Let us now consider the effect of only one tide-generating body, such as the moon. As demonstrated in the previous section, the tide-generating forces of the moon can be specified completely by the shape and geographic orientation of the tidal ellipsoid, whose major axis is oriented along the line joining the centres of earth and moon. Now for the moment, let us consider what would happen if the moon remained at a constant distance from the earth and revolved about the earth in the equatorial plane with constant speed. An observer located at any given geographical position would experience two maxima and two minima of the equilibrium tide each lunar day. The amplitude would be a maximum at the equator and would decrease with increasing northern or southern latitude to a value of zero at the poles. The rise and fall of the equilibrium tide would be approximately harmonic with speed $n = 2(\gamma-\sigma)$ where γ denotes the angular speed of the earth's rotation relative to the stars and σ the mean speed of revolution of the moon about the earth; and the equilibrium tide would be represented very closely by a single harmonic constituent. Since the moon's speed of revolution is small compared to the earth's speed of rotation. the period of this constituent is approximately semidiurnal. The moon's varying declination (angular distance from equatorial plane), varying apparent angular speed of revolution about the earth and varying distance from the earth cause many modifications in this simplified example.

If the moon revolved about the earth with constant angular speed at some constant declination not equal to zero, one of the two poles of the equilibrium tidal ellipsoid would be always in the northern hemisphere, and the other in the southern hemisphere. The two equilibrium high waters that a point on earth not on the equator would experience as the earth rotates would therefore not be equal, and the introduction of a new constituent of speed $n = \gamma-\sigma$, approximately diurnal, would be required. This effect is known as the diurnal inequality. The variable declination of the moon results from the moon's motion in an orbit whose plane intersects the earth's equatorial plane at an angle I. The lunar declination thus passes through a monthly cycle but since both north and south declinations have essentially the same effect; *i.e.,* that of decreasing the semidiurnal and increasing the diurnal contribution, the two constituents suffer a fortnightly modulation. Strictly speaking, such constituents cannot be considered harmonic, as there is implied in this term the invariability of amplitude. speed and epoch. These constituents can, however, be expressed precisely as the sum of a number of strictly harmonic terms, and more will be said about this point later.

The distance from earth to moon varies throughout a monthly cycle giving rise to a monthly modulation in the amplitude of the equilibrium tide. The maxima occur when the moon is at perigee, the point on the moon's orbit which is closest to the earth; the minima occur at apogee, when the moon is farthest from the earth. The time between successive lunar passages through perigee or apogee is the so-called anomalistic month, whose average length is 27.jj (mean solar) days. The speed of revolution of the moon about the earth varies inversely with the moon's distance according to Kepler's laws (see ORBIT). This causes the epoch of the equilibrium tide to vary according to the moon's position in its orbit, resulting in an apparent increase of period at apogee as compared to perigee. This monthly modulation of both amplitude and epoch of the equilibrium tide can again be expressed by a sum of purely harmonic constituents.

There are many other irregularities in the moon's motion, all of which can be expressed by the addition of more harmonic terms insofar as their effect on the equilibrium tide is concerned. The plane of the lunar orbit does not remain with constant orientation in space. Its movement is best described by the motion of the moon's nodes, which are the two points on the lunar orbit which lie on the plane of the ecliptic. Relative to the stars these nodes describe a westward motion known as the regression of the nodes, completing a cycle in about 19 years. Also, the major axis of the lunar orbit revolves eastward relative to the stars, completing a cycle in about nine years.

The solar effects are in every way analogous to the corresponding lunar effects.

Species.—In the above section it was seen that many cases arise where a constituent having a slow periodic variation of amplitude or epoch can be represented by the sum of two or more purely harmonic constituents. The speeds of these purely harmonic constituents will belong to the series, $n \pm \omega$, $n \pm 2\omega$, $n \pm 3\omega$, . . . , where n is the speed of the original constituent and ω is the speed corresponding to the fundamental period of variation of its amplitude or epoch. If ω is small as compared to n, the speeds of the purely harmonic constituents will cluster closely about the speed of the original constituent. In the case of the actual tide, most of the constituents are approximately semidiurnal, diurnal, or of a longer (fortnightly or longer) period of variation, and their amplitudes and epochs pass through a much longer period of variation than that of the actual constituent. As a result, the periods of purely harmonic constituents representing the equilibrium tide are clustered about 12 hr., 24 hr. and much longer periods, offering a logical basis for classification of the tidal constituents.

The scheme of .classification shown in Table I was developed by

George Darwin in 1882 and has been adopted by most of the world's tidal authorities. Within any given species the coefficient is proportional to the equilibrium amplitude, and this proportionality holds roughly between constituents belonging to different species. The subscript on the symbol designating the constituent refers to the species to which it belongs. The long-period constituents have no subscript, the diurnal species have the subscript "one," the semidiurnal species the subscript "two." In addition to the constituents tabulated in Table I, there are terdiurnal, 4-diurnal, etc., constituents in the equilibrium tide, but these are of much lower amplitude and are not of much importance on earth.

TABLE I.—Tidal Constituents

Symbol	Name	Speed	Speed in °/hr.	Coefficient
Long-period species				
Mf	Lunar fortnightly	2σ	1.098	.078
Ssa	Solar semiannual	2η	.082	.036
—	Nineteen yearly	N	.002	.033
Diurnal species				
K_1	Lunisolar	γ	15.041	.265
O_1	Larger lunar	$\gamma-2\sigma$	13.943	
P_1	Larger solar	$\gamma-2\eta$	14.959	
Semidiurnal species				
M_2	Principal lunar	$2(\gamma-\sigma)$	28.984	.454
S_2	Principal solar	$2(\gamma-\eta)$	30.000	.211
N_2	Larger lunar elliptic	$2\gamma-3\sigma+w$	28.440	.088
Kz	Lunisolar	2γ	30.082	.058

The earth's speed of rotation γ is the largest of all the parameters contributing to the speeds of the tidal constituents, and its numerical multiplier in the expression for the speed determines to which species a given constituent belongs. The other quantities in Table I which determine the speeds of the constituents are the mean motion of the moon σ, the mean motion of the sun η, the speed of revolution of the moon's nodes N, and the mean motion of the lunar perigee w. These quantities have a smaller effect and merely determine the period of the constituent within its species. It can therefore be said that the fundamental reason that the tidal constituents clump conveniently into species is that the day is much shorter than either the month or the year.

The equilibrium constituents of any given species all have the same geographical form. The long-period constituents are characterized by a standing wave symmetrical about the earth's axis. The polar regions oscillate in phase with each other and are 180° out of phase with the equilibrium tide in low latitudes. The two nodal lines lie along latitudes 35.26° north and south. The diurnal constituents have the form of a progressive wave rotating relative to the earth about its axis from east to west. At any given instant there are two maxima at opposite extremes of the earth and two minima similarly situated, all lying at latitudes 45° north and south on a great circle passing through the earth's poles. The amplitude of the diurnal equilibrium tide vanishes at equator and poles. The semidiurnal constituents also have the form of a progressive wave rotating about the earth from east to west. There are two maxima on the equator at opposite extremes of the earth and two minima also on the equator 90° from the maxima. The amplitude of the semidiurnal equilibrium tide is maximum at the equator and dies off with increasing latitude, vanishing at the poles.

Description of the Constituents.— Let us consider first the semidiurnal constituents. As can be seen from the value of their coefficients tabulated in Table I, the principal lunar constituent M_2 is the most important. The other semidiurnal constituents "beat" against M_2 giving rise to a modulation, the speed of which is equal to the difference of speeds of the two constituents. That is, the period of the modulation is the synodic period of the two constituents. The next strongest semidiurnal constituent is the principal solar constituent S_2, which beats against M_2 causing the fortnightly spring-neap modulation. Next comes the larger lunar elliptic constituent N_2 which beats with M_2 causing a monthly modulation of the latter associated with the variable distance between earth and moon resulting from the ellipticity of the moon's orbit. The lunisolar constituent K_2 actually represents the sum of two constituents, one of lunar the other of solar origin, which cannot be separated from each other by analysis because their periods are equal. The lunar part of this constituent beats with M_2 giving rise to a fortnightly modulation associated with the variable declination of the moon. It will be recalled that the amplitude of the semidiurnal part of the tide is at a maximum when the tide-generating body has zero declination. In similar fashion the solar part of the K_2 constituent beats with S_2 causing a semiannual modulation of this principal solar constituent which is associated with the variable declination of the sun.

The lunisolar diurnal constituent K_1 is similarly composed of a lunar and a solar contribution. The lunar part of this constituent beats with the larger lunar constituent O_1 causing a fortnightly modulation associated with the variable declination of the moon. It will be recalled that the amplitude of the diurnal part of the equilibrium tide vanishes when the tide-generating body has zero declination. Similarly, the solar part of the constituent K_1 beats with the larger solar constituent P_1 causing a semiannual modulation associated with the variable declination of the sun.

The constituents Mf and Ssa result from the variable declination of the tide-generating body and are at a maximum when this body is at zero declination. The lunar fortnightly constituent Mf thus reflects the variable declination of the moon, and the solar semiannual constituent Ssa similarly reflects the variable declination of the sun. In addition there is a small 19-year constituent which arises from the 19-year cycle in the regression of the moon's nodes, as well as many other minor long-period constituents.

In Darwin's harmonic development the tide-generating forces (the equilibrium tide) are not analyzed into strictly harmonic constituents; that is, the amplitudes and epochs of Darwin's constituents are not truly constant. They exhibit the 19-year cycle of the regression of the moon's nodes. However, during any one year the amplitudes and epochs vary so slightly that the constituents can be considered as true harmonic terms without incurring appreciable error. The nodal variation in amplitude is accounted for by taking the constituent coefficients c (those values tabulated in Table I) to be constant in time while denoting the true amplitude of the equilibrium constituents by the quantity fc where f is called the node factor and is the quantity which varies. The mean value of f is taken to be unity, and its values have been tabulated for each year for all important constituents. The value of f changes so slowly that it is adequate to take its mean value during any given year in place of its true value at any instant during that year.

In 1921 Doodson developed the equilibrium tide into a series of harmonic constituents whose amplitudes and epochs do not exhibit this 19-year cycle, and therefore do not need the artifice of node factors. For this reason it may be said that Doodson's development is more nearly perfectly harmonic than is Darwin's. Even though Doodson's development does not attempt to take into account such long-term variations as secular changes in the distance between earth, moon and sun, and geologic changes in sea level, it is doubtful that a more elaborate development will ever be needed for tidal work.

IV. DYNAMICS OF OCEAN TIDES

Equations of Motion.— The dynamical theory of tides introduced by Laplace in the 18th century has given much insight into the problem of tides in the ocean. The following assumptions and approximations are commonly introduced:

(1) The water is assumed to be homogeneous; (2) vertical displacements and velocities of the water particles are assumed small in comparison to the horizontal displacements and velocities; (3) the water pressure at any point in the water is given adequately by the hydrostatic law; *i.e.,* it is equal to the head of water above the given point; (4) all dissipative forces are neglected; and (5) the ocean basins are assumed rigid (as if there were no bodily tide), and the gravitational potential of the tidally displaced masses is neglected.

If assumptions (1) and (3) are valid it can readily be shown that the tidal currents at any locality are uniform with depth.

Take a to denote the radius of the earth and g the acceleration of gravity at its surface. Position on the earth's surface will be designated by the longitude ϕ and the co-latitude (angular distance from the north pole to the point under consideration) θ. Let h denote the depth of the ocean at any point, so that h is a function of θ and ϕ. Also, let ζ denote the elevation of the free surface at any point of the ocean above its mean level, and u and v the southward and eastward components of the tidal current, so that these three quantities are functions of θ, ϕ as well as of the time t. Then the equation of continuity, which expresses the condition that the volume of any mass of water must remain constant, may be written in the form

$$\frac{1}{5\sin\theta}\left\{\frac{\partial}{\partial\theta}(hu\sin\theta)+\frac{a}{\partial\phi}(hv)\right\}+\frac{\partial\zeta}{\partial t}=0 \qquad (1)$$

provided that the elevation of the sea surface is everywhere small compared to the depth of water. If this is not the case then h must be replaced by h $+\zeta$ in equation (1). This equation may be derived by expressing the condition that the net rate at which volume of water enters the sides of a vertical column is equal to the rate of increase of the volume at the top of this column by virtue of the time rate of increase of the elevation of the sea surface ζ. Along a coast line the condition that the tidal current have no component perpendicular to the coast must be satisfied.

The equations of motion are formed by equating the southward and eastward components of acceleration of the water particles to the sum of all the forces per unit mass acting on the water in the southward and eastward directions, respectively. The acceleration consists of three parts: the local acceleration; the field acceleration; and the Coriolis acceleration resulting from the earth's rotation. As an example, the southward component of acceleration is equal to

$$\frac{\partial u}{\partial t}+\frac{u}{a}\,\frac{\partial u}{\partial\theta}+\frac{v}{a\sin\theta}\,\frac{\partial u}{\partial\phi}-\frac{v^2}{a}\cot\theta-2\omega v\cos\theta$$

where the first term represents the local, the second, third and fourth terms combined represent the field, and the last term the Coriolis accelerations, respectively. Here ω represents the angular speed of the earth's rotation. At this point an additional assumption shown to be valid for tidal motion in true oceanic regions is introduced: that the field acceleration is negligible as compared to the local acceleration. In accordance with the foregoing approximations, the only forces acting on the water are the tide-generating forces and those attributable to the pressure gradient resulting from the slope of the sea surface. The southward and eastward components of the pressure gradient are given by

$$\frac{g\rho}{a}\,\frac{\partial\zeta}{\partial\theta},\quad \frac{g\rho}{a\sin\theta}\,\frac{\partial\zeta}{\partial\phi},$$

p being the water density, and the southward and eastward components of the tide-generating force are given by

$$\frac{g\rho}{a}\,\frac{\partial\bar{\zeta}}{dB'}\quad \frac{g\rho}{o\sin\theta}\,\frac{\partial\bar{\zeta}}{a+'}$$

where $\bar{\zeta}$ represents the elevation of the equilibrium tide. This quantity is a function of θ, ϕ and t and is assumed known as it can be deduced from knowledge of the relative movements of the earth, moon and sun. The equations of motion can then be written in the form

$$\begin{aligned}\frac{\partial u}{\partial t}-2\omega v\cos\theta&=-\frac{g}{a}\,\frac{\partial}{\partial\theta}(\zeta-\bar{\zeta})\\ \frac{\partial v}{\partial t}+2\omega u\cos\theta&=-\frac{g}{a\sin\theta}\,\frac{\partial}{\partial\phi}(\zeta-\bar{\zeta}).\end{aligned}\qquad (2)$$

The equations (1) and (2) serve to determine completely, at least in theory, the tidal currents and elevation over the entire oceans and for all times, given a complete description of the tide-generating forces and the boundaries of the ocean basins. In practice, however, such a general solution has never been obtained owing to the complicated nature of the distribution of sea and land masses and the varying depth of water. For this reason tidal research has been based primarily on observations and general principles (such as linearity, etc.) derived from theory.

It may be noted that these equations are linear in u, v, ζ and $\bar{\zeta}$ with the result that the tide-generating forces may be separated into several constituents, the sum of whose effects are exactly equivalent to the effect produced by the sum total of all the tide-generating constituents. Indeed, as has already been pointed out, this is the basis of the harmonic development of the tide. Let us review under what conditions the ocean tide is truly linear and under what conditions this linearity breaks down. Unless the elevation of the sea surface above its mean position is always small as compared to the mean depth h, equation (1) becomes nonlinear. Similarly, if the field acceleration becomes so large it is no longer negligible as compared to the local acceleration equations (2) become nonlinear. This is most likely to occur in regions of large tidal currents with a large spatial rate of change (current shear). Nonlinear dissipative forces may be another source of nonlinearity. All these effects are quite small in the vast oceanic regions but tend to become larger in regions of shallow water and in the vicinity of the coast line, and consequently are referred to as shallow-water tides.

As to the other approximations, that of neglecting all dissipative mechanisms (4) is not a very good one, but more will be said about this point in the section on Tidal *Friction.* The bodily tides of the earth invalidate to a certain extent assumption (5) by virtue of a small variable movement of the sea floor and of the earth's own gravitational field. If ζ_e designates the variable elevation of the sea floor above its mean position, equation (1) will stand unaltered if we take ζ to denote the elevation of the sea surface relative to the sea floor. but in the formulas for pressure gradients ζ must be replaced by $\zeta+\zeta_e$. The disturbance in the gravitational forces brought about by the displacements of water and solid earth must be accounted for by adding a term $\bar{\zeta}_e$ to $\bar{\zeta}$. Inhomogeneities in the sea water have been neglected according to assumption (1), but may have a more important effect in tidal motions than has been anticipated. At any given time of the year a large part of the ocean is covered by a nearly homogeneous layer of light, warm water 50 to zoo m. thick. Such stratification of the sea water may influence the vertical structure of the tidal current with resulting deviations from their generally assumed uniformity with depth. Bottom friction will also introduce vertical shear in the tidal current.

Suppose now that we consider the ocean's response to one harmonic constituent of the equilibrium tide. If we take a long-period constituent, $\bar{\zeta}$ will have the form of a standing wave over the entire earth. A constituent of any other species will have the form of a progressive wave rotating relative to the earth about its axis in the westward direction. Such progressive waves can, however, be expressed as the sum of two standing waves separated in longitude by go°, and separated in time also by go°. In any case, therefore, it will suffice to express $\bar{\zeta}$ in the form

$$\bar{\zeta}=H_0\cos n(t-\tau_0)$$

where n and τ_0 are absolute constants and H is a function of geographic position but independent of time. The actual response of the ocean will then be the sum of a number of solutions to such inputs. The solutions for the tidal elevation ζ and current u, v from equations (1) and (2) will have the form

$$\zeta=H\cos n(t-\tau)$$
$$u=U\cos n(t-\tau_1),\qquad v=V\cos n(t-\tau_2),$$

where H, U, V, τ, τ_1, and τ_2 are all functions of geographical position only. While it is not feasible to actually determine these functions analytically, if their values are determined for a certain location on the earth by appropriate analysis of tidal observations. the response to the constituent under consideration could be predicted for all time. In the case of the tidal elevation, wherever Hand τ have been determined for all important constituents, the tidal elevations there can be predicted for any time. It may be remarked that at a given place H_0 and H are generally quite different; *i.e.*, the true tide bears little resemblance to the equilibrium tide.

Nonlinear Distortion (Shallow-Water Tides).—At places where the tidal elevation becomes appreciable as compared to the water depth, or other nonlinear effects occur, the principle of superposition breaks down. One might think that under these circumstances the concept of harmonic constituents would be completely useless, but it has been found possible to retain this concept provided that additional constituents, the so-called shallow-water tides, be included. The regions where this phenomenon occurs are generally confined to rivers, estuaries and shallow gulfs. The shallow-water constituents are not produced by the direct action of the tide-generating forces, but by the distortion attributable to shoal water of already existing tidal constituents which have been formed in the ocean. In fact, if the region of distortion is small enough (as it usually is), the tide-generating forces have little or no direct effect on the shallow-water tide.

It is no longer correct to consider separately the reactions to individual equilibrium constituents, but let us take the simple example of only one equilibrium constituent in order to gain insight into the problem. The response of a nonlinear system to the harmonic forcing constituent will not be harmonic, but at least it will be periodic having the same period as the forcing or primary constituent. If $2\pi/\sigma$ is the period of the primary constituent, it is well known from the theory of Fourier series that a periodic function of this period can be expressed as the sum of purely harmonic terms having speeds a, za, 3a, etc. Extending this idea to the actual situation one should expect to find shallow-water constituents having periods of one-half, one-third, etc., of those of the major tidal constituents. The shallow-water constituents obtained in this way are called overtides because of their analogy to overtones in acoustics. The same symbol is used to designate these overtides as is used to designate the equilibrium constituent which gives rise to them, and again the subscript designates the species (approximate number of periods in a day) to which the overtide belongs. For example the constituent M_2 gives rise to the series of overtides M_4, M_6, etc., and K_1 gives rise to the overtides K_2, K_3, etc. In some cases an overtide will have exactly the same period as another equilibrium constituent and it will be impossible to separate the two by harmonic analysis. For example, K_2 represents the lunisolar semidiurnal constituent, but an overtide of exactly the same period as K_2 is produced by nonlinear distortion of the lunisolar diurnal constituent K_1. In this and in similar cases the symbol K_2 (referring to the actual tide) represents the combined effect of both the linear reaction to the equilibrium constituent K_2 and the overtide.

The theory of progressive shallow-water waves of finite height has been used to estimate the relationship between the amplitudes of the overtides and primary tide. The amplitude of the nth overtide is found to be proportional to the nth power of the amplitude of its primary at any given place, as the amplitude of the primary varies in time. For example, if the range of the semidiurnal tide is twice as great during the spring tides as during the neap tides, the range of the quarter-diurnal overtide resulting from distortion of the semidiurnal tide will be approximately four times as great during the spring tides as during the neaps. The range of the 6-diurnal overtides will be eight times as great during the spring tides, etc. As to the 19-year nodal variation in amplitude, the node factors f of the overtides bear a relation to those of the primary as illustrated in the following example in the case of the overtides of the constituent M_2:

$$f(M_4) = [f(M_2)]^2, \quad f(M_6) = [f(M_2)]^3, \text{ etc.}$$

The above relations seem to be confirmed fairly well in most cases by tidal observations in spite of the fact that assumptions in the theory from which they have been derived are far from fulfilled. For example, in many regions where overtides are important, such as some rivers and estuaries, the tidal wave has more nearly the form of a standing wave than that of a progressive wave, but the theory for standing shallow-water waves of finite height has not been adequately developed. Also, the nonlinear effects caused by one constituent cannot, strictly speaking, be superimposed on those caused by another.

The nonlinear interaction between two or more primary constituents can be accounted for by the inclusion of compound constituents. In the case of two interacting primary constituents having speeds σ_1, and σ_2, a series of compound constituents will result, having speeds $\sigma_1 \pm \sigma_2$, $\sigma_1 \pm 2\sigma_2$, $2\sigma_1 \pm \sigma_2$, etc., including all possible combinations of the form $a\sigma_1 \pm b\sigma_2$, a and b being integers. The relationship of the amplitudes of the compound constituents to those of their primaries has been approximated by assuming that the system responds like a power-law filter; *i.e.*, like a system whose output is equal to a polynomial function of the input. In this way the relative importance of the compound constituents of any given species as well as the dependence of their node factors on those of the primary constituents can be evaluated. No general conclusions can be drawn concerning the relative importance of two compound constituents belonging to different species.

TABLE 11.—Shallow-Water Constituents

Symbol	Speed	Speed in °/hr.	Node factor
$2SM_2$	$2\gamma+2\sigma-4\eta$	31.016	$[f(M_2)]^2$
MNS_2	$2\gamma-5\sigma+2\eta+\varpi$	27.424	$f(M_2)$
MK_3	$3\gamma-2\sigma$	44.025	$f(M_2)f(K_1)$
MK_3	$3\gamma-4\sigma$	42.927	$[f(M_2)]^2f(K_1)$
M_4	$4\gamma-4\sigma$	57.968	$[f(M_2)]^2$
MS_4	$4\gamma-2\sigma-2\eta$	58.984	$f(M_2)$

Table II includes the more important shallow-water constituents, both overtides and compound constituents. In the table, only two of each of the semidiurnal, terdiurnal and 4-diurnal shallow-water constituents are given for illustration, but there are ports for which many others would be needed to give an accurate representation of the tide. In fact for some ports the number of these constituents that would be needed is so high that the harmonic method becomes impractical. It may be noted that the two terdiurnal constituents listed in Table II are given the same symbol. Actually there is some confusion as to the designation of the compound constituents. The designations given in Table II are based on the nomenclature used by the United States coast and geodetic survey.

V. ACTUAL TIDES IN THE OCEAN

Progressive Tides in Canals.—Let us consider a long narrow canal, open at both ends, along which a tidal wave is progressing. In accordance with the uell-known properties of progressive waves, the water particle velocity at the crests of the wave will be in the same direction as that of the propagation of the wave form, while the water particle velocity at the troughs will be in the opposite direction.

Now, the rotation of the earth tends to deflect any particle in motion to the right (in a horizontal plane in the northern hemisphere) relative to the earth with an acceleration proportional to the speed of the particle. This is the so-called Coriolis acceleration that was discussed above. In order to balance this Coriolis acceleration the water surface at the crest must slope upward to the right (in the northern hemisphere), if one is facing in the direction of propagation of the wave. Similarly, the water surface at the trough must slope upward toward the left. Therefore, the crests are higher and the troughs lower along the right coast of the canal, and at any point on the right coast of the canal there will be a higher range of the tide than for a point situated on the left coast.

The above considerations are substantiated by tidal observations in the English channel and Irish sea. The tidal wave progresses eastward through the English channel passing out through the Straits of Dover into the North sea. The tidal range is greater on the French coast (the right side) than on the English coast. In the Irish sea, the tidal wave progresses northward, and the tidal range is greater on the English and Welsh coasts (again the right side) than on the Irish coast.

Tides in Adjacent Seas.—If the region under consideration is small enough the tide within it is influenced predominately by the tide immediately outside the region and not appreciably by the direct action of the tide-generating forces. It is on the water of the great oceans that the gravitational forces of the moon and sun generate the greater part of the tide, while the tides in the small seas bordering the oceans can be considered as free waves.

A great deal of theoretical work has been done on the tides of adjacent seas, but invariably it is necessary to approximate the sea by some simple geometric shape. Nevertheless, many satisfactory explanations of the actual tide in small bodies of water have been obtained.

The theory of free long waves states that a tidal wave in a narrow canal of constant depth is propagated with a velocity of $\sqrt{gh}$, the wave length being given by the expression $T\sqrt{gh}$, where g is the acceleration of gravity, h is the water depth and T is the period of the wave (time interval between successive high waters). In the case of the tide, T will have approximately the value of 12 hr. for the semidiurnal tide, or 24 hr. for the diurnal tide.

Let us neglect, for the time being, the effect of the earth's rotation and consider a tidal basin of constant depth having rectangular shape with one end closed and the other end in communication with the ocean. Only motions parallel to the length of the basin will be considered. The tides within the basin are influenced by the boundary conditions (1) that the elevation at the mouth of the basin is at any instant the same as that in the ocean immediately exterior to the basin; and (2) that the horizontal orbital motion at the closed end vanishes. The situation is analogous to the acoustical problem of stationary oscillations within an organ pipe open at one end. The spatial distribution of amplitude of the oscillation is characterized by the positions of nodes, or places where there is no tidal oscillation of the water surface, or no pressure oscillation in the case of the organ pipe, and of antinodes or places where the oscillations attain their maximum amplitude. A standing wave in the pipe has an antinode at the closed end, while one quarter of a wave length away there is a node, and so forth, with nodes and antinodes alternating along the length of the pipe with a quarter of a wave length between them. If the open end is at or near a node the oscillation within the pipe attains a magnitude much greater than that outside the mouth of the pipe, and resonance is said to occur. Thus, in the case of the rectangular tidal basin, resonance would occur if the length L of the basin had any of the values

$$\tfrac{1}{4}T\sqrt{gh},\ \tfrac{3}{4}T\sqrt{gh},\ \tfrac{5}{4}T\sqrt{gh},\ \text{etc.}$$

Or, for a given length, resonance would occur if the period of oscillation had any of the values

$$\frac{4L}{\sqrt{gh}},\ \frac{4L}{3\sqrt{gh}},\ \frac{4L}{5\sqrt{gh}},\ \text{etc.}$$

but in actual practice the successive values have diminishing importance and usually only the first one, corresponding to a quarter wave-length basin, is considered. This is called the gravest free mode.

If the basin is less than a quarter of a wave length long, the entire basin oscillates with the same phase. If the length of the basin is between a quarter wave length and a half wave length, there is one nodal line and the oscillation at the head of the basin is 180° out of phase with that at the mouth. Every node line represents a phase change of 180°.

The Bay of Fundy on the east coast of North America has the greatest tidal range of any place on earth. and this fact is attributed to a resonance phenomenon based on the foregoing considerations. The shape of the Bay of Fundy is reasonably well approximated by a rectangular basin having a length of 170 mi. and a depth of 240 ft. The above relationships indicate that such a basin would have a resonance period of approximately $11\frac{1}{2}$ hr., which is very close to that of the semidiurnal tide. It should therefore be expected that the semidiurnal tide would be greatly magnified relative to the diurnal, and this is found to be the case. At certain places at the head of the bay the spring tide attains a range of 50 ft.

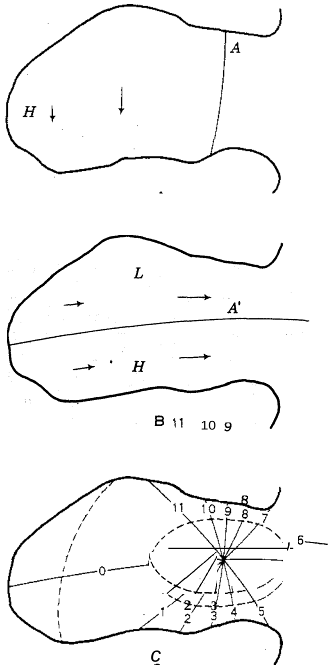

FIG. 2.— MOVEMENT OF THE TIDES IN A GULF. H INDICATES HIGH-WATER LEVEL, L LOW-WATER LEVEL. (SEE FURTHER TEXT FOR EXPLANATION.)

Elongated seas of variable depth and cross-sectional area also can be studied mathematically provided these quantities vary slowly enough along the length of the sea. Good agreement between theory and observation has been obtained for tides in the Gulf of California, the Red sea and other adjacent seas. The Gulf of California is computed to have a resonance period of approximately 25 hr., roughly that of the diurnal tide. The tide at the head of the gulf near the mouth of the Colorado river has been observed to be predominantly diurnal in character with a maximum range of approximately 20 ft. The computed variation of amplitude and phase of the M_2 constituent in the Red sea is in good agreement with the observed variation, and both theory and observations indicate the presence of a nodal line close to Port Sudan, near the mid-point of the sea's length.

To consider geostrophic effects (i.e., those resulting from the earth's rotation) it is necessary to take into account the Coriolis acceleration. Consider a standing oscillation in a gulf as shown in fig. 2A at the instant of high water at the head of the gulf. The curve A has been drawn through all points where the deviation of the water level from its mean is zero at this instant. One quarter period later the water is flowing out of the gulf. At this instant, in the absence of the Coriolis force, the elevation everywhere within the gulf would have its mean value (except for a small frictional effect), and the curve A would represent a nodal line. Actually, the elevation will be higher to the right of the outward flowing current, as is shown in fig. 2B, with the curve A' lying along points whose elevation is at the mean level. Continuity considerations show that there must have been currents flowing at the instant of high water within the gulf in order to produce the distribution of water level shown in fig, 2B. Possible directions for these currents are shown in fig. 2A.

At the intersection of the curves A and A' there will be no rise and fall of sea level, and such a point is known as an amphidromic point. Let it be assumed that the constituent under consideration

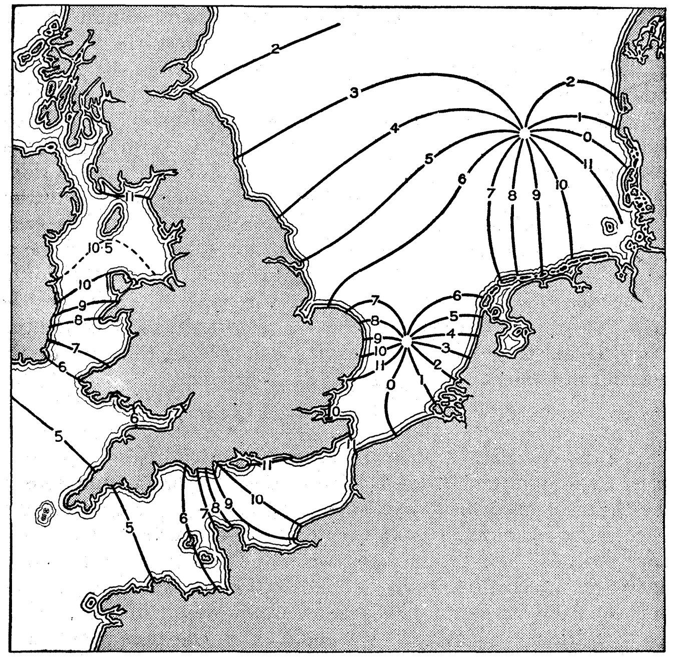

FIG. 3.— COTIDAL LINES FOR M_2 CONSTITUENT IN BRITISH SEAS. NUMBERS GIVE GREENWICH MEAN LUNAR TIME OF HIGH WATER

is a semidiurnal one, and divide its period into 12 equal time intervals called constituent hours, and let the zero constituent hour

FIG. 4.—COTIDAL CHART OF THE ATLANTIC OCEAN

correspond to the instant of high water within the gulf as depicted by fig. 2A. Fig. 2C then gives the curves along which high water occurs for each of the 12 constituent hours. Such curves are called cotidal lines. The hypothetical distribution of range of tide is indicated by the dashed curves, called corange lines, each of which connects points having equal range of tide. The amphidromic point, at which the tidal range is zero, lies in the centre of the concentric family of corange lines. The cotidal lines indicate the position of the crest of the tidal wave at any instant, and it is seen that this crest rotates in counterclockwise fashion (in the northern hemisphere) about the amphidromic point. Such amphidromic systems with counterclockwise movement of the tidal crest are characteristic also of the oceans and adjacent (large) bodies of water.

Geographical Distribution of the Ocean **Tide.**—Cotidal maps, such as the one described above, are useful in illustrating the distribution of tidal elevation in a body of water, but it should be kept in mind that such charts are, strictly speaking, useful only in describing a single harmonic constituent. In theory it would be necessary to have one complete cotidal map of the world's oceans for each and every tidal constituent in order to characterize completely the form of the tidal wave, or the rise and fall of water at every point in the ocean. The only constituent for which such charts have been prepared, to any extent, has been the M_2 constituent, which is somewhat representative of the other semidiurnal constituents.

Except along the boundaries of the oceans the tidal elevations are extremely difficult to measure, and what meagre knowledge we have of the geographic distribution of the tide in the whole ocean has been deduced principally by extrapolating from coastal tide stations and, where possible, making use of tidal current measurements. The equations of motion connect the tidal currents with the elevation gradients and external forces, including those of friction, and so from a knowledge of the currents and a law for the frictional forces the elevation gradients can be calculated. When the elevation is also known at a particular point, the directions of the cotidal and corange lines and also the distance apart of neighbouring members of these families of lines can be calculated. Such conditions are fulfilled for many coasts. If the elevation gradients can be calculated along a line which passes through one or more points at which the elevation is known, it is clear that the elevation can be calcuiated all along the line. In this way the semidiurnal (M_2) tide over the North and Irish seas was determined by Proudman and Doodson in 1923 (see fig. 3).

Cotidal charts for the M_2 constituent have been prepared for the oceans but they are uncertain, however, especially at large distances from the coasts and islands where tide gauge observations have been made. Tidal current determinations are rarely made in the open ocean. Another difficulty is that tide gauges are frequently located in sheltered bays or atoll lagoons where the time of high water may be delayed by as much as several hours. The cotidal chart of the Atlantic ocean shown in fig. 4 was prepared by Sterneck in 1920.

Mathematical solutions for the tide in ocean basins of simplified shapes have been obtained. Laplace in 1776 studied the dynamical problem of the semidiurnal tide in an ocean covering the entire earth and having constant depth. His solution takes into account the inertia of the water and the rotation of the earth. Some interesting aspects of this solution are summarized in Table III.

TABLE III.—*Laplace's Solution of the Dynamical Problem of the Semidiurnal Tide*

Depth (fathoms)	Ratio of elevation to equilibrium elevation at equator	Depth (fathoms)	Ratio of elevation to equilibrium elevation at equator
1,210	−7.4	4,840	11.3
2,420	−1.8	9,680	1.9

Positive values in the second column indicate that the tide at the equator is direct—that is, that high water occurs simultaneously with high water of the equilibrium tide. Negative values indicate that the tide is inverted, or 180° out of phase with the equilibrium tide. For the diurnal tide Laplace obtained the curious result that there is no tidal oscillation of elevation on this worldwide ocean of constant depth, although there are tidal currents.

Several solutions have been obtained for the special case of an ocean of constant depth bounded by two meridians. The result of one of the solutions obtained by Proudman and Doodson is shown in fig. 5, which represents a cotidal chart of the K_2 tide in an ocean of depth 14,520 ft. bounded by meridians 70° apart. The K_2 tide was selected because of mathematical simplifications, but the M_2 tide should be quite similar. Comparison of fig. 5 representing a mathematical solution with fig. 4 derived from observations discloses no striking similarities except for the general occurrence of amphidromic systems.

FIG. 5.—COTIDAL CHART OF A HYPOTHETICAL OCEAN OF CONSTANT DEPTH BOUNDED BY MERIDIANS SEPARATED BY 70°

Tides in Lakes.—If all natural periods of oscillation of a completely enclosed basin are short as compared to those of the tidal constituents, the tide should be approximately at equilibrium with the tide-generating forces at all times. According to the theory of long-standing waves in a rectangular basin of constant depth, the length of the basin is equal to one-half wave length of its gravest free mode. The period of the gravest mode is given by the expression $2L/\sqrt{gh}$ where L is the length of the basin. For example, the gravest mode of a lake 20 km. long having constant depth of 40 m. will have a period of approximately $\frac{1}{2}$ hr. according to the above formula, and the tide in such a lake would therefore be determined with quite sufficient accuracy by static principles.

If the above condition is fulfilled the slope of the lake's surface is equal, at any instant, to the slope of the equilibrium tide at that location, and the actual tidal elevation at any point within the lake is determined by the condition that the total volume of water remain constant. The tide will usually differ considerably from the equilibrium tide according to these conditions, generally being considerably smaller in amplitude. For example, the maximum slope of the equilibrium tide is of the order of a metre in one-fourth the earth's circumference, 10,000 km., giving a value of 10^{-7}. For a lake whose length is 10 km. the maximum difference of elevation between its extremes will be of the order of 10×10^{-7} km. or 1 mm. The tide in small lakes is thus seen to be extremely small, and is usually overshadowed by other effects such as a variable amount of water volume related to variable runoff and evaporation, wind effects, seiches, etc.

There is no variation of tidal elevation at the centroid of the lake's surface area. If the gravest free oscillation of the lake approaches that of the semidiurnal tide, then of course the above concepts no longer are true, and a dynamical treatment of the problem is necessary. This elementary discussion has also omitted two other important effects: the yielding of the lake's bottom with the tidal deformation of the earth's body, and the potential of the tidally displaced matter of the earth (*see* section X).

VI. TIDAL ANALYSIS AND PREDICTION

Tidal Observations. — Probably the greatest achievement of tidal study is that it has been made possible to predict to a fair degree of accuracy what the sea level would be at any desired time for a great number of ports. The method used is essentially the following: The constants in the harmonic development of the tide at any place are determined by analysis of a long series of observations at that place. Knowing the values of these constants, it is possible to reconstruct or synthesize the tide for any past, present or future time. This is the harmonic method, and it can be applied to any observable tidal quantity which depends linearly on the tide-generating forces, such as the north or east components of the tidal current (not the speed or the direction of the current), the tidal variations of gravity or atmospheric pressure, etc.

The theoretical problem of the tide in the oceans has not been solved, and knowledge of the tide at any place depends on some observations having been made at the place. The prediction process may be loosely considered as one of extrapolation of the observations. It is possible that at some future time tidal theory will have been advanced sufficiently that full knowledge of the tide at a given place may be obtained theoretically without the need of previous observations at the place.

Observation of the variable elevation of the sea surface is carried out by means of an instrument called a tide gauge, which usually consists of a float and pulley system so arranged that the height of the float determines the position of a recording pen on a moving chart. The chart is made to move at constant speed by means of a clock mechanism, so that in the result one obtains a graph of the height of sea level as a function of time. Such a graph is called a marigram.

The float is usually suspended within a vertical pipe or well having a small orifice at the bottom in order that the float not be subjected to rapid erratic motions by the ocean waves. A pier piling is an ideal structure on which to fasten the tide well. The diameter of the orifice and the inner cross-sectional area of the tide well determine the frequency response of the gauge. The orifice must be small enough to insure that the ordinary high-frequency ocean waves have greatly reduced amplitude within the well, but large enough so that no appreciable lag be introduced in case of the tide. The frequency response of the tide gauge is usually arranged so that fluctuations of water level taking place over five minutes or longer are quite faithfully reproduced on the marigram, so that the gauge may be useful in recording tsunamis (seismic sea waves) and other such phenomena. The gauge is periodically levelled in with a series of bench marks located nearby on the land in order to compensate for any long-period changes in the height of the gauge as a whole that might be brought about by slow sinking of the pier on which it is fastened, etc. In this way the gauge is useful for studying extremely long-period phenomena such as the year to year variation of mean sea level.

After the marigram is obtained, the usual procedure is to read off at hourly intervals the height of sea level, and to correct these hourly tidal heights for any variation of datum that may have occurred. Vast quantities of these hourly tidal heights for many seaports are on file at the world's principal tidal agencies.

Analysis of Observations. — If a long enough series of observations has been obtained from a locality, it is possible to determine the harmonic constants for each important tidal constituent with good accuracy. The procedure for finding the harmonic constants for any one constituent will be illustrated in the case of the principal solar series, S_1, S_2, S_4, whose periods are exactly 24, 12 and 6 hr. At instants of time separated by 24 hr. each constituent of this series will have the same value. Let us assume that we have a whole year of data. If we take the average of the 365 hourly tidal heights corresponding to the zero hour of each day, the resulting value will be practically free from the effects of all the other constituents whose periods are not submultiples of 24 hr., because their phases will differ from the zero hour of one day to the zero hour of the next day. Such a constituent will sometimes have positive values on the zero hour, and another day it will have a negative value, and on the average its value will be close to zero. The constituents of the principal solar series, on the other hand, will have the same value, on the average of all the zero hours, as for the zero hour of any given day. This averaging is repeated for each of the 24 hr. of the day and in the result one obtains a complete daily cycle of the combined effect of the constituents S_1, S_2, S_4 practically free of the effects of the other constituents. The amplitudes and epochs of each of the constituents of this series can now be found by the well-known methods of harmonic analysis.

For constituents other than those of the principal solar series the averaging must be carried out in similar fashion but based on the fundamental period of the constituent under consideration instead of 24 hr. Here there is a slight complication if the data are tabulated in the form of hourly tidal heights, as the times for which the tidal values are needed do not coincide exactly with the times at which the values are tabulated. In this case it is customary to use the tabulated value in closest proximity to the time for which the value is actually needed, and it is seen that the error in time will never exceed 30 min. The small error incurred in this process can be corrected by applying an augmenting factor.

If the series of observations is short it is not possible to separate completely any given constituent from the disturbing effects of the others. However, the harmonic constants of all the constituents can be determined approximately, using the above technique, and a first order correction can then be applied. This process is called elimination.

Inference of Harmonic Constants. — It is impractical to use the method discussed above for a constituent whose amplitude is small as compared to possible errors arising from various sources. The harmonic constants of such a constituent are usually inferred from those of one of the major constituents having approximately the same period. Such inference is based on the supposition that the ocean's response to a periodic tide-generating force varies continuously and relatively slowly with the period of the force. Hence it is assumed that two equilibrium constituents whose periods are nearly equal will cause tidal constituents in the ocean at any given locality, whose amplitudes are proportional to those of the equilibrium constituents causing them.

It is best to infer harmonic constants of a given constituent X from those of one of the most important constituents whose period is as close as possible to that of X. Suppose that the constituent M_2 meets these requirements. If H represents the actual amplitude of the constituents and c their constituent coefficients (which are proportional to the amplitudes of the equilibrium constituents), the relationship

$$\frac{H\ (X)}{c\ (X)} = \frac{H\ (M_2)}{c\ (M_2)}$$

is used to relate the amplitudes of X and M_2. The epochs (intervals by which the oceanic constituents lag behind their equilibrium counterparts) can be set equal, to a first approximation, while a more refined method of estimating the epoch of constituent X is given in *Special Publication* 98, *U.S.* coast and geodetic survey. The constituent coefficients have been precisely determined from astronomic observations, and if the amplitude and epoch of M_2 have been determined from tidal observations, the amplitude and epoch of X can be calculated from the above relationships. The validity of the above relations can be checked by also evaluating the constants of X by conventional means, and it is usually found that the inference method gives fair results if the periods of the two constituents are nearly enough to being equal. It should be emphasized that the inference method can never be used to relate the constants of constituents belonging to different species.

Prediction: Tide Tables.—For many purposes it is of great importance to know in advance the times and heights of high water at a particular place on a particular day. Consequently governments and harbour authorities publish, a year or so in advance, tables giving such information for all the principal ports of the world. In a few cases tables are similarly published giving the height of water above some datum at every hour of the year, while for a certain number of navigable channels tables of the times of slack water are also issued.

The standard method of tidal prediction is the harmonic method based on the idea of harmonic constituents, and the necessary information for any particular place is provided by the process of analysis discussed above. The only theoretical results which are utilized in tidal prediction are (1) the decomposition of the entire tide-generating force as the sum of a number of harmonic equilibrium constituents; and (2) the linearity of the ocean tide. Thus, the periods of the constituents are obtained from the observed motions of earth, moon and sun, while their amplitudes and epochs are obtained from tidal observation: tidal prediction is largely an empirical science.

The process of harmonic prediction consists of the calculation of the value of each harmonic constituent for a given time, and then the addition of the values obtained for all the constituents. When this is done for every hour of a year, the computational task becomes enormous. and to obviate this special computing machines, called tide-predicting machines, have been constructed. Those in use at mid-20th century were of the analogue type and usually consisted of a series of gears or pulleys by which means the analogue addition of the constituents could be carried out. The amplitude and epoch of each constituent could be adjusted into the machine so that it could be used for any location and for any tidal quantity.

Of course. only that part of the rise and fall of the sea surface related to astronomical quantities can be predicted, and hence any individual prediction is liable to differ considerably from the actual occurrence, as will be seen below.

VII. NONASTRONOMICAL VARIATIONS OF SEA LEVEL

"Geologic" Tides.—Any change in shape of the ocean basins or in the total quantity of water in them can bring about changes of level at a given locality. Another effect, however, is to change the dynamical response of the oceans to the tide-generating forces, and we should consequently expect the tidal harmonic "constants" to change.

The geological change in sea level is quite slow as compared to that effected by the moon and sun, and is manifested by a small year to year variation in mean annual sea level. There is evidence that the average sea level over the entire earth rose by the order of 10 cm. from 1850 to 1950. This has been related to a shrinking of the ice caps of the world, particularly those over Antarctica and Greenland. About 1000 B.C., during the postglacial temperature maximum, sea level probably stood about 5 m. above its present level. At the present time there are localities where the average annual sea level is rising and others where it is falling, and this is attributed to a relative downward or upward motion of the land area in the vicinity. The horizontal extent over which these year to year sea level records appear similar gives a good indication as to the size of the portions of the earth's crust that are sinking and rising. Actually, the similarity extends over many hundreds of kilometres, indicating that masses somewhat smaller than continents are moving as a whole.

Variation of the tidal harmonic "constants" by the processes just described is probably a slow process, and it may be doubted that a detectable change would occur within tens of thousands of years. At locations where the tidal constants depend critically on the local, small-scale topography, however, this is not the case. For example, the tide up a river may depend critically on the conditions of the channel at the river's mouth. At many ports the tide has changed noticeably after the construction of port facilities, such as breakwaters, etc. In such cases the altered regime of sedimentation and erosion of sand usually plays an important part. Also, sand bars can form and disappear quite rapidly, and a semienclosed lagoon behind such a condition would experience variable tidal "constants."

Meteorologic Tides.—The principal meteorologic effects can be ascribed directly or indirectly to variations in atmospheric pressure on the sea surface, tangential stress on the sea surface exerted by the wind. heating and cooling of the sea water.

A varying atmospheric pressure acting on the oceans has the characteristic of a body force, as the pressure gradients are transmitted through the water practically simultaneously from the sea surface to the bottom. For this reason. the dynamical problem is formally equivalent to that concerned with the effect of the tide-generating forces on the oceans, and equations (1) and (2) are still valid provided that ζ is replaced by $-p_a/\rho g$, p_a being the atmospheric pressure and ρ the water density.

Under certain circumstances the dynamical response of the ocean to the atmospheric pressure disturbance can become large. If a tidal basin is subjected to a variable atmospheric pressure disturbance acting periodically with a frequency near that of one of the free modes of oscillation of the basin. the amplitude of its response will tend to increase until it is ultimately limited by frictional dissipation. The same is true in the case of a pressure disturbance travelling across the sea surface with the same velocity as that of a long free wave, or $\sqrt{gh}$. It may be noted that the depth of the open ocean is so great that storms seldom attain this critical velocity. and so suck magnifying effects are more often encountered in shallow seas.

For a longer-period fluctuation the dynamical effects are less important, and under these conditions the ocean's response is similar to that of an inverted liarometer. The sea surface is depressed approximately a centimetre for each millibar of pressure increase, and vice versa. according to the hydrostatic law

$$\zeta = -\frac{p_a}{\rho g}$$

Pressure changes of 20 millibars occurring in a few days are common at many ports. and so it may be seen that this efiect could be one of the principal sources of error in tidal predictions.

Wind blowing across the water surface exerts a horizontal stress on the water directed downwind, largely by virtue of the difference in air pressure on the lee and windward sides of the water waves generated by the same wind. An exact law for this stress as a function of wind speed has not yet been discovered, but the semi-empirical relationship

$$\tau = \gamma \rho_a v^2$$

gives a good approximation. Here τ is the wind stress, ρ_a the density of air, v the wind speed at an elevation of 15 m. above the water surface and γ is a numerical constant for which the value ,0026 gives the best fit to the empirical data.

Wind stress on the sea surface directed toward the coast has the effect of piling up water against the coast, raising the sea level. Longshore winds blowing so that the land lies to the right relative to the wind direction also tend to raise the sea level against the shore (in the northern hemisphere). owing to the effect of the earth's rotation. There are dynamic effects to be considered in both these cases as the wind is seldom so steady that static equilibrium is reached, except in small basins whose period of free oscillation is quite short.

The effect of the wind stress is enhanced by shoal water for the following reason, based on static considerations. Let us consider the balance of forces in one dimension only, say, the east-west direction The stress caused by a nest wind (blowing eastward) must be balanced by a slope of the sea surface in which its elevation increases eastnard. The horizontal pressure gradient associated with this surface slope is essentially constant with depth, so that the greater the water depth the greater is the total force exerted on a vertical water column. Therefore a given surface slope will require greater wind stress to balance it in deeper water than in the shallower water.

Meteorologic disturbances over shallow seas have given rise to disastrous storm surges, such as those that frequently inundate the coasts of the North sea and the Gulf of Mexico. These surges frequently have a roughly periodic character with periods of the order of hours, and under severe conditions their amplitude can attain several metres. The horizontal stress on the water surface due to the wind is usually more important in these surges than the normal force due to the atmospheric pressure disturbance. Such variations of sea level cannot be predicted by the same procedures used to predict the astronomic tide, but considerable success has been obtained in understanding the dynamics of these phenomena, and in a few cases fairly accurate predictions have been made, particularly in the North sea area by a method developed by R. H. Corkan and Proudman. In order to make such a prediction the wind and pressure fields must be knonn (or estimated with sufficient accuracy) over the water surface of the region and for all necessary instants of time preceding the hour to be predicted.

Variations of water density. caused either by local heating and cooling or by advection of water of different properties, give rise to variations in elevation of the sea surface. If the change in surface level is calculated on the basis that the total water mass in a vertical column remains constant, the hydrostatic law shows that the relative height of the surface is

$$\zeta_s = -\frac{1}{g}\int_{p_a}^{p_b} \alpha\, dp$$

where a is the specific volume of the water, and p_b is the bottom pressure. The quantity ζ_s has been called the steric height. and is quite closely related to the dynamic height used in dynamical oceanography. Changes of the order of 10 cm. taking place from one month to the next are common in the ocean. In the seasonal variation of sea level the changes of density of the water are much more important than the long-period tidal constituents.

VIII. MISCELLANEOUS TIDAL PROBLEMS

Tidal Friction. — The effect of dissipation of the ocean tide by friction has so far been left out of the discussion. but it is known to be an important factor. Harold Jeffreys has calculated that if the tide-generating forces of the moon and sun could be suddenly turned off, half the tidal energy in the earth's oceans would be dissipated in approximately a day. This dissipation is known to occur practically entirely by the friction of tidal currents against the bottom of a few shallow seas of the earth, and against the long shorelines of the continents and islands. It is a curious fact that probably half of the entire tidal dissipation of energy in the ocean takes place in the shallow Bering sea. This rapid rate of energy dissipation should have a considerable effect on the tides of the world.

The matter of tidal friction is of considerable importance in the motions of the planets and their satellites because it provides a mechanism whereby angular momentum is transferred from one type of motion to another. The tidal protuberance created on the primary by the tide-generating force of one of its satellites is not symmetrical with respect to the line joining their centres, and the satellite's own gravitational attraction on this protuberance exerts a torque on the primary. It can be shown in general that if there were no tidal dissipation, there would be no such torque, and that if the angular speed of the planet's rotation is faster than that of the revolution of its satellite about it, then this torque always tends to decelerate the planet's rotation. In such a case, the, gravitational force of the primary on its satellite deviates slightly from the direction toward the primary's centre of gravity. and tends to accelerate the revolution of the satellite about its primary, provided this revolution has the same sense as the rotation of the primary about its axis. Then, the distance between the primary and its satellite will increase as the satellite's speed of revolution is increased, according to Kepler's laws. The above-stated conditions apply. of course, in the case of the earth-moon system.

The same deductions can be arrived at by an alternative point of view: the frictional force of the tidal currents on the sea bottom and coasts must itself exert a decelerating torque on the earth. If the tidal currents were known accurately enough over all critical regions where the bulk of the tidal dissipation takes place, the decelerating torque could be calculated, since it is known that by far the greater part of the tidal dissipation occurs in the oceans and only a negligible amount in the lithosphere. Actually. the form of the tide over the vast regions of the oceans is so poorly known that neither the gravitational torque method nor the frictional torque method can be applied quantitatively, and it is through records of ancient eclipses and modern observations on the moon's position that the average rate of lengthening of the day and lunar period of revolution has been estimated. It should be remarked that the lunar effect on the earth's rotation should be about three to five times as large as the solar effect.

There are four principal effects: (1) tides raised in the satellites by their primaries will tend to make each keep the same face toward its primary (as the moon presently faces the earth); (2) tides raised in the primaries by the satellites will alter the rates of rotation of the primaries; (3) tides raised in the primaries by the satellites will alter the distances between them; and (4) solar tides will affect all the rotations.

On the basis of the above considerations it has been deduced that during previous ages the earth had a much shorter day and much shorter month (period of lunar revolution), and that the moon was much closer to earth. The day has probably lengthened by a second in the last 120.000 years.

Internal Tides in the Ocean. — It has been shown that the tidal current would be uniform from top to bottom at any given locality and instant provided that the sea water had uniform density throughout the oceans. In the actual case, however, variations in the salinity and temperature lead to both time and space variations in the density, and it is possible that this condition would lead to a vertical shear in the tidal current. In any case, there is no reason to believe that there should not exist tidal variations in the water density at any given point in the ocean, and there is evidence on several occasions that such tidal variations may have been actually observed.

The outstanding feature of the density structure of the ocean is that the lighter water is found in the upper layers of the ocean, and in a large number of dynamical problems the ocean can be treated successfully as though the water were stratified; *i.e.,* as though the water in any horizontal plane were homogenous. In such a situation there can exist an important class of wave motions in which the maximum amplitude of the vertical displacement of the water particles occurs at some depth beneath the surface. These are called internal waves to contrast them with the more familiar surface waves, for which the vertical displacements of the water particles have their maximum amplitude at the surface. Internal waves are similar in many respects to surface waves, but have some important differences: their speed of propagation is much less than that of a surface wave having the same wave length; and the vertical movement of the water particles (at the level of maximum movement) is a great deal larger than in the case of a surface wave having the same energy. Such waves have been observed by making periodical determinations of the vertical density profile from an anchored ship, and the results of such observations indicate that such internal wave motion is common, and that amplitudes of the order of tens of metres are to be expected. The oscillations are irregular, but frequently there appear to be dominant waves of diurnal or semidiurnal period having all the characteristics of a tidal variation. In order to prove conclusively the tidal origin of such waves. a considerable series of observations would be necessary, and the difficulties and expense of having a ship remain at the same location for a protracted period of time have prevented this study from being carried out.

