24, 1664. His father was a sugar baker, and his grandfather, Gillis van Brugg, came to England from Ghent in James I's reign. The Vanbrughs left London during the Plague and went to Chester. After a few years at the King's school, Chester, John at 19 was sent to France to study the arts; after two years' absence he returned to take up a commission in the regiment soon to be known as the 13th Foot. In the early autumn of 1690 Vanbrugh was arrested at Calais on a charge of espionage, on the information of a lady. He was imprisoned at Vincennes, but on Feb. 1, 1692, by a *lettre de cachet,* he was removed to the Bastille. His enforced leisure was responsible for the first draft of the *Provok'd Wife*. For a time after his return he resumed his commission.

The production of Cibber's *Love's Last Shift* at the Theatre Royal in Jan. 1696 kindled afresh his attachment to the comic muse. He thought it would be interesting to develop the situation upon which Cibber had rung down the curtain, and the result was *The Relapse*, "got, conceived and born in six weeks' space." It was given on Boxing day 1696, with Cibber as Foppington, one of the three parts borrowed from the preceding comedy. The Sir Novelty Fashion of Cibber was developed in this play into Lord Foppington, who has been pronounced "the best fop ever brought upon the stage." Foppington, Tunbelly Clumsy and Miss Hoyden are as fine a trio of comic characters as any play can show. *Aesop* at Drury Lane followed. This ran for a week only, but the success of *The Relapse* was so triumphant that Montague, afterward Lord Halifax, asked at once for the *Provok'd Wife* for the theatre in Lincoln's Inn Fields, and it was produced at that theatre in May 1697. Sir John Brute, the husband, is Vanbrugh's masterpiece, and as usual the servants' characters are well drawn. The play was a complete triumph, and Brute was one of Garrick's great parts. Vanbrugh was fiercely attacked by Jeremy Collier for immorality in 1698, and wrote nothing more for the stage until 1700, when an adaptation of the *Pilgrim* of Beaumont and Fletcher was produced at Drury Lane. In this play, in the part of Alinda, Anne Oldfield scored her first success. Two years later appeared *The False Friend,* a version of Le Sage's *Traître puni.* Other adaptations from the French were *A Country House*, from Dancourt's *Maison de campagne; Confederacy* (1705), from the same author's *Bourgeoises à la mode; Squire Trelooby* (1704), a version of Molière's *Monsieur de Pourceaugnac;* and *The Mistake* (1705). from Moliere's *Dépit amoureux.* As a dramatist Vanbrugh is less polished than Congreve and less remorseless than Wycherley. He was not primarily a man of letters, and, as Cibber said, his dialogue is "common conversation committed to paper." No one would trouble to defend his dramatic morality, but his worst efforts are less repulsive than Wycherley, because there is less ruthless realism and more fun in his attitude. His plays are farce, very often, rather than strict comedy, and warmed with humour.

Collier's attack and the resulting movement must have been responsible in part for "Van" turning his attention to architecture. The demand for splendid country seats in the new Palladian style was steadily increasing, and his reputation as a modern wit was an introduction in itself. In 1702 he was entered as comptroller of the Royal Works (now the board of works, where several of his designs may still be seen). In 1703 he wrote to ask his friend Jacob Tonson to procure him a "Palladio," and in the same year he was a commissioner at Greenwich. In the meantime, Vanbrugh had been appointed architect to the earl of Carlisle, and the result. completed in 1714, was the Corinthian mansion of Castle Howard. The work is an extension of the Palladian plan introduced by Inigo Jones, with the addition of immense corridors in segmental colonnades leading from the main entrance to the wing blocks. From a scenic artist's point of view, it is a magnificent (and certainly his best) piece of work. The earl procured for Vanbrugh a high place in the College of Arms. In March 1704 he was actually promoted Clarenceux, though he not only knew nothing of heraldry but had openly ridiculed that grave science in *Aesop*. His next work was to prepare designs for Kneller hall near Hounslow. But the success of Castle Howard now caused him to entertain the rash project of building a theatre in the Haymarket, from his own design, for the acting of his own plays. Congreve joined in the venture. The magnitude of Vanbrugh's architectural ideas grew as the work went on, and with the ideas the structure grew till a theatre meant for the delicate *bijouterie* work of polite comedy seemed growing to the proportions of the Roman Colosseum.

When at length the time came to test the acoustics of the pile, they were found to be sadly defective. What changes were made to rectify the errors of structure does not appear. The theatre was opened to the public with an Italian opera, which was followed by three of Molière's comedies, and these by the *Confederacy,* Vanbrugh's masterpiece.

Vanbrugh at last withdrew from the disastrous speculation; Congreve had already withdrawn. But a man to whom fortune had been so kind as she had been to Vanbrugh could hardly be depressed by any of her passing frowns. Queen Anne at once sent him abroad on an important state errand, and afterward he was commissioned to build Blenheim. Upon the merits and demerits of this famous "hollowed quarry" there has been much conflict of opinion. Blenheim palace is probably the largest domestic building in England, and consists of three blocks, the centre containing the private living rooms, one wing the stables and the other the kitchens and storehouses. It is planned on a colossal scale. Vanbrugh considered a building and the parts of a building as simply so much material for effect, without regard to their reasonable use and the necessary limitations of design. Personal comfort was sacrificed to perspective. Windows were to adorn the elevation, not to light the interior, and, as Voltaire said, if the rooms had only been as wide as the walls were thick, the château would have been convenient enough. After Blenheim and Castle Howard, his next largest palace was probably Fleurs, near Kelso. Blenheim, however, was a source of great sorrow to the kindly dramatist. Though parliament had voted for the building of it, no provision had been made for the supplies. The queen while she lived paid them, and then Vanbrugh was left to the meanness of the duke of Marlborough, and afterward to the insolence of the "wicked woman," who did her best to embitter his life. Besides Castle Howard and Blenheim, he built many other country mansions, such as Grimsthorpe and Duncombe hall in Yorkshire, Eastbury in Dorsetshire.

In Jan. 1719 Vanbrugh married Henrietta Maria, daughter of Colonel Yarborough of Heslington, and four years afterward, at the accession of George I, he was knighted. He afterward wrote again for the stage, and the unfinished fragment of the *Journey to London* (completed by Cibber as *The Provok'd Husband* in 1728) shows that his powers remained to the last as fine as ever. His married life was mostly spent at Blackheath, very probably in "Bastile house" on Maze hill, repaired in 1904 and now known as Vanbrugh castle. His wife died there at a great age in 1776, but "Van" himself died on March 26, 1726, in his modest town house in Whitehall. The site is occupied today by the war office.

The famous epitaph, "Lie heavy on him, earth," is attributed to Abel Evans.

Vanbrugh's works were edited in 2 vol., 1893, by W. C. Ward (portraits). *Select Plays* were issued in the "Mermaid Series" (ed. A. E. H. Swaen) in 1896. *See* G. H. Lovegrove's *Life, Works and Influence of Sir John Vanbrugh* (1902), Max Dametz's *Vanbrughs Leben und Werke* (1898), and *Swift's Works* (Bohn), xii. 80 sq. *The Complete Works of Sir John Vanbrugh* (Plays and Letters) edited by B. Dobree and G. Webb with introduction by B. Dobree (1928).

VAN BUREN, MARTIN (1782–1862), 8th president of the United States, mas known as the "Little Magician" because of his reputed cunning and skill as a politician. He was the third of five children, born in Kinderhook, N.Y., on Dec. 5, 1782, to Abraham and Maria (Hoes) Van Buren, both of Dutch descent. His father, a small farmer and tavern keeper, fought in the American Revolution, engaged in local politics and served as town clerk. Van Buren acquired considerable knowledge of human nature by working in his father's tavern; his formal education was conducted in the Kinderhook schoolhouse and later the village academy. In 1796 he took up the study of law in the office of Francis Silvester and later completed his legal studies in New York city under the tutelage of William P. Van Ness. He was admitted to the bar in 1803 and returned to Kinderhook where he began a long and highly successful law practice. On Feb. 21, 1807, he married Hannah Hoes, by whom he had four sons: Abraham, John, Martin and Smith Thompson. His wife died of consumption in 1819 and he never remarried.

Van Buren entered politics about the same time he began his law practice. In 1808 he was appointed surrogate of Columbia county. His talents as an industrious lawyer and astute politician were quickly recognized and he was elected in 1812 to the state senate over Edward P. Livingston on an antilandlord, antibank ticket. He served t o terms (1812–1820) and during his tenure was appointed state attorney general. He prosecuted Gen. William Hull for treason resulting from the surrender of Detroit to the British during the War of 1812. Hull was found guilty but the sentence of execution was remitted by Pres. James Madison. As senator, Van Buren actively supported the war, favoured the construction of the Erie canal and helped sponsor a convention in 1821 to revise the constitution of the state of New York. He was a delegate to the convention and succeeded in resolving differences between the conservative and radical members on several important issues, notably suffrage and qualifications for holding office. Because of his skill as an organizer, his ability to execute political schemes which weakened his opponents, and his engaging personality as a leader of men, he won command of the Bucktail faction (those Republicans opposed to Gov. De Witt Clinton and his policies) of the state Republican party. Over a period of 15 years he battled Clinton for political control of New York; the struggle did not end until Clinton died in 1828. After his election to the U.S. senate in 1821 Van Buren created the Albany regency (*q.v.*), a political organization to govern the state during his absence in Washington. His name became closely linked with machine politics and his reputation as a statesman suffered accordingly.

Van Buren regarded himself as a disciple of Thomas Jefferson. He supported the doctrine of states' rights, opposed a strong central government in Washington and disapproved federally sponsored internal improvements. He voted for the tariff bill of 1824 but later became a free trader. Above all, he insisted the party system of government was the best means of advancing democratic ideals. In the presidential election of 1824 he managed the campaign of William H. Crawford against John Q. Adams, Andrew Jackson and Henry Clay. He called the last congressional caucus for the purpose of nominating a presidential candidate. After the election of Adams he recognized the necessity of adjusting his political thinking to the changing times. The Crawford, Jackson and Calhoun factions of the Republican party were joined; the popularity of Jackson was exploited; and the political principles of Thomas Jefferson were reasserted. Out of this union an organization gradually emerged which became known as the Democratic party.

To promote Jackson's election to the presidency in 1828 Van Buren skillfully maneuvered passage of the Tariff of Abominations; to assist Jackson's victory in New York, which had been menaced by the sudden rise of the anti-Masonic party (*q.v.*), he successfully ran for the office of governor, and resigned his senate seat. After two and a half months he resigned the governorship to accept appointment as Jackson's secretary of state. Before resigning, however, he introduced the safety fund, an improved banking system to provide New York with more dependable financial institutions.

As the leading member of Jackson's cabinet, Van Buren was criticized for extending the spoils system throughout the federal government, but the criticism was exaggerated. Van Buren did not introduce the system, nor was he as ruthless a spoilsman as his opponents claimed. He was, on the other hand, responsible for initiating effective co-operation between the president and party leaders in congress. His tact and good judgment in the social situation involving Mrs. John H. Eaton (("Peggy O'Neill"), wife of the secretary of war who had been maligned by the wives of the other cabinet members, earned Jackson's confidence and respect. As secretary of state he helped resolve the dispute between Great Britain and the United States over West Indian trade; he was instrumental in securing agreement from the French for subsequent payment of spoliation claims originating during the Napoleonic wars; and he negotiated the first treaty with Turkey providing American access to the Black sea and a reciprocal most-favoured-nation commerce agreement. He drafted Jackson's message vetoing the Maysville road bill and approved the president's decision not to recharter the Second National Bank of the United States. He resigned in 1831 to permit the reorganization of the cabinet and was appointed minister to Great Britain.

Four months after arriving in England, Van Buren learned that his nomination had been defeated in the senate by the tie-breaking vote of Vice-Pres. John C. Calhoun. The jealousy and rivalry between the two men went back to the beginning of Jackson's administration. Calhoun's action ensured Van Buren's nomination for the vice-presidency on the Jackson ticket in 1832 by the first national convention of the Democratic party. (*See* NATIONAL CONVENTION). He was elected with Jackson on an antibank ticket and he endorsed the president's handling of the nullification controversy. In 1835 he became Jackson's choice for the presidency and was unanimously nominated in the Baltimore convention. Van Buren received 170 electoral votes against 73 for William Henry Harrison, 26 for Hugh L. White, 14 for Daniel Webster and 11 for Willie P. Mangum.

Van Buren's presidency began as the financial panic of 1837 spread throughout the nation. He called a special session of congress and proposed removing government funds from state banks and putting them in an "independent treasury." After a prolonged congressional battle the bill passed (1840) but many conservative Democrats deserted to the Whig party. Although Van Buren displayed statesmanlike courage and firmness during the struggle, hostility and bitterness born of the panic continued to mount against him. A costly war with the Seminole Indians in Florida and his failure to support the proposed annexation of Texas also lessened his popularity. In foreign affairs he had difficulties with Great Britain arising out of the U.S.S. "Caroline" incident. The U.S.S. "Caroline" was a U.S. steamer which had been transporting supplies to Canadian insurgents and had been set afire and sunk by Canadian troops. One American was killed in the melee and Alexander McLeod, a participant, was subsequently arrested in New York and charged with murder and arson. Great Britain threatened war but in time the disputes were settled peaceably. The question of the northeast boundary of the United States provoked conflict between the inhabitants of Maine and their Canadian neighbours bordering the Aroostook river. Armed clashes over rights to the territory were halted by Van Buren and a permanent settlement was later negotiated in the U'ebster-Ashburton treaty of 1842. One of his last acts in office was to order that no person should labour more than ten hours a day on federal public works.

Van Buren was unanimously renominated in 1840 by the Democrats and was opposed by the Whig candidate, William Henry Harrison. Songs, ballyhoo and slogans were the devices employed by both parties to solicit votes during this "log cabin and hard cider campaign," as it was called, and the popular expression "O.K." (meaning Old Kinderhook) is said to have originated during the election. Van Buren was decisively defeated, winning only 60 electoral votes to Harrison's 234.

Four years later Van Buren was a contender for the Democratic nomination but failed to obtain the required two-thirds vote because of his opposition to the annexation of Texas. In 1848 he was nominated by the antislavery Democrats (Barnburners) and then by the Free-Soilers with whom the Barnburners and "conscience" Whigs coalesced. Failing of election, Van Buren retired to his estate "Lindenwald" in Kinderhook and spent several years traveling in Europe. He continued an active interest in politics until his death in Kinderhook on July 24, 1862. *(See* also UNITED STATES [OF AMERICA], THE: *History.)*

Van Buren wrote his memoirs to 1833, which were published in 1920 under the title *The Autobiography of Martin Van Buren.* He also wrote an *Inquiry into the Origin and Course of Political Parties in the United States* (1867). *See* also Index references under "Van Buren, Martin" in vol. 24.

VANCOUVER, GEORGE (1757–1798), English navigator, was born at King's Lynn on June 22, 1757. He entered the navy at the age of 13, and accompanied James Cook on his second (1772–75) and third (1776–80) voyages of discovery. After nine years' service in the West Indies, Vancouver, on Sir Alan Gardner's recommendation, was appointed to command an expedition to the northwest coast of North America, to take over from the Spaniards the territorial right they had claimed (and later relinquished) at Nootka Sound, to explore the coast from 30° N. round to Cook's river (or inlet), to search for an eastward passage to Hudson bay and to ascertain the true character of Juan de Fuca strait. Vancouver in the sloop "Discovery" (not Cook's old ship) accompanied by the "Chatham" under Lieut. W. R. Broughton, left Falmouth on April 1, 1791, and proceeded by way of the Cape of Good Hope to Australia, where he surveyed part of the southwest coast, especially King George's sound. He next made for Dusky bay, New Zealand, then sailing northeast, discovered Oparo islet (27° 36' S.; 144° 1' 30" W.), and on Dec. 30 reached Tahiti, where he was rejoined by Broughton, who had discovered Chatham Island.

After staying at Tahiti and at the Hawaiian Islands, Vancouver, on April 17, 1792, sighted the west coast of North America at 39° 27' N. He examined the coast up to 52° 18' N., with minute care, surveying all the intricate inlets and channels in the region of Vancouver Island, and naming (among others) Puget sound and the Gulf of Georgia. By August he was negotiating with the Spanish at Nootka; and he refitted at Monterey.

After another visit (Feb.–March 1793) to the Hawaiian Islands, Vancouver resumed his exploration of the North American coast in April, surveying north to 56° 44' N., and south (past the Spanish Californian settlements) to 35° N. In the autumn he was again at Nootka and Monterey. Refreshing at the Hawaiian Islands (Jan.–March 1794), Vancouver accepted their submission to Great Britain, but his annexation seems never to have been officially ratified. On his third season's work, in 1794, Vancouver sailed to Cook's inlet, which was proved to be no river. After a fresh survey of much of the coast north of San Francisco, he set homeward via Cape Horn and St. Helena reaching the Thames on Oct. 20, 1794. By this great voyage of four and one-half years, on which only one man was lost by disease, Vancouver "had completed perhaps the most arduous survey that it had fallen to any navigator to undertake" (E. Heawood, *A History of Geographical Discovery in the 17th and 18th Centuries*, p. 297, University Press, Cambridge [1912]); and he had effectively disproved the existence of any channels between the Pacific and Hudson bay.

Vancouver immediately set about the preparation of his narrative; but he died at Richmond in Surrey on May 10, 1798, before he had completed his task. His brother John assisted by Capt. Peter Puget, who commanded the "Chatham" in 1793–94, published the complete record in 1798.

See *A Voyage of Discovery to the North Pacific Ocean and Round the World . . . 1790–95,* 3 vol. (1798), with an atlas of maps and plates; G. S. Godwin, *Vancozrver: a Life* (1930). (R. A. SN.)

VANCOUVER, a city of British Columbia, Can., the most important Canadian seaport on the Pacific coast, has a superb site facing the sea and mountains: on the north there is the deep fiord, Burrard inlet, and its backdrop of forested slopes culminating in peaks 5,000 ft. high; southward the large urban area stretches to the delta of the Fraser river. Pop. (1961), city of Vancouver, 384,522; metropolitan area (which includes the adjacent cities of New Westminster [*q.v.*], North Vancouver, Port Coquitlam and Port Moody as well as eight district municipalities), 790,165.

Vancouver has one of the mildest climates in Canada. Essentially maritime conditions prevail, with temperatures for January averaging 37° F. and for July, 64° F. Two-thirds of the precipitation of about 60 in. occurs between October and March.

The city takes its name from Capt. George Vancouver of the Royal Navy, who explored Burrard inlet in 1792. For many years thereafter no white men visited the area, but by 1865 there was a small settlement on the inlet around the Hastings sawmill. Construction of the Canadian Pacific railway across Canada in the 1880s led to the founding of Vancouver and it was incorporated as a city in 1886. In the same year a disastrous fire burned most of the 800 business establishments and homes of its 2,000 citizens. They vigorously rebuilt their city, which soon had an assured prosperity when it became the railway terminus (originally planned to be in Port Moody, 12 mi. E. of Vancouver) and the port for many ships trading with the orient. The first Canadian Pacific train arrived on May 23, 1887. Settlers poured in and by 1910 the population had jumped to 100,000. The city became firmly established as a great seaport after the completion of the Panama canal in 1915, by which prairie grain could be shipped via Vancouver to Europe.

Vancouver is the industrial and commercial heart of British Columbia. Trade and transportation are basic functions and one-third of the labour force is engaged in these activities. Another third is in service industries and finance, and one fifth in a number of extremely diversified manufacturing industries. Wood processing, based on the extensive forest resources of coastal British Columbia, is an important industry; it includes sawmilling, plywood and pulp and paper manufacturing. Iron and steel fabrication, oil refining, food processing and chemical manufacturing are also important. Hydroelectric developments near the coast and oil and natural gas pipelines from the east side of the Rocky mountains provide ample supplies of power.

Ships of any size can be accommodated in Vancouver's harbour, which has a depth of 40 ft. The port is particularly active when eastern Canadian ports are closed by ice. Its general-cargo, deep-water docks are used by freighters from all parts of the world and Vancouver is also home port for a large fleet of fishing vessels. Auto ferries ply between Vancouver and Nanaimo and Victoria on Vancouver Island.

Vancouver is the terminus for four railways: the Canadian Pacific and Canadian National, which are transcontinental lines; the Pacific Great Eastern, extending to north-central British Columbia; and the Great Northern to Seattle and other U.S. cities. Vancouver International airport at the mouth of the Fraser river is one of the major air centres in North America.

The commercial and industrial core of the city adjoins the port facilities along the shores of Burrard inlet and False creek. Large residential suburbs with their own shopping districts extend from the downtown area. There are relatively few tall buildings because ground space has been plentiful. Few of the buildings exhibit impressive architecture, but the face of the city was given a special character by the thousands of beautifully landscaped homes built during the rapid post-World War II expansion.

The Lions Gate bridge, a splendid suspension structure, links the city of Vancouver to North and West Vancouver at the First narrows of Burrard inlet, and two bridges cross the Second narrows. The north shore communities cover the lower mountain slopes. North Vancouver has some industry of its own, mainly shipbuilding and sawmilling.

Among the outstanding amenities of the city is Stanley park, which occupies a seagirt promontory forming the entrance to Vancouver harbour. Although there are gardens, an aquarium and zoo. a large proportion of the 1.000 ac of the park has been left in a natural forest of Douglas fir and Western Red cedar.

The campus of the University of British Columbia, founded in 1908, has a scenic location overlooking the ocean at the tip of Point Grey. Faculties include arts and science, applied science, agriculture, law, pharmacy, medicine, forestry, commerce and business administration, education and graduate studies.

Golf and tennis are year-round games in Vancouver. Three subalpine areas have been developed extensively for skiing. Boating enthusiasts cruise and fish in the waters of Burrard inlet and neighbouring Howe sound. A unique feature of Vancouver is that it is possible to hunt for ducks and geese on the Fraser delta, practically within the city limits, and to fish for steelhead trout in Capilano creek only four miles from the city centre. In the juxtaposition of mountains and sea nature has endowed Vancouver with particular advantages for outdoor recreation. (G. A. W.)

VANCOUVER, the seat of Clark county in southwestern Washington, U.S.. 8 mi. N. of Portland, Ore., located at the head of deep-water navigation on the Columbia river. It is the oldest permanent settlement in the Pacific northwest, having been established in 1824 as a post of the Hudson's Bay company. Its location at the confluence of the northwest's principal natural travel routes accounted for its selection as headquarters for all the company's operations west of the continental divide until the area was taken over by the U.S. in 1846.

Fort Vancouver was the scene of the Pacific northwest's first farming, horticulture, dairying and wool growing; its first gristmill, sawmill and brickyard; and its first school. The first seagoing craft constructed in the northwestern United States was built there in 1829. There, too, in 1836, the U.S S. "Beaver," first steamboat to enter the Pacific, made its first trip under steam. Built on the Thames in England, it arrived under sail with engines and paddle wheels as deck cargo, to be installed at Fort Vancouver. The fort became a U.S. military reservation in 1848, adjoining the town which had formed about the trading post. Washington's first post office and first hospital were located there. Incorporated as a city in 1857 it has a council-manager form of government, in effect since 1952. Its growth has been steady except during the 1940s, when the population more than doubled as a result of war industries. For comparative population figures ***see*** table in WASHINGTON. *Population.*

Vancouver is the Bonneville Power administration's distribution centre for all hydroelectric energy produced in the Columbia river drainage basin. Availability of ample electric power accounts for local production of aluminum, abrasives and chemicals. Other manufactures include lumber, wood products, paper, beer, malt and canned fruits. The city is a major grain shipping point. Intensive agriculture, horticulture, dairying and poultry raising in the surrounding area are aided by a 208-day growing season.

Among the U.S. army officers stationed at the military post at Vancouver were Ulysses S. Grant, "Phil" Sheridan, George B. McClellan, George E. Pickett, William S. Harney, O. O. Howard, Nelson A. Miles, Frederick Funston and George C. Marshall. In 1948 the old stockade site became Fort Vancouver National monument. Grant House museum occupies a building erected by the U.S. army in 1849. Clark college, a public junior college organized in 1933, and the state schools for the deaf and the blind are in Vancouver. (H. J. Bu.)