IX. ATMOSPHERIC TIDES

As air, like all other matter. is subject to gravitational influence, there will be tides in the atmosphere possessing many features of similarity with those in the ocean. One of the characteristics of these tides will be a very small oscillatory variation in the atmospheric pressure at any place, and this may be regarded as the superposition of harmonic constituents with the ordinary tidal periods. By the systematic analysis of long series of regular barometric records, the principal lunar semidiurnal constituent M_2 of the barometric variation has been determined for a number of places, and found to have an amplitude of the order of .001 in. The dynamical theory of these tides has been the subject of considerable study. The derivation of the equations is not so simple as for ocean tides. one difficulty being that of taking account of the physical conditions in the upper regions. The equations which have been proposed are of the same general form as those for ocean tides, but the theory is still imperfect. The results of analysis for the S_2 constituent show a much larger oscillation with an amplitude of barometric variation of the order of .03 in. For this constituent, however, it is certain that thermal factors play a larger part than gravitational factors, and the theory is far from complete.

X. BODILY TIDES

The solid body of the earth, or lithosphere, suffers periodic deformation because of the tide-generating forces just as do the oceans and atmosphere. These bodily tides manifest themselves in the folloning ways: (1) a variation of the vertical, or plumb line, with respect to any solid structure imbedded in the earth's crust; and (2) a variation in the acceleration of gravity at any point due to the potential of the displaced matter in the earth's body, quite aside from the variation of gravity directly associated with the tide-generating forces.

The gravest free elastic oscillations of the earth's body as a whole have periods of the order of an hour, which is much less than those of the principal tide-generating forces. Therefore, it is probably correct to assume that the bodily tides will approximate closely to their equilibrium forms, or in other words, that they may be calculated on the principles of statics. Owing to the earth's rigidity, the vertical rise and fall of the earth's solid surface at any position on it is somewhat less than that based on the equilibrium tide. The fractional height of the equilibrium tide attained by this surface vertical displacement is practically independent of geographical location, and is designated by the symbol h. The potential of the displaced matter is additive to the tide-generating potential, its fractional contribution to the latter at any point on the earth's surface being designated by the symbol k. As in the case of h, k also is practically independent of geographical location. The numbers h and k were introduced by the theoretician in the field of elasticity, A. E. H. Love, and henceforth have been called the Love numbers.

The values of h and k depend on the geographical form of the disturbing potential, but it is common usage to consider only those values corresponding to a disturbing potential having the form of a spherical harmonic of the second degree, of which the semidiurnal equilibrium form is an example.

Various types of geophysical observations have been used to evaluate the Love numbers. For instance, it can be shown that the acceleration of the earth's gravity at the surface is altered by the amount

$$-\frac{2g\bar{\zeta}}{a}\left(1-\frac{3}{2}k+h\right)$$

where $\bar{\zeta}$ is the equilibrium tidal height at the place under consideration and a is the radius of the earth. A body of water whose natural period is short compared with the tidal periods will set itself so that its free surface is one of constant potential. If ζ' is the elevation of the water surface at a given position relative to the bottom, it can be shown that $\zeta' - (1+k-h)\bar{\zeta} = \text{const.}$ provided that the total volume of water in the basin remains constant. The yielding of the bottom tends to diminish the apparent tide while the additional potential of the displaced mass in the earth tends to increase it, hence the algebraic signs in the terms of h and k.

Thus it is seen that precise measurements of the acceleration of the earth's gravity at a point would give a determination of the quantity $1-\frac{3}{2}k+h$ while measurements of the water level in a long sheltered tube, free from winds and other disturbances would give a determination of the quantity $1+k-h$. This quantity also determines the position of the vertical as can be measured by a plumb line or a special instrument called the horizontal pendulum.

It should also be possible to determine the quantity $1+k-h$ by means of observations of the ordinary ocean tide, provided its dynamics were well understood. The long-period tides, especially the lunar fortnightly tide Mf, have usually been utilized for this purpose. It is generally assumed that the periods of these constituents are very much longer than those of all natural oscillations in the ocean basins, and that the equilibrium law would therefore hold. This assumption is certainly valid in the case of ordinary inertio-gravitational standing wave motion in the oceans. but serious objections have been raised on the basis of the possible existence of geostrophic or planetary wave modes characterized by steady or nearly steady ocean currents. There is a further serious difficulty in isolating the purely astronomical long-period constituents in analysis. and it may well be doubted whether reliable constants for the Mf constituent have ever yet been obtained from the records of observation. The values of h and k determined vary considerably depending on the type of observation used, and for this reason are subject to appreciable error. The value of h is somewhere in the vicinity of 0.6, that of k is near 0.3.

The above discussion of the bodily tide has omitted any reference to the complications introduced by the tides in the ocean. There are two effects: the warping of the earth's crust by the varying load on the ocean floor; and the contribution to the total gravitational potential by the displaced water mass. Generally, these effects are more serious closer to the coast and the greater the tidal range at the coast nearby. For this reason measurements of the bodily tide are usually attempted near the centre of large continents.

If the rigidity and density at all points in the earth's body were exactly known, it should be possible to calculate the Love numbers theoretically without need for recourse to observations. The internal constitution of the earth is not precisely known, but certain hypotheses concerning this internal constitution can be rejected on the basis of results of bodily tide observations. Lord Kelvin used the observed height of the fortnightly tide to show that the earth's rigidity, on the average, is greater than that of steel. See also references under "Tides" in the Index volume.

TIDORE (TIDOR), a mountainous island of the Moluccas, Indonesia, lying south of Ternate, nearly circular in shape, with an area of 45 square miles. The southern part is occupied almost entirely by an inactive volcanic peak (5,676 ft.). Below the 1,000 ft. level coffee, fruit and tobacco are cultivated, the soil being very fertile.

The northern half consists mostly of hills, though there are a few level strips along the coast. Pop., about 20.000. Tidore is part of the residency of Ternate, and, with neighbouring islands. comes under the resident of Ternate. The inhabitants are akin to the Ternatans. They dislike work, but sell fish and cultivate garden produce. Some Tidorese do smiths' work, in which they are proficient.

The other islands of the Ternate-Tidore group are Hiri, Mayu, Taifore, Maitara, Pilonga, Maré, Pasuraja. Moti, Makian. Waidoba, Taneti and the Kajoa and Goraityi groups All stretch along by the coast of Halmaheira towards Bachian. with the exception of Taifore and Mayu, which lie out in the Molucca passage. Kajoa (of coralline and crystalline rock formation), is nearly 10 mi. long and has a mountain range traversing most of its length. The people are Mohammedans, and grow rice and maize, and fish. Makian has a mountain of more than 4,000 ft., is well-wooded, volcanic, and has suffered from eruptions. It has a population of more than 8,000 Mohammedans, resembling the people of Ternate and Tidore, who weave, fish and grow tobacco, fruit, rice and sugar cane. Sago, the staple food, is imported from Halmaheira. Moti is surrounded with coral reefs. Maitara has mountains which attain an elevation of 1.266 ft.. and is well forested and fertile. Like Ternate. Tidore is the seat of an ancient and once powerful sultanate. The Portuguese established themselves there in 1521 and fought the sultan, whose capital they destroyed. Later, the Spaniards, when Portugal had become incorporated with Spain, obtained a hold which they retained until nell into the 17th century. aiding the Tidorese in maintaining their independence in Ceram, Halmaheira and other islands, against the sultan of Ternate and the Dutch. The latter, in 1654, conquered the island, but recognized the nominal power of the sultan. Japan occupied Tidore in 1942. (E. E. L.; X.)

TIDYTIPS, common name applied to *Layia* species, especially *L. elegans,* small North American herbs of the family Compositae, native to California. It is an attractive spring-blooming annual, about a foot high, bearing showy flowering heads, $1\frac{1}{2}$ in. broad, with sulfur-yellow rays tipped with white. This plant and other related Californian species, as L. *platyglossa,* are groun as garden annuals. The white daisy, *L. glandulosa,* found from British Columbia to Mexico, is also cultivated.

TIECK, JOHANN LUDWIG (1773–1853), German poet, novelist and critic, was born in Berlin on May 31, 1773, his father being a rope maker. He was educated at the Friedrich-Werdersche gymnasium, and at the universities of Halle, Gottingen and Erlangen. At Gottingen Shakespeare and the Elizabethan drama were the chief subjects of his study. In 1794 he returned to Berlin, resolved to make a living by his pen. He contributed a number of short stories (1795–1798) to the series of *Straussfedern,* published by the bookseller C. F. Nicolai and originally edited by J K. A. Musaus, and wrote *Abdallah* (1796) and a novel in letters, *William Lovell* (3 vols. 1795–1796). Tieck's transition to romanticism is to be seen in the series of plays and stories published under the title *Volksmarchen von Peter Lebrecht* (3 vols., 1797), a collection which contains the admirable fairy-tale *Der blonde Eckbert,* and the witty dramatic satire on Berlin literary taste, *Der gestiefelte Kater.* With his school and college friend W. H Wackenroder (1773–1798), he planned the novel *Franz Sternbalds Wanderungen* (vols i–ii 1798), which was the first expression of the romantic enthusiasm for old German art.

In 1801 Tieck went to Dresden, then lived for a time near Frankfort-on-the-Oder, and spent many months in Italy. In 1803 he published a translation of *Minnelieder aus der schwäbischen Vorzeit,* between 1799 and 1804 an excellent version of *Don Quzxote,* and in 1811 two volumes of Elizabethan dramas, *Altenglisches Theater.* The stories *Der Runenberg, Die Elfen, Der Pokal,* and the dramatic fairy tale, *Fortunat,* with earlier works, appeared in the collection *Phantasus* (3 vols., 1812–17). In 1817 Tieck visited England in order to collect materials for a work on Shakespeare (unfortunately never finished) and in 1819 he settled permanently in Dresden; from 1825 on he was literary adviser to the Court theatre, and his semipublic readings from the dramatic poets gave him a reputation which extended far beyond the Saxon capital. The new series of short stories which he began to publish in 1822 also won him a wide popularity. Notable among these are *Dze Gemalde, Die Reisenden, Die Verlobung, Des Lebens Überfluss.* More ambitious and on a wider canvas are the historical or semihistorical novels, *Dichterleben* (1826), *Der Aufruhr ın den Cevennen* (1826, unfinished). *Der Tod des Dıchters* (1834), *Der junge Tischlermeister* (1836; but begun in 1811), an excellent story written under the influence of Goethe's *Wilhelm Meister. Vittoria Accorombona* (1840), in the style of the French Romanticists, shows a falling-off. In later years Tieck carried on a varied literary activity as critic *(Dramaturgische Blätter,* 2 vols., 1825–26; *Kritische Schriften,* 2 vols., 1848); he also edited the translation of Shakespeare by A. W. Schlegel, who was assisted by Tieck's daughter Dorothea (1799–1841) and by Graf Wolf Heinrich Baudissin (1789–1878); *Shakespeares Vorschule* (2 vols., 1823–29); the works of H. von Kleist (1826) and of J. M. R. Lenz (1828). In 1841 Friedrich Wilhelm IV of Prussia invited him to Berlin where he enjoyed a pension for his remaining years. He died on April 28, 1853.

Tieck's *Schriften* appeared in zo vols. (1828–46); and his *Gesammelte Novellen* in 12 (1852–54). *Nachgelassene Sclzrijten* were published in z vols, in 1855. Of modern editions of *Ausgewählte Werke see* those by G. Klee (with an excellent biography, 3 vols., 1892), and G. Witkowski (4 vols., 1903). *The Elves* and *The Goblet* were translated by Carlyle in *German Romance* (1827), *The Pictures* and *The Betrothal* by Bishop Thirlwall (1825). See for Tieck's earlier life R. Kopke, *Ludwig Tieck* (z vols., 1855), for the Dresden period, H. von Friesen, *Ludwig Tieck: Erinnerungen* (2 vols., 1871); Also A. Stern, *Ludwig Tieck in Dresden (Zur Literatur der Gegenwart,* 1879); B. Steiner, *L. Tieck und die Volksbücher* (1893); H. Bischof, *Tieck als Dramaturg* (1897); H. Lucdeke, L. *Tieck und das alte englische Theater* (Frankfurt, 1922); A. E. Lussky, *Tieck's approach to Romanticism* (Borna-Leipzig, 1925).

TIEL, a town in the province of Gelderland, the Netherlands, on the right bank of the Waal (here crossed by a pontoon bridge), 25 mi. by rail west of Nijmwegen. Pop. (1957 est.) 16,870 (mun.). It possesses fine streets and open places, but of its fortifications the Kleiberg gate (1647) alone remains. The principal buildings are St. Martin's church (15th century), the town hall, courthouse and the historical castle of the family of van Arkel.

TIELE, CORNELIUS PETRUS (1830–1902), Dutch theologian and scholar of comparative religion, was born at Leiden on Dec. 16, 1830. He was educated at Amsterdam high school and afterward at the seminary of the Remonstrant Brotherhood. He served as pastor at Moordrecht and Rotterdam, then as professor at the Remonstrant seminary. In 1877 followed his appointment at the University of Leiden as professor of the history of religions, a chair specially created for him. During his tenure, which lasted until 1901, his influence on the developing study of comparative religion was great, most especially in the Netherlands. He died on Jan. 11, 1902.

Among the best known of Tiele's numerous learned works are *Outlines of the History of Religion* (1876; Eng. trans. 1877) and his Gifford lectures, published as *The Elements of the Science of Religion* (1897–99). He was also the author of the article "Religions" in the 9th edition of the *Encyclopædia Britannica.*

See S. Cramer in *Realencyklopadie fur protestantische Theologie und Kirche,* 3rd ed., vol. xix, pp. 766–775 (190.5).

TIEN SHAN (Russian TYAN'-SHAN; Chinese T'IEN SHAN, "celestial mountains"), one of the great mountain systems of central Asia. Situated in the Soviet Union and China, the Tien Shan is about 1,500 mi. long, trending generally west-southwest to east-northeast. The system is located between latitudes 40° and 44° N. and extends from the Samarkand area (67° E.) in the west to the Kansu border (96° E.) of China in the east. There is no general agreement as to its northern and southern boundaries. In the north, the Dzungarian Ala-Tau is sometimes regarded as part of the Tien Shan because it is linked to the system by the Borokhoro (Boro Horo Uula) range *(see* ALA-TAU). Others regard the Dzungarian Ala-Tau as an independent range, with the Ili valley as the northern border of the Tien Shan. In the southwest, the Turkistan, Zeravshan and Alay ranges are sometimes included in the Tien Shan because of geologic similarities. But on the basis of orographic and tectonic data, these ranges are excluded and the Fergana valley is regarded as the southwestern boundary of the system.

The Khan-Tengri (22,949 ft.), situated in a mountain knot on the Soviet-Chinese border, was long regarded as the highest peak of the Tien Shan system. In 1943, however, a Soviet expedition discovered a peak with an elevation of 24,406 ft., 13 mi. S. of

Khan-Tengri. and named the new summit Pobeda (Victory) peak in honour of Red army victories in World War II. From the mountain hub. subranges fan out toward the west into the Soviet section of the Tien Shan system, and toward the east into the Chinese section.

Western **Tien Shan.**—The western, or Soviet, section of the Tien Shan is complex in structure. It consists of a number of branches and subranges fanning out from the mountain hub of Khan-Tengri and Pobeda peak. The northern branch includes the Rungey Ala-Tau. which encloses the large mountain lake Issyk-Kul on the north. Parallel to the Kungey Ala-Tau in the north is the Trans-Ili (Zaili) Ala-Tau, rising to 16.243 ft. in Talgar peak. The Trans-Ili Ala-Tau continues westward in the Chu-Ili mountains. while the Kungey Ala-Tau extends on into the Kirghiz range. The central branch fanning out from the mountain hub consists of the Terskey Ala-Tau, which encloses the Issyk-Kul basin on the south. The southwestern branch is made up by the Kokshaal-Tau. These major branches of the western Tien Shan are tall, snow-clad ranges of an alpine character. In sharp contrast is the section bordered in the north by the Terskey Ala-Tau and in the south by the Kokshaal-Tau, where mountain ranges were eroded and converted into peculiar flat-topped summits known as *syrts*. These *syrts* are separated by broad valleys or tectonic depressions. While the outer alpine ranges rise abruptly for 10.000 ft. or more above the adjoining lowlands, the relative elevation of the *syrts* above the intervening valleys is only about 2,000–3,000 ft.

Eastern **Tien Shan.**—The eastern, or Chinese, section of the Tien Shan consists of two parallel series of subranges. The main southern series. extending eastward from the Khan-Tengri mountain hub, consists of the Khaliq-Tau (13,220 ft.) and the Boro Hatan (12,402 ft.) and terminates at the lake basin of Baghrash Kol.

The northern series of subranges includes the Borokhoro. the Bogdo Uula (17,946 ft.), the Bar Kol Tagh range (13,950 ft.) and the Karlik Tagh (14.090 ft.). South of the Bogdo Uula lies the Turfan depression. whose salt-marsh-covered floor lies at 427 ft. below sea level, the lowest point in China. The eastern Tien Shan, which divides China's Sinkiang Uigur Autonomous Region, into Dzungaria (north) and the Tarim basin (south) is characterized by an echelonlike arrangement of subranges and broad intermontane valleys and basins.

Geology. — The mountains of the Tien Shan are made up of sedimentary. metamorphic and igneous rocks of Paleozoic and Pre-Cambrian age. The most common rocks are schists, sandstone, limestone. marble. gneisses, granites and syenite-porphyries. The intermontane basins, on the other hand, are filled with unconsolidated continental sediments of Tertiary and Quaternary age, The northern ranges were originally uplifted during the so-called Caledonian revolution in the Lower Paleozoic period. while the southern ranges arose during the Hercynian revolution of the Upper Paleozoic. These initial ranges mere gradually eroded and converted into a peneplain by the Mesozoic and Tertiary eras. Toward the end of the Tertiary and early in the Quaternary, new uplifts took place to give the mountain ranges of the Tien Shan their present appearance. Downwarping associated with the uplifts produced intermontane valleys and basins. In the process of erosion of the mountains, these depressions became partly filled with eroded material.

Climate. — The climate of the Tien Shan is determined largely by its location in the interior of the Eurasian continent among arid desert lowlands of the middle latitudes. The climate of the region is sharply continental, but local contrasts in precipitation and temperatures are due to the great elevation of the Tien Shan and its complex relief. The piedmont plain and the foothills of the system have typically the same desert climate as the adjoining lowlands. Westerly Atlantic air masses carry most of the precipitation received by the Tien Shan system, discharging it mainly on the mest-facing slopes at middle and high altitudes. .Annual precipitation on these slopes reaches more than 30 in. On east-facing slopes and in intermontane basins. annual precipitation is only about 10 in. Precipitation reaches a maximum in the summer. In keeping with heavier precipitation on the western slopes, these slopes and westward-facing valleys have a heavier snow cover in winter. reaching almost 10 ft. The east-facing slopes and intermontane valleys have virtually no snow in winter. In general the snow line is much higher in the Tien Shan than it is in the European Alps or the western Caucasus. Even some passes of 13,000 ft. or more are known to be snow-free in summer. Average temperatures vary with elevation. In the valleys and on low-elevation slopes the July average is 70°–75° C., on medium-elevation slopes 55°–60° and on the mountain peaks near freezing. The large lake basin of the Issyk-Kul exerts a moderating influence on temperatures of nearby areas.

Glaciation. — The general trend of the mountain ranges of the Tien Shan is east-west, although some short ranges are also oriented north-south. Characteristic features of the Tien Shan are the so-called mountain knots from which short ranges fan out in several directions. Relatively humid air coming from the west condenses on the west-facing slopes of the north-south ranges and the mountain knots giving rise to valley glaciers. The principal glaciation centres are therefore the Khan-Tengri and Pobeda knot and the short north-south range of Akshiyrak. In the larger mountain knots. glaciers cover a total area of 10,000 sq.mi. The largest ones are the southern Inylchek glacier (37 mi. long), on the southern side of the Khan-Tengri; the northern Inylchek glacier (22 mi. long) on the northern side; and the 13-mi.-long Semenov glacier descending from Semenov peak (19,081 ft.), northwest of Khan-Tengri.

The Petrov glacier, on the west slopes of the Akshiyrak range, is 11 mi. long. In addition to the valley glaciers, glaciation is also in evidence on some of the flat-topped summits of the western Tien Shan, where peculiar ice shields are formed on the summits.

Hydrography. — The Tien Shan is mainly a region of interior drainage. whose rivers flow either into the desert lakes of central Asia or into mountain lakes without outlet to the sea. Most of the western Tien Shan is drained by the Syr-Darya (*q.v.*), one of the great streams of central Asia, which flows to the Aral sea. The principal rivers on the northern side of the Tien Shan are the Chu. which disappears in the desert west of Balkhash lake, and the Ili (*q.v.*), which flows to that lake. On the southeastern side of the Tien Shan, the drainage pattern is dominated by the Tarim (*q.v*), which also disappears in the desert sands near Lop-Nor (*q.v.*) lake. The river valleys of the Tien Shan tend to be broad except when they cut through transverse ranges. Rising generally at high elevations, the rivers of the Tien Shan are fed by glaciers and reach their high water stage in the summer, when they are most useful for the irrigation of crop lands in the piedmont plains. Some of the smaller rivers rising at lower elevations are fed by ground water, snow and rain. Several of the rivers are used to generate hydroelectric power, notably the Chirchik. a tributary of the Syr-Darpa; the Syr-Darya itself, and the Chu river. The Issyk-Kul, largest of the mountain lakes in the Tien Shan. occupies a broad tectonic depression.

Vegetation. — The vegetation of the Tien Shan follows a vertical zonation. The lower foothills are covered with desert vegetation. which dries up in about mid-May. Irrigated cotton and fruit trees dominate among the cultivated crops. At somewhat higher elevation, above 1.200 ft., an increase in precipitation assures a semidesert vegetation, such as wheat grass, which lasts until the end of June and can be used as spring and summer pastures.

Above the semidesert belt of the foothills lies the dry mountain steppe of feather grass and fescue, which serves as summer and fall pasture and for the cultivation of dry grains. At an elevation of 4,000 ft. begins the grassy steppe with bushes and patches of deciduous trees (walnut, apple, maple). This is a main area of unirrigated agriculture, used for hay and grains. The next higher zone of subalpine meadows also contains coniferous forests of spruce and fir as well as juniper groves. These meadows. which reach up to the snow line, are the principal summer pastures of the Tien Shan region.

Minerals. — Outflows associated with Hercynian magmatism have produced some highly mineralized areas in the Tien Shan, notably in nonferrous and rare metals. Among the most important Soviet mineral sites are the copper and lead-zinc ores of Almalyk of the Uzbek Soviet Socialist Republic, the antimony and mercury mines of Khaydarken in Kirghiz S.S.R. and the tungsten site of Chorukh-Dayron in the Tajik S.S.R. Jurassic coal of low caloric value is mined at Angren (Uzbek S.S R.) and on the periphery of the Fergana valley at Kyzyl-Kiya. Tashkumyr, Kok-Yangak and Sulyukta. The accumulation of sediments in the Fergana valley has also produced deposits of petroleum, natural gas. sulfur and ozocerite. Geologic exploration is still in its infancy in the Chinese portion of the Tien Shan, but oil fields are already in operation at Tushantze and Karamai in the northern foothills and several sites of nonferrous and rare metals are known.

Settlement and Transportation. — The heaviest population concentrations in the Tien Shan are found in the Tashkent (*q.v.*) oasis, the Fergana valley and the Chu valley of the Soviet Union, and in oases at the north foot (Urumchi) and south foot (Kashgar. Aqsu) of the eastern Tien Shan in China's Sinkiang (*q.v.*) The lower valleys and foothills of the Tien Shan, where irrigated agriculture (mainly cotton) is practised, were invaded by indigenous central Asian cultivators, such as the Uzbeks in the Tashkent and Fergana areas of the Soviet Union and the Uigurs in the oases at the southern foot of the mountain system in China. Among the pastoral peoples of the mountains are the Kirghiz in the western Tien Shan and the Kazakhs and Mongols in the eastern Tien Shan.

The population centres of the Soviet portion of the Tien Shan are reached by branches of the Soviet rail system, extending from Tashkent into the Fergana valley and through Frunze (*q.v.*) into the Chu valley and to Rybachye on the Issyk-Kul. A central Asian railroad linking China and the Soviet Union, completed in 1960, runs along the northern foot of the eastern Tien Shan and through the Dzungarian Gate. a natural passage way at the eastern end of the Dzungarian Ala-Tau. The higher valleys of the Tien Shan are served by roads, many of which can be used by motor vehicles. (T. SD)

TIENTSIN, an industrial and commercial city in the province of Hopeh, China. 70 mi. S.E. of Peking. Pop. (1953) 2,693,831 (1957) 3 220,000. The city is situated at the confluence of several streams on the lower coastal plain, 32 mi. by river from the Yellow sea. Until 1782 the place nas only a garrison tonn. but it became a treaty port in 1860, and began to grow rapidly A foreign settlement was located downstream on the right bank of the Hai Ho, and the entire city, native and foreign, suffered severely during the Boxer uprising (1900). After this the walls were razed. and the city was rebuilt on occidental lines. Originally covering only a small area, the former foreign concessions were integrated and the limits have since expanded steadily. The port area of Ta-ku and T'ang-ku was included within the city limits in 1949, and the area along the Hai Ho was annexed in 1953 to make the total area of the city 888 sq.mi. Tientsin, a chartered city since 1929, is an independent municipality administered directly by the central government from Peking.

Subject to flooding by the six small rivers coming together just west of the city, the main river below the city has long been shallow and subject to silting. The Communists have both maintained the earlier pattern of dredging the river, and have built a bypass flood canal around the city on the south side to relieve flood pressures. Though dredging can keep the river navigable for small ships. a new artificial port, Sinkang, able to take 10,000 ton ships at all times. was created at T'ang-ku. This is kept open for about two months during winter by icebreakers.

Tientsin is a leading seaport of China and a rail, an air traffic and a regional trade centre. Its industrial beginnings predate 1900, but it remained for some decades a centre of such light manufacturing as matches, bicycles, cotton and wool textiles, grain milling, tobacco manufacturing and simple chemicals. Gradually its variety of industry broadened as assembly operations, heavy machinery. iron and steel and the fuller range of chemical manufactures were added. Under the Communists its rank has increased as heavy manufacturing industries were located in the newer industrial areas toward the coast. In the mid-1950s marked expansion took place in iron and steel, and in heavy manufacturing. By the late 1950s Tientsin was the leading chemical manufacturing centre of China, and had become the third ranking industrial region. behind only Shanghai and the central Liaoning province region of southern Manchuria. It is the seat of Nankai university. (J. E. SR.)

TIEPOLO, the name of a family of Venetian painters comprising Giovanni Battista. by far the most important, and his two sons Giovanni Domenico and Lorenzo

GIOVANNI BATTISTA TIEPOLO (1696–1770), the greatest Venetian painter of the 18th century, was born on March 5, 1696. in Venice, the son of a merchant. He first studied painting under Gregorio Lazzarini, but quickly came under the influence of F. Bencovich and G. B. Piazzetta. His earliest known work, "The Sacrifice of Isaac" in the church of the Ospedaletto, Venice (1715–16). is sombre and still in the manner of Piazzetta. In 1717 his name first appears on the lists of the guild of Venetian painters, and for the next few years he concentrated chiefly on small easel paintings of classical and biblical subjects.

Throughout his life Veronese's was the pervasive influence on Tiepolo's art. The return of G. A. Pellegrini to Venice in 1721 was also crucial for Tiepolo's development, for his work inspired Giambattista to adopt a lighter and gayer palette. These two factors are apparent in his decorations for the Sandi and Dolfin palaces in Venice (both *c.* 1725, the latter now dispersed) and in those for the archiepiscopal palace and the cathedral at Udine (1726–27). In 1731 he was called to Milan to decorate the Archinti and Dugnani palaces (destroyed and damaged respectively, in 1943). In 1732–33 he frescoed the upper parts of the Colleoni chapel, Bergamo. By now he was widely recognized as the leading decorator in Italy. The Swedish envoy Tessin happily characterized Tiepolo's work as "full of spirit . . . of an infinite fire, brilliant colouring and an astonishing speed." Notable among his frescoes in the next 15 years were the ceilings in the Gesuati church, Venice (1737), the Palazzo Clerici, Milan (1740. destroyed 1943), the Scuola dei Carmini, Venice (1740–43). the Villa Cordellina, Montecchio Maggiore (1743), the church of the Scalzi, Venice (1743–44, destroyed 1915). the decorations of the Palazzo Barbarigo, Venice (1744–45. dispersed) and, probably about 1750, his most admired work in Venice, the scenes from the life of Cleopatra in the great saloon of the Palazzo Labia. He was also producing such masterpieces of oil painting as the huge "Road to Calvary" and its companion paintings the "Flagellation" and the "Crowning With Thorns" for S. Alvise as well as secular and religious paintings for patrons at home and abroad.

BY COURTESY OF THE METROPOLITAN MUSEUM OF ART ROGERS FUND 1937

SKETCH FOR ALTARPIECE "INTERCESSION OF ST THECLA" BY TIEPOLO IN THE METROPOLITAN MUSEUM OF ART, NEW YORK CITY

In 1750 he was commissioned by the prince-bishop of Wiirzburg, Ger., to decorate the ceilings of the Kaisersaal and staircase of the new palace with historical and allegorical subjects. These huge frescoes, perhaps his greatest achievements, were completed in 1753. On his return to Venice. his outstanding decorations were the Villa Panigai, Nervesa della Battaglia (1754, now in Berlin), the ceiling of the church of the Pietà, Venice (1754–55), the Villa Contarini, Mira (1756, now in Paris), the Villa Valmarana, Vicenza (1757), the Palazzo Rezzonico, Venice (1758). the Palazzo Canossa, Verona (1761, destroyed 1944) and the Villa Pisani at

Strà (1761–62). The huge altarpiece of the "Intercession of St. Thecla" at Este, his most moving religious work, was completed in 1759. In 1761 he was invited to Spain by Charles III and in 1762, accompanied by his sons, he arrived in Madrid where he decorated three rooms in the royal palace (1762–67). He also executed seven altarpieces for S. Pasquale at Aranjuez (1767–69) and began the decoration of the vault of the apse of S. Ildefenso shortly before his death in Madrid on March 27, 1770.

Tiepolo's work is characterized by his skilled draftsmanship, the high key of his multicoloured palette, his mastery of composition and the extraordinary fertility of his imagination. Besides decorations and altarpieces he painted one or two portraits and a number of *Teste di Fantasia* ("imaginary heads") in the manner of Rembrandt. He produced vast numbers of sketches and finished drawings for collectors, to whom he also supplied numerous freely painted oil sketches—often reductions from larger works. Between about 1740 and 1760 he etched plates distinguished for their imaginative force and brilliance.

In order to achieve his enormous output Tiepolo employed assistants, among whom were Mengozzi-Colonna (for architecture) and his two sons, GIOVANNI DOMENICO TIEPOLO (1727–1804) and LORENZO TIEPOLO (1736–1776). Giandomenico, born in Venice on Aug. 30, 1727, was completely overshadowed by his father as a religious and decorative painter, but he had a real talent for genre painting, especially of scenes from contemporary life and of the popular theatre, such as the decorations of his own villa at Zianigo (1791–93).

Notable among his early works are the "Stations of the Cross" for S. Polo, Venice (1747–49), and the *chinoiserie* decorations of the guest wing of the Villa Valmarapa (1757). After his father's death Giandomenico returned to Venice where he executed a number of frescoes and easel paintings, especially of scenes from the *commedia dell'arte*. He, too, produced large numbers of drawings for collectors, besides nearly 200 etchings after his own and his father's designs. He died in Venice on March 3, 1804. Lorenzo, born in Venice on Aug. 8, 1736, seems to have specialized chiefly in genre scenes in pastel. He died in Madrid on Aug. 8, 1776.

TIERCERON, in architecture. an intermediate vaulting rib running from the spring of the vault to the ridge, at an angle between the cross rib and the diagonal or groin rib, or in cross vaults between the diagonal rib and the wall rib. Tiercerons came into use in the early Decorated period of English Gothic. Exeter cathedral (1308–67) shows the delicate beauty and lightness that tiercerons gives. *See* GOTHIC ARCHITECTURE; ARCH AND VAULT.

TIERRA DEL FUEGO, an archipelago lying between 52° 27' and 55° 59' S. lat. 'and 63° 43' and 74° 44' W. long at the southern extremity of South America, and separated from the mainland by Magellan's strait. In shape the main island is a triangle with its base on Beagle channel. The total area is 27.476 sq mi . about two-thirds of which is Chilean and one-third Argentine. The boundary agreed upon in 1881 follows the meridian of 68° 36' 38″ W. from Cape Espiritu Santo on the Atlantic. and the west-east Beagle channel. Lennox. Nueva. Picton and several small islands at the mouth of the channel are disputed between the tno republics. The western and southern. Chilean, part is known as the Tierra del Fuego department of Magallanes province, pop. (1952) 4.768; the eastern, Argentine, side is the province of Tierra del Fuego. pop. (1956) 10.596.

Physical Features.—The greater part of the main island north of the Almirantazgo sound-Lake Fagnano depression consists of Tertiary sediments and volcanic material, overlain north of the Inhtil-San Sebastián bays depression by glacial material deposited during the Pleistocene ice age. The distribution of land and nater and the major relief features in this area are the result of the location of great glacial lakes, the excavation of their overflow channels and the dumping of great moraines. The Altos de Boqueron, north of Inutil (Useless) bay, is one such undulating morainic plateau from which drain all the rivers of north Tierra del Fuego. Most of the northern area is, therefore, under 600 ft. in height and the Atlantic and Magellan strait coasts are low-lying.

The southern and western parts of the main island and the archipelago are a great contrast. Cretaceous foothills pass into the southern prolongations of the Andes with crystalline rocks, peaks exceeding 7.000 ft. and mountain glaciers. Mt. Sarmiento (7,333 ft.) and Mt. Darwin (7,005 ft.) are the highest summits. The western half of Magellan's strait, therefore, is bordered by the precipitous cliffs, rugged coasts and fiords of Desolación, Santa Inés, Clarence, Aracena and Dawson islands. South of the Beagle channel a similar group of islands, of which Hoste and Navarino are the largest, spread into the waters of Drake strait and terminate in the headland of Cape Horn, generally regarded as the southernmost point of South America, although the Diego Ramirez group lies 60 mi. to the southwest.

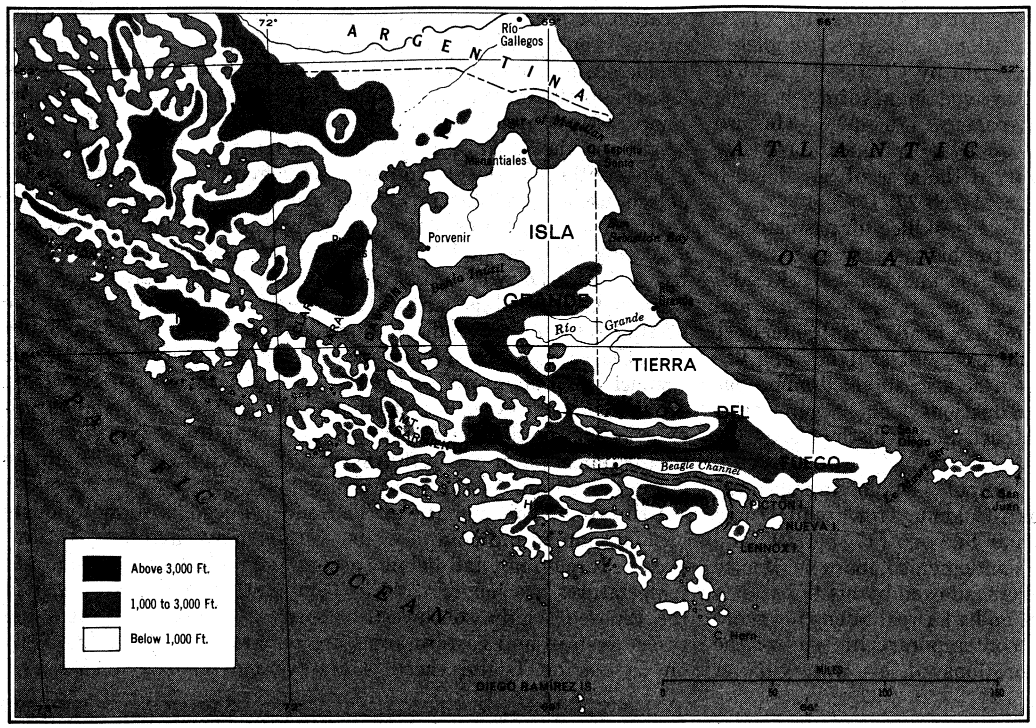
Climate.—The climate of Tierra del Fuego is monotonously cool in summer and cold in winter, although average temperatures even in July do not fall below freezing point, and average summer temperatures are below 52° F. Temperature ranges are least in the exposed windy southwestern areas. Rainfall contrasts between western and eastern areas are remarkable. At Bahia Félix on Desolación Island there is an average annual precipitation of 200 in, while at Rio Grande in Argentine Tierra del Fuego only one-tenth as much rain falls. The Beagle channel areas have usually less than 30 in. Three days out of four are wet in the west; one in four in the east.

E. AUBERT DE LA RÜE

AUSTRAL RAIN FOREST OF BEECH-LIKE TREES WITH YELLOW HANGING LICHENS ON NAVARINO ISLAND. TIERRA DEL FUEGO

Vegetation.—In the exposed. precipitous, southern and western areas vegetation is limited to mosses and stunted trees, but nhere terrain permits. evergreen beech clothes the islands, deteriorating upward into bushes. bare rock and ice and snow. The central part of the main island from the Atlantic to Inutil bay has deciduous beech forests, and the northern plains have a tussock grass cover.

History and Exploration.—Tierra del Fuego was discovered by Ferdinand Magellan in 1520 when he sailed through the strait named after him and called this region "land of fire" In 1578 Sir Francis Drake first sighted the point which in 1616 was named Cape Hoorn (anglicized into Horn) by the Dutch navigators Jacob Lemaire and Willem Schouten In 1619 the brothers Garcia and Gonzalo de Nodal first circumnavigated the archi-



SURFACE FEATURES OF TIERRA DEL FUEGO

pelago. No systematic exploration was attempted until the British admiralty undertook a thorough survey of the whole group by Philip Parker King and Robert Fitzroy during the decade 1826–36. They were accompanied on the voyage of the Beagle by Charles Darwin, then a young man. The present place names of the region are due in large measure to these surveys; although Chilean naval exploration and aerial mapping have filled in much detail. most hydrographic charts are based on King and Fitzroy's original work.

For 350 years after Magellan's voyage the region was left in the undisputed occupation of its indigenous peoples, but in the 1880s two events led to its colonization by European immigrants and Chilean and Argentine nationals. These mere the introduction of sheep farming, which in 20 years spread from Gente Grande bay to occupy all the grassland areas?and the discovery of gold along the eastern and southeastern coasts and on the beaches of the islands south of Beagle channel. In the 18'90s the gold rush spread to the northern rivers of the main island. The political result of this colonization was the partitioning of the island between Chile and Argentina, Porvenir on Magellan's strait becoming the main Chilean town and Ushuaia on Beagle channel the Argentine capital. The Ushuaia area together with Dawson Island, Rio Grande and Lake Fagnano became the main scene of missionary activity among the Indian peoples. Both Chilean and Argentine areas were at first territories administered by the central governments but they were raised to provincial status in 1929 and 1955 respectively.

The **People.**—Ona Indians occupied the pampa and deciduous forest belt of the north of the main island and were hunters of the guanaco and tucu-tucu (similar to a cavy). Yahgan Indians lived in the Fuegian archipelago, especially on Beagle channel, anchoring their canoes in the dense masses of kelp in those waters and gaining their livelihood from shellfish, seals and otters. Small groups of Alacalufs penetrated the northwestern channels from the fiords of western Magallanes. Few of these indigenous people now survive, as European settlement of their lands and the ravages of disease spelled their doom.

The present inhabitants of Tierra del Fuego are the immigrants and their descendants who were attracted by the pastoral industry, the gold rush, the discovery of oil and the general economic expansion of the region. In addition to Chileans and Argentinians, a great variety of European nationalities are represented. Yugoslavs are the predominant element derived from the gold-rush days. with Spaniards, British and Italians forming smaller minorities. Ushuaia still retains a penal settlement, and a colony of Italians was established nearby in 1948, Most of Tierra del Fuego's people live on the main island, but a subsidiary concentration is on Navarino Island where its sheep farms represent the world's southernmost land-based economic activity.

The Economy. — Pastoralism and petroleum exploitation dominate the region's occupational and commercial life. Enormous sheep farms were established in the favourable northern areas, one of which still exceeds 1,000,000 ac. in extent, while another carries 185,000 sheep. On the expiry of some of the leases in 1938 and 1957, subdivision of the farms was undertaken to increase the density of settlement. The discovery of petroleum at Manantiales in 1946 converted the northern part of Chilean Tierra del Fuego into that republic's only oil field; pipelines were laid to Magellan's strait for export of the petroleum to central Chile. A small refining plant on the oil field produces the needs of Magallanes province. There is also some lumbering in the forested areas of Beagle channel and Magellan's strait, fish and crayfish canning at Ushuaia and Porvenir, and fur hunting for nutria and seal. A meat refrigerating plant is located at Rio Grande but most surplus sheep are processed at mainland *frigoríficos.*

Road communications are poor. there are no railways but air services based on Punta Arenas and Rio Gallegos maintain links with the principal settlements in the Chilean and Argentine areas respectively. Sea communications are also of importance; a regular service plies between Porvenir and Punta Arenas, and naval vessels supply Navarino and Ushuaia.

(G. J. B.)

TIFFANY, CHARLES LEWIS (1812–1902). U.S. jeweler who made a specialty of importing historic gems, jewelry and art works, was born in Killingly, Conn., on Feb. 15, 1812. He moved to New York city in 1837, and with John B. Young opened a fancy goods store. It became Tiffany, Young and Ellis in 1831 and. after branching out into jewelry manufacture, was reorganized as Tiffany & Co. in 1853. Tiffany adopted the standards of English silver in 1851, thereby establishing the term "sterling" in the U.S. and affirming the high prestige of his firm.

In 1858 Tiffany obtained a surplus section of the newly laid Atlantic cable. which he cut into pieces and sold as souvenirs with great success. At the beginning of the Civil War he turned most of his capital to the manufacture of swords, medals and other war material. In 1868 the company was incorporated and branches were established at London and Geneva. In 1887 he bought some of the crown jewels of France. He was made a chevalier of the Legion of Honour in 1878. He died in Sew York city on Feb. 18,

1902. He was the father of Louis Comfort Tiffany (*q.v.*).

See F. Heydt, *Charles L. Tiffany* (1893).

TIFFANY, LOUIS COMFORT (1848–1933), U.S. painter, craftsman and decorator, who is considered one of the leading original U.S. designers, was born in New York city on Feb. 18, 1848. the son of Charles L. Tiffany (*q.v.*). He became internationally famous for the inimitable glass which he named favrile, a neologism from the Latin faber. Tiffany began experimenting with glass in 1875 and could produce it reliably by the 1890s, when examples were donated to the Smithsonian institution and the Metropolitan Museum of Art; he won a grand prize at the 1900 Paris exhibition. Favrile glass, iridescent and freely shaped, was sometimes combined with bronzelike alloys and other metals; it enjoyed widespread popularity from 1890 to 1915, and again in the 1950s. Trained as a painter of narrative subjects in Paris, Tiffany visited Morocco; eastern and Amerindian influences mark his work. Returning to the U.S., Tiffany became a recognized painter. He established a decorating firm later known as Tiffany Studios, which served wealthy New Yorkers. redecorated the reception rooms at the White House. Washington, D.C., and was most active in church interiors. Stained-glass windows were its specialty, best known being the huge glass curtain (1911) at the Palacio de Bellas Artes in Mexico City. Tiffany, a director of his father's firm, established the Louis Comfort Tiffany foundation for young artists at his luxurious and celebrated Long Island estate (sold in 1946 to provide scholarship funds). He died, Jan. 17, 1933.

See R Koch, *Louis Comfort Tiffany, 1848–1933* (1958). (Er K)

TIFFIN, a city of northwestern Ohio, U.S., on the Sandusky river 40 mi. S.S.E. of Toledo; the seat of Seneca county. The present city began as Fort Ball, military depot in the War of 1812; the first settlement came in 1817 when Erastus Bowe built a tavern on the north bank of the river. In 1820 Josiah Hedges founded on the south bank another settlement, Tiffin, named for Edward Tiffin, the first governor of Ohio. Incorporated in 1835, Tiffin merged with Fort Ball in 1850. The discovery of natural gas in the vicinity in 1888 provided momentum for the growth of a community of well-diversified industries in a fertile agricultural region. Educational facilities include Heidelberg college, a coeducational liberal arts college opened in 1850 and supervised by the Evangelical and Reformed church (now the United Church of Christ). In Tiffin are a county historical museum, the national home of the Daughters of America and a state mental hospital. For comparative population figures see table in OHIO: Population. (C. G. K.)

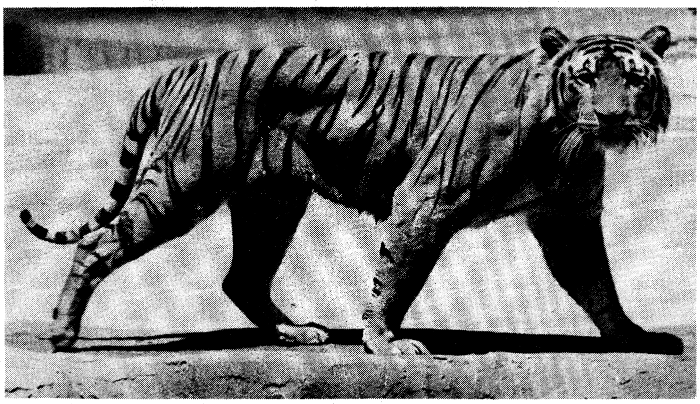
TIFLIS (renamed, as in Georgian, TBILISI, also TPILISI), the capital of the Georgian Soviet Socialist Republic, U.S S.R., and the chief town of Transcaucasia, situated on both banks of the Kura river. and on the railway linking the Black sea and the Caspian, in 41° 41' N., 44° 48' E. Pop. (1959) 694,000. It is sheltered by hills (1,500–2,400 ft.). Products include tobacco. vegetable oils. soap, cognac, leather goods, furniture, textiles and machinery. On the left bank of the Kura stands the Metekhi castle. formerly a palace of the Georgian kings. the foundation of which is ascribed to King Vakhtang Gorgasali (Gurgaslan) of Iberia (5th–6th century). The Sion cathedral traces its origin to the 5th century; other churches date from the 14th and 15th centuries, and the Armenian cathedral of Van rebuilt in the 18th century, from 1480. There are numerous museums and educational institutions. The tonn is at the southern extremity of the Georgian military road, which links it through the Darial gorge with Orjonikidze. The oriental markets and bazaars. where Iranians. Kirghiz. Tatars and peoples from the east congregate, display the work of Georgian silversmiths, gunsmiths and swordmakers; carpets, dried fruits and silken goods are important items.

The foundation of Tiflis dates from the 4th century A.D., but it succeeded Mtskhet as the capital of Iberia (eastern Georgia) in the 5th–6th century. After the temporary abolition of the Iberian monarchy, after 532. Tiflis was made the residence of the Iranian viceroys (*marzbans*). It then suffered successive plunderings at the hands of the Byzantines in 626, during the wars of the emperor Heraclius; the Arabs took it in the same century, and from the 8th century it was the seat of an Arab emirate until its incorporation into the kingdom of Georgia in 1122, by David II the Builder, and its installation as the national capital. In 1225–31 it was taken by the Khwarizm-Shah Jalaladdin and in 1234 by the Mongols. In the autumn of 1386 Tiflis fell to the Mongol conqueror Tamerlane, who led into captivity King Bagrat V of Georgia and his queen, Anne of Trebizond. Afterward the Turks seized it several times, and toward the end of the 17th century the Lesghians attacked it. In 1795 the shah of Persia, Agha Mohammed Khan, sacked and plundered Tiflis in the war intended as a reprisal for King Heraclius II's treaty of alliance with Russia of 1783. The Russian troops sent later to the aid of Georgia were instrumental, upon the death of the last king, George XIII, in 1800, in effecting the Russian annexation of that kingdom.

TIGELLINUS, TOFONIUS, minister and favourite of the emperor Nero, was a native of Agrigentum, possibly of Greek descent. During the reign of Caligula he was banished (A.D. 39) for adultery with the emperor's sisters, but recalled by Claudius (41). Having inherited a fortune, he bought land in Apulia and Calabria and devoted himself to breeding race horses. In this manner he gained the favour of Nero. In 62 he was promoted to the prefecture of the praetorian guards. The great fire of 64 broke out afresh in his gardens, and he was suspected of being concerned with it. In 65, during the investigation into the abortive conspiracy of Piso, he and Poppaea formed a kind of imperial privy council. In 67 he accompanied Nero on his tour in Greece. He deserted Nero at the last, and took the praetorians with him. Under Galba he was obliged to give up his command, but managed to save his life. Otho, on his accession (69), determined to remove him. While in the baths at Sinuessa, Tigellinus received the news that he must die, and, having failed to gain a respite, cut his throat.

TIGER (Panthera tigris), an animal rivaled only by the lion in size, strength and ferocity among the catlike beasts of prey (see CARNIVORA), the difference between the two lying mainly in the skin and its coverings. A tiger's skull may almost always be distinguished from that of a lion by the circumstance that the nasal bones extend higher on the forehead than the maxillae, instead of stopping on nearly the same line.

Although examples of both species do present considerable variations in size, the length of the largest Bengal tiger may exceed that of any lion. Ten feet from the tip of the nose to the end of the tail is no unusual length for a large male tiger. The female is somewhat smaller, and has a lighter and narrower head. The tiger has no mane, but in old males the hair on the cheeks is rather long and spreading. The ground colour of the upper and outer parts of the head, body, limbs and tail, is bright rufous fawn; and these parts are beautifully marked with transverse stripes of a



W. SUSCHITZKY

TIGER (PANTHERA TIGRIS), NATIVE OF SOUTHEAST ASIA

dark, almost black colour. The markings vary much in different animals. and even on the two sides of the same animal. The under parts of the body, the inside of the limbs, the cheeks and a large spot over each eye are nearly white. The tigers which inhabit hotter regions, as Bengal and the south Asiatic islands, have shorter and smoother hair, and are more richly coloured and distinctly striped than those of northern China and Siberia, in which the fur is longer, softer and lighter coloured. Black and white phases have been recorded, but they are rare. The tiger is exclusively Asiatic, but has a wide range in that continent, having been found in almost all suitable localities south of a line drawn from the Euphrates river, passing along the southern shores of the Caspian and Sea of Aral by Lake Baikal to the Sea of Okhotsk. Its most northern range is the territory of the Amur, its most southern the islands of Sumatra, Java and Bali. Westward it reaches to Turkish Georgia and eastward to the island of Sakhalin. It is absent, however, from the great elevated plateau of Central Asia, nor does it inhabit Ceylon, Borneo or the other islands of the Indo-Malay archipelago, except those named.

The principal food of the tiger in India is cattle, deer, wild hog and peafowl, and occasionally human beings. The regular "man-eater" is generally an old tiger whose vigour is past, and whose teeth are worn and defective; it takes up its abode in the neighbourhood of a village, the population of which it finds an easier prey than wild animals. Though chiefly affecting grassy plains or swamps, tigers are also found in forests, and seem to be fond of haunting the neighbourhood of old ruins. As a rule, they do not climb trees; but when pressed by fear, as during an inundation, they have been known to do so. They take to the water readily and are good swimmers.

The tigress gives birth to from two to six cubs, but three is the common number. She is an affectionate mother, and generally guards and trains her young with watchful solicitude. They remain with her until nearly full-grown, or about the second year, when they are able to kill for themselves. While they remain with her she defends them with courage and energy, but she has been known to desert them when pressed, and even to eat them when starved. As soon as they begin to require other food than her milk, she kills for them, teaching them to do so by practising on small animals.

Although the tiger is superficially distinct from the lion, both species are very closely allied anatomically and physiologically. Under certain conditions, as in enforced confinement in zoos, they occasionally hybridize. The offspring of such matings are called "tigons" when the father is a tiger or "ligers" when the father is a lion.

See Sir J. Fayrer, *Royal Tiger of Bengal (1875);* F. W. Champion, *With a Camera in Tiger Land* (1927); R. I. Pocock, *Fauna of British India, Mammalia,* vol. 1 (1939).

TIGERFLOWER, botanically *Tigridia,* a genus of tender herbaceous bulbous plants of the iris family (Iridaceae), natives of Mexico, Central America. Peru and Chile. They have long narrow plicately veined leaves springing from the bulb and a stem bearing two or three scattered smaller leaves and above a few flowers emerging from a spathe. The striking flowers are spotted (whence the name tigerflower or tiger iris) and have free segments springing from a tube; the three large broad outer segments are concavely spreading, the three inner are much smaller and more erect. T. *pavonia* (flower of Tigris or tigerflower) has large red flowers spotted with yellow and purple; however, many colourful variants exist in the garden varieties.

J. HORACE MCFARLAND CO.

TIGERFLOWER (TIGRIDIA PAVONIA)

TIGLATH-PILESER (Assyrian Tukulti-pal-E-sarra, "my confidence is the son of E-sarra," *i.e.,* the god In-Aristi), the name of several Assyrian kings. Their numbering is not certain.

TIGLATH-PILESER I, the son of Ashur-ris-isi, ascended the throne c. 1120 B.C., and was one of the greatest of Assyrian conquerors. His first campaign was against the Moschi who had occupied certain Assyrian districts on the Upper Euphrates; then he overran Commagene and eastern Cappadocia, and drove the Hittites from the Assyrian province of Subarti northeast of Malatia. In a subsequent campaign the Assyrian forces penetrated into the Kurdish mountains south of Lake Van and then turned westward, Malatia submitting to the invader. In his fifth year Tiglath-Pileser attacked Comana in Cappadocia, and placed a record of his victories engraved on copper plates in a fortress he built to secure his Cilician conquests. The Aramaeans of north Syria were the next to be attacked, and he thrice made his way as far as the sources of the Tigris. The command of the high road to the Mediterranean was secured by the possession of the Hittite town of Pethor at the junction of the Euphrates and Sajur, and at Arvad he received presents, including a crocodile, from the Egyptian king, and, embarking in a ship, is said to have killed a dolphin in the sea. He was a great builder, the restoration of the temple of Ashur and Hadad at Ashur being one of his works.

TIGLATH-PILESER II or III, son of Hadad-nirari II, appears to have reigned from about 950 to 930 B.C., but nothing is known about him.

TIGLATH-PILESER III or IV was a successful general who usurped the Assyrian throne on the 13th of Iyyar 745 B.C., after the fall of the older dynasty, and changed his name of Pulu (Pul) to that of the famous conqueror of earlier times. In Babylonia, however, he continued to be known as Pulu. He was a man of great ability, both military and administrative, and initiated a new system of policy in Assyria, which he aimed at making the head of a centralized empire bound together by a bureaucracy uho derived its power from the king. The empire was supported by a standing army and an elaborate system of finance. The first task of Tiglath-Pileser was to reduce the Aramaean tribes to order, and so win the gratitude of the Babylonian priests. Then he struck terror into the wild tribes on the eastern frontiers of the kingdom by a campaign which extended into the remotest parts of Media. Next came the defeat of a northern coalition headed by Sar-duris of Ararat, more than 72,000 of the enemy being captured with the city of Arpad, where the Assyrian king received the homage of the various Syrian princes. Arpad revolted soon afterward, but was retaken by a siege in 740 B.C. The following year Azariah of Judah appears among the enemies of Tiglath-Pileser, who had overthrown his Hamathite allies and annexed the 19 districts of Hamath. The conquered populations were now transported to distant parts of the empire. In 737 B.C. Tiglath-Pileser again marched into Media, and in 735 he invaded Ararat and wasted the country around the capital Van to a distance of 450 miles. In 734 B.C. he was called to the help of Yahukhazi (Ahaz) of Judah, who had been attacked by Pekah of Israel and Rezon (Rasun) of Damascus. Rezon, defeated in battle, fled to his capital which was at once invested by the Assyrians, while with another portion of his army Tiglath-Pileser ravaged Syria and overran the kingdom of Samaria. Ammon, Moab, Edom and the queen of Sheba sent tribute, and Teima in northern Arabia was captured by the Assyrian troops. In 732 B.C. Damascus fell; Rezon was put to death, and an Assyrian satrap appointed in his stead. Tyre also was made tributary.