VANCOUVER ISLAND, British Columbia, the largest of innumerable islands which fringe the Pacific coast of Canada, and the largest island on the west coast of North America. It is 282 mi. long, averages 50 mi. wide and has an area of 12,408 sq mi. It extends in a northwest-southeast direction and is separated from the state of Washington to the south by Juan de Fuca strait, and from the mainland to the east by the Strait of Georgia and Queen Charlotte strait. The island was made a British crown colony in 1849 (having previously been held under grant by the Hudson's Bay company), and in 1866 it was united with British Columbia, which had become a crown colony in 1858; the enlarged crown colony of British Columbia entered the Dominion of Canada as a province in 1871.

Vancouver Island has a deeply dissected, mountainous interior averaging 2,000 ft.–4,000 ft. above sea level (highest point, 7,250 ft.), flanked on the east by a coastal plain and on the west by deep fiords and numerous rocky islets. Alberni Inlet, at the head of which lie the twin cities of Alberni and Port Alberni, nearly bisects southern Vancouver Island and provides an excellent 20-mi.-long waterway for deep-sea vessels. Softwood forests clothe much of the island and logging, sawmilling and other wood processing are the most important industries. A variety of minerals is present and considerable quantities of coal, iron ore and copper are produced. Fishing, agriculture and tourism are also significant, agriculture (primarily dairying, poultry raising, and the growing of small fruits and vegetables) being confined to the favourable soils and topography of the east coastal plain. Population and road and rail transport facilities are also concentrated along the east coast. the main cities being Victoria. Duncan, Nanaimo, Port Alberni, Courtenay and Campbell River. Victoria (*q.v.*), about 60 mi. S. across the Strait of Georgia from the city of Vancouver on the mainland. is the capital and second largest city in the province (1961 population, city proper 54,941; metropolitan area, 154,152). Esquimault, a municipality within the Victoria metropolitan area, has long been a naval and garrison centre. As early as 1854 a small Royal Navy hospital was built near the entrance to its harbour. some 3 mi. W. of Victoria, and in 1865 an official base was established there. Since 1905 Esquimault has been Pacific coast headquarters of the Royal Canadian navy. The army garrison is at Work Point, facing Victoria harbour. See also BRITISH COLUMBIA. (A. L. FY.)

VANDALS, a term used by early writers only as a collective designation for a group of Teutonic tribes including, according to Pliny, the Burgundians and the Goths. The Vandals as a separate people figure in the earliest legends both of the Goths and the Lombards, and first came into contact with the Romans during the Marcomannic War. In the time of Aurelian they invaded Pannonia, and during the reign of Probus we find them fighting in Dacia. In the time of Constantine I, according to Jordanes, they suffered a great defeat at the hands of Geberich, king of the Goths, their own king Visimar being killed, and the survivors were allowed by the Romans to settle in Pannonia.

Invasions. — In AD. 406 they moved westward, according to some writers at the instigation of Stilicho, who is himself said to have been of Vandal origin, and crossing the Rhine at Mainz proceeded towards Gaul.

Owing to defeat at the hands of the Franks the Vandals could not settle in Gaul and in 409 their king Gunderic led them across the Pyrenees. They appear to have settled in Spain in two detachments. One, the Asdingian Vandals, occupied Galicia, the other, the Silingian, Andalusia. The Silingian Vandals were almost exterminated during the next 20 years but their Asdingian brethren marched across Spain and took possession of Andalusia. In 428 or 429 the whole nation set sail for Africa, upon an invitation received by their king from Bonifacius, count of Africa, who had fallen into disgrace with the court of Ravenna. Gunderic was now dead, and supreme power was in the hands of his bastard brother Gaiseric who was for 50 years the terror of Constantinople and Rome. Probably in the month of May 428, he assembled all his people on the shore of Andalusia, and numbering the males among them from the greybeard down to the newborn infant found them to amount to 80,000 souls. The nation was transported to Africa in ships supplied by Bonifacius. Although he soon returned to the Imperial allegiance only three cities of Roman Africa—Carthage, Hippo and Cirta—remained untaken by the Vandals by May 430. At length (Jan. 30, 435) peace was made between the emperor Valentinian III. and Gaiseric. The emperor was to retain Carthage and the small but rich proconsular province in which it was situated, while Hippo and the other six provinces of Africa were abandoned to the Vandal. Gaiseric observed this treaty no longer than suited his purpose. On Oct. 19, 439, he suddenly attacked and took Carthage. The Vandal occupation of this great city, the third among the cities of the Roman empire, lasted for 94 years. Gaiseric seems to have counted the years of his sovereignty from the date of its capture. Henceforward he made of Carthage a pirate's stronghold, whence he issued forth, like the Barbary pirates of a later day, to attack, as he himself said, "the dwellings of the men with whom God is angry," leaving the question who those men might be to the decision of the elements. Almost alone among the Teutonic invaders of the empire he set himself to form a powerful fleet, and was probably for 30 years the leading maritime power in the Mediterranean. Gaiseric's celebrated expedition against Rome (455), undertaken in response to the call of Eudocia, widow of Valentinian, was only the greatest of his marauding exploits. He took the city without difficulty, and for 14 days, in a calm and business-like manner, emptied it of all its movable wealth. Eudocia and her two daughters were carried into captivity.

Empire and Defeat. — There does not seem to be in the story of the capture of Rome by the Vandals any justification for the charge of wilful and objectless destruction of public buildings which is implied in the word "vandalism." It is probable that this charge grew out of the fierce persecution which was carried on by Gaiseric and his son against the Catholic Christians. The bishops were almost universally banished, and the congregations were forbidden to elect their successors, so that the greater part of the churches of Africa remained "widowed" for a whole generation. In 476, at the very close of Gaiseric's life, by a treaty concluded with the Eastern emperor, the bishops were permitted to return. There was then a short lull in the persecution; but on the death of Gaiseric (477) and the accession of Hunneric it broke out again with greater violence than ever.

On the death of Hunneric (484) he was succeeded by his cousin Gunthamund, Gaiseric having established seniority among his own descendants as the law of succession to his throne. Gunthamund (484–96) and his brother Thrasamund (496–523), though Arians, abated some of the rigour of the persecution, and maintained the external credit of the monarchy. On the death of Thrasamund, Hilderic (523–31), the son of Hunneric and Eudocia, at length succeeded to the throne. He adhered to the creed of his mother rather than to that of his father; and, in spite of a solemn oath sworn to his predecessor that he would not restore the Catholic churches to their owners, he at once proceeded to do so and to recall the bishops. Hilderic, elderly, Catholic and timid, was very unpopular with his subjects, and after a reign of eight years he was thrust into prison by his cousin Gelimer (531–534).

The wrongs of Hilderic, a Catholic, with the blood of the emperor Theodosius in his veins, afforded to Justinian a long-coveted pretext for overthrowing the Vandal dominion. A great expedition under the command of Belisarius reached Africa in the beginning of Sept. 533. A large force of Vandals was then occupied in Sardinia under Gelimer's brother Tzazo, and the landing of Belisarius was entirely unopposed. He marched rapidly towards Carthage and on Sept. 13, defeated Gelimer at Ad Decimum, 10 m. from Carthage. Next day he entered Carthage and ate the feast prepared in Gelimer's palace for its lord. Belisarius, however, was too late to save the life of Hilderic, who had been slain by his rival's orders as soon as the news came of the landing of the imperial army. On the return of Tzazo from Sardinia a force was collected considerably larger than the imperial army, but the Vandals were defeated and Gelimer took to flight. He took refuge in a mountain fortress called Pappua on the Numidian frontier, and there, after enduring great bardships in the squalid dwellings of the Moors, surrendered to his pursuers in March 534. The well-known stories of his laughter when he was introduced to Belisarius, and his chant, "Vanitas vanitaturn," when he walked before the triumphal car of his conqueror through the streets of Constantinople, probably point to an intellect disordered by his reverses and hardships. The Vandals who were carried captive to Constantinople were enlisted in five squadrons of cavalry and sent to serve against the Parthians under the title "Justiniani Vandali." Four hundred escaped to Africa and took part in a mutiny of the imperial troops, which was with difficulty quelled by Belisarius (536). After this the Vandals disappeared from history. The overthrow of their kingdom undoubtedly rendered easier the spread of Saracen conquest along the northern shore of Africa in the following century. (F. G. M. B.; T. H.)

VANDAMME, DOMINIQUE RENÉ, Count (1770–1830), French soldier, was born at Cassel, near Dunkirk, on Nov. 5, 1770. He enlisted in the army in 1786, served in Martinique in 1788 and on returning to France entered into the Revolutionary movement, raising a company of light infantry. He was promoted and after Hondschoote he was made general of brigade. serving in the Low Countries (1794), on the Rhine (1795) and in Germany (1796). In 1799 he was promoted general of division, and served in Holland, Germany and Switzerland. He was a devoted servant of Napoleon. In 1805, for his leadership at Austerlitz, he was given the Grand Eagle of the Legion of Honour, and in 1806–07 he commanded a small corps of the *Grande Armée* which reduced the Silesian fortresses. In 1808 he was made count of Unebourg. In 1809 he served in the Eckmühl campaign, but in 1812, while commanding the Westphalian contingent he quarrelled with King Jerome Bonaparte and returned to France. He returned to the army in 1813, but his corps, sent against the line of retreat of the Allies at the battle of Dresden, surrendered at Kulm. (*See* Napoleonic Campaigns.) At the end of the war he was forbidden to enter Paris. When Napoleon returned Vandamme joined him and was made a peer of France and placed at the head of the 3rd corps in the army of the north. (*See* Waterloo Campaign, 1815.) The Restoration first imprisoned and then exiled him. He died at Cassel on July 15, 1830.

VANDEGRIFT, ALEXANDER ARCHER (1887–), U.S. marine corps officer who commanded the 1st marine division in one of the most outstanding actions of World War II in the Pacific, the capture and holding of Guadalcanal, was born at Charlottesville, Va., March 13, 1887. After attending the University of Virginia, Charlottesville, he received a commission in the marine corps in 1909, advancing to the rank of major general in 1942. Vandegrift led the 1st marine division on Aug. 7, 1942, in the assault on Guadalcanal, the first large-scale U.S. offensive action against the Japanese, and held the island against repeated counterattacks, being aided later by other marine and army units. He also commanded the 1st marine amphibious corps in the Bougainville landing in the autumn of 1943. Appointed the 18th commandant of the U.S. marine corps on Jan. 1, 1944, he became the first marine officer to hold the rank of general, to which he was advanced in March 1945. Vandegrift retired Jan. 1, 1948. (J. B. Hn.)

VANDERBILT, a U.S. family whose fortune was founded on steamship and railway lines. Cornelius Vanderbilt (1794–1877), nicknamed "Commodore," was born at Stapleton, N.Y., May 27, 1794, and when 16 bought a sailboat, in which he carried farm produce and passengers between Staten Island and New York city. He successfully established his fortune in the shipping business, particularly through his reduction of the route from New York to San Francisco following the Gold Rush of 1849 By 1855–61 he also operated a freight and passenger line between New York and Le Havre

In 1857–62, houever, he sold his steamships and turned his attention to railways. He purchased the New York and Harlem railroad stock in 1362 at a low price and later that of the Harlem's competitors, the Hudson River railroad, and the New York Central railroad running from Albany to Buffalo. In all three cases he thnarted attempts by financial opponents to prevent his success. In 1868 he sought control of the rival Erie railway by buying stock. Honever, Daniel Drew, Jay Gould (*q.v.*) and James Fisk (*q.v.*) who controlled the Erie, placed fraudulent stock on the market to prevent Vanderbilt's purchase. Although he lost millions in the abortive attempt to control the Erie, Vanderbilt continued his railroad expansion by acquiring the Lake Shore and Michigan Southern in 1873 to establish a through route bet een New York and Chicago At the time of his death he controlled many railroads and his fortune was estimated at more than $100,000,000. He endomed Vanderbilt university.

His eldest son, WILLIAM HENRY VANDERBILT (1821–1885) was born in New Brunswick, N J , May 8, 1821. After a career as receiver and president of several railroads he succeeded his father as president of the Lake Shore and Michigan Southern, the Canada Southern. and the Michigan Central railways.

William Henry's son, GEORGE WASHINGTON (1862–1914) was an outstanding agriculturist and forester. He established the vast Biltmore estate near Asheville, N.C., and devoted considerable money and time to the advance of scientific farming and forestry. Another son, WILLIAM KISSAM (1849–1920) was active in the Vanderbilt railroad empire and was an enthusiastic yachtsman and race horse owner. His eldest son, CORNELIUS (1843–1899) was also active in managing the Vanderbilt fortunes. Of his sons, the eldest, CORNELIUS III (1873–1942) was devoted to numerous financial interests, while the other two sons, ALFRED GWYNNE (1877–1915) and REGINALD CLAYPOOL (1890–1925) were noted for their interests in show horses.

VANDERLYN, JOHN (1775–1852), the first U.S. painter to study in Paris, where he was much influenced by J. L. David, was born at Kingston, N.Y., on Oct. 15, 1775. While still very young he copied some of Gilbert Stuart's portraits, including one of Aaron Burr, and Burr was so impressed that he placed him under Stuart as a pupil and later employed Vanderlyn to paint his portrait and that of his daughter, Theodosia. In 1796 Vanderlyn went to Paris, and in 1805 to Rome, where he painted his "Marius Amid the Ruins of Carthage"; this was shown in Paris, and obtained a gold medal there; it is now in the New York Public library. Vanderlyn remained in Paris for seven years, during which time he prospered greatly. In 1812 he showed a nude "Ariadne" (engraved by Durand, and now in the Pennsylvania Academy of the Fine Arts, Philadelphia), which increased his fame. When Aaron Burr fled to Paris, Vanderlyn was for a time his only support. Vanderlyn returned to America in 1815, but did not meet with success. In 1842, through friendly influences, he was commissioned by congress to paint "The Landing of Columbus" for one of the panels in the rotunda of the Capitol at Washington, D.C. Going to Paris, he employed as assistant a French artist, who, it was said, did most of the work; though this was common practice, it led to his being charged with fraud. Vanderlyn was in actual want when he died at Kingston, N.Y., on Sept. 23, 1852.

VAN DER ROHE, LUDWIG MIES: *see* MIES VAN DER ROHE, LUDWIG.

VANDERVELDE, EMILE (1866–1938), Belgian statesman, was born on Jan. 25, 1866 at Ixelles near Brussels. He studied law at Brussels university and in 1885 took his doctorate in social science. In the following year he joined the Belgian Labour party and soon became its acknowledged leader. He first entered parliament in 1894 as Socialist member for the Charleroi constituency. but after 1900 was returned continuously by Brussels. In the chamber he achieved both influence and prestige and played a prominent part in the struggle to attain universal suffrage, a struggle which resulted in more than one national general strike. On the outbreak of World War I, Vandervelde devoted himself to the problems of national defence, the liberation of his invaded country, and in Aug. 1914 was summoned to join the government as minister of state, later becoming member of the cabinet. At the time of peace negotiations and the signing of the Versailles treaty, he used his influence to obtain the insertion of labour clauses, relating especially to the eight-hour day. As minister of justice in the Liberal-Catholic-Socialist cabinet formed after the war, Vandervelde effected great humanitarian and scientific reforms in the prison system. After the important successes achieved by the Labour party in the general elections of 1925 he entered the Socialist-Catholic coalition cabinet as minister for foreign affairs and played an important part in negotiating the Locarno pact in 1925, which he signed on behalf of Belgium. He retained the portfolio of foreign affairs on Jaspar's ministry of "national unity" He came to be regarded abroad as well as in Belgium as essential in Belgian foreign policy, partly because of his success at Locarno and the high esteem in which he was held by his foreign colleagues at Geneva. But he was constantly subjected to criticism because of his genuine internationalism, and early in 1927 he had some difficulty in soothing his non-Socialist critics. In internal politics he fought for a reduction of the term of military service to six months and thorough reorganization of the army system. This attitude of the Socialist members of the Jaspar cabinet was the immediate cause of its fall. Vandervelde was minister without portfolio, 1935–36, and minister of public health, 1936–37. Considered by some to be the most powerful Socialist orator in the French language since Jaurès, Vandervelde played a conspicuous role in the modern international Socialist congresses.

VAN DE VELDE: *see* VELDE, VAN DE.

VAN DOREN, CARL CLINTON (1885–1950), U S. author, editor and critic, was born on a farm near Hope, Ill., Sept. 10, 1885. He graduated from the University of Illinois in 1907 and received his Ph.D. from Columbia university in 1911. His first book, a biography of Thomas Love Peacock, was also published in 1911. He taught English at Columbia from 1911 to 1930. From 1917 to 1921 he was managing editor of the *Cambridge History of American Literature*. He was literary editor of the *Nation* (1919–22) and of *Century Magazine* (1922–25).

His writings ranged through surveys of literature to novels, biography and criticism. In 1939 he received a Pulitzer prize for his biography *Benjamin Franklin* (1938). His works included *The American Novel* (1921; revised 1940); *Contemporary American Novelists* (1922); *American and British Literature Since 1890* (1925), in collaboration with his brother, Mark Van Doren, and revised in 1939; *American Literature: An Introduction* (1933), reissued as *What Is American Literature?* (1935). Some of his other important works were *James Branch Cabell* (1925); *Swift* (1930); *Sinclair Lewis* (1933); and his autobiography, *Three Worlds* (1936).

VAN DYCK (VANDYKE), **SIR ANTHONY** (1599–1641), after Rubens, the most prominent Flemish painter of the 17th century. He was a prolific painter of portraits, of which about 500 are extant, aside from many repetitions, copies, imitations and forgeries that go under the artist's name. He also painted many religious and mythological subjects and ranks high as a draftsman and etcher.

LIFE

Van Dyck was born in Antwerp on March 22, 1599, the seventh of 12 children of Frans Van Dyck, a well-to-do silk merchant. When Anthony was eight years old the family moved from the house "Den Berendans" ("To the Bears' Dance"), which had belonged to Van Dyck's grandfather, into a very stately dwelling called "To the City of Ghent." At the age of ten, Van Dyck was apprenticed to Hendrik van Balen, a successful Antwerp painter specializing in small religious and mythological pictures. Van Dyck soon must have come under the influence of Rubens who after his return from Italy in 1608 quickly assumed undisputed leadership of art in Antwerp. Some scholars believe that the youthful Van Dyck was also in close contact with Jacob Jordaens, whose vigorous first manner dated from 1612.

1613–21.—Van Dyck's first surviving work, the portrait of a man, is dated 1613; a self-portrait (Academy, Vienna) cannot have been done much later. His precociousness showed also in other ways. When only 18, he acted as family representative in a lawsuit; before he mas 19 his father declared him legally of age. On Feb. 19. 1618, Van Dyck was inscribed as master in the Antwerp guild. It is uncertain when he entered the studio of Rubens, but on July 17, 1620, a correspondent of the earl of Arundel reported that "van Dyck is still staying with Rubens and his works begin to be appreciated as much as those of his master." In March 1620 Rubens had received a large commission permitting him to use the assistance of "Van Dyck and some other disciples." It is generally believed that Rubens referred to Van Dyck when he described a painting he offered in April 1618 to the English ambassador at The Hague as having been painted "by my best pupil." Thus there must have been a close association of the two men even before 1618. In view of Van Dyck's fully developed personal style in these years. however. it is probably more accurate to call him Rubens' collaborator rather than his pupil.

Although the relationship between Rubens and Van Dyck became strained after 1630, there is no evidence for the belief that Rubens tried to hamper the career of the young rival. On the contrary, he probably helped him with recommendations on his first trip to England (Nov. 1620 to Feb. 1621) where Rubens' admirer the earl of Arundel was also Van Dyck's protector.

1621–27.—Apparently unwilling to remain at the court of King James I, despite an annual salary of £100 sterling, Van Dyck returned to Antwerp and in Oct. 1621 set out for Italy. There, too, Rubens' recommendations paved his way. His first goal was Genoa. where in 1606/7 Rubens had been employed as a painter of portraits, and where Van Dyck was immediately patronized by the same group of aristocratic families for whom Rubens had been active. At the end of the 18th century there were still 99 paintings by Van Dyck in Genoa, 72 of which were portraits.

Genoa remained his headquarters, but he is known to have visited Rome, Venice, Padua Mantua, Milan and Turin. In 1624 he spent some time in Palermo, where he painted the Spanish viceroy Emanuel Philibert of Savoy (Dulwich), who in the same year died of the plague; Van Dyck also made a drawing of Sofonisba Anguisciola. a 96-year-old, blind woman painter (Chatsworth house, Derbyshire, Eng.). In 162j he is said to have visited Nicolas Peiresc, the great scholar and friend of Rubens, in Aix-en-Provence Although every here employed with commissions. Van Dyck used the opportunity of his Italian years to study the works of the great Italian painters. A sketchbook at Chatsworth house testifies to his attraction to the Venetian masters. above all Titian. He made many rapid sketches of their compositions, occasionally adding notes about colour and spontaneous words of praise.

1627–32.—In July 1627, Van Dyck was again in Antwerp, where he remained until 1632. The frequent absence of Rubens between 1626 and 1630 on diplomatic missions may have induced many patrons to turn to Van Dyck. He received numerous commissions for altarpieces and for portraits, which forced him to employ assistants. During this period Van Dyck also began to make small monochrome portraits in oil and drawings in chalk of princes, soldiers. scholars, art patrons and especially of fellow artists, with the view of having them engraved and published. At least 15 of these portraits were etched by Van Dyck himself. The others were engraved, primarily by Lucas Vorsterman and Paul Pontius. The series. popularly knoan as Van Dyck's "Iconography," was first published in 1645–46.

After 1632.—After a brief trip to Holland in Feb. 1632. Van Dyck again went to England and succeeded brilliantly. King Charles I appointed him "principalle Paynter in ordinary of their Majesties" and knighted him. He gave him a golden chain and settled upon him an annual salary of £200 sterling. Yet in March 1634 Van Dyck returned once again to Antwerp, ostensibly to settle matters connected with his family estate, but probably also to establish contacts with the new Spanish governor, Cardinal Infante Ferdinand, expected in the fall of that year. While in Belgium Van Dyck painted a huge portrait of the 23 members of the Brussels magistracy which unfortunately perished in the French bombardment of 1695. The Antwerp guild of artists appointed him "honorary dean," a title which had been bestowed before only on Rubens. In 1635 Van Dyck was again in England, after about a year's absence.

He had been settled in Blackfriars, outside the jurisdiction of the local guild. Charles I liked to visit him there and in 1635 had the approaches to the house improved. During the summer Van Dyck was given a place in Eltham castle, Kent. His work now consisted almost exclusively of painting portraits. He organized it in an efficient manner designed also to increase his prestige. He gave hourly appointments to his sitters, leaving the execution of accessories to his assistants who also had to prepare for him a new palette at the beginning of each session. While the king paid slowly and at times was even forced to reduce the artist s demands, Van Dyck derived a comfortable income from his many portraits. His life matched in luxury that of his clients.

He must have realized, however, that the political fortunes of the Stuart monarchy were declining. He had failed in an ambitious plan to decorate the banqueting hall at Whitehall with a "Procession of the Knights of the Garter" in tapestry (sketch at Belvoir castle, Leicestershire). In Sept. 1640 he again left England, induced possibly by the hope of taking Rubens' place. since Rubens had died in May. In nervous haste he went from Antwerp (October) to Paris (Jan. 1641). thence back to London (May) and again to Paris (November). At the end of that month he returned to London, sick and beaten, having failed in all his projects. He died on Dec. 9, 1641, and was buried in St. Paul's, London, in accordance with his own wishes. His tomb, located next to John of Gaunt's, was destroyed in the Great Fire of 1666.

He was survived by his wife, Mary Ruthven, whom he had married in 1639, and an infant daughter,Justina Anna (Justiniana). born Dec. 1, 1640. An illegitimate daughter, Maria Theresia, born in 1620, was brought up by one of his sisters, a *béguine*, or lay sister, in Antwerp. He bequeathed most of his continental possessions to this sister for the benefit of Maria Theresia. Whatever assets he had in England went to his widow and daughter in equal shares, but all was lost in the Great Rebellion. A pension of £200 sterling granted by Charles II to Justiniana in 1662 was paid irregularly. Justiniana herself acquired a modest reputation as a painter. At the age of 12 she married Sir John Baptist Stepney by whom she had four children; the line died out in 1825. Maria Theresia, married to Gabriel Essers, had seven children.

Van Dyck was a handsome man, but his features lacked strength and he was rather short. Although socially ambitious, he remained devoted to the members of his family and on cordial terms with fellow artists. His manners were suave and ingratiating. Legend has it that he inclined to licentiousness and extravagance, but the evidence is inconclusive. Whatever the faults of his character, he certainly was never idle. Only by cbmbining facility of execution with great industry could a man who died at the age of 42 have painted a body of nork as large as his.

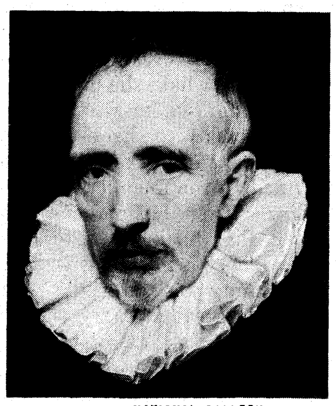
WORK

Development.— For the sake of convenience one generally distinguishes four periods in Van Dyck's activity. In the figural compositions of his first period (1613–21), the emulation of Rubens' melodramatic style is obvious, but there are distinctly personal aspects. Instead of using Rubens' technique of enamel-like glazes. Van Dyck painted directly and with a rather coarse texture. His colour scale is darker and warmer than Rubens', his lights and shades are more abrupt, his figures more angular in their gestures and less harmoniously proportioned. As if to outdo Rubens, he exaggerated the expression of his figures, from the fierce fanaticism or feverish ecstasy of saints and the brutality of executioners to the voluptuous smiles of satyrs and the drunken stupor of Silenus (Brussels, Madrid, Munich, Ottawa, Dulwich).

The few figural compositions of Van Dyck's second period (1621–27) betray a trend towards colouristic and expressive refinement under the influence of the Venetian school. Recollections of Rubens and of Bolognese masters may be seen in his most accomplished religious work done in Italy, the "Madonna of the Rosary" (Palermo). The tendencies first manifested in works done in Italy carry over into Van Dyck's third period (1627–32). He, as well as his patrons, appear to have realized that his talent was better suited to themes involving tender emotion than violent action. The happiest works of that period show the Virgin as the affectionate mother with the infant Jesus in her arms, or as the Mater Dolorosa in Lamentation scenes (Munich, Buckingham palace, Paris, Berlin and Antwerp); equally appealing are pictures showing saints in religious transport (Antwerp, Church of the Augustinians, and Vienna). In memory of his father Van Dyck painted in 1629 the crucified Christ with St. Dominic and St. Catherine of Siena, one of his noblest works and a prime example of the spiritual intensity fostered by the Counter-Reformation. Some of Van Dyck's most enchanting stories from mythology or fable were done during these years (Paris, Vienna and Baltimore). His manner of painting was now quite economical The pigments were put on thinly, in delicate combinations of blue, gray, pink, ochre and sienna. The emphasis is on mellonness, in colour and tone. Although he continued to give an almost sensuous appeal to textures like silk, hair and human skin, his paintings became increasingly cool and artificial. Narrative painting practically disappears in his last period (1632–41).

Portraits. — The enduring fame of Van Dyck rests on his portraits. Whether he painted the patricians and artists of Antwerp, the nobles of Genoa or the court of Charles I, Van Dyck succeeded in idealizing his models without sacrificing any of their individuality. He adopted patterns of portraiture that had been formulated before, chiefly by Hans Holbein, Antonio Moro, Titian and Rubens, but he invented innumerable variations, never losing sight of the fundamental necessity to retain an impeccable formality no matter how exact the likeness.

The Belgian patricians and their wives of his first period generally are rendered in bust- or knee-length; their hands hold gloves, books, handkerchiefs, feathers, flowers or golden chains, or fall idly over the back or armrest of a heavy baroque chair. When married couples or parents and their children appear on one canvas they often hold or touch each other's hands. His earliest portraits had neutral backgrounds but under Rubens' influence he introduced columns, curtains, balustrades and flower vases to enrich the setting. With consummate skill he rendered details of costume and décor, making — perhaps not quite inadvertently — propaganda for Antwerp's celebrated silk and lace.



BY COURTESY OF NATIONAL GALLERY, LONDON

"CORNELIS VAN DER GEEST" BY SIR ANTHONY VAN DYCK. IN THE NATIONAL GALLERY, LONDON

Always convincing as likenesses, his portraits show the models calm, dignified and reserved. In contrast to the ebullient Dutch burghers Frans Hals was painting at the same time, Van Dyck's sitters are genteel and wary. Their expressions are quizzical rather than self-revealing, guarded rather than warm. Among the finest are a father and his son (Paris), Frans Snyders and his wife (New York, Frick collection), a family group (Leningrad) and Isabella Brant (Washington).

The portraits done in Italy stress grandeur and aristocratic refinement. Many are in full-length, like Rubens' Genoese portraits of 1606/7. There he also did his first equestrian portraits. While in earlier portraits the sitters generally look at the beholder, now they often are turned away as if concerned with weightier matters. Some of his Genoese ladies, portrayed in glitter and silk, have a condescending look. An outstanding group of such portraits is in Washington (the Marchese Brignole-Sale, Grimaldi-Cattaneo and Balbi). The seignorial portrait of Cardinal Bentivoglio (Florence) and the unknown elderly couple (Berlin) are equally stunning and psychologically more penetrating.

In his third period, bust- and half-length figures were again in the majority. Among his models were many members of the great princely houses of Europe but some of the finest pictures are of collectors and art patrons (Cornelis van der Geest. Peter Stevens, Everard Jabach), as well as scholars, churchmen and a great many Antwerp artists. To this group should be added the portraits done during his visit to the continent in 1634–35, among them that of the Abbé Scaglia. the skillful diplomat, for whom Van Dyck also painted one of his last religious pictures, a Lamentation (Antwerp). In these portraits a new predilection for rhetorical poses is noticeable. With agile hands, some figures seem to address an audience. Caught in momentary and dramatic actions, Van Dyck's figures represent well the baroque taste in portraiture.

Van Dyck's English portraits are his most popular. Our visual image of English society prior to the revolution of 1648 has forever been shaped by Van Dyck. The Cavalier king himself was frequently portrayed by the master, and nowhere perhaps more revealingly than in the beautiful canvas in Paris where he appears "as he would have wished to live in history: a figure of matchless elegance, of unquestioned authority and high culture, the patron of the arts and the upholder of the divine right of kings" (Ernst H. J. Gombrich, The Story of Art, Phaidon Publishers Inc., Oxford University Press, New York, 1950). (See PORTRAIT PAINTING: Baroque and Rococo) A portrait showing three views of the king was made to serve for a bust to be made by Gianlorenzo Bernini; the sculpture perished, however, in 1697.

As in his Italian portraits, full-length renderings prevail, but his English patrons seem more rigid and as a rule more prosaic than their Latin counterparts. An unusual feature, reflecting a literary vogue, are allegorical attributes and mythological disguises. Ladies often point at, touch, or pick roses, or hold a hand under water running from an urn. Portraying himself with a sunflower, Van Dyck expresses emblematically his devotion to the king. In portraits, now lost, he painted ladies as "Pallas" or "Venus." Still preserved are the countess of Southampton as "Fortuna," Lady Digby as "Prudence" and the so-called Margaret Lemon as "Flora."

Van Dyck's gift for combining formality and casualness shows up particularly well in portrait commissions involving groups of people. In Genoa he had painted the Lomellini family (Edinburgh) and the delightful Balbi children (London, Lady Lucas). To his last decade belong the little-known family of John, count of Nassau-Siegen (Panshanger), and the largest of all of Van Dyck's extant paintings (more than 19 ft. wide), the family of the earl of Pembroke (Wilton house). In his several versions of the children of Charles I (Windsor castle, Turin) and the unidentified group of seven children (Detroit), he gives to his models all their youthful innocence no matter how gravely dignified their pose. An equally celebrated picture of William II, prince of Orange, and his little bride Mary (Amsterdam) is generally attributed to Sir Peter Lely (Pieter van der Faes), though it may have been begun by Van Dyck.

Influence. — Van Dyck's influence was pervasive and lasting. Many of the younger Flemish painters (such as Willeboirts, Boeyermans, Thys, the two Franchoys and Gonzales Coques) owe more to him than to Rubens. Dutch and German portraitists, especially those active in London, continued his manner (Cornelis Janssens van Ceulen, Hannemann, Gerard van Honthorst. Lely and Sir Godfrey Kneller), as did several native Englishmen (William Dobson, Robert Walker). The style of the great 18th-century English portrait painters, above all that of Thomas Gainsborough, was deeply indebted to Van Dyck; and Spanish painters who appear to have known Van Dyck's works mainly from engravings (Antonio Pereda, Don Juan de Miranda Carreiio. Mateo Cerezo, etc.) imitated and occasionally copied the religious compositions of the Flemish artist.

Van Dyck's fame was always high, but whereas formerly the works of his last period were most admired, those of his youth and his Genoese period have been favoured in the 20th century for their freshness and spontaneity. The interest of scholars has turned toward works neglected before, such as the oil sketches and the many drawings in chalk, pen and wash, and watercolour. Particularly sensitive and delightful are some of his sketches of landscapes (*e.g.*, the "View of Rye," dated Aug. 27. 1633; New York, Pierpont Morgan library). *See* also **PAINTING**: *Rise of European Schools: Flanders.*

(J. S. HD.)

VANE, SIR HENRY (1589–1654), English secretary of state. was born at Hadlow, Kent, on Feb. 18, 1589, was educated at Brasenose college, Oxford, entered Gray's Inn in 1606, and was knighted in 1611. He purchased various court offices, and sat in parliament for various constituencies from 1614 onward. Vane was sent on many foreign missions, and in 1630 became one of the king's chief advisers. He was made a commissioner of the admiralty in 1632 and for the colonies in 1636. He was one of the eight privy councillors appointed to manage affairs in Scotland on the outbreak of the troubles there, and on Feb. 3, 1640, through the influence of the queen and of the marquis of Hamilton and in opposition to the wishes of the earl of Strafford, he was made secretary of state in the room of Sir John Coke.

In the Short parliament, which assembled in April, it fell to Vane to demand supplies. He proposed that the king should give up ship money and receive in return 12 subsidies. Parliament proved intractable and was dissolved on May 5 to prevent a vote against the continuance of the war with the Scots. In the impeachment of Strafford, Vane asserted that Strafford had advised the king at a meeting of the privy council to employ the Irish army against England. He was on bad terms with Strafford, who had opposed his appointment to office. Vane was accused of collusion and treachery, and there is no doubt that he desired Strafford's removal, believing that his sacrifice would satisfy the demands of the parliament. Nevertheless, the charge that he deliberately compassed his destruction is not proved. Suspicions of his fidelity, however, increased, and after accompanying the king to Scotland in Aug. 1641, he was dismissed from all his appointments on Nov. 4, on Charles I's return.

Vane immediately joined the parliament; he was placed on the committee for Irish affairs on Dec. 13, was made lord lieutenant of Durham on Feb. 10, 1642, became a member of the committee of both kingdoms on Feb. 7, 1644, and in this capacity attended the Scots army in 1645, while the parliament in the treaty of Uxbridge demanded for him from Charles a barony and the repayment of his losses. He adhered to the parliament after the king's death, and in the first parliament of the Protectorate he was returned for Kent, but the house refused to appoint him a member of the council of state in Feb. 1650. He died in 1654.

VANE, SIR HENRY (1613–1662), English statesman and author, known as "the younger" to distinguish him from his father, Sir Henry Vane (*q.v.*), was baptized on May 26, 1613, at Debden, Essex. After an education at Westminster and at Magdalen hall, Oxford, he spent some time at Geneva or Leyden and in 1631 joined the suite of the ambassador to Vienna. He had already acquired strong Puritan views, and, in 1635, in order to obtain the free exercise of his religion, he emigrated to Massachusetts, where he was elected governor in 1636. His actions in supporting a certain measure of religious toleration brought him into collision with a more rigid and influential group headed by John Winthrop the elder, who in 1637 succeeded him as governor.

Vane returned to England in Aug. 1637. He was made joint treasurer of the navy with Sir William Russell in Jan. 1639, was knighted on June 23, 1640, and was elected for Hull in the Short and Long parliaments. He at once became a prominent opponent of royal policy and by allowing John Pym to copy a transcript which he had made of his father's notes on the privy council meeting of May 5, 1640, he helped to bring the earl of Strafford to the scaffold. In 1643 he was the leading man among the commissioners sent to treat for a league with the Scots. Vane, who was bitterly opposed to the tyranny of the Presbyterian system, succeeded in getting the proposed bond between the parties termed the Solemn League and Covenant, and further in substituting the whole expression "*according to the word of God* and the example of the best Reformed churches" for the latter part alone. He succeeded to the leadership of the war party on Pym's death and was engaged in all the principal negotiations which followed. His leadership ended when the Presbyterian party obtained the supremacy in parliament in 1646. During the subsequent struggle he was one of the six commissioners appointed to treat with the army by the parliament, but failed to effect a compromise because he was distrusted by both the Levellers and the Presbyterians. His views of government may be studied in *The People's Case Stated.*

In spite, however, of these free opinions, Vane still desired the maintenance of the monarchy and the constitution. He supported the renewal of negotiations with the king and mas appointed in 1648 one of the commissioners for the treaty of Newport. He showed a desire to come to terms on the foundation of toleration and a "moderate episcopacy," of which Oliver Cromwell greatly disapproved, and opposed the shaking off of the conferences. He withdrew from the commons after Pride's Purge and remained absent until after Charles I's death. On Feb. 14, 1649, he was placed on the council of state, though he refused to take the oath approving the king's execution. Vane served on innumerable committees of importance. He furnished the supplies for Cromwell's expedition to Scotland and was one of the commissioners to negotiate a union between the two countries (1651–52). He was a leading member of the committee dealing with foreign affairs and in 1651 went on a secret mission to negotiate with Cardinal de Retz. To Vane, as chief commissioner of the navy, belongs largely the credit of the victories obtained against Tromp.

In domestic politics Vane continued to urge his views of toleration and his opposition to a state church. On Jan. 9, 1650, he brought forward as chairman the report of a committee advocating reform of the franchise on a property basis, the disfranchisement of certain existing boroughs and increased representation to the large towns; the sitting members, however, were to retain their seats. But Cromwell and the army desired an entirely new parliament. On April 20, 1653. Cromwell forcibly dissolved the Long parliament while it was in the act of passing Vane's bill. Hitherto they had lived on intimate terms of friendship, but Vane's protests and the ensuing argument created a permanent breach. In his retirement Vane wrote the *Retired Man's Meditations* (1655). In 1656 he proposed in *A Healing Question* (reprinted in vol. vi of Lord Somers, *A Collection of Scarce and Valuable Tracts*, 2nd ed., rev. by W. Scott, 13 vol. [1809–15]) a new form of government, insisting as before upon a Puritan parliament supreme over the army. The seditious movements of the Anabaptists were attributed to his influence, and on July 29, 1656, he was summoned before the council. Refusing to give security, he was imprisoned at Carisbrooke castle from September to the end of the year. In the parliament of Richard Cromwell he sat for Whitchurch in Hampshire and urged that the protector's power be limited.

He allied himself with the officers in setting aside the protectorate and in restoring the Rump parliament. On Richard Cromwell's abdication he became a member of the committee of safety and of its successor, the council of state (May 1659). He was a member of all the principal commissions and had the virtual management of foreign affairs. When John Lambert turned out the Rump in October, Vane remained in office. He endeavoured to reconcile the factions in the army and sought by negotiation to prevent the defection of the navy. In consequence, at the restoration of the Rump (December) he was expelled from the house and ordered to retire to Raby.

At the Restoration Vane was imprisoned in the Tower and later in the Scilly Isles. After several conferences between the houses of parliament, it was agreed that he should be excepted from the indemnity bill, but that a petition should be sent to Charles II asking that his life might be spared. The petition was granted. But the new parliament of 1661 demanded his trial on the capital charge. He was found guilty and was executed on June 14, 1662.

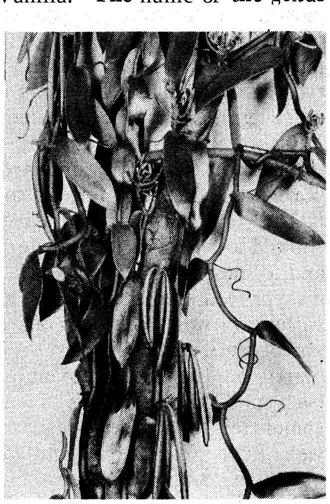
VAN GOGH: see GOGH, VINCENT WILLEM VAN.

VANILLA, a genus of tropical herbs and the extract made from any of several of its species. The flavouring agent is largely used in the manufacture of chocolate, in confectionery and in perfumery. Like cacao. it was first cultivated by the Indians, who, however, never combined the two to make sweet chocolate. Vanilla consists of the fermented and dried pods of several species of orchids belonging to the genus Vanilla. The name of the genus comes from the Spanish *vainilla,* a diminutive of vaina ("a pod"). The great bulk of the commercial article is the produce of V. *planifolia,* a native of southeastern Mexico, also cultivated in several tropical countries, especially on Réunion, the Seychelles and Madagascar in the Indian ocean; and in Tahiti and Java.



BY CO''RTESY OF CHICAGO NATURAL HISTORY MUSEUM

VANILLA WITH PODS

The plant has a long fleshy stem and attaches itself by its aerial rootlets to trees; the roots also penetrate the soil. The leaves are alternate, oval-lanceolate and fleshy; the light-greenish flowers form axillary spikes. The fruit is a pod from 6 to 10 in. long, when mature, and about ½ in. in diameter. The wild plant yields a smaller and less aromatic fruit, distinguished in Mexico as *Baynilla* cimarona; the cultivated vanilla is B. *corriente*.

Mexican vanilla is principally consumed in the United States. On Réunion large areas are under cultivation; the crop, which is called Bourbon vanilla. is sent to Bordeaux, the chief centre of the trade in France. Its odour differs from that of the Mexican variety in having a suggestion of tonka bean. The best varieties of vanilla pods are of a very dark chocolate brown or nearly black colour, and are covered with a crystalline efflorescence technically known as givre, the presence of which is taken as a criterion of quality. The peculiar fragrance of vanilla is due to vanillin, $C_8H_8O_3$, which forms this efflorescence. Chemically speaking. it is the aldehyde of methyl-protocatechuic acid. It is not naturally present in the fleshy exterior of the pod. but is secreted by hairlike papillae lining its three internal angles, and ultimately becomes diffused through the viscid, oily liquid surrounding the seeds. Besides vanillin, the pods contain vanillic acid (odourless), about 11% fixed oil, 2.3% soft resin, sugar, gum and oxalate of lime.

Vanillin forms crystalline needles, melting at 81° C. and soluble in alcohol, ether and oils, hardly soluble in cold, but more so in boiling water. Vanillin has been found in Siam benzoin and in ram sugar, and has been prepared artificially from coniferin, a glucoside found in the sapwood of fir trees, from asafetida and from a constituent of oil of cloves named eugenol. It is prepared synthetically on a commercial scale in Germany.

VANINI, LUCILIO, or, as he styled himself in his works, GIULIO CESARE (1585–1619), Italian freethinker, was born at Taurisano, near Naples. He studied at Rome, Naples, and at Padua, and was ordained priest. Subsequently he led a roving life in France. Switzerland and the Low Countries.

Vanini was obliged to flee from Lyons to England in 1614, but was imprisoned in London for some reason for 49 days. Returning to Italy he made an attempt to teach in Genoa. but was driven once more to France, where he tried to clear himself of suspicion by publishing a book against atheists. *Ampitheatrum* aeternae providentiae *divino-magicum* (1615). Though the definitions of God are somewhat pantheistic, the book is sufficiently orthodox, but the arguments are largely ironical, and cannot be taken as expounding his real views. Vanini expressly tells us so in his second (and only other published) work, De admirandis naturae reginae deaeque *mortalium arcanis* (Paris, 1616), which, originally certified by two doctors of the Sorbonne, was afterward reexamined and condemned. Vanini then left Paris, where he had been staying as chaplain to the maréchal de Bassompierre, and began to teach in Toulouse. In Nov. 1618 he was arrested, and after a prolonged trial was condemned as an atheist. He was burned on Feb. 9, 1619.

VAN LOO (VANLOO), **CHARLES ANDRÉ** (CARLE) (1705–1765), French painter, whose works, more than those of any of his contemporaries. typify rococo painting, was born in Nice on Feb. 15, 1705, of a noted family of artists of Flemish origin. His elder brother, Jean Baptiste Van Loo, brought him up, taught him his profession and took him to Rome. Back in Paris, he worked with his brother and in 1724 won first prize in the Academy competition. He went back to Rome in 1727 and was awarded various distinctions. On his way home to Paris he stopped in Turin where his nephew had died and painted works for the king of Sardinia's palaces. After his return to Paris in 1734, he became the most popular painter of the time, and was in 1763 elected director of the Academy. Van Loo was also appointed first painter to the king and shared with François Boucher the favour of Paris society and foreign courts. Mme. de Pompadour commissioned the artist to work for her at her chhteau at Bellevue. A horn painter with almost excessive facility. he influenced many pupils. He died in Paris on July 15, 1765. His portraits and genre scenes are most appreciated.

VANNES, a town of western France, capital of the *département* of Morbihan, 84 mi. N.W. of Nantes on the railway to Brest. Pop. (1954) 23,377. Vannes (Dariorigum), the capital of the Veneti (whence *Gwenea,* the Breton name of the town), led the Armorican league against Julius Caesar, who in 56 B.C. overcame their fleet and opened up their country by six roads. St. Paternus, the first bishop, was consecrated in A.D. 465. In the 5th century Vannes was ruled for a time by independent counts, but soon came under the yoke of the Franks. Nomenoé, the lieutenant of Louis I, the Pious, in Brittany, assumed the title of king in 843, and one of his brothers was the founder of a line of counts who resisted the Normans in the 9th and 10th centuries. Vannes became part of the duchy of Brittany at the end of the 10th century. The estates of Brittany met there for the first time in 1203. In the course of the War of Succession the town was besieged in 1342. Duke John IV built here the castle of L'Hermine and made it his habitual residence. In 1487 the town was for a year in the hands of Charles VIII of France. In 1532 Brittany was definitively united to France.

Vannes is 10 mi. from the open sea, at the confluence of two streams forming the Vannes river, which opens into the landlocked gulf of Morbihan about a mile below the town. The old town, lying on a hill facing the south, is surrounded by fortifications of the 14th, 15th and 17th centuries. The modern suburbs surround the old town. The archaeological museum includes one of the richest collections of prehistoric remains in Europe. The cathedral of St. Peter, burned by the Normans in the 10th century, was rebuilt in the 13th, 15th and 18th centuries. Among the industries are tanning and cotton weaving. The port of Vannes, south of the town, is accessible only to small vessels.

VAN RENSSELAER, STEPHEN (1764–1839), U.S. political leader and soldier, "last of the patroons," was born at New York city. Nov. 1, 1764. He was fifth in descent from Killian van Rensselaer, original patroon of Rensselaerwyk, N.Y. He was a member of the New York assembly 1789–90, 1808–10, and in 1818; a member of the state senate 1791–95 and of the national house of representatives 1822–29. He served as a major-general in the second war with Great Britain, commanding the first division of the detached militia of the state of New York, and on Oct. 13, 1812 was defeated at the battle of Queenston Heights. Because he was a Federalist he mas severely criticized and censured for this defeat and resigned from the army. At the close of the war the Erie Canal project was renewed, and from 1816 until his death he was a member of the board of canal commissioners, and for nearly

15 years was its president. In 1818 he was again elected to the assembly; in 1819 he became a regent of the state university of which he was for a time chancellor. From 1822 to 1829 he was a member of the national house of representatives, and there voted for John Quincy Adams for the presidency. He died at Alhany (N.Y.), Jan. 26, 1839.