The next year Tiglath-Pileser entered Babylonia, but it was not until 729 B.C. that the Chaldaean prince Ukin-zer (Chinzirus) was driven from Babylon and Tiglath-Pileser acknowledged as its legitimate ruler. In the early part of Tebet 727 B.C. he died, after having built two palaces, one at Nineveh, the other at Calah.

BIBLIOGRAPHY.—Sidney Smith, *Early History of Assyria* (1928) ; A. T. Olmstead, *History oj Assyria* (1923) ; S. A. Pallis, ***The** Antiquity of Iraq: a Handbook of Assyriology* (1956).

TIGRANES (DIKRAN), king of Armenia (c. 140–55 B.C.), was the son or nephew of Artavasdes of Armenia, and a member of the dynasty founded by Artaxias. (See SELEUCID DYNASTY.) He was given to Mithradates II of Farthia as a hostage, and purchased his freedom by ceding 70 valleys bordering on Media.

Tigranes ascended the throne in 95 or 94 B.C. (Plut. Luc. 21), and immediately began to enlarge his kingdom. He deposed Artanes, king of Sophene, and entered into alliance with Mithradates VI Eupator of Pontus, whose daughter Cleopatra he married. In 93 he invaded Cappadocia in the interest of Mithradates, but was clriven back by Sulla in 92. During his first war with Rome, Mithradates nas supported by Tigranes. although he abstained from interfering openly. But he meanwhile began war with the Parthians. whose empire mas weakened after the death of Mithradates II (about 88) by internal dissensions and invasions of the Scythians. Tigranes reconquered the valleys which he had ceded, and laid waste a great part of Media; the kings of Atropatene Gordpene (now Bohtan), Adiabene (Xssyria) and Osroene (Edessa) became his vassals, who attended him like slaves wherever he went; he also annexed northern Mesopotamia. In 83 he invaded Syria, defeated the last successors of Seleucus and occupied Cilicia. In the war between Mithradates and Sulla he did not interfere, but after the death of Sulla (78) he occupied Cappadocia again and expelled King Ariobarzanes I, the vassal of the Romans. During the next years he had a nar in Syria, against Cleopatra Selene. and in Cilicia, nhere he destroyed the Greek tonn of Soli. Tigranes now had become "king of kings" and the mightiest monarch of Asia So he built a new royal city, Tigranocerta, on the borders of Armenia and Mesopotamia, between Mt. Masius and the Tigris, where he accumulated all his wealth and to which he transplanted the inhabitants of 12 Greek touns of Cappadocia, Cilicia and Syria (for the situation, which is much disputed, cf. Tac. *Ann.* xiv, 24, xv, 5, ed. Furneaux). He also transplanted many Arabic tribes into Mesopotamia. But the Romans could not tolerate encroachment upon their sphere of power, and in 69 Lucullus invaded Armenia. Tigranes was beaten at Tigranocerta on Oct. 6, 69, and again near Artaxata in Sept. 68. The recall of Lucullus gave some respite to the two kings, who even invaded Asia Minor again. But meanwhile a son of Tigranes and Cleopatra, called Tigranes, like his father, rebelled against him (as the old man had already killed two of his sons, he had reason enough to be afraid for his life) and found refuge with the Parthian king Phraates III, who sent him back with an army. The old king now gave up all hope of resistance; he put a price on the head of Mithradates, and when Pompey advanced into Armenia and united with the younger Tigranes, he surrendered (66 B.C.). Pompey now changed his policy; he received the old Tigranes graciously and gave him back his diadem. while he treated the son very coolly and soon made him prisoner. The younger Tigranes was led in triumph into Rome, where he found his death when he tried to escape from his confinement by the intrigues of P. Clodius in 58. The father after his defeat ruled about ten years longer over Armenia as vassal of the Romans. He died about 56, and was succeeded by his son Artavasdes. (See also MITHRADATES.)

TIGRÉ (SHOA), a northern province of Ethiopia; one of the four former principal divisions of the country. Pop. (1956 est.) 1,000,000; area 26.500 sq.mi. Tigré contains the towns of Axum (Aksum, *q.v.*), capital of the ancient Ethiopic empire, and Adua (Aduwa, *q.v.*). (*See* ETHIOPIA.) Tigriña, the dialect spoken in Tigré and Lasta, is nearer the ancient Gîz than is Amharic, the official and more widely diffused language of Ethiopia.

See J. Schreiber, *Manuel de la langue tigrai* (Vienna, 1887–93); and L. de Vito, *Grammatica della lingua tigrigna* (Rome, 1895).

TIGRIS, the more eastern of the two rivers of Mesopotamia. It rises from two principal sources. The eastern branch rises from several streams to the south and west of Lake Van. The western branch rises about 10 miles south of Lake Geuljik. The upper waters of the Tigris therefore lie on the southern slopes of the Taurus the northern slopes of which are part of the basin of the Euphrates. The Tigris in its lower course seems to be particularly unstable. Although there is no evidence of any great change in the upper waters, from Kut al Amara onward the bed of the river has shown considerable variations. At the beginning of the second millennium B.C. the river appears to have been flowing along the Shatt al Hai; indeed the position of Lagash makes it almost certain that this was its normal course in Sumerian times. In Sassanid times it followed its present easterly course; during Arab times, however, it was apparently flowing along the Shatt al Hai. There are no ancient remains on the Tigris therefore below Kut al Amara, and owing to the changeable nature of the stream even few modern villages. In the alluvial area the Tigris lies lower than the Euphrates as far as the Shatt al Hai, and therefore in ancient times received the tailings of the canals, but did not supply water except locally for irrigation. It appears not to have deposited its silt as much as the Euphrates, probably due to the lack of suitable terrain for the formation of fresh water lakes, which are usually a silting ground for river deposits. Since its abandonment of the old channel the Tigris has probably contributed very considerably to the formation of new land at the head of the gulf. The upper drainage area also seems to have altered to a slight extent. The Arab geographers suggest that at one time at least part of the waters of the Khabur, a tributary of the Euphrates, flowed into the Tigris by a channel which was navigable when in flood. As late as 1832 Ormsby reported a stream from Jabal Sinjar which joined the Euphrates near Sharqat. This stream still appears to exist, but it no longer empties itself into the Tigris and in view of the waywardness of the rivers of Mesopotamia it is possible that Ormsby's observation was made at an unusual period.

Topography.— The Western Tigris, on whose banks lies the important town of Diarbekr flows east along the southern slopes of the Taurus and receives a number of tributaries of small size. The two main branches join at Til, from which point it runs in a southeasterly direction. It continues to receive a number of small tributary streams, mostly on the left bank. From the neighbourhood of Mosul to the confluence of the Greater Zab there lies a fertile triangle of land between the hills and the river. Nineveh lay on the left bank opposite Mosul. A little lower down the stream was the city of Kalakh. At this point two great barrages were erected in ancient times, which still effectively block the river for navigation. From a little above the confluence of the Greater Zab down to Tekrit the river flows through an uninhabited desert, the only important town being Kalaat Sharqat, the ancient Assur, which at present forms the railhead of the southern part of the Baghdad railway. About 30 miles below Sharqat the Lesser Zab joins the Tigris. From Tekrit, a city founded during the Persian domination, downwards, signs of ancient irrigation begin, although the alluvial plain is not entered until Samarra is reached. Below Samarra as far as Kut al Amara, a distance of about 200 miles, there was in ancient times a canal which served to straighten the course of the stream. The two principal tributaries in this region, the Adhem and the Diala, were also canalized, the Adhem reaching the main stream just below Samarra, the Diala below Baghdad. Close to the mouth of the Adhem are the ruins of an ancient city probably to be identified with Xenophon's Opis. Near this point the river makes a great bend and flows south to Baghdad (*q.v.*) at which point the Tigris and the Euphrates are only about 35 miles apart. In ancient times the two rivers ran close to one another and there are traces of numerous old irrigation canals connecting them. Below Baghdad lie the ruins of ancient Ctesiphon, on the left bank; opposite Seleucia on the other bank Kut al Amara marks the point where the Shatt al Hai leaves the present main stream. Below this point owing to the change in the course of the stream there are no ancient remains along the Tigris. The modern towns are Ali al Gharbi, Ali esh Sharki Amara, Qalaat Saleh and Kurna, below which point the two rivers unite to form the Shatt al Arab.

Navigation.—Although before World War I a launch navigated the river between Baghdad and Samarra (about 90 miles), and in 1838 a steamer went to within 28 miles of Mosul the upper Tigris is only navigable for native rafts. These rafts which may be as much as 35 tons burden are made of timber supported by inflated skins. During flood they cover the 27; miles between Baghdad and Mosul in three or four days. At their destination the wood finds a ready market in this treeless country, and the skins are carried back again on the backs of asses. No upstream traffic is carried on. The river flows over a bed of clay, sand or conglomerate, and is full of obstructions. Opinion has however been expressed that if these obstructions and the ancient barrages at Sharqat were cleared away, navigation to Mosul would be possible. In the lower part of the river there are bridges of boats at Baghdad, Gerara, Kut, Kut al Amara and Kale Sale. Between Baghdad and Kale Sale the Tigris is navigable all through the year by vessels drawing up to 5 feet of water. Below this point the river is in a bad condition, largely owing to the barrages built by native cultivators, but great efforts have been made to restore the channel. At low water it is generally estimated that only three feet of water is available. The low water period is reckoned from July to November, and high water from December to June, but the river is extremely liable to sudden floods.

The statistical details so far as at present recorded are as follows. From Baghdad to Kut the distance by river is 216 miles, the distance by land being 103 miles. At Baghdad the river is 114 feet above sea level, at Kut it is 57 feet, the fall in the river surface being 1 in 20,000. The width of the river is about a quarter of a mile, its depth at high water 26 feet, and at low 4½. The discharge in flood is 5,500 cubic metres a secbnd, dropping to as low as 300 cubic metres at low water. The velocity in flood is a little under 4 miles an hour, dropping at low water 1¼. At Kut the Shatt al Hai discharges about 1,000 cubic metres at high flood, but is dry at low water. Between Kut and Kut al Amara the river distance is 153 miles, and by land 119. The mean level at Amara is 28 feet, the drop between the two points being therefore about 19 feet, the gradient of the river level is 1 in 35,000. The average width of the river in this reach, which is singularly free from any obstacles for navigation, is about 365 yards, while the depth is 25 feet in flood and about 6 ft. 6 in. at low water, with a respective velocity of about the same as in the upper reach. The discharge at low water is similar but at high water about 1,000 cubic metres less at the head of the reach; owing however to branches at the lower end of the reach the discharge at high water only reaches about 2,500 cubic metres per second.

Between Amara and Kurna the river is affected by various channels which drain off much of the water. At Amara on the left bank the Chala, with a bed about 6 feet lower than the main stream, discharges about 1,000 cubic metres a second at high water falling to rather more than a tenth of that amount at low. Below this point first the Majar Kebir and then the Machera draw off about the same amount. Considerable changes take place therefore in the size of the stream between Amara and Kurna, at which point the level is 10 feet above sea level. The average width of the Tigris at this reach is a little under 200 yards, with a depth of 13 feet in flood and 6 ft. 6 in, at low water with a discharge of only 1,250 cubic metres per second and 150 at high water and low water respectively. Below Kale Sale although the depth is the same the average width is only 65 yards. Below Ezra's Tomb some of the lost waters return to the river from swamps and the stream becomes once more nearly 200 yards broad. The two rivers meet at Karmat Ali at which point the Tigris, full of dark marshy water, is more than 30 feet deep and more than 400 yards broad.

It will be seen from these details that the river presents great difficulties for navigation. In flood time it is liable to overrun its banks and convert the whole region into a vast lake. In addition to river steamers two types of native boats are used, a large coracle or Quffeh and river boats, *Safineh*, capable of carrying a cargo of as much as 100 tons. The coracles can only go downstream but the river boats are poled or towed upstream and are sailed or rowed with the current.

TILAK, BALGANGADHAR (1856–1920), Indian nationalist leader, a Chitpavan Brahmin, was born at Ratnagiri July 23, 1856. At an early age he took the lead in providing education in Poona under Indian direction. In 1890 he was proprietor and editor of two weekly papers, Mahratta, in English, and *Kesari* (*Lion*), in Mahratti, which he used for antigovernment propaganda. His violent condemnation in 1897 of the plague prevention regulations resulted in his being convicted for sedition and sentenced to 18 months' imprisonment. For a similar offence he was sentenced in 1908 to six years' transportation, later commuted to simple imprisonment. After his release he took part in the home-rule campaign, and secured for his party control of the national congress. He died in Bombay Aug. 1, 1920. His formative part in the cult of Indian unrest is shown in the report of the Rowlatt sedition committee (1918). His speeches are collected in Lokamanaya B. G. *Tilak* (2nd ed. Madras, 1920).

TILBURG, a town, province of North Brabant, the Netherlands, and a junction station 13½ mi. S.E. of Breda by rail. Pop. (1954) 106,949. Tilburg rose to importance after the separation of Belgium from Holland as one of the chief industrial (mainly textile) centres of the south. In 1927 a Roman Catholic graduate school for business administration was established there. Tilburg was the favourite residence of King William II.

TILBURY DOCKS, on the north shore of the Thames, in Essex, Eng. They lie opposite Gravesend 25 mi. below London bridge and about the same distance from the Nore, being thus within the Port of London. They were constructed in 1886. but the rapid development of the Port of London necessitated many changes and they now accommodate the largest liners using the port. Railway communication provides direct connection for goods traffic with all northern lines. The system has a total land area of 72J ac. and a water area of 104 ac. It consists of a main dock with three branch docks, connected with a tidal basin. The principal entrance lock is 1,000 ft. long, 110 ft. wide, with a depth on the sills of 45½ ft. There are three small dry docks; a fourth is 750 ft. long and 110 ft. wide. A river cargo jetty, 1,000 ft. by 50 ft., was completed in 1921, while a passenger landing stage 1,142 ft. long, also in the river, with 3J ft. depth alongside at low water, was opened in 1930. The total length of dock quayage is nearly 4 mi. A new quay, 842 ft. long, and a passenger terminal with frontage of 550 ft. on the north side of the main dock was under construction in the mid-1950s. To meet the growing volume of road transport a new system of dock roads was built.

TILDEN, SAMUEL JONES (1814–1886), U.S. statesman, was born at New Lebanon, N.Y., Feb. 9, 1814. In 1834 he entered Yale university, but soon withdrew on account of ill health, and later studied in the College of the City of New York. He was admitted to the bar in 1841. In the financial troubles between 1850 and 1860 it is said that more than half the railways north of the Ohio river and between the Hudson and the Missouri rivers were at some time his clients. Tilden served in the state assembly in 1846 and in the state constitutional conventions of 1846 and 1867. In 1848 he participated in the revolt of the "Barn-burner" or free-soil faction of the New York Democrats, and in 1855 was the candidate of the "softshell" or antislavery faction for attorney general of the state. During the Civil War, although he opposed several of Lincoln's war measures, he gave the union cause his heartiest support.

In 1866 Tilden became chairman of the Democratic state committee, and soon came into conflict with the notorious "Tweed ring." As the "ring" could be destroyed only by removing the corrupt judges who were its tools, Tilden, after entering the assembly in 1872, took a leading part in their impeachment. By analysing the bank accounts of certain members of the "ring," he obtained legal proof of the principle on which the spoils had been divided. His fame as a reformer brought him to the governor's chair in 1874, and he gave his attention to breaking up the "canal ring," made up of members of both parties who had been robbing the state through maladministration of its canals.

In 1876 the Democrats nominated him for the presidency, the Republicans nominating Rutherford B. Hayes of Ohio. The result was the disputed election of 1876, when two sets of returns were sent to Washington from the states of Florida, Louisiana, South Carolina and Oregon. As the federal constitution contained no provision for settling a dispute of this kind the two houses of congress agreed to the appointment of an extra-constitutional body, the "Electoral Commission" (*q.v.*), which decided all the contests in favour of the Republican candidates. Tilden counselled his followers to abide quietly by the result. The remainder of his life was spent in retirement at his country home, Greystone, near Yonkers, N.Y., where he died Aug. 4, 1886. Of his fortune (estimated at $5,000,000) approximately $4,000,000 was bequeathed for the establishment and maintenance of "a free public library and reading-room in the City of New York"; but, as the will was successfully contested by relatives, only about $2,000,000 of the bequest was applied to its original purpose; in 1895 the Tilden Trust was combined with the Astor and Lenox libraries to form the New York public library.

See *Writings and Speeches of Samuel J. Tilden* (1885) and *Letters and Literary Memorials of Samuel J. Tilden* (1908), both edited by John Bigelow; also Bigelow's *Life of Samuel J. Tilden* (1895); and P. L. Haworth, *The Hayes-Tilden Election* (1927).

TILDEN, WILLIAM TATEM II (1893–1953), U.S. tennis player, first American to win the men's singles at Wimbledon, dominated tennis in the 1920s. Born in Philadelphia, Feb. 10, 1893, Tilden was 27 when he won his first national championship, in 1920. For 10 straight years he ranked at the top, winning seven national championships — six (1920–25) in a row and the last in 1929. He won the Wimbledon title in 1920, 1921 and 1930, was on 11 Davis cup teams and led the battle that kept the prized cup in the U.S. for seven straight years. He won a total of 70 U.S. and international championships.

Tilden had powerful shoulders, a light frame and long legs—the perfect tennis build; he was famous for his cannonball serve and a paralyzing forehand and backhand. He died in Hollywood, Calif., June 5, 1953. (J. D. McC.)

TILE, a thin, flat slab or block, usually of burned clay, glazed or unglazed, used either structurally or decoratively in building. The usage of the word varies widely; in connection with roofing, flat slabs of any material are sometimes termed tiles, as, for instance, the marble tiles of some Greek temples or the bronze tiles of ancient Rome. Similarly, stone slabs, used for roofing, as in certain parts of England, are termed stone tiles; slate, however, is never so called. Many forms of rough terra cotta used structurally in building are called tiles; thus an arch of hollow terra-cotta blocks between steel beams is known as a tile arch; partitions built of hollow terra-cotta blocks are known as hollow-tile partitions; rough terra-cotta pipes used for drainage are called drain tiles; and the steel forms used for casting certain types of reinforced concrete floors are frequently referred to as steel tiles.

The differentiation between tile, terra cotta (*q.v.*) and brick is thus exceedingly vague. (See BRICKWORK.) Modern usage extends the word "tile" to include blocks or panels made of plastics, glass and sound-absorbing materials.

Roofing Tile. — There is no evidence of the use of roofing tiles in the Mediterranean basin prior to the development of Hellenic civilization, but the most ancient examples of roof tiles show such highly developed forms that earlier usage must be assumed. The Greek form of temple roof which remained constant throughout the history of Greek architecture (*q.v.*) consisted of two types of tile, used together. First the roof surface was covered with tiles generally flat, but with adjoining edges raised, laid in overlapping courses, and all of equal size. Convex covering tiles, also overlapping, were then laid over the joints of the flat tiles below; in this manner an absolutely watertight roof could be produced. In order to make the architectural effect more delicate the ends of both lower tile and covering tile were rebated, so that the thickness of the overlapping portion was only half the thickness of the tile. At the bottom of each row of covering tiles was either a marble or tile upright, curved, decorative member known as an antefix.

In some cases the covering tiles were of pointed, straight-line section — the most common Greek type — in others a tile of semicircular section was used, easy to manufacture but lacking in the extreme refinement of the other type; in the simpler domestic work, the lower courses were also of curved section, a segmental concave shape replacing the flat tile with raised edges. The marble tile used in some Greek temples, as in that of Bassae (5th century B.C., by Ictinus), is universally of the type with flat under tile and pointed covering tile, although at times, in order to reduce the number of joints, the covering tile and the under tile are cut from the same piece of marble.

Two other types of roof tile were common in Roman architecture (*q.v.*) and probably represent common Mediterranean types of much earlier origin. One of these is the so-called "Spanish tile," also called "pantile," with a contour resembling the letter S, in which the convex part of each tile fits over the edge of the concave portion of the next. The other type is the shingle or flat tile found frequently in the Roman ruins of the northern provinces. These flat tiles are often of stone.

The usual material of all of these types of tile is burned clay, varying in colour from orange-yellow to purple-red. It is known, however, that bronze tiles were relatively common on the most monumental buildings of the Roman empire. Due to the rarity and value of bronze during the middle ages and the Renaissance, no examples of ancient bronze roof tiles are known.

All of the classic forms of clay tile continued in use in various parts of the world during the medieval period, but their supremacy as a roofing material gradually yielded to lead and zinc for churches, public buildings, palaces, etc., and to slate, stone and thatch for the smaller private houses.

Clay roof tiles remain of substantially the same form; improvements have been only in methods of manufacture and not in design. The flat tile designed to hook over roof battens or boards is perhaps the most common type of small house-roof covering in England and parts of France, and the combination of concave under tile and convex over tile is almost universal on pitched roofs in Italy, Spain, Greece and Turkey. The S-shaped tile is also common around the Mediterranean. The curved tiles are almost always laid in a heavy bed of waterproofed mortar, with ridges and hips covered by courses of overlapping tiles, similarly bedded; with flat tiles, the use of mortar is restricted to the convex or pointed tiles covering the hips and ridges.

The best modern usage in laying tiles of this type demands the complete covering of the roof surface with a watertight material such as slaters' felt or heavy waterproofed paper before the tile is applied. The tiles themselves are held in place sometimes by copper nails which secure the under tiles direct to the roofing and the covering tiles to wood battens which run up the slope of the roof under each row of covering tiles, and sometimes by copper wire brought up through two holes in each tile and twisted together.

Although various attempts have been made to imitate clay tiles in stamped metal and concrete, these imitations are so lacking in the individual variation typical of ceramicware that their use has been restricted to the cheapest type of jerry-built construction; their use, even there, is seriously questionable. Quite different are the roofing tiles of reinforced and waterproof concrete, which are common in industrial buildings, especially in Europe. These modern, industrial tiles are usually of large size — sometimes running to four feet in length, and arranged to interlock, with the exposed surfaces grooved or channeled in such a way as to lead the water away from any joints. In these concrete tiles colouring matter is usually added in the material itself. (See also ROOF.)

Roofing Tile in the Far East. — Although the principle of the roofing tiles of China and Japan is the same as that in the west, there are many differences in detail. Thus, in temples and palaces in China, the under tiles are slightly concave and overlap, much like those of classic roofs; the covering tiles, however, are made absolutely cylindrical in general contour, with rebated ends, so that they form long, unbroken lines of shadow down the roof. Moreover, instead of the upright antefix of the classic roof, the Chinese tiles have ornaments that project downward, in generally scalloped shapes, over the face of the cornice. There is also, particularly in north China, a tremendous elaboration of ridge and hip tiles, which are frequently of great height, with an elaborately molded section, carrying at their ends rows of animals — a great dragon or the like. At the ends of the ridge are large, grotesque beasts with their heads pointing inward; all these ornaments are modeled and baked in the tile itself. One of the chief glories of the Chinese roof tiles is their colour. This is produced by a shiny glaze that reveals the expected Chinese ceramic skill.

The usual colour of temple and palace roofs is bright yellow, but other colours frequently occur. In central and south China, even temple roofs are frequently black. The cheap roof tile of the ordinary house is also almost black, but without lustre and with overlapping covering tiles like those of the west. (See also CHINESE ARCHITECTURE; TEMPLE.)

The same pattern of rebated, continuous, cylindrical covering tiles is common in the Buddhist shrines of Japan, but colours are rare, the ordinary tile being gray, with a very effective and artistic silvery lustre. (See also JAPANESE ARCHITECTURE.)

Floor Tile.—Except as small fragments of tile occur in classic mosaic (*q.v.*) and terrazzo, tile for floors does not seem to have been common in Europe prior to the 12th century. In the late 12th and 13th centuries, however. tile floors became usual in churches and other important buildings. The most common type consisted of square tile in two colours, usually a dark brown-red and a pale orange or brownish yellow. They were made by casting clay in such a manner that the parts to be in a lighter colour were sunk; when dry, these parts were filled with a clay of different composition which would bum to a lighter colour; the tile thus prepared was then burned. Patterns were formed of many tiles and consisted usually of circles or stars containing heraldic beasts, ecclesiastical symbols, etc.; in many cases the pattern was made with reversed colours, so that what was background colour in one tile was ornament colour in the one next to it. In the earliest examples designs were formed by a mosaic treatment in which the pattern was made by the shape and size of the individual tiles, as in the 13th century example found at Fountains abbey and at Prior Crauden's chapel at Ely (1321–41), both in England. Other common types of medieval pavement have the pattern merely incised, producing the artistic effect of a sketch.

The development of floor tiles in Gothic France was similar. The 12th-century examples are usually mosaic in type with black, dark green, light green and yellow as the predominating colours. The richest examples of these are in the abbey church of St. Denis, near Paris, where certain elaborate, chapel floor pavements still exist from the original building (1140–44) by Abbot Suger. By the end of the century, mosaic had yielded to two-coloured tiles of red and yellow, similar to the English tiles mentioned above. The same type remained constant until well into the 15th century, the designs becoming continuously thinner and more delicate; in the 16th century the art died out, superseded by the painted majolica pavements of the Renaissance.

The Gothic revival of the middle 19th century led, in England, to the revival of the designing and making of tiles of the medieval type and many modern pavements were placed in old churches as a result. Most of this tile has a simple lead glaze and is made not by casting damp, plastic clay, as in the medieval examples, hut by compressing po dered clay in steel dies so that shapes are more perfect and the rapidity of manufacture is vastly increased.

This type of tile, usually known as encaustic, is especially associated with the English ceramic works at Stoke-upon-Trent, particularly those of Minturn.

Meanwhile the Moorish skill in tilemaking had gradually come to be applied to floors. This type of majolica tile was adopted in early Renaissance churches, both in Italy and Spain, although not many examples remain, as the glaze was too soft. The decoration of the Italian majolica pavements consists of the same type of free and graceful classic arabesque trophies, acanthus ornament and coats of arms that is found on contemporary majolica.

In France not only were Italian tiles imported and used, but there soon grew up a local manufacture of similar painted floor tiles, especially at Rouen (established by Masseot Abaquesne, 1542–57), Nevers and Marseilles. With the increasing use of oak parquetry flooring for houses and marble for churches, toward the end of the 17th century, the use of tile diminished. There was similar importation of Italian and Spanish tiles into England during the early Renaissance and possible spasmodic attempts toward the making of certain types of this tile in England itself.

In the 18th century the use of plain, undecorated, square, red tiles, now commonly known as quarry tiles, became common all over northern and western Europe, and to a less extent in the American Colonies.

The greatest advances in modem floor tiles have been made in simple, vitrified, mosaic tiles for use in bathrooms, kitchens, swimming pools and public corridors. These are always machine-pressed and are made of fine clays, thoroughly vitrified and very hard. These are made in small squares, rectangles, hexagons and circles, in a few simple colours. Some, by the addition of gritty substances, such as alundum or carborundum, are given a surface which prevents slipping, even when the tile is wet.

Wall Tile.—Earthenware was used spasmodically for wall decoration by the Egyptians, as in the doorway of the Abusir pyramid of Neterkhet (3rd dynasty). More usually, however, they were in the form of mosaic (*q.v.*). Perhaps based upon earlier Egyptian examples, the people of Crete (*q.v.*) developed to an even higher degree the use of fai'ence for walls. Thus our knowledge of early Cretan houses is largely furnished by many fragments of small fai'ence plaques from the 18th century, B.C., which formed portions of a large, mosaic, fai'ence wall decoration. Moreover, there are in existence many modeled reliefs of fai'ence from the middle and late Minoan period which were apparently inserted in the plaster of walls.

Farther east, in the Tigris-Euphrates valley, a tradition of ceramic wall decoration was early established. (See PERSIA: Archaeology.) This took the form of glazed and enameled bricks rather than tiles proper. It is, nevertheless, important as being one of the first attempts to cover large and continuous wall surfaces with a decorative, ceramic material, and the friezes of marching beasts from Chaldean and Babylonian palaces, from the later Assyrian palaces and from their Persian successors, the famous friezes of the archers and the lions from the early 4th-century palace of Artaxerxes II at Susa, have remained models of this type of decorative work.

Moreover, the tradition of fine ceramic work continued vital throughout the stormy period of the fall of the Roman empire and the Islamic conquest. It is in Syria, the Tigris-Euphrates valley and Persia that wall tiles were, undoubtedly, first made. Thus tradition relates that the lustre tiles of the mosque of Sidi Okba at Kairouan were brought from Baghdad in 894, and it is certain that by the 13th century the manufacture of wall tiles for both exterior and interior use was well established in various centres in Persia, notably Rhages and Veramine. The exterior use of wall tiles was most highly developed, and in Persia, also, the transition from enameled and modeled brick to true, thin tile can easily be seen. By the 15th century tile decoration was supreme in Persia and the character had changed. Mosaics and moldings in relief yielded to a flat treatment with the richness entirely in the coloured, foliated ornament and the inscriptions painted on the tiles themselves. In later Persian art there is no distinguishable difference between the tiles of the exterior and the interior.

These Persian tiles governed the taste of the eastern part of the Islamic world; the same running patterns of leaves, palmettes, the carnation and other flowers that appear on Persian carpets decorate alike the interiors of mosques in Persia, Mesopotamia and Turkey, from potteries as far apart as Rhodes, Damascus and Kutayieh. In colour these have, universally, a blue-white ground with patterns predominantly blue and green, with lesser touches of vermilion and rose and occasional yellows. Several potteries in Asia Minor still operate and produce exquisite wall tiles in the traditional patterns and colours. Because of the gracious delicacy of the interlacing stems and the careful spacing of the leaves and flowers, together with a springlike clarity of the colours, these Turkish, Syrian and Persian wall tiles are among the most perfect wall decorations of their type.

Moorish *Wall* Tile.—Farther west, in Spain and North Africa, the Islamic potters were developing a new type of design which gave rise to the famous Spanish *azulejos*, whose decorative richness was such an important feature in the Alhambra (*q.v.*) at Granada (13th and 14th centuries), the so-called house of Pilate at Seville and similar buildings. Although transitional types occur, like the great plaque from Malaga at the beginning of the 15th century in the collection of M. de Osma, in which the patterns are of an almost Persian freedom, with twining foliage, in the greater number the design was almost purely geometric, being formed of interlacing lines than generate 8- and 10-pointed stars, octagons, irregular pentagons and similar figures. There are, in addition, a great many early tiles from the 13th and 14th centuries in which the influence of Christian heraldry is dominant. Even in the transitional plaque mentioned above, coats of arms appear and it is evident that the Islamic potters produced much purely heraldic tilework for Christian consumption. Many of these tiles are rich with metallic lustre decoration; the chief colours are blue, green and brown, with white lines, and in the later work a growing use of black and yellow.

The earliest examples of Moorish wall tiles produced their geometric patterns by a mosaic method in which each bit of separate colour is formed by a separate tile. In order to develop a more facile method of producing the same effect, the technique known as *cuerda* seca (dry cord) was developed, in which the tiles are rectangular, and the pattern on each tile is formed by raised fillets between the different colours, which prevented the adjoining enamels from running together. After the Christian conquest a third method was introduced, called *cuenca* (bowl), somewhat similar to the northern Gothic process in which the portions to be coloured were depressed and then filled with their enamels. These tiles, even in their old traditional Islamic patterns, were popular throughout the 16th century and even later for wainscots in Renaissance houses. The potters were evidently Moors; the great centres of manufacture remained as before in Malaga, Valencia, Granada and Seville.

In the 16th century the Italian majolica type of tile was introduced by Francesco Niculoso of Pisa, and these Spanish majolica tiles were much used, as in the door of the convent of St. Paula at Seville (early 16th century) or the exquisite altarpiece in the Alcazar at Seville made by the same artist in 1503, where the design is purely Italian. Both the cuenca and the *pisano* or majolica types of tile have been made in Spain almost continuously ever since. (See ISLAMIC ART.)

North European Wall Tile.—Meanwhile in Germany there had been developing a type of tile used principally for stoves, with ornament in relief and a glaze of green, yellow or brown. This tile was in widespread use as early as the 14th century and many examples exist throughout Germany, upper Austria and Switzerland, in which the ornament is of great richness, with Gothic architectural forms in the earlier types and Renaissance forms later.

The most important of the north European tiles are undoubtedly those made in Delft, Holland, from 1600 on. These are plain, square tiles, each containing a figure, a bit of landscape or a genre group, freely painted in a gray-blue upon a background of bluish-white. The little freehand sketches were so instinct with life, and the colour so subtly beautiful, that by the middle of the 17th century these tiles enjoyed a great vogue, not only throughout the Germanic countries, but in England and the American Colonies as well. Although outside of Holland they were chiefly used for fireplace and stove facings, in Holland itself they were often employed for wall wainscotings. Some of the later examples have the decorations in manganese purple instead of blue. During the 18th century many attempts were made to imitate the delftware and during the latter half of the 18th century, particularly in England, scenes printed from copper plates were used instead of the painted scenes.

Although many of the ancient pottery centres are still producing tiles in the traditional manner and although modern imitations of old wares are of excellent quality, the greatest modern contribution to wall-tile design was the development of square or rectangular tiles with relatively uneven surfaces and shapes on which colours and glazes of the greatest variety are unevenly flowed. so that each tile has marked individuality of colour and texture. All sorts of crackled and crystalline effects are common, as well as the blending of two or more colours. The scientific development of glazings and colourings gave the decorator an almost unlimited palette for either exterior or interior use. There was a corresponding development in the use of tile in relief, usually with the background sunk and glazed in a different colour.

During the late 19th century, light, flat tiles often provided an ideal material for vaults and domes. Their advantages over wood and stone had earlier been recognized by the Romans, who laid flat tiles verticallv and horizontallv between thick brick ribs in order to lighten vaults, keep them fireproof and gain both support and form for the concrete infilling poured between ribs. The biggest 19th-century innovation was the Guastavino vault, named for a Catalan engineer who developed a light, fireproof vault in which bonded layers of small, light and flat tiles were built into curved surfaces with a minimum of centring. Especially popular in the United States, examples of the Guastavino vault appear in New York's Carnegie hall and St. Thomas's church; St. Paul's chapel at Columbia university, New York city; Boston's public library; and the state capitol at Lincoln, Neb.

Cheaper materials compete with traditional kinds of tile and are called tiles even though some are not made of terra cotta. Fibreboard, sound-absorbing panels, referred to as "acoustic tiles," are used in modern ceilings. Glass block, sometimes called "Glasstile." appears in partitions. A wide variety of mass-produced ceramic veneers is available in different colours, finishes, textures and shapes, though figurative patterns are unusual.

Ceramic-glazed structural tile, hollow and approximately $33 \times 3\frac{1}{2} \times 11\frac{1}{2}$ in. in size, remains an attractive, economical and permanent material for partitions in schools, hospitals, railroad stations and cafeterias.

TILEFISH (*Lopholatilus* chamaeleonticeps), a beautifully coloured fish of the family Latilidae, living in rather deep water in the western Atlantic. It was first discovered on a bank about 80 mi. S.E. of Boston, and proved to be a valuable food fish.

The tilefish is said to reach a weight of 50 lb., but about 10 lb. is more nearly the average size.

TILIACEAE, the linden family of trees, shrubs or (rarely) herbs, with 35 genera and about 300 species, found in most parts of the world, but largely tropical. Most of the genera are small, but *Grewia,* in the old world tropics, contains about 70 species. *Tilia,* various species of which are known as linden and as basswood (originally bast wood), is typical of the north temperate zone of both hemispheres. The bast of many representatives of the family is tough-and strong; Corchorus *capsularis* and C. *olitorius* being jute (*q.v.*) of commerce, largely produced in India. See LINDEN.

TILLAGE MACHINERY. Tillage includes soil management practices such as reducing residues of previous crops, plowing, harrowing, rolling and cultivating. The primary purposes of tillage are to prepare the seedbed, to retard weed growth and to improve the physical condition of the soil. Manures and fertilizers often are applied in connection with tillage operations.

The field operations that accomplish these purposes include: (1) crop-residue treatment; (2) primary tillage or plowing; (3) secondary tillage, or harrowing (refining the seedbed); (4) cultivation (primarily to retard weed growth); (5) fertilizing and manuring; (6) subsoiling or deep tillage. The kinds of machinery needed depend on the type or combinations of practices employed, and are dealt with under the following headings:

- I. Implements for Treating Crop Residues
  - 1. Stalk Cutters
  - 2. Rotary Cutters or Shredders
- II. Primary Tillage or Plowing Implements
  - 1. Moldboard Plow
  - 2. Tractor-Mounted Plows
  - 3. Two-Way Plows
  - 4. Listers and Middlebusters
  - 5. Disk Plows
  - 6. Disk Tillers
  - 7. Rotary Plows
- III. Secondary Tillage or Harrow Implements
  - 1. The Disk Harrow
  - 2. The Spike-Tooth Harrow
  - 3. Spring-Tooth Harrows
  - 4. Special Harrows
  - 5. Clod Crushers, Packers and Mulchers
- IV. Cultivation or Hoeing Implements
  - 1. Row-Crop Cultivators
  - 2. Field Cultivators
  - 3. Rotary Hoes
  - 4. Rod Weeders
  - 5. Spring-Tooth Weeders
- V. Subsoiling or Deep Tillage Equipment
  - 1. The Subsoiler
  - 2. The Chisel Plow
- VI. Fertilizer Distributors
  - 1. Manure Spreaders
  - 2. Distributors for Commercial Fertilizers
  - 3. Broadcast Distributors
  - 4. Distributors for Anhydrous Ammonia
  - 5. Applying Fertilizer Solutions
- VII. Small-Scale Tillage Equipment

I. IMPLEMENTS FOR TREATING CROP RESIDUES

Although most tillage implements mix crop residues with the soil, certain special implements are used for reducing the stalks of cotton, corn (maize) and other crops having heavy stalks.

1. Stalk Cutters. — These are made in animal-drawn and tractor-drawn sizes. The former has one section, of suitable width for cutting down the stalks of t o rows of corn or cotton; the latter employs two sections and covers four rows. The free-rolling cutting cylinder, with eight or ten sharp-edged knives mounted equidistant from their axis of rotation, is weighted to give a thorough cutting action as the cylinder rolls through the field. Some models have wheels for transport and depend for pressure upon a heavy compression spring. Others are transported by turning the unit upside down and using the transporting runners mounted on the upper side of the implement.

2. Rotary Cutters or Shredders. — Cutters or shredders are used for shredding stalks of cotton and corn, chopping prunings from orchards, cutting crops for silage and mowing pastures for weed control. These machines have many different names, including field shredder. brush beater, rotocycle and hammer knife mower. Tractor-mounted and -trailed models are available; both are driven by the tractor power take-off. One type uses a long horizontal shaft to which are attached flails or hammers. When rotated at high speed the pounding action reduces the stalks or trash to a fine mulch.

Other types have knives which cut rather than lacerate. Power-driven rotary cutters do more satisfactory work than the rolling stalk cutter.

II. PRIMARY TILLAGE OR PLOWING IMPLEMENTS

The main objectives of primary tillage are to loosen and aerate the soil, invert it to cover trash and weed seeds and expose a large area of fresh soil to weathering so it can be more readily harrowed into a good seedbed. The implements for primary tillage include moldboard plows, disk plows, listers, middlebusters or middle-breakers, one-way disk tillers and rotary tillers.

1. Moldboard Plow. — In its simplest form this is a single-furrow, animal-drawn implement held by the plowman who walks behind it. It consists of a beam to which is attached a pair of handles for controlling it; a bottom made up of a share (lay or sock) for cutting the furrow slice loose; the landside for taking the side thrust; a moldboard or breast for turning the furrow; braces; a colter for cutting a vertical side or wall of the furrow (this may

MODERN TILLAGE MACHINERY IN OPERATION

Top left: Direct-connected, two-way (reversible) moldboard plow

Top right: Hillside plowing with two-way pickup plow which turns furrows uphill for better control of erosion

Centre left: Left hand plowing on the contour, with tractor-mounted two-way, two-disk plow. Disks are easily reversed to throw to the right on the return trip, thus eliminating back furrows and dead furrows.

Bottom left: Firming the soil with a land presser attached behind the plow

Bottom right: Spring-tooth weeder, used for destroying small weeds with shallow roots

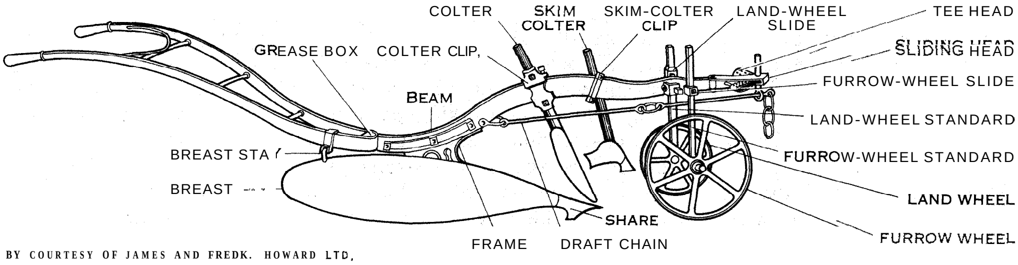

FIG. 1.—PARTS OF A SINGLE-FURROW WALKING HORSE-DRAWN PLOW WITH LEA BREAST

be a vertical knife, a circular knife or a rolling-disk colter); and an adjustable hitch. Most European and some U.S. plows have one or two gauge wheels at the front end of the beam that help keep the plow level, steady and at uniform depth. In oriental countries gauge wheels are not commonly used and depth control depends on adjustment of the clevis, or hitch (*see* fig. 2), at the front of the plow. This clevis also provides for adjusting the width of cut.

Fig. 1 is typical of an English walking plow and fig. 2 of a U.S. walking plox, and the essential parts are named there. The principal parts of moldboard plow bottotns are similar in walking plows and tractor plows. Because soil conditions vary greatly throughout the world, many different shapes of bottoms are required, and several different materials are used. The basic shapes are shown in fig. 3. Not shown is the breaker bottom with its long. easy-turning moldboard, adapted to virgin or tough sod. The English lea bottom (*see* fig. 1) is used mainly in sod and for fall plowing, and the English digger bottom—similar to the stubble bottom—is used for spring plowing.

Plain cast iron is preferred for sandy soils, which scour easily. Eut chilled cast iron. hardened by a special process, scours even better, resists abrasion well and is more widely used. Solid (crucible) steel is favoured where there are many rocks and stones because of its resistance to breakage. Soft-centre steel (two outer layers of hard steel cushioned by an inner layer of soft steel) is generally used in heavier soils.

Coverage of trash and weeds is improved by a rolling colter and skim colter, or jointer. Used together, they cut the edge of the furrow slice cleanly, tear off a corner of the slice with its projecting grass or weed growth and deposit it in the open furrow where it is well covered. These attachments may be used separately.

The width of furrow cut by single furrow plows varies from 6 to 12 in. These smaller sizes are commonly used in many countries—India, Mexico, Japan, China—where they are drawn by animals.

Moldboard plows, powered by farm tractors, vary in the width of furrow from 10 in. for a small, single bottom to 96 in. cut by six 16-inch bottoms of large tractor plows. Tractor plows are drawn behind the tractor or mounted on it. Smaller sizes with one or two bottoms are usually mounted, although available as trailed models also. Larger sizes with three or more bottoms are tractor drawn. They have wider bottoms. Some can plow 12 in. deep, although usually moldboard plowing is much shallower. An extremely large size is used in the western United States for making ditches and for mixing fertile subsoil with surface soil. Its huge. single moldboard turns a furrow six feet wide and three feet deep.

Tractor-drawn plows are attached with an adjustable hitch. This permits horizontal adjustment to insure correct width of the front furrow, and vertical adjustment to prevent nosing (downward tilting of plow points). which causes rapid wear of the underside of the share point and gives poorly turned furrow slices. A spring release or other protective device is incorporated in the hitch. This disconnects the plow when it strikes a firmly anchored obstacle. In some tractor plows the protecting device is applied to each bottom individually. as each bottom is held in working position by a heavy spring. Should it strike an obstruction, the spring permits the bottom to raise and pass over the obstruction.

Tractor-drawn plows have a lifting mechanism to raise them from or lower them to their working position. This may be either mechanical or hydraulic. The mechanical lift is controlled through a cord pulled by the tractor driver. The cord actuates a clutch usually located in the land wheel (the wheel that runs on the unplowed ground). The clutch connects or disconnects the motion of the wheel to a crank which raises or lowers the plow. Two principal levers may be furnished on tractor-draan plows, one for regulating depth and one for leveling the plow.

2. Tractor-Mounted Plows.—The tractor and the mounted plow are a compact unit, easily maneuverable and readily adjusted by the operator. Mounting plows, cultivators and other implements marked a milepost in the development of farm machinery. Prior to this development, the tractor was in a sense simply a mechanical draft horse.

The mounting of implements led to the development of hydraulic controls. The control levers are placed on the tractor itself rather than on the implements. Hydraulically controlled mounted implements showed so many advantages that in some countries—New Zealand, for instance—they became widely used within a very few years.

The hydraulic system consists of a pump driven by the tractor engine. an oil reservoir and distribution lines that convey the hydraulic liquid under pressure to a piston enclosed within a cylinder. The piston transmits the hydraulic force lo the leverage of the plow or other implement. Hydraulic cylinders are of two types, one-way and two-way. The one-way has a piston that can exert pressure in one direction only, the two-way piston may receive hydraulic pressure from either side and so can exert pressure in either direction and either lift a load or force it downward.

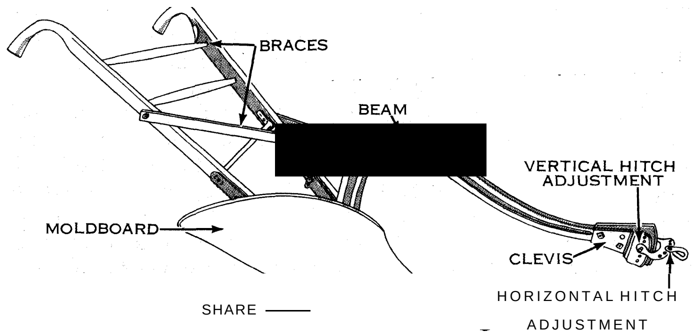

FIG. 2.—HORSE-DRAWN WALKING PLOW

Hydraulic power is applied to the control of many implements, both mounted and trailed. With trailed implements the hydraulic cylinder is placed on the implement Hydraulic liquid under pressure is conveyed to the cylinder through heavy hoses.

Mounting implements on the tractor also brought methods for quickly attaching and detaching such implements. The operator can attach or detach a plow or other implement without leaving the tractor seat. This convenience not only saves time but also lessens danger, since the operator need not stand behind the tractor when attaching an implement.

3. Two-Way Plows.—Two-way, or reversible, plows are used in hilly regions, in irrigated fields where dead furrows (open trenches) are a hindrance in controlling water and in irregularly shaped fields. They have a right- and left-hand plow bottom, one of each on animal-drawn plows and generally two of each on tractor plows. The operator can plow in either direction and throw all the furrows one way, thus eliminating all dead furrows, or he can throw all the furrows uphill to maintain soil in proper place for contour plowing. Two-way plows are available in walking models and in tractor-mounted and tractor-drawn models. The "turn-wrest" plow is a walking model used in India, where it is drawn

by two bullocks. After releasing a latch, the plowman can manually turn (wrest) the beam so as to alternately use the right and left bottoms.

4. Listers and **Middlebusters.**—The term middlebuster is used where crops are planted on beds. and the term lister where they are planted in the open furrow. Both listers and middlebusters have a right- and a left-hand bottom mounted back to back. They prepare ridges for cotton, potatoes, sweet potatoes and other crops that are planted on the tops of shallow beds. Listers and middlebusters are essentially the same. However, the lister moldboard is of the general-purpose shape, while the middlebuster moldboard is more like the black-land moldboard. The right and left moldboard on both listers and middlebusters are joined together so they throw furrow slices in both directions at one time. In semiarid regions the lister ridges the soil to preserve moisture and to lessen wind erosion. It is also combined with a planter which drops seeds into the open furrow to be covered by a planter attachment.

The listers and the middlebusters range in size and design from the single-bottom, animal-drawn units to the giant tractor models with six bottoms. A variety of bottoms can be used with a tractor employing the tool-bar method of mounting. The tool bar can carry different tillage tools. It is a heavy steel bar, usually square, mounted across the rear of the tractor. The bar itself is connected to the linkage operated by the tractor hydraulic system. Accordingly, implements attached to the tool bar are controlled by the hydraulic system. Also, the ground-working tools can be spaced horizontally on the tool bar as desired. Tool bars with their own wheels are also furnished as tractor-drawn units.

5. Disk Plows.—The disk plow has one or more concave disks varying in diameter from 20 in. for animal-drawn models to 40 in. for tractor models. Disk plows work well in dry, hard soils where moldboard plows penetrate with difficulty, and also in sticky soils where moldboard plows do not scour well. They also work satisfactorily in land having rocks or stones because the disks ride over such obstructions without breakage, and they are effective in loose soil and where there are many roots, shrubs and bushes.

Small tractor-mounted models may have only one disk; but large, tractor-drawn sizes may have seven or more. Most tractor models are controlled hydraulically, although some have a mechanical power lift.

The angle of the disks is adjustable vertically and horizontally. Adjusting the disk nearer to a vertical position makes it penetrate better. Adjusting it closer to a line perpendicular to the direction of travel makes it cut wider. In some models, the distance between the disks may be varied. Penetration depends upon field conditions, the diameter of the disk and the weight placed upon the disks. Accordingly, disk plows are quite heavy and wheel weights are often required to improve penetration.

6. Disk Tillers.—These ruggedly built tractor implements have the disks set at a fixed angle of about 45°, and the disks are smaller than those of the disk plow. They do not penetrate as deeply and they mix surface growth with the soil rather than invert it. They are used to mix the stubble of the previous crop with the surface soil, but leave enough stubble exposed to retard wind erosion and to improve water infiltration. Small sizes, about five feet wide, may be tractor mounted or semimounted. Large sizes, with sixteen 24-in disks spaced about 9 in. apart, may cut a 12-ft. swath. Hence, the rate of work is fast—up to 50 ac. per day. A special type, developed in Australia, is the stump-jump disk cultivating plow. The disks are assembled in pairs, each pair being held to its working position by spring pressure. When a solid obstruction is encountered a pair of disks can rise over the obstruction, against the spring pressure, without disturbing the rest of the implement. Modifications of this stump-jump plow are used in the range lands of the western United States.

Disk tillers are knoun also by other names, such as one-way disk, harrow plow, wheatland disks and vertical disk plow. Some may have a seeding attachment so that certain crops can be seeded at the same time the seedbed is prepared. (See also **PLANTING** MACHINERY.)

7. Rotary Plows.—Rotary plows have been used in Europe for many years. They employ an assembly of tines or knives mounted on a horizontal. power-driven shaft. The smallest sizes, powered by garden tractors, cut a swath of about 12 in.; larger garden tractor models cut a 30-in. swath. Large rotary tillers cut up to a 6-ft. swath, require up to 90 h.p., and may have a separate engine mounted on the tiller itself. Other models are mounted on farm tractors and driven by the power take-off.

In most designs the rotating knives cut on the downward stroke and mix the surface growth evenly throughout the seedbed Depth of cut can be varied through a wide range. Hence, rotary tillers are used not only for preparing seedbeds but also for surface cultivation.

Under favourable conditions rotary tillers prepare a seedbed in one trip over the ground. However, when conditions are difficult the rotary tiller can make a second trip over the tilled ground, which is not feasible with a moldboard plow.

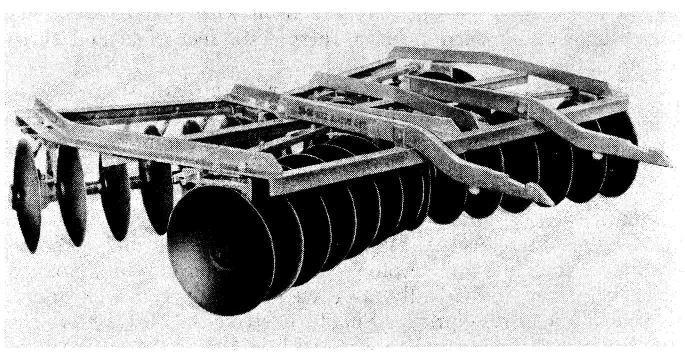
III. SECONDARY TILLAGE OR HARROWING IMPLEMENTS

Various types of harrows are used to refine the seedbed, to level the plowed soil, compact it and destroy weed seedlings.

1. The Disk Harrow.—A truly general-purpose implement, the disk harrow is sometimes used before plowing and quite generally after plowing. Disk harrows have gangs of disks assembled so that the side forces are balanced. One gang throws the soil to the right, the other to the left. Single-cut, animal-drawn disk harrows give a width of cut from four to six feet. Tractor disk harrows are usually of the tandem type having two gangs in front and two in the rear, thus giving a double action.

The offset tractor disk harrow has only two gangs; one is behind the other, somewhat like one-half of a tandem harrow. The two gangs throw the soil in opposite directions, the rear gang reworking the soil moved by the front gang so as to leave it quite level. This type is commonly used in orchards and vineyards because the operator can get under projecting branches and near to the trees or vines.

Penetration may be regulated by adjusting the angle of the disk gangs. In animal-drawn models this is accomplished by levers found on each gang. Tractor-drawn harrows may employ a power-angling device operated by movement of the tractor, or a hydraulic



BY COURTESY OF INTERNATIONAL HARVESTER CO

FIG. 4.—TRACTOR-MOUNTED. TANDEM DISK HARROW WITH FAST-HITCH CONNECTION

cylinder may be used to control the angle.

Some large tractor models are supported by transport wheels and the gangs are set at a fixed angle. Penetration is regulated by raising or lowering these transport wheels by hydraulic power.

Tractor disk harrows, five to eight feet wide, may be fully mounted, making them convenient for working in the corners of fenced fields. Larger tandem tractor harrows may cut a swath as wide as 14 ft. Special single-cut tractor harrows (up to 20 ft. wide) are used for controlling weeds on summer fallow and to reduce stubble and corn stalks previous to plowing.

2. The Spike-Tooth Harrow. — This implement aids materially in breaking up clods and leveling fields, and may be used for covering seed. It consists of a number of horizontal bars to which teeth or tines are attached. The teeth are spaced so that each tooth makes a separate cut through the soil; no one tooth trails another. With a typical five-foot section every two inches of ground is cut by a tooth. The number of sections used depends upon the power available. varying from perhaps only one section when drawn by an animal to eight six-foot sections for large tractors. Some tractor models are wheel-supported and the sections can be folded for transportation.

3. Spring-Tooth Harrows. — These also are made in sections with horizontal tooth-retaining bars. The flexible spring teeth are more widely separated than in the spike-tooth harrow. They resist damage from stones or other obstructions and penetrate well in hard ground. An implement of suitable width can be obtained for whatever power is available. Some models are carried on transport wheels that aid in regulating the depth. In others, depth is controlled by levers that change the position of the spri'ng teeth. With some types the operator can clear the teeth of trash without leaving the seat of the tractor.

4. Special Harrows. — Specially designed harrows are used for intensive grassland cultivation. Chain harrows, consisting of studded metal links fastened together like a net: brush harrows (made by drawing brushwood through a frame in such a way as to form a rough smoothing surface) or spike-tooth harrows are used in the spring for dragging out moss or matted undergrowth and dispersing lumps of manure, molehills. etc.

5. Clod Crushers, Packers and **Mulchers.**—These are used to break up lumps left by harrows and to compact the soil, thereby eliminating large air spaces. The plain roller is often used to compact grassland damaged by winter heaving. It is used frequently on alfalfa fields also. Corrugated rollers—single or tandem—crush clods and firm the soil after plowing. After wheat is sown, the corrugated roller compacts the soil around the seed to improve germination, and the corrugations left on the surface reduce soil-blowing.

Another effective clod crusher and packer is made of a series of sprockets loosely fitted at the hub and mounted on an axle between sharply ridged rollers. In moist soil the lagging of the sprockets lessens clogging of the ridged rollers. In England. land pressers or packers often are used. These have heavy wedge-shaped wheels about three feet in diameter. They are used in dry seasons to compress the soil at the bottom of the furrow; some designs may be hitched directly behind the plow to press down the freshly turned furrow slices.