VAN'T HOFF, JACOBUS HENDRICUS (1852–1911), Dutch physical chemist who was named the first Nobel laureate in chemistry (1901) for his work on chemical dynamics and osmotic pressure in solutions. was born in Rotterdam on Aug. 30, 1852. He studied at the Polytechnic at Delft, at the University of Leiden, then under Friedrich A. Kekulé van Stradonitz at Bonn, Charles A. Wurtz at Paris in the Ecole de Medecine and with G. J. Mulder at Utrecht, where he obtained his doctorate in 1874. He was lecturer in physics at the veterinary school. Utrecht (1876); professor of chemistry, mineralogy and geology in Amsterdam university (1878); and professor to the Prussian academy of sciences in Berlin (1896), accepting an honorary professorship in the university so that he might lecture if he wished. He was elected a foreign member of the Royal society in 1897 and awarded its Davy medal in 1893. He died March 1, 1911, at Berlin.

Van't Hoff's earliest important contribution to science was made in 1874. Starting with the results of the work of Johannes Wislicenus (*q.v.*) on the lactic acids (1873), he showed that the four valencies of the carbon atom were probably directed in space toward the four corners of a regular tetrahedron. In this way optical activity, shown to be always associated with an asymmetric carbon atom could readily be explained. An identical idea was put forward two months later (Nov. 1874), quite independently, by Joseph A. le Bel (*q.v.*), whose name is generally linked with that of van't Hoff in connection with the theory of asymmetric carbon. Though van't Hoff and Le Bel had been fellow students under Wurtz, they "never exchanged a word about the carbon tetrahedron, though perhaps both of us cherished the idea in secret." The concept was attacked by Hermann Kolbe (*q.v.*), but its value was soon universally realized and it laid the foundation stone of the science of stereochemistry (*q.v.*). In 1877 van't Hoff published his *Ansichten über die organischen Chemie*, the second part of which contains the beginnings of his studies in chemical thermodynamics and affinity. In his *Études de dynamique chimique* (1884) he developed the principles of chemical kinetics, described a new method of determining the order of a reaction, and applied thermodynamics to chemical equilibriums. He deduced the connection between the equilibrium constant of a reaction and the temperature. in the form of an equation known as the "van't Hoff isochor." which he generalized in the form of the "principle of mobile equilibrium," a special case of the principle developed by Henry Louis le Châtelier (*q.v.*) at the same time (1884). He also introduced the modern concept of chemical affinity as the maximum work obtainable as the result of a reaction and showed how it may be calculated from measurements of osmotic pressure, gas pressure and the electromotive force of reversible galvanic cells. In 1886 he published the results of his study of dilute solutions and showed the analogy existing between them and gases, since both obey equations of the type $pv = RT$. During the next nine years he developed this work in connection with the theory of electrolytic dissociation enunciated by Svante A. Arrhenius (*q.v.*) in 1887. The abnormality in the case of electrolytes was explained by the equation $pv = iRT$, in which the factor i was a measure of the deviation from the simple expression. With Wilhelm Ostwald (*q.v.*) he started the important *Zeitschrift für physikalische Chemie* in 1887, the first volume of which contained the famous paper by Arrhenius on electrolytic dissociation, along with the fundamental paper of van't Hoff.,

VAN TIEGHEM, PHILIPPE EDOUARD LÉON (1839–1914), French botanist, the dominant figure in French botany for almost half a century, was born April 19, 1839, at Bailleul. After graduating from the College of Bailleul, he entered the Sorbonne where Pasteur influenced him to take a degree in chemistry, but, still determined to work in botany, he prepared a second doctorate. In 1864 he was appointed professor at the École Normale Supérieure, a post he held until 1879 when he was made professor of botany at the Museum of Natural History, Paris. In 1898 he became professor at the National Institute of Agronomy. occupying this position until he died April 28, 1914.

Van Tieghem's more than 600 publications ranged throughout the plant kingdom, but he is best known for his studies on bacteria, blue-green algae, the mucors and. particularly, on plant anatomy.

See *Revue Générale de Botanique*, 26:353–440 (1914); *Ann. Sci. Nat.* (Bot.), vol. xix. series 9, pp. i–viii (1914). (J. N. C.)

VAPHIO, an ancient site in Laconia. Greece, on the right bank of the Eurotas, some. 5 mi. S. of Sparta, famous for its "beehive" tomb, excavated in 1889 by Dr. Tsountas. A walled approach, about 97 ft. long, leads to a corbel-vaulted chamber 33 ft. in diameter, in the floor of which the grave was cut. The tomb, which probably belonged to Amyclae, is now almost entirely destroyed. Its contents are typical of the "First Late Minoan" period (about 1500 B.C.) and include engraved gems and amethyst beads, articles in gold, silver, bronze. lead, amber and crystal; also an iron ring, unusual at this early date.

VAPORIZATION is the general term denoting the change in state of a pure substance from a solid or a liquid to a vapour. The converse change from a vapour to a solid or a liquid is called condensation. The term sublimation refers specifically to the vaporization of a solid. In a more extended sense the term vaporization is applied to the change in state whereby one or more substances pass from a condensed complex consisting of any number of solid and liquid phases to a vapour phase, and the term condensation is applied to the converse change. Certain aspects of vaporization are discussed in the articles on THERMODYNAMICS: DISTILLATION; LOW-TEMPERATURE PHYSICS; CALORIMETRY; HEAT and SOLUTIONS.

Definitions and the Phase Rule.—The number of discrete parts. each of uniform chemical composition and physical structure. into which a thermodynamic system can be divided is the number of phases, s, in the system. The minimum number of pure substances required to produce a system in all of its equilibrium states that are considered possible is the number of components, e, of the system. The number of intensive variables whose values can and must be specified in order to fix the intensive properties (those properties that are independent of the quantity of material) of every phase of a system is the variance, v, of the system. Examples of intensive variables are pressure, temperature, specific volume and mole fraction of a component in a phase. The phase rule of J. Willard Gibbs states that

$$v = c + 2 - s \tag{1}$$

in a system which is in equilibrium and is uninfluenced by gravity, electricity, magnetism, capillary tensions and distortion of solid phases The phases of a system in equilibrium are said to be coexistent. The relative amounts of the coexistent phases of a system do not enter into the phase rule in any way. In the folloning discussion the term solid will always denote a crystalline solid and the terms vapour and gas will be used interchangeably. A system may consist of any number of solid and liquid phases but, in the absence of internal partitions, of only one gaseous phase A system is said to be nonvariant, univariant, bivariant, etc., when its variance v is zero, one, two, etc., respectively.

One-Component Systems.—The phase rule states that a system composed of a pure substance in two coexistent phases is univariant. Hence all of the intensive properties of each phase of such a system depend on a single intensive property, as, for example, pressure or temperature or the specific volume of one of the phases. Some of the relationships among pressure, temperature and specific volume are shown in fig. 1 and 2. Fig. 1(A) is a pressure-temperature plot, or phase diagram, for water at low pressures. The curve AB is the sublimation pressure curve of ice I (one of the crystalline forms of solid water) and BC is the vapour pressure curve of liquid water. These curves always have a positive slope and are concave upward. For completeness the fusion curve BE of ice I is also drawn. The three curves have the point B in common and divide the plane in the neighbourhood of B into three parts. The co-ordinates of a point in one of the regions labeled ice I, liquid or vapour represent the pressure and temperature at which water exists in the aggregation state indicated. A point on one of the curves AB or BC gives the conjugate values of pressure and temperature at which vapour coexists with solid or with liquid, respectively. If the temperature is arbitrarily specified, there is only one pressure at which two specified phases coexist, namely the pressure read from the appropriate curve. Increasing the pressure above this value will cause the vapour phase to disappear; and decreasing the pressure below this value mill cause the condensed phase to disappear. At the point B the liquid and solid phases have the same vapour pressure, all three phases can coexist, and the system is nonvariant. This is the ice I-liquid-vapour triple point. The values of pressure and temperature at a specified triple point are unique. For example, the triple point ice I-liquid water-water vapour is at 0.0060 atm. and +0.01° C. Any variation of either temperature or pressure with the other variable held constant will cause two of the coexistent phases at a triple point to disappear.

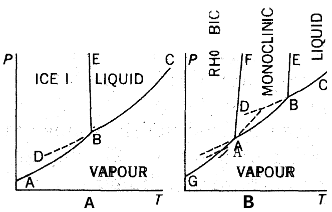

FIG. I.—PHASE DIAGRAMS AT LOW PRESSURES: (A) WATER AND (B) SULFUR

In general, equilibrium between liquid and vapour can be realized experimentally below the freezing point of the liquid, and this is inbicated by'the dotted curve DB, which is a continuation of BC. When a speck of ice I is introduced into a system of undercooled liquid and vapour ahile the volume and temperature are maintained constant, all of the liquid freezes and the pressure drops to the sublimation pressure corresponding to the specified temperature. A system at equilibrium in regard to small changes in the states of existing phases but not to the formation of an entirely new phase is said to be in metastable equilibrium. When one of the phases is a vapour, the pressure of the metastable univariant system is always greater than that of the stable univariant system at the same temperature. The vapour pressure curve of the liquid extends upward to the critical point where it ends. At this unique temperature and pressure all of the intensive properties of the liquid and vapour become identical. In the neighbourhood of this point the distinction between liquid and vapour ceases to exist and the substance is said to be a fluid. The critical point of water is at 218 atm. and 374° C. The sublimation curve of a solid does not extend above the triple point B, since in general a solid cannot be heated above its melting point. The curve AB continues downward to the absolute zero of temperature unless a new solid phase forms

Fig. 1(B) is the phase diagram for sulfur, and this substance undergoes a change in crystalline form from monoclinic to rhombic at A on the sublimation curve. There are three triple points, A, D and B, at which one of the phases is a vapour, the triple point rhombic-liquid-vapour at D being metastable. The triple points are at about 0.01 mm. of mercury and 95° C., 0.02 mm. and 110° C. and 0.03 mm. and 115° C. Not all triple points which include a vapour phase are at low pressures. For example, the solid-liquid-vapour triple point of carbon dioxide is at five atmospheres and $-57°$ C., and this accounts for the fact that carbon dioxide gas condenses directly to a solid at one atmosphere.

The slope dp/dT of any sublimation or vapour pressure curve at any point is given by the Clapeyron equation:

$$\frac{dp}{dT} = \frac{\Delta S}{AV} = \frac{\Delta H}{TAV} \tag{2}$$

where ΔS, ***AH*** and ΔV are the increase in entropy, heat content (or enthalpy) and volume accompanying the vaporization of a definite mass of solid or liquid at a constant pressure and temperature, and T is on the absolute thermodynamic temperature scale. These quantities are all positive for vaporization and sublimation except at the critical point where ***AS,*** ΔH and ΔV are all zero. The slope of the vapour pressure curve for the stable condensed phase at the right of a triple point is less than the slope of the corresponding curve at the left. At a triple point ***AS, AH*** and ΔV all change abruptly, but the decreases in ΔS and ***AH*** when we pass from left to right through this point have a greater effect on dp/dT than the increase or decrease in ΔV. Equation (2) is an exact thermodynamic relation. An approximate form of equation (2) can be obtained by assuming that the volume of the condensed phase is negligible and that the vapour is a perfect gas; and this expression can be integrated on the assumption that ΔH is constant.

These forms are

$$\frac{d\ln_e p}{dT} = \frac{\Delta \tilde{H}}{RT^2},\ \ln_e p = -\frac{\Delta \tilde{H}}{RT} + B \tag{3}$$

where B is an integration constant, $\Delta\tilde{H}$ is the molar heat of vaporization or sublimation and R is the universal gas constant (1.987 cal./° K.-mole). Actually a plot of $\ln p$ against $1/T$ is very nearly a straight line over a wide range of temperature for most solids and liquids. This unexpected linearity must arise through a compensation of errors of the approximations and the slope of this line cannot be interpreted as $-\Delta\tilde{H}/R$ except at low pressures where ,the approximations do apply. Equation (3) is made more accurate as an empirical relation by addition of the terms $CT + DT^2 + \ldots$ to the right-hand member.

Fig. 2 is a portion of the pressure-volume diagram of a pure substance, for example water. Here the curves ***T,,*** T_1, T_2 are plots of the conjugate values of the pressure and volume of a unit mass for each of three temperatures: the critical temperature T,, a lower temperature T_1 and a higher temperature T_2. In this diagram the curve BC of fig. 1(A) becomes the region underneath the curve ABC, this curve being known as the steam dome, the limit of absolute stability or the binodal curve. It passes through the critical point B. A single point in the curve BC of fig. 1(A) is now a horizontal line, as G'G". The co-ordinates of G' and G" represent the vapour pressure and the so-called saturated or orthobaric specific volumes of unit mass of liquid and vapour respectively, at T,; and points in the line G'G" represent the volumes of various mixtures of liquid and vapour under the same conditions of pressure and temperature.

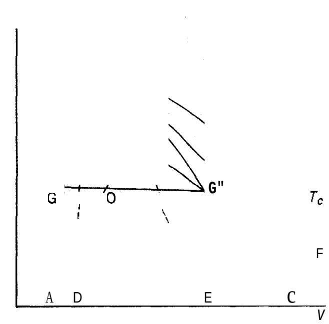

FIG. 2.—PRESSURE-VOLUME GRAM FOR UNIT MASS OF WATER NEAR ITS CRITICAL POINT

The curve FG″OG′H is the normal course of an isotherm at a temperature T_1. The segment FG" represents the states of the vapour during isothermal compression; G″OG′ represents states of the system during condensation to a liquid at constant pressure and temperature; and G'H represents isothermal compression of the liquid. This entire curve becomes simply a vertical line in fig. 1(A). The curves G″K″ and G'K' represent states of a vapour compressed above its condensation point and states of a liquid below its vapour pressure, respectively. Parts of these curves can be realized experimentally. If we suppose that a vapour can be completely transformed into a liquid isothermally without the system's becoming heterogeneous, the course of an isotherm T_1 below the critical temperature would be that indicated by the curve FG″K″OK′G′H, known as the Thomson continuous isotherm. The segments G'K' and G″K″ represent metastable states, but the segment K'OK represents unstable states where the compressibility is negative. Such states can have only fleeting existence, but there is theoretical and experimental evidence to indicate that when a fluid near its critical state is expanded rapidly and adiabatically it passes into unstable states and exists in these states momentarily. The curve DBE passes through all the minima and the maxima of the continuous isotherms. It is called the limit of essential instability or the spinodal curve. For each isotherm the areas G'K'O and G″K″O must be equal by thermodynamic necessity. All analytical equations of state such as that of J. D. van der Waals (1878) give curves below the critical temperature resembling the continuous isotherm. The critical isotherm T_c has a horizontal tangent and a point of inflection at the critical point, that is, $(\partial p/\partial V)_T = 0$ and $(\partial^2 p/\partial V^2)_T = 0$; and a second inflection point without zero slope at a lower pressure, $(\partial^2 p/\partial V^2)_T = 0$, and $(\partial p/\partial V)_T < 0$. Isotherms above the critical, as T_2, may also have inflection points without zero slope. At high temperatures an isotherm approximates a rectilinear hyperbola with the equation $pV =$ a constant.

Other types of plots are used to exhibit the properties of condensed and gaseous phases and of the liquid-vapour region of a pure substance. Gibbs (1873) discussed the energy-entropy-volume surface, the temperature-entropy diagram and the volume-entropy diagram; and R. Mollier (1904) introduced the heat content-entropy diagram which is much used in engineering work.

The saturation heat capacity C_{sat} of a phase is related to its heat capacity at constant pressure C_p by the relation

$$C_{sat} = C_p - T\left(\frac{\partial V}{\partial T}\right)_p \left(\frac{dp}{dT}\right)_{sat} \tag{4}$$

At each point on a vapour or sublimation pressure curve there are two such equations: in one every quantity except $(dp/dT)_{sat}$ refers to the vapour phase, and in the other each corresponding quantity refers to the condensed phase. If the symbol Δ refers to the value of a quantity for a vapour minus its value for the coexistent condensed phase, we can derive by thermodynamics the following relations that hold along a saturation curve:

$$T\left(\frac{d(\Delta H/T)}{dT}\right)_{sat} = T\left(\frac{d\Delta S}{dT}\right)_{sat} = \Delta C_{sat} \tag{5}$$

$$\left(\frac{d\Delta H}{dT}\right)_{sat} = \Delta C_p + \frac{\Delta H}{T}[1 - \frac{T}{\Delta V}\left(\frac{\partial \Delta V}{\partial T}\right)_p] \tag{6}$$

In these relations the subscript $_{sat}$ denotes that the pressure varies along the vapour pressure curve (AB or BC of fig. 1[A]) and the subscript p denotes that the pressure remains constant.

The most direct and accurate methods for the measurement of vapour pressures are: (1) the dynamic method in which a liquid is boiled in a vertical tube nith a thermometer (shielded against radiation) placed in the condensing vapour and the pressure transmitted to a pressure gauge by means of a gas of smaller molecular weight than that of the vapour; and (2) the static method in which the coexistent liquid and vapour are enclosed in a bomb maintained at a constant temperature T and the pressure transmitted to a pressure gauge through a capillary containing the vapour phase if T is below room temperature or the liquid phase (or an inert liquid, as mercury) if T is above room temperature. The static method is also applicable to the measurement of the sublimation pressures of solids. Exceedingly small vapour pressures are determined by measuring the rate of effusion of the vapour through a small hole and applying the effusion equation of kinetic theory. Because of the difficulty of measuring temperatures in the liquid helium range, the International Committee on Weights and Measures in 1958 proposed as the international standard of thermometry a scale in the range from 1° to 5.2° K. based on the vapour pressure of liquid He^4.

Univariant Systems in General.—A system of c components is univariant when there are c + 1 coexistent phases present. In all such systems every intensive property of each phase is a function of a single independent variable. In particular, when one of the phases is a vapour, the vapour pressure depends on temperature alone and can be represented by a curve in the pressure-temperature plane. Examples of such a system are: (1) solid $CaCO_3$, solid CaO, gaseous CO_2; (2) solid NaCl, a saturated solution of NaCl in water, water vapour; (3) a saturated solution of ether in water, a saturated solution of water in ether, vapour containing both water and ether. The Clapeyron equation gives the slope dp/dT of the pressure-temperature curve along which all three phases coexist and AS, AH and ΔV are the increase in entropy, heat content and volume accompanying the formation of any definite mass of the gaseous phase.

Bivariant Systems.—A system of c components in c coexistent phases has a variance of two. Thus the intensive properties of each phase of a system of two components in coexistent liquid and vapour phases are fixed only if two intensive properties are specified; for example, pressure and temperature, or pressure (or temperature) and the mole fraction of one of the components in either the liquid or the vapour phase. Some of the properties of such systems may be exhibited on a pressure-composition diagram for a specified temperature and on a temperature-composition diagram for a specified pressure (see fig. 3 and 4, which are simply the traces of the pressure-temperature-composition surfaces; fig. 5, in planes corresponding to a specified temperature or to a specified pressure).

Fig. 3 is a pressure-composition diagram at a constant temperature and a temperature-composition diagram at a constant pressure for a pair of liquids, say benzene and toluene, which do not have a maximum or minimum boiling mixture. In the diagrams the solid curves are plots of the vapour pressures P or of the boiling points T of various liquid mixtures against the mole fraction X, of component 2 in the liquid phase, the so-called bubble point curves; and the dotted curves are plots of these same values of P or T against the mole fraction Y_2 of component 2 in the coexistent vapour phase, called the dew point curves. A point outside the lens-shaped area represents a homogeneous liquid or vapour in the state P,T,X_2 or P,T,Y_2. A point B inside the lens-shaped area represents a heterogeneous system consisting of coexistent liquid and vapour at a definite pressure and temperature. The horizontal co-ordinate of B is the average composition X_2 of the entire system, and the co-ordinates of the intersections A and C of a horizontal line (a tie-line) through B with the vapour and liquid curves give the actual compositions of the two coexistent phases. The ratio of the number of moles of liquid to the number of moles of vapour is equal to the ratio of the length of the line AB to the length of the line BC. If the temperature of a liquid in the state D is increased slowly at constant pressure in a closed system of variable volume, boiling starts at E and the first portion of vapour has the composition indicated by F. As the temperature is further increased the liquid continues to boil away and the two coexistent phases each become richer in the higher boiling component. When the system has reached the state indicated by the point G it consists of a very small proportion of the liquid H and a large proportion of vapour G. At K the system is a homogeneous vapour. During this process there has been a large increase in volume.

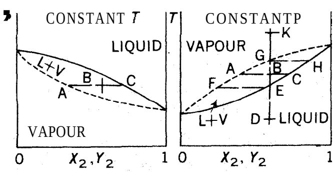

FIG. 3.—PRESSURE-COMPOSITION AND TEMPERATURE-COMPOSITION DIAGRAMS FOR A PAIR OF LIQUIDS THAT DO NOT HAVE A MAXIMUM OR A MINIMUM BOILING MIXTURE

Fig. 4 is a pressure-composition and a temperature-composition diagram for a two-component system, as water and nitric acid, which exhibits a minimum in the vapour pressure curve and hence a maximum in the boiling point curve. At the point M the coexistent liquid and vapour phases have the same composition and the system is said to be an azeotrope or in an indifferent state. A liquid of the azeotropic composition can be completely converted into vapour at a constant pressure and temperature, and in this respect it behaves like a pure substance. Some pairs of substances, as for example benzene and ethyl alcohol, have a maximum in the vapour pressure curve and a minimum in the boiling point curve (see fig. 5).

A simple experimental method for determining the temperature-composition curves for a pair of substances at one atmosphere pressure is to distill and condense a small portion of vapour from a relatively large quantity of liquid and then determine the compositions of the residue and of the distillate by measuring some property, as density. A thermometer in the vapour phase measures the equilibrium temperature. A plot of these two composition points against the temperature gives one point in the TX_2-curve and one point in the

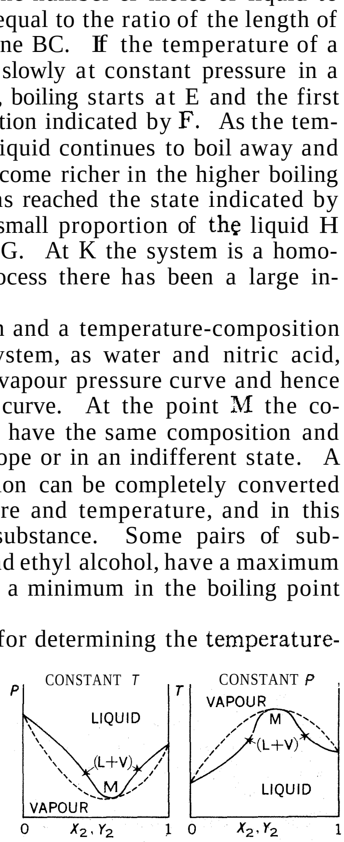

FIG. 4.— PRESSURE-COMPOSITION AND TEMPERATURE-COMPOSITION DIAGRAM FOR A PAIR OF LIQUIDS THAT HAVE A MAXIMUM BOILING MIXTURE

TY_2-curve. The complete curves can be plotted from similar measurements on a number of liquids of different compositions. The points for $X_2 = 0$ and $X_2 = 1$ are the boiling points of the pure components 1 and 2, respectively.