IV. CULTIVATION OR HOEING IMPLEMENTS

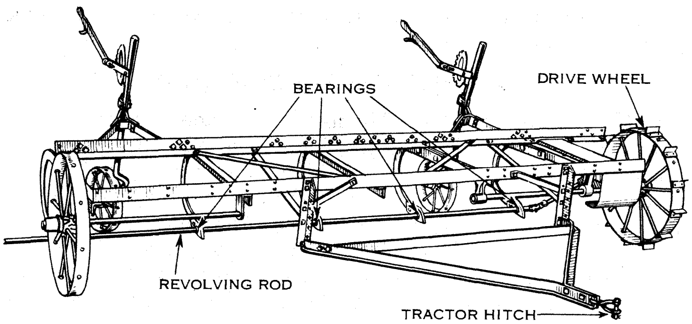
In general, weed destruction is the primary purpose of cultivation (hoeing). Cultivating implements can be divided into three main classes: (1) row-crop cultivators; (2) field cultivators; and (3) rotary hoes.

1. Row-Crop Cultivators. — These implements employ various shapes of steel shovels to work the soil. Typical shovels are short, narrow, slightly curved, pointed steel pieces with polished front surfaces that dig into the soil in proportion to the pressure applied. For very shallow cultivation, special shovels or sweeps (sometimes called duck-foot sweeps) are available in different widths.

Row-crop cultivators range in size from one-horse, between-row walking types to tractor models for cultivating (astraddle) six rows or more at a time. The kind and number of shovels used per gang depend on the crop and the soil characteristics. Shovels or sueeps are sometimes replaced by disks or disk hillers when a considerable quantity of soil is to be moved, or where trash and vines must be cut. The gangs carrying the shovels of a tractor cultivator may be front-mounted. centre-mounted or rear-mounted. Some designs combine a centre and rear mounting and others carry the cultivating steels on tool bars.

2. Field Cultivators. — These are designed primarily for open-field rather than row-crop cultivation. They are used also for controlling meeds in summer fallow, for renovating pastures and for stubble mulching. The large models are wheel-supported and hydraulically controlled. The cultivating tools may be spring teeth, shovels or sweeps. When equipped with spring teeth the larger. sturdier models penetrate deeply.

3. Rotary Hoes. — The rotary hoe works best when the tractor is operated at a fairly high speed. It is made up of gangs 42 to 46 in. wide. Within the gang a group of 14- to 20-in, hoe wheels. with radial projecting fingers. is mounted on a horizontal axle. Several gangs or sections are combined to make a tractor unit — sometimes 12 sections, which would cut a 40-ft. swath. Each section is of proper width to cover a typical corn row and has about seven hoe



BY COURTESY OF JOHN DEERE

FIG. 5.— TRACTOR-DRAWN ROD WEEDER

wheels. The rotary hoe is particularly useful in the early growth stages of corn and other row crops, and is effective in breaking crusts caused by hot sunshine after a hard rain. Sometimes the gangs are assembled in tandem to obtain double action.

When the rotary hoe is drawn backward the teeth do not penetrate. Instead, they give a treading action which crushes clods and pulverizes stalks and surface residue. One section may be used behind the plow to pack the freshly turned furrow slices.

Special rotary-hoe attachments are used with row-crop cultivators. These narrow attachments work directly on the row of plants, while the shovels work between the rows.

4. Rod Weeders. — The rod weeder is used for weed control in open fields where summer fallow is practised. Its working element is a square. horizontal rod driven by one of the supporting wheels and revolving one to five inches below the soil surface. Roots and weeds are caught on the rod and pulled out, but do not collect on it. Sizes vary from 8 to 12 ft. in single units up to combinations of sections sufficient to cut a 36-ft. swath.

5. Spring-Tooth Weeders. — These have light spring teeth designed for destroying surface needs only. They can be operated directly over the rows of growing plants because the light, wirelike teeth flick out the shallow-rooted weeds without injuring growing plants. These implements reduce the number of later cultivations because they destroy weeds effectively just as they emerge.

V. SUBSOILING OR DEEP TILLAGE EQUIPMENT

Heavy tillage implements are employed to encourage deeper root growth. to break up hardpan and compacted soils and to improve water infiltration, With tool bars, heavy ground-working tools can be used — large disks, heavy tines, shovels of various types, chisel points and subsoil blades. Such heavy equipment is often required for the hard, rough conditions frequently encountered in tropical agriculture.

1. The Subsoiler. — This implement employs a single long shank carrying a steel point. The various sizes and lengths of shanks permit penetration from 16 to 36 in. Draft of this implement is great, and larger sizes require a powerful tractor. The subsoiler opens a slit in the soil through which moisture can enter; it reduces compaction caused in some areas by implement traffic on the field. By improving water infiltration it reduces runoff and erosion.

A mole, shaped like a bullet or ball, is sometimes attached to the rear of the subsoil point. Such mole plows are used for draining land having a clay subsoil. The mole may be set to work at different depths and when drawn through the ground compresses the subsoil in its passage, leaving a drainage channel of its own diameter. The narrow slit cut by the subsoiler shank closes up and water then passes into the drain by percolation. Mole drains thus prepared should have suitable outlets and a natural gradiant following the contour of the land.

2. The Chisel Plow.—This plow has a number of shanks mounted on a transverse tool bar. Horizontal distance between the shanks may be adjusted, from 12 in. to 3 ft. apart, to suit field conditions. The work of the chisel plow is similar to that of the subsoiler, but shallower. Either rigid tines or spring-tooth shanks are used. They may penetrate as much as 18 in. and can also be used for shallow tillage. The shanks may be fitted with various shapes of steels such as narrow, double-pointed shovels, or wide sweeps for shallow tillage.

VI. FERTILIZER DISTRIBUTORS

I. Manure Spreaders.—The manure spreader carries manure, tears it up and spreads it on the field. The basic design has remained that of a four-wheeled wagon, although tractor models may have only two wheels and have the front of the spreader supported on the tractor. The distributing mechanism consists of a drag-chain conveyor at the bottom of the box. This carries the manure to the rear of the spreader where it is shredded and scattered. This is accomplished by an upper beater that levels and shreds the manure as it is driven into the lower spike-tooth beater, which tears it to bits. Wide rotating spiral fins complete the operation by spreading the manure widely in a uniform layer, the thickness of which is determined by the speed of the conveyor.

Both animal-drawn and tractor-operated spreaders are available. Some models have the distributing mechanism driven by the tractor power take-off; in others it is driven by the spreader wheels. Capacity is determined by the size of the box, which varies from 50 to 140 bu.

Loading manure spreaders by hand is a laborious and unpleasant task. Hence it is often done by tractor-operated loaders. These are powered by the tractor engine and controlled hydraulically.

2. Distributors for Commercial Fertilizers.—Commercial fertilizers are available in solid, gaseous and liquid form. Anhydrous ammonia, a popular source of nitrogen, is liquid under pressure but becomes a gas when it is freed from this pressure as it enters the soil.

Distributors for solid commercial fertilizers must give a uniform distribution whether heavy or light applications are being used. It is important that distributors can be easily cleaned because some fertilizers are highly corrosive. Solid-fertilizer distributors differ mainly in the method of distributing the material. Most designs have a wide hopper that carries the material. Wheels at the ends of the hopper serve for transport and also drive the distributing mechanism. Distribution in some models is effected by a roller at the bottom of the hopper. This revolves so as to work the fertilizer out backward as the machine advances. Other designs have agitators placed over holes in the hopper bbttom. Another uses an endless chain with projecting fingers which travel across the bottom of the hopper. Still another employs rotating fingers which work the fertilizer out. In several types the material falls straight down to the ground and is distributed along the full width of the machine. However, some designs use tubes for distributing the material in rons.

3. Broadcast Distributors.—These are quite different in design. They have a tub-shaped hopper from which the solid material falls on to two revolving disks. which are driven by the spreader wheels. The broadcaster may be drawn behind a motor truck or other vehicle, from which its hopper is filled. The revolving disks distribute fertilizer, lime or marl (clay and lime) in a broad swath, up to 20 ft. wide. Lime also is applied with an end-wheel type of distributor having a hopper about eight feet long.

4. Distributors for Anhydrous Ammonia.—These distributors require a heavy tank because this material must be stored under considerable pressure. Application is controlled by carefully designed valves and an accurate metering device. The ammonia passes through heavy tubing to applicator teeth that cut gashes four to six inches deep through the soil. When released at this depth the ammonia gas is sealed in by the soil falling above it. Anhydrous ammonia applicators may be obtained as tractor-trailed or -mounted models. Attachments are also available for row-crop planters.

5. Applying Fertilizer Solutions.—Water solutions of nitrogen and also solutions containing all three major plant foods—nitrogen, phosphorus and potassium—are available. Applicators may employ boom-type sprays with nozzles, as these solutions can be sprayed on pasture, small grain or the soil without loss of nitrogen to the atmosphere. Some applicators have a number of rubber or plastic hoses, attached to the ends of the boom openings, which drag on the ground and apply the solution to the surface. The rate of application is controlled by a metering device or by a positive type of pump that regulates flow from the tank. *See* also FERTILIZERS AND MANURES.

VII. SMALL-SCALE TILLAGE EQUIPMENT

For market gardeners, horticulturists, amateur gardeners and growers with small acreages a wide variety of tillage tools is available to fit practically every requirement. This includes garden tractors—both walking and riding—that are provided with tilling and cultivating implements suitable for many purposes. For the garden there are many hand-operated tools such as the push-hoe cultivator and seeder, as well as a wide assortment of tools.

Farm machinery dealers and hardware merchants can furnish information on practically any kind of tillage tool or advise customers where it can be obtained.

(AR. A. S.)

TILLEMONT, SÉBASTIEN LE NAIN DE (1637–1698), French ecclesiastical historian, was born in Paris on Nov. 30, 1637. The boy was brought up in the little schools of Port Royal, and in 1660 he was made a tutor in the seminary of Buzenval, Jansenist bishop of Beauvais. Ten years later he came back to Paris, and became a chaplain at Port Royal. In 1679 the storm of persecution drove him to settle on his family estate of Tillemont, where he spent the remainder of his life.

Tillemont died on Jan. 10, 1698.

From the age of 20 he was at work on his two great books—the *Mémoires pour servir à l'histoire ecclésiastique des six premiers siècles,* and the *Histoire des empereurs* during the same period. Both works began to appear during his lifetime—the *Histoire* in 1690, the *Mémoires* in 1693—but in neither case was the publication finished until long after his death.

There is a full account of his life in the 4th volume of Sainte-Beuve's *Port Royal*.

TILLETT, BENJAMIN (1860–1943), British Labour politician, was born at Bristol, on Sept. 11, 1860. He started work in a brickyard at eight years. and was a "Risley" boy for two years He served six months on a fishing smack, was apprenticed to a bootmaker, and then joined the royal navy. He was. invalided out of the navy and made several voyages in merchant ships.

He then settled at the London docks and organized the Dockers' union of which he became the general secretary, taking a prominent part in the dock strike of 1889. He was one of the pioneer organizers of the General Federation of Trades, National Transport Workers' federation, National Federation of General Workers, International Transport federation, and of the Labour party.

For many years he was an alderman on the London County council, and was twice elected member of parliament by the Labour party. He died in London, Jan. 27, 1943.

His publications include *A Brief History of the Dockers' Union* (1910), and *A History of the Transport Workers' Strike* (1911).

TILLEY, SIR SAMUEL LEONARD (1818–1896), Canadian statesman, was born at Gagetown, New Brunswick, on May 18. 1818, the son of Samuel Tilley, an American Loyalist, who had settled in St. John in 1783. From 1860 to March 1865 he was premier of the province, and was prominent in organizing the conference on the union of the maritime provinces, which met at Charlottetown in 1864, and which soon widened into a discussion of Canadian federation.

In 1865 he was defeated in a general election on the federation question, but returned to power in 1866, partly through an intrigue of the colonial office. From 1868 till November 1873 he held various portfolios in the Dominion cabinet; from 1873 to 1878 he was lieutenant-governor of New Brunswick, but in 1878 was agair elected as member for St. John, and entered the Conservative cabinet as minister of finance.

Later in 1878 he introduced and carried through parliament the "national policy" of protection, on which issue the election of 1878 had been won. The tariff so introduced became the basis of Canadian financial policy.

In Oct. 1885 ill health forced him to retire from the cabinet. He was again lieutenant-governor of New Brunswick from 1885 to 1893. He died on June 25, 1896.

His *Life*, by James Hannay (1907), forms one of the "Makers of Canada" series.

TILLODONTIA, a group of extinct mammals from the Eocene of North America and Europe. The average size was about that of a living brown bear. The canine teeth are very small, one pair of incisors in each jaw much enlarged and chisel-like. The general structure is very primitive, the brain small and elongate, the cheek teeth of generalized (tuberculo-sectorial) type, the feet plantigrade, with five toes. The skull is more carnivore- than rodent-like in general aspect. The best known genera are *Tillotherium, Esthonyx* and *Trogosus.* Despite the relative large size of its members, the group is probably more suggestive of the Insectivora than of any other established order and it is apparently an early, extinct, rather aberrant offshoot of the earliest stock of the placental mammals. (G. G. S.)

THE SKULL OF TILLOTHERIUM FODIENS, AN EXTINCT MAMMAL

TILLOTSON, JOHN (1630–1694), English archbishop, was the son of a Puritan clothier in Sowerby, Yorkshire, where he was born in October 1630. He was a fellow of Clare Hall, Cambridge, and about 1661 he was ordained without subscription by T. Sydserf, a Scottish bishop. Tillotson was present at the Savoy Conference in 1661, and remained identified with the Presbyterians till the passing of the Act of Uniformity in 1662. Shortly afterwards he became curate of Cheshunt, Herts., and in June 1663, rector of Kedington, Suffolk. He now devoted himself to an exact study of biblical and patristic writers, especially Basil and Chrysostom. The result of this reading, and of the influence of John Wilkins, master of Trinity College, Cambridge, was seen in the general tone of his preaching, which was practical rather than theological. In 1664 he became preacher at Lincoln's Inn. The same year he married Elizabeth French, a niece of Oliver Cromwell; and he also became Tuesday lecturer at St. Lawrence, Jewry. In 1670 he became prebendary and in 1672 dean of Canterbury. In 167j he edited John Wilkins's *Principles of Natural Religion,* completing what was left unfinished of it, and in 1682 his *Sermons.* With Burnet, Tillotson attended Lord Russell on the scaffold in 1683. It was partly through Lady Russell that he obtained influence with Princess Anne, who followed his advice in regard to the settlement of the crown on William of Orange. He possessed the special confidence of William and Mary, and was made clerk of the closet to the king and dean of St. Paul's. On his advice the king appointed an ecclesiastical commission for the reconciliation of the Dissenters. He was elected to succeed the Nonjuror Sancroft as archbishop of Canterbury, but accepted the promotion with extreme reluctance, and it was deferred from time to time, at his request, till April 1691. In 1693 he published four lectures on the Socinian controversy. He died on Nov. 22, 1694.

Ralph Barker edited his *Sermons* together with the "Rule of Faith" (14 vols 1695–1704). In 1752 an edition of his *Complete Works* appeared in 3 vols., with *Life* by Thomas Birch.

TILLY, JOHANN TZERCLAES, COUNT OF (1559–1632), general of the Catholic League in the Thirty Years' War, was born in 1559 at the château of Tilly in Brabant. He was destined for the priesthood and received a strict Jesuit education. But, preferring the career of a soldier, he entered a Spanish foot regiment about 1574 as a volunteer, and in the course of several campaigns rose to the command of a company. This being reduced, he again became a simple pikeman, and as such he took part in the famous siege of Antwerp by Parma. He distinguished himself by his bravery, and the duke of Lorraine gave him the governorship of Dun and Villefranche, which he held from 1590 to 1594. Henry IV. attempted unsuccessfully to induce him to enter the service of France. Somewhat later he left the Spanish service for that of Austria to fight against the Turks. In 1602 he became colonel in the imperial army, and raised a regiment of Walloon infantry which he commanded in the assault on Budapest, receiving a severe wound. In 1604 he was made general of artillery; having shown great capacity and devotion to the emperor and the Catholic religion, he was made a field-marshal in 1605 In 1610 he left the service of the emperor to enter that of Maximilian, duke of Bavaria, the head of the Catholic League. In 1620 he became lieutenant-general to Maximilian and commander-in-chief of the field forces.

With the victory of the White Mountain (1620) the new army and its leader became celebrated throughout Germany and the subsequent campaigns (*see* THIRTY YEARS' *WAR)* established their reputation. The battle of Hochst (1622) won for Tilly the title of count.

The defeat of King Christian was soon followed by the intervention of Gustavus Adolphus. The opening stages of the campaign did not display any marked superiority of the Swedes. At this time Tilly was commander of the imperial forces as well as of his own army. The first great contest was for the possession of Magdeburg (1631). Tilly has been blamed for the atrocities which accompanied the sack of this town after its fall (May 20). Yet his personal exertions saved the cathedral and other religious buildings from pillage and fire. Four months later Tilly and Gustavus, the representatives of the old and the new art of war, met at Breitenfeld (*q.v.*). The victory of Gustavus was complete, though the imperial general, although severely wounded, drew off his men in good order. On the Lech, a few months later, Gustavus was again victorious, and Tilly received a mortal wound. He died on April 30, 1632, in Ingolstadt.

See O. Klopp, *Tilly im 30-jährigen Krieg* (Stuttgart, 1861); K. Wittich, *Magdeburg, Gustav Adolf und Tilly;* also memoir of Tilly in *Allg. deutsche Bzographie;* Keym-Marcour, *Johann Tzerclaes, Graf v. Tilly;* Villermont, *Tilly, ou La Guerre de trente ans* (Tournay, 1859).

TILSIT, a town formerly in East Prussia. was renamed Sovetsk in the Kalinin *oblast,* Russian Soviet Federated Socialist Republic, G.S.S.R.

Pop. (1956 est.) 60,000.

Tilsit, which received civic rights in 1552, grew up around a castle of the Teutonic order, known as the "Schalauner Haus," founded in 1288. It owed most of its interest to the peace signed there in July 1807, the preliminaries of which were settled by the emperors Alexander and Napoleon on a raft moored in the Memel.

This treaty, which constituted the kingdom of Westphalia and the duchy of Warsaw, registered the nadir of Prussia's humiliation.

TIMAEUS (*c.* 345–*c.* 250 B.C.), Greek historian, whose writings shaped the tradition of western Mediterranean history, was born at Tauromenium in Sicily. He was expelled by Agathocles, the tyrant of Syracuse. and migrated to Athens where he studied rhetoric under Isocrates' pupil Philiscus and passed 50 years of his life. Whether he ever returned home is uncertain. The 38 books of his *Histories* went down to Agathocles' death in 289. but a separate work on Pyrrhus of Epirus seems to have reached the Roman crossing into Sicily in 264. Books 1–5 contained the early history of Italy and Sicily, books 6–33 the history of Sicily from the foundation of the Greek colonies to Agathocles' accession with digressions, sometimes touching on Greece, and books 34–38 a separate account of Agathocles. The *Olympionikai* ("Victors at Olympia") was probably a chronological study.

Timaeus was bitterly attacked by later historians, especially Polybius. Some of his faults, such as the composition of artificial rhetorical speeches, are common to the historiography of the age; but a somewhat naive attitude toward marvels reflects a genuine feeling for folklore. He was spiteful to those he disliked such as Dionysius and Agathocles, and he exaggerated the virtues of the Corinthian general Timoleon. Above all he showed the faults of the armchair historian. But his interests were wide; he was assiduous in assembling material, including inscriptions; and Polybius' charge of ignorance and willful dishonesty is unjust. Timaeus' system of reckoning by Olympiads furnished a valuable chronological tool for his successors, including Polybius. He employed a pleasing "Asiatic" style, nhich Cicero approved.

TIMARU, a seaport of Geraldine county, New Zealand, on the E. coast of South Island. 100 mi. S.W. of Christchurch by rail. Pop. (1956) 23,308. The slight inward sweep of the coast forms the Canterbury Bight. The harbour is formed by breakwaters enclosing a space of 50 ac. The chief shipments from the port are wool. flour and frozen and chilled meat, and the town's industries arose chiefly in connection with these.

Timaru, the chief town in the South Canterbury district, is well served by rail and road; it is a popular seaside resort.

TIMBER. The terms "wood" and "timber" are not synonyms, for wood occurs in the veins of leaves and as strings in thick palm stems, as well as in thicker cylindrical form in twigs of shrubs and trees.

The term timber, synonymous with the North American term lumber, applies solely to wood of considerable dimensions produced by trees. (See LUMBERING.)

Two great classes of trees provide timber. (1) Conifers, including pines, spruces and larches, usually have more or less needle-like leaves, and their naked seeds are most frequently borne on cones; they yield the so-called softwoods. (2) Dicotyledons, including oak, ash, beech and teak, commonly have broader flat leaves, and their seeds are always produced in closed seedcases; they provide the hardwoods.

Origin and Structure of Timber.—The part of the tree above ground typically consists of a main trunk and the branch system, whose ultimate finest branches are the leaf-bearing twigs.

The trunk and branches grow in length solely at their tips, so that the oldest part of a trunk or branch is at its base and its slender tip is the youngest. Tree trunks and branches grow in diameter by the addition of new wood and bark by a microscopically thin layer of cells, the cambium, lying between the wood and the bark. The cambium deposits new wood on the outer side of the pre-existing wood and new bark on the inner side of the pre-existing bark, thus pushing the bark outward.

In temperate climates the cambium produces new wood only during spring and part of the summer and is inactive during autumn and winter; the mood produced first in each year is frequently (*e.g.*, in ash, oak, pine) different from that produced later in the year, so that a distinction is drawn between the early springwood and the later summerwood (frequently termed autumnwood). In such cases a cross section of the tree trunk will show a number of concentric annual rings, whose number is equal to the age of the region of trunk cut.

In the case of the beech and a number of other trees, the annual rings show no marked differentiation into springwood and summerwood but are recognizable because a very thin layer produced latest in the growing season differs in appearance from the rest of the wood. Finally many kinds of evergreen tropical trees (*e.g.*, mahogany) show no distinct annual rings.

In many species of trees (*e.g.*, pines and oaks) the inner wood becomes darker with age. This darker, central portion is called heartwood in distinction to the outer, lighter portion, called sapwood. In other species (*e.g.*, most spruces and firs) there is little or no difference in colour of sapwood and heartwood.

Structure of Wood.—With the aid of the microscope it can be seen that a softwood consists mainly of very narrow, hollow, spindle-shaped fibres (properly, tracheids), running parallel to the long axis of the trunk or branch. The solid wall of each fibre consists of wood substance and on at least two of its sides shows a series of thin round areas, the pits, through which water or sap can pass from fibre to fibre.

In addition to the fibres, certain softwoods, including those of true pines, have very thin resin-containing tubes, the resin ducts, which run parallel with the fibres. In structure each duct in microscopic miniature recalls a tall factory chimney, as its central tubular hollow is surrounded by microscopic, short, more or less brick-shaped cells, which are hollow and have thin walls. All commercial softwoods (excluding that of the yew) contain resin; but some of them (*e.g.*, California redwood) have in place of resin ducts merely resin-containing short cells.

Traversing the wood at right angles to the fibres are thin string-like or ribbonlike structures that run from the outside of the wood radially inward toward or actually to the pith. These are the wood rays, which are usually nearly or quite invisible to the naked eye in cross sections of softwoods. They consist of more or less brick-shaped cells, which in the sapwood contain albuminous substances and at times such other nutritive substances as sugar, starch or fatty oil; in the sapwood they consequently invite attack by animals and fungi. Softwoods that, like true pines, have resin ducts in the wood also possess these in the thicker rays.

The fundamental difference between softwoods and hardwoods is best understood if a number of the wider "water fibres" are imagined to be very greatly widened and strung end to end with their terminal walls absorbed, so that long continuous tubes. sometimes yards in length, are produced. These water-conducting tubes are termed wood vessels; in cross section they are often visible to the naked eye as "pores." All commercial hardwoods have wood vessels, which in the sapwood contain air with or without liquid sap. In addition to the vessels, the different hardwoods have "fibres" of various forms.

Wood rays also are present in all hardwoods, and in many of them are much thicker than in the softwoods, being distinctly visible to the naked eye in cross section. On radial longitudinal surfaces the rays occasionally are conspicuous and ornamental, being up to several inches wide in oaks and producing the so-called silver grain. The contents in the sapwood are similar to those of the softwoods.

Sapwood and Heartwood.—In the living tree the inner portion of the sapwood gradually changes into heartwood by the death of all remaining living cells and the infiltration of tannins, gums, resins and other materials, the exact nature of which is not fully known, into the cell walls and cavities. During this change the pores of some hardwoods also become plugged by bladderlike intrusions, tyloses, from the surrounding cells. Furthermore, many of the microscopic pits in the cell walls are reduced in size or closed. As a result of these changes, heartwood often is less permeable to liquids and gases than sapwood. Hence, sapwood is more easily impregnated by wood preservatives and other liquids and dries faster than heartwood. In some species of timber the materials deposited in the heartwood make it more resistant to decay (*see* DRY ROT) and insect attack, as is the case in certain oaks, cedars and redwood. Since the materials infiltrated into the heartwood are very small in amount, it is neither appreciably heavier nor stronger than sapwood. Some species characteristically have narrow sapwood (*e.g.,* larches, cedars and black locust), whereas others have wide sapwood (*e.g.,* maples, birches and ponderosa pine).

Grain of Timber. — Most frequently the fibres and other structural elements of knotless timber run parallel with the long axis of the trunk or branch, and the wood is described as straight-grained. If a plank or post is sawed in a direction not parallel to the axis of the trunk, the grain of the sawed article is not parallel to the sides of this and the plank or post is described as cross-grained. But not infrequently the grain of the trunk (or branches) runs in a spiral direction, as if the trunk had been twisted round its long axis; the grain is then described as spiral or torse, and the timber when cut up is inevitably cross-grained. There are yet other, especially tropical, woods in which the grain more or less swings from a left-handed to a right-handed spiral direction, so that the wood when cut into plain boards shows a double cross grain or interlocked grain and when cut along the radii of the trunk ("on the quarter," rift-sawed) shows roe figure, as in mahogany.

In addition to these deviations from the straight grain, the structural elements of the wood may pursue a wavy or sinuous course, as for instance in so-called rammy ash. When the waviness is irregular, the grain is said to be curly.

Knots, being the basal parts of branches that have become embedded in the thickening trunk, are naturally associated with a change of direction of the fibres. The wood of large excrescences on the trunks of certain trees known as burrs, or burls, exhibits structure similar to that which would be produced by many small crowded branches. Bird's-eye maple results from numerous conical depressions in the tree trunk.

The fibres of most timbers overlap and dovetail with one another at their ends, which are at different levels, and the wood rays as seen in circumferential or tangential views are arranged apparently irregularly or in spirals. But some woods when examined from the same viewpoints show very fine lines running across the grain and producing what is known as ripple marking; this is caused by either contiguous fibres ending at the same levels with little or no overlapping or wood rays placed at the same levels, so that the structure of the wood is tiered. Such structure is often shown by true American mahoganies.

Chemical Composition. — The wood substance composing the walls of the hollow structural elements that constitute the solid framework or skeleton of wood may, for the present purpose, be regarded as always being composed of two main constituents, lignin and cellulose. together with smaller quantities of additional more or less gumlike bodies.

The lignin can be removed from the wood by steam or warm weak acids and alkalies (and is so removed in the manufacture of chemical wood pulp), the cellulose remaining.

The various substances here described collectively as cellulose are carbohydrates, which may be popularly defined as sugars or substances capable of being converted into sugars. Thus cellulose of wood yields for instance a sugar, glucose, which by fermentation can produce ethyl alcohol (spirits of wine). Cellulose by appropriate treatment with nitric or acetic acid produces soluble compounds which when precipitated serve to make artificial silk, dopes. films (collodion, etc.) and, in the case of nitric acid, explosives.

The general agreement of all kinds of timbers as regards chemical composition is illustrated by the fact that all these under destructive distillation yield tar and tar derivatives, methyl alcohol (wood spirit) and acetic acid.

But the various kinds of wood also have additional chemical bodies which differ in the different species and include tanninlike bodies, resins, scented ethereal oils and colouring substances.

Physical Constitution. — Physically wood substance is a very stiff jelly or gel, and consequently is comparable with glue, gelatin or gums. Like these it is hygroscopic and swells as it absorbs water and shrinks as it dries. Wood substance can take up only a definite amount of water, which lies near 30% of its dry weight when the wood is in a saturated atmosphere. 4 piece of wood containing this maximum amount in its walls but none in its cavities is described as having reached fibre-saturation point. and has attained its maximum volume; when liquid water is added to it the water enters the cavities and no additional swelling ensues.

It is a familiar fact that when water is added to dry glue or gelatin these show a decline in hardness, strength and stiffness and a rise in flexibility and extensibility; as wood substance is a gel, the same changes in properties take place when water is added to a piece of dry wood until fibre-saturation point is reached. Moreover. just as when heat is applied together with water to glue this shows increased loss of stiffness (by "melting"), so when moist steam is applied to wood this can readily be bent for the manufacture of furniture and so forth.

The weight or heaviness of wood is recorded as the weight of a unit of volume of the wood, which is the density. The units employed in the British Commonwealth and the United States are cubic feet and pounds avoirdupois; elsewhere and in scientific work they are cubic centimetres and grams.

Since the fundamental chemical composition of wood substance approaches identity in all timbers, its specific gravity in these varies but slightly. lying near 1.55; that is, dry wood substance weighs slightly more than $1\frac{1}{2}$ times as much as water. Consequently when two perfectly dry pieces of wood of equal size differ in weight, the one is heavier than the other because it contains more wood substance; in other words the density of perfectly dry wood is a measure of the amount of wood in a unit volume. The various kinds of timbers differ in their densities; some woods, including ebony and box, even when fully seasoned, sink in water, whereas some balsawoods are lighter than cork. Consequently density facilitates identification of different woods.

Water Content. — The amount of water present in a piece of wood is of profound practical importance, since it determines the weight (consequently cost of transport), size, shape, heat-raising power, hardness, strength and stiffness of the piece. as well as the vulnerability of the wood to attacks by fungi and insects; it also determines the changes in these characters that will ensue when the wood is transferred to another place.

The water content of wood may be stated as the percentage of the weight of the wood and the contained water (always less than 100%) or as the percentage of the weight of the absolutely dry wood. Usually the latter basis is used. According to this method of recording. a log of wood is described as containing 200% of water when it contains 200 lb. of water to every 100 lb. of dry wood. Such a high water content does occasionally occur naturally, as for instance in freshly felled swamp (Louisiana) cypress; more frequently in freshly felled timbers it is around 100% in the sapwood. Heartwood usually contains much less. Here a popular error must be corrected: in cold-temperate regions the wood of a tree does not contain less water in winter than in summer; often the reverse is the case.

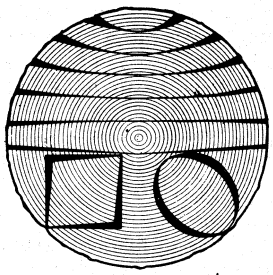
When exposed to the open air, preferably under cover, a freshly felled piece of wood dries and shrinks until the water content at its surface has a vapour pressure equal to that of the atmosphere. The water content of pieces of timber thus seasoned in the open air, and not too massive, varies according to the season and site between 15% and 20% in Great Britain but is much less in drier climates; in Egypt, for instance, it may be 6%.

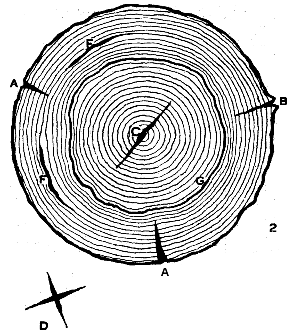
Brought indoors into heated workshops or rooms, further drying and shrinking take place, so that furniture in Great Britain contains about 7% to 9% and in drier parts of South Africa and the United States only 6% or less of water.

Placed in a drying oven at a temperature of 100° C., all the water, save that which is chemically combined, is regarded as having been dried out, and the wood is described as absolutely dry. When dry wood is once more exposed to moister air it reabsorbs water and swells. Under constant atmospheric humidity all species of wood attain about the same percentage of moisture based on their oven-dry weight.

Different kinds of wood undergo different changes of volume with the same percentage gain or loss of water. Heavy woods generally shrink or swell more than light woods, but shrinkage and swelling are not exactly proportional to wood density, for woods of the same density show considerable differences in this respect; for instance. Central American mahogany with changed water content undergoes comparatively slight change of size or shape

A piece of mood tends to shrink and swell unequally in different directions. Along the grain shrinkage and swelling are so slight that measuring rods made of well-seasoned wood are very reliable. Across the grain shrinkage and swelling are many times as great—in a radial direction 2% to 9% and tangentially (or parallel to the annual rings) 4% to 14%. Consequently when a piece of wood dries it undergoes greater or less change of shape. The accompanying diagrams show cross sections of pieces of wood respectively cut into boards, squares and cylindrical rods, and the change of shape caused by drying; the warping of boards cut off centre contrasts with the preservation of fatness of the board cut through the centre.





FIG, 1.—SHRINKAGE AND CHANGE OF SHAPE. INCLUDING WARPING
FIG. 2.— SHAKES AND SPLITS: (A) SEASONING SPLIT. (B) FROST RIB AND SPLIT, (C) SIMPLE HEART SHAKE. (D) DOUBLE HEART SHAKE. (E) STARLIKE HEART SHAKE, (F) PARTIAL CUP SHAKE. (G) COMPLETE CUP SHAKE

A piece of wood whose fibres, like those of very knotty wood or burrs, run in various directions obviously is especially liable to split when dried. It is partly for this reason that the burr wood used in the manufacture of beautifully figured furniture is cut into very thin sheets, termed veneers, which are glued onto straight-grained wood.

Plywoods (including the commonest of these, three-plywood) consist of thin veneerlike sheets glued together so that the grains of the successive sheets cross one another at a given angle (usually at right angles). with the consequence that plywood warps less and shrinks more uniformly than does plain wood and is less unequal in strength in different directions. (See PLYWOOD.)

Colour.—The different kinds of wood may be wholly white or in the heart may be black or have colours ranging from brown. yellow, red, green to violet, or mixtures of these. It is quite exceptional for one and the same wood when perfectly sound to show such a wide range of variation as does that of *Liriodendron* (English name Canary white wood and North American name yellow poplar); this wood varies in colour from light yellow to green and iridescent blue. The colour thus facilitates identification and helps to decide the decorative use to which a wood shall be put.

It is not true that dark-coloured woods are more durable than light-coloured. though this is true of the heartwood when compared with the' sapwood of the same timber. Abnormal discoloration of wood is very frequently caused by fungi attacking the wood or its contents. as is the case with the blue sap(wood) of softwoods, rusty red of woods attacked by various fungi (including some causing dry rot), black lines and white patches of many rotting timbers. and sometimes false heartwood in trees which normally lack a coloured heartwood.

Heating Power.— The heat-yielding power of a piece of wood decreases with increase of its water content; consequently the succeeding remarks refer to n-ood absolutely dry. During the combustion of wood the heat liberated is mainly derived from the wood substance; as the weight of this in a unit volume of wood is the density, it follows that the heavier a wood is the more heat it can supply: the presence of resin in wood, however, increases the heat-giving power.

When wood is used as fuel, however, the most important character often is the form in which the heat is liberated. Very heavy woods produce short or no flames and burn slowly, light woods can produce long flames and burn fiercely; consequently for fire lighting or steam producing the latter are used, whereas for keeping rooms warm, woods of intermediate density (*e.g.,* oak and beech) are most efficient.

Mechanical Properties.— The trunk and woody branches of a tree owe their strength and stiffness mainly to their wood. Accordingly, wood must possess strength to resist breakage or permanent damage by slow crushing, stretching, bending and twisting; it must also resist shock in the form of sudden application of these stresses; it must possess sufficient stiffness to give the requisite pillar strength to the trunk, and when a deforming stress is removed must return to its former shape.

In conformity with its difference of structure along and across the grain. wood differs in strength and stiffness in these two main directions. As regards crushing (compression) and stretching (tension) wood is strongest and stiffest along the grain and .weakest at right angles to this. As regards shear. however: it is strongest at right angles to the grain; a beam in bending is strongest and stiffest when the load is applied perpendicular to the grain. Consequently; joists, beams, floorboards, posts, ax handles, wheel spokes and so forth are strongest when their grain is straight and parallel to the sides of these objects, and they are weakened by cross grain and considerable knots.

The remarkable mechanical property of wood is its combination of strength and lightness; for instance, if the crushing strength is divided by the density in the cases of constructional wood and iron, steel and other metals, the resultant value is highest in wood. Severtheless, the tensile strength of steel or iron is so much higher than that of wood that one of the former is used in engineering construction for members required to resist rupture by tension, whereas wood is often used where resistance to bending or compression is needed. (See MATERIALS, STRESGTH OF.)

The peculiar elastic properties of wood render possible its employment as resonance wood, used for instance in the bellies of violins and in the sounding boards of pianos. Wood undergoing decay soon declines in strength and elasticity, and even when only partly decayed emits when struck a dull, in place of a sharp ringing sound.

Wood, thanks to its structure, elasticity, low tensile strength and relative softness. can be riven or cleft along the grain and yields a more or less smooth surface.

Defects of Timber.— Standing *Tree.*—Wood may have structural peculiarities that represent defects from the mechanical point of view but that may enhance the value because of the decorative effect. This is the case where deviations of the grain, such as wavy or curly grain, or abundance of knots weaken the wood.

Always decreasing the value of timber are long splits, termed shakes. directed along the grain of the standing tree. These in cross section may run parallel with the annual rings (or contour of the trunk) and are termed cup shakes. They may assume the form of short arcs or complete circles (ring shake); in the latter case when the log is sawed the central part separates from the outer part. But in cross section the shake may run in a radial direction; it is then a heart shake. Such a shake is widest toward the centre and tapers outward. and contrasts with the radial splits induced by drying of the felled timber which are wider at the outside and taper inn-ard.

Heart shake may assume the form. in cross section. of a single split traversing the centre. in which case it is described as simple; or this split may be crossed at right angles by another, thus producing double heart shake; or, finally a number of splits may radiate from the centre and thus constitute star shake. which is often associated with discoloration and decay. Radial frost shakes are frequently associated with frost ribs that are visible on the growing tree as ridges running down one or more sides of the trunk. With these shakes contrast the internal radially directed splits that first arise in felled timber which has been so rapidly dried that case-hardening has resulted.

In the resinous coniferous woods, such as the pines. lens-shaped, resin-containing cavities from less than an inch to several inches in width, known as resin pockets or pitch pockets, occasionally occur. Sometimes longer resin veins easily visible to the naked eye traverse the wood, or this may clearly show a general excess of resin in the absence of veins or pockets. In some cases excess of resin or abnormal development of the ducts is caused by injury to the cambium.

In hardwoods so-called gum veins are occasionally present in Australian species of eucalyptus, including jarrah, and in true mahoganies.

Felled Timber.—Tunnels or other cavities are also produced by animals in felled timber. In sea water they result from attacks by Mollusca (e g., shipnorms) or small Crustacea (cf. shrimps), and on land are caused by insects. Decay or rot of timber taking place in the standing tree or felled timber is always attributable to fungi (see DRY ROT), and is associated with discoloration and weakening of the wood but much less frequently with the production of internal cavities.

Opposed to the shakes already considered are cross shakes, which are cracks or splits running at right angles to the grain. In the overwhelming majority of cases they result from decay of the wood, caused by fungi, and consequent shrinkage (see DRY ROT). They render wood useless for mechanical purposes. But the logs of certain species of trees. including spruce, sabicu and some African mahoganies, occasionally show cross shakes even in freshly felled timber and when there is no trace of decay.

For a discussion of felling, forms and sizes see LUMBERING.

Special Softwoods.—The name cedar is given to various unrelated, usually fragrant, softwoods and hardwoods. The true cedars (Cedrus) are familiar as trees of three kinds: the Himalayan deodar, the cedar of Lebanon and the Atlas mountains cedar. Junipers (*Juniperus*) supply the pencil-wood 'cedar, the most important being the North American J. virginiana, though pencil slats are also made from another species growing in Kenya; the heartwood is durable, as the scented cedarwood oil is antiseptic and distasteful to insects.

Lawson's cypress (Chamaecyparis lawsoniana), indigenous in western United States, yields the valuable Port Orford cedar. Other Sorth American cedarwoods are produced by arbor vitae trees (*Thuja*), the durable red cedarwood (T. plicata) being used for shingles.

Bald, marsh or Louisiana cypress (*Taxodium distichum*) grows in swamps of southeastern United States and Central America; its durable wood is unsurpassed for conservatories.

The European larch (*Larix decidua*) is rather heavy and the red heartwood is very durable. The rather similar North American timbers are those of the tamarack (L. *americana*) and the western larch (L. *occidentalis*). Larch timbers find many of the same uses as hard pines (see below).

True Pine.—The name pine is given to a medley of softwoods but should be restricted to timbers belonging to the genus *Pinus*. Such genuine pine timbers may be ranged into two classes. hard pines and soft pines, the former of which are generally heavier.

Hard pines include one of the two most important softwoods of Europe; Baltic red deal (*Pinus sylvestris,* the Scots pine), which grows widely over Europe and is represented in North America by a very similar timber, red or Norway pine (P. *resinosa*).

The name pitch pine as applied to North (and Central) American timbers in Great Britain and the United States. respectively, is liable to cause confusion: in the latter country it refers to relatively poor wood of P. *rigida,* whereas in Great Britain and Europe it refers to pine timbers of the highest class produced by P. *palus*tris and two or three other species all exported from southeastern United States to England.

Soft pines include two North American species, eastern white pine (P. *strobus*), known in England as Weymouth pine and Canadian yellow pine. and western white pine (P. *monticola*), also called Idaho white pine. They are used for house construction, patterns, matches and packing boxes.

So-Called Pines.—A nide range of coniferous trees are known in Australasia as pines and include the kauri pine (Agathis *australis*) of Sen Zealand and huon pine (*Dacrydium franklinii*) in Tasmania. The Oregon or British Columbian pine is Douglas fir (*Pseudotsuga* taxifolia), which grows in the western portion of North America.

California redwood (*Sequoia sempervirens*) has a reddish heartwood, is light in weight, durable and used for building construction. tanks, wood-stave pipe, silos and coffins.

White deal is the wood of the Norway spruce (Picea excelsa), which is widespread over Europe. The white wood ranges in quality from the common grades used in packing cases, woodwork of houses and pulp. to mountain-grown wood of the highest quality which provides the best sounding boards of pianos. To similar uses the black, white, red and Sitka spruces (Picea spp.) are put in North America. (See SPRUCE.)

Special Hardwoods.—The ash tree (Fraxinus excelsior) is widespread over Europe and supplies the timber of commerce, which is almost solely sapwood, as any heartwood is produced late in life. The wood is remarkably tough and, after steaming, can be permanently bent without losing its shock-resisting power. It is used in the manufacture of fork handles, oars. baseball bats, tent poles and so forth. In North America six species of Fraxinus supply commercial timbers.

The beech timbers of commerce are the woods of *Fagus* sylvatica and F. *grandifolia* in Europe and North America respectively. The latter shows a distinction into white sapwood and reddish heartwood, but not so the former. which is of uniform reddish white. Being perishable out of doors beechwood is mainly made into articles used indoors, including furniture.

In addition to the softwoods enumerated a number of scented hardwoods from various countries are termed cedars; of these the most familiar is the tropical American cedar (Cedrela odorata) used in the manufacture of cigar boxes and small boats.

Very similar to the timbers of ordinary oaks are those of the true chestnuts, Castanea *vesca* of Europe and C. dentata of North America. but these lack wide rays and consequently display no striking silver grain, and they are weaker.

Species of Diospyros growing in tropical Asia and Africa supply the black ebonies of commerce. The black of the heartwood may be interrupted by patches of white (in Andaman marblewood) or brown (in calamander wood). The Japanese and North American persimmon woods also are species of Diospyros, but pieces of the latter have little or no black wood.

The commercial timbers are produced by several species of European and North American elm (*Ulmus*). They generally have heartwoods lasting well in permanent contact with water; the water pipes of London in old times were often made of hollowed trunks of elms.

Australia is the world's centre for the growth of eucalyptus trees. a number of which produce hard, heavy, strong timber of large dimensions, and include jarrah, karri, tallowwood and tuart.

Greenheart is a tropical South American wood, which is generally stated to be that of Ocotea *rodiaei;* it varies in colour from yellow-green to darker admixtures of colours. Resistant to shipworms, it is used widely for piling in docks; for fishing rods it is pre-eminent.

Commercial hickory woods of good quality are produced by a number of species of Hicoria in the United States. These find much the same uses as ash, since they are tough, but being stiffer they are used more for handles of striking tools, such as hammers.

The name mahogany is improperly given to a medley of woods which range from white to bluish red in colour and grow in various countries. The original mahogany was that of Swietenza *mahagoni,* growing in the West Indies; this species, together with the allied S. *macrophylla* growing on the mainland of tropical America. supply true American mahogany. These reddish-brown woods shrink and warp little, are durable, light and polish readily to yield beautiful decorative effects. Any other woods named mahogany should share these characters. Such is the case uith West African mahoganies produced by certain species of Khaya (belonging to the same family, Meliaceae, as Swtetenia), which are indistinguishable by most persons from the American mahogany. The West African Gaboon mahogany is a wood belonging to trees (or a tree) of an entirely different family. and is not a mahogany; neither are any of the so-called mahoganies of India, Australia, the United States and South America.

Maples, including the European sycamore, belong to the genus Acer and vield white firm woods that have a silverv sheen. North America supplies maples used in floorings. bowling pins, novelties and the beautiful bird's-eye maple used in furniture.

True oak timbers are produced by species of Quercus, which is a genus not growing south of the equator, and the commercially important ones are European, North American and Japanese in origin. The European timber is mainly derived from the wide-spread Q. *pedunculata* and Q. *sessiliflora,* and stands apart from the other commercial kinds in being the sole one that can be safely used alone in the construction of casks and barrels for the storage of beer, wines and spirits without causing deterioration of flavour of these. Great Britain produces a unique type, termed brown oak, which is used in the manufacture of panelling and furniture in Europe and North America, The European oak imported into England is known as Russian oak when exported from Baltic ports and as Austrian oak when exported from Fiume. North American commercial oak timbers are produced by a larger number of species of *Quercus* belonging to two groups. the white and red oaks, which contrast in structure, durability and uses.

Genuine lustrous satinwoods in origin are respectively East Indian (*Chloroxylon swietenia*) and West Indian (Xanthoxylum).

Teak timber is produced by Tectona *grandis,* which yields commercial supplies only in the Indian peninsula, Burma, Siam and Java. The valuable yellow to brown heartwood is hard, strong, stiff and very durable; moreover, unlike oak, it does not attack iron. As the wood also "stands" well, it is excellently suited for use in windowsills, ships and flooring. The wood shows annual rings and thus contrasts with such spurious teak timbers as West African teak (Chlorophora) and Indo-Malayan eng or yang teak (*Dipterocarpus*).

The two most important walnut timbers are those of *Juglans regia,* whose distribution stretches from England to northern India, and J. *nigra,* which is North American. The heartwood of both species is brown; that of the former species is often traversed by brown lines, while that of the American species is wholly of a blacker brown. Both woods are unrivalled for the manufacture of gunstocks and are excellent furniture wood; when it has been thoroughly seasoned and polished, it shrinks and swells very little. The wood has clearly marked annual rings and thus contrasts with two tropical spurious walnuts. the East Indian (Albizzia lebbek) and West African (Lovoa klaineana). 4 third misnamed wood is known in Great Britain as satin walnut (also as hazel pine) and in the United States. its native country, as gum (sweet or red).

Confusion frequently arises in England as to the identities of several woods that are more or less white. From the United States there are exported to England several kinds of wood having that character. One is named canary whitewood in Great Britain but yellow poplar in America; it is produced by the tulip tree (Lirio-*dendron tulipifera*) and ranges in colour from light yellow to iridescent blue. In addition are woods produced by true poplar trees (*Populus*), which are named cottonwoods in the United States. Third, there are woods known in England as lime and in America as basswood, that are produced by lime trees (*Tilia* spp.), which of course are very different from the limes (Citrus) producing the familiar juicy fruits.

The European sycamore is a maple, and when artificially coloured gray is marketed as hardwood. What is known as sycamore in the United States is the plane tree of Europe.

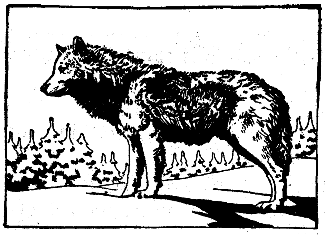
TIMBER LINE, the boundary above which there is no natural tree growth. In any elevated area in low or middle latitudes the line is generally clearly marked, but its height is dependent not only on general but also on local climatic and soil conditions. See SNOW LINE.

TIMBER WOLF, a name applied to the large wolf (*Canis lupus*) of the eastern and northern narts of North America. The colour is usually gray but ranges from black to white.



COURTESY NEW YORK ZOOLOGICAL SOCIETY
THE TIMBER OR GRAY WOLF

Timber wolves reach a length of 66 in., of which the tail is 12 in., and a weight of about 100 lbs. Over much of their former range. wolves have been exterminated.

See WOLF; CARNIVORA.

TIMBREL or **TABRET** (the *tof* of the ancient Hebrews. the *deff* of Islam, the adufe of the Moors of Spain), the principal musical instrument of percussion of the Israelites, identical with the modern tambourine.

The tabret or timbrel was a favourite instrument of the women, and was used with dances, as by Miriam, to accompany songs of victory, or with the harp at banquets and processions; it was one of the instruments used by King David and his musicians when he danced before the Ark.

TIMBUKTU (Fr. Tombouctou), chief town of a district of the Republic of Mali, 9 mi. N. of the main stream of the Niger in 16° N. and 5° W.

Timbuktu lies on a terrace formed by the southern scarp of the Sahara, about 800 ft. above sea level, surrounded by sandy dunes covered with mimosas and other spiny trees. Timbuktu communicates with the Niger by a series of marigots or channels nith alternating flow, which fill at flood time and empty themselves into the Niger when the dry season supervenes. In January, the maximum period the waters reach the walls of the town through the marigot from Kabara, which is the port of Timbuktu.

Timbuktu has been described as "the meeting point of the camel and the canoe," "the port of the Sahara in the Sudan." and (more correctly) "the port of the Sudan in the Sahara." It was formerly a much larger place than it was found to be at the time of its occupation by the French in 1893–1894. Extensive ruins exist north and west of the present town. The great mosque which at one time stood in the centre of the town now lies near the western outskirts, where its high but unsightly earth tower forms a striking landmark. The mosque of Sidi Yahia (in the centre of the town) and that of Sankoré in the north-east also possess prominent towers. Whereas in 1895 the town was little more than a vast ruin. under French protection the inhabitants, relieved from the fear of Tuareg oppression, set about repairing and rebuilding their houses; new streets were built; European schools, churches and other establishments were opened. But Timbuktu has not yet recovered; pop. (1955 est.) 7,468, including 68 Europeans. The majority are Songhoi. At the time of the commercial transactions from March to June, the population reaches 25,000. The industries of Timbuktu—cotton-weaving, earthenware, leatherwork and embroidery—are of subordinate importance, and the great bulk of the people are occupied exclusively with trade. The whole traffic of the surrounding lands converges on Timbuktu; two great caravans of 3,000 or 4,000 camels are yearly charged with salt from the Taudeni district.

Timbuktu, which possesses some valuable Arabic manuscripts —notably the Tarik *es-Sudan,* a 17th-century history of the Sudan written by Abderrahman Sadi of Timbuktu—and is a centre of Moslem teaching, is a converging point of the chief west Sudanese and Saharan races—Arabs or Arabized Berbers to the west; Sonrhaï in the immediate vicinity, and thence south-eastwards along the Niger; Ireghenaten or "mixed" Tuareg southwards across the Niger as far as the Hombori Hills and in the fertile Libbako plains beyond them; Fula, Mandingos, and Bambara in and about the city; and Imoshagh (Tuareg) belonging to the Awellimiden confederation mainly to the north and east.

The local administration—which French rule preserved—was placed in the hands of an hereditary *kahia,* a kind of mayor, descended from one of the Ruma families. (A. BE.)

History.—The history of Timbuktu is intimately connected with that of the city of Jenné and the Songhoi empire. The Songhoi are a negro race who are said to have come to the Niger countries from the Nile valley. In the 8th century they made themselves masters of a considerable tract of country within the bend of the Niger, and built the city of Gao (*q.v.*), zoom. in a direct line S.S.E. of Timbuktu, making it their capital. In the 11th century they were converted to Islam. Besides Gao, the Songhoi founded Jenné (*q.v.*), which early attained considerable commercial importance. Meanwhile (11th century) a settlement had been made at Timbuktu by Tuareg. Perceiving the advantages for trade with the north offered by this desert rendezvous, the merchants of Jenné sent agents thither (12th century), and Timbuktu shortly afterwards became known to the inhabitants of the Sahara and Barbary as an excellent market for their goods, and also for the purchase of the many commodities of the western Sudan. In the 12th or 13th century Timbuktu fell under the power of the Mandingo kings of Melle or Mali, a country lying west and south of Jenné. Its fame as a mart for gold and salt spread to Europe, "Timboutch" being marked on a Catalan map dated 1373. In 1353 it had been visited by the famous traveller Ibn Batuta. In 1434 the Tuareg made themselves masters of the city, which in 1469 was captured by the Songhoi king Sunni Ali. It was at this time (1470) that Timbuktu was visited by an Italian, Beneditto Dei. In the days of Sunni's successor Askia (1494–1529) the Songhoi empire reached its highest development, and Timbuktu rose to great splendour. The "university" of Sankoré became a chief centre of Mohammedan culture for the peoples of the western Sudan.

The riches of Timbuktu excited the cupidity of El Mansur, sultan of Morocco, who, in 1590, sent an army across the Sahara under an "Andalusian" Moor (that is, a Moor descended from those expelled from Spain), which captured Timbuktu (1591) and completely broke up the Songhoi empire. For about 20 years after the conquest the pasha who ruled at Timbuktu was nominated from Morocco, but the distance of the Niger countries from Marrakesh enabled this vast viceroyalty to throw off all allegiance to the sultan of Morocco. The Niger Moors, known as *Rumas* after El Mansur's musketeers, quarrelled continually among themselves, and oppressed the negro tribes. By the end of the 18th century two hundred years of oppression had reduced Timbuktu to comparative desolation and poverty. By this time the whole country was in a state of anarchy, and in 1800 the Tuareg swooped down from the desert and captured the place. They were in turn (1813) dispossessed by the Fula, who in 1840 gave place to the Tukulor. (See SENEGAL, History.)

At this period European interest in the region had revived. Maj. Gordon Laing, who had reached Timbuktu from Tripoli in 1826, had been murdered by order of the Fula; but Rent. Caillié, coming from the south, had been in the city in 1828 and had returned in safety. Heinrich Barth, an officially accredited representative of the British Government, reached Timbuktu from the Central Sahara in 1853 and some effort was then made to bring the place under British influence. El Backay (Bakhai), the sheikh who received Barth, gave him letters professing much friendship for the British, and in a letter to El Backay, dated April 15, 1859, Lord Clarendon, secretary of State for foreign affairs, said that "the friendship binding us shall not diminish through the centuries" and "as our Government is very powerful we will protect your people who turn to us." A nephew of El Backay's went to Tripoli, saw the British consul and was told that a British steamer was ascending the Niger and that the Government had recommended those on board "to make every effort" to reach Timbuktu. But no one from the lower Niger reached El Backay, whose influence appears to have declined after Barth's visit; and no further attempt appears to have been made by the British to keep in touch with Timbuktu. Indeed. between Barth's visit and the French occupation only one white man, Oskar Lenz, in 1880, reached Timbuktu and he crossed the desert from Morocco. It was in the following year, 1881, that the French. thrusting forward from Senegal, began the conquest of the countries of the Niger bend. When they reached Timbuktu in December 1893 they found that the town had again fallen beneath the rule of the Tuareg. The townsfolk, indeed, from the time of the decay of the Ruma power being at the mercy of all comers, were content to pay tribute to each in turn and sometimes to more than one simultaneously, for which they indemnified themselves by peaceful intervals of trade whenever the land routes were open and the Niger clear of pirates. But at times even the short tract separating the town from Kabara was so beset with marauders that it bore the ominous name of "Ur-immandess," that is, "He (God) hears not." Little wonder then that the townsfolk freely opened their gates to the French as soon as Lieut. Boiteux reached Kabara in command of a small flotilla.

The occupation of the town, against orders, was a daring exploit of a handful of marines. The force which "garrisoned" Timbuktu consisted of seven Europeans and twelve Senegalese. The somewhat larger body left with the gunboats was attacked by the Tuareg (Dec. 28) and suffered severely. Col. T. P. E. Bonnier, who was at Mopti, zoom. to the south-west, marched to the relief of Boiteux and entered Timbuktu without opposition on Jan. 10, 1894. He then set out with about 100 men to chastise the nomads. In the night of Jan. 14–15 his camp was surprised and the colonel and nearly all his men perished. The enemy did not follow up their victory, and within a short period French rule was firmly established in Timbuktu. In 1903 the French authorities placed commemorative tablets on the houses occupied by the four travellers, Laing, Barth, Caillié and Lenz, during their stay in Timbuktu. Under French rule the town has regained a measure of importance.

TIMBY, THEODORE RUGGLES (1819–1909), American inventor, was born on April 5, 1819, in Dover, New York. His most noted invention was the revolving turret, which he first conceived in 1841. He first constructed a small model and displayed it in Washington. Later he built a steam-propelled model in Syracuse, N.Y. (1842). This he exhibited in the city hall, New York, where it was inspected by President Tyler and his cabinet. In 1843 he obtained a caveat from the patent office. During the Civil War, when the "Merrimack" had been constructed with heavy iron armour by the Confederate Government, it became evident that a new type of ship must be built to compete with it. At this juncture John Ericsson came forward with plans for a floating battery. These plans were presented to the naval department and promptly accepted. Immediately an organization known as the "Battery Associates" was formed to build armoured ships according to Ericsson's plans. When Timby heard of this Government contract, he presented the caveat for his patent on the revolving turret, which was to be the main feature of Ericsson's floating battery. The Battery Associates, recognizing Timby's claim, agreed to pay him $5,000 on each turret built. Soon afterwards. with Ericsson as engineer of the design and construction, the battleship "Monitor" was completed. When she met the "Merrimack" and gained her famous victory, Ericsson was given general recognition as the inventor of the revolving turret. No serious efforts were made to correct the misapprehension until Timby's death. From 1861 to 1891, Timby invented and patented, at home and abroad, a system of coast defences, such as the sighting and firing of heavy guns by electricity; the tower and shield; the cordon across a channel; the planetary and subterranean systems, and numerous modifications of the turret system. He died in Brooklyn, N.Y., on Nov. 9, 1909.

TIME, the general term for the conscious experience of duration. For the distinction between man's subjective impression of time and an attempted scientific, hence entirely objective, description, independent of any observer, see SPACE-TIME. For the methods of reckoning time, see CALENDAR; DAY; MONTH; TIME MEASUREMENT; TIME, STAXDARD. See also Index references under "Time" in the Index volume. (H. B. LM.)

In Music. — Time is a term signifying the number of beats in a measure or bar. When there is an even number of beats, as two or four, the music is said to be in common or duple time. When there are three beats in a measure it is said to be in triple time. Further; when the beats are of the value of an aliquot part of a semibreve the time is termed simple. Thus four crotchets, or their equivalents, in a measure constitute simple common time. while three crotchets. or their equivalents, constitute simple triple time. When, on the other hand, the beats are of the value of dotted notes, and therefore not aliquot parts of a semibreve, the time is termed compound. Thus four dotted crotchets in a measure constitute compound common time. while three dotted crotchets in a measure constitute compound triple time. (X.)

TIME, STANDARD. In an isolated community clocks and watches would be set to the local mean time (see TIME MEASUREMENT), and before the period of railway communication the different towns as a rule kept local time. The need for a more systematic plan of standard times was chiefly felt in the United States. While the railways in England were run by Greenwich time and the railways in France by Paris time, it was not to be expected that railway systems in the middle and western states would adopt Washington, D.C., time. differing by several hours from the local time of the region which they served. Hence each railway had its own time. or, in the case of the longer lines, several different time zones, and great confusion arose at overlapping points. The question of bringing order out of chaos through a system of standard time was actively discussed in the principal commercial nations during the decade before 1880. Sandford Fleming in Canada and Charles F. Dowd in the United States being the principal proponents of the system. This involved adopting for the whole earth 24 standard meridians 15° apart in longitude, starting from Greenmich. These meridians were to be the centres of 24 time zones; in each zone the time adopted would be uniform, and it would change by one hour in passing from one zone to the next. After long discussion railway managers of the U.S. and Canada decided to adopt the system. Zone time based on the Greenmich meridian is now adopted almost everywhere. In most countries the time differs by an integral number of hours from Greenwich time, in accordance with the original plan; but in some countries a compromise involving half-hour differences was adopted. European countries are ranged in three groups, keeping respectively Greenwich time, mid-European time (one hour fast). east European time (two hours fast). In the U.S. there are four time zones: Eastern, Central, Mountain, Pacific, respectively 5, 6, 7, 8 hours slow on Greenwich time. A full list of standard times of the different countries, and of those on non-standard time is published yearly in the British *Nautical Almanac*.

The advent on an international scale of shipping and. later, of air travel has necessitated world-wide agreement on the 15° time zone system. Slight adjustments have been made in some of these parallels of longitude so that a particular standardization may cover a specific geographical area; for example in certain countries in east Asia (see map). The parallel of longitude at 180° (12 hours) is also known as the "date line" because just to the vest of this line countries are one calendar day ahead of Greeawich; again this line has been adjusted so that it does not pass through the middle of a country — in this case New Zealand. Some countries adopt. as an internal policy within their own borders, a zoning every $7\frac{1}{2}$°, giving time intervals of one-half hour; examples are India. Pakistan and other countries in the far east.

In the summer months some countries advance their time by one hour, or adopt the time of the next zone to the east. Thus legal time in Britain is Greenwich time in winter and mid-European time in summer. The advantage of summer or daylight saving (*q.v.*) time depends much on the latitude, and it is scarcely suitable for more northerly or southerly countries; it is unpopular in agricultural communities, but is widely favoured in urban areas.

The advantage of adopting a continuous reckoning of the hours from 0 to 24 instead of using the divisions A.M. and P.M. is obvious, and this reckoning has been adopted for many public services in some countries, but confusion has arisen through uncertainty as to when 0 hr. occurs. Astronomers from time immemorial have used a 24 hr. reckoning beginning at noon, but for civil purposes it has seemed more natural to count from midnight. At the meeting of the International Astronomical union in 1922 astronomers were recommended to use time beginning at Greenwich midnight from 1925, but no recommendation was given as to the name. In England it was believed that the intention was to use the name Greenwich mean time (G.M.T.) in a sense differing by 12 hr. from what it had previously meant. In other countries, however, other names were available for time counted from Greenwich mean midnight and these were used. At the meeting of the International Astronomical union in 1928 it was decided to use *temps* universe1 (T.U.) in France, universal time (U.T.) in England and *Weltzeit* (W.Z.) in Germany. The designation Greenwich civil time (G.C.T.), which had been used in England, France and the Gnited States, was dropped, and it was recommended that anyone who still wanted to use time counted from noon should call it Greenwich mean astronomical time (G.M.A.T.).

(A. S. E.; J. JN.)

See *The American* ***Ephemeris*** *and Nautical Almanac* (annual).

TIME MEASUREMENT. Time is a basic concept which deals with the occurrence of events. There is a definite order in which any two nonsimultaneous events occur. Thus, if *A* and B are such events, either *A* occurs before *B* or B occurs before *A*. Between two nonsimultaneous occurrences there is the lapse of an interval of time.

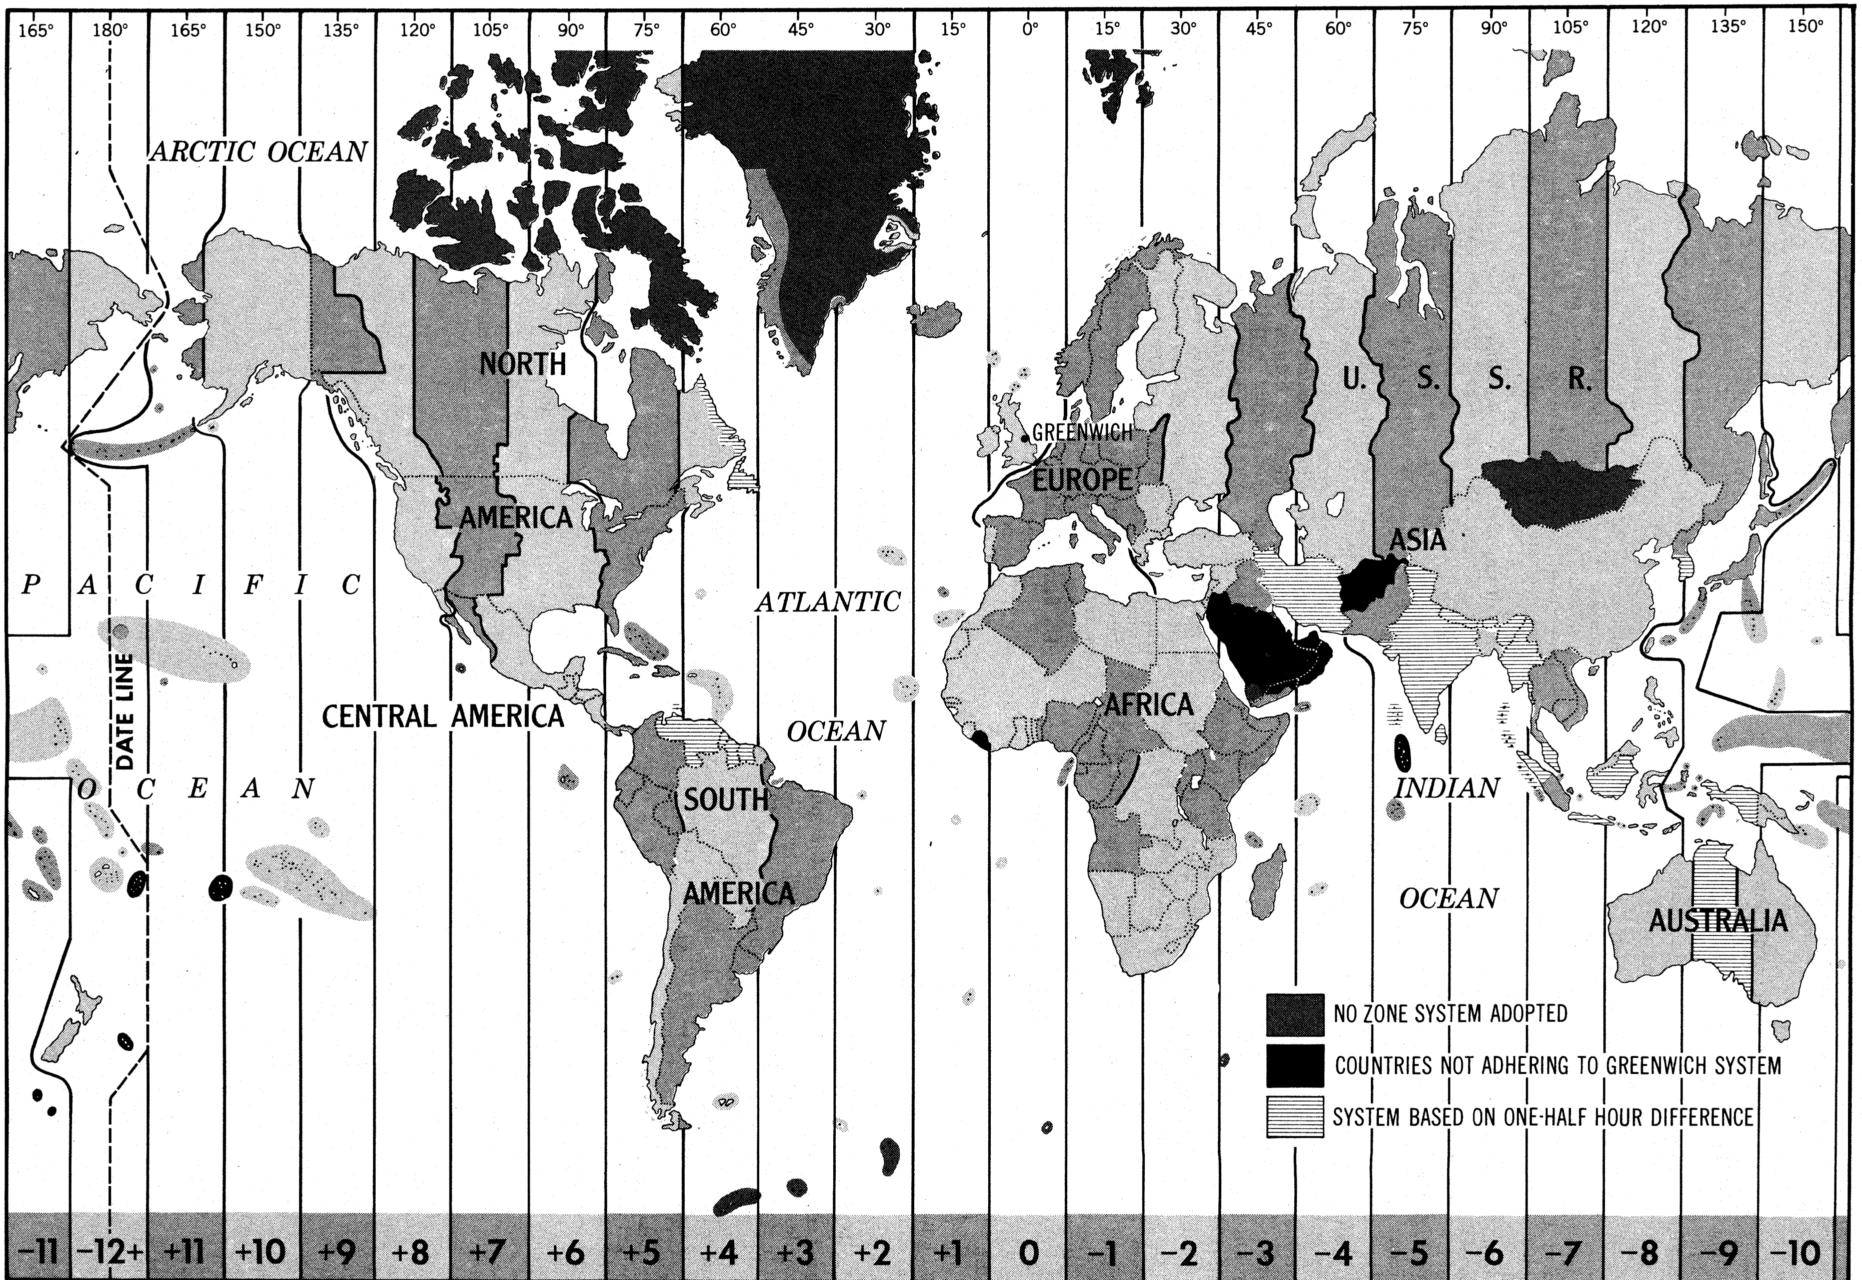
The measurement of time involves establishing a precise system of reference for specifying when any event occurs, that is, specifying the epoch, and establishing a standard interval of time. Astronomy and civil affairs are concerned both with epoch and with time intervals, whereas physics deals almost entirely with time intervals. The fundamental unit of time interval is the second. There is a similarity between time and length as dimensions, and also a difference. A unit of length may be made, and preserved in a vault. **A** unit of time: however, must be continually redetermined.

Analogous to equal intervals of length are equal intervals of time. The rhythm of music. the beat of a clock and the daily rising of the sun are recognized as manifestations of equal intervals of time. Our senses, however, are not a good judge of equal intervals, and if accuracy is required a clock of some kind must be used. A clock, in the general sense, may be defined as anything which can be used to measure an elapsed interval of time. We distinguish between two types. natural and artificial. The natural type is based on some process of nature, such as the rotation of the earth about its axis, the revolution of the moon about the earth or the decay of a carbon isotope. The artificial type consists of two parts, a constant frequency element and a counting element. Examples are the pendulum: quartz-crystal and atomic clocks.

The rotation of the earth was the sole standard of time determination until about 1940 when it became certain that the speed of rotation of the earth was not constant. Since mean solar time, which is based on the rotation of the earth, is nonuniform, a new kind of time which is uniform. called ephemeris time (E.T.), was introduced (see below). E.T. is defined by the revolution of the earth about the sun, but is obtained in practice from the motion of the moon about the earth. In 1955–56 the fundamental unit of time was redefined to be identical with the second of ephemeris time instead of the second of mean solar time, but mean solar time continued in civil use while ephemeris time is used for scientific and technical purposes whenever the requirement for accuracy in absolute time exceeded one part in 10,000.000 (1 in 10^7).

After an explanation of the basis of time measurement the above concepts are discussed in detail under the following headings:

I. Rotational (Nonuniform) Time
  A. Solar Time



BASED ON DATA FROM THE U.S. NAVY HYDROGRAPHIC OFFICE

TIME IS CALCULATED FROM THE MERIDIAN OF GREENWICH, ENG. THE MIDDLE OF THE ZERO TIME ZONE PASSES THROUGH GREENWICH WITH ITS EAST AND WEST LIMITS 7° 30′ ON EACH SIDE. EACH 15° ZONE EAST AND WEST OF THE INITIAL ZONE REPRESENTS ONE HOUR OF TIME. THE NUMBER OF HOURS THAT MUST BE ADDED TO OR SUBTRACTED FROM LOCAL TIME TO GIVE GREENWICH TIME IS INDICATED ON THE MAP FOR EACH ZONE

B. The Second
C. Atomic Frequency Standards
D. Gravitational Time and Atomic Time
E. Uses of Time Systems

Basis of Time Measurement.— Mechanical clocks might be used as a basis for a system of time measurement; however, they are affected by variations in friction. and are not suitable as a basis for accurate time determination. To be free of the effects of friction we may either utilize the motions of members of the solar system or of atoms. The astronomical basis of time measurement will be given first. the atomic basis later.

The motions of celestial bodies are predictable from the laws of celestial mechanics. Knowing the masses, co-ordinates and velocities of a number of bodies at one epoch, it becomes possible to find the co-ordinates for any epoch, t, by the solution of the appropriate differential equations.

The solution for some particular co-ordinate of one of the bodies, say x_1, may be written

$$x_1 = f_1\ (t; a_1, a_2, \ldots a_n), \qquad (1)$$

where f_1 is a function of t and the constants of integration a_1, $a_2 \ldots a_n$. By postulate, the t of equation (1) is uniform astronomical time.

A table which gives the predicted positions of a celestial body, based on an equation of the form (1). is called an ephemeris. For this reason the uniform time of celestial mechanics is called ephemeris time.

I. ROTATIONAL (NONUNIFORM) TIME

A. Solar Time.—The apparent daily motion oi the sun from east to west provides a measure oi time called apparent solar time, which is indicated by a sundial. The interval between two successive transits of the apparent sun across the meridian is called an apparent solar day.

The annual revolution of the earth about the sun causes the sun to appear to move eastward with respect to the stars. Hence, an apparent solar day is not equal to the period of rotation of the earth with respect to the stars. The apparent motion of the sun is 360° in a year, or nearly 1° per day, and an apparent solar day is almost 4 min. longer than the period of rotation.

The earth moves about the sun in an elliptical path in a plane called the ecliptic, which is inclined about $23\frac{1}{2}°$ to the equator. In consequence of these factors the component of the daily motion of the sun along the equator varies. As a result, apparent solar days are of variable length, and apparent solar time is nonuniform.

The development of clocks and watches in the 17th century made apparent solar time unsuitable ior civil use, and mean solar time was introduced. The mean solar day is the mean period of rotation of the earth with respect to the sun. Mean solar time is so defined as to be a measure of the rotation of the earth. The difference between apparent solar and mean solar time is called the equation of time. Its numerical value varies from 0 to about 16 min.

B. Sidereal (Equinoctial) Time.—For various astronomical purposes, such as locating a celestial object, the astronomer uses sidereal time. In the discussion given here astronomical co-ordinates, etc., are treated only briefly. For additional details see ASTRONOMY: *Modern Descriptive Astronomy*: *Time.*

The intersection of the true equator and the ecliptic provides a fundamental reference point called the true vernal equinox. Right ascensions are measureti along the celestial equator from the equinox. The interval between two successive meridian transits of the true equinox is called a true sidereal day. The hour angle of the true equinox, that is, the angle west of the meridian measured along the equator, is the true sidereal time.

The true equinox is not fixed with respect to the system of stars but moves very slowly in a retrocrade direction along the ecliptic, in a period of about 25,000 years. The secular, or steady, part of the motion is called precession and the periodic, or oscillating, part is called nutation. In consequence of nutation true sidereal days are of variable length. The maximum variation from the mean is only about 0.01 sec., but improvements in the pendulum clock made about 1925 required that uniform equinoctial time be introduced.

Uniform equinoctial time is defined as the hour angle of the mean equinox, that is, of the equinox freed of nutation. A mean equinoctial day is the interval between successive transits of the mean equinox.

The difference between apparent and mean sidereal time is called the nutation in right ascension, or the equation of the equinoxes. It varies from 0 to a little more than 1 sec.

C. The Relation Between Solar and Sidereal Time.— Mean solar time is dehned as 12 hours plus the hour angle of the fictitious mean sun. The latter is a point moving uniformly in the celestial equator with the mean speed of the apparent sun. In practice the right ascension of the fictitious mean sun is obtained from a formula, and the operational procedure is such as to keep mean solar time rigorously proportional to the speed of rotation of the earth.

Mean equinoctial time is also proportional to the speed of rotation of the earth, so that mean solar and mean equinoctial time are two iorms of time denoted as rotational. They would be uniiorm measures of time ii the earth rotated at a constant speed.

A clock keeping mean equinoctial time gains 3 min. 56.555 sec. of mean equinoctial time on a clock keeping mean solar time in one mean solar day. This relation holds irrespective of the speed of rotation of the earth.

Apparent solar time and apparent sidereal time have two sources of nonuniformity: (1) inequalities arising from the motion of the earth about the sun and from the motion of the equinox; and (2) variations in the speed of rotation of the earth. The inequalities due to (1) may be accurately calculated. To express the motion of the earth about the sun S. Nemcomb constructed a detailed mathematical development called the theory of the sun, based on the laws of celestial mechanics. A theory of the motion of the earth about its centre of mass, including precession and nutation, was developed, similarly. by E. W. Woolard. Such developments allow the inequalities due to (1) to be removed, giving mean solar and mean equinoctial time. The variations in speed of rotation of the earth include irregular changes of speed of unknown nature which cannot be determined, however, by computation. Hence, any system of time which involves the rotation of the earth cannot serve as a measure of uniform time.

D. Time Units.—A mean solar day is divided as follows:

1 mean solar day = 24 mean solar hours.
1 mean solar hour = 60 mean solar minutes.
1 mean solar minute = 60 mean solar seconds.

One mean solar day = 86,400 mean solar seconds. The other kinds of days are similarly divided, giving for example, the mean equinoctial (sidereal) second by subdivision of the mean equinoctial day.

E. Reckoning of Days and Hours.—From time to time changes were made in the notations concerning the reckoning of time. Definitions given below were in use in 1956.

Local mean time is the hour angle of the mean sun increased by 12 hours. Local mean time at Greenwich is called Greenwich Mean Time (G.M.T.) or universal time (U.T.). The designation G.M.T. is used in navigation. U.T. is the term used by astronomers. Standard time (zone time) differs irom U.T. by an integral number of hours.

The day begins at midnight and runs through 24 hours. In the 24-hour system of reckoning, used in Europe anti by military agencies of the United States, the hours and minutes are given as a four digit number. Thus 0028 means 28 minutes past midnight. and 1240 means 40 minutes past noon. Also, 2400 of May 15 is the same as 0000 of May 16. This system allows no uncertainty as to the epoch designated.

In the 12-hour system there are two sets of 12 hours; those from midnight to noon are designated A.M. (ante meridiem, beiore noon) and those from noon to midnight are designated P.M. (post meridiem, after noon). Neither A.M. nor P.M. may be used to designate either noon or midnight without ambiguity. To desinnate noon the word noon or 1200 should be used. To designate midnight without ambiguity the two dates between which it falls should be given unless the 24 hour notation is used. Thus, we may write midnight, May 15–16, or 0000 May 16.

Formerly, astronomers used a day which began at noon. Since 1925, however, the day used by astronomers commences at midnight, as does the day in civil use. It would be inconvenient to use local time strictly, ior no two places in different longitudes have the same mean solar time. The variation amounts to one hour for 15° of longitude, or about five sec. to the mile in middle latitudes. A system of zones was devised whereby within each zone the same mean time rules. but changes abruptly by one whole hour at its borders. Mean solar time, so regulated, is called zone time or standard time. (Srr TIME, STANDARD.)

Another convention regulates the date line, in travelling across which a calendar day is added to the reckoning in passing westward, or is dropped in passing eastward. (Src DATE LINE.)

During World War I clocks were advanced by one hour in summer in various countries in order to save fuel by reducing the need for artificial light. The advanced time is known as summer time in England and as daylight-saving time in the United States. Advanced time is adopted each year by many European countries. In the United States adoption is by local authorities, and coniusion often results because such adoption is not uniiorm.

During World War II England used "double-summer time" for part of the year, whereby the clock was advanced two hours ahead of standard time.

F. Practical Determination of Rotational Time.—The determination of time has become a highly specialized branch of astronomy which is usually carried out by a governmental observatory in each country. The basic definitions concerning time determination are standardized by the International Astronomical union (I.A.U.). Under the auspices of the I.A.U., the Bureau International de l'Heure (International Time bureau) at Paris makes comparisons of the various time determinations and serves to co-ordinate them.

The steps involved in the determination of universal time (U.T.) are as follows: (1) the transit of a star of known position is observed to determine local mean equinoctial (sidereal) time (L.S.T.); (2) the position of the mean sun is computed by means of a formula and L.S.T. is then converted into local mean time (L.M.T.); (3) the difference in longitude is added to convert L.M.T. into U.T.

Transit Instrument.—The apparatus required for time determination consists basically of a telescope and a clock. Specialized equipment of the highest precision is used. The telescope most commonly used is a transit instrument, which is constrained to move in the plane of the meridian. This is a small form of the transit circle. (*See* TRANSIT CIRCLE.) The reading of a clock being checked is recorded on a chronograph at the instant of transit as noted by the observer.

Transit circles which observe both the sun and the stars can, with the aid of a clock, determine the fundamental positions of the stars. Positions so obtained after many years of observation are used to form a fundamental catalogue. These positions are the ones used in time determination with transit instruments. The catalogue in use at mid-20th century was that of A. Kopff, designated FK3.

The positions in FK3 are for the standard epoch 1950.0. To obtain the apparent position at the moment of transit, corrections are made for proper motion, precession, nutation, aberration and, if sensible, parallax.

Let the clock used indicate, approximately, mean solar time. Observation of the transit of a star determines the mean solar time (except for the error of observation). The difference, computed time of transit minus reading of clock at transit, is called the correction to the clock. It is the quantity which is to be added to the reading of the clock in order to obtain the correct time as determined by observation. In practice the correction is obtained from the mean of observations of about 4 to 20 stars for a night.

A correction is obtained on each clear night, and a series of corrections establishes the rate of the clock. The word rate is customarily used to indicate the departure from the rate it is nominally keeping. Thus a clock which beats 86,401 sec. in a day is said to have a gaining rate of 1 sec. per day.

Knowing the correction to the clock for some epoch and its rate, the correction for any epoch may be computed and applied to the clock reading. In this manner a clock bridges the interval between observations and makes time continuously available.

Photographic Zenith Tube.—An instrument more accurate than the transit instrument for time determination is the photographic zenith tube (PZT), which was used for this purpose since 1934 at the U.S. Naval observatory. The PZT is fixed in a vertical position, and only stars which transit near the zenith are observed. A basin of mercury reflects the rays of light from the stars as the rays pass through the lens and defines the zenith, which lies in the meridian.

The plate is held by a carriage which is driven by a motor so as to track the star being observed. Four exposures of 20 sec. each are made of each star, and the lens and plate are rotated 180° as a unit between exposures. The motion of the carriage during the exposures initiates timing impulses which are read on the clock being compared with the stars. Through measurement of the positions of the star images it is possible to determine what the clock read when the star crossed the meridian. A comparison with the predicted time gives the correction to the clock.

The PZT was designed by F. E. Ross for the determination of the variation of latitude. Ross followed the design of Sir George Airy's reflex zenith tube, installed at Greenwich, Eng., in 1851. Ross improved on this obsolete instrument by placing what is known as the second nodal point outside of the lens and by making the instrument photographic. The photographic plate, which is small, is placed just beneath the lens at the nodal point. The position of the image of a star on the plate thus becomes insensitive to tilt of the lens, which is the essential feature of the design of the PZT by Ross.

This PZT, designated no. 1, was installed at Washington, D.C., in 1915 for the determination of the variation of latitude. It was adapted for the determination of time also in 1934 by F. B. Littell and J. E. Willis. A PZT of improved design was placed in operation in 1949 at a substation of the Naval observatory at Richmond, Fla. A similar PZT was installed at Washington in 1954 to replace PZT no. 1. By the latter 1950s a number of other observatories had placed or were placing PZTs in operation. These included Ottawa in Canada; Greenwich (at Herstmonceux) in England; Hamburg in Germany; Tokyo and Mizusawa in Japan; and Canberra in Australia.

Impersonal Astrolabe.—A. Danjon, of the Paris observatory, devised an accurate instrument for time determination which is quite different from those described. (The use of the word astrolabe in this connection should not be confused with the designation for the astrolabe of the days before the telescope.)

The astrolabe makes use of a reflecting basin of mercury and a 60°-prism to form direct and reflected images of a star. When the altitude of a star is exactly 60° the images coincide. In earlier forms of the instrument it was difficult to determine when coincidence occurred. Danjon introduced a Wollaston prism to obtain four images, two of which are suppressed. The observer manipulates a motor so as to keep the remaining images parallel to a spider thread, and the instant when the altitude is 60° is automatically recorded on a chronograph. Observations are made in various azimuths and both time and latitude are obtained.

G. Practical Determination of Time Intervals.—Artificial clocks used to measure elapsed intervals of time include:

Pendulum Clocks. Galilei Galileo discovered about 1581 that the time of swing of a pendulum was nearly independent of the amplitude of swing. Christiaan Huygens, in 1656, made a practical pendulum clock by adding an escapement (the counting element) to the pendulum (the frequency element). Numerous improvements were subsequently made, and pendulum clocks reached a high stage of precision in the years from 1900 to 1925. The most precise of these are the Riefler (German), the Leroy (French), and the Shortt (English). The last of these is noteworthy in that it forced the introduction of mean equinoctial time. The rate is constant to about 0.002 sec. per day. (*See* CLOCKS.)

Quartz-Crystal Clocks.—A quartz crystal if deformed, produces a difference in electric potential across certain of its faces. Conversely, a difference in electric potential produced across certain faces of a quartz crystal causes it to become deformed. This property, known as the piezo-electric effect, enables the quartz crystal to be incorporated in an electronic oscillator. The frequency of oscillation is controlled by the frequency of mechanical vibration of the crystal. (In physics, frequency is the number of occurrences per unit of time of a repetitive phenomenon. Frequency f and period p, of a cyclic occurrence are related by the expression $f = 1/p$.) The frequency of vibration is dependent on temperature, so that the crystal of the oscillator of a clock is kept at a constant temperature in a small oven.

The output of the oscillator, commonly 100,000 cycles per second, is reduced by a factor of 100 with a frequency divider. The resulting current of 1,000 cycles per second is used to drive a synchronous motor which in turn drives a seconds contact wheel and hands of a clock.

The frequency of an oscillator is often expressed as a deviation from some nominal value. Thus, if a quartz clock is gaining one sec. per day the frequency of the oscillator is said to be $1/86{,}400 = 1.157 \times 10^{-5}$ higher than nominal. The deviation is a ratio.

Quartz crystals tend to drift higher in frequency, that is, to vibrate more rapidly with age. This phenomenon, called aging, prevents the use of quartz crystals as absolute standards of frequency. For use in timekeeping it is necessary to determine for each crystal clock, from an extended series of observations, its law of drift and, for some epoch, the rate and correction of the clock.

Quartz-crystal clocks have been brought to a high stage of reliability and precision. Through their use it was possible to determine accurately the variations in speed of rotation of the earth of periods of a year or less. The day-to-day variation in frequency of the best crystal oscillators is about 2 parts in 10^{10}, which corresponds to 0.00002 sec. per day.

The use of quartz as a frequency control was described by W. G. Cady in 1922. In 1928 W. A. Morrison and J. W. Horton built the first quartz-crystal clock at the Bell Telephone laboratories. P. Sollenberger introduced a crystal-controlled clock for the automatic transmission of time signals at the U.S. Naval observatory in 1934. About 1942 timekeeping at the Greenwich observatory and at the Naval observatory was based on a combination of Shortt clocks and quartz clocks. A few years later the quartz clocks came into sole use at these observatories.

Two types of high precision crystals used at mid-20th century were the ring-crystal developed by L. Essen in 1938 at the National Physical laboratory (N.P.L.), Teddington, Eng., and the GT-plate developed by W. P. Mason in 1940 at the Bell Telephone laboratories. These are frequently used in a circuit designed by L. A. Meacham which uses a bridge to stabilize the amplitude of oscillation.

The Radio laboratories of the British post office supplied a number of ring-crystal oscillators to the Greenwich observatory, the U.S. Naval observatory, the Dominion observatory at Ottawa, and to other observatories. The U.S. national bureau of standards uses specially selected GT-crystals operated as resonators to obtain high precision.

By means of electronic devices known as oscilloscopes, decimal counters and beat counters, it is possible to compare quartz clocks with very high precision, about one part in 10^{12} in frequency and about one microsecond in time.

H. Variations in Rotation of the Earth.—The types of rotational time discussed above are nonuniform because of variations in the speed of rotation of the earth. These variations are of three types: (1) irregular; (2) seasonal; and (3) secular.

The irregular changes are of the order of 5×10^{-8}, or about 1.5 sec. per year. Because of these the earth, considered as a clock, wandered from the reading of a perfect clock by as much as 30 sec. during the past few centuries. This irregularity was detected through a study of the motions of the moon and planets.

About 1900 Simon Newcomb found that during the preceding two centuries the moon was sometimes ahead of its computed position and sometimes behind He suspected that this might be due to an error in the clock (the earth) instead of the lunar tables, but was not able to decide the matter Later studies by E W Brown in 1926 and W de Sitter in 1927, utilizing both the moon and planets, indicated that the rotation of the earth was not uniform Sir Harold Spencer Jones definitely proved that the rotation was nonuniform He showed that discrepancies in the orbital motions of the earth, Venus and Mercury corresponded to those shown by the moon, the apparent errors in position at any time were proportional to the mean motions.

It was formerly believed that the changes in speed occurred suddenly. About 1950, however, it began to he thought that the changes are the result of small random changes which gradually build up, and that large sudden changes do not occur

The seasonal variation in the speed of rotation consists of periodic terms whose periods are a year or less Such terms, annual and semiannual, were reliably ohtained by N Stoyko in 1937 at the Bureau de l'Heure. The total effect was such as to place the earth, as a clock, ahead or behind a perfect clock by about 0 060 sec. during the course of the year

Stoqko made use of a combination of pendulum and crystal clocks. His results were confirmed in 1949 by H Finch at Greenwich, who used only the precise crystal clocks available there, and by others For the year 1950, however, H M Smith at Greenwich ohtained an amplitude of 0 033 sec., and in succeeding years even less This led to questions as to the nature and stability of the seasonal term

A homogeneous solution made at the Naval ohservatory for the three years 1951 to 1954 showed that the seasonal variation was uniform for the years concerned; the amplitude was about 0.030 sec These results were based on observations made with the Washington and Richmond PZTs and two quartz resonators of the National Bureau of Standards Solutions made at other observatories for these years generally gave similar results.

Y. Mintz and W. Munk have calculated the effects of winds on the speed of rotation of the earth. There is a reasonable accordance of their results with astronomical observations for the annual term.

A study of records of ancient eclipses indicates a very gradual, secular diminution in the speed of rotation of the earth. This is accounted for by the effect of tidal friction acting in shallow seas. It was pointed out that the sun may act through atmospheric tides to increase the speed of rotation so as to offset tidal friction. It appears probable, however, that a secular decrease in speed is taking place.

I. Corrected Universal Time (UT2).—During the course of a year or so universal time is nonuniform because of the following effects: (1) polar motion; (2) annual and semiannual terms in speed of rotation of the earth; and (3) direct and indirect lunar terms. The International Astronomical union decided that as of Jan. 1, 1956, universal time would be computed so as to include corrections for (1) and (2); (3) is too small to he of effect. The time so computed is denoted UT2; it is relatively uniform time.

The complete notation adopted is as follows:

UT0 is classical universal time.
UT1 is UT0 corrected for (1).
UT2 is UT0 corrected for (1) and (2).

UT2 is the time given by radio time signals UT0 and UT1, used in precise surveying, differ from UT2 by less than 0 1 sec Corrections are furnished to make it possible to convert from one system to another.

Although the seasonal terms are not strictly repetitive and are largely empirical it was decided that a correction for these terms could be employed advantageously.

The polar-motion term arises from the motion of the pole of rotation in an approximate circle of about 30 ft. in radius (*see* GEODESY: VARIATION OF LATITUDE). The motion of the pole causes not only the latitude of an observatory but also its longitude to vary in a period of 14 months. The instantaneous value of the longitude must be added to the observed local mean time to obtain U.T. if U.T. is to be the same for all observatories. Formerly the polar motion was obtained much in arrears, but a Rapid Latitude service was established by the International Astronomical union in 1955 for the needs of time determination.

The Bureau de l'Heure computes and distributes the corrections ior variation of longitude, which differ for each observatory, and the correction for seasonal variation, which is alike for all observatories.

The moon affects the time determined in two ways, directly by altering the direction of the vertical and indirectly by tidal action on the earth's crust. A change in the form of the earth alters its moment of inertia and hence its speed of rotation. The period of the direct term is 0.5 day. There are two tidal terms of short periods, 13.6 days and 27.6 days. The amplitudes of all three terms are each about 0.001 sec. in time, and all three were detected with the PZTs of the Naval observatorq.

J. Dissemination of Time Signals.— Accurate time is needed in surveying and navigation, for the determination of longitude, and for other technical and scientific purposes. These needs are met by the transmission of time signals by radio stations, such as GBR and MSF in England and NSS and WWV in the United States. Corrections to the signals are issued periodically for use where great accuracy is required. Time signals direct from the Royal Greenwich observatory, are broadcast in England by the British Broadcasting company, and in the United States some commercial stations rebroadcast signals from NSS or WWV. In many cities of the world time may he ohtained automatically by telephone. The telegraph is used to distribute U.S. Naval observatory time to subscribers to this service.

II. UNIFORM TIME

A. Ephemeris Time.— The variations in the speed of rotation of the earth make universal time unsuitable for precise scientific purposes, so that ephemeris time (E.T.), which is uniform, was devised. It is defined in terms of the orbital motion of the earth about the sun, but is obtained in practice from the orbital motion of the moon about the earth. The moon can be used because the ratio of the periods of revolution of the sun and moon are known accurately. The moon is preferred because of its rapid angular motion.

An observation of the moon gives its apparent co-ordinates for an epoch recorded in universal time. The observed geocentric co-ordinates are obtained by corsecting for parallax. The computed geocentric co-ordinates of the moon are tabulated as a function of ephemeris time in the *Improved* Lunar *Ephemeris*. The Ephemeris is entered with the observed co-ordinates and the corresponding ephemeris time is taken out The difference between E.T. and U.T. is given by the formula $\Delta t = \text{E.T.} - \text{U.T.}$

The position of the moon was usually ohtained from observations of occultations and meridian transits. A dual-rate moon position camera developed at the U.S. Naval observatory in 1952 by W. Markowitz enables the position to be ohtained photographically. By means of a dark glass filter which tilts, the moon is held fixed relative to the stars in the background during a simultaneous exposure of 20 sec.

As long as the necessity for uniform time was limited to astronomical research, corrections for nonuniform rotation of the earth could be made several years in arrears. Developments in the field of electronics, however, required that uniiorm time should be immediately available, and formal action on the adoption of ephemeris time became necessary. The matter was considered or acted upon by the Conference on the Fundamental Constants of Astronomy, Paris, 1950; the International Astronomical union, Rome, 1952; and the Tenth General Conference on Weights and Measures, Paris: 1954.

B. The Second.— Until 1955 the fundamental unit of time was the second of mean solar time, defined as 1/86,400 of the mean solar day. Because of variations in the speed of rotation of the earth the second of mean solar time is not a constant unit of time. A redefinition of the second as 1/31,556,925.9747 of the tropical year for 1900 January 0 at 12 hrs. E.T. was adopted by the International Astronomical union in 1955, at Dublin, and by the International Committee on Weights and Measures in 1956, at Paris. This second is a fixed unit of time: and is identical with the second of ephemeris time. Technically, the use of the word second without a qualifying adjective is reserved for the ephemeris second.

The second of mean solar time may differ from the second of ephemeris time by nearly 1 part in 10^7. This difference is important in many scientific applications hut no account of it need be taken for ordinary purposes.

C. Atomic Frequency Standards.— The possibility of using the frequency of a spectral line to control a clock the rate of which would he absolutely constant was long considered. The frequencies corresponding to wave lengths of visible radiation (about 5×10^{-5} cm.) are too high to be generated electronically, being about 10^{15} cycles per second. The development, however, of methods of generating frequencies of the order of 10^{10} cycles per second opened up the possibility of utilizing spectral lines in the one-centimetre microwave region for frequency standardization.

R. V. Pound outlined in 1946 the use of spectral lines to stabilize an oscillator, and in 1947 W. V. Smith and co-workers confirmed the method of Pound by constructing an oscillator which was stabilized in frequency with the 3,3 inversion line of ammonia (NH_3). W. D. Hershherger and L. E. Norton stabilized a klystron oscillator with ammonia in 1948 H. Lyons and co-workers used an ammonia-controlled oscillator in 1949 to control a clock for brief periods.

In the preceding applications ammonia is used in absorption. Radio frequency (rf) energy is introduced into a cell containing ammonia and some of the energy is absorbed if the rf field matches the frequency at which the ammonia inversion occurs. The absorption of energy can be observed with a suitable detector.

A spectral line has a finite width so that transitions occur over a range of frequencies. Various techniques are employed to narrow the range, hut in the case of ammonia in absorption basic difficulties appeared to limit the degree to which this can be done.

C. H. Townes developed in 1951 a microwave amplifier called MASER which is stabilized in frequency by ammonia in emission. An intercomparison of two MASERs indicated a high degree of stability, but as of 1956 the MASER was not yet compared for stability with other standards of frequency although a number of MASERs were under construction and study.

Atomic frequency standards in 1956 were based on the transition of caesium designated $F\,m\ (4,0)\leftrightarrow(3,0)$. They employ an atomic beam technique developed by I. I. Rabi and co-workers in 1939. Caesium atoms emitted by an oven are subjected to an rf field. If the field is of the proper frequency a transition occurs which changes the magnetic properties of the atoms. Through use of magnets to deflect the atoms, and a hot-wire ionizer as a target, it is possible to determine when the rf field is at the proper frequency. A method, developed by N. F. Ramsey, of exciting the atoms with the rf field provides a spectral line with a sharp central peak. Early experiments with a caesium beam were made by H. Lyons and co-workers in 1952.

Many difficulties stood in the way of producing a practical atomic standard that would give measurable frequency with high precision. The production of a standard of this type was first accomplished by L. Essen and J. V. L. Parry in June 1955 at the National Physical laboratory. This standard, which employs caesium appears to be stable to about 1 part in 10^{10}. In co-operation with J. R. Zacharias, the National Company, Malden, Mass., placed in operation several caesium standards in Sept. 1956 in the United States.

The caesium standards described were operated as frequency standards and not as clocks. An atomic clock, however, may be obtained in effect by use of a quartz-crystal clock of high precision. The frequency of the crystal is regulated (about once a day) so that its frequency with respect to the caesium standard remains constant. The crystal clock will thus provide atomic time.

For additional information on atomic transitions *see* QUANTUM MECHANICS. Approximate values of frequencies utilized in atomic standards in 1956 were 23,870,130,000 cycles per second for ammonia and 9,192,631,800 for caesium.

D. Gravitational Time and Atomic Time.—The measure of uniform astronomical time is based on the motions of celestial bodies subject to the force of gravitation. The measure of uniform atomic time is based on the motions of atoms (or atomic particles) subject to electric and nuclear forces. The possibility exists that these two measures of time are different; they may be diverging.

'The nature of the possible difference may be understood from a description of the procedure used to test for its existence. By the latter 1950s the frequency of the caesium standard was being determined with respect to the second of ephemeris time, and a value accurate to about 1 part in 10^9 was expected to be available by 1960. A second determination made about 10 years later will give another value of the frequency. If the difference in the two values of the frequency is greater than can be accounted for by errors of observation then the gravitational and atomic time scales are diverging.

In addition to examining the relation between gravitational and atomic time scales the relation between various kinds of atomic time will also be examined. Thus, experiments will be made, for example, to determine if the frequency of ammonia with respect to caesium changes in the course of years.

E. Uses of Time Systems.—The construction of the atomic standard means that there is a choice of reckoning time on either an astronomical or an atomic basis. Astronomical time is closely related to civil affairs; it is based on units in common use such as the day and year. Atomic time provides the unit of time with high precision, but does not mark an epoch as does astronomical time. In the latter 1950s it appeared that physical measurements involving the unit of time with high precision would be referred to atomic time, but universal time (or standard time) would continue in common use.

TIMGAD, a ruined city 23 mi. S.E. of Batna in the department of Constantine. Alg. Timgad, the Thamugas of the Romans, was built on the lower slopes of the northern side of the Aures Mountains, and was situated at the intersection of six roads. It was traversed by two main streets, the Cardo Maximus running north and south, and the Decumanus biaximus east and west. The residential part of the town was on a lower level than the capitol and most of the other public buildings. The ruins of the capitol occupy a prominent position in the southwest of the city. Some of the columns of the façade (which are of the Corinthian order and 45 ft. high) have been re-erected. The dimensions of the capitol correspond with those of the Pantheon at Rome. Immediately north of the capitol are the remains of a large market; to the east are the ruins of the forum, basilica and theatre. The auditorium of the theatre, which held nearly 4.000 persons, is complete. A little west of the theatre are baths, containing paved and mosaic floors in perfect preservation. Ruins of other and larger thermae are found in all four quarters of the city, those on the north being very extensive.

Across the Decumanus Maximus just northeast of the market is the arch of Trajan— still erect, and restored in 1900. The arch is of the Corinthian order, and has three openings, the central one being 11 ft. wide. Each façade has four fluted columns 19 ft. high. The chief material used in building the arch was sandstone. The fluted columns are of fine white limestone and smaller columns are of coloured marble. At the other (eastern) end of the street are the remains of another triumphal arch. West of the capitol are the ruins of a large church, a square building with circular apse, built in the 7th century. There are also remains of six other churches. About 400 yd. south of the city, the walls nearly entire, is a ruined citadel, a quadrangular building 360 ft. by 295 ft.. with eight towers. It was built (or rebuilt) by the Byzantine army in the 6th century. Near the northern thermae is the house of the director of the excavations and a museum containing small objects found in the ruins.

Numerous inscriptions have been found on the ruins, and from them many events in the history of Thamugas have been learned. In the year A.D. 100 the emperor Trajan gave orders to build a city on the site of a fortified post on the road between Theveste and Lamhaesis. This city, called Colonia Marciana Traiana Thamugas (Marciana in honour of Trajan's sister) appears from the inscriptions to have been completed, as far as the principal buildings were concerned, in 17 years. In the 3rd century Thamugas became a centre of Christian activity, and in the next century espoused the cause of the Donatists. The city declined in importance after the Vandal invasion in the 5th century, and was found in a ruinous condition by the Byzantine general Solomon, who occupied it A.D. 535. It is believed that the Berbers from the neighbouring mountains destroyed the city, hoping thus to prevent it being used as a stronghold from which to harry them. Thamugas was, however, repeopled, and in the ith century was a Christian city. After the defeat of Gregorius, governor of Africa, by the Arabs in 647. Thamugas passes from history.

After centuries of neglect James Bruce, the African traveler, visited the spot (1765), made careful drawings of the monuments and deciphered some of the inscriptions. Bruce was follo ed, more than a century later (1875), by Sir R. Lambert Playfair, British consul general at Algiers, and shortly afterward (1875–76) Masqueray published a report on the state of the ruins. Since 1881 Thamugas has been systematically explored, and the ruins excavated under the direction of the *Service des monuments historiques.*

Among the objects discovered are a series of standard measures —five cavities in a stone slab. Seventeen miles west of Timgad, on the site of the Roman city Lambaesis, is Lambessa (*q.v.*).

TIMISKAMING: *see* PRE-CAMBRIAN TIME.

TIMIŞOARA (formerly TEMESVAR), a city of western Rumania, in the region of the same name. Pop (1956) 142,257. On the Bega canal and the Bega river. it consists of the inner town, formerly strongly fortified, and of four outlying suburbs, the intervening space, formerly the glacis, having been laid out in park areas.

Timisoara is the seat of a Roman Catholic and a Greek Orthodox bishop. Among its principal buildings are the Roman Catholic cathedral, built (1735–57) by Maria Theresa, the Greek Orthodox cathedral; a castle built by John Hunyady in 1442, now used as an arsenal; the town and county hall, the museum and large barracks. In the principal square rises a Gothic column, 60 ft. high, erected by the emperor Francis Joseph in 1851 to commemorate the successful resistance of the town to the siege of 107 days laid by the Hungarian revolutionary army in 1849. Timisoara is a centre of commerce.

Timisoara is an old town, and although destroyed by the Tatars in 1242, it was a populous place at the beginning of the 14th century, and was strongly fortified by King Charles Robert of Anjou, who resided there several years The Hunyady family had also their residence there In 1514 the peasant leader. Gyorgy Dozsa, was defeated by the Transylvanian voivod, John Zápolya, near Timisoara, captured and executed. It was taken by the Turks in 1552, and recovered by Prince Eugene of Savoy in 1716.

After this it grew steadily in importance, serving as the capital of the whole Banat. It was again besieged by the Hungarians in 1849, and occupied by Serbia in 1919, but ultimately allotted to Rumania.

TIMKEN, HENRY (1831–1909), U.S. manufacturer and inventor, was born near Bremen, Ger., Aug. 16, 1831. He accompanied his family to the United States in 1838 and worked during his boyhood on his father's farm near Sedalia, Mo. At the age of 16 he went to St. Louis and apprenticed himself to a wagonmaker. In 1855 he established his own carriage factory in St. Louis, giving it up in 1860 to prospect for gold in Colorado. During the Civil War he served for three years as a captain in the 13th regiment of the Missouri militia. Returning to his business after the war, he invented a new type of carriage spring and patented it in 1877. It proved so successful that his carriage factory became primarily a spring-manufacturing plant. Timken retired in 1887 and went to California but returned to active business in St. Louis six years later. In 1898 he patented a tapered roller bearing that had even greater success than his Timken spring. He founded the Timken Roller Bearing Co. at Canton, O., to produce it.

He retired from business soon afterward and died at San Diego, Calif., March 16, 1909.

TIMMERMANS, FELIX (1886–1947), Flemish writer, an outstanding representative of regional literature, was born at Lier, July 5, 1886. He made his name with the novel Pallieter (1916; Eng. trans. 1924), an "ode to life" written after a moral and physical crisis. To express his praise of life, Timmermans depicted his native Brabant as a paradise and created a character, Pallieter, who has taken his place in literature as the embodiment of a typically Flemish enjoyment of living: at once sensual and mystical, because for him the world's joys are the gift of God. Timmermans was also a painter and illustrator, and found inspiration in old prints and the paintings of Brueghel. For his characters he drew on the people of his native town. His kindly, humorous style, succulent language, wealth of anecdote, sympathetically caricatured characters and pictorial skill hide his lack of depth. As well as many novels and short stories, he wrote romanticized biographies of Brueghel (1928), St. Francis (1932) and Adriaen Brouwer (1948), travel tales, autobiographical works and plays.

In 1935 he reached new heights with *Boerenpsalm,* a song of praise showing keen insight into life and a new lyrical strength. The lighthearted sensuality of Pallieter is modified by a deeper knowledge of suffering, and praise of nature gives way to praise of humanity represented by the peasant, Wortel, who feels that his life is in God's hands.

Warm colouring is the outstanding characteristic of Timmermans' manner. His expressive style is rooted in the language of the people and excels in the spontaneity and variety of its imagery. It is suited both to the treatment of sensual and spiritual subtleties and to the revelation of Timmermans' exuberant yet melancholy temperament. Another aspect of his art is shown in some prose works of great restraint (De *zeer schone uren* van *juffrouw Symforosa, begijntjen* [1918]; *Ik* zag Cecilia komen, [1938]) and in the few serene poems (Adagio, 1947) written shortly before his death at Lier, Jan. 24, 1947.

TIMMINS, the principal town in the Porcupine gold mining area of northern Ontario, Can., is 268 mi. N. of North bay on the Mattagami river and the Ontario Northland railway. It was founded in 1911 by Noah Timmins to house employees of the Hollinger mine, but is not a company town. The town is laid out in grid fashion on sandy terraces overlooking the Mattagami river and prides itself on being the largest town in Canada—the population. 27,551 (1956), is larger than that of many Canadian cities.

The Hollinger Consolidated Gold Mines, Ltd. became the largest producer of gold in Canada. Mine shafts extend to depths of over 5,000 ft. and there are many miles of underground workings. By the 1950s about 1,000,000 tons of ore were mined each year, and the total annual gold production in the area amounted to about 1,000,000 oz., or one-quarter of Canada's total gold production. Hydroelectric plants at Wawaitin falls and Sandy falls furnish energy for the town and for the mines. Power is also brought from the Abitibi river. (F. A. CK.)

TIMOLEON (c. 411–c. 337 B.C.), of Corinth, Greek statesman and general. As the champion of Greece against Carthage he is closely connected with the history of Sicily, especially Syracuse (*q.v.*). He was driven into exile for 20 years by the anger of his family at his acquiescence in the death of his brother Timophanes, who had made himself tyrant. In 344 (Plutarch, Diodorus gives 343–342) he was chosen to go to Syracuse in answer to an appeal to Corinth for help against factions within and the Carthaginians without. He landed at Tauromenium (Taormina) and first attacked Hicetas, tyrant of Leontini, who was master of Syracuse at the time. Carthage first supported Hicetas, then abandoned him, and he was besieged in Leontini and surrendered. Timoleon then reorganized Syracuse on the basis of the constitution of Diocles, and introduced new settlers from Greece. About 340 Hicetas was reinforced by a new army from Carthage, which Timoleon defeated on the Crimissus, and a renewed attempt ended in Hicetas' final defeat and death in 338. A treaty was concluded confirming the dominion of Carthage to west of the Halycus. Timoleon then (337–336) retired into private life. He became blind some time before his death, but persisted in attending the assembly and giving his opinion, which was usually accepted as a unanimous vote. He was buried at the cost of the citizens of Syracuse, who erected a monument to his memory in their market place, and a gymnasium called Timoleonteum.

Lives by Plutarch and Cornelius Nepos; *see* also Diod. Sic., vol. xvi, pp. 65–90; monograph by J. F. Arnoldt (1850), which contains an exhaustive examination of the authorities; also SICILY: *History;* and SYRACUSE, with works quoted.

TIMON, of Athens, the noted misanthrope, celebrated in Shakespeare's play, lived during the Peloponnesian War. He is more than once alluded to by Aristophanes and other comedians. Plutarch introduces a short account of his life in his biography of Mark Antony (ch. 70), who built a retreat called Timonium (Strabo xvii, 794) at Alexandria. Timon also gave his name to one of Lucian's dialogues.

TIMON (c. 320–*c.* 230 B.C.), of Phlius in the northeastern Peloponnese, Greek skeptic philosopher and man of letters, was a pupil of Stilpo the Megarian and Pyrrho of Elis. Having made a fortune by lecturing (particularly in Chalcedon), he retired to Athens c. 275, where he died. Only fragments remain of his works, which included not only 20.000 lines of prose but also numerous tragedies, satyr-plays and comedies, poems in elegiacs and iambics and three books of silloi, or sarcastic attacks on dogmatic philosophers in mock-heroic hexameters.

For the fragments *see* F. W. *A.* Mullach (ed.), *Fragmenta philosophorum Graecorum,* vol. i (1860); and H. Diels (ed.), *Poetarum philosophorum fragmenta* (1901). *See* further W. Nestle, "Timon," Pauly-Wissowa, *Realencyclopadie,* 2nd series, Halbband 12 (1937).