Azeotropes.—A system in which a finite phase transformation can take place at constant pressure, constant temperature and constant composition of every phase is called an azeotrope. When heat flows from the surroundings to such a system and the volume is suitably varied, one group of phases, called the low entropy complex, decrease in amount, and the remaining phases, called the high entropy complex, increase in amount; and during this process pressure, temperature and all compositions remain constant. All univariant systems (that is, systems in which $s = c + 1$) are necessarily azeotropes. Gibbs proved that a system of c components in s phases where s is equal to or less than c is an azeotrope when all of the determinants of the s by s matrices of the composition matrix

$$\left\| \begin{matrix} X_1' \; X_2' \cdots X_c' \\ X_1'' \; X_2'' \cdots X_c'' \\ \cdots\cdots\cdots\cdots \\ X_1^s \; X_2^s \cdots X_c^s \end{matrix} \right\| \qquad s \lesseqgtr c \qquad (7)$$

are zero. Here X_i^k is the mole fraction of the i-th component in the k-th phase. This means that the quantities of the s phases in an azeotropic system can be so adjusted that when heat flows to the system at constant pressure and temperature the low entropy complex of phases is converted to the high entropy complex without a residue of any phase, and the converse change takes place when heat flows to the surroundings. Moreover in an azeotropic system with $s \lesseqgtr c$ the pressure is a maximum, a minimum or a minimax (a saddle point) at constant temperature, and conversely.

One example of an azeotrope was mentioned above. Fig. 5 is the pressure-temperature-composition diagram for the liquid and vapour regions of a two-component system that has a minimum boiling mixture, as for example benzene and ethyl alcohol. The upper surface represents liquid compositions and the lower surface vapour compositions.

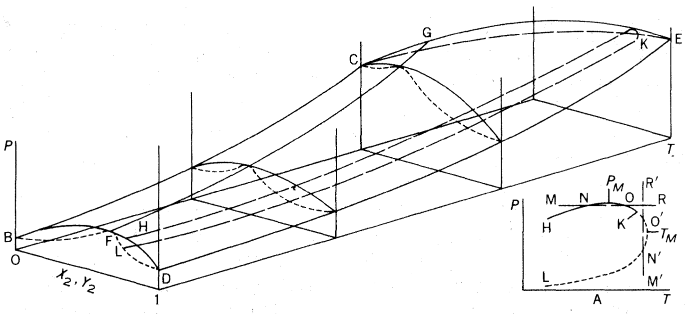

FIG. 5.— PRESSURE-TEMPERATURE-COMPOSITION DIAGRAM FOR A PAIR OF LIQUIDS THAT HAVE A MINIMUM BOILING MIXTURE

Tie-lines joining coexistent phases are parallel to the X_2 axis. The curves BC and DE are the vapour pressure curves for the pure components, and FG is the corresponding curve for the azeotropes. Although the composition of the azeotropic mixture varies along the curve FG, the slope dp/dT of this curve is given by the Clapeyron equation.

Water, ethyl alcohol and benzene provide an example of a three-component system that has an azeotrope of three coexistent phases, two liquids and a vapour (see DISTILLATION).

A system of variance three or greater can also form azeotropes; for example, a liquid mixture of three or more components that coexists with a vapour of exactly the same composition.

Retrograde Vaporization and Retrograde Condensation.—In fig. 5 the curve CKE represents the critical states of various binary mixtures and HKL is the pressure-temperature trace of the pressure-temperature-composition surface in a plane representing mixtures of constant composition. An enlargement of the critical region for this mixture is shown at the lower right. In contrast to a pure substance the critical point K of the mixture is neither the maximum temperature T_M nor the maximum pressure P_M of the PT curve. If the temperature of a liquid in the state M (at a pressure between P_M and K) is slowly increased at constant pressure, its state moves along the line MNOR. At N the liquid begins to boil. At first the proportion of vapour increases with increasing temperature, but then it decreases, and finally at O all of the vapour has condensed, since the point O lies in the liquid composition curve. This behaviour is called retrograde vaporization. Similarly if the pressure of a vapour in the state M' (at a temperature between K and T_M) is increased slowly at constant temperature, it starts to condense at N', but on further increase in pressure the liquid begins to boil and has all boiled away at O′ which lies in the vapour composition curve. This is called retrograde condensation.

VAR, a de'partement of France, formed in 1790 of a part of lower Provence. but in 1860 reduced by the transfer of the district of Grasse to the newly formed *département* of the Alpes-Rlaritimes. It is bounded north by the de'partement of the Basses-Alpes, east by that of the Alpes-Maritimes, south by the Mediterranean. and west by the de'partement of the Bouches-du-Rhône. Pop. (1954) 413.012. Area 2,326 sq.mi. The east of the de'partement is built up of the Estérel and the Massif des Maures, a block of Archaean and Palaeozoic rocks, the two parts named being separated by the Argens river. The rest of the *département* is mostly made up of the east-to-west lines of the Alpes de Provence. The valley lines for the most part run east and west between the hills. The coast shows evidences everywhere of a recent sinking movement and has numerous islands. The harbour of Toulon is a case of a sunken valley.

The chief industries are spinning and weaving of silk, manufacture of soap, paper, cork, pottery and tanning. Tobacco is grown and there is much fishing for tunny and anchovy. Trade is in wood and coal. Cut flowers are largely exported from Hyhres. The principal towns are Toulon, La Seyne, Hyhres, Draguignan, its political capital, Brignoles and Fréjus.

VARALLO SESIA, a town of Piemonte, Italy, in the province of Vercelli, from which it is 34 mi. N.N.W. by rail, situated in the valley of the Sesia, 1,480 ft. above sea level. Pop. (1957 est.) 7,743 (commune). The churches of S. Gaudenzio, Sta. Maria delle Grazie and Sta. Maria di Loreto all contain works by Guadenzio Ferrari (1471–1546). The Sacro Monte, above the town. is approached by a path leading past 45 chapels.

VARANASI (BENARES; BANARAS), a city, tehsil (administrative subdivision), district and revenue division in Cttar Pradesh. India, is of great antiquity and was the capital of the ancient janapad (kingdom) of Kashi. In a commanding position on the concave crescent formed there by the left bank of the Ganges, it lies 435 mi. N.W. of Calcutta, 941 mi. N.E. of Bombay and 503 mi. S.E. of Delhi. Situated in the middle Ganges valley, not far from the Vindhya mountains to the south, it communicates with the surrounding region by the navigable Ganges (crossed there by the Dufferin bridge), by rail and by road. The city owes its importance to its peculiar site and the nature of the Ganges bank at this point. Pop. (1961) 573,553; the remainder in the cantonment, university area and suburban township of Sheopur.

The riverside presents a magnificent panorama of multistoried buildings in many varieties of architectural design. The crescent-shaped bank is entirely lined with stone and has several broad flights of ghats or steps; an array of shrines, temples and palaces (of Hindu nobles and princes) rise tier over tier from the water's edge. but few of the buildings are of great antiquity. Among the most conspicuous are the Aurangzeb mosque (lying in the middle of the Hindu quarter), Madhodas Ka Dharahara, Vishveshwara (or Vishwanath) golden temple, Durga temple (a 17th-century Maratha building noted for the swarms of monkeys inhabiting the trees nearby) and the observatory of Raja Jai Singh (Man Mandir). The beautifully carved temples (mostly small) are placed in the street angles under the shadow of tall houses.

The general plan of the city resembles a crescent with radial streets. the outer edge being formed by the Grand Trunk and Yidyapeeth-Durgakund roads. The inner streets of the town are winding, narrow and impassable for motor traffic; only two of the ghats (the Dashahwamedh and Harishchandra) are accessible by car. Few of the streets are wider than 60 ft. The streets of the central parts form the main residential area, or "true living streets." With the establishment of the City Improvement trust, some of the streets have been widened, with footpaths. grassy roundabouts (traffic circles) and modern street lighting. The chief means of conveyance are bicycle-rickshas. After 1950 the state government provided some bus services within the city limits. The level of the roads is considerably lower than the ground floors of the houses. which generally have arched rooms in front with little shops behind them and above these they are richly embellished with verandas, galleries, oriels and broad overhanging eaves supported by carved brackets. Western-style houses with simple architecture are also in evidence.

Varanasi is by far the most crowded city of Uttar Pradesh. It possesses national characteristics since people from different parts of the country have settled there. Although it is a stronghold of Hinduism. the Muslim population is conspicuous, being about one-third of the total and concentrated in the middle zone of the city. Many of the people are engaged in commerce, industry and transport. The core of the commercial activity corresponds more or less to the heart of the city; the old business quarter, which lay to the north near Rajghat, has declined. New shopping areas have grown up along some principal roads; the main areas are Lanka. Assi. Madanpura (south) and Chetanj, Jagatganj, Nadeshuar and Orderly Bazar (north), as well as several shopping plazas.

In the northwest of the city are the cantonment of Sikraul (once of considerable military importance) and the suburb of Sigra, the seat of the chief missionary institution. The principal modern buildings are the Sheo Prasad hospital (previously known as the Prince of Wales Hospital in commemoration of the visit of the prince [later King Edward YII] to the city in 1876), the town hall and the old mint house occupied by the maharaja. The Sanskrit college, opened in 1791, has now formed the nucleus of the Sanskrit university established in 1957. Toward the south in Malviyanagar stands the premier university of India. the Banaras Hindu university (1916), with 14 colleges of different faculties (including a women's college), a university library, Sir Sundar Lal hospital and the hostels for students and quarters for the staff. An attractive temple of Shiva has been erected on the university campus. which has an architectural beauty of its own; the crescent-shaped plan of the university with radial and concentric roads is imposing. In the northwest of the city is the Udai Pratap degree-granting college, founded in 1909 as a public school for Rajput boys by Raja Udai Pratap Singh of Bhinga (a state of Bahraich district of Uttar Pradesh). Kashi Vidyapeeth (college) gives training in social sciences up to degree standard. Besides various technical colleges of the university, there are other technical institutions in the city: the government toy institution. Khojwa; the government Central Weaving institute, Chowkaghat; and the municipal leather school at Pieree. The city has a large number of Brahmins and scholars of sanctity and learning. through whom Varanasi has become the most famous centre of Sanskritic studies. The sacred area of Varanasi is bounded by a road 50 mi. in circuit known as "Panchkosi road" which every Hindu hopes to tread once in his life. Varanasi draws considerable revenues from pilgrims who come from almost every part of the country as well as from Tibet. Burma and elsewhere for religious salvation.

Most areas in the city have electricity and telephone services. Varanasi is served by railways (both metre and broad gauge) and by roads. It also has air services to Delhi and Calcutta. Varanasi is known for silk fabrics, gold and silver thread, gold filigree work, German-silver work, embossed brass vessels, lacquered wooden toys and tobacco manufacturing. The brassware, once famous, is now not so important as other leading industries. In the mid-20th century Varanasi developed industries such as cotton textiles. oil crushing, iron and steel rolling, general engineering and the manufacture of chemicals, aluminum, soda ash and ice. which employ more than 6.000 permanent workers. But cottage industries are still predominant and employ more than 71,000 people. Among these, silk fabrics are largely concentrated in the areas of Muslim settlement.

History. — The early history of Varanasi is that of the first Aryan settlements in the middle Ganges valley. By the 2nd millennium B.C. it was a seat of Aryan philosophy and religion. Royal patronage also made it a commercial and industrial centre. Even during the pre-Buddhist period it was famous for its soft and thin muslins, silk fabrics, perfumes, ivory works and sculpture. The Hindu kingdom of Varanasi lost its identity as an independent state about 650 B.C., being annexed to the kingdom of Koshala. It then came under Magadha domination during the reign of Chandragupta Maurya (321–296). It was under the rule of Asoka (c. 274–232) that the Buddhist township of Isipattana or Sarnath (5 mi. N. of Varanasi) reached its zenith. Varanasi did not fall under foreign yoke until the third quarter of the 1st century A.D., when Kanishka (king of Kabul) annexed it to his empire. During the first half of the 7th century, it was part of Harsha's kingdom. Hsuan Tsang, the celebrated Chinese pilgrim (7th century), observed that the kingdom of Varanasi was 667 mi. in circuit and the capital was 3 mi. long and 1 mi. wide along the western bank of the Ganges. The city changed hands on several occasions until, in 1033. it suffered Muslim invasion by Nialtagin. It was then occupied by the Gaharwar kings up to the end of the 12th century. Archaeological excavations (begun in 1957) in the Rajghat plateau area (north of the city) have unearthed some findings of this period. The city was conquered in 1193 by Mohammed of Ghor and was included in the dominions of the sultans of Delhi, later becoming the headquarters of their deputies. Under the Sharki dynasty of Jaunpur (*q.v.*), Varanasi lost its importance. During Akbar's rule, the famous Vishveshwara temple was reconstructed by Raja Todarmal, his finance minister. Varanasi suffered a period of harsh treatment and destruction at the hands of Aurangzeb (1618–1707). A succession of philosophers, reformers and holy men like Chaitanya, Ramanand, Kabir and Tulsi Das kept the lamp of scholarship burning even during this dark period, and the lack of royal patronage was made good'by the industrial and commercial contribution of the Muslim settlers in the city. The spinning and weaving of silk, cotton and wool, which are now the legacy of the Julaha (Muslims), were perhaps at their zenith under the Moguls.

With the decline of the Mogul empire, Hindu rule was re-established by Mansa Ram, who obtained the management of its zamindari about 1725. His son Balwant Singh established an independent state of Varanasi by the mid-18th century and built several forts, including that of Ram Nagar on the right bank of the Ganges. The Nadeshwar palace, mint house, Raja bazaar and the raja's house at Kamachha were some of the many buildings constructed during the Varanasi raj period. The Marathas, Sikhs and Nepalese also contributed to its buildings and religious centres. In the early British period. Varanasi remained a chief centre of commerce. It felt the impact of improvements in the communications together with a close contact with Europeans through military settlement and missionary institutions. After the reinstatement of the famous Chet Singh's nephe by the East India company. the tracts around Varanasi. which had been managed on behalf of the Oudh wazirs, were taken over by the British and the raja was confirmed in the possession of his own "family domains" for which Balwant Singh had received a grant from the Delhi emperor.

In 1911 Varanasi was recognized as a separate state and Prabhu Narayan Singh was given full ruling power. It was finally merged with Uttar Pradesh in Oct 1949.

VARANASI TEHSIL has a population of 1,043.466 (1951) and its area is about 596 sq mi.

VARANASI DISTRICT extends over both sides of the Ganges and has an area of 1,965 sq mi. and a population of 1,978,634 (1951). Except for Chakia *tehsil*, it forms part of the Ganges plain. Chakia *tehsil* contains a large area of hilly jungle land and is a part of the Vindhyan plateau. The surface of the plain area is remarkably level with several deep ravines in the calcareous kankar formations. The soil is mostly clay and sandy loam. It is very fertile except where covered with reh (saline efflorescence). The Ganges, Barna (Varuna), Gumti, Nand, Hathi, Karamnasa, Gangi and Chandraprabha rivers form the main drainage system of the district. The cultivated area comprises 61.2%, cultivable waste 9.4%, current fallow 3.4% and forest 15.2% of the total area. The chief crops are barley, rice. wheat, pulses and sugar cane.

The district has 631 villages and 12 towns. Of the total population. 400,000 live in towns; 85.6% of the urban population is in Varanasi city. About 40.3% of the total population of the district depends on nonagricultural resources. The two *tehsils*, Bhadohi (west) and Chakia (southeast), that formerly made up the princely state of Benares were merged in the district in Oct. 1949. A chemical factory was established on the bank of the Ganges near Moghal Sarai, employing about 1,500 persons; and a railway workshop has been set up at Maruadih.

VARANASI DIVISION. with an area of 10,378 sq.mi., comprises the districts of Varanasi, Mirzapur, Jaunpur, Ghazipur and Ballia. In 1951 the population was 6,849,031. (R. L. SI.)

VARDANES, the name of two Parthian kings.

VARDANES I succeeded Artabanus II, probably his father, in A.D. 39, but had continually to fight against his rival Gotarzes (*q.v.*). The coins show that he was in full possession of the throne from 42 to 45. In 43 he forced Seleucia on the Tigris to submit to the Parthians again after a rebellion of seven years. Ctesiphon, the residence of the kings on the left bank of the Tigris, opposite to Seleucia, profited by this war; and Vardanes is therefore called founder of Ctesiphon by Ammianus Marc. xxiii, 6, 23. He also prepared for a war against Rome, with the aim of reconquering Armenia, but did not dare to face the Roman legions In a new war with Gotarzes he gained a great success against the eastern nomads. In the year 47 he was assassinated while hunting, and Gotarzes became king again.

VARDANES II rebelled against his father Vologaeses I in A.D. 54 (Tac. *Ann* xiii, 7). We know nothing more about him.

VARENIUS, BERNHARDUS (BERNHARD VAREN) (1622–1650), one of the most famous geographers of his time, whose influence lasted for more than a century, was born in the district of Hanover in 1622. He trained in medicine at Konigsberg and Leyden, and settled in Amsterdam where he wrote his two books, *Descriptio Regni Japoniae* (1649) and *Geographia Generalis* (1650). The first was reprinted at Cambridge in 1673; the second went through four editions at Amsterdam (1650, 1664, 1671 and 1672), was edited by Sir Isaac Newton and published at Cambridge in 1672 and 1681, was further edited by J. Jurin at Cambridge in 1721, and was translated into Italian (1716), Dutch (1750) and French (1755). There were English translations by R. Blome (1693) and Dugdale and P. Shaw, the last of these appearing in 1765. Varenius died at Leyden in 1650.

The *Descriptio* consists of five works: a description of Japan, a Latin translation of J. Schouten's description of Siam, a discourse on Japanese religion, some excerpts from Leo Africanus on religion in Africa and a short *Dissertatio de Republicis in Genere*. The *Geographia* dealt with what would now be called systematic geography on a scale not previously attempted, and because of its scholarly character and orderly arrangement had a wide influence. It also contained a scheme for "special," now known as "regional," geography of which the *Description of Japan* was a sample. Varenius collected other material and wrote of "several volumes to come" but died before anything was published, and the content of these volumes is unknown. But without these his reputation is secure for he was one of the first to see the subject of geography as a whole and to emphasize its importance "both in the world of letters and for everyday use."

L. Baker, "The Geography of Bernhard Varenius," *Trans. Inst. Brit. Geogr.*, no. 21, p. 51 (1955). (J. N. L. B.)

VARESE, capital of the province of the same name in Lombardia, Italy. The town, 1.253 ft., is near Lake Varese, 30 mi. N.W. of Milan. Population (1957 est.) 59,501 (commune). The basilica of S. Vittore (1580–1615) has a 12th-century baptistery and a campanile 246 ft. high. There is also an 18th-century *palazzo communale* (former ducal palace). To the northwest is the pilgrimage church of the Madonna del Monte (2,885 ft.). Varese province had a populafion in 1951 of 477,055.

VARGAS, GETULIO DORNELLES (1883–1954), president of Brazil (1930–45, 1951–54) and the dominant personality on the Brazilian scene during the quarter-century after 1930. Vargas was one of the most capable politicians and contradictory public figures that Brazil has produced. His name is closely associated with the major political and socio-economic transformations that occurred in Brazil after 1930. His policies contributed to many of these changes, such as the expansion of power by the central government, the growth in the size and influence of the bureaucracy, the political emergence of the urban working class, industrialization of the economy and the rise of nationalism.

Vargas was born at Sbo Borja, Rio Grande do Sul, on April 19, 1883, into a family prominent in state politics. He joined the army as a private at the age of 16. He entered politics in 1908 shortly after studying law and graduating from the University of Pôrto Alegre. He practised law and held various positions in the executive and legislative branches of the state government until 1922, when he was elected to the national congress, in which he served four years. In 1926 Vargas became minister of finance in the cabinet of Pres. Washington Luis, a post he retained until his election as governor of Rio Grande do Sul in 1928. From his position as state governor Vargas campaigned unsuccessfully for the presidency of Brazil in 1930. Failing in his bid, he led the revolution in October of that year which overthrew the republic. For the next 15 years Vargas was chief executive of Brazil. He held power as provisional president from Nov. 3, 1930, until July 17, 1934, when he was elected president by the constituent assembly. On Nov. 10, 1937, Vargas presided over the coup d'état that destroyed the constitutional government and set up the avowedly totalitarian "New State" *(Estado Novo)* that in turn was overthrown by coup d'état on Oct. 29, 1945. Although he was forced from office, Vargas retained wide popular support. In Dec. 1945 he was elected both as senator and congressman from several states and he chose the position of senator from Rio Grande do Sul. However, he went into semiretirement until 1950, when he emerged as the successful presidential candidate of the Brazilian Labour party. He took office on Jan. 31, 1951. Faced with overpowering opposition from the armed forces, Vargas committed suicide on Aug. 24, 1954, rather than accept forced retirement.

Vargas' reputation rests largely on the accomplishments of his first regime, which effected a controlled social revolution. Prior to 1930 the national government had been in effect a federation of autonomous states, dominated by rural landholders and financed largely by the proceeds of agricultural exports. Under Vargas this system was destroyed. The tax structure was revised to make state and local administrations dependent upon the central authority, extensive social reforms were enacted, the electorate was quadrupled, labour was organized and controlled by the government, and a program of rapid industrialization was undertaken. For his role as the champion of the common man, Vargas came to be called "Father of the Poor."

During World War II Vargas cast his lot with the democracies and Brazil contributed large quantities of raw materials as well as fighting forces to the war effort.

Removed from office in the wave of democratic sentiment that swept over postwar Brazil, Vargas was recalled five years later, largely by a working-class vote. His reputation for political wizardry led the public to expect easy solutions to the problems of underemployment, inflation and widespread demands for economic expansion at a rising rate. As an elected president restrained by congress, a profusion of political parties and public opinion, Vargas was unable to satisfy his labou: following and resorted increasingly to ultranationalistic appeals to hold popular support. By mid-1954 criticism of the government was general, and the armed forces joined in the call for his withdrawal. This pressure led to his suicide. (R. E. P.)

VARIATION. All kinds of living organisms vary. It is the business of the biologist to find out the range of such variation in wild and domesticated animals and plants; to decide what share of variation is due to hereditary and what to environmental causes; and to see whether heritable variations, the raw material of evolution, can be artificially produced in the laboratory. (See also SELECTION; EVOLUTION, ORGANIC; HEREDITY.) (X.)

VARIATION IN NATURE

The variation of animals and plants in nature is, so far as known, subject to the fundamental laws revealed by experiment and pedigree-breedings (see HEREDITY). Only by such experiments and culture is it possible to decide authoritatively how a given variation is produced and whether it is heritable or not. Nevertheless it is desirable to know—(a) the actual kinds of variation that occur in nature, (b) which of these we may assume to be heritable and (c) the effect which isolation (topographical, habitudinal, etc.) and interbreeding may have on the distribution of variant characters in nature. Variation in the habits of animals, the food they eat, their breeding-seasons and all their complex inter-relationships is moreover of cardinal importance in evolutionary studies and can only be effectively observed among animals in nature. The kinds of structural variation that occur in nature will be best illustrated by means of the following classification which, although it is not exhaustive, will show the circumstances in which such variation typically occurs.

1. Variation regularly occurring in the presence of a given environmental condition or factor.

(a) Gross variation in form and 'size associated with the excess or deficiency of some tissue-forming substance.

The periwinkle, clam and mussel when living in water of reduced salinity (*e.g.,* in the Baltic Sea) are found to be smaller than in normal sea-water. Low night-temperature and inferior soil render various hawkweeds (Hieracium) living at high altitudes more stunted than those living at lower altitudes.

(b) Special modifications.

The tail-lamellae of the brine shrimp (Artemia *salina*) are reduced in water of high salinity. The shape of the common cockle (Cardium edzcle) is more elongate in water of salinity above that of normal sea-water. Terrestrial animals living in damp situations or in humid atmosphere are often darker than representatives of the same species which live in drier conditions. This is recorded among slugs, birds and mammals. The greater part of the variation exemplified by (a) and (b) is in all probability non-heritable. Experiment has however shown that in a few cases variation induced by external causes may be inherited either permanently (Lepidoptera, Harrison and Garrett) or temporarily (Amphibia, Kammerer; Crustacea, Agar). Similarly the colour-differences recorded by Sumner have been shown to be hereditary.

A series of allied varieties or races which replace each other in succession, either in time or place, will sometimes exhibit progressive modification. Such variation may be simply correlated with a change in geographical position, the causes of structural change being obscure.