TIMOR, the largest of the Nusa Tenggara Islands in the Malay archipelago, is divided from the main group by the Savu sea and Ombai strait and from Australia by the Timor sea. It is 294 mi. long and has a maximum width of 66 mi., extending from lat. 8° 19' to 10° 27′ S. and from long. 123" 27' to 127° 18' E. The northeastern part, with a small enclave (Oe-Cusse or Ocussi-Ambeno) on the northwestern coast is Portuguese (area 7,332 sq.mi.) while the southwestern section (formerly Dutch or Netherlands Timor) is part of Indonesia. Portuguese Timor had a population of 442,378 in 1950 (including only 568 Europeans); that of Indonesian Timor (1956 est.) 822,915. The adjacent islands of Roti and Savu, with west Timor part of the Indonesian Nusa Tenggara province, are considered here (see The People below).

Timor is on the outermost and apparently the first formed of the arcuate folds characteristic of the East Indian region. The great submarine ridge of which it is the crest lies near the Sahul shelf, the submerged extension of the Australian continental mass, and is roughly parallel to it. It is close to the area where alpine fold lines meet the Pacific marginal folds and where mountain-building is more active than anywhere else. The highly contorted and metamorphosed sediments, ranging in age from Palaeozoic to Mesozoic. show the intensity of these movements. The great volcanic activity in the islands to the north of Timor show that they are not yet over. In Timor there are no volcanic deposits later than Tertiary, but the presence of raised coral reefs of Pleistocene age at heights up to 4,500 ft. as well as many raised beaches at lower levels show how rapid and how extensive have been the changes of level on the island.

Timor is generally mountainous but cut by deep valleys. The highest points are. in Portuguese Timor, Tata Mailau (Mt. Romelau, 9,771 ft.) and, in Indonesian Timor, Mutis (7.759 ft.). both on the main central divide. A coastal range behind Dili (Dilli) reaches 4.650 ft. and there are extensive limestone plateaus behind the southern coastal plain. The climate is like that of northern Australia and different from that of Java and Sumatra in having a well-marked dry season in winter. There are wide local variations in annual rainfall from 30 in. on the north coast to 100–110 in. in the south and west.

The vegetation, too, is Australian in character with forests of *Casuarina equisetifolia* in the northern valleys and *Eucalyptus alba* on the southern coastal plains. Vegetation is scanty and scrubby generally, though the uplands yield fairly well under cultivation. The woodlands, which nonhere develop into good forests, contain much excellent sandalwood. The fauna of Timor is of special interest since it proves, conclusively. that Timor has never formed part of Australia within recent geological epochs. The deep sea channel between has proved such an obstacle that only one Australian type is found—the cuscus, a marsupial. whereas Asiatic types include the gray monkey, deer, wild pig, civet cat, shrew mouse, bat and a particular species of wildcat. found only in Timor and Roti. There is a slight preponderance of Asiatic birds over Australian. Among the insects are a few beetles. a rare rose chafer, such moths as the *Noctuae, Ophiodes, Remiga virbia,* and a humming bird moth *(Protoparce orientalis*), and many butterflies. Pieridae and Lycaenidae being common, others including the rare and beautiful swallowtails *Papilio aenomaus* and *P. liris,* and the deep purple-winged *Cethosia leschenaultiz.* The few land shells of Timor are allied to or identical with Moluccan and Celebes forms. There are snakes, and a species of crocodile. An interesting item in the fauna is the native pony, probably not however indigenous but certainly introduced before the arrival of the Portuguese.

The island has been little developed and has only one motor road in the Indonesian part. The staple crop is maize though rice is also gronn, sometimes on terraces. A little coffee, copra and rubber are produced for export and some sandalwood is also shipped. The presence of oil deposits has been known for many years and trial borings before World War II showed they had commercial possibilities.

Kupang (pop. 14.892) the main port of the island and the capital of Indonesian Timor stands on a bay at its western extremity. Dili (3,321) on the northern coast is the capital of Portuguese Timor. (T. Her.)

Beside the northeastern part of the island and Oe-Cusse-Ambeno, Portuguese Timor also includes the smaller islands of Atauro (Cambing) and Jaco. Until 1864 Portuguese Timor was administered from Portuguese India, from then to 1926 it was subordinated to Macao in China. It became successively a separate colony and (1951) an overseas province. In Feb. 1942 the island of Timor was occupied by the Japanese; it was liberated in 1946. Until about 1934 the administration was military, but by the mid-1950s many of the officials were graduates of the Escola Superior Colonial of the Technical university of Lisbon.

In addition to the municipality of Dili, there are five *circunscrições* (districts) with capitals at Lautem (Vila Nova de Malaca), Baucau (Vila Salazar), Manatuto, Aileu (Vila General Carmona) and Bobonaro. These are further subdivided into posts. Imports include cottons, wine and general merchandise. There are a few minerals. (H. V. L.)

History.—It was probably about 1520 when the Portuguese first began trading to Timor, principally for sandalwood. Missionaries soon came with the traders, but for many years the Portuguese based themselves on the island of Solor (100 mi. to the north) where a fort was built in 1566. At the beginning of the 17th century the Dutch appeared in the East Indies, capturing Solor in 1613 and landing on Timor shortly afterward. They established themselves at Kupang, and the Portuguese had to retire to the north and east of the island, with their capital at Dili.

In 1662 a treaty put an end to the long war between Dutch and Portuguese, but conditions in Timor remained far from settled. For over a century there was intermittent fighting between the Dutch. the white Portuguese, the "black" Portuguese of mixed race and the native Timorese, especially in 1749 when a combination of enemies attacked Kupang. but the Dutch succeeded in relieving the garrison and the Portuguese were almost annihilated. When the Netherlands passed under French domination in the revolutionary wars, the Dutch in Timor also beat off two British attacks made in the name of the exiled prince of Orange, but after the fall of Java they succumbed. Before Dutch Timor was handed back by the convention of 1814 the Portuguese seized the district of Atapupu, but were driven out again by the Dutch, and this led to many incidents and frontier disputes.

During the 19th century the problem of defining frontiers proved to be difficult, being complicated by claims for enclaves and by dissensions among the native chiefs concerned. who forcibly prevented the survey of territories in dispute between themselves. Attempts in 1851, 1859 and 1893 all failed to produce a final solution, and though a treaty was made in 1903, ratification was postponed until the frontier of the Portuguese enclave of Oe-Cusse was surveyed. After further frontier affrays in 1913 recourse was had to arbitration, and in 1914 the Swiss plenipotentiary at Paris, M. Lardy, a member of the Hague court of arbitration. decided in favour of the Dutch view of the track of the eastern frontier of the Oe-Cusse enclave; Portugal accepted it and the treaty of 1904 was then carried into effect.

After Japan's entry into World War II Great Britain asked Antonio Salazar for permission to occupy Portuguese Timor, but the Portuguese refused and decided to take on its own defense. On Feb. 20, 1942, the Japanese landed on Dili airfield and quickly occupied the whole island. After the Japanese surrender Portuguese troops reoccupied the eastern half of the island, but Dutch Timor soon became part of the new republic of Indonesia.

(K. H. D. H.)

The People.—The population of Timor in 1956 was estimated to be nearly 1,300,000, that of Roti in 1954, 68,330 and of Savu in 1954, 78,783'. It includes few Europeans and Eurasians, or foreign Asiatics (the latter being mostly Chinese, with a small number of Arabs). The natives are of mixed origin. The basic element is Papuan, a variety of the Oceanic negroid stock. but there has been a fairly considerable Indonesian (Mongoloid) admixture. In the interior there are traces of a negrito (pygmy) strain. and along the coasts Malay influence is marked. The people of Roti and Savu are lighter complexioned and have less Papuan blood; they have interbred to some extent with the natives of west Timor (Kupang, Semau. etc.). The Timorese proper are generally dark-skinned, lightly built and tall or medium in height. There are small communities of Christian converts, Roman Catholic and Protestant in Indonesian Timor, Roman Catholic in Portuguese Timor and a few Moslems along the coast. The people of Roti and Savu are largely Christian or Moslem.

Except along the coast, the Timorese have been comparatively little touched by civilization. They lead a primitive life and war between the small native kingdoms persists. The usual dress of the men consists of two pieces of patterned cotton material, with a decorated belt, often a sort of shawl, thrown over the shoulder when not in full use, and sometimes a kind of turban headgear, and a cloth wallet is carried. Women wear a sarong, also with a shawl, and they are fond of armlets of gold and silver, necklaces of glass, quartz or clay, and gold and silver chest plaques. Chiefs have special decorative garments. Tattooing is practised. Weapons are the bow and arrow, spear, shield and sword; and the blowpipe is used for hunting. The use of the gun is known, and the men are good horsemen. The usual Timorese house is built of wood, on piles, and is round in shape, with a roof of grass or palm-leaf thatch, and only one room (except in the case of chiefs); villages and houses are sometimes stockaded. There is a special hut in ahich the leader of a successful head-hunting expedition undergoes purification. to appease the ghosts of the slain. *Pomali,* or taboo, is prevalent, and apart from the custom of placing a palm branch. as a sign of taboo, before fruit trees, houses, crops. etc.. to protect them — villages have a regular *pomali* house, or *uma-luli.* It stands in a cleared space, within which not a stone may be overturned or a twig plucked. The presiding official at *pomali* ceremonies is known as the dato *luli,* and has great power. Certain relics are preserved in the *pomali* house where offerings are made to the *vatu luli,* or sacred stone. Some houses have a *luli* chamber, where sacrifices of animals (pigs) are made and where a bunch of rice is hung — to ensure a bountiful harvest. The dead are placed on a stage raised above the ground, sometimes covered with a roof, and kept until a burial feast can be arranged. Stone carved seats for graves are known in Roti, and stone graves in parts of Timor. The cult of a sun dweller is important. Polygamy and concubinage are practised.

Industry consists of weaving, plaiting and the making of ornaments and weapons. There are fishing and copra production along the coast. Trade is mostly in Chinese, Arab and Malay (Bugis) hands.

Many languages and dialects are spoken: Roti and Savu have languages of their own. (X.; B. A. L. C.)

TIMOSHENKO, SEMEN KONSTANTINOVICH (1895–), Soviet army officer, marshal of the Soviet union, was born in Furmanka, then Bessarabia, in 1895. Conscripted into the tsarist cavalry during World War I, Timoshenko was awaiting court-martial for striking an officer when freed at the outbreak of the Revolution. He joined the Red army and, aided by Stalin's friendship, became a cavalry division commander during the Russian civil war. Timoshenko's greatest contribution to the Red army was the system of training and rigid discipline he instituted after early Soviet failures in the Russo-Finnish War of 1939–40. Credited with the ultimate victory, Timoshenko was rewarded with the post of commissar of defense, an assignment he held until succeeded by Stalin after the U.S.S.R. entered World War II. After some initial success as a commander, Timoshenko failed in an important campaign and was relegated to a staff assignment at Stalin's personal supreme headquarters. After the war he served as a military district commander, never regaining his prewar prestige. He appeared to have little voice in the formulation of soviet postwar military policy. (H. E. KH.)

TIMOSHENKO, STEPHEN PROKOPOVICH (1878–), Russian-born specialist in mechanics, a leader in strengthening the teaching of mechanics in the United States. Born in Kiev. Russia, Dec. 23, 1878, he attended the Institute of Engineers of Ways of Communication, St. Petersburg, 1896–1901, and the University of Gottingen, Ger. (diploma engineer), 1905–06. He was assistant professor at the Polytechnic institute. St. Petersburg, 1903–06; professor at the Polytechnic institute, Kiev, 1906–11; professor at the Electrotechnical and Polytechnic institutes, St. Petersburg, 1913–17; professor at the Polytechnic institute, Zagreb, Tugos., 1920–22. He then moved to the United States and worked as a research and consulting engineer at Westinghouse Electric and Manufacturing Co., Pittsburgh, 1923–27. He became a citizen of the U.S. in 1927, the same year he became professor of mechanics at the University of Michigan. He m s named professor of theoretical and applied mechanics at Stanford university. Calif., in 1936, becoming emeritus in 1944. He wrote many papers on mechanics and leading U.S. texts on strength of materials and elasticity. His Collected Papers with a biographical sketch was published in 1953. (S. C. HR.)

TIMOTHEUS, Athenian statesman and general, son of Conon, the restorer of the ualls of Athens. From 378 to 356 B.C. he frequently held command in the war between Athens (in alliance with Thebes) and Sparta. In 375 Timotheus was sent with a fleet to sail around Peloponnesus by way of demonstration against Sparta. He gained over Cephallenia, secured the friendship of the Acarnanians and Molossians and took Corcyra, but used his victory with moderation. In 373 Timotheus was appointed to the command of a fleet for the relief of Corcyra, then beleaguered by the Spartans. But his ships were not fully manned, and to recruit their strength he cruised in the Aegean. For this delay he was brought to trial but acquitted. Having been superseded in his command he took service with the king of Persia. We next hear of him about 366, when, having returned to Athens, he was sent to support Ariobarzanes, satrap of Phrygia. But, finding that the satrap was in open revolt against Persia, Timotheus, in conformity with his instructions, abstained from helping him and turned his arms against Samos, then occupied by a Persian garrison, and took it after a ten months' siege (366–365). He then took Sestus, Crithote, Torone, Potidaea, Methone, Pydna and many other cities; but two attempts upon Amphipolis failed. During Athens' war mith its allies, Timotheus was sent with Iphicrates, Menestheus and Chares to put down the revolt. The hostile fleets sighted each other in the Hellespont; but a gale was blowing, and Iphicrates and Timotheus decided not to engage. Chares, disregarding their opposition, lost many ships, and in his dispatches he complained so bitterly of his colleagues that the Athenians put them on trial. Timotheus, disliked for his arrogance, was condemned to pay a heavy fine. Being unable to pay, he withdrew to Chalcis, where he died in 354.

TIMOTHY (TIMOTHEUS), **SAINT,** in the New Testament, was one of the younger companions of the apostle St. Paul (*q.v.*). He was connected with Lystra in Lycaonia, born of a pagan father and of a Jewish mother called Eunice, his grandmother being also a Christian. When the apostle came across him at home, he was still uncircumcised, but a full member of the church at Lystra (Acts xvi, 1 ff.; II Tim. i, 5 ff.). When the defection of Barnabas and Mark left St. Paul alone, he took Timothy with him as a colleague, first of all circumcising him out of respect to the prejudices of the communities in which he was to do mission work. This was a matter of convenience, not of principle. He accompanied St. Paul and Silas to Europe, where he was employed by them on various missions, especially among the Macedonian churches which he helped to found. But Gorinth as well as Thessalonike and Philippi drew out his activities as an "apostle" in the wider sense of the term (II Cor. i, 19, etc.). From Corinth he appears to have accompanied the apostle to Ephesus and Asia Minor (Acts xix, 22; I Cor. xvi, 10 ff.). He is then associated with St. Paul in his imprisonment, as the collocation of his name in the titles of Colossians, Philemon and Philippians indicates, whether that imprisonment was at Rome or elsewhere. In the Pastoral Epistles he is absent from his chief, in charge of work at Ephesus, and there is a notice of him in Hebrews (xiii, 23) which chronicles his release from imprisonment, though there is no clue to its date or place.

Tradition, probably based on inferences from the New Testament, made him bishop of Ephesus, where it is said he was martyred under Domitian, one legend asserting that he was clubbed to death by the mob for protesting against the orgies of Artemis worship. The Greek martyrology celebrates his death on Jan. 22, the Latin on Jan. 24. (J. MOF.)

TIMOTHY (HERD'S-GRASS; *Phleum pratense*) is an important and commonly cultivated hay and perennial pasture grass, either when grown alone or in combination with red clover or other grasses. It is better, however, as hay than for pasturage. (J. M. BL.)

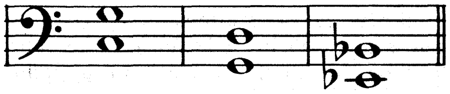
TIMOTHY, EPISTLES TO: see PASTORAL EPISTLES.

TIMPANI, the name given to the kettledrums in the orchestra (It. *timpano,* pl. timpani). Introduced in the orchestra in the second half of the 17th century, they first appear in scores of Matthew Locke (*Psyche,* 1673), Lully (*Thésée,* 1675) and Purcell (Fazry *Queen,* 1692), where they were used in pairs of one small and one large, each pair tuned to the tonic and dominant.

Each of the kettledrums consists of a bowl-shaped "shell" of copper. brass or other metal, over which is stretched a "head" of calfskin secured by a metal hoop. A hole is pierced at the bottom of the shell to avoid air concussion and the splitting of the head in *fortissimo* passages. The tension of the skin, and accordingly the pitch of the drum, is varied either by means of hand screws fixed to the shell or by a number of mechanical devices. These devices include a pedal or a hand mechanism that varies the tension of the head by means of rods connected to the hoop. The skin vibrates when struck with the drumsticks, the tone produced depending on the texture of the hard or soft felt or other substance forming the head of the stick. The tone also varies according to whether the drum is struck nearer the rim of the shell or the centre of the head. Occasionally the head is made to vibrate by means of the fingers, as in works of Constant Lambert and Benjamin Britten.

Two instruments, one tuned to the tonic and the other to the dominant, were normally used in 18th-century scores. In later scores three or more instruments were used with a variety of tunings. Sixteen kettledrums, requiring ten players, were used by Berlioz in his Requiem (1837).

The orchestral kettledrum has a practical compass of five full tones. The compass covered by a pair of timpani is normally an octave from F below middle C downward. The tuning of an orchestral set of three instruments generally covers the following ranges:



In certain cases this compass has been extended upward as far as B (in Stravinsky's *Le Sacre du printemps,* 1913) and downward to D flat (in the symphonies of Mahler).

The expressive resources of the timpani are by far the widest among percussion instruments. They include the reiteration of persistent rhythms, dramatic crescendos. sudden *sforzando* effects and atmospheric "rolls." Special effects include damped or muffled notes, as in Liszt's "Faust" Symphony, the striking of a note with two sticks, as in Alban Berg's *Wozzeck,* and a pedal glissando on a roll. used by Bartók. Occasionally muted timpani are used. as in Mahler's First Symphony, a strip of cloth being placed over the drumhead.

See also DRUM (J. BL.)

TIMROD, HENRY (1828–1867), U.S. poet. called "the laureate of the Confederacy," was born in Charleston, S C., on Dec. 8. 1828, the son of a bookbinder. He attended Franklin college (later the University of Georgia), Athens, for two years and for a short period of time read law in Charleston.

For a number of pears he worked as a tutor. and in 1860 a collection of his poems was published. During the Civil War he enlisted in the Confederate army but was soon discharged for reasons of health. Later he was an editor and part owner of the *South Carolinian* in Columbia. After the city was burned by Union forces, however, he suffered from poverty and chronic ill-health He died on Oct. 6. 1867.

In 1873 the southern poet Paul Hamilton Hayne, who was Timrod's lifelong friend, edited *The Poems of Henry Timrod.* Among Timrod's poems supporting the south were "Ode Sung at the Occasion of Decorating the Graves of the Confederate Dead." "The Cotton Boll" and "Ethnogenesis." *Katie,* a lyric poem to his wife. was published in 1884 and *Complete Poems* in 1899.

See H T. Thompson, *Henry Timrod, Laureate of the Confederacy (1928)*; G A Wauchope, *Henry Timrod: Man and Poet (1915).*

TIMUR (*Timur i Leng,* "the lame Timur"), commonly known as TAMERLANE (1336–1405). the renowned oriental conqueror, was born at Kesh (modern Shahr-i-Sabz. "the green city"), 50 mi S. of Samarkand in Transoxiana. The Timurid tradition (which is highly suspect) represents his father Taragai as head of the Barlas tribe and a descendant of a certain Karachar Noyan, described as the powerful minister of Jagatai, son of Genghis Khan, and a distant relative of the latter. The apocryphal *Memoirs* of Timur display him as a leader of expeditions during the disturbances that followed the death of Amir Kazgan, the governor of Transoxiana. in 1357. After the invasion of Tughlak Timur, the khan of Kashgar (1361), and his appointment of his son Ilyas Rhoja as governor of Transoxiana, Timur was selected as his minister, but shortly afterward he fled and rejoined his brother-in-law Amir Husain. the grandson of Razgan. After many wanderings and adventures they defeated Ilyas Khoja (1364) and set out to conquer Transoxiana. About 1370 Timur joined in a revolt against his ally Husain. besieged him in Balkh and, after his assassination, proclaimed himself sovereign of the Jagatai and restorer of the Mongol empire.

For the next ten years Timur was engaged in a struggle against the khans of Jatah (eastern Turkistan) and Khwarizm, finally occupying Kashgar in 1380. He then intervened in the conflicts between the rival princes of the Golden Horde in Russia; his protégé Toktamish defeated the ruling khan Mamai. replaced him as khan and, to avenge a defeat inflicted on Mamai by the prince of Moscow in 1380, occupied Moscow in 1382.

In 1381 Timur began his conquests in Persia with the capture of Herat. The political and economic situation of Persia at this time was precarious in the extreme. The signs of recovery visible under the later Ilkhans (*see* MONGOLS) had been followed by a setback after the death of the last Ilkhan, Abu Sa'id (1335). The vacuum of power was filled by rival dynasties, torn by internal dissensions. These warring principalities could put up no joint or effective resistance to Timur. Khurasan and all eastern Persia fell to him in 1382–85; Fars. Iraq, Azerbaijan and Armenia in 1386–87 and 1393–94; Mesopotamia and Georgia in 1394. In the intervals he was engaged with Toktamish, now khan of the Golden Horde, whose forces invaded Azerbaijan in 1385 and Transoxiana in 1388, defeating Timur's generals. In 1391 Timur pursued Toktamish into the Russian steppes, defeated and dethroned him. The khan again invaded the Caucasus in 1395, but was finally defeated on the Kur river. The revolts which broke out all over Persia during these campaigns were repressed with ruthless vigour.

In 1398, when Timur was over 60 years of age, he invaded India. He crossed the Indus on Sept. 24 and, leaving a trail of carnage, marched on Delhi. The army of Mahmud Tughlak was destroyed at Panipat (Dec. 17) and Delhi reduced to a mass of ruins, from which it took more than a century to emerge. By April 1399 Timur was back in his own capital beyond the Oxus. An immense quantity of spoil was conveyed away. Before the end of the same year Timur set out on his last great expedition. After restoring his control over Azerbaijan, he marched on Syria; Aleppo was stormed and sacked, the Mameluke army defeated and Damascus occupied (1400). In 1401 Baghdad was taken by storm, 20,000 citizens massacred and all its monuments destroyed. After wintering in Georgia, Timur invaded Anatolia, destroyed Sultan Bayezid I's army near Ankara (July 20, 1402) and captured Smyrna from the Knights of Rhodes. Having received offers oi submission irom the sultan of Egypt and from John VII, co-emperor of the east, Timur returned to Samarkand (1404) and at once began to make vast preparations for an expedition to China. He set out at the end of December, fell ill at Otrar on the Syr-darya west of Chimkent and died on Jan. 19, 1405. His body was embalmed, laid in an ebony coffin and sent to Samarkand, where it was buried in the sumptuous tomb called Gur Amir. Before his death he had divided his territories among his two surviving sons and his grandsons, and after years of struggle they were reunited by his youngest son Shahrukh.

During his lifetime Timur had a record kept of all his acts, and arranged ior the preparation of an official biography. This survived in the contemporary recension of Nizam ud-Din Shami, ed. by Tauer (Prague, 1937) and in the more florid version of Sharaf ud-Din Yazdi, trans. by F. Petis de la Croix (1723). The opposite point of view, bitterly hostile to Timur, is given by another contemporary, Ibn 'Arabshah, trans. by J. H. Sanders, *Tamerlane; or Timur, the Great Amir (1936).* The supposed *Memoirs* (*Malfuzat*), trans. by C. Stewart (1830), and *Institutes (Tuzukat)* of Timur are generally held to he iorgeries.

There are supposed paintings of Timur in Persian works; these are idealized Persicized portraits and in no way resemble the authentic description of him as very tall, with a large head, highly coloured and white-haired since childhood.

In the absence of a critical historical study of Timur the following works may be consulted: L. Bouvat, *L'Empire mongole, 2e phase* (1927); Ruy Gonzalez de Clavijo, *Embassy to Tamerlane,* trans. by G. Le Strange *(1928);* Harold Lamb, *Tamerlane; the Earth Shaker (1932).* (H. A. R. G.)

TIN is a metallic chemical element. symbol Sn. atomic number 50 and atomic weight 118.70. It has 10 naturally occurring isotopes (*q.v.*), more than any other element. The isotope with mass number 124 is radioactive. disintegrating by double β decay with a half life of about 6×10^{15} yr. By the mid-1950s 17 artificially radioactive isotopes had been prepared, either by nuclear reactions or in the fission of uranium.

History. — Bronzes containing tin were made more than 30 centuries B.C., but whether metallic tin was first isolated and then combined with copper, or tinstone was added to copper under reducing conditions is not known. In early Hebrew. Greek and Latin writings words that came to designate tin had a different meaning. making it difficult to establish with certainty when tin was first recognized.

The word "tin" in English Bibles, for example! corresponds to the Hebrew *bedhil,* which is a copper-tin alloy. Homer distinguishes between tin and bronze in his *Iliad* and Herodotus discusses the existence of the Cassiterides (*q.v.*), or tin islands. from which tin mas said to have been imported in his time. Pliny the Elder referred to tin as "white lead" and lead as "black lead." He also used the term stannum, but this apparently referred to a silver-lead alloy. An imitation stannum was made at that time which contained two-thirds "white lead." and by the 4th century the meaning of stannum had changed to tin.

The earliest known objects made of pure tin are a ring and a pilgrim bottle found in Egyptian tombs of the 18th dynasty (1580–1350 B.C.). However, tin ores are not found in Egypt. so the tin must have been imported. About 1000 B.C. the Cornwall (Eng.) deposits were worked by the Phoenicians. hut references to the Mediterranean tin trade of this era are scanty. The Cornish tin industry was dated back to 300–200 B.C. by the discovery of tin containing slag in excavations made at the castle of Chun near St. Just, and tin was imported from Cornwall into Italy after. if not before, the invasion of Britain by Julius Caesar.

That tin was known to the South American Indians prior to the advent of the Europeans was shown by the discovery of pure tin at Machu Picchu. Peru. Tin was not used by them for the manufacture of artifacts as such. however, but for the preparation of bronzes with compositions varied according to ultimate use. Hernan Cortes found small pieces of tin used as money among the natives of Taxco when he arrived in Mexico in 1519.

Geochemistry. — Tin,although not an extremely rare element. is nevertheless not as abundant as several less familiar elements such as lithium, vanadium and titanium. It occurs to the extent of 40 g. per ton in the earth's crust; while in meteorites the abundance is 100, 15 and 5 g. per ton in the iron-nickel. troilite and silicate phases. respectively. Because of the distribution in these meteorite phases, tin is classed as a siderophile, or iron lover. It is probable that tin is more abundant in the iron-nickel core of the earth than in the crust. When the earth's crust formed by crystallization of the molten rocks. the tin compounds were among the last to solidify.

In low temperature deposits the tin crystallized in sulphidic minerals, whereas in high temperature deposits the oxide crystallized. The tin deposits are in or closely connected with granite or acid-eruptive rocks of the same type. The minerals of tin are listed in Table I.

All the commercially important tin-bearing deposits contain cassiterite (*q.v.*), or tinstone, as the predominant tin mineral with the exception of the, Bolivian ores which contain both cassiterite and a variety of sulphidic ores.

TABLE *I.* — *Minerals of Tin*

Name	Formula	occurrence
Cassiterite	SnO_2	*See* text
Cylindrite	$Pb_3Sn_4Sb_2S_{14}$	Bolivia
Franckeite	$Pb_5Sn_3Sb_2S_{14}$	Bolivia
Stannite	Cu_2FeSnS_4	Bolivia, Cornwall, central Europe
Arandisite	$Sn_5(OH)_8(SiO_4)_8$	South West Africa
Canfieldite	Ag_8SnS_6	Bolivia, Saxony
Cuprocassiterite. . .	$Cu_2Sn(OH)_6.4SnO_2$	wit11 stannite (weathered stannite?)
Hulsite	$10(Fe,Mg,Ca)O.2Fe_2O_3.SnO_2.3B_2O_3.2H_2O$	Alaska
Native tin	Sn	Sew South Wales, Stromboli
Nordenskiöldine . .	$CaSn(BO_3)_2$	Norway
Paigeite	$30FeO.5Fe_2O_3.SnO_2.6B_2O_3.5H_2O$	Alaska
Plumhostannite. . .	$Pb_2Fe_2Sn_2Sb_2S_{11}$	Peru
Stokesite	$H_4CaSnSi_3O_{11}$	Cornwall (one specimen)
Teallite	$PbSnS_2$	Bolivia, Saxony

Mining and Metallurgy. — Tin deposits are of two kinds — the primary deposits found as veins traversing granite and related acid igneous rocks and the secondary. alluvial deposits formed by the disintegration of the primary deposits. Cassiterite is highly resistant to weathering and is found unaltered in the secondary deposits. The greatest part of the world's tin ore comes from secondary deposits which are worked by panning, gravel pump and open-cut mining and dredging, whereas the primary deposits, mainly the Bolivian ores, are worked by lode mining Subsequent treatment of the ore depends upon its other components. Those ores nhich contain only cassiterite, iron oxides and quartz feldspars are termed simple ores; nhile the sulphidic ores and other ores containing metals such as copper. iron, tungsten and lead are complex ores The ores generally contain 1% to 5% SnO_2 and must therefore be concentrated prior to reduction. The concentration processes are based on the high density, nonmagnetic character and nonreactivity of cassiterite.

The simple ores are dressed to a concentrate by multiple sluicing, followed. in some cases. by magnetic separation to remove tungsten minerals, iron oxides and other magnetic impurities. The complex ores require more extensive treatment to break down the sulphidic minerals and to remove a large part of the other metals present. This treatment involves grinding, roasting, gravity concentrations and magnetic separations.

Metallic tin is obtained by reducing the ore concentrate with coal in blast or reverberatory furnaces. Little preliminary treatment is required for the simple ore concentrates. but the complex ore concentrates still contain other metals which are removed in part by roasting and leaching prior to reduction. The crude tin which comes from the furnaces is purified by liquation, poling, tossing, boiling, electrolysis, or a combination of some of these processes. Liquation takes advantage of the low melting point of tin compared to the usual impurities to separate molten tin from the unmelted impurities. This is accomplished by slowly heating the crude tin to a temperature just above the melting point of tin and collecting the part that melts. Lead and bismuth melt with the tin and must be removed by subsequent treatment. Poling and boiling oxidize the impurities and part of the tin by a strong bubbling action caused by stirring the molten metal with poles of green wood or by agitating the metal nith compressed air. In tossing the oxidation is accomplished by pouring the molten metal from ladles at a height back into the kettles, so the impurities are oxidized by the air. In all these oxidation processes the oxidized impurities and tin oxide form a scum on the surface of the molten tin which is skimmed off and reprocessed During the smelting of tin much of the metal is either entrapped in the slag or reacts with the fluxes, because of the amphoteric nature of stannic oxide, and goes into the slag as tin compounds. Molten tin, moreover, is a mobile liquid and tends to escape from the furnaces through s all openings. Consequently, the recovery of tin from slags, furnace linings and drosses is an important phase in the metallurgy of tin, and these materials are always processed before being discarded.

In Malaya ore is smelted at Penang and Singapore and shipped as the metal; however, Bolivian and Thailand concentrates are shipped to the United States and the United Kingdom, Indonesian concentrates to the Netherlands and the United States, the Nigerian concentrates to the United Kingdom and the Belgian Congo concentrates to Belgium, Prior to World War II the main smelters were in the United Kingdom, the Netherlands, Malaya and Batavia. During the war the Japanese overran the Asian smelters and the Germans took over the continental European smelters. As a result the Longhorn smelter was constructed at Texas City, Tex.. in 1941 and extensive smelting was begun in the United States, mainly with Bolivian ores. After the war the continental European and Malayan smelters were again put into operation, but the Batavian smelters were not immediately reactivated.

The leading tin smelters in the mid-1950s were in the Federation of Malaya, the United States, the United Kingdom, the Netherlands and Belgium.

When supply and demand considerations make it profitable, the recovery of tin is of considerable importance. Some waste materials may be reworked by a combination of liquation and smelting; tin plate scrap is detinned, however. by electrolytic or chemical oxidation of the tin. Dry chlorine, which attacks tin more readily than iron, was largely replaced by hot oxidizing alkaline solutions for the latter. The secondary, or recovered, tin is obtained in the form of metallic tin or tin compounds and is generally sold in the form recovered.

Uses.—By far the largest part of the tin produced is used as the metal, the major uses being for plating and in alloys. Tin is less active than iron and will serve as protection only if it completely covers the iron object, whereas zinc, which is more active than iron, will protect the object even if the coat is not perfect. Tin plating, therefore, has to be more thorough than galvanizing to be effective. An object may be plated by electrolysis, chemical displacement or hot dip processes. The hot dip process gives, a heavier plate than the other methods; electrolytic plating gives a dull surface which has to be polished if a bright plate is desired. Terneplate, a protective coating of a tin-lead alloy applied by hot dip processes, is also used as a protective coating (see TIN PLATE AND TERNEPLATE).

The alloys of tin belong to two major classes, bronzes and white metals. In general, bronzes are copper base alloys which contain tin and smaller amounts of other elements to give alloys with specific properties (see BRONZE) while white metals are tin base alloys, such as Babbitt's metal, Britannia metal, pewter (*qq.v.*), antifriction metal (*see* BEARING METALS) and tin base die casting alloys, and alloys with other bases, such as type metal (*q.v.*), low-tin bearing metals, die casting alloys with lead or zinc bases and low melting alloys (*see* FUSIBLE ALLOYS). Solder (*see* SOLDERING) is an alloy of tin and lead containing from 20% to 80% tin.

TABLE 11.—*Composition of Typical Tin Alloys*

Alloy	% Tin	% Copper	% Lead	% other elements
Bronzes				
Bell metal	15–25	85–75		
Gun metal	8–14	92–86		
Coinage bronze	4	95		Zinc 1
White metals

Type metal	26	1	58	Antimony 15
Wood's metal	12.5		25	Bismuth 50, Cadmium 12.5

Tin metal is also used in the construction of block tin stills and tin pipes for the distillation and circulation of distilled water, for thin foil to wrap various objects and for collapsible tubes to dispense tooth paste, ointments, etc. Conservation measures instituted during World War II, when tin was in short supply, resulted in the substitution of other metals for tin in some applications and the use of much thinner plate on cans. Aluminum foil and tubes in large part supplanted tin foil and tubes for most uses, but in some cases, such as the packaging of alkaline substances, aluminum is not satisfactory. Lead is also substituted for tin. but it is not a satisfactory replacement in many instances because of its toxicity.

Compounds of tin used commercially represent less than 1% of the tin consumption. The main uses are in textile manufacture, dyeing and in glasses. ceramics and porcelains. The compounds used industrially are SnO_2 (tin ash), $SnCl_5.5H_2O$ (butter of tin), $SnCl_2.2H_2O$ (tin salt), $(NH_4)_2SnCl_6$ (pink salt). $Na_2SnO_3.10H_2O$ (preparing salt), $SnSO_4$, SnC_2O_4, $SnC_4H_4O_6$, $Sn_3(PO_4)_2$ and $Sn_3(PO_4)_4$.

Physical Properties.— Tin is a soft, ductile, white metal which is readily extruded, drawn, stamped and spun. Although it does not work-harden appreciably, it has a low elastic limit. When bent. the cast metal emits a creaking sound called the "cry of tin". This is thought to be caused by the grinding of crystals of the metal against one another when the bar is bent. The metal has at least two allotropic modifications. In the usual commercial form it is a white massive metal, but, when exposed to temperatures below

TABLE 111.—*Some Physical Properties of Tin*

Property	Value	Remarks
Melting point	231.9° C.	National Bureau of Standards standard
Boiling point	2,270° C.	
Transition temperature	13.2° C.	gray to white
	161° C.	white to γ (?)
Critical temperature	3730° C.	
Critical pressure	650 atmospheres	
Density	7.311 (20°/4°)	white
	5.85	gray at 15°
Hardness	1.8	white on Von Moh scale
	14.0	silver = 100
		silver = 100
Coefficient of linear expansion	2.03×10^{-5}	white, 8°–95° C.
Heat of fusion	14.2 cal./g.	
Heat of vaporization	525 cal./g.	
Heat of transition	4.2 cal./g.	gray to white
	0.02 cal./g.	white to γ
specific heat	$0.0534+0.0000348t$ (t=0 to 100° C.)	cal./g. White
Ionization potential I	7.30 e.v.	
II	14.5 e.v.	
III	30.5 e.v.	
IV	39.4 e.v.	
Electrode potential Sn–Sn^{++}	0.136 volts	
Sn^{++}–Sn^{4+}	−0.15 volts	
Radius Covalent	1.40 Å (1 Angstrom—	single bond
	1.30 Å 10^{-8} cm.)	double bond
Sn^{++}	0.93 Å	
Sn^{4+}	0.74 Å	

13° C. for sufficient time, it becomes brittle and may be readily crushed to a gray powder. Tin objects eventually crumble to this gray powder spontaneously if kept in a cold climate for years. Before the change was understood, it was named tin pest or tin disease, for the transformation appears to be contagious. It is autocatalytic, and a single grain of the gray form in contact with a piece of white metal below the transition temperature will start the transformation. The gray and white modifications have been designated α tin and β tin. Another modification, termed γ tin, was reported to form at 161° C. and exist up to the melting point, but authorities disagreed as to its existence. It is not generally accepted as an allotrope of tin.

Chemical Properties.— Tin is a member of group IV of the periodic table (see PERIODIC LAW, THE), being associated with carbon, silicon, germanium and lead. It falls between germanium and lead in atomic weight and resembles these two elements the most closely. The four valency electrons of tin occupy the $5s^2$ and $5p^2$ orbitals and consist of two sets from the consideration of the energy required to remove each electron. Accordingly, tin forms two series of compounds, the stannous tin(II) series in which tin has an oxidation number of +2 after losing only the 5p electrons, and the stannic tin(IV) series with an oxidation number +4 corresponding to the loss or sharing of all four outer electrons. Tin also forms a few compounds in which it can be considered to have the oxidation number −4. In these compounds the outer electron shell is built up to eight electrons by sharing electron pairs with other more electropositive atoms. The electrode potentials show that tin is oxidized to Sn^{++} by the hydrogen ion, but that hydrogen is oxidized to the hydrogen ion by Sn^{4+}.

TABLE IV.—*Some Chemical Reactions of Metallic Tin*

Reagent	Product	Conditions of reaction
Air	superficial tarnish	room temperature
	SnO_2	high temperatures
Oxygen	SnO_2	accelerated by water and heat
Hydrogen, nitrogen	no reaction	
Fluorine	SnF_4	100° C.
Chlorine, bromine	$SnCl_4$, $SnBr_4$	room temperature
Hydrofluoric acid	feeble attack	
Hydrochloric acid	$SnCl_2$	slow if dilute, more rapid if hot, concentrated
Hydrobromic, hydriodic acids	$SnBr_2$, SnI_2	hot
Chloric acid, aqua regia	$SnCl_4$	room temperature
Sulphuric arid	$SnSO_4$	cold, dilute (slow)
	$Sn(SO_4)_2$	hot, concentrated
Nitric acid	$Sn(NO_3)_2$	dilute
	$SnO_2.5H_2O$	concentrated
Alkali hypochlorites	basic stannic chlorides	
Sulphur	SnS or SnS_2	heat
Hydrogen sulphide, Sodium sulphide, or Sulphur dioxide	SnS	heat
KOH	$K_2Sn(OH)_4$	heat

The simple cation Sn^{++} exists in moderately acidic solutions; but there is some question about the existence of the simple cation Sn^{4+} because of extensive hydrolysis. In most solutions the stannic ion is undoubtedly present as some kind of complex ion because it has a high charge density, but there is some evidence that Sn^{4+} may be present in certain sulphuric acid solutions. For the most part, however: compounds containing tin(IV) are either covalent in nature or else contain tin in a co-ordinated cation or anion. In both oxidation states tin is amphoteric, but $Sn(OH)_4$ is a stronger acid than $Sn(OH)_2$ as would be expected for the smaller, more highly charged tin(IV) ion. Although it has been customary to write ions such as SnO_3^{--} in the stannate solutions, the salts isolated from such solutions retain their original nature only when dehydrated as far as the composition illustrated by $K_2SnO_3.3H_2O$. Further dehydration, which is more difficult, gives salts which have lost ready solubility in water; so it is probable that the stannate ion is $Sn(OH)_6^{--}$. The stannites are much less stable than the stannates and are efficient reducing agents. They also tenaciously retain sufficient oxygen and hydrogen to indicate that the stannite ion is $Sn(OH)_4^{--}$.

Binary compounds of tin in both oxidation states have been prepared with the halogens. oxygen, nitrogen. sulphur, selenium and tellurium. The hydride and phosphide of tin(IV) are also known. The salts of the common oxyacids have been reported, for the most part in both series, although the tin(IV) salts are more difficult to prepare because of hydrolysis and in some cases have not been isolated. Co-ordination compounds containing tin generally have a co-ordination number of four for tin(II) and six for tin(IV); however, a few compounds with co-ordination number six for tin(II) and eight for tin(IV) are known. Some examples of compounds of these kinds are $K_2SnCl_4.2H_2O$ and $(NH_4)_2SnBr_4$ [tin(II), co-ordination number four], $Na_2SnBr_6.6H_2O$ and $K_2Sn(OH)$, [tin(IV), co-ordination number six], $(NH_4)_4SnBr_6.H_2O$ [tin(II), co-ordination number six] and $H_4Sn(C_2O_4)_4$ and $Sn(C_{32}H_{16}N_8)_2$ [tin(IV), co-ordination number eight].

The stereochemistry (*q.v.*) of the various tin compounds is, in general, what is expected from bonding considerations. In those compounds with four covalent bonds linked to tin(IV), such as $SnCl_4$ and the organotin(IV) compounds, the bonds are directed to the four corners of a tetrahedron as with carbon and other elements which form compounds using sp^3 orbitals for bonding. The resolution of methylethylpropyl tin iodide into optically active isomers is classical evidence for the tetrahedral structure of these tin compounds. In compounds such as K_2SnCl_6 the six chlorine atoms are arranged in octahedral fashion about the tin atom in the same way the chlorine atoms are arranged around the platinum atom in K_2PtCl_6. The configuration in $K_2SnCl_4.H_2O$ is that of infinite chain ions of composition $SnCl_4^{--}$ formed by $SnCl_6$ octahedra sharing two opposite edges. In the gaseous state. molecules such as $SnCl_2$ are angular in shape, a configuration to be expected because the 5*s* electron pair is still present in the outer electron shell of tin. so the *p* orbitals, which are at a 90° angle, determine the configuration. Stannous oxide, SnO. also shows the effect of this inert pair of electrons. It has a layer structure in which four oxygen atoms are arranged in a square bonded to one side of the tin and the inert pair occupies the other side. thus forming the apex of a tetragonal pyramid. The oxide SnO_2 has the rutile structure in which the tin atoms are surrounded octahedrally by six oxygen atoms. gray tin has the diamond lattice and white tin has a metallic lattice.

Table V.—*Some Properties of Typical Tin Compounds*

Formula	Melting point	Boiling point	Density	Colour	Solubility
SnO	decomposes	>385° C.	6.9	black	alkali, acid
Precipitated SnO_2	1,132° C.		6.6–7.0	white	alkali, acid
$SnCl_4$	−33° C.	114° C.	2.3	colourless	water, organic solvents
SnF_4	sublimes 750° C.		4.8	white	water
$SnCl_2$	246.8° C.	603°–606° C.	2.6	white	water, organic solvents
SnF_2				white	water, alkali, fluoride
SnS	880° C.	1,230° C.	5.1	brown	concentrated HCl, $(NH_4)_2S_x$
SnS_2	decomposes		4.5	yellow	basic sulphides, concentrated HCl
$K_2SnCl_4.H_2O$			2.5	white	water
$(NH_4)_2SnCl_6$	decomposes		2.4	white	water
$Sn(C_2H_5)_4$	−112° C.	181° C.	1.2	colourless	organic solvents
$(CH_3)_2SnI_2$	43° C.	228° C.	2.9	white	hot water, organic solvents
$Sn(C_6H_5)_4$	226° C.	>420° C.	1.5	colourless	hot organic solvents
SnH_4	−150° C.	−52° C.		colourless	concentrated H_2SO_4, concentrated alkali

Under the proper conditions compounds corresponding to stannic acid can be isolated. Two stannic acids, one prepared by the acidification of stannate solutions and the other by the action of concentrated nitric acid on tin, have been said to exist and were named a and β stannic acids or stannic and metastannic acids, respectively. Stannic acid prepared by the two methods differs in properties (the α form is readily soluble in acids and bases, whereas the β form is difficultly soluble in these reagents), but the reason for the differences has not been definitely established. X-ray diffraction patterns for the two forms are the same and identical with that of cassiterite: so the difference is not one of isomers. It is probably essentially one of particle size and amount of adsorbed water, with the β form a modification with larger particles. The conversion of α to β occurs readily, whereas the reverse transformation is more difficult. Treatment of a stannic acid with hydrogen peroxide yields a peroxyacid of tin with the formula $H_2Sn_2O_7.3H_2O$. Sodium and potassium salts of this acid are also known.

Stannic sulphide also possesses amphoteric properties, being soluble in basic sulphide solutions to give thiostannates, but stannous sulphide is so much less acidic than the tin(IV) compound that it is insoluble in basic sulphide solutions.

Tin resembles silicon and germanium in the compounds it forms which are analogous to the extensive series of organic compounds of carbon. The hydride SnH_4 (see Hydrides) is the only gaseous binary hydride known to be formed by tin. but chains of tin atoms occur in the organometallic compounds with the formula $(CH_3)_3Sn[Sn(CH_3)_2]_nSn(CH_3)_3$ in which n may be 0, 1 or 3. A large number of organotin compounds have been prepared in which tin is bonded to from one to four alkyl or aryl groups. In those compounds containing tin(IV) the other bonds may be to halogens, hydrogen or oxygen. A few organotin compounds have been prepared which contain tin(II), but they disproportionate fairly easily to tin and tin(IV) compounds. Metallic tin dissolves in a liquid ammonia solution of potassium to give a blood-red solution which contains the polystannide ion Sn_9^{4-}. In this ion there are eight tin atoms associated with a Sn^{4-} ion. The tin hydride, SnH_4, and this unusual polystannide ion are two of the few compounds containing tin in the −4 oxidation state.

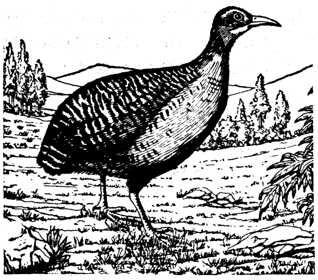
Stannic oxide, SnO_2, is prepared commercially by the high temperature ignition of metallic tin. The reaction of chlorine with tin at low temperatures supplies $SnCl_4$ from which the hydrates and $(NH_4)_2SnCl_6$ are made by subsequent treatment with water or ammonium chloride. Tin is treated with moist hydrogen chloride to make $SnCl_2.2H_2O$ and dissolved in dilute sulphuric acid to make $SnSO_4$. $Na_2SnO_3.10H_2O$ is made by the fusion of metallic tin with Chile saltpetre and caustic soda. On a laboratory scale tin compounds are made from tin by dissolving it in an acid or base and treating the resulting solution with the proper reagents for the usual metathetical preparations. Some of the compounds of tin are water-sensitive and must be prepared under anhydrous conditions. The organotin compounds are prepared by the reaction of tin halides with the Grignard reagent or organozinc compounds. To prepare metallic tin in the laboratory an insoluble compound is fused with potassium cyanide and carbon or a solution of a soluble compound is treated with zinc.

Analysis.—In the field cassiterite is usually recognized by its high density and extreme hardness. A chemical test that distinguishes it from those minerals with which it might be confused is the treatment of the mineral with cold dilute hydrochloric acid or sulphuric acid in the presence of zinc or iron. This reduces the surface oxide to a gray coating of metallic tin which can be washed and rubbed to a silvery surface. The minerals most frequently confused with cassiterite are zinc blende, ilmenite, rutile, haematite, wolframite, tantalite. columbite. zircon, garnet, tourmaline and axinite. In the usual wet qualitative analysis scheme both Sn(II) and Sn(IV) are separated as insoluble sulphides in dilute hydrochloric acid. The sulphides are then dissolved in a basic sulphide solution containing polysulphide to oxidize Sn(II) to Sn(IV). Arsenic and antimony are the only elements of those considered in most qualitative schemes which go into solution with tin. These elements are recovered as sulphides. and tin sulphide is then separated from the arsenic and antimony sulphides by various procedures, most of which depend upon the solubility of stannic sulphide in concentrated hydrochloric acid, the stability of the oxalate complex of tin. or the selective reduction of tin(IV) to tin(II). Several spot tests have been suggested for tin. the most satisfactory of which are reported to be the violet colour formed by Sn(II) with cacotheline. the blue colour imparted to a colourless Bunsen burner flame when hydrogen generated from zinc and hydrochloric acid in the presence of tin compounds (except highly refractory compounds) is burned. and the blue colour formed by the reduction of molybdophosphoric acid by Sn(II). Quantitatively, tin is determined gravimetrically as the ignited oxide after the removal of other ions or as the electrolytically deposited metal. Titrimetric determinations are made by the iodometric titration of Sn^{++} or $K_2SnS(C_2O_4)_2$ with iodine in the presence of starch. The titrimetric method is generally considered the superior quantitative procedure.

Deposits and Production.—The important tin deposits are confined to the following geographical locations: (1) Burma. Thailand. Malaya and Indonesia, (2) Bolivia. (3) Nigeria and the Belgian Congo, (4) west England, Brittany and the Erzgebirge and (5) Australasia. The major ore producing areas in the mid-1950s were Malaya, Indonesia. Bolivia, Belgian Congo. Thailand and Nigeria. The deposits at Cornwall, Saxony and Bohemia. major producers in the 18th and 19th centuries, were almost depleted and are mainly of historical interest, although some ore was still obtained from them. Other sources of lesser amounts of tin ores are Portugal, Spain, the Union of South Africa. Burma. China and Australia. North America is the only continent which does not have commercially important deposits of tin ores. Both Canada and Mexico produce small tonnages. but North America depends almost entirely on imports for its tin.

Bibliography.—A thorough treatment of the industrial and historical aspects of tin may be found in *Tin: Its Mining, Production, Technology, and Applications* by C. L. Mantell, 2nd ed. (1949). The chemistry of tin is discussed in N. V. Sidgwick, *The Chemical Elements and Their Compounds,* pp. 551–627 (1950). (B. P. B.)

TINAMOU, the name of a group of birds peculiar to South America. having some superficial resemblances to the partridge. The elongated bill. small head and slender neck are diagnostic. The plumage is some shade of brown, variously barred with darker tints. The wings are short and rounded, and the male incubates the highly burnished eggs. They are exceedingly stupid and are excellent to eat. More than 60 species are recognized. They are considered a group of palaeognathine birds and form the family Tinamidae. The little tinamou *(Crypturus pileatus)* ranges from the Amazon to Mexico, while the rufous tinamou *(Phychotus rufescens)* inhabits southern Brazil and Paraguay.



RUFOUS TINAMOU

TINDAL, MATTHEW (d. 1733), English deist. the son of a clergyman, was born at Beer Ferrers (Ferris), Devonshire, probably in 1653. He studied law at Lincoln college, Oxford, under the high churchman George Hickes, dean of Worcester; in 1678 he was elected fellow of All Souls college. About 1685 he became a Roman Catholic, but returned to the Church of England at Easter, 1688. His early works were an *Essay of Obedience to the Supreme Powers* (1694); an *Essay on the Power of the Magistrate and the Rights of Mankind in Matters of Religion* (169;); and *The Liberty of the Press* (1698). The first of his two larger works. *The Rights of the Christian Church Asserted Against the Romish and All Other 'Priests Who Claim an Independent Power Over It*, pt. i, appearing anonymously in 1706 (and ed., 1706; 3rd, 1707; 4th, 1709), is a forcible defense of Erastianism. Author, publisher and printer were prosecuted, but this did not prevent the issue of a fourth edition and gave the author the opportunity of issuing *A Defence of the Rights of the Christian Church,* in two parts (and ed., 1 jog). The book was burned by order of the house of commons, along with Henry Sacheverell's sermon, by the common hangman (1710). It was the object of denunciation for years, and Tindal scented in a pastoral letter by Edmund Gibson, bishop of London, a charge of having undermined religion and promoted atheism and infidelity. He replied in the anonymous tract, *An Address to the Inhabitants* of *London and Westminster* (2nd ed., 1730). In this he defends the deists, and anticipates his *Christianity as Old as the Creation; or, the Gospel a Republication of the Religion of Nature* (London, 1730; 2nd ed., 1731; 3rd, 1732; 4th, 1733), which was regarded as the "Bible" of deism.

Tindal died at Oxford Aug. 16, 1733.

TINEA VERSICOLOUR (Pityriasis Versicolour) is a harmless skin disease caused by the deposition of a fungus of the ringworm group. *Microsporon furfur.* It thrives on the trunk of adults and forms slowly spreading brown patches with fine branny scaling. Sunshine bleaches the brown patches. and after continued exposure the normal skin becomes darker than the bleached spots because the fungus colonies hinder the penetration of the tanning sun rays; hence the name "versicolour," which means changing colour. The fungus deposits itself only on the skin of a few specifically susceptible persons and is not transierable by contact. (S. Ron.)

TINGUIAN, a tribe of north Luzon, in the Philippines. of Malayo-Indonesian stock; more brachycephalic and probably belonging to a later wave of immigration than the Igorot (*q.v.*) group, and showing stronger traces of Indian influence on culture; probably traceable to Sumatran origin. The same influence appears in rice cultivation methods, and irrigated terraces are less elaborate than those of the Igorot, who do not use the buffalo. Marriage restrictions are based on blood relationship only, not on clan; and the polity is democratic.

A creator is believed in. and spirits of various functions, good and bad, some of which inhabit guardian stones. The home of the dead, where life goes on as on earth, is sometimes placed in a mountain. The dead are dried before burial. Mediums, usually female, communicate with spirits.

See Fay Cooper Cole, *The Tinguian* (1922).

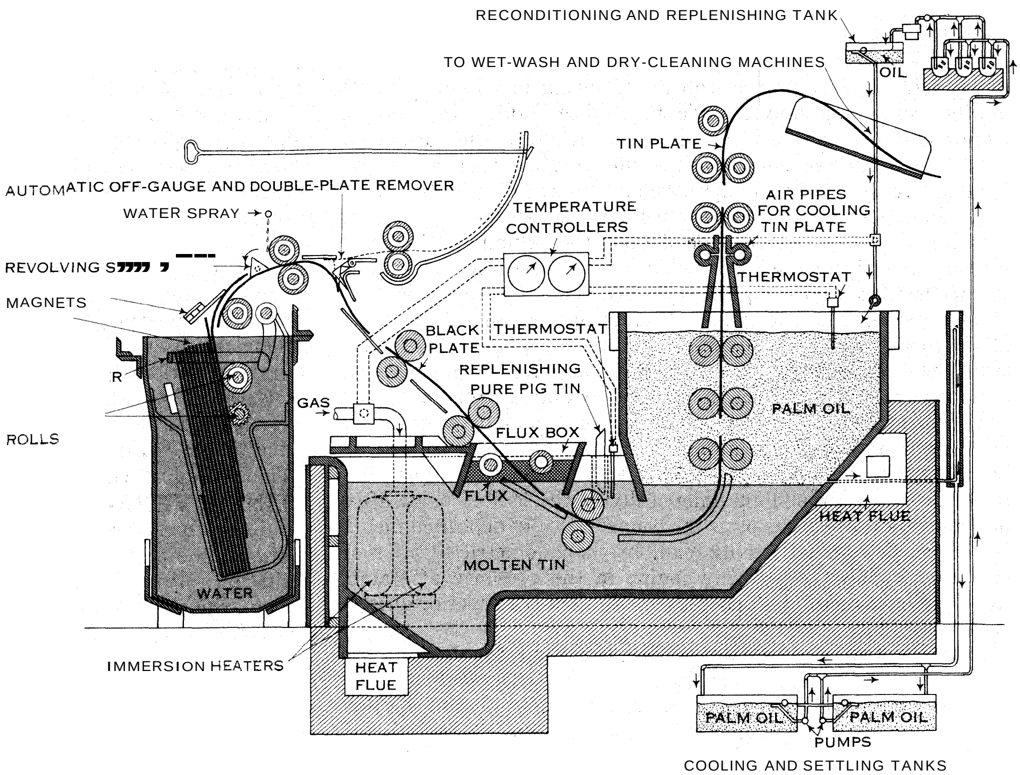
TIN PLATE AND TERNEPLATE. Tin plate is a low-carbon steel sheet or strip thinly coated with commercially pure tin. thus comprising in one inexpensive material the strength and formability of steel and the corrosion resistance, solderability and good appearance of tin. Tin plate is made by rolling mild steel to a finished gauge of about 0.01 in. and then applying a coating of pure tin by dipping in molten metal or by electrodeposition. Tin plate is available in various grades ranging from thinly coated electrolytic tin plate carrying coatings as thin as 0.000015 in. to thickly coated hot-dipped tin plate carrying coatings of 0.0001 in. to 0.0008 in.