2. Variation resulting from adaptation to diverse conditions.

In the arrow head (Sagittaria) the same plant may have some leaves adapted for aerial and others for aquatic conditions. Protective "mimicry" affords some striking examples of this type of variation among animals (see MIMICRY).

3. Variation known to be heritable but not referable to known external causes.

Many variations in colour, form and pattern that are known by experiment to be hereditarily stable have been recognized in nature. Such variations may be distributed at random through a large natural population, or the latter may be divided into topographically isolated races or colonies, each of which has a more or less distinct appearance. These divergences may likewise be associated with other modes of isolation, *e.g.,* with mutual sterility, difference in breeding-period, etc. Other examples of this kind of variation are to be found in the "colour-phases" of mammals (*e.g.,* foxes) and birds. Stresemann's important work on the occurrence and heredity of such colour-phases in the latter should be consulted. It is also known in flowers.

4. Variation due to accident, interference with growth-processes, etc.

It is not always easy to differentiate between this type of variation and that described in (1). For example the shells of the water snail Planorbis seem to assume the uncoiled ("scalariform") form in water of unusually high temperature. This may be described as an accidental malformation, but it is actually produced by a particular state of the medium in which these snails live.

Scalariformity is more obviously "accidental" when produced in the Gastropod Trochus by parasitic infection. Plant lice sometimes produce green colour in flowers and the attacks of a rust fungus (Aecidium) produce shorter and broader leaves in Euphorbia *cyparissias.*

5. Seasonal Variation.

This is a familiar phenomenon among vertebrate animals, and is also known among invertebrates (Insects, Cephalopods). The change of coat-colour in the mountain hare from "smoky-brown" in summer to white or "blue" in winter is a notable example. In the rufous horseshoe bat of India (*Rhinolophus rouxii*) the fur after the spring and autumn moults is mouse-brown on the upper surfaces. This changes in course of time into brighter colours, probably owing to oxidation of the pigment.

6. Variation due to sexual dimorphism and growth-changes.

Strictly speaking this should not come under the rubric of variation as described here; but it is important to notice that some of the differences in size, colour and shape among animals of the same species may be due to these causes.

The data presented above relate only to the structure of animals and plants. Although the distinction between structural characters and those of physiological constitution and habits is arbitrary, it is convenient to retain the distinction in a survey of this kind. Our knowledge concerning modes of variation other than that of structure is less complete. Each species is probably as variable in its physiological constitution as it is in its structure. This has been shown by exact tests, and also may be inferred from such facts as the infection of hosts belonging to different families and genera by individuals of the same species of parasite, the occupation by members of the same species of habitats radically different in physical and bionomic factors, varying susceptibility to disease and so on. The variability of habits may be illustrated by Darwin's observations on the behaviour of the great titmouse, certain individuals of which species sometimes behave as birds of prey.

A number of highly important considerations are omitted from this discussion. The problem of intermediacy, the degree of variability in different species of the same genus, the relation between natural variation and classificatory units, observations on the effect of Natural Selection and on the first appearance, increase or decrease of variant individuals are dealt with in the undermentioned works. (G. C. R.)

EXPERIMENTAL VARIATION

The Types of Variation.—Not everything differentiating an offspring from its parents can be handed down to later generations (see above). Only the alterations occurring in the hereditary determiners, or genes (*q.v.*), can furnish actually new materials for the permanent fabric of a race, and these changes in the genes, called gene-mutations, are remarkably rare. However, after the mutations have occurred, the changed or mutant genes enter into varying combinations with each other and with the old genes, in successive generations, and so the actual degree of variation becomes increased. Individuals having assortments of characteristics different from their parents are thus formed, by recombination, in somewhat the same way as, by drawing some cards out of each of two given hands, we might obtain new hands, having one or another new assortment of cards. Besides the above two kinds of variation, which involve the genes, there are also many important variations not due to the genes, but to the environment. These variations may be grouped together under the term *modifications.* For detailed consideration we may best treat these three classes of variations in an order the reverse of the above.

Modifications Caused by Environment — The common question, "Which is more important, heredity or environment?" permits of no answer, except that both are equally and absolutely essential. We are related to our heredity and environment more nearly as an arithmetical product of the two than as a sum, and, with either annulled, the product must be zero. The genes provide the egg, not with the guarantees of developing certain characters, but only with the possibilities of reacting in certain ways so as to produce given adult structures and peculiarities, provided food and other conditions are appropriate. Change the environment (it cannot really be abolished completely) and these genes may exercise their possibilities of reacting in very different ways, to produce a different type of development, or disintegration.

It is, however, more pertinent to put our question in the form, "Which set of factors are ordinarily responsible for a larger part of the *variation* which actually occurs, *differences* in heredity or *differences* in environment?" If, now, we take variation in the larger sense, to include differences between all living things, it is obvious that, all in all, differences in environment are an insignificant cause of the existing variation as compared with hereditary differences, and this is usually true even of two individuals chosen from closely related yet different species. On the other hand, within a given population of one species, the variation due to environment is sometimes comparable to, or even much greater than, that dependent on the genes. Which sort of variation predominates, and to what extent, will depend on many circumstances, and to answer our question will therefore require separate study, and often elaborate experimentation and measurement, in the case of each population considered and even in the case of different characteristics in the same population. The unravelling of any intimate combination of hereditary and environmental effects will usually demand either that we hold the effective features of the environment constant (often an impossible operation), or else that we secure a set of individuals identical in their genes (as a result of inbreeding, twinning or asexual reproduction) ; under such circumstances the residual variation, due to the influence that was not held constant, may then be ascertained.

It is especially desirable to discover not only the extent of variation due to environmental differences, but the principles governing the production of this variation. This quest, however, leads to a study of all the intricacies of embryonic development, physiology and mechanistic biology in general. Although the details of the chemistry and physics comprised in these phenomena are for the most part scarcely guessed, we at least know, from our observations on the grosser visible occurrences, that the processes whereby most adult organs and characteristics are formed are highly involved, interdependent in a complicated way and composed of many successive reactions. Make one change, and effect follows effect until the final result bears no resemblance to the initial one. So, for example, a quantitative change in some primary process may appear in the adult as a qualitative change, and vice versa. It should also be observed that there are often regulatory mechanisms which automatically compensate for effects produced, as in regeneration of a lost limb or in the accelerated growth of a child following temporary stunting.

Genetics has adduced cogent evidence that, despite the strong influence of the environment in modifying the body as a whole, and even the protoplasm of its cells, the genes within the germ-cells of that body retain their original structure without specific alterations caused by the modification of the body, so that when the modified-individual reproduces it transmits to its offspring genes unaffected by its own "acquired characters." The offspring, then, will not tend to repeat the parental modifications, unless the same peculiar environment is itself repeated. Our sins and our successes are not reborn in our children, though the latter may inherit our original tendency and capacity for these. Modifications, therefore, unlike mutations, cannot be a cause of biological evolution or degeneration. Now, if modifications acquired before the conception of children are not visited upon the latter, it certainly holds true that any modifications acquired by the mother after the embryos are partly developed, but prior to their birth, would not be transmitted to them. Mothers may rest assured that there is no more ground either *a priori* or in observation, for supposing that a fright received during pregnancy (or before) will give their child a fearsome disposition than that it will give him spots.

Variation Due to Segregation and Recombination of Genes. — Whenever an individual breeds, having received a different hereditary contribution from its two parents, its offspring will tend to vary from one another. Thus, if we had received a gene for brown eyes from our mother, and one for blue eyes from our father, then, although we ourselves would have brownish eyes (brown being said to be "dominant" and blue "recessive"), nevertheless we would transmit our gene for brown only to half of our reproductive cells, and the gene for blue, unalloyed by brown, to the remainder. This process of separation is called segregation (*see* **HEREDITY**). If our parents had given us different genes for hair-form also, we would produce reproductive cells having all the possible assortments of the two pairs of genes, namely, some having "brown curly," others "blue straight," still others "brown straight" and the rest "blue curly." This phenomenon is recombination. Since such variation can be produced in our children only in respect to genes which already differed from one another in our parents, it is evident that the primary cause of this variation lies in the events whereby these genes came to differ in the first place, that is, in the gene-mutations such as originally changed a gene for brown eyes into the gene for blue. These mutations, that make possible the recombinations of to-day, may have happened in the remote past.

The explanation of segregation and recombination is to be found in the behaviour of the chromosomes, those tiny separate filamentous bodies, visible under the microscope, which contain the invisible genes "linked" together within them, like beads in so many separate chains. Several or many chromosomes, each probably containing hundreds of different genes of distinctive natures and effects, are contained in each of the two uniting reproductive cells derived from the two parents. While the majority of the genes from one parent are always like those from the other; since the parents are in general similar organisms, yet in the case of most matings there are some gene-differences, and these give an opportunity for the operation of the segregation and recombination processes above mentioned, after the individual formed by the union of the two cells in question develops and reproduces reproductive cells for a still later generation.

It will be seen that the more gene-differences exist the more different combinations can then be formed. The numerical relations resulting from recombination are calculable according to definite laws, provided the effects of the genes concerned, and their positions in the chromosomes, have been determined by prior experimentation. The character-effects of untried combinations cannot, however, be predicted with certainty, as unexpected developmental results, including even new traits, are occasionally produced by recombination. As some new combinations may be more advantageous for the race than the original combinations, the function of recombination, of segregation, and in fact of sexual reproduction itself, becomes explained in terms of their value in evolution.

The development of most characters depends on the combined action of numerous genes. A difference in any one of these genes may affect either the quality, or the degree of development of the character in question. Now, when a number of mutations, in different genes all concerned with the same character (*e.g.,* stature), have some time previously occurred in a population, random crossing and recombination will result in the transmission, to different offspring, of many different assortments of the mutated and non-mutated genes. Thus the population may tend to exhibit many different grades of expression of the character. These grades will often differ only by small steps, which become blurred into an apparently continuous gradient through the effect of environic modifications. Such quantitative variation, as well as all other variation of recombinational origin, is of course especially evident when individuals are bred which resulted from the crossing of widely different stocks, in which many differing gene-mutations had become established since these stocks diverged from their common ancestor.

Many abnormal types of recombination occasionally occur, owing to such disturbances of chromosome-behaviour as the loss or reduplication of a chromosome or section of a chromosome, or the reduplication of one or more entire sets of chromosomes. When such an occurrence alters the proportions existing between the different kinds of genes (by changing the numbers of some and not of others) there generally results a combination of various (usually detrimental) abnormalities at once. At other times, a chromosome may become broken in two, or two chromosomes unite to form one, or a piece broken off one chromosome and united to another. The genes thereby become rearranged, but the characteristics of the individual probably remain little affected, since they depend rather on the kind and numbers of different genes present than on their arrangement. X-rays, cold and other influences are known to induce such disturbances of chromosome behaviour.

Mutations in the Genes.—It has been found in fruit flies (*Drosophila*) that any given gene, existing in a fly at the present day, has probably remained constant in its composition for several thousand years. This stability is not passive, for, as every organism grows and reproduces through a process of repeated cell growth and cell division, each gene must repeatedly reproduce itself, and in so doing it must each time construct a daughter-gene that possesses exactly its own peculiar structure. Occasionally, however, something goes wrong, and either the mother-gene becomes altered in its composition or else the daughter-gene is not formed exactly in the image of the old gene. As a result of this mutation there arises a new type of gene, having a different effect upon the organism, and this mutant gene is then capable of reduplicating its own new type—a process which it usually performs with as constant accuracy as that which the old gene had exhibited. It is this peculiarity of the gene—its retention of the power of self reduplication despite the occurrence of alterations (mutations) in its composition—which makes heritable variations possible, and hence organic evolution.

There is evidence that, when one gene in a cell mutates, the thousands of others, even including the similar or identical gene derived from the other parent, remain unaffected and constant. The mutation, then, may be regarded as an "accident" of submicroscopic dimensions, dependent on the occurrence of certain "chance" configurations of atoms, electrons and energy-quanta within or near the gene in question. It is not strange, in view of this, that it has not yet been proved possible, by particular external conditions, to dictate the occurrence of specified types of gene mutations in preference to others.

Though the kind of mutation which shall occur has not been brought under control, experiments with a number of different organisms have shown that heavy treatment with X-rays will make the mutational accidents in general occur far more frequently than otherwise, so that gene mutations of varied kinds may be produced at a rate in some cases more than a hundred times higher than that at which they previously were found to occur. This raises the conjecture, as yet untested, that possibly the y-rays (related to X-rays) which originate in minerals of the earth's crust have played an essential role in the causation of the varied "natural" mutations through ahich evolution has come about. However, there is evidence that temperature, genetic composition, and perhaps other factors, also affect the general frequency of gene mutations. No particular stage in the life cycle is known to be especially favourable for the occurrence of gene mutations; certainly they may happen either in embryos or in adults, and in somatic as well as in germinal tissue, though of course only mutations in germ cells can be inherited.

Though most gene mutations seem, in the sense above explained, to be accidents, some genes appear to be less stable than others, and a few are definitely known to be exceedingly mutable (ever-sporting). In the latter cases, which may represent changes of a different sort from most gene mutations, the stability of the mutable gene may be much affected by specific conditions. These effective conditions differ in different cases. Some are determined by the nature of the tissue and developmental stage in question, others by the external environment, and still others by the genetic composition.

A given gene has the capability of mutating in various ways so as to form a number of different kinds of genes (multiple allelomorphs). Usually the effects of these differing changes in a given gene resemble each other strongly, and often, though not always, the discernible differences between them lie chiefly in the degree of change produced. There are also numerous cases on record of mutations that seem quite identical in kind with other mutations which occurred independently in homologous genes of other individuals belonging to the same or a related species. Not infrequently, too, different kinds of genes (nonhomologous) will, on mutating, produce similar or indistinguishable final effects on the characteristics of the organism. In this connection it is found that certain character changes can be produced by mutations in a greater number of different genes, and hence tend to occur more commonly, than others.

The most frequently produced effect, so far as known, is the lethal effect; that is, mutant genes are usually so deleterious in their action that they tend to kill the organism. When they are not positively lethal they are usually retrograde in direction, and hinder rather than help the organism to fulfil the functions of its existence. Such results are to be expected of accidental changes occurring in any complicated organization. A race, therefore, will tend gradually to undergo degeneration in any respect in which selection (natural or artificial) does not persistently weed out the degenerative mutations that continue to occur. It can be only the rare mutations that are helpful which furnish material for evolution. These latter, however, when they show, will tend to multiply.

As a matter of fact, most gene mutations never show. For most (though not all) mutant genes are recessive to the type from which they arose, and in their cases an obviously mutant individual cannot appear unless—usually many generations subsequently to the original gene mutation—two reproductive cells, each bearing the identical mutant gene, meet in fertilization.

Both conspicuous and inconspicuous, minor and major, fundamental and superficial character changes are produced by gene mutation, and either one character or several at once may be altered by a single gene change. The more far-reaching the change, the more apt it is to be deleterious rather than advantageous. Hence geneticists are returning to a view essentially similar to Charles Darwin's, namely, that the origin of one species from another usually involves the accumulation of numerous selected small steps of heritable variation.

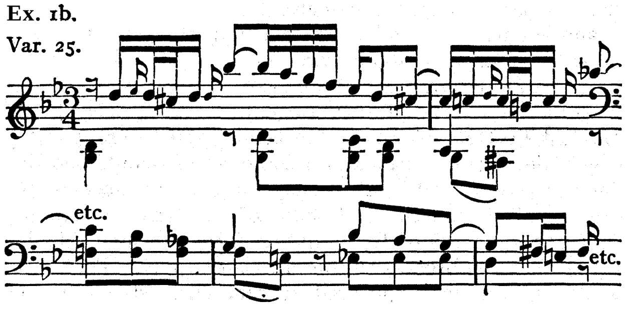
See ANIMAL BREEDING; CHROMOSOME; CYTOLOGY; DARWINISM; GENE; HEREDITY; PLANT BREEDING. (H. J. M.)

VARIATIONS, in music, the term given to groups of progressively developed versions of a complete self-contained theme, retaining the form of that theme though not necessarily its melody. This is the classical sense of the term, but there are modern developments of the variation form to which this definition is at once too broad and too precise to apply. The aesthetic principle of variations appeared at very early stages of music. During the 16th century an artistically mature variation form automatically rose in the polyphonic treatment of Gregorian hymns verse by verse. Accordingly, the hymns and Magnificats of Palestrina might be described as contrapuntal sets of variations on ecclesiastical tunes, like rich and free examples on the simple plan shown later by Haydn's variations on his Austrian national anthem in the "Emperor" quartet (opus 76, no. 3). Already in the 16th century instrumental music was climbing up the trellis of a primitive variation form. A favourite plan (*see* the *Fitzwilliam* Virginal Book, passim) was to put together several popular or original tunes, with an ornamental variation sandwiched between. Sometimes sets of variations on a single tune were produced, with excellent effect, as in Byrd's variations on "The Carman's Whistle." Such variations were naturally grouped in order of increasing brilliance, and they often include passages that would catch the greatest pianoforte players.

In the 17th century a highly artistic form of variation solved with great simplicity the problem of expanding instrumental pieces to a length admitting of growth to a big climax. This was the ground bass, a single phrase placed in the bass and repeating itself ad infinitum. It originated in the dance forms of the *passacaglia* and the ***chaconne.*** Both were in slow triple time, the chaconne having a strong accent on the second beat, while the passacaglia, by some chance, developed the liberty to transfer its theme to other parts than the bass. The genius of Purcell was cruelly hampered by the non-existence of large musical forms in his time, and he seized upon the ground-bass with avidity. By the time of Bach and Handel lighter sets of variations, consisting essentially of embroidery on a melody, had come into vogue. Bach's *Aria variata alla maniera Ztaliana* tells us where this fashion began; and in France the *air et doubles* was taken over from early English virginal music. Doubles are variations each of which divides the rhythm into quicker notes than the one before. The most familiar example is that known as "The Harmonious Blacksmith" in Handel's E major suite. Sometimes the air itself was stated in a tangle of ornamentation, while the doubles simplified the melody and varied the accompaniment. But Bach had meanwhile applied the principle of the ground-bass to variations on a complete symmetrical movement in binary form. His Air and 30 Variations, commonly known as the "Goldberg" variations, is (with the exception of Beethoven's 33 *Veranderungen* on a waltz by Diabelli) the most gigantic set of variations in the world. A melodically interesting ground-bass could not be maintained on so large a scale; but the 32 bars of Bach's theme are so many clear harmonic steps which can be represented by many analogous progressions, without loss of identity. (Ex. 1a.) There is no question of retaining or varying the melody of the aria, which is a tissue of ornaments that will bear neither development nor simplification.

Ex. 1a. Harmonic theme. (**BACH.** "*Goldberg*" *Variations.*)

Ex. 1b.
Var. 25.



The rise of the sonata style again brought the melodic embroidery variation into prominence; for in sonata forms we identify themes entirely by their melodies. Now, with not more than three or four exceptions, the best sets of variations by Mozart and Haydn are movements in their sonata works; and their independent sets are either early or perfunctory exercises and encore-pieces. Two common mistakes of professional and amateur criticism are, first, the judging of Haydn's and Mozart's variations by these parerga, and secondly, the much graver error of despising the embroidery variation on principle. It is either vulgar or sublime. And it is handled lovingly by precisely the greatest masters of deep harmonic and rhythmic variation, Beethoven and Brahms. Haydn is fond of a special form first known in Philipp Emanuel Bach. It consists of alternating variations on two themes, alternately major and minor; the first a rich and complete binary melody, and the other a shorter binary melody, often beginning with the same figure as the first. The first theme usually returns as if it were going to be unvaried, but its first repeat is an ornamental variation. The form is rarely worked out far enough to include more than one variation of the second theme; and sometimes (as in the famous "Gypsy" trio) there are new episodes instead of variations of the second theme, so that the form becomes a sectional rondo. The only strict example of Haydn's type of alternating variations in later music is the first allegretto of Beethoven's pianoforte trio in E flat (op. 70, No. 2); but a magnificent application of it, without change of mode, though with a wide range of key, is shown in the slow movement of his C minor symphony.

Beethoven, in his last works, invented another variation-form on two themes, of which the second is in a different key and time. The examples of this are the slow movement of the 9th symphony and the Lydian figured chorale in the **A** minor quartet. In the slow movement of Brahms's F major string quintet (op. 88), the alternation of the two keys gives rise, in the last line of the movement, to one of the most astonishing dramatic strokes in all music. Beethoven uses embroidery variations as means of obtaining extraordinary repose in slow movements. The extreme case of this is the slow movement of the sonata op. 57 (commonly called "Appassionata"), which is described in the article on SONATA FORMS. In this, and in many other instances, his method is that of the **air** *et doubles,* which grows to a natural climax which can subside into the rhythm of the plain theme. Until his latest works, such sets of variations are never finished. Their dramatic intent is that of a repose which is too unearthly to last; and at the first sign of dramatic motion or change of key the sublime vision "fades into the light of common day," a light which Beethoven is far too great an idealist to despise. *See* the andante of the B flat trio (op. 97); and the slow movement of the violin concerto, which contains two episodic themes in the same key. In his later works Beethoven found means, by striking out into foreign keys, of organizing a coda which finally spins down in fragmentary new variations, or even returns to the plain theme. Thus he was able to end his sonatas, opp. 109 and 111, with solemn slow movements.

Beethoven also found other applications of the variation forms. Thus the finale of the Eroica symphony has not only the theme but many other ideas in common with the brilliant set of variations and fugue for pianoforte on a theme from *Prometheus* (op. 35); and the fantasia for pianoforte, chorus and orchestra, and the choral finale of the 9th symphony, are sets of melodic variations with freely-developed connecting links and episodes. In the case of the 9th symphony, a second thematic idea eventually combines with the figures of the first theme in double fugue.

But Beethoven's highest art in variation-form is independent of the sonata. From his earliest display of pianoforte playing, the wonderful 24 variations on a theme by Righini, to his supreme variation-work, the 33 on Diabelli's waltz, he uses and transcends every older means of variation and adds his own discoveries. Before Beethoven the basis of variations might be a ground bass, a melody or a harmonic scheme. Beethoven discovered that rhythm and form can, with a suitable theme, be a solid basis for variations. The aria of Bach's Goldberg variations is in its phrasing as uniform as a chess-board; and if its harmonies had not a one-to-one correspondence with each variation the form would be lost. But there are themes, such as Haydn's Chorale St. Antoni, which Brahms varied, where the phrasing is interesting in itself. A similar example is the theme by Paganini (Ex. 2a) which inspired Brahms to compose two complete sets on it.

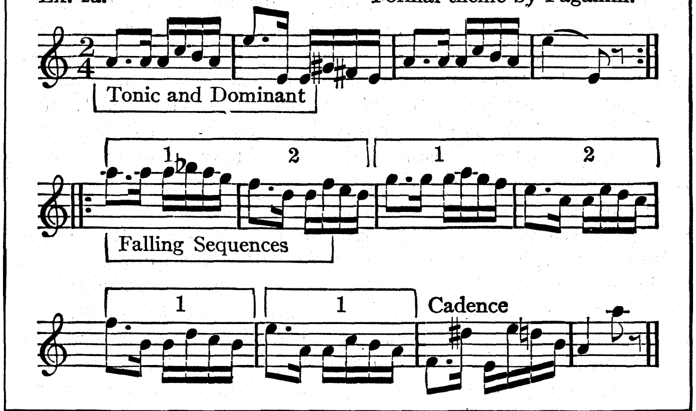
The climax in the history of variations dates from the moment when Beethoven was just about to begin his 9th symphony, and

received from A. Diabelli a waltz which that publisher was sending round to all the musicians in Austria, so that each might contribute a variation to be published for the benefit of the sufferers in the late Napoleonic wars. Diabelli's theme was absurdly prosaic, but it happened to be, perhaps, the sturdiest piece of musical anatomy that Beethoven (or any composer since) ever saw; and it moved Beethoven to defer his work on the 9th symphony! The shape of Diabelli's waltz may be illustrated by a diagram which represents its first 16 bars; the upright strokes (not the spaces) being the bars, and the brackets and dots (together with the names underneath) indicating the rhythmic groups. The second part also consists of 16 bars, moving harmonically back from the dominant to the tonic, and rhythmically the same as the first part. This plan is astonishingly elastic. The alternation of tonic and dominant in the first eight bars may be represented by another familiar form in which three bars of tonic and a fourth of dominant are answered by three bars of dominant and a fourth of tonic; as in variation 14 (which must be reckoned in half-bars). Again, when the theme answers the tonic by the dominant it raises the first melodic figure by one step, and this may be translated by the answer on the supertonic harmony. In the course of 50 minutes a few of these 33 variations become vague as to more than the beginnings and cadences of the theme; and there are three simple variations in which one would like to ask Beethoven whether he had not inadvertently omitted a bar; but the momentum of the theme is never lost; and after a group of three slow and rather free variations this momentum breaks into an entirely free fugue (variation 32) on a salient feature of what must by courtesy be called Diabelli's melody. A free fugue is a favourite solution of the problem of the coda in a set of variations. The momentum produced by the revolution of true variations in the orbit of the theme gives the key to the whole problem. A fugue solves it by flying off at a tangent. Very sublime is the way in which Beethoven, after letting his fugue run its torrential course, returns to the orbit of his theme in an ethereal little minuet with a short coda of its own which, 16 bars before the end, shows signs of beginning to revolve again.