Terneplate is a low-carbon steel sheet or strip coated with terne metal, which is an alloy of lead and tin. Lead alone does not alloy with the iron but when 7% to 12% of tin is incorporated in the alloy, the tin readily wets the steel and forms a solid solution with the lead. Terne sheets are seldom manufactured of thinner gauge than 0.014 in.. thicker than 0.125 in. or wider than 48 in. The clean cold-reduced mild steel sheet or strip is coated by a hot-dip process similar to that used in the tin-plate industry with the exception that the coating is applied at a higher temperature. Terneplate is sold on the basis of a coating weight of 0.3 to 1.45 oz. per square foot.

Tin-Plate Manufacture.—The base sheet for tin plate is made principally from open-hearth steel, hot-rolled' to strip (0.07 × 36 in.), pickled continuously in hot dilute sulfuric acid, cold-reduced to finished gauge (0.01 in.), then annealed and temper-rolled to impart the required hardness and surface finish.

(See IRON AND STEEL: *Mills for Semi-Finished Materials.*) The tin coating is applied either by hot-dipping in molten tin or by electroplating from tin-bearing electrolytes. About 30% of world tin-plate production is hot-dipped and 70% electroplated.

Hot-Dip Tin Plate.—In a modern tinning plant (see figure), the cold-reduced steel is sheared to sheet length and passed through a pickling unit attached to and driven synchronously with the tinning units. The tinning unit comprises a thermostatically controlled vessel of molten tin held at about 600° F. In the molten tin is submerged a mechanism of rollers and guides for conducting the pickled sheets downward through a layer of zinc chloride flux into the tin and then upward and out of the tin through a thick covering layer of palm oil. The sheets are subjected to the squeegeeing action of tinned steel rollers which serve to regulate and control the final thickness of coating on the sheets. The tinned sheets are cooled by an air blast and then cleaned and polished, usually by a combination of alkaline detergent washing and dry absorbent cleaning with bran or wood meal to absorb the oil. A conveyor automatically separates the sheets into prime sheets (free from defects), seconds (slightly defective but usable) and menders (to be retinned).



BY COURTESY OF WHEELING STEEL CORP.

SCHEMATIC DIAGRAM OF SINGLE SWEEP TIN POT

Electrolytic Tin Plate.—The world's first commercial electrolytic tin-plate line was installed at the United States Steel Corp.. Gary, Ind.. in 1937. The cold-reduced steel is handled as a continuous strand through all operations of preparation and tinning. In a typical electrolytic line the following operations follow in sequence: decoiling and welding of the trailing end of the previous coil to the leading end of the following coil; electrolytic cleaning in dilute sulfuric acid; light pickling; electrolytic deposition of the tin from alkaline or acid tin-containing electrolytes; melting of the dull matte coating to give it a brilliant surface; chemical dipping in chromate solutions; oiling; shearing; inspection and piling. Five grades of electrolytic plate are available, viz., $\frac{1}{4}$ lb., $\frac{1}{2}$ lb., $\frac{3}{4}$ lb., 1 lb. per basis box and differential plate with 1 lb. on one side and $\frac{1}{4}$ lb. on the other. The basis box is the unit of area and consists of 112 sheets each 20 × 14 in. equivalent to 31,360 sq.in. of tin plate.

Where the can manufacturer is equipped to accept tin plate in coils (36 in. wide, 20,000 lb. in weight), the final shearing and classification operations are omitted. Utilization of tin plate in coils may well become general practice.

Terneplate Manufacture.—The process of coating terneplate is quite similar to that for tin plate. A more active flux consisting of zinc chloride and hydrochloric acid is used, and the terne metal is maintained at about 700° F. In some cases. an additional machine operation with palm oil substituted for the flux is used which allows complete control of coating weight over a wide range.

Applications.—Tin plate is very ductile and can be bent, drawn and folded into complicated shapes without risk of failure. The tin coating follows, to a remarkable degree, the movement of the steel base when tin plate is formed into useful shapes. The coating is very adherent, and spalling or peeling of the coating from the base is almost unknown. It protects the steel from corrosion and is resistant to the wide range of processed foods and other merchandise which is packed in tin plate. The coating renders the material easily solderable at high speeds and imparts a surface which can be readily decorated, painted, enameled or lacquered. Tin and iron are nontoxic and are safely used in all applications where contact with foods or beverages occurs.

The uses of tin plate are varied and widespread. The choice between hot-dipped tin plate and electrolytic tin plate is dictated by technical and economic factors.

Hot-dipped tin plate is used for the severer and more corrosive packs, typified by certain acid fruits and baby foods. Heavily coated stock is used for hardware, kitchen utensils, gas meters, toys and returnable containers. Electrolytic tin plate ($\frac{3}{4}$ lb.) is widely used for packaging evaporated and condensed milk and for certain closures. The thinner coated tin plate ($\frac{1}{2}$ lb. and $\frac{1}{4}$ lb.) is used for a wide variety of general line containers, caps and closures, for packaging dehydrated and dry goods and cigarettes and nonfood products. Internally lacquered $\frac{1}{4}$ lb. electrolytic tin plate is used for canned beer and dog food.

Terneplate has good forming properties. It is used for roofing, and is ideal for fabrication into automobile gasoline tanks, fireproof doors and door frames and for lining caskets. It is used extensively for packaging paints, lubricating oils and greases.

TINTAGEL, a village in the Camelford rural district of Cornwall, Eng., 20 mi. N. of Bodmin by road. Pop. (1951) 1,451. It stands by the sea on a bare upland, to the south of Tintagel head, a rugged promontory united by a narrow isthmus to the shore. The village is sometimes known as Trevena. Below is Tintagel haven, or Porth, a small cove surrounded by cliffs of almost black slate. Great numbers of visitors are attracted to Tintagel by the castle, with its romantic associations as the reputed birthplace of King Arthur, and its striking situation. The ruins stretch from the precipitous cliff across the isthmus to the mainland. The castle was built in the 12th century on the site of a Celtic monastery and this settlement appears to have existed from *c.* A.D. 350–850. The earls of Cornwall occupied the castle in Norman times and built the chapel. The parish church of St. Merteriana, isolated on a high cliff west of the castle, shows traces of Saxon workmanship.

There is much Norman masonry and 12th-century iron hinges to the north door. The church contains an inscribed stone, probably Roman and referring to the emperor Licinius. Many of the gravestones in the churchyard are buttressed against the violent storms that sweep this coast at times. The church once belonged to Fontevrault abbey in Normandy, but Edward IV made it over to the collegiate church of Windsor. The old post office, a 14th-century stone house built like a medieval manor house with a large hall, stands in Tintagel village; it belongs to the National Trust.

Bossiney, part of the civil parish, appears in Domesday Book as *Botcinnii.* It surrendered its charter to Charles II and obtained a new one in 1685. In 1784 the vicar of Tintagel, as mayor and only qualified elector, enjoyed the probably unique privilege of returning two members to the house of commons. In 1832 there were ten resident voters within the borough and nine outvoters. The Reform act transferred their votes to the county, and Tintagel is included in the North Cornwall division.

TINTERN ABBEY, in Monmouthshire, one of the most famous ecclesiastical ruins in England, on the river Wye. The abbey was founded by Walter de Clare in 1131 for Cistercian monks. The existing church, however, dates from the latter part of the 13th century; it is unroofed, and the nave is imperfect, but many of the finest details of a style transitional from Early English to Decorated are preserved. The church is cruciform. Cloisters and other monastic buildings, of which there are considerable remains, lay to the north of the church. The foundation was dissolved by Henry VIII.

TINTORETTO (Jacopo Robusti) (1518–1594). Italian painter who was the greatest Mannerist painter of Venice and one of the giants of late Renaissance art, was the son of Battista Robusti. a Venetian dyer *(tentore),* hence his nickname of "little dyer," *tentorello* in the Venetian dialect (It.. *tintoretto*). An early bent for drawing was noticeable, and Jacopo's biographer, Carlo Ridolfi. relates that he was apprenticed to Titian. who after ten days dismissed him from the studio because he did not like the boy's drawing methods. The effect upon the lad was dismaying in the extreme. and in later years there was never any cordiality between the two men, although Tintoretto. ever the conscious professional, sedulously collected works by Titian. Ridolfi says that after the expulsion Tintoretto was self-taught by means of studies from life and from casts after the antique. Michelangelo and Sansovino, and that he evolved his style as a conscious synthesis of Michelangelo and Titian. "Michelangelo's drawing and Titian's colour" is the motto he is said to have put on his wall. Ridolfi's story, that the young Tintoretto haunted the colour shops and sought walls upon which to work for nothing, may well be correct. Ridolfi also mentions, in passing, that Tintoretto worked with Bonifazio Veronese and Andrea Schiavone.

Attempts to reconstruct Tintoretto's earliest works remain unconvincing. Either much later works are dated too early, or the works of others are confused with his early manner. An "Apollo and Marsyas" in Hartford, Conn., has been plausibly (if not certainly) identified with a ceiling painted for Pietro Aretino in 1545. An unfinished and mostly wrecked "Christ Among the Doctors" in the Opera del Duomo, Milan, may also be put at this time, and, possibly, an altarpiece with "Three Male Saints" in the former cathedral at Korcula, Yugos.

The first certain work is the "Institution of the Eucharist," signed and dated 1547, on the north wall of the chancel of S. Marcuola. In this work are the hallmarks of Tintorettos style: consummate draftsmanship; brilliant brushwork, in which the brushstrokes in broken colour are made into a decorative as well as a functional pattern (an innovation of Tintoretto's); a sensitive use of colour and light for dramatic emphasis; and a conscious borrowing from the antique.

The young man's reputation was made by his obtaining the commission for the "Miracle of the Slave," done for the Scuola di S. Marco in 1548. The work is lucidly composed and brilliantly painted with an emphasis upon colour, sun and shade, texture and dramatic cogency. There are evidences of his awareness of other painters, Paris Bordone for one. and Cecco di Salviati for another, from whose works in S. Giovanni Decollato, Rome, he seems to be copying. This may be taken as internal evidence of a trip to Rome for which no direct evidence is available. In 1549 Tintoretto completed an "Apotheosis of St. Marziale" for the church of S. Marziale. This work shows Tintoretto's a areness of some of Michelangelo's Sistine chapel figures (more evidence to support a putative Roman journey), Raphael's "Sistine Madonna," which he could have seen in Vicenza, and the "Assumption" which Titian had painted for the high altar of the Frari in Venice. The canvas is, however, no mere pastiche but, rather, a simple and heroic work. In 1549 Jacopo also received a major commission for the church of S. Rocco, the large horizontal decoration of "St. Rocco Visiting the Plague-Stricken." This work carries forward the brilliant invention of the S. Marco picture and the technical distinction of the S. Marziale canvas. In it he introduces a nocturnal scene with as much mastery as Raphael had shown in his Vatican decorations.

Tintoretto's reputation and financial position were now secure, and in 1550 he married Faustina de' Vescovi, the daughter of a Venetian banker. The couple occupied a house on the north side of Venice near the church of the Madonna dell'Orto, Tintoretto's home parish.

In 1552 Tintoretto executed a masterly pair of canvases for the Magistrato del Sale, "SS. Andrew and Jerome," and "SS George and Louis and the Princess." These works are brilliant in tonality and execution, and in construction Jacopo anticipates the baroque in his broken picture surface with pictorial elements thrust out at the spectator. In the same year he executed in the simplest terms and cheapest pigments the organ shutters for Sta. Maria del Giglio. These works show his most glittering brush technique and again borrow from the Sistine ceiling. Between 1550 and 1553 he executed a cycle of "Creation" for the Scuola della Trinità. in which his bravura style is slightly modulated by a note of elegiac poetry, especially in his treatment of landscape.

By 1556 Tintoretto completed the organ shutters for his home parish of the Orto. showing on the front "The Presentation of the Virgin" (with reminiscences of Sebastiano del Piombo, and, more surprisingly, of Lotto's "Presentation" in Bergamo, even to the point of a similar colour scheme). "St. Peter's Vision of the Cross" and the "Death of St. Andrew." These show his varied ingenuity of design and. more important, his narrative ability. They also show early evidence of the hands of helpers. In 1559 he painted the "Miracle of the Paralytic" for the church of S. Rocco. This design he adjusted, Ridolfi says, to that of the Pordenone work opposite, and this fact may account for the crowding of forms and colours and the increased mannerist emphasis.

Tintoretto began his long association with the Scuola di S. Rocco in 1564. As a building it is deficient in natural illumination, so that it required brilliant tonalities in its decoration and careful placement of the pictures. A competition was announced, and four of the five who were invited to compete presented sketches on the appointed day, while Tintoretto. who had contrived to have his full-sized work installed in place, uncovered a finished piece. to the fury of some members of the governing confraternity. Tintoretto then presented the picture to the *scuola,* aware that its constitution forced it to accept all offered gifts. Thus. Tintoretto began an association to last the rest of his life. In 1577 he contracted to deliver three pictures a year for 100 ducats. and by the end of his life he had received almost 2,500 ducats.

The work of 1565 was the "Crucifixion." in which the painter is seen at his most awe inspiring. showing unparalleled brilliance of invention and execution, but reflecting various celebrated, works, including the statue of Bartolommeo Colleoni of Verrocchio and the Gattamelata of Donatello. Of this work John Ruskin observed that it "is beyond all analysis and above all praise." The other works for the confraternity, which continued for 30 years. are of the greatest variety of design and concept, and certain of them, such as the "Temptation," with its borrowings from the Grimani marbles and dazzling bravura execution, almost blind the spectator to the fact that Tintoretto is perhaps as great a storyteller as Giotto, and that as an analyst of human motivation he is without equal.

In the 1560s Tintoretto also carried out three more works for the Scuola di S. Marco, the "Finding of St. Mark's Body" (Milan), the "Theft of St. Mark's Body" and the "Saving of the Saracen at Sea" (both Venice). These display Tintoretto's technique at its best, with an unsurpassed integration of architecture and figures, and an atmospheric presentation the equal of anything in El Greco. To these years also belong the first works for the ducal palace. This set of commissions occupied Tintoretto till 1594 and his studio still longer. The work became especially heavy after the fire of 1577 when the bulk of the commissions for a few years were distributed between Tintoretto and his colleague and intimate friend, Veronese. These commissions included such large set pieces (machines) as the "Excommunication of Barbarossa," the "Capture of Zara" (1584–87), the "Glorification of N. Da Ponte" (1581–84), "Venice. Queen of the Seas," and the last large work, the "Paradise" (1588) (which was to have been done by Veronese, who died before he could accept the commission) and such decorative masterpieces as the "Bacchus and Ariadne" and its three pendants.

Tintoretto died on May 31. 1594, and was buried in the Madonna dell'Orto next to his favourite child, Marietta, who had died about four years earlier. Tintoretto left his son Domenico. a most accomplished painter, in charge of the studio, as well as another painter-son, the brilliant and apparently erratic Marco, and his son-in-law, Sebastiano Casser, who kept the studio open till 1627. Among other students and helpers were Martin de Vos, Leonardo Corona and Andrea Vasilacchi called l'Aliense.

A basic problem with Tintoretto is that the works which he executed for patrons outside of Venice were almost always done by studio members. Even work in Venice shows strong traces of helpers. especially in the later years. He seems to have felt a curious indifference about the final execution of a great amount of his studio's work. This in itself relates to the methods of the studio. Though a vast store of drawings still exist which came from the studio and the master himself, there are almost no sketches by him; indeed, the only absolutely certain ones are a large one in Paris and a small one in Providence, R.I. Apparently Tintoretto outlined his compositions through the use of an illuminated shadow box with small modeled figures set behind a grid of string. If it were an out-of-town commission, he then would have members of the studio finish it, even though he might add some finishing touches of his own. This procedure accounts for the uncanny brilliance of certain designs and the rather inferior quality of the finish of the same pictures, such as the Dresden "Arsinoe." which is surely Tintoretto's invention and almost just as surely Aliense's execution. The same thing seems to be true of the "Bacchus and Ariadne," "Three Graces," "Minerva and Mars" and "Forge of Vulcan" in the ducal palace which are certainly Tintoretto's design and concept, but which must have been largely executed by his son Domenico.

The case of the portraits is even more extreme. Except for a very few which are surely autographic the calibre is not what one would expect. His two great self-portraits (1548 and 1590/94) show a degree of penetration and distinction which looks straight to the romantics. Certain others, the "Senator" (Eastman house, Rochester, N Y.) and the "Andrea Capello," one of the most awe-inspiring images of a sick man ever painted (Venice), rank with the greatest portraits of the 16th century. The usual portraits from the studio, however, are dull, even though the brilliant and difficult Marco has been accounted in his own day as a fine portraitist.

The Venetians said in Tintoretto's own day that he had three styles, one of gold, one of silver and one of iron. This obviously refers to the quality and autographic extent of execution as much as to matters of tonality. The sobriquet *il Furioso* summarizes his capacities but it does not indicate their full extent. The various versions of the "Last Supper" in Venice (S Giorgio, S. Marcuola, S. Polo, Scuola di S. Rocco, S. Simeone. S. Stefano and S. Trovaso), like the "Annunciation" in Scuola di S. Rocco, were at times criticized for their frenzy and sometimes for their unbiblical character. This latter censure is undiscerning, as Tintoretto seldom sought to be merely a historical narrator. Rather, he usually

ALINARI

"BACCHUS, WITH ARIADNE CROWNED BY VENUS" BY TINTORETTO. IN THE SALA DELL' ANTICOLLEGIO. DUCAL PALACE. VENICE

gives a good bit of theological exegesis. For example, the "Annunciation" is more than an illustration of the Gospel; it also is a commentary upon the Virgin as the new Eve. The "Last Supper" in S. Giorgio shows the light shining in darkness and epitomizes the new dispensation, just as its pendant, the "Fall of Manna," shows shadows upon a field of light and symbolizes the old dispensation.

Together these pictures can only properly be seen by the celebrant at Mass for whom they form pendants to a continuing mystery, just as the personages in the Orto "Presentation" may be taken to symbolize the Old and New Testaments.

Tintoretto is the major figure of the Mannerist epoch in Venetian painting. In his work amazing intimations of the baroque are fully visible. He is a perfect exemplar of the method and theories of the Counter-Reformation as it evolved in Venice. He also is probably the greatest dramatic decorator of western painting. His work is almost impossible to see outside of Venice, for prime examples of it are rare, and works given to him outside his native city are shop productions of variable interest. The works in Venice have all darkened, some of them disastrously. This is partly, as Goethe shrewdly noted, because of Tintoretto's fondness of using a dark priming on his canvas without preliminary heightening with white, and it is partly the result of dirt and bad varnish. The evidence indicates that when his great works were new they owed much to the technique of fresco painting, at which he was adept in his youth. Also the technique paralleled that of the scene painter. When one adds the bad light which prevails for most of Tintoretto's work still in place, the resulting image is far from clear, and Tintoretto's position as a great and epoch-making colourist seems hard to understand. If the viewer will try to recall the purposes, both theological and dramatic, for which these works were done, and if he will try to visualize their vanished pristine state, he then, perhaps, can get some inkling of the true stature of Tintoretto.

TIPASA, a town and commune on the coast of Algeria, in the *département* of Alger, 30 mi. W. of the capital. Pop. (1954 census) 671 (town); 6,210 (commune). The modern village, founded in 1857. is a favourite tourist spot, with Roman and Byzantine ruins (the former are more interesting), and summer resort with its beach and pleasant situation, facing across a bay the small summer resort of Chenoua Plage at the foot of the impressive Chenoua mountain.

The Roman ruins are on the western edge of the town. Mosaics of artistic interest may still be excavated. The Byzantine ruins are just to the east of the town. Of the houses. few traces remain, but there are remains of three churches, two cemeteries, baths, theatre, amphitheatre and nymphaeum.

Tipasa was founded by the Phoenicians, was made a Roman military colony by the emperor Claudius and afterward became a municipium. Christianity was early introduced, and in the 3rd century Tipasa was a bishop's see. In 484 the Vandal king Huneric (477-484) sent an Arian bishop to Tipasa; whereupon a large number of the inhabitants fled to Spain, while many of the remainder were cruelly persecuted. After this time the city disappears from history.

TIPPERA, a district in the Chittagong division of East Pakistan. Area, 2.531 sq.mi.; population (1951) 3,797,310. The administrative headquarters are at Comilla, pop. (1951) 47,195. The district has a fat and open surface, with the exception of the isolated Lalmai hills (100 ft.), and is for the most part laid out in well-cultivated fields! intersected by many rivers and creeks.

The principal rivers are the Meghna, or estuary of the Brahmaputra, Gumti, Dakatia and Titas.

TIPPERARY, a county of Ireland in the province of Munster, bounded northwest by Galway, northcast by County Offaly, east by Leix (Laoighis) and Kilkenny. south by Waterford and west by Cork. Limerick, Clare and Galway. Tipperary is the sixth in size of the Irish counties, having a land area of 1,051,292 ac. or 1,642.6 sq.mi. Pop. (1956) 129,415. The northern and western parts of the county are flat and generally fertile. with a group of prosperous market towns including Nenagh, Thurles and Tipperary; the southern portion. along the Suir valley, is also fertile and includes Clonmel. The central part of the county consists mainly of the Galtee mountain range. Sandstone heights stand out above the limestone plain; the Knockmealdown mountains on the southern border reach an elevation of 2.597 ft.; to the north are the Galtee or Galty mountains (Galtymore 3.018 ft.); to the east. bordering Kilkenny. are the Slieveardagh hills, and near Templemore the Devil's Bit mountains (1,577 ft.) with a curious gap on the summit; in the northwest is Keeper hill, 2,278 ft. The folded character of the Carboniferous Limestone is seen in the anticlinal boss on which stands the acropolis of Cashel. The Suir has its source in the Devil's Bit mountains? and flows southward and eastward by Templemore, Thurles. Cahir and Clonmel. The Nore, which also rises in the Devil's Bit mountains, soon passes into County Laoighis and the Shannon forms part of the western border. The Mitchelstown stalactite caverns, in the extreme southwest of the county. were discovered accidentally in 1833 and explored by M. Martel in 1895. The subsoil in the loner grounds is limestone: which is overlaid by a rich calcareous loam. The Golden vale. the most fertile district in Ireland. stretches from Cashel to the town of Limerick. There is some mining, and anthracite mines at Ballingarry have been reopened. The lead ore mined for many centuries at Silvermines south of Nenagh is silver bearing and is associated with zinc blende. Indications of ore have been traced along the junction of the limestone with the older rocks. Good slates are quarried in the Silurian area in Clashnasmuth townland on Slieve-na-Man. The county has a considerable number of meal and flour mills. It has benefited considerably from the electric power stations built along the lower Shannon.

Tipperary is one of the counties generally considered to have been formed by King John in 1210; in 1328 Edward III made it a county palatine in favour of the earl of Ormonde. In 1372 the grant was confirmed to James Butler, earl of Ormonde, the lands belonging to the church retaining, however, a separate jurisdiction and being known as the county of Cross Tipperary or the Cross of Tipperary. The Protestant see of Cashel was in 1833 united with those of Emly. Waterford and Lismore. The Roman Catholic see of Cashel, with its seat at Thurles. is an archbishopric, comprising the dioceses of Cashel and Ernly. It has eight suffragan dioceses, in Cloyne, Cork, Kerry, Killaloe, Limerick, Ross, Waterford and Kilfenora.

From the 19th century County Tipperary has been prominently connected with the revival of traditional sports and games, especially through the Gaelic Athletic association. It was the scene of the abortive Young Ireland insurrection in 1848. which collapsed at Ballingarry. and later it was an active centre of the Land league and of the Sinn Féin conflict with British forces prior to the treaty of 1921. The administrative counties of Tipperary North Riding and Tipperary South Riding together return seven members to *dail eireann.*

TIPPERARY, a town of County Tipperary, Ire., near the Slieve-na-&luck or Tipperary hills. a branch of the Galtee range, 113 mi. S.W. of Dublin by road. Pop. (1956) 4,790. Its butter market ranks next to that of Cork. Condensed milk is manufactured. The town first acquired importance through the erection of a castle by King John. of which there are no remains. A monastery founded for Augustinians by Henry III gave a second impulse to its growth. The gatehouse is all that remains of this foundation. Formerly Tipperary was a corporation from a grant made in 1310 by Edward II. New Tipperary was founded outside the town in 1890.

TIPTON, a municipal borough in the Rowley Regis and Tipton parliamentary division of Staffordshire. Eng., 4 mi. S.E. of Wolverhampton. Pop. (1951) 39.382. Area 3.4 sq.mi.

The modern town sprang up around Tibbington, mentioned in Domesday, and the parish registers, dating from 1513, are the oldest in England. The borough was incorporated in 1938. The industries include engineering, iron founding, the making of electrical appliances and many more. The borough has 12 mi. of canals and 7 railway stations.

TIPU SAHIB (1750–1799), sultan of Mysore, son of Hyder Ali (*q.v.*). was born in 1750. He was instructed in military tactics by French officers in the employment of his father. In 1767 in the invasion of the Carnatic he commanded a corps of cavalry and fought against the Marathas on several occasions between 1775 and 1779.

On the outbreak of the second Mysore War in 1780 he mas put at the head of a large body of troops and defeated Brathwaite on the banks of the Coleroon in Feb. 1782. He succeeded his father in Dec. 1782, and in 1784 concluded peace with the British and assumed the title of sultan. He subjugated the Nairs of Malabar in 1787-88 and in 1789 provoked British invasion by ravaging the territories of the rajah of Travancore. When the British entered Mysore in 1790. he retaliated by a counterinvasion, but was compelled by Cornwallis' victory near Seringapatam to cede half his dominions (March 16, 1792). When the British renewed hostilities in March 1799 he was shut up in Seringapatam and killed during the storming (May 4, 1799).

TIRADENTES (JOAQUIM JOSÉ DA SILVA XAVIER) (1 748–1792), Brazilian patriot and martyr, was born at Pomhal, Minas Gerais. With indifferent results he tried a number of professions, including dentistry, from which he derived his sobriquet "tooth puller" (*tiradentes*). Enlisting in the Portuguese army, he rose quickly to the rank of lieutenant of the cavalry but was unable to gain further promotion.

In 1788 he took a prominent part in a conspiracy. the so-called *Conjuração mineira,* inspired partly by the example of the United States and aiming at Brazilian independence from Portugal. Betrayed the following year, the leaders of the plot were arrested and tried. Tiradentes was executed: the others were exiled. Three decades later. after Brazil gained independence, Tiradentes became a national hero.

Tiradentes appears to have been motivated by a combination of personal and patriotic aims: frustration in his career and resentment against the advantages enjoyed by Portuguese-born officials, as well as a desire to end Portuguese domination so that Brazil's great wealth might be employed for the benefit of the Brazilian people' His political ideas were poorly defined hut he anticipated future developments nith his call for the abolition of slavery, improved educational opportunities and social assistance to large families. (R. E. P.)

TIRAH, a mountainous tract on the Afghanistan-Pakistan frontier, west of Peshawar, West Pakistan. It lies between the Khyber pass and the Khanki valley and is inhabited by the Afridi and Orakzai tribes. It is chiefly notable as the scene of the Tirah campaign of 1897–98. It is a cul-de-sac in the mountains, lying off all the roads into Pakistan, comprises an area of between 600 and 700 sq.mi. and includes the valleys lying round the source of the Bara river. The five chief valleys are Maidan, Rajgul, Waran, Bara, Mastura. The chief passes are Sampagha pass (6,500 ft.), separating the Khanki valley from the Mastura valley; the Arhanga pass (6,995 ft.), separating Mastura valley from Maidan; Saran Sar (8,650 ft.), leading from the Zakka Khel portion of Maidan into the Bara valley; the Tseri Kandao (8,575 ft.), separating Maidan from the Waran valley; and the Sapri pass (5,190 ft.), leading from the east of the Mastura valley into the Bara valley in the direction of Mamanai.

Tirah Campaign. — This was an Indian frontier war in 1897–98. The Afridis had for 16 years received a subsidy from the Indian government for safeguarding the Khyber pass, and the government had maintained for this purpose a local regiment composed of Afridis. Suddenly, however, the tribesmen rose, captured all the posts in the Khyber held by their own countrymen and attacked the forts on the Samana ridge near Peshawar. It was estimated that the Afridis and Orakzais could, if united, bring from 40,000 to 50.000 men into the field.

The general commanding the Tirah expedition was Gen. Sir William Lockhart, commanding the Punjab army; he had under him 34,882 men, British and Indian, in addition to 20,000 followers. The frontier post of Kohat was selected as the base of the campaign, and it was decided to advance along a single line. On Oct. 18 the operations commenced. The Dargai heights, which commanded the line of advance, were captured without difficulty, but abandoned because of lack of water. On Oct. 20 the same positions were gallantly stormed by the Gordon highlanders and 3rd Sikhs, with a loss of 199 killed and wounded. The progress of the expedition, along a wretched track through the mountains, was obstinately contested on Oct. 29 at the Sampagha pass leading to the Mastura valley, and on Oct. 31 at the Arhanga pass from the Mastura to the Tirah valley. The force, in detached brigades, then proceeded to traverse the Tirah district in all directions and to destroy the fortified hamlets of the Afridis. The two divisions available for this duty numbered about 20,000 men. A force about 3,200 strong, commanded by Brig. Gen. Richard Westmacott, was first employed to attack Saran Sar, which was easily carried, but during the retirement the troops were hard pressed. On Nov. 11 Saran Sar was again attacked by the brigade of Brig. Gen. Alfred Gaselee. The traversing of the valley continued, and on Nov. 13 Brig. Gen. F. J. Kempster's brigade visited the Waran valley via the Tseri Kandao pass. On Nov. 16, during the return march, the rear guard was hotly engaged all day and had to be relieved by fresh troops next morning. The casualties numbered 72. Almost daily the Afridis, too wise to risk general engagements, waged a guerrilla warfare. On Nov. 21 a brigade under Brigadier General Westmacott was detached to visit the Rajgul valley. The road was exceedingly difficult and steady opposition was encountered. The last important work undertaken was the punishment of the Chamkannis, Mamuzais and Massozais. This was carried out by Brigadier General Gaselee, who joined the Kurram movable column ordered up for the purpose. The Mamuzais and Massozais submitted immediately, but the Chamkannis offered resistance on Dec. 1 and 2. The Kurram column then returned to its camp, and Lockhart prepared to evacuate Tirah, dispatching his two divisions by separate routes — the 1st under Maj. Gen. W. Penn Symons to return via the Mastura valley, destroying the forts on the way, and to join at Bara, within easy march of Peshawar; the 2nd division under Maj. Gen. Yeatman Biggs, and accompanied by Lockhart, to move along the Bara valley. The base was thus to be transferred from Kohat to Peshawar. The return march began on Dec. 9. The cold was intense. The movement of the 1st division, though arduous, was practically unopposed, but the 40 mi. to be covered by the 2nd division were contested almost throughout. The actual march down the Bara valley (34 mi.) commenced on Dec. 10 and involved four days of the hardest fighting and marching of the campaign. The road crossed and recrossed the icy stream, while snow, sleet and rain fell constantly. On the 10th the casualties numbered about 20. On the 11th about 50 or 60 casualties were recorded among the troops, many followers were killed or died of exposure and quantities of stores were lost. On the 12th the column halted for rest. On the 13th the march was resumed in improved weather, though the cold was still severe. The rear guard was heavily engaged and the casualties numbered about 60. On the 14th, after further fighting, a junction with the Peshawar column was effected. The 1st division, aided by the Peshawar column, then took possession of the Khyber forts without opposition. Negotiations for peace were begun with the Afridis, who at length agreed to pay fines and to surrender the rifles demanded. The expeditionary force was broken up on April 4, 1898.

See C. E. Callwell, *Tirah* (1911) ; H. D. Hutchinson, *The* Campaign in *Tirah (1898).* (C. J. B.; X.)

TIRANE (Alb. TIRANË), the capital of Albania, lies at the southern end of the fertile plain of Kruje, 20 mi. inland from the Adriatic coast, on the Ishm river. It is beautifully situated at the foot of the wooded highlands. It was founded early in the 17th century by a Turkish general, Barkinzadeh Suleiman Pasha. At the beginning of the 20th century it had about 15,000 inhabitants; nearly three-quarters of the total were Moslem, the remainder being Orthodox or Roman Catholic. In 1955 the population was 108,183.

Tirane was chosen as capital of independent Albania in 1920 by a congress of Albanian patriots held at Lushnja. Under the reign of King Zog I considerable new quarters were built by Italian architects with government offices around Skanderbeg square. The biggest of the city's many mosques is the Haji Ethem, completed in 1821. Tirane was occupied by Italy in April 1939, at which time it had about 35,000 inhabitants, and was recovered by the Albanians from the Germans on Nov. 17, 1944. On Jan. 11, 1946, a people's republic was proclaimed there. New residential districts were built and about 20 factories erected by Russian specialists. In 1950 a hydroelectric power station was completed nearby, supplying the capital with electric power and water. In 1951 Tirane was linked by rail with the port of Durazzo (Durres). In addition to elementary and secondary schools, there are vocational schools and six institutions of higher education. There are also four museums, a national theatre and a concert hall.

TIRARD, PIERRE EMMANUEL (1827–1893), French politician, was born at Geneva, Switz., on Sept. 27, 1827. Elected mayor of the 2nd *arrondissement* in 1870 and representative of the Seine *département* in the national assembly in Feb. 1871, he withdrew to Versailles after the outbreak of the Commune. In 1876 he was returned for the 1st *arrondissement* of Paris to the chamber of deputies. He held office in a series of ministries between 1879 and 1885, and when Sadi Carnot became president of the republic in 1887 he asked Tirard to form a ministry. His refusal to proceed to the revision of the constitution of 1875 led to his defeat on March 30, 1888. He returned to power the next year, but resigned on March 15, 1890, on the question of the Franco-Turkish commercial treaty. He replaced P. M. Rouvier in the A. F. J. Ribot cabinet (1892–1893) as minister of finance, and died in Paris on Nov. 4, 1893.

TIRE. The tire of a wheel is the outer circumference portion that rolls on the ground or on a track prepared for it. Railway vehicle wheels usually have hard steel tires, which together with the hard steel rail give high endurance and low rolling resistance. The common tire for the exterior rim of nonmotor road vehicles which serves to hold together the parts of the wheel is ordinarily made of steel or iron in the form of a flat hoop fitted tightly over the exterior of the wheel. Its chief attributes are strength, durability and resistance to wear. On airplanes, bicycles, automobiles and other motor-driven vehicles in which freedom from shock is sought, pneumatic rubber tires are almost universally used. Solid rubber tires are employed mostly on industrial trucks for use in warehouses and factories.

The principle of the pneumatic tire was patented by Robert William Thomson in England in 1845, in France the following year and in 1847 in the United States. Thomson's patent substantially covers the tire as it is known today. It showed a nonstretchable outer cover and an inner tube of rubber to hold air. An early set of tires made on this basis covered 1,200 mi. when placed on an English brougham.

FIG. 1.—CROSS SECTION OF SOLID TIRE

Almost half a century later, when the bicycle became popular, pneumatic tires were revived by John Boyd Dunlop of Belfast, Ire. He obtained patents in England in 1888 and 1889 on bicycle tires, which served as the foundation of the Dunlop company. This company early acquired the patents of Charles K. Welch in England (1890) and of A. T. Brown and G. F. Stillman of Buffalo, N.Y. (1892), pertaining to a method of fastening the tire by wires running through thickened edges of the fabric, engaged by a channeled metallic rim. The Brown and Stillman patent became the basis for the Dunlop company's tire business in the United States and for licences by Dunlop to other rubber companies to make wired-on tires.

In 1890 the first "clincher" tire, held in position by inwardly curved flanges of the wheel rim, was patented by William Erskine Bartlett in England, and in 1892 by Thomas B. Jeffery in the United States. The thread or cord tire was patented by John Fullerton Palmer in England and in the United States in 1893. Pneumatic tires were first applied to motor vehicles by the French rubber manufacturers Michelin and company. Rubber tires were adopted by Panhard and Levassor and other French automobile manufacturers about 1895. The first tires used in the U.S. on commercial motor vehicles were made by the B. F. Goodrich company in 1896 for Winton cars manufactured in Cleveland, O. These were single-tube tires.

TYPES OF TIRES

Rubber tires are of two types: (1) solid or cushion tires, in which the rubber portion functions to carry the load, to absorb shocks and to resist cutting and abrasion; and (2) pneumatic tires, in which the load is carried and the shocks are absorbed mainly by compressed air. The structure of the pneumatic tire is designed to provide a nonextensible but flexible cover with impermeable lining to contain and restrain the compressed air. This cover is provided with a rubber tread portion designed to withstand the cutting and abrasive wear of road contact and to protect the tire against puncture and loss of air. Such a structure has, as distinct from a solid rubber or cushion tire, no capacity in itself either to carry load or to absorb shocks. It is entirely dependent on the contained compressed air to enable it to function, and is therefore correctly named a pneumatic tire.

Solid Tires.—Introduced in 1881 on the wheels of hansom cabs in London and formerly used for many types of road vehicles, these disappeared from highways, mostly because of legislation that discouraged their use because they were hard on roads. Large sizes were supplanted by large pneumatic tires (truck and bus casings), but small solid tires came to be used extensively on industrial trucks and tractors. Some of these are made with metal base bands to which the rubber (and in some cases, rubbery polyurethan compositions) is firmly attached. (See fig. 1.) These bands are the full width of the base of the tire and are often dovetailed to secure firm anchorage of a hard-rubber layer interposed between the metal and the soft rubber constituting the main portion of the tire. Alternatively, the soft rubber may be adhered directly to the base either by means of brass plating or an adhesive layer. This type of tire is forced over the periphery of the wheel in a hydraulic press and remains fixed for the period of its life. In other cases the tire is vulcanized directly to the rim of a metal wheel instead of to a separate band.

FIG. 2.—CROSS SECTION OF SEMI-CUSHION SOLID TIRE

Cushion Tires.—There are a number of variations of the solid tire which are designed to provide greater deflection under load and increased cushioning against shocks. These objectives are attained by the use of softer rubber compounds and by insertion of cavities in the tire. (See fig. 2.)

Pneumatic Tires.—The simplest form of pneumatic tire is that known as the single-tube tire. It consists of an endless tube of rubber-coated fabric having on its inner face an impermeable rubber lining and on its outer surface a covering of rubber to protect the fabric from wet or damage, with an additional thickness of rubber on the tread portion to resist road wear. In the C.S. the use of single-tube tires for bicycles, which prevailed for many years, gradually diminished because of the difficulty in repairing them. Single-tube tires, which were discontinued for automobiles about 1900, persisted in low-speed services as on wheelbarrows and hand trucks.

The necessity for a ready means of repair resulted in tires taking the form of a separate inflatable inner tube with a detachable outer cover. Out of a multitude of types of detachable covers introduced in the early 1890s two emerged: the wired-on or straight-side type and the beaded-edge or clincher type.

The wired-on type quickly secured a dominating position in cycle tires, whereas clincher tires were used extensively for several years on automobiles but were dropped as original equipment by U.S. automobile manufacturers in 1923.

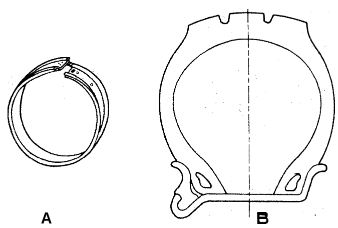

FIG. 3.— (A) TRANSVERSELY SPLIT RIM. (B) WIRED OR STRAIGHT-SIDE PNEUMATIC TIRE ON FLAT-BASE RIM WITH DETACHABLE FLANGE

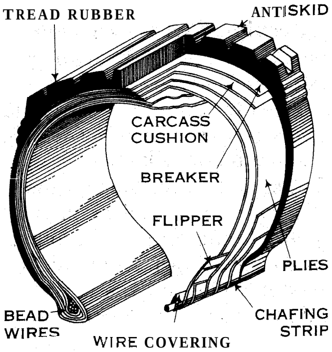
With the development of pneumatic tires the design of rims also underwent change. In the U.S. the straight-side rim of the flat-base type came to be most commonly used for trucks and motor coaches. Its construction varies principally in the method of mounting the tire and in attaching the rim to the wheel. Some of these rims are made with a loose flange of a self-locking type; some have two loose flanges with a separate locking ring; and there is also the transversely split type. They all require the use of a flap or band of rubber to cover the line of contact between the beads and the rim to prevent chafing of the inner tube. For passenger-car tires. a rim, continuously used for cycle tires and known as the well-base or drop-centre rim, mas universally adopted for automobiles both in England and in the U.S. These drop-centre rims enable the tires to be very readily and easily mounted and dismounted. The method, well known to motorists may be briefly described as depressing the endless wired edge of the tire into the well of the rim at one point in its circumference, thus allowing the wired edge of the tire to be lifted over the edge of the rim at the opposite point of its circumference.

Cord and Canvas Tires.—The bodies of pneumatic tires are made universally of parallel cabled cords which are the load-supporting elements of the tire carcass. This form of fabric reinforcement replaced the square woven fabrics of earlier days in which the warp and filling were substantially equal in size and strength. In canvas tires these cross threads under flexure were abraded against each other so that tires developed failures of the carcass (the foundation structure) at low mileages. In cord tires the cords, nhich are surrounded by rubber to protect them against abrasion, are usually made of rayon or nylon. For certain kinds of service, steel cords are used. Cords in bicycle tires are usually made of cotton.

High-Pressure and Low-Pressure (or Balloon) Tires.—The superior performance of cord tires over canvas tires led to developments in which the cross sections of tires were considerably increased, and with these larger sections came the transition to tires with lower inflations to support a given load. These low-pressure (balloon) tires, with cushioning properties superior to the high-pressure tires, became standard equipment on automobiles in the United States after 1933. About 1947 U.S. manufacturers began to furnish automobiles equipped with extra low-pressure tires and to advertise the easier riding quality of cars thus equipped. The table shows the dimensions and air pressures for these three types of tires for approximately the same load-carrying capacity, 900 lb.



BY COURTESY OF U. S. RUBBER CO

FIG. [illegible] STEP-DOWN SECTION OF BALLOON PASSENGER-CAR TIRE

The designation of tire size indicates the type of tire. For example, all high-pressure tires are described by placing first the over-all wheel diameter and second the tire height in inches, thus 32 × 4 in.; in balloon sizes the tire width (sectional diameter) is placed first and rim diameter in inches second, thus 6 × 16 in.

In order to impart to vehicles stability against side sway there has been a consistent trend toward increase in the width of the rims. Thus 6 × 16 in. tires are mounted on rims measuring 4 in.

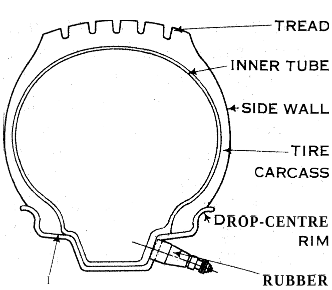
Type	Year	Size designation (in.)	Sectional diam. (in.)	Rim diam. (in.)	Rim width (in.)	Max. tire diam. (in.)	Inflation pressure (p.s.i.)
High pressure	1924	32 X 4	c. 4	24	[illegible]	[illegible]	[illegible]
Lowpressure	1936	6.00×16	6	16	4.00	28.4	[illegible]
Extra low pressure	1947	6.70×15	6.7	15	5.00	28.0	24
	1957	7.50×14	7.5	14	5.50	27.2	22

between flanges instead of 2.97 in., the width of the rims for high-pressure tires, which they superseded. All passenger-car tires are mounted on drop-centre rims. (See fig. 5.)

All rims and tire dimensions and their designations are regulated in the U.S. by the Tire and Rim association, which co-operates with similar groups in other countries with a view to establishing international standards for tire and rim dimensions.

Aircraft Tires.—Modern high-speed airplanes, particularly jet fighters, operating from hard-surfaced runways, have take-off and landing speeds in excess of 200 m.p.h. The stresses set up in the tires on landing and during braking are severe. Moreover, stowage space for the landing gear in the wings is very restricted. Tire designers have met these demands by building small tires of natural rubber tread and carcass stocks reinforced with nylon cords which operate at very high inflation pressures, in the range of 250 to 350 p.s.i. (pounds per square inch). As an example, a 26 × 6.6 tire weighing only 29 lb., inflated to 265 p.s.i. pressure, has a load-carrying capacity of 12,000 lb. and can be used on aircraft with landing speeds up to 250 m.p.h. Under average service conditions, the tread on this tire affords ten take-offs and landings. With the introduction, in 1958, of fabric-reinforced treads by B. F. Goodrich company tire designers, landing speeds up to 300 m.p.h. have been attained.

Farm Tractor and Implement Tires.—Pneumatic tires have become standard equipment on agricultural vehicles, especially in the U.S. and Great Britain. Such tires offer two definite advantages over steel tires: (1) much lower rolling resistance over soft, uneven ground permitting haulage of heavier loads with lower fuel costs; (2) ability to run directly from the farms onto public roads without the fitting of special road bands as were required with the steel tires formerly in use.



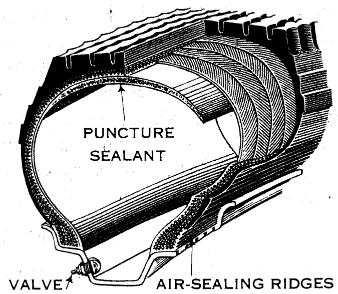
BY COURTESY OF THE B. F. GOODRICH CO.

FIG. 5.— PNEUMATIC TIRE ON WELL-BASE RIM

Off-the-Road Tires.—Most spectacular in appearance are the large pneumatic tires fitted on the earth-moving machinery used in modern road building, airport and dam construction. The larger ones stand up to 8½ ft. high and weigh about one ton apiece. They provide the necessary grip and mobility demanded by 500-h.p. scrapers that can scoop up 40 tons of earth, sand and rock in a minute, transport this load at speeds to 30 m.p.h. and redistribute it at the desired location.

Rigid Breaker Tires.—Sometimes called restricted periphery tires, these (exemplified by the X-type made by the Michelin Co. of France and used to some extent on passenger and sports cars and on trucks and buses) are characterized by extremely flexible side walls but with a tread area as rigid as a steel hoop. These characteristics, quite different from those of ordinary tires, are obtained by altering both the number and distribution of the carcass plies and by altering the angle of the cords with relation to the axis of the tire. Though textile materials can be used, the cords in X-type tires, especially those in the breaker strips, are usually of steel wire. In general, rigid breaker tires have excellent cornering power and excellent tread life in high-speed operation. At low speeds on uneven roads, these tires do not run so smoothly as conventional ones and they tend to be heavy in parking. They show to best advantage on cars which have especially designed suspension and steering systems.

Tubeless Tires.—A puncture-sealing tubeless tire, developed about 1947 and widely sold in the United States, combines a thin lining of butyl rubber as a barrier against diffusion of air into the tire casing with a layer of puncture-sealing material in the crown area. Multiple sealing ridges molded integrally with the bead are compressed against the rim flanges under inflation pressure to form an effective seal without the need for an inner tube. (See fig. 6.)



BY COURTESY OF THE B F. GOODRICH CO.

FIG. 6.— PUNCTURE-SEALING TUBELESS TIRE

Success in the use of tubeless tires led to their adoption as original equipment on the 1955 models of U.S. automobiles. These original-equipment tires were not provided with a puncture-sealant layer. The advantages to motorists of the tubeless type over the inner-tube type of tires include lower unsprung weight on the wheel assembly, less variation in static and dynamic balance, the almost complete elimination of blowout hazards and increased mileage in service. Tubeless tires also find use on airplanes and in truck and bus service.

TIRE CONSTRUCTION

See Rubber: Production and Manufacture for materials used in the industry.

Casings.—The assembly of pneumatic tires consists of a series of steps: the preparation of the cord material, either from viscose rayon (Tyrex) or nylon yarns by twisting (doubling) into cords and in some cases by weaving them into cord fabric; the application of a suitable adhesive treatment to the cords, usually an aqueous dispersion of resins and rubber; drying; and calender coating the cord fabric on both sides with a thin coat of rubber composition at the calender rolls. These rubberized strips are then cut into bias strips of suitable widths and brought to building machines on which the casing is built up, and the wire rings (bead wires) which retain the finished tire upon the rim are enclosed within the edges of the casing. Various parts of rubberized fabric and rubber are added in the form of chafing strips, filler strips, rubber insulation plies and fabric breaker strips, and finally the tread and side-wall coverings are added with care to exclude trapped air or other inclusions between any of the plies. The early practice of building this structure over a core of approximately the finished shape of the tire was generally discontinued.

In the second half of the 20th century tires were built in the form of wide, flat endless bands which, before vulcanization, were subjected to a shaping process either by producing a vacuum outside the band in a forming box or by applying pressure against the inner surface of the band. The tires thus formed may be mounted on expansible rubber bags and placed in steel molds for vulcanization.

For many years it was common practice to stack the molds containing the tires one above another on a hydraulic ram inside a vertical cylindrical steam-pressure vessel. After the cover of the vessel was closed the ram was raised, forcing the halves of the molds tightly together around the tires, and heat was supplied by steam outside the molds while the bags inside the tires were expanded with air, steam or hot water or combinations of them.

Hot water or steam furnished heat from the inside in addition to that supplied by the steam surrounding the molds In some factories the tires and their enclosed bags were each placed and cured in individual, steam-jacketed molds. In later practice the enclosed bags were eliminated entirely by the use of a curing press in which is provided a cylindrical diaphragm (bladder) of special rubber which is inflated by steam to conform the tire casing to the mold during the cure.

This process of vulcanization under pressure results in the molding of the tire into its finished form, uniting all parts firmly, and produces within the rubber mass certain reactions between the rubber and the sulfur and other ingredients which have been previously incorporated in the rubber, resulting in a tough and durable product.

Inner Tubes. — These are to hold the air inside the tire casings. The early practice of vulcanizing straight tubes on cylindrical mandrels and afterward splicing their ends together was abandoned in favour of vulcanization in circular, steam-jacketed molds while the rubber is expanded by air or steam against the mold surface. All tubes are, of course, fitted with nonreturn valves.

Metal valve stems, once universally used, were largely supplanted by flexible rubber stems with metal inserts. Inner tubes are made 15% to 20% smaller in volume than the casings into which they fit. When inflated they expand to fill the inside of the casings. Most inner tubes are made of butyl rubber because it has unusual resistance to air diffusion.

FUNCTION OF TIRES

Cushioning. — When a tire strikes an obstacle protruding above the road surface, the road and the tire both experience shocks, shock impact to the road and shock reaction to the vehicle. In the case of steel-tired wheels or even with solid rubber-tired wheels, these shock reactions are severe at any ordinary speed because the vehicle tends to ride up over the rough spots .in a road. But pneumatic tires, especially the Ion--pressure type. have a high degree of compliance, which is unique, and they cushion the ride by enveloping the road inequalities, permitting the high-speed travel common in the second half of the 20th century.

Avoidance of Slipping. — Depending on the material and smoothness of road surfaces and on weather conditions, the coefficient of friction between tires and road may range widely—from 0.02 to 0.70. Nonskid designs are formed on treads during the vulcanization process when inflation inside the tires expands them against an engraved mold presenting the desired design in reverse. The designs most effective in preventing slipping and skidding on wet. hard surfaces are those that nipe the water from the highway under the tread, permitting the rubber to grip a nearly dry surface. On dirt roads traction and steadiness are enhanced by deformation of the road material as it sinks into depressions in the tire tread. This condition is encountered with farm tractors that are used over plowed ground. Tires for such equipment and snow tires for automobiles are consequently made with sturdy, thick crossbars of rubber.

Cornering Power, Cushioning and Durability. — Directive control of an automobile driven at the prevailing speeds can be achieved sdequately by no other mechanism than the pneumatic tire. The "roadability" of the modern motor vehicle is dependent upon cornering power, the lateral force directed at each In- stant at right angles to the path of travel of the tire and vehicle. Steel-shod wheels, for example, slip and slide if maneuvered at relatively high speeds.

Factors that contribute to the cornering power (sidenise push of the tire against the roadway) of tires are the camber of the wheels, the radial load, the speed, the inflation, rim width, tire size and cord angle. The cushioning properties and durability of tires are also of importance because of considerations of comfort and cost. In the design and construction of tires the elements contributing to cornering power, cushioning and durability have to be reconciled by compromise because they are to a large degree antithetical.

At one time the useful life of tires was limited by failure of the fabric in the carcass. After about 1930 the carcasses of tires usually outwore the tread even though the durability of treads had been greatly improved. The practice of retreading or of recapping tires, often advantageous, was of strategic importance during the years of World War II. Truck tire carcasses of rayon or nylon cord proved remarkably durable and were able in some instances to wear out the original and two or more recapped treads in highway service. In recent years the use of nylon cord in replacement tires for passenger cars has become widespread. The use of natural rubber for truck, bus and airplane tires is standard practice because of its low hysteresis; but smaller-size tires for passenger cars are mostly made of SBR (styrene-butadiene rubber), especially in the U.S. Adoption of the newer oil-furnace carbon blacks (grades HAF and ISAF) in tread compounding has greatly improved abrasion resistance, and some of the newer synthetic rubbers, notably cis-1,4-polybutadiene, promise further improvements in tread durability.

TIREE, an island of the Inner Hebrides, Argyllshire, Scot. Pop. (1951) 1,216. Area (including Skerryvore) 29.5 sq.mi. It lies 2 mi. S.W. of Coll; its length from northeast to southwest is nearly 12 mi.; its breadth varies from $\frac{3}{4}$ mi. to 6 mi, Between Coll and Tiree lies the Isle of Gunna. Tiree is composed of rocks of Lewisian gneiss mostly covered with blown shell sand (machair). Ben Hynish (460 ft.) is its highest point. The machair, when dressed with cobalt, makes fertile arable land. Clydesdale horses are bred on the island. Green-spotted pink marble is mined. The vast beaches and the lakes, especially Loch Bhasapoll, attract thousands of ducks! terns and other birds on migration. Steamers from Oban call regularly at Scarinish and there is a daily air service from Glasgow. Skerryvore lighthouse, on a lonely rock in the Atlantic about 12 mi. S.W., was completed in 1844.

TIRIDATES or TERIDATES, a Persian name, given by Arrian in his Parthica (preserved by Photius, cod. 58, and Syncellus, pp. 539 ff.) to the brother of Arsaces I, the founder of the Parthian kingdom, whom he is said to have succeeded. But Arrian's account seems to be quite unhistorical (cf. PARTHIA).

The king commonly called TIRIDATES II was set up by the Parthians against Phraates IV in 32 B.C., but expelled when Phraates returned with the help of the Scythians (Dio Cass., vol. li, p. 18; Justin, vol. xlii, pp. 5 ff.; cf. Horace, Od., vol. i, p. 26). Tiridates fled to Syria, where Augustus allowed him to stay, but refused to support him. During the next years Tiridates invaded Parthia again; some coins dated from March and May, 26 B.C., with the name of a king Arsaces Philoromaios. belong to him; on the reverse they show the king seated on the throne, with Tyche stretching out a palm branch toward him. He was soon expelled again, and brought a son of Phraates into Spain to Augustus. Augustus gave the boy back to his father, but declined to surrender "the fugitive slave Tiridates" (Justin, vol. xlii, p. 5; Dio, vol. liii, p. 33; cf. *Mon. Ancyr.*, 5:54; in vol. li, p. 18, Dio wrongly placed the son's surrender in 30 B.C.).

TIRIDATES III, grandson of Phraates IV, lived as a hostage in Rome and was educated there. When the Parthians rebelled against Xrtabanus 11 in A.D. 35, they applied for a king to Tiberius, who sent Tiridates. With the assistance of L. Vitellius, Tiridates entered Seleucia. but could not maintain himself long (Tacitus, *Ann.*, vol. vi, pp. 32 ff.; Dio Cass., vol. lviii, p. 26). (ED. M.)

TIRLEMONT (Flemish THIENEN), a town in the province of Brabant, Belg., 11 mi. S.E. of Louvain. Pop. (1947) 22,383. It still preserves its enceinte, 6 mi. in circumference. The principal church, Our Lady of the Lake, begun in the 12th century and enlarged in the 15th, is still unfinished. The church of St, Germain, also 12th century, contains a fine altarpiece by Wappers.