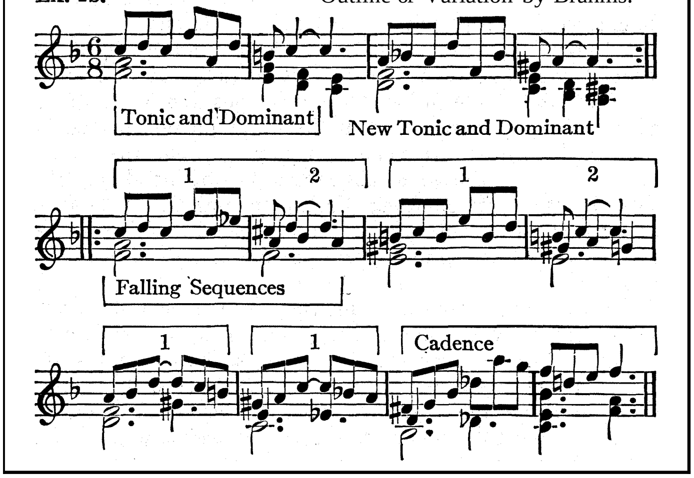
Again, let us regard the period of the theme not as an orbit but as diurnal rotation. We can then describe the codas of Brahms's Paganini-variations as produced by accelerating the spin till it breaks away for a while and then resumes for a few final catastrophic whirls; exactly like a dying top (though this, of course, does not accelerate its spin). Without acceleration Beethoven ended his wonderful C minor variations (most perfect of passacaglias) in this way. Brahms found in Haydn's Chorale St. Antoni the opportunity for another method. He took the first five bars as a ground-bass, within which narrow orbit the finale moves until its climax broadens out into the rest of the glorious theme, and so rounds off the whole work.

Bach poised the contrasts and climaxes of the Goldberg variations so accurately that the ending of the whole by a simple *da capo* of the theme is astonishingly effective. It is as if a charming old ancestress of a living line of great folk were to step from the frame of her Holbein portrait and bow to her assembled posterity.

To speak of the progress in variation-form since Beethoven is like speaking of the progress in reinforced concrete since the Parthenon. The classical variation-form is limited only by the composer's imagination and technique; and the removal of its foundations does not enlarge it at all. There is no reason to condemn other kinds of variation; and many great and beautiful works in non-classical variation-form exist, from Schumann's *Etudes Symphoniques* to Elgar's "Enigma" variations and Dohnányi's *Variations on a Nursery Tune.* But no "free" variation that breaks down the phrasing of its theme and follows its own discursive ways will ever achieve anything externally so unlike the



Ex. 2a. Formal theme by Paganini.



Ex. 2b. Outline of Variation by Brahms.

theme as a strict harmonic and rhythmic variation on classical lines. (*See* Ex. 2b.) Nor will a series of such variations acquire anything like the classical momentum. On the contrary, in clumsy hands the free variation becomes apologetic in the way in which it offers raw chunks of the original melody as evidence that it has not forgotten its duty, like Lewis Carroll's poetic *Tema con Variazioni,* the preface to which is an unconscious epitome of modern misunderstandings of the form.

Variation writers may be scientifically classified into those who know their theme and those who do not. There is no reasonable doubt that many very clever composers, from Mendelssohn onwards, have completely misunderstood the nature of the deeper classical variations, and have thought that anything so unlike the original tune must be quite independent of it. Mendelssohn's *Variations sérieuses* have a beautiful theme with a structure that might have given rise to splendid features; but Mendelssohn simply ignores this structure and replaces it by weaker things in almost every variation. Schumann shows more insight. He has no great grip of his theme, but he tries to distinguish by titles those variations which are true from those which are episodic; thus in the *Études Symphoniques* the etudes are numbered separately from the variations; the andante of the F major quartet is called *quasi variazioni;* and the strictest set he ever wrote (on a theme by Clara Wieck) is called Impromptus.

Brahms stands alone in his grip of his theme. Reger is no nearer the classical form in his variations than in his other works. The present state of the form seems to indicate that if the composer does not aim at strict variations his most vital results will be on the line of melodic development, as in the above-mentioned works of Elgar and Dohnányi, the Symphonic Variations of Dvořák, and those variations of Reger which are closest to this type. (D. F. T.)

VARICOSE VEINS, the term by which is meant an abnormal dilatation and tortuosity of the superficial veins of the limbs, particularly of the lower extremities. This condition is widespread throughout the population, being one of the most important afflictions of the venous system. It has been recognized since the time of Hippocrates and probably dates back to the time when man first assumed the erect position. The disease has never been found in quadrupeds. Although it is rarely a serious threat to life or limb, its complications may result in the loss of many productive hours from industry or household duties.

Among the causative factors in the production of varicosities are (1) an inherited weakness of the fibrous structure of the bicuspid valves in the veins; (2) absence of the valves in strategic locations in the deep veins; (3) prolonged standing, and (4) an increase of abdominal pressure due to such mechanisms as chronic straining (from constipation or persistent cough), tumours in the bony pelvis, pregnancy and tight foundation garments. Even when the pregnancy group is removed from the statistical studies, women still show a much higher percentage of varicosities than do men. The possibility of an unidentified endocrine factor, as well as periodic congestion of the pelvic area during menstruation, has been suggested as explanations for such a difference.

Blood normally flows out of the lower extremities by entering superficial veins and then deep ones through communicating vessels. For this to take place in the erect position, in the face of gravity tending to keep blood in the lower portion of the limb, certain mechanisms must come into play. Among these are the action of valves in the veins, allowing a flow of blood only in the upward direction, the pumping effect of the muscles in the legs as in walking, and the continuous stream of blood entering the veins from the arterial tree, moving the portion already in the vessels forward.

Varicosities result from an inefficiency in the action of the valves in the superficial veins, due to the causative factors already enumerated. As a consequence of the changes, the free edges of the valves no longer meet in the lumen of the vessels, thus allowing a backward flow of blood in the direction of the leg and foot. This produces an overdistention of the superficial veins, which contributes even further to the incompetency of the valves, and hence to an exaggeration of the existing pooling of blood in the vessels. The resulting rise in pressure in the veins is responsible for such complications of varicosities as smelling of the feet and ankles at the end of the day and changes in the skin, such as a weeping type of eczema and the serious complication of ulcers of the skin around the ankle. Furthermore, the walls of the superficial varicose veins may become so thinned out that they may rupture, leading to serious hemorrhage unless the limb is immediately elevated and simple compression applied to the bleeding point. Another relatively frequent complication is a clot in a varicose vein

The severity of the varicosities and the complaints of the patient are not necessarily related directly. Some individuals have very large, tortuous and dilated veins and little or no symptoms, while others with relatively small varicosities experience aching pain, night cramps, fatigue and fullness in the legs

For many years various types of sclerosing solutions have been injected into varicose veins in order to produce a chemical inflammation that changes the vessels into fibrous cords or in order to cause them to fill nith clots. The great disadvantage of such a procedure is that frequently the obstructed vein becomes recanalized (without valves), resulting in a return of the condition. For the most part, therefore, this type of treatment has been largely superseded by surgical therapy, which involves either multiple ligation of the varicosities or their actual removal by means of an instrument called a stripper. Elastic stockings or bandages are used only as a temporary measure. (D I. A)

VARIOLITE, a basaltic or doleritic rock with prominent spherulitic (variolitic) texture, the spherulites or varioles consisting usually of radial aggregates of feldspar. These varioles. especially on weathered surfaces, appear as pale-coloured spots, giving the rock a pockmarked appearance. The name is from Lat. *variola* ("smallpox"), in allusion to this characteristic feature.

The variolitic texture of the basic rocks is closely akin to the spherulitic texture of the acid lavas, as seen in rhyolites, etc

Variolites frequently form the tachylytic selvages of dolerite dikes (*see* TACHYLYTE), and also appear in the form of pillow lavas (*see* SPILITE). The varioles are usually rounded in outline and are often about ¼ in. in diameter, but may much exceed this size. With few exceptions they are built up of divergent fibres of feldspar embedded in dark brown glass.

As variolites are frequently much decomposed, the glassy matrix is represented by secondary alteration products or has been devitrified. (C. E. T.)

VARNA (formerly STALIN), a fortress, seaport, district capital and episcopal city of Bulgaria; on the Stalin gulf, an inlet of the Black sea, in 40° 12′ N. and 27° 56′ E. Pop. (1956) 124,951. Varna is built on the hilly north shore of the bay, overlooking the estuary of the Devna river. It is the eastern terminus of the railway to Rustchuk and Sofia. The "Varna quadrilateral," so important in Bulgarian military history, consists of the fortresses of Varna, Shumla, Rustchuk and Silistra (*q.v.*). Varna ranks with Burgas as one of the two principal seaports of Bulgaria. Its deep and capacious bay is sheltered from northerly and north-easterly winds, and the harbour works are modern.

The principal exports include cattle and dairy produce, grain, lamb and goat skins, and cloth (*shayak*); the imports include coal, iron and machinery, textiles. petroleum and chemicals. The headquarters of the Bulgarian Steamship Co., which traded with Turkey, Greece and Russia, were established there. Its trade was affected by the cession of the Dobruja to Rumania until 1940, but it became a popular seaside resort. During World War II, Germany used the port as a shipping supply base to provision axis armies fighting in the U.S.S.R.

Varna mas the ancient Milesian colony of *Odessos*, founded 585 B.C. Close by was fought in 1444 the battle in which Murad II slew Wladislaus III of Poland and Hungary, and routed his forces under Hunyadi János. Varna was occupied in 1828 by the Russians, in 1854 by the allies, who there organized the invasion of the Crimea, and in 1877 by the Egyptian troops summoned to the defense of Turkey against the Russians. By the treaty of Berlin (1878) it was ceded to Bulgaria. Long the seat of a Greek metropolitan, it became in 1870 the seat of a Bulgarian bishop.

In 1949 it was renamed Stalin and made the capital of a newly formed district of the same name. In 1956 it was renamed Varna.

VARNHAGEN VON ENSE, KARL AUGUST (1785–1858), German man of letters who, with his wife, Rahel (*see* below), played a small but influential part in literary life in the romantic period, was born on Feb. 21, 1785, in Düsseldorf and died in Berlin on Oct. 10, 1858. He studied medicine in Berlin, Halle and Tübingen and then entered upon a military and later a diplomat, career. He served as an officer in the struggle against Napoleon, first in the Austrian and then in the Russian army; he was adjutant to General von Tettenborn, recording his experiences in *Geschichte der Hamburger Ereignisse* (1813) and *Geschichte der Kriegszüge des Generals von Tettenborn* (1815) He accompanied the Prussian chancellor, Prince von Hardenberg. to the congress of Vienna and to Paris and became Prussian resident minister in Karlsruhe until, being suspected of "democratic intrigue," he was recalled and pensioned in 1819.

He then lived in Berlin where he pursued the literary activities he had begun in 1804 when with Adalbert von Chamisso he founded and edited the *Berliner Musenalmanach.* He produced a variety of work including poems, but his most important books were elegantly written biographies and memoirs, where he used the material gathered during a varied life in which he strove to meet as many of the famous as possible. These are a valuable source of information though not to be used uncritically. He was an enthusiastic admirer of Goethe and an acquaintance and correspondent of the poet: *Goethe in den Zeugnissen der Mztlebenden* (1823) is one of his chief works. Varnhagen's *Biographische Denkmale,* 5 vol., was published during 1824–30; seven volumes of *Denkwürdigkezten und vermischte Schrzften* appeared during 1837–46, and two further volumes following posthumously in 1859 (new ed. by J Kühn, *Denkwürdigkeiten des eigenen Lebens,* 1922–23; by K. Leutner, 1950). *Blätter aus der preussischen Geschichte,* 5 vol., appeared in 1868–69. His diaries and much correspondence were also published.

As a personality, however. Varnhagen is overshadowed by his wife RAHEL. Rahel Levin (1771–1833) was a Jetvess by birth though she professed Christianity before her marriage with Varnhagen in 1811. Of acute intuitive intelligence and sensibility, Rahel was one of the foremost women of her time and the *salon* she initiated in Berlin became a centre of literary life and the meeting place of writers of both the romantic and the Young Germany groups. She too was a Goethe worshiper and J. P. Eckermann records that Goethe called her one of the first people in Germany to understand his work. Her husband published a memorial volume for her in 1831, *Rahel, ein Buch des Andenkens,* and many of her letters have been printed. Rahel's brother was the poet who wrote under the name of Ludwig Robert.

BIBLIOGRAPHY.—R. Haym, *Varnhagen von Ense* (1863); and on Rahel biographies by O. Berdrow (1900), E. Key (1907) and L. Feist (1927); also W. Moog in *Goethe Handbuch,* III (1918) and C. May, *Rahel Varnhagen, ein Berliner Frauenlebea im 19. Jahrhundert* (1949).

VARNISH is a transparent, homogeneous, heat-treated blend of drying oils, resins. driers and volatile solvents. R⁷hen varnish dries, its solvent portion evaporates and the remaining materials oxidize or polymerize to form a hard, continuous. transparent film that protects against weather, insulates against electricity or can be made to serve other useful purposes.

In recent years the meaning of varnish has been broadened to include any transparent, homogeneous film-forming composition such as alkyd resins, oil-modified polyurethanes, polyesters. copolymerized oils, hydrocarbon polymers and epoxy esters. These modern coating materials are called varnishes because their general appearance, performance characteristics and end uses resemble those of the classical and historical oil varnishes', which they have displaced to a large extent. In addition, several other coating materials that are quite different from the oil and synthetic varnishes in composition, application and other respects are frequently called varnishes because they, too, give a continuous. hard. transparent finish; such materials include: (1) Spirit varnishes. which are solutions of resins in volatile solvents. These dry entirely by evaporation of the solvent, leaving a hard coating of resin that remains soluble in the original solvent. Spirit varnishes include shellac, lacquer and asphalt, pyroxylin or nitrocellulose. dammar and japan varnishes *(see* also BRUNSWICK BLACK; JAPANNING; LACQUER). (2) Lithographic varnishes, which are usually linseed oils that have been oxidized and polymerized to high viscosity. These are used primarily for the manufacture of printing inks. *(See* also INK.) *(3)* Water varnishes, which are solutions or emulsions of resins or glues in water. These become more or less water insoluble on drying and are used to seal or bind powdery surfaces.

History.— The use of varnish dates from prehistoric times. The name itself is a corruption of Berenice. the name of an ancient Egyptian queen. When Egyptian warriors brought a gift of amber (a natural resin and early varnish ingredient) to Ptolemy III Euergetes. king of Egypt, *c.* 250 B.C.. the colour of the specimens matched the hair of his queen, Berenice. and the material was named for her. The word developed into the Latin *vernis,* later into the Italian *vernice* and finally into the English varnish.

The ancient Egyptians melted soft resins, such as sandarac, mastic or pitch. with oil to form a varnish that could be applied while warm. Early artists painted with oleoresins, linseed oil. gums, glues and the like. Galen *(c.* A.D. 130–*c.* 200) wrote of the use of the nut, hempseed and linseed oil as drying oils. The use of oil varnish and resins was described by Theophilus in the 11th century; these finishes were used largely on works of art. By the 16th century, varnishes were used on furniture and in home finishing. What may be called the modern varnish era dates from the late 18th century, when the first printing of Jean Felix Watin's formulary appeared (about 1772). Few technological changes were made during the following century, so that a varnish manufacturer of 1900 used formulas and procedures hardly different from those described by Watin At the beginning of the 20th century, tung oil (*q.v.*) and other drying oils began to be used as replacements for linseed oil, and synthetic resins began to replace the naturally occurring resins.

Uses.––Furniture, floor, marine spar and label overprint varnishes are used on surfaces that are to remain visible but need protection and enhancement; *e.g.,* wood surfaces such as those of fine furniture and violins. Other. less expensive types of varnishes are employed to protect less valuable surfaces that also do not need to be hidden by pigments; *e.g.,* bottle caps and can interiors. Certain varnishes have unusual physical and chemical properties that are utilized in insulating varnishes, wire coatings, marine varnishes, sandpaper binders and floor varnishes. Tremendous quantities of varnish are used in the manufacture of paints and enamels, which are essentially varnishes that are coloured and opacified with pigments. In many of these products, particularly enamels. varnishes made with synthetic resins, such as the alkyd and epoxy resin.;, have almost completely displaced the classical oil varnish. *(See* also PAINT.)

Properties.— The classical oil varnish contains the following ingredients, which produce the indicated properties: (1) Resins or gums—to impart hardness and lustre, shorten drying time and improve chemical resistance; (2) drying oils—to impart flexibility and toughness; (3) volatile solvents—to thin the varnish to a consistency suitable for application; (4) driers and other modifiers—to hasten the rate of drying, control lustre and prevent skinning; *i.e.,* the formation of a skin over the liquid surface of a partly filled container.

Generally. a high proportion of resin will produce harder, faster drying, more brilliant but less durable varnishes, whereas a high proportion of oil will provide more elastic, more durable, more waterproof but softer varnishes. The oils and resins are blended in proportions designed to give the properties desired for specific applications. The ratio of oil to resin is expressed in gallons of oil per 100 pounds of resin and is called the oil length of the varnish. Varnishes are usually classified in terms of oil length, as well as according to the major type of oil and resin used in the preparation.

Varnish Classes by Oil Length

Oil length	Examples
Short (5–15 gal.)	Furniture varnishes that dry quickly and produce good hardness and sanding qualities
Medium (15–30 gal.)	Floor varnishes where hardness and flexibility (toughness) are required
Long (35–50 gal.)	Exterior varnishes where elasticity is important to enable the film to withstand atmospheric variations
Extra long (60–200 gal.)	Usually known as fortified oils and used where extreme flexibility is needed, *e.g.,* cable coatings

The ultimate property to be achieved in any varnish is a high molecular weight—by either a chemical and/or physical interaction of oil and resin. Oils and resins are unsaturated esters of high molecular weight that are capable of entering into many types of chemical reactions including ester interchanges, ethylenic polymerizations and oxidation processes. Varnishes based on run, or "fused," natural resins incur thermal decomposition reactions such as depolymerization and formation and recombination of reactive by-products. Physical dispersion of one component in another is also a distinct possibility. Because they consist of so many complex, competing factors, varnish reactions are poorly understood.

Manufacture.— The art of combining oils, particularly linseed. with hard gums developed over many centuries. Practices and recipes varied from country to country and were often shrouded in secrecy. Early varnish kettles, generally made of copper, were about three feet in both height and diameter, with the bottom riveted on so that it could be replaced when necessary. The kettle was set on a small frame truck to permit easy handling. Heat was provided by a fire of coke, gas or fuel oil situated below the floor level. While the varnish resins were heated, they were stirred with a large. mooden-handled iron rod thrust through a hole in the loose-fitting cover. This cover also had a short central chimney to lead off fumes. and sometimes a thermometer. 'lhe manufacturing process usually began uith the melting of a hard fossil gum; the latter was crushed to approximately ½ in. lumps and 50 to 150-lb. charges of it were placed in the varnish kettle. As the kettle was heated to a final temperature of 330°–340° C., the gums, insoluble in oils before this running process, became pasty and eventually liquid. This was accompanied by a loss in weight varying from 20% to 35%.

At a critical point in the resin running process, which was determined solely by the judgment of the varnish maker. preheated linseed oil was added slowly while the gum was stirred vigorously. Because of the danger of fire, the gum kettle was removed from the fire while the oil was added. When all the oil was incorporated into the molten resin, the cooking was resumed until solution was complete; this point was judged to have been reached when a drop of solution appeared clear after it had cooled on glass. The driers (consisting of oxides or salts of lead, manganese or cobalt, or combinations of them, in amounts sufficient to provide from about 0.03% to 0.6% of metal based on the oil) were next added and the mixture further boiled until these were converted into soluble soaps and until, again in the judgment of the varnish maker, the desired degree of bodying, or polymerization. was obtained. The kettle was cooled at a safe distance from the fire, and the contents were thinned to a suitable consistency. The varnish was strained or filtered to remove insoluble material, pumped into storage tanks and allowed to age.

With the advent of the closed kettle method of alkyd resin processing in the late 1930s. varnish manufacture was modernized so that the resin was synthesized and combined with the oil in one operation. In this uniphase or in situ process, the basic oil components such as glycerol, fatty acids and the basic varnish resin components such as rosin, polyol, maleic anhydride or phenolic syrups were charged and processed in a reaction kettle in a definite order, heated. cooled and thinned to a desired viscosity. The final product, prepared in one operation, is essentially the same as the varnish prepared classically. Performance properties differ slightly, but because of better control, favourable economics and availability of closed kettles, the in situ process is the preferred varnish-making process today.

Raw Materials.—Resins.—The term resin designates solid or semisolid mixtures of complex polymeric substances of closely related structure (see also RESINS). Hard fossil gums are natural resins that were exuded from ancient trees (some species of which are no longer extant) and were made hard, brittle and lustrous by centuries of burial or exposure.

Natural resins (other than shellac or rosin) originate mainly in the Congo, Zanzibar and north coast districts of Africa, in New Zealand. Malaya, the East Indies, the Philippine and nearby islands, and in South America. They are classified in various categories: as spirit soluble or (potentially) oil soluble; as fossil (such as animé from Zanzibar, kauri from New Zealand, Congo and East Indian copals), semifossil (East India, of the dammar family) and recent, or from living trees (dammar, sandarac, accroides, soft Manilas, elemi and mastic); and according to degrees of hardness and insolubility, depending usually upon their age. Amber, from the shores of the Baltic, has long been too rare for use in varnish.

Ester gum, the earliest synthetic resin, was made (about 1900) by esterifying rosin (essentially abietic acid) with glycerin. By cooking the gum with tung oil in lengths of 40 gal. to 50 gal., it was possible to make spar varnishes (so named because they were suitable for use on spars and masts of ships) that dried hard overnight and were not injured by boiling water or long immersion in cold water. About 1910, coumarone-indene polymers (made from coal-tar light oil) and phenol-formaldehyde-rosin-glycerin (modified phenolic) resins were introduced. These brought still faster drying rates, embodied in the so-called four-hour varnishes. but they tended to discolour on exposure. In 1928 the first "100% phenolic" oil-soluble resin appeared, a thermoplastic condensate of para-phenylphenol with formaldehyde: this was followed later by the introduction of a number of resins of better colour retention made from alkyl-substituted phenols. With these resins, 20-gal. varnishes were more durable than longer ones, reversing the usual rule; compared with the other varnishes of that period, they showed remarkable resistance to water and chemicals.

Similar in general properties to the modified phenolics are the maleic ester gums or maleic alkyds (glycerides of an adduct of rosin with maleic or fumaric acid). They are pale, hard, colour-retentive and find use in lacquers as well as oil varnishes. New ways were found of improving rosin by (1) hydrogenation or dehydrogenation; (2) polymerization; or (3) esterification with pentaerythritol, sorbitol and other polyhydric alcohols.

The most important group of synthetic resins are the alkyds, basically the chemical combination of a polyhydric alcohol (*e.g.*, glycerol, ethylene glycol, pentaerythritol) with a polybasic acid (such as phthalic, maleic or sebacic acid) and a fatty acid (or mixture of acids such as those of linseed, soybean or castor oils). The alkyd resins can replace, in part or in whole, the blend of natural fossil or other hard gum with drying oils of the earlier varnish type. By changing each of the three types of ingredients and their relative proportions, the properties of alkyds can be modified over a wide range extending from hard and brittle to extremely flexible, tough and durable. In the late 1940s, epoxy resins, made by polymerizing the product that results from reacting bisphenol A with epichlorohydrin, provided additional hardness, adherence, flexibility and alkali resistance. This polymer has residual hydroxyl groups and may be combined with fatty acids, amines or polyamides to enhance these properties. Because of the superior performance of the modern synthetic resins, the classical oil varnishes were slowly replaced by their synthetic counterparts.

Varnish Oils.—Varnish oils are film formers consisting of naturally occurring triglycerides of unsaturated fatty acids. These comprise slow-drying oils with isolated double bonds (soft oils, *e.g.*, linseed, fish, safflower, soybean, tobacco seed oils) and reactive oils containing conjugated double bonds (hard oils, *e.g.*, tung, oiticica. dehydrated castor oils). (Double bonds are conjugated when separated from one another by a single bond.) In addition, there are the chemically modified oils such as the soft oils modified by maleic anhydride, copolymer oils, nonglycerin synthetic oils and isomerized oils.

For the manufacture of varnish, the natural oils (other than tung and oiticica) are refined by heating them with small amounts of lye or sulfuric acid, which precipitates the traces of chlorophyll and mucilaginous matter (chiefly phosphatides) remaining when the oil is pressed from the seed; otherwise a discolouring break, or cloud, forms during the cooking of the varnish. Sometimes the oils are bodied (polymerized) before incorporation into varnishes; or they may be blown with air, introduced through perforated pipes, at temperatures of 60° to 120° C., causing partial oxidation and thickening. Boiled oil is usually made by dissolving small amounts of soluble driers in linseed oil and then heating the mixture at moderate temperatures. In the early stages of the varnish-cooking process, the oils serve as resin solvents. This property of the oils is directly related to their degree of unsaturation; tung oil is the best and unbodied soybean oil the poorest. When soft oils are bodied, the relation is reversed.

Solvents.—The combined resin-oil blends are quite viscous, hence they must be diluted with volatile organic liquids. Historically, spirits of turpentine was the earliest and most commonly employed solvent. By 1930 it became too scarce and expensive to be used generally as a paint and varnish solvent. Distillates from petroleum in approximately the same boiling range (155°–175° C.), called white spirits or mineral spirits, almost entirely replaced it. These distillates, consisting mostly of aliphatic hydrocarbons, are weaker solvents than turpentine for some of the highly polymerized synthetic resins or oxidized oils and may produce cloudiness or precipitation. The tendency to produce cloudiness can be offset by the use of toluene, xylene or high-boiling aromatic hydrocarbons either alone or in conjunction with the aliphatic thinner. Special application conditions, such as spraying, dipping, tumbling, roller coating, etc., require that the thinner employed be the one most suitable for the method.

Miscellaneous.—As catalysts for the oxidation and polymerization reactions, soluble salts or soaps (*e.g.*, resinates, linoleates, naphthenates) of metals with two valence levels (especially cobalt, manganese and lead) are effective. Other elements, such as iron, vanadium, zinc (for hardening) and calcium (to minimize wrinkling), are sometimes employed. Waxes or ultrafine silica produce flat or matte finishes without reducing transparency. Modern varnishes may include minute amounts of surface-active agents to modify application properties; antioxidants to reduce the tendency to skinning; and other additives for special purposes.

VARNISH TREE, a name applied to various trees that yield a milky juice from which varnish or lacquer is prepared, including such genera as *Ailanthus, Aleurites, Firmiana* and *Koelreuteria.* The name is, honever, most correctly applied to the varnish or lacquer tree *(Toxicodendron verniciflmum)* of China and Japan. On being tapped this tree exudes a thick milky emulsion which has the peculiar property of drying only in a moist atmosphere. From this is obtained the lacquer used in producing the highly polished woodenware of China and Japan with the hard and durable coats that are unaffected by water. This tree is a close relative of poison ivy (*q.v.*) and poison sumac, and is also highly poisonous. *See* also POISONOUS PLANTS. (J. M. BL.)

VARNUM, JAMES MITCHELL (1748–1789), American Revolutionary War general, was born at Dracut, Mass., on Dec. 17, 1748. He graduated from Rhode Island college (later Brown university) in 1769 and two years later was admitted to the bar. He soon became known for his courtroom eloquence. After serving as colonel and later as brigadier general of Rhode Island troops, he was appointed brigadier general in the Continental army in 1777. He held various commands and won commendations, though he was unsuccessful in defending Fts. Mercer and Mifflin on the Delaware river. During the winter of 1778 he was with George Washington at Valley Forge and then served in the campaign in Rhode Island. Varnum resigned from the Continental army in March 1779 but served as major general of Rhode Island militia from 1779–88. He was also a member of the continental congress at various times. In 1787 he was appointed U.S. judge in the Northwest Territory, migrated there and helped write a code of territorial laws. He died at Marietta, O., on Jan. 10, 1789. (H. H. P.)

VARRO, MARCUS TERENTIUS (116 B.C.–27 B.C.), a man of immense learning and a prolific Latin writer mostly of works of scholarship, was born probably at Reate in the land of the Sabines in 116 B.C. He was a pupil of the earliest Roman philologist, L. Aelius Stilo, and at Athens of the Academic philosopher Antiochus of Ascalon. He was not attracted to a political career, but he played some part in public life and became a praetor. He served under Pompey in the campaign against the rebel Sertorius in Spain in 76 and was Pompey's pro-quaestor in that country. In 67 he served under Pompey in the war against the pirates.

In 59 Varro wrote a political pamphlet entitled *Trikaranos* ("The Three-headed") on the coalition of Pompey, Caesar and Crassus. In this year also he was a member of the Board of Twenty charged with the assignment of grants of land to veterans in Campania. He fought for Pompey in Spain in 49 but without success Caesar pardoned him and in 47 Varro dedicated to him his *Antiquitates rerum divinarum* (the second part of the *Antiquitates rerum humanarum et divinarum*) and was appointed by Caesar librarian of a collection of books which he intended to establish. In 43 Varro was outlawed by Antony; his books were plundered, but his life was spared. He spent the rest of his life in study and writing.

Works. — It has been estimated that Varro wrote about 74 works which together formed about 620 books. They included works on agriculture, grammar. Roman history and antiquities, geography, law, rhetoric, philosophy, astronomy, education, history of literature and drama; also included were satires, poems, orations and letters.

The only complete work of Varro which has survived is his Res *rusticae* in three books, a work written in Aristotelian dialogue form when he was in his 80th year. The first book is concerned with agriculture proper, the second with the larger animals and the third with the smaller stock of a farm such as birds, bees and fish. Each of the three books has its own setting. Varro's aim was to foster a love of country life and to produce a work of practical instruction; but he took pains to give it literary merit. He is no great artist and his liking for headings and subheadings is tedious, but the introductions are particularly attractive, the dialogue is sometimes brisk and a vein of rough humour runs through the work. Varro owed something to his own experience and to what others had told him, but he depended much on Greek and Latin authors.

Of Varro's *De lingua Latina,* a dry discussion in 25 books of etymology, accidence and syntax in an unpolished style, there remain, apart from short fragments, only books v to x and there are considerable gaps in these six books. Books ii to iv were dedicated to Varro's quaestor P. Septimius and probably formed an earlier smaller work. The other books and the work as a whole were dedicated to Cicero. The work was in three main parts after an introduction (book i). The first consisted of six books in two triads concerning etymology. The first triad discussed what was to be said for and against etymology as a branch of learning and examined its usefulness and its nature. The second triad, books v to vii, discusses the origin and sources of words, words referring to places and objects in places, words referring to time or having some idea of time and poetic expressions. The second part was concerned with derivations of words from other words, including stem derivation, the declension of nouns and the conjugation of verbs.

The first triad discusses in particular the principles of anomaly based on usage and of analogy based on relation of form to form and presents a resolution of the conflicting views of anomalists and analogists. The second triad discussed, in the light of the conclusions of the first triad, nouns of place and similar terms, words concerned with time, especially verbs, and poetic words. The last 12 books were given to syntax. Varro was ignorant of the principles of phonetic change and he produced absurd derivations because he was guided by superficial resemblances. But sometimes his knowledge of old forms led him to true identifications.

Although he was an analogist, he saw the limitations of analogy. His work is not only of interest as a study of language but it also contains valuable incidental information on many subjects.

Of the *Saturae Menippeae* in 150 books some 90 titles and nearly 600 fragments have survived. They are humorous medleys in mixed prose and verse in the manner of the Cynic philosopher Menippus of Gadara of the 3rd century B.C. The titles of these treatments of serious matters in comic form in lively and varied settings are often Greek with, or without, a Latin title as well. Some are drawn from mythology, as *Meleagri, Endymiones, Tithonus, Eumenides;* some are proverbs or maxims, as *Dis paides hoi gerontes* ("Old Men Are in Their Second Childhood"), *Gnothi seauton* ("Know Thyself"), *Nescis quid vesper serus vehat* ("You Do Not Know What Evening May Bring"). The subjects of the satires range from eating and drinking ("The Pot Has Its Limit or On Drunkenness"; "On Eatables"; "The Water-Dog") to literature ("Parmeno") and philosophy ("The Voyage"; "On Philosophical Sects"; "A Battle of Words"; "Shadow-Boxing"; "The Award of the Arms"). Varro shows himself a man of the old stamp making fun of the follies and absurdities of modern times. He preaches a simple life of old-fashioned Roman virtue and piety and opposes luxury and philosophic dogmatism. He freely uses archaic and colloquial words and proverbial expressions.. His use of Greek has parallels in the satires of Lucilius and the letters of Cicero. He shows considerable skill in handling several metres and poetic manners. In his styles both the new and the old are found.

Varro can write like this (fragment 36):

> non fit thesauris, non auro pectus solutum;
> non demunt animis curas ac religiones
> Persarum montes, non atria divitis Crassi

("Neither treasure nor gold can set free the heart, nor can the golden mountains of Persia or the halls of rich Crassus cure worry and fear") and like this (fragment 111):

Vino nihil iucundius quisquam bibit:
hoc aegritudinem ad medendam inuenerunt,
hoc hilaritatis dulce seminarium,
hoc continet coagulum conuivia

("Nobody has drunk anything more pleasant than wine. Men found this a cure for sickness, a sweet nursery of mirth. Wine is the bond that binds the banquet")

and like this (fragment 375):

ante auris modo ex subolibus parvuli intorti demittebantur sex cincinni, oculi suppaetuli nigellis pupulis liquidam hilaritatem significantes animi, rictus parvissimus ut refrenato risu roseo

("Before her ears just six little curls hung down from close-bound hair. Her eyes with dark pupils sideways glancing showed the bright gaiety of her spirit. Her mouth was tiny and as if she was checking a rosy smile")

The loss of all but fragments of these satires is much to be regretted both by the historian and by the student of language and literature.

It is possible to mention here only a few of Varro's many lost works. His most famous work in the field of scholarship was his *Antiquitates rerum humanarum et divinarum,* in *41* books, the fullest work on Roman antiquities in Latin literature. Another work which had great influence in later generations was an encyclopaedia of *artes liberales.* The work was entitled *Disciplinae* (in nine books) and embraced grammar, dialectic, rhetoric, geometry, arithmetic, astronomy and music (the subsequent *trivium* and *quadrivium, i e.,* groups of three and four sciences) with medicine and architecture. Varro's *Hebdomades vel de imaginibus,* in 15 books, was an illustrated biographical dictionary containing 700 portraits of Greeks and Romans in equal numbers each with an epigram and a text in prose. It seems to have been the first illustrated book in Latin. Varro may have been influenced by some contemporary Greek illustrated botanical books. Varro's *Logistorikoz,* in 76 books, consisted of discussions on such matters as education, fortune, health, history, probably enlivened by evidence drawn from history or personal experience. Each aork had a double title—the name of a person and the theme, as *Sisenna de historia* or *Marius de fortuna.* Varro's works on literary subjects included a work on Plautus.

Purpose and **Influence.**—Varro was Rome's greatest scholar and his eminence was recognized in his lifetime. In the library founded at Rome by Asinius Pollio his was the only statue of a living person, and Cicero paid him a warm tribute in the course of which he says that he enabled the Romans at last to realize who and where they were when they were straying about like visitors (*Academica* i: *3,* 9). He was astonishingly many-sided. He invented the new literary form of the *Logistorikos* and was a capable writer of verse. His vast learning extended beyond the nine disciplines of his encyclopaedia to law and geography. But his greatest interest was in Latin philology and Roman antiquities. Unlike the Hellenistic scholars, whose methods of investigation he followed, he was inspired by a deep patriotism. Written not only with a love of learning but also with a warm feeling for Rome's past history, his work was intended by its moral and educational quality to further Roman greatness He desired to link a coming epoch with the glorious past of the Roman people and his works must have greatly influenced men's minds before and after the founding of the principate.

VARTHEMA (BARTHEMA, VERTOMANNUS, etc.), **LUDOVICO** DI, of Bologna (*fl.* 1502–1510), Italian traveller and writer, left Europe near the end of 1502; early in 1503 he reached Alexandria and ascended the Nile to Cairo. From Egypt he sailed to Beirut and thence travelled to Tripoli, Aleppo and Damascus, where he managed to get himself enrolled, under the name of Yunas (Jonah), in the Mameluke garrison—doubtless after adopting Islam. From Damascus he made the pilgrimage to Mecca and Medina as one of the Mameluke escort of the Hajj caravan (April–June 1503); he describes the sacred cities of Islam and the chief pilgrim sites and ceremonies with remarkable accuracy, almost all his details being confirmed by later writers. With the view of reaching India, he embarked at Jidda and sailed down the Red sea and through the Straits of Bab-el-Mandeb to Aden, where he was arrested and imprisoned as a Christian spy. He gained his liberty—after imprisonment both at Aden and Radaa—through the partiality of one of the sultanas of Yemen, made an extensive tour in south-west Arabia (visiting Sana, etc.), and took ship at Aden for the Persian Gulf and India. On the way he touched at Zaila and Berbera in Somaliland; he then (early in 1504?) ran across to the Indian port of Diu in Gujarat, afterwards famous as a Portuguese fortress. From Diu he sailed up the Gulf of Cambay to Gogo, and thence turning back towards the Persian Gulf made Julfar (just within the entrance of the gulf), Muscat and Ormuz. From Ormuz he seems to have journeyed across Persia to Herat, returning thence south-west to Shiraz, where he entered into partnership with a Persian merchant, who accompanied him during nearly all his travels in South Asia.

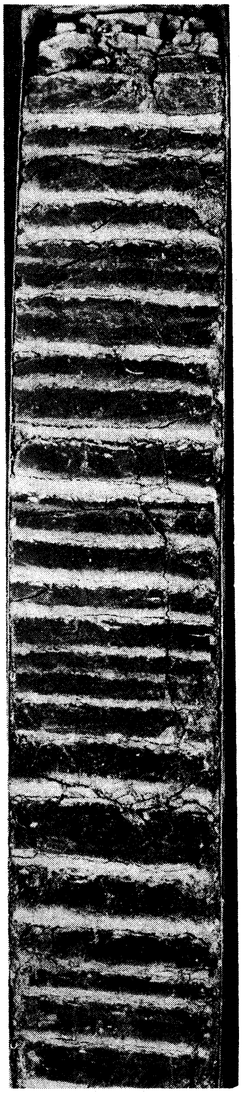
After an unsuccessful attempt to reach Samarkand, the two returned to Shiraz, came down to Ormuz, and took ship for India. From the mouth of the Indus Varthema coasted down the whole west coast of India, touching at Cambay and Chaul; at Goa, whence he made an excursion inland to Bijapur; at Cannanore, from which he again struck into the interior to visit Vijayanagar on the Tungabudra; and Calicut (1505?), where he stopped to describe the society, customs and institutions of Malabar, as well as the topography and trade of the city. Passing on by the "backwater of Cochin," and calling at Kulam (Quilon), he rounded Cape Comorin, and passed over to Ceylon (1506?). Though his stay here was brief (at Colombo?), he learnt a good deal about the island, from which he sailed to Pulicat, slightly north of Madras, then subject to Vijayanagar. Thence he crossed over to Tenasserim in the Malay peninsula, to Banghella, perhaps near Chittagong, at the head of the Bay of Bengal, and to Pegu, in the company of his Persian friend and of two Chinese Christians (Nestorians?) whom he met at Banghella. After some successful trading with the king of Pegu, Varthema and his party sailed on to Malacca, crossed over to Pider (Pedir) in Sumatra, and thence proceeded to Bandan (Banda).

From the Moluccas he returned westward, touched at Borneo, and there chartered a vessel for Java, the "largest of islands," as his Christian companions reckoned it. He notes the use of compass and chart by the native captain on the transit from Borneo to Java, and preserves a curious, more than half-mythical, reference to supposed Far Southern lands. From Java he crossed over to Malacca, where he and his Persian ally parted from the Chinese Christians; from Malacca he returned to the Coromandel coast.

Varthema was now anxious to resume Christianity and return to Europe; after some time he succeeded in deserting to the Portuguese garrison at Cannanore (early in 1506?). He fought for the Portuguese in various engagements, and was knighted by the viceroy Francisco d'Almeida, the navigator Tristan da Cunha being his "sponsor." For a year and a half he acted as Portuguese factor at Cochin, and in 1507 (?) he finally left India for Europe by the Cape route. Sailing from Cannanore, Varthema apparently struck Africa about Malindi, and (probably) coasting by Mombasa and Kilwa arrived at Mozambique, where he notices the Portuguese fortress then building, and describes the negroes of the mainland. He finally arrived safely in Lisbon.

Varthema's work (*Itinerario de Ludouico de Varthema Bolognese . . .*) was first published in Italian at Rome in 1510 *(ad instãtia de Lodouico de Henricis da Corneto Vicẽtino).* Other Italian editions appeared at Rome, 1517, at Venice, 1518, 1535, 1563, etc. The first English translation was of 1576–77 (in Richard Eden's *History of Travayle)*; an extract from Varthema was inserted in Samuel Purchas's *Pilgrimage* (1625–26); and in 1863 appeared the Hakluyt Society edition by J. W. Jones and G. P. Badger (*Travels of Ludovico di Varthema*). (C. R. B.)

VARVE ANALYSIS. A varve is the distinguishable annual deposit of a sediment. It consists of two or more laminas of different grain-size, material, chemical composition or colour. Simple varves superficially resemble annual rings in wood.



BY COURTESY OF ERNST ANTEVS

SAMPLE OF VARVED GLACIAL CLAY FROM STEEP ROCK LAKE, ONTARIO, SHOWING (LIGHT) SUMMER LAYERS AND (DARK) WINTER LAYERS

Varves form under various conditions: *e.g.,* by seasonal changes in organic or chemical sedimentation; as a result of a spring flood and of otherwise moderate stream flow (postglacial varves in bays of the northern Baltic); by summerly influx of mud from a glacier into a lake with the coldest water (less than 39.2' F.) at top (normal glacial varves).

Varves of any kind may be counted, and from this count the rate of sedimentation and the time represented can be determined. Varves of some kinds may be used for chronology building. The most important are Gerard de Geer's chronology of the last ice retreat from Sweden, Ragnar Lidén's postglacial chronology of northern Sweden (the past 8,560 years), and Ernst Antevs' partial chronology of the deglaciation of North America. The method devised by De Geer is described below.

Glacial varves formed in cold lakes from mud brought by glacial streams. The relatively coarse fractions of the mud sank quickly, making a silty summer lamina, while the fine: colloidal portions settled to form a greasy, usually dark-coloured lamina during the quiet of the winter. A lamina couplet is a varve. This frequently averages one inch in thickness. Since the proximal limit of a varve was the ice edge, and since this normally receded, the varves cover each other as the shingles on a roof, and they may extend for tens of miles from the ice.

Series of varves can be measured in stream bluffs, brickyard clay pits and other exposures. The clay wall, for example, is smoothed so that the varve limits stand out sharply. A strip of thick, tough paper is pinned to the wall, and the varve limits are marked on the strip. It is desirable. if possible, to measure long continuous series of varves from the substratum.

These measurements are graphed on paper with lines spaced exactly 5 mm. Each consecutive varve is marked on a line from the edge of the paper, and the marks are connected. The resulting curve has characteristic features. maxima and minima reflecting the amount of deposition and ice melting during the individual years. Therefore. varve graphs of measurements made up to tens of miles apart may be correlated. If the bottom varves were measured, the number of those present only at the site first uncovered gives in years the time of the ice retreat from the distal to the proximal site. Since the amount of the annual ice melting was largely controlled by the total warmth, the varve graphs and the rate of the ice retreat furnish data on the summer temperatures.

See GEOCHRONOLOGY; MAN, EVOLUTION OF: *Estimation of Geological Antiquity.* (ER. AN.)

VASA (VAASA or NIKOLAISTAD), a seaport of Finland in 63° 6' N., 21° 36' E., on the east coast of the Gulf of Bothnia. Pop. (1960) 42.688. It is the chief town of a department of the same name. Vessels enter from the sea at Rönnskär, 26 mi. distant, and the channel is safe for vessels drawing 22 ft. The exports are timber, tar, etc., and the imports coal and salt, and there is a ship-repairing yard. The town was founded in 1606, and after its destruction by fire in 1852 was rebuilt'nearer the shore.

VASARI, GIORGIO (1511–1574), Italian painter, architect and writer, whose main distinction rests on his valuable history of Italian art, was born at Arezzo on July 30, 1511. At a very early age he became a pupil of Guglielmo da Marcilla, a skillful painter of stained glass. At the age of 13 he went to Florence, where he studied under Michelangelo, Andrea del Sarto and Baccio Bandinelli, aided by the patronage of the Medici princes. In 1531 he visited Rome in the suite of Ippolito Cardinal de' Medici and studied the works of Raphael and others of his school. The paintings of Vasari were much admired, and many still exist, the most important being the wall and ceiling paintings in the great hall of the Palazzo Vecchio in Florence and his frescoes on the cupola of the cathedral. He died at Florence on June 27, 1574, and was buried in the chapel of S. Giorgio in the Pieve of Arezzo.

Personally Vasari was a man of upright character, always ready to appreciate the works of others; in spite of the very different taste of his time, he expressed a warm admiration of the works of Giotto, which is very remarkable.

As an art historian of his country he must always occupy the highest rank. His great work, *Delle Vite de' più eccellenti pittori, scultori, ed urchitettori (Lives of the Most Excellent Italian Architects, Painters and Sculptors),* was first published in 1550, and afterward partly rewritten and enlarged in 1568. It was dedicated to Cosimo de' Medici, and was printed at Florence by the Giunti; it is a small quarto illustrated with many woodcut portraits. This first edition of the complete work is usually bound in three volumes, and also contains a very valuable treatise on the technical methods employed in all branches of the arts: entitled *Le Tre Arti del disegno, cioè architettura, pittura, e scoltura.* Vasari's biographies are written in a very pleasant style, interspersed with amusing stories. With a few exceptions his judgment is acute and unbiased. The work in any case remains a classic; however. it may be supplemented by the more critical research of modern days.

Vasari gives his own biography at the end of his *Vite*, and adds further details about himself and his family in his lives of Lazzaro Vasari and Francesco Salviati.

The first edition of his *Vite* was issued by the Torrentino Press (1550). The best edition is that published at Florence by Milanesi (1878–82), which embodies the valuable notes in the earlier edition by Le Monnier (1846). The *Lives* has been translated into French, German and English.