TIRMIDHI (ABU ISA MOHAMMED IBN ISA UT-TIRMIDHI) (d. 892), Arab traditionalist, was born at Tirmidh on the Jihun. He travelled through Khurasan, Iraq and Hejaz. His *al-Jami us-Sahih* (published at Bulaq, 1875) is one of the six canonical collections of traditions. He included every tradition that had ever been used to support a legal decision. He also wrote the *Kitab ush-Shamail* (printed at Calcutta, 1846) on the character and life of Mohammed.

TIROL or TYROL, a province of Austria, 135 mi. long, with an average width of 35 mi. and an area of 4,882 sq.mi. It is wholly alpine and consists of the basin of the Inn river together with the upper Lechtal.

Physiography. — The province includes three east-west belts — the North Tirolean Alps, the Inn valley and the northern slopes of the Central Alps. The northern ranges and the Lechtal constitute a limestone region characterized by jagged skylines, deeply cut valleys and high plateaus. It is a barren, unproductive and thinly populated region. The Inn from Landeck to Innsbruck follows the lithological boundary between the limestone regions and the crystalline band of the Central Alps. East of Innsbruck the southern highlands are of shales and slates, and the *Almen* provide rich pastures. The river finally cuts north through the limestone country at Kufstein, having traversed from Landeck a sheltered and agriculturally rich valley nearly 100 mi. long and averaging a mile broad. The river is incised in a rather flat floor bordered by terraces which are intensively cultivated, both wheat and maize growing well. There are also many orchards. An almost continuous line of village settlements runs along the middle terraces where soil and drainage are good; they are above the winter fogs, receive abundant sunshine and enjoy the benefit of the *Fohn* winds (43 days, average at Innsbruck).

On the crystalline hills south of the valley, life is of the classical alpine type, based on cattle rearing and dairying with transhumance. The highest part of Tirol lies south of the Inn, along the ridge of the Central Alps — the Ötztal Alps (Wildspitze. 12,382 ft.), the Stubai and Zillertal Alps, descending to the lower Kitzbühl Alps; with another ridge running east and south along the Hohe Tauern (Grossglockner, 12,461 ft.) to the Pusertal. (See also ALPS; AUSTRIA.)

The climate of Tirol is bright and sunny. The abrupt scarps of the limestone country overlooking the Inn valley shut out cold northerly winds. Rainfall is only half that of the Bavarian foreland north of the ridge, and temperatures are appreciably higher. Sunshine records at Innsbruck are nearly three times those of Vienna.

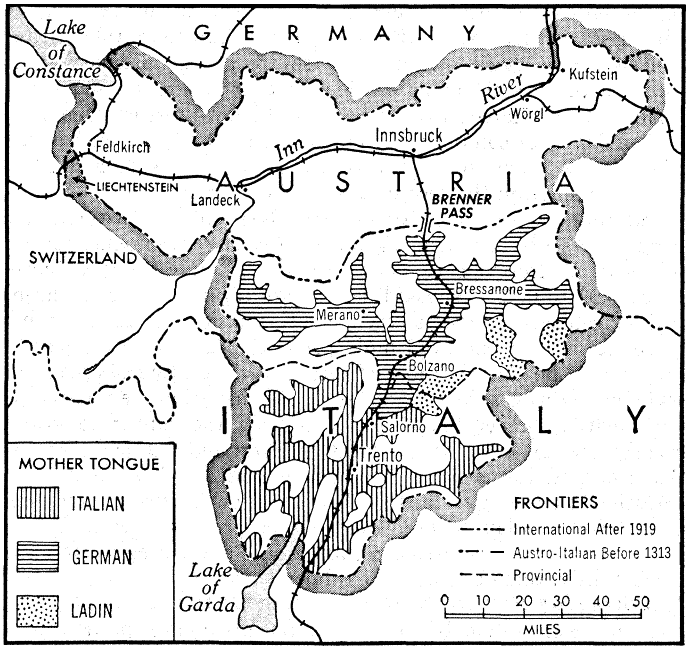
Population. — The population (1951 census, 426,271) is almost entirely German in speech and Roman Catholic in religion. It is surprisingly dense along the Inn (250 per square mile) in comparison with the rest of Austria (214 per square mile for the whole country); but Tirol as a whole has the least dense population of all the provinces. Quite one-third of the population lives at altitudes of more than 2,400 ft.; and tiny hamlets are found up to nearly 6,000 ft. Innsbruck (*q.v.*) is the only large town, with a population (1951) of 95,055.

Industry. — In the early and middle ages Tirol was an important mining area, more particularly for silver (at Schwaz) and copper, but its mineral output is now insignificant. Salt, brought from the Salzberg as brine, is still worked at Hall, and cement is manufactured at Wörgl and Kufstein. The many streams provide abundant opportunities for hydroelectric power plants. The main railway line from the Arlberg tunnel to Vienna is electrified. The most important industry in the Tirol, however, except for agriculture, is the tourist industry, for the grandeur of the mountain scenery is enhanced by the sunny climate. (T. HER.)

HISTORY

In 15 B.C. the Rhaetians, who inhabited the country later known as the Tirol, were defeated by Drusus and Tiberius, the stepsons of Augustus, and their territory became the Roman province of Rhaetia separated from Italy by a frontier which crossed the River Isarco (Eisack) at Chiusa (Klausen). The Christianization of the territory began about A.D. 400. After 600 years of Roman rule the modern Austrian *Land* of Tirol-Vorarlberg was occupied by the Baiovarii (Bavarians) who flowed over the Brenner into South Tirol, the modern Italian province of Bolzano (Bozen) or Alto Adige. About the same time the province of Trent (Trentino) to the south was occupied by the Lombards and therefore remained of the same language and culture as the rest of Italy, whose originally German-speaking Lombard conquerors had been assimilated by their Italian subjects.

Bavaria and Lombardy were absorbed into the Carolingian empire in the 8th century and later passed to the German kings who succeeded in part to that empire. In 1004 the Saxon emperor Henry II gave land in the Brenner area to the bishop of Trent, and in 1027 Conrad II enlarged this fief by the counties of Bozen and Vintschgau, bestowing the counties north of this line on the bishop of Brixen (Bressanone). It was at this time the imperial policy to make the church the instrument of royal, as distinct from princely, control; and these bishops held their lands directly from the emperor, not from the dukes of Bavaria. However, they delegated their secular rule, mainly to the counts of Tirol. who took their name from the castle of Tirol near Merano but who gradually extended their rule over the whole of Tirol. The lands ruled by the counts of Tirol were eventually inherited by Margaret Maultasch (*q.v.*). On the death of her son in 1363 Margaret made over Tirol to the duke of Austria, Rudolph IV, and from that time until the breakup of the Austrian empire at the end of World War I Tirol was a Habsburg possession. In the 16th century the doctrines of the Reformation made considerable progress in Tirol and were largely responsible for a formidable peasants' revolt in 1525. But Protestantism was completely stamped out in the area in the second half of the century. In 1803 Tirol (entirely German in speech with the exception of some surviving Ladin in the south) was enlarged by the addition of the Italian-speaking province of Trentino, which had remained until then an independent prince-bishopric of the Holy Roman empire.



TIROL AND SURROUNDING AREAS, SHOWING THE DISTRIBUTION OF PRINCIPAL LANGUAGES AT THE ITALO-AUSTRIAN FRONTIER

Tirol was a land of intense provincial pride, with a strong feeling for its own institutions and local government, its people thinking of themselves as Tirolese rather than Austrian. Accordingly when in 1805 after the treaty of Pressburg, Napoleon established French and Bavarian rule in the area, the people found it intolerable. Bavaria meddled with matters that Vienna had wisely left to Tirol itself. Consequently in 1807 there was a rising under Andreas Hofer (q v.) during which a surprising number of defeats were inflicted on the occupying troops. But after the peace of Schonbrunn (1809) had given Tirol mainly to Bavaria (the south went to Italy and Lienz to Illyria, then French), the revolt was ruthlessly crushed. Hofer was shot in Mantua on Feb. 10, 1810, it was said, by Napoleon's express order. The treaty of Paris (1814) reunited Tirol and restored it to Austria. Northern Tirol was well pleased, but the Italian-speaking province of Trentino became a focus of irredentist claims against Austria, an irredentism which grew steadily stronger from 1870 until the outbreak of World War I in 1914.

The South Tirol Question. — From the beginning of World War I the Italian government negotiated both with Austria and nith the Allies on a price for Italy's co-operation. Austria was prepared to cede Trentino, but would yield nothing further. Italy thereupon signed the secret treaty of London (1915) with the Allies by which it was promised among other rewards the Brenner frontier. In 1919 the treaty of St. Germain fixed the Italo-Austrian frontier on the Brenner and handed over to Italy not only Italian-speaking Trentino, but the whole of South Tirol (5,420 sq.mi.), called by Italians the province of Bolzano, where, according to the Austrian census of 1910, there were 215,796 German-speaking Tirolese against 16,510 Italians and 5,990 Ladins. (These last speak a Rhaeto-Romanic language similar to the Romansh of Switzerland.)

Italy was bound by no treaties for the protection of minorities such as were signed by lesser states in 1919, and, although its ministers declaimed in 1919 that Italy was under a moral obligation to apply the provisions of the minorities treaties, a disregard for the rights of a minority developed into an oppressive tyranny with the advent of the Fascists to power in 1922. Efforts were made to stamp out the German language by educational measures, by putting Italian-speaking officials in administrative posts and by settling Italians, largely from the overpopulated regions of south Italy, in the towns.

On Oct. 21. 1939, Germany and Italy signed an agreement under which the South Tirolese were to opt once and for all for transfer to Germany or for the retention of Italian citizenship. Of the 267,000 German-speaking Italian subjects in the provinces of Bolzano. Trentino. Belluno and Udine 185,365 opted for Germany, including 166,500 (73%) in the province of Bolzano. Since half the population were engaged in farming and most of these families had been settled on their farms for centuries the size of the vote for migration to Germany showed the strength of the hatred of Italian rule. About 70,000 actually left Tirol, mostly people from the towns.

In 1945 there was a strong feeling in Great Britain as well as in Austria that an injustice had been done in 1919. The history of the area suggested that a strategic frontier might have been found further south of the Brenner, where the deep Salorno gorge forms a natural barrier and that a line might have been drawn along the Italian provincial boundary betneen Trentino and Alto Adige, this line uould also largely have coincided with the ethnic boundary. (See map.) The strongest point, however, in the Italian case for the retention of Alto Adige lay in the economic development of the province betneen 1919 and 1939. By 1939 Alto Adige had become one of the chief sources of the hydroelectric poner essential to the industries of the north Italian towns. Other industries, particularly the chemical and aluminum, had also been developed in Bolzano.

The Council of Foreign Ministers finally decided in 1946 that there would be no change in the Italo-Austrian frontier. But article 10 of the Italian peace treaty of 1947 bound Italy to make arrangements with Austria to guarantee free movement of passenger and freight traffic between North and East Tirol, and took formal note of the agreement made between Italy and Austria in Paris on Sept. 5. 1946. This agreement promised complete equality of rights to the German-speaking inhabitants of Alto Adige and of the neighbouring bilingual townships of the province of Trentino and undertook to grant a measure of legislative and executive autonomy to the population.

By a decree of Feb. 2, 1948, the Italian government made it possible for Tirolese who opted for Germany to return and recover their Italian nationality. By Sept. 30, 1952, 28,593 applications had been made of which 1,012 were refused on the ground of the applicants' past associations with Naziism.

The Italian constitution of 1948 recognized Trentino-Alto Adige as one of the five special regions which should have a considerable measure of legislative and executive autonomy. But, as the region included Trentino as well as Alto Adige, there was an Italian majority in the region as a whole. According to the census of 1951, the autonomous region had a total population of 728,604. An Italian source gave the estimate of the population of the Alto Adige on Oct. 31, 1953, as follows: German-speaking inhabitants 214,257; Italian 114.568; Ladin 12,696. Further, the powers of local government within the region granted to the provinces of Bolzano (Alto Adige) and Trentino were narrowly limited, and the German-speaking population consequently felt that the Italian interpretation of the 1946 agreement was not wholly satisfactory. At the general election of June 7–8, 1953, the Sudtiroler Volkspartei obtained 122,474 votes and gained three seats in the Italian chamber of deputies.

TIRPITZ, ALFRED VON (1849–1930), German admiral and chief builder of the German navy at the turn of the century, was born on March 19, 1849, at Kiistrin, Brandenburg. He entered the Prussian navy in 1865 and became an officer in 1869. In the 1880s he was the fleet's outstanding torpedo specialist. After serving during 1892–96 as chief of staff of the navy high command, he commanded the far eastern cruiser division and selected Tsingtao, China, as a future German naval base. On June 16, 1897, he was appointed secretary of state for the navy, his position for almost 20 years. Created a noble in 1900, he attained the rank of admiral in 1903 and of grand admiral (*Gross*-admiral) in 1911.

On the evaluation of his personality, of his aims, unflinchingly set on a definite course, and of his successes and failures largely depends the historical judgment on the short period of German imperialism; for. with the gifted but erratic and dilettante emperor William II, Tirpitz was its dominant figure. The association of these two personalities was the fateful coincidence which determined the splendour and the fall of the German empire. The military prerogatives of the emperor under the Bismarck constitution, combined with the naval mania and ambition of William II, had led in 1889 to the splitting up of the admiralty into the *Reichsmarineamt* (office of the secretary of state fr the navy) for administration, the *Oberkommando* der *Marine* (navy high command) for plans and operations and the imperial *Marine-Kabinett,* a counterpart to the royal (Prussian) military cabinet, for officer personnel. This arrangement immensely strengthened the direct influence of the monarch on navy matters.

To transform a coast defense force into a high seas battle fleet in less than two decades was an achievement comparable only with the creation of the Russian fleet by Peter the Great. Tirpitz was a born, sometimes an overbearingly ruthless, leader. His qualities are beyond question: fervent patriotism, cleverness, administrative ability in the technical domain and in the domain of organization, capacity for detailed work as well as for plannicg on a grandiose scale, inexhaustible energy and indefatigable industry. He could be aggressive and conciliatory, pressing and patient. None of his co-actors on the political scene — three chancellors of the reich and seven secretaries of state of the foreign ministry among them — equalled him in strength. Bismarck and Tirpitz represent the two different eras of imperial Germany. When visiting Bismarck in 1897. Tirpitz felt that the founder of the German empire still lived with the idea of Germany in 1871 and of England in 1864.

Naval Program.—Modern imperialism found its military expression in the "new navalism" of the 1890s, and Germany was no exception. Tirpitz brought Germany within 16 years from the sixth place among sea powers to the place next to Great Britain.

As chief of staff of the navy, Tirpitz developed the principles of offensive navy tactics under the recognizable influence of convictions held by Gen.-Adm. Albrecht von Stosch, chief of the admiralty, 1872–83, his venerated mentor. His tactical memorandums applied the offensive idea of land warfare to the navy, deriving the necessity of offensive action from the strategic defensive.

The *Flottennovelle* of 1898 created the basis for building a fleet according to a plan fixed by law; it provided for a navy of 17 battleships and a cruiser force of 9 large and 26 small cruisers to be built in six years. Such a navy was regarded as strong enough for limited offensives in a war against France and Russia. The navy law of June 14, 1900, expanded the building plan and set 1917 as the year of completion. By this time the German battle fleet provided by the 1898 bill was to be doubled. Supplementary laws of 1904, 1906, 1908 and 1912 were further steps in expanding the navy. The fleet of 1920 was to comprise 41 battleships and 20 large and 40 small cruisers, the battle fleet consisting of three active battleship squadrons.

Political Aspects.—Seen in retrospect, the navy law of 1900 appears as Germany's declaration of "cold war" against Great Britain. For the real goal of Tirpitz was not so much the defense of the German coast or protection of German overseas trade; it was nothing less than a change in the distribution of world power, although conceding a certain margin of naval superiority to Britain. Germany's bold attempt to intrude in the sphere of naval supremacy led to catastrophe. German statesmen did not grasp the political significance and potentialities of naval power or realize that the building of the German navy radically changed the Bismarckian concept of Germany's position in the world. They clung tenaciously to the alliance with Austria-Hungary and Italy, adding prestige liabilities by their Turkish policy. German naval policy was not supplemented by an appropriate revision of Germany's alliance policy.

Tirpitz favoured a pro-Russian orientation, believing that by coalition with other navies a certain new balance of power on the sea, comparable with the continental balance of power, could be established. German imperialism made its cardinal mistake by overestimating German strength, thus simultaneously provoking British enmity by building a competitive navy and Russian hostility by clashing with Russian interests by an active near east policy.

The Germans bitterly resented Winston Churchill's statement (Feb. 9, 1912) on the German *Luxusflotte,* but the British stand in the naval competition could hardly have been defined more precisely: "The purposes of British naval power are essentially defensive . . . The British navy is to us a necessity, and from some points of view the German navy is to them more in the nature of a luxury."

Tirpitz coined the phrase of the temporary "danger zone" which Germany had to pass through in its relationship to England during the construction of the navy, until it became a *Risikoflotte; i.e.,* a navy of such strength that war against it would endanger the superiority of even the strongest navy. The theory of the *Risikoflotte* hypnotized the German people. Based on the assumption that French and Russian enmity against Great Britain could be regarded as permanent factors in international relations, it became invalid when Great Britain's previously isolationist position was changed by the alliance with Japan and the entente with France and Russia. Both slogans, the danger zone and the *Risikoflotte,* proved to be fallacious; the danger zone became unending. since in the Anglo-German naval rivalry a static relationship of mutual strength over a long period of time never was established.

A master propagandist, Tirpitz wielded influence on the kaiser through the naval attachés, his devoted aides. Through his press office, through the *Nauticus* yearbook and the Navy league (Flottenverein, since 1898) he influenced the *Reichstag* and the general public Anglophobically, creating a general sentiment which limited the freedom of responsible German statesmen to negotiate an accord with England. The German Colonial league and the Pan-German league served as propaganda auxiliaries.

Pushing the construction of the battle fleet, Tirpitz before 1914 was opposed to large-scale submarine and naval airship building, lest the navy become a "museum of experiments."

The "Dreadnought" (1906) revolutionized naval architecture and strategy and sharpened the Anglo-German conflict. A new phase in the armament race started when the Germans immediately took up construction of the same type of giant battle ships. Between 1908 and 1912, a period of frantic but futile search for a mutually acceptable formula of armament limitation, Tirpitz exercised decisive influence on Anglo-German relations—an influence heightened by the emperor's siding with Capt. Wilhelm Widenmann, the naval attaché in London, against the ambassador, Count Paul Wolff-Metternich.

War and Postwar Activities.—Seldom has the combination of fierce economic rivalry, unbridgeable political positions, an atmosphere of deep-seated mutual suspicion, misunderstandings, miscalculations, misinformation and provocative utterances on both sides led to more tragic consequences, culminating in 1914 in the Anglo-German war. But the war brought about Tirpitz' deepest disappointment: the mighty weapon which he had forged was not employed. His repeated efforts to obtain command of the navy and exercise decisive influence on its use. either by the creation of a supreme navy command or by becoming himself commander of the high seas naval forces. were rejected. While the army was defeated in applying "the recipe of victory of dead Schlieffen" (Tirpits), he was refused opportunity to try out his plan for victory on the high seas. To subjugate England he became an early advocate of mercantile submarine warfare, which, after his resignation, brought the United States into the war, making inevitable Germany's ultimate collapse.

Snubbed by the government in the deliberations about submarine warfare, Tirpitz resigned on March 1S, 1916, from the navy secretaryship.

In retirement he was identified with rightist movements such as the annexationist Vaterlandspartei in 1917–18. A member of the *Reichstag,* 1924–28, for the Deutschnationale Volkspartei, he persuaded the reluctant Paul von Hindenburg to accept the nomination as candidate for the presidency in 1925.

Tirpitz died in Ebenhausen, near Munich. on March 6. 1930.

TIRSO DE MOLINA (pseudonym of the Spanish dramatist, GABRIEL TÉLLEZ) (*c.* 1584–1648), who was born at Madrid, studied at the University of Alcalá and was professed in the Mercenarian order of which, as its official historian, he wrote the *Historia de la Merced,* and in which he was a theologian of repute. Guided to drama by an inborn sense of the theatre, and inspired by the achievements of Lope de Vega. he built on Lope's national foundations to Lope's free-and-easy prescriptions, sometimes accentuating the religious and philosophical aspects that attracted his theological interest, sometimes drawing on his own topographical and historical knowledge, stored while travelling on the business of his order through Spain, Portugal and the West Indies, sometimes borrowing from the vast common stock of Spanish stage material and sometimes relying on his fantastic imagination.

Three of his dramas appear in *Los Cigarrales* de *Toledo* (1621), a set of verses, tales, plays and critical observations which, arranged after the Italian fashion in a picturesque framework, affect to provide a series of summer recreations for a group of friends. Otherwise his extant output of about 80 dramas, a fragment of the whole. was published chiefly in five *Partes* between 1627 and 1636.

Part ii, containing several of his famous pieces, presents apparently insoluble problems of authenticity, and the authorship of certain others outside this *Parte* has also been disputed.

The most powerful dramas associated with his name are two tragedies: El *Burlador de Sevilla* and *El Condenado por desconfiado*. The first. introducing the hero-villain, Don Juan; himself derived ultimately from popular legends but recreated with Tirsian originality. rises to a majestic climax of nervous tension where the libertine is confronted with the statue-ghost of the man he has killed, and deliberately chooses to defy this emanation of his diseased conscience. El *Condenado por desconfiado* exteriorizes a startling theological paradox by opposing to the case of a notorious evildoer who has kept and developed the little faith he had. and is granted salvation by an act of divine grace, the example of a hitherto good-living hermit. eternally damned for allowing his one-time faith to shrivel. Among the psychological conflicts and contradictions involved in these master characters Tirso is at his best. At times he reaches Shakespearean standards of insight, tragic sublimity and irony. The same qualities are found in isolated scenes of his historical dramas, for instance in *Antona Garcia,* notable for its objective analysis of mob emotionalism; in *La Prudencia en la mujer*, with its modern interpretation of ancient regional strife; in the two parts of *Don Alvaro de Luna*, with its study of the clash of personal and political interests in the friendships of public men; and in the violently realistic scenes of the biblical *La Venganza de Tamar*.

On such occasions Tirso, even against the talented background of Spain's golden age, stands out uniquely. When inspired, he had the rare gift of dramatizing personality, and his best characters are also memorable as individuals. He is more stark and daring than Lope. and less ingenious; more spiritually independent than Calderón. and less poetic. Where he approximates to the golden age norm his plays of types and manners. like El *Vergonzoso en palacio*, are animated, varied in mood and usually lyrical. But his style is erratic and can be trite. In pure comedy he excels in cloak-and-sword situations. and in. for example, *Don Gil de las calzas verdes,* he manipulates a complex, rapidly moving plot with exhilarating vitality. He is famous, in both tragedy and comedy, for his clowns, whose wit has a tonic air of spontaneity. Naturalness .in diction suited his dramatic purpose better than the ornamental rhetoric which was then coming into vogue, and generally he avoided affectations, remaining in this respect nearer to Lope than to Calderón. He is not as consistently brilliant as some of his dramatic contemporaries, but at his greatest, even in comedy, the Spanish speciality, he can rival them, and in tragedy he towers above them all.

TIRUNELVELI (formerly TINNEVELLY), a town and district of Madras state, India. The town is on the left bank of the Tambraparni river, on the other side of which is Palamcottah. the capital of the district. Pop. (1951) 73,476. It is on the South Indian rail ay, 444 mi. S.W. of Madras. A branch line was opened to Tiruchendur in 1923. Its most noteworthy building is a beautifully sculptured temple of Siva.

The DISTRICT OF TIRUNELVELI has an area of 4,344 sq.mi. It is for the most part a plain with an average elevation of zoo ft., sloping to the east with slight undulations. It is watered by numerous short streams, the principal being the Tambraparni with a length of 80 mi. The chief irrigation work is the Srivaikuntam anicut or dam on this river.

In the north the scenery is unattractive and the soil poor; in the south red sandy soil prevails in which little save the palmyra palm will grow. This palm yields toddy as well as a coarse sugar. Along the banks of the rivers are rice fields. cotton, millet, pulse and oilseeds are grown, and cloth, mats. lace and sugar manufactured. There is a trade in cotton stuffs, and fishing is carried on.

The district contains many ancient and magnificent buildings. The population was 2,506,275 by the 1951 census.

The Society for the Propagation of the Gospel and the Church Missionary society have important stations at Tirunelveli town and Palamcottah, as also have the Jesuits.

It was there that St. Francis Xavier began his preaching in India.

The early history of Tirunelveli is mixed up with that of Madura and Travancore. Down to 1781 it is a confused tale of anarchy and bloodshed. In that year the nawab of Arcot assigned the revenues to the East India company, which then undertook the internal administration. Several risings subsequently took place, and in 1801 the whole Carnatic. including Tirunelveli, was ceded to the Eritish.

TIRUPATHI (Telugu "venerable lord"; vulg. TRIPETTY), a famous holy place in Chitoor district, Andhra Pradesh. India, 67 mi. W.N.W. of Madras. The sacred hill range, Tirumalai, has at its base the main town of Tirupathi (pop., 1951, 25,207), noted for brasswork and wood carving, and, above, Upper Tirupathi, the centre of pilgrimage.

There. near Seshachalam (serpent hill): one of the range's seven sacred peaks, is the great temple. No European visited Tirupathi till 1870; none has entered the temple. The cult is of Vishnu. overlaid with non-Aryan ritual elements.

Women undertake at Tirupathi certain ceremonies to ensure fertility and in thanksgiving for childbirth or deliverance from sickness; that girls serve there for several years as "wives of the god" has been alleged.

See A. F. Cox, *Manual of* N. *Arcot District,* p. 146 ff. (Madras, 1881); W. Crooke in *Encyclopaedia of Religion and Ethics,* ed. *by J.* Hastings, xii, *s.v.* "Tirupati" (Edinburgh, New York, 1921).

TIRYNS, a prehistoric fortress and afterward a small Greek city, on an isolated ridge of rock near the east side of the plain of Argos in Peloponnese, about 3 mi. from the coast and from the port of Nauplia. There is a railway station close to the site. In Greek legend it was founded by Proetus, brother of Acrisius, king of Argos. His successor, Perseus, founded Mycenae about 10 mi. farther inland. Later, Heracles there served Eurystheus in many "labours," and Tydeus and his son Diomedes held it. After the Dorian conquest *(see* DORIANS) Tiryns. like Mycenae, declined as Argos grew; it sent its small contingent to fight at Plataea (*q.v.*) in 479, but about 460 it was destroyed by the Argives. Pausanias (*c.* A.D. 170) was shown there the "palace of Proteus," and the "chambers of his daughters." and wondered at the "Cyclopean" walls, the τίρυνς τειχιόεσσα of Homer. *Il.*, ii. 559. The same walls in 1884 attracted the attention of Heinrich Schliemann, the excavator of Troy (1871) and Mycenae (1875), who uncovered, with W. Dorpfeld. a prehistoric "palace" remarkable for many points of resemblance to the house of Odysseus in the *Odyssey;* Schliemann however made only a few soundings into the stratified remains under its floors. These were carefully examined from 1908 onward by members of the German Archaeological Institute in Athens, and though their conclusions were not fully published, the outline of the archaeology of Tiryns as described below is assured.

The natural ridge on which Tiryns stands is about 330 yd. from north to south and 112 yd. at widest from east to west; the greater heights of its southern half now is mainly due to superstructures. From about 2000 B.C. a small unfortified settlement can be traced on and also around this ridge, with three superposed layers of mud-brick houses; on what was probably the summit (under the later *megaron*) was a remarkable round building, nearly 90 ft. across, also of mud brick but roofed with slates and tiles, probably for some public or official use.

About 1600 B.C. the southern half of the ridge was heavily fortified with rude but massive walls, to protect a new "palace" of which the plan is obscure (for it lies underneath its successor), but the arts and industries are derived. like those of the contemporary shaft graves at Mycenae, from the Middle Minoan culture of Crete (*q.v.*). The settlement which it dominated extended several hundred feet south and east of the ridge. Communication was by a gateway in the east wall, underneath the later propylaea. About ½ mi. away, on the hill called St. Elias, cist graves and rock-chambers are found, of various dates, and on the same hill is a ruinous "beehive tomb" like those at Mycenae, Heraeum and Midea, and probably contemporary with them; but nothing has survived from its contents.

The "early palace" perished by violence and was succeeded, about 1300 B.C., by another, which occupied the whole area of the early citadel, and was in turn defended by the massive but rudely-fashioned walls which are now conspicuous. These considerably enlarge the area of the fortress and enclose also the whole of the northern half of the ridge. The latter, however, was not occupied by buildings (except a pot kiln and some workshops) but was levelled upwards with debris as a place of refuge for dependants and their cattle. The same principal entrance, heavily fortified, in the middle of the east side, served both this "lower citadel" and the "upper" section south of it, which was further protected by an inner gate with bolted doors, as at Mycenae, within which a covered porch (*propylaea*) panelled with wood above a stone plinth, gave access to a level outer court occupying the whole of the south end, and sustained by very thick substructures. These contain, on their east and south frontages, the famous "galleries" which served as store rooms in peace, and as casemates in war. As the "later palace" within these fortifications was not itself designed for defence, its construction was slighter, and it has perished above plinth level. Its plan, however, which has attracted the attention of commentators on Homer, since Schliemann's time, is completely traceable. The outer court gives access, through a second porch, to an inner one, about 53 ft. by 70 ft., containing a domestic altar, furnished to east and west by colonnades. and giving access northward through a deep portico with two columns to a vestibule (with three doors outward and one inward) and so to a great hall to which the Homeric name *megaron* is commonly applied. This hall, about 40 ft. by 30 ft., has a central hearth, between four column bases, which supported a roof with some kind of louvre or clerestory to let out the smoke. On the cement floor, which is ornamented with painted panels of octopus and dolphins, a space is marked out between the hearth and the east wall, as the place of honour; but there is neither dais nor any other doorway but that of the vestibule. From the latter a small door leads west to a bathroom, of which the floor is a single limestone slab draining to the main sewer, as at Cnossus (see CRETE: *Archaeology:* Palatial Architecture); in this room were found the remains of a clay bathtub.

This "later palace" also perished by violence, and parts of its mud-brick walls were so calcined that at first sceptical scholars acclaimed them as Byzantine, and there was, in fact, a small Byzantine church (now removed), with a graveyard near the south end of the site. As it evidently lay long desolate, little remains of its decorative splendour except fragments of fresco, and of an alabaster frieze inlaid with blue enamel like the θριγκὸς Κυάνοιο of *Od.* vii. 87. The pottery is of degenerate Late Mycenaean style.

The frescoes of the "earlier palace," with rich spiral and floral designs, resemble those of contemporary Cnossus (*L M.*, i. ii); those of the "later" included a majestic procession of women bearing offerings, an elaborate hunting scene, in which a boar is attacked by hounds and men, and other animals are represented; an assault on a palace; a chariot procession; and bull-baiting gymnastic of the Cnossian kind. A small painted plaque shows the worship of an armed goddess; and a fragment with ass-headed personages may be a masquerade.

To the centuries after the destruction of the palace belong a series of graves with pottery of "geometrical" style, safety pins, and other objects of the Early Iron age. In the 7th century a temple was dedicated to Hera on the site of the Mycenaean *megaron*, and furnished with rude terracotta offerings.

TISA (Ger. *Theiss*), tributary of the Danube, rises in the northeastern Carpathian mountains in Ruthenia at a height of about 6.300 ft., and is formed by two streams, the Black Tisa (Cerna Tisa) and the White Tisa (Bila Tisa) which unite above Rachovo where the mountain valley begins to widen. A few miles below Rachovo the river takes a generally westerly direction and makes a great curve around the Nyirség plateau entering Hungary near the top of the curve and then continuing southwest to Szolnok. From there its course across the Hungarian plain is parallel to the Danube, which it enters near the small plateau of Titel, 20 mi. E. of Novisad. The winding course is 509 mi. long and the basin, covering an area of 56,600 sq.mi., is shared by Czechoslovakia, Hungary, Rumania. Yugoslavia and the Soviet Union. Two of its tributaries, the Szamos and Maros, coming from the impermeable rocks of Transylvania, bring a great volume of water, but these and the main stream quickly lose their velocity on reaching the plain where the fall is less than 3 cm. per kilometer. Two periods of high water occur on the middle and lower Tisa, one in spring due to snow melting, the other in June following the summer rain; to this the Koros is a big contributor. The spring flood coincides with that of the Danube which. having a quicker flow, dams back the Tisa and causes extensive flooding sometimes felt as far as Szolnok.

Huge canalization and diking works have been undertaken to protect the surrounding lowland. The Tisa is navigable for steamers as far as Szolnok, 197 mi., or as far as Tiszafhred. 2jj mi., depending upon the stage of the water, and for rafts and floating timber almost anywhere. It is joined to the Danube by the Francis Joseph canal and its tributary the Bega, and is canalized to Timişoara.

TISCHBEIN, a Hessian family of artists. Throughout three generations more than 20 members of the family embraced artistic careers of one sort or another, though their greatest successes were achieved as portrait painters.

JOHANN HEINRICH TISCHBEIN the Elder (1722–89), who studied with Charles Andrew Vanloo and in Venice with G. B. Piazzetta, was active after 1752 as court painter in Cassel, Ger. In addition to painting portraits of members of the court, Tischbein created mythological canvases and conversation pieces. Best known is his "Gallery of Beauties," a series of portraits of ladies of the court, at the palace of Wilhelmstal, near Cassel.

JOHANN VALENTIN TISCHBEIN (1715–68) and ANTON TISCHBEIN (1730–1804) were portrait painters of lesser importance who worked at some of the smaller courts of the old German empire.

JOHANN FRIEDRICH AUGUST TISCHBEIN (1750–1812), the representative painter of the second generation of his family, studied with his father. Johann Valentin, and later in Paris and Italy. The artist's duties as court painter to the prince of Waldeck were light and allowed him to spend considerable time in Holland. His experience with social life in Holland gradually induced him to turn away from court life and devote his talents to painting wealthy burghers in the grand style of English society painters. Many of these portraits may be seen in German and Dutch museums.

JOHANN HEINRICH WILHELM TISCHBEIN (1751–1829), a grandson and a pupil of Johann Heinrich and a cousin of Friedrich August, began his career by painting portraits at the Prussian court in Berlin. In 1779 he went to Italy and in 1789 succeeded in being appointed director of the art academy in Naples. Forced to leave in 1799 because of war, the painter retired to north Germany. Tischbein's most famous picture is that of "Goethe in the Campagna," painted in 1787 at the time the two men traveled from Rome to Naples. While Goethe had induced the artist to turn his interest toward the classical movement, Tischbein later became interested in the ideas of German romanticism. (Hs. H.)

TISCHENDORF, LOBEGOTT FRIEDRICH KONSTANTIN VON (1815–1874), German biblical critic, was born on Jan. 18, 1815, at Legenfeld, near Plauen, in the Saxon Vogtland. He was educated at the Gymnasium of Plauen and the University of Leipzig, where he qualified as a lecturer in 1840 with a dissertation on the recensions of the New Testament text. These studies convinced him of the absolute necessity of new and exacter collations of manuscripts.

From Oct. 1840 to Jan. 1843 he was in Paris, studying in the great library, eking out his scanty means by working for other scholars and for the publisher Didot. The great triumph of these laborious months was the decipherment of the palimpsest Codex Ephraemi Syri Rescriptus, abandoned as illegible by earlier collators. The New Testament part was printed before he left Paris and the Old Testament in 1845. From Paris he had paid short visits to Holland (1841) and England (1842).

In 1843 he visited Italy, and after a stay of 13 months went to Egypt, Sinai, Palestine and the Levant, returning by Vienna and Munich. (*See* his *Reise in den Orient*, 1845–46.) From Sinai he brought a great treasure, 43 leaves of what is now known as the Codex Sinaiticus. He kept the place of discovery a secret, and the fragments were published in 1846 as the Codex Friderico-Augustanus, a name given in honour of the king of Saxony. He now became professor extraordinarius in Leipzig, and married (1845). In the same year he began to publish an account of his travels in the east (2 vol., 1845–46). In 1850 appeared his edition of the Codex Amiatinus and of the Septuagint version of the Old Testament; in 1852, among other works, his edition of the Codex Claromontanus.

In 1853 and 1859 he made a second and a third voyage to the east. In the last of these, in which he had the active aid of the Russian government, he at length acquired access to the remainder of the precious Sinaitic codex, and persuaded the monks to present it to the tsar, at whose cost it was published in 1862 (in four folio volumes).

In 1859, Tischendorf had been made professor of theology and biblical paleography. The manuscripts brought to Europe on the first two journeys were catalogued in the *Anecdota sacra et profana* (1855; enlarged, 1861). *See* also the *Monumenta sacra inedita* (1846), and *Nova collectio* of the same (1855–69). The third volume of the *Nova collectio* gives the results of his last eastern journey. Side by side with his industry in collecting and collating manuscripts, Tischendorf pursued a constant course of editorial labours, mainly on the New Testament, until his health failed in 1873.

Tischendorf died on Dec. 7, 1874, at Leipzig.

Four main recensions of Tischendorf's text of the New Testament may be distinguished, dating respectively from his editions of 1841, 1849, 1859 (ed. vii), 1869–72 (ed. viii). The edition of 1849 may be regarded as historically the most important from the mass of new critical material it used; that of 1859 is distinguished from Tischendorf's other editions by coming nearer to the received text; in the 8th edition the testimony of the Sinaitic manuscript received great (probably too great) weight.

His edition of the Roman text, of the Septuagint, with the variants of the Alexandrian manuscript, the Codex Ephraemi and the Friderico-Augustanus, was of service when it appeared in 1850, but, being stereotyped, was not greatly improved in subsequent issues.

Beside this may be mentioned editions of the New Testament Apocrypha (*De Evangeliorum apocryphorum origine et usu* [1851]; *Acta Apostolorum apocrypha* [1851]; *Evangelia apocrypha* [1853; 2nd ed., 1876]; *Apocalypses apocryphae* [1866]) and various minor writings, in part of an apologetic character, such as *Wann wurden unsere Evangelien verfasst?* (1865; 4th ed., 1866), *Haben wir den echten Schrifttext der Evangelisten und apostel?* (1873) and *Synopsis evangelica,* 7th ed. (1898).

See in addition to the handbooks on New Testament criticism, Carl Bertheau's article on Tischendorf in Herzog-Hauck, *Realencyklopädie,* 3rd ed. (1907).

TISELIUS, ARNE WILHELM KAURIN (1902–), Swedish chemist, born at Stockholm, Aug. 10, 1902, was awarded the 1948 Nobel prize for chemistry for his researches on electrophoresis and adsorption analysis. especially for his discoveries concerning the complex nature of the serum proteins.

He received his early schooling at Gothenburg and then studied chemistry at the University of Uppsala, where he obtained his doctorate in 1930. He was assistant to T. Svedburg in the Physical Chemical institute at Uppsala (1925–32) and lecturer in chemistry (1930–38). In 1934–35 he worked at the Institute for Advanced Studies at Princeton university, and on his return to Uppsala in 1937 a professorship of biochemistry was created for him and a new institute was built to house his department. He was chairman of the Swedish State Council for Research in Natural Science from 1946 to 1950 and became vice-president of the Nobel foundation in 1947.

The method of electrophoresis, which consists in the measurement of the displacement of dissolved molecules under the influence of an electrical charge. offers a means of separating substances which differ only slightly in their chemical constitution. The separations obtained are indicated by changes in the refraction of light.

The method is extremely delicate and can be used not only for the separation of complex substances but also for the detection of minute impurities. One of its most important applications is the analysis of normal and pathological sera. Equally important is Tiselius' work on the related methods of chromatography and adsorption analysis. (W. J. Bp.)

TISSAPHERNES (Pers. CITHRAFARNA), Persian soldier and statesman, son of Hydarnes. In 413 he was satrap of Lydia and Caria, and commander in chief of the Persian army in Asia Minor.

When Darius II ordered the collection of the outstanding tribute of the Greek cities, he entered into an alliance with Sparta against Athens, which in 412 led to the conquest of the greater part of Ionia. But Tissaphernes was unwilling to take action and tried to achieve his aim by astute and often perfidious negotiations; Alcibiades persuaded him that Persia's best policy was to keep the balance between Athens and Sparta. and rivalry with his neighbour Pharnabazus of Hellespontic Phrygia still further lessened his energy.

When, therefore, in 408 the king decided to support Sparta strenuously, Tissaphernes was removed from the generalship and limited to the satrapy of Caria, whereas Lydia and the conduct of the war were entrusted to Cyrus the Younger. On the downfall of Athens, Cyrus and Tissaphernes both claimed jurisdiction over the Ionian cities, most of which acknowledged Cyrus as their ruler; but Tissaphernes took possession of Miletus, where he was attacked by Cyrus, who gathered an army under this pretense with the purpose of using it against his brother Artaxerxes II. The king was warned by Tissaphernes, who took part in the battle of Cunaxa, and afterward tried to destroy the Greek mercenaries of Cyrus by treachery.

He was then sent back to Asia Minor to his old position as general in chief and satrap of Lydia and Caria. He now attacked the Greek cities, to punish them for their allegiance to Cyrus. This led to the war with Sparta in 399.

Tissaphernes, who once again had recourse to subtle diplomacy, was beaten by Agesilaus on the Pactolus near Sardis (395); and at last the king yielded to the representations of Pharnabazus, strongly supported by the chiliarch (vizier) Tithraustes and by the queen mother Parysatis, who hated Tissaphernes as the principal cause of the death of her favourite son Cyrus. Tithraustes was sent to execute Tissaphernes, who was lured to Colossae and slain in 395. (Ed. M.)

TISSERAND, FRANÇOIS FÉLIX (1845–1896), French astronomer best remembered for his theoretical researches and for his excellent textbooks, especially his *Traitk de mdcanique ckleste* (4 vol., 1889–96), was born at Nuits-Saint-Georges, Côte-d'Or, on Jan. 13, 1845. Having studied science at the École Normale supérieure in Paris, he was appointed assistant at the Paris observatory under U. J. J. Leverrier in 1866. He went to direct the observatory at Toulouse in 1873, but five years later returned to Paris to succeed Leverrier in the Académie des Sciences, subsequently entering the *bureau des longitudes.* In 1892 he became director of the Paris observatory on the death of Adm. A. E. B. Mouchez, and died in Paris on Oct. 20, 1896.

Tisserand went to Malacca to observe the total solar eclipse of Aug. 1868, and made expeditions to observe the transits of Venus of 1874 and 1882, the first to Japan. the second to Martinique. On becoming director of the Paris observatory he took over the task of completing the reobservation of the Lalande catalogues and the organization of the work on the great international photographic catalogue known as the *Carte du Ciel*, besides continuing his *Traité de mécanique céleste*. This latter work may be compared, as a comprehensive compilation, with a similar study by P. S. Laplace nearly a century earlier, and it is still read with profit by students of this branch of astronomy. Tisserand also founded the well-known astronomical journal *Bulletin astronomiqzte* (1884), mhich contains his work on the theory of the capture of periodic comets. (J. JN.)

TISSOT, JAMES JOSEPH JACQUES (1836–1902), French painter and illustrator, was born at Nantes, Oct. 15, 1836. After studying under Louis Lamothe (Edgar Degas' master) and H. Flandrin, he began in 1859 to exhibit at the Salon, his genre being that of the amusements of the young and well dressed. After joining the Commune (*see* COMMUNE [OF PARIS, 1871]). he went to London in 1871, continuing his genre subjects and in 1875 taking up drypoint etching and book illustration.

At this time he produced works as varied as the "Ball on Shipboard" (Tate gallery. London) and the portrait of the balloonist Frederick Burnaby (National Portrait gallery. London), and ten plates illustrating the Goncourts' *Renee Mauperin*. His last 15 years, clouded by the death of a mistress in London, mere spent in Palestine and France and devoted to biblical illustration. The first volume of his *Life of Christ* (865 plates) appeared in 1896. Tissot died at Buillon, Doubs, Aug. 8, 1902.

See J. Laver, *Vulgar Society: the Romantic Career of James Tissot, 1836–1902* (1936). (D. C. T. T.)

TISSUE CULTURE: *see* ANIMAL CELL (TISSUE) CULTURE; PLANT CELL (TISSUE) CULTURE.

TISTA, a river of northern India, which rises on the edge of the Tibetan plateau, has a tumultuous course southward through the mountain gorges of Sikkim and Darjeeling and flows through West Bengal and East Pakistan for another 170 mi. till it joins the Brahmaputra in the district of Rangpur.

In the 18th century the course of the Tista was due south to join the Ganges; but in 1787 great floods diverted the stream toward the southeast, and it made its way by a new channel into the Brahmaputra.

"TITANIC" DISASTER. On April 14–15, 1912, one of the greatest disasters in maritime history occurred about 95 mi. S. of the Grand Banks of Newfoundland when the 46.000-ton White Star liner "Titanic" struck an iceberg on her maiden voyage and sank with the loss of 1,513 lives. The great ship, at that time the largest and most luxurious afloat, had a double-bottomed hull divided into 16 watertight compartments. Since four of these compartments could be flooded without endangering the liner's buoyancy, it mas considered "unsinkable." Shortly before midnight on April 14, however, while steaming at 22 knots, too fast for existing conditions, the ship collided with an iceberg which ripped a 300-ft. gash in the left side of the liner, ruptured five of her watertight compartments and caused her to sink at 2:20 A.M. the following morning. The Leyland liner "Californian," which might have aided the stricken luxury vessel, was less than 20 mi. away all night, but its radio operator was asleep. Only the arrival of the Cunard liner "Carpathia" 20 minutes after the "Titanic" went down prevented further loss of life in the icy waters. As a result of the disaster, inquiries were held in the U.S. and Great Britain and in 1913 the first International Convention for Safety of Life at Sea was called in London. The convention drew up rules requiring that every ship have lifeboat space for each person embarked (the "Titanic" had only 1,178 boat spaces for the 2.224 persons aboard); that lifeboat drills be held during each voyage (none was held on the "Titanic," leading to confusion on the fateful night); and, because the "Californian" had been deaf to the distress calls of the "Titanic," that ships carry enough radio operators to maintain a 24-hour radio match. Another important innovation was the establishment of the international ice patrol (*see* SHIPPING ROUTES) to warn ships of ice in the North Atlantic shipping lanes.

BIBLIOGRAPHY.—W. Lord, *A Night to Remember* (1955); B. Kartman and L. Brown (eds.), *Disaster!* (1948); British Parliamentary Papers: no. 2253, *Shipping Casualties (Titanic)* (1912) (ed. 6352).

TITANIUM, a metallic element, changed after 1947 from a rare metal to an important structural metal. Because of its light weight (0.163 lb. per cubic inch) and high strength particularly in alloy form, it is in demand for use in structural parts in high-speed airplanes. Because of its excellent corrosion resistance. it is used in many applications in the chemical industry. No other structural metal has been studied so extensively nor has advanced in technical stature so rapidly as titanium. This rapid advance in the technology of titanium began with development by the U.S. bureau of mines of the process for refining titanium, first disclosed by Wilhelm Kroll in 1936. A laboratory curiosity became the raw material for a commercially feasible process.

A multitude of problems arose in handling titanium: new melting techniques had to be developed; standard fabrication and processing methods had to be modified; and an understanding of the metallurgy of titanium had to be disseminated to the users of the new metal. To assist in the development of the technology of titanium, the U.S. department of defense contracted for a titanium metallurgical laboratory at Battelle Memorial institute, Columbus, O., in 1955, to provide a central facility available to both industry and government for the collection, storage and dissemination of information on titanium; to provide engineering assistance on problems encountered in the production. fabrication and application of titanium; and to provide technical data and advice to the department of defense.

History. — Titanium was named by M. H. Klaproth, a German scientist, who, in 1795. when studying the mineral rutile. discovered the new element. He named it for the mythological first sons of the earth, the Titans. an allusion to the incarnation of natural strength in the metal. In 1797. Klaproth found that titanium also was present in the mineral ilmenite and recognized that it was the same element discovered by William Gregor in England in 1791 that he had called menachanite (or menaccanite) after the Cornish town Manaccan near which he discovered it. Not until over a century later did anyone succeed in isolating elemental titanium. Between 1797 and 1910 many investigators attempted to isolate it, but the metal-appearing products were usually compounds of titanium with nitrogen, carbon and oxygen, for all of which titanium has a great affinity. In 1910, M. A. Hunter succeeded in isolating titanium by reducing titanium tetrachloride with sodium in an airtight steel cylinder. After Hunter's work, titanium remained a laboratory curiosity until 1946 when the U.S. bureau of mines, using Kroll's process. succeeded in producing titanium on a pilot plant scale by the magnesium reduction of titanium tetrachloride.

Occurrence. — Titanium occupies the ninth place in abundance in the earth's crust, exceeded only by oxygen, silicon, aluminum, iron, calcium. magnesium, sodium and potassium It has been found in 98% of all rocks examined in a study of the relative abundance of elements and occurs in practically all sand. clay and other soils. Also, it has been found in oil, coal, natural waters. vegetation. animal flesh and bones, volcanic ash, deep-sea dredgings and meteorites and stars. Despite this widespread distribution there are numerous deposits of highly concentrated titanium minerals mhich are readily accessible and easily mined. Many minerals contain titanium, but only two are of prime commercial importance, ilmenite and rutile. Ilmenite, the more abundant of the two minerals, is a combined iron-titanium oxide usually expressed as iron titanate ($FeO\text{-}TiO_2$) although its composition varies considerably. Usually, ilmenite contains about 32% titanium and 37% iron. Ilmenite occurs frequently with hematite and magnetite (iron bearing ores) in rock formations and in sand in beaches and rivers. Rutile, which in pure form is titanium dioxide (TiO_2), is richer in titanium content than ilmenite but is generally diluted with other minerals either in rock formations or beach and river sand. Known deposits of rutile are not so extensive as ilmenite.

The important sources of titanium ore in North America are the Allard lake district of eastern Quebec; Sanford lake, N.Y.; Iron

Mountain. Wyo.; and Pablo Beach. Fla. Of these, the Allard lake district contains the largest known ore reserve, two large high-grade deposits estimated to contain many hundreds of millions of tons of ore. Known deposits of titanium ores are located in Virginia, Minnesota, Rhode Island, Montana, California, Oklahoma, Colorado and New Mexico, although the extent and usefulness of these deposits was not fully known in the second half of the 20th century. Titanium ores are also abundant in Australia. Brazil. India, Malay States, Norway, Russia. Sweden, Finland. Portugal and various places in Africa. Travancore, India, has been one of the major sources of titanium orcs because of its high TiO_2 content. Much of the titanium ores imported by the Cnited States for production of titanium dioxide pigments has come from India.

Production. — Titanium is produced by a chemical process in which titanium tetrachloride ($TiCl_4$) is reduced with magnesium or sodium. The Kroll process, which is used in the United States, consists of reacting four parts by weight of liquid $TiCl_4$ with one part by weight of molten magnesium in an iron reactor at about 850° C. to form one part of titanium and four parts of magnesium chloride. The sodium-reduction process, used principally in Great Britain. requires two parts by weight of sodium to reduce four parts by weight of $TiCl_4$ and produces one part of titanium and five parts of sodium chloride. Both processes are conducted in large reactors producing about 1,000 to 2,000 lb. of titanium per batch. An argon atmosphere is used within the reactor because all air must be excluded from the reaction to prevent oxygen, nitrogen and hydrogen contamination of the final product. Both of these methods produce titanium in the form of a sponge with magnesium chloride or sodium chloride entrapped in the pores. This sponge is crushed to a suitable size for handling and then leached with water and acid or heated in a vacuum to remove the entrapped chlorides. Titanium sponge is the raw material used for melting ingots of titanium and titanium alloys. Its purity is dependent on the purity of the TiCl, from which it was made, the purity of the magnesium or sodium reducing agent and the purity of the atmosphere during the reduction process. Common impurities in sponge titanium are oxygen, carbon, nitrogen, hydrogen and iron.

Extremely pure titanium can be made by the thermal decomposition of titanium tetraiodide and by an electrorefining process. Both of these processes use impure sponge titanium as the starting material, so they cannot be considered as primary production processes. Much research had been directed toward the development of an electrolytic process for producing titanium in the second half of the 20th century, and although considerable success had been obtained on a laboratory scale, no one had been successful in scaling the process up to a production scale.

Properties. — Titanium in pure form is a soft ductile metal. It has a density of 4.5 g. per cubic centimetres (0.163 lb. per cubic inch) which is about midway between aluminum (2.702 g. per cubic centimetres) and iron (7.9 g. per cubic centimetres). It has a silvery gray colour and can be polished to a high lustre. However, it is not so lustrous as chromium or stainless steel.

Titanium melts at 1.670° C. (3,040" F.). Common impurities, carbon, oxygen and nitrogen, raise the lnelting point while most metallic impurities. such as iron, manganese, chromium and copper. lower the melting point. There are two crystal structures of titanium. At temperatures below 882° C. (1.620" F.) titanium has a hexagonal close-packed structure known as the alpha phase, while at temperatures between 882° C. and its melting point titanium has a body-centred cubic structure known as the beta phase. Titanium is paramagnetic. and has very low electrical a'nd thermal conductivity. Its atomic number is 22 and atomic weight is 47.9. It occurs in three valence forms, 2, 3 and 4, the most stable of which is 4, thus forming compounds of the type TiO, Ti_2O_3 and TiO_2.

Perhaps the most important property of titanium is its ability to be alloyed. Titanium can be alloyed with most of the other metals and many of the nonmetals. Alloying additions increase the strength of titanium both at room temperatures and elevated temperatures. Pure titanium has a tensile strength of about 40,000 lb. per square inch (p.s.i.). By alloying titanium, tensile strengths as high as 200,000 p.s.i. can be obtained. It is this property of titanium that has made it useful as a structural metal.

Like stainless steel and aluminum. titanium has excellent corrosion resistance in many environments because of the formation of a passive oxide surface film. Titanium resists corrosive attack by oxidizing acids such as nitric acid and aqua regia, organic acids, moist chlorine gas, chloride solutions. dilute solutions of sulfuric acid and hydrochloric acid, and dilute solutions of alkalies. It will ignite and burn in dry chlorine gas and is attacked by hydrofluoric and phosphoric acids and moderate concentrations of the alkalies. In fuming red nitric acid, titanium is severely attacked. Several instances of pyrophoric reactions, including explosions. have occurred when titanium has been exposed to red fuming nitric acid. In marine atmospheres and sea water the corrosion resistance of titanium is outstanding. No noticeable corrosion of titanium has been found after exposure to sea water for over three years. Although at room temperatures titanium is resistant to oxidizing atmospheres, at elevated temperatures titanium reacts with the oxygen in the air. At temperatures as low as 500° F. the surface of titanium becomes tarnished, forming an oxide film which ranges in colour from blue to gold. At higher temperatures a thicker oxide film or scale is formed which is yellow-brown. The rate of oxidation increases as the temperatures are increased but it is not until temperatures above about 1.200" F. are reached that oxidation becomes a problem if long-time exposures are involved. At temperatures between 1.200" and 2,200" F., short-time heating can be done in air. Forging and fabrication of titanium alloys are done at these temperatures with no detriment to the properties so long as the oxide scales are removed after fabrication. However, in the liquid state, titanium is very reactive and reduces all known refractories.

Titanium-Base Alloys. — The major alloying elements that are added to titanium are aluminum, vanadium, molybdenum, manganese, iron and chromium. All of the titanium-base alloys contain one or more of these elements. The gaseous elements, carbon, oxygen. nitrogen and hydrogen, are present in almost all titanium alloys in small quantities. The tensile strengths of titanium alloys vary from about 120,000 p.s.i. to over 200.000 p.s.i.

Titanium alloys can be classed in three basic types: alpha, alpha-beta, and beta alloys. Alpha alloys contain elements that dissolve in the hexagonal close-packed alpha phase. Alpha-beta alloys contain limited quantities of elements that dissolve in the body-centred cubic beta phase resulting in a two-phase alpha-beta alloy. Beta alloys contain large quantities of elements that dissolve in the beta phase resulting in all beta structure. Alpha alloys have medium strengths (120.000 to 150,000 p.s.i.) and good elevated-temperature strengths. can be welded and are used mostly as forgings. Alpha-beta alloys are the most versatile. In the annealed condition, they have medium strengths but can be heat treated to very high strengths. These alloys have good forming characteristics and can be used in both sheet and bar stock form. Generally they are not weldable. Beta alloys have medium strengths and excellent forming characteristics, but contain large quantities of high-density alloying additions. Compositions and properties of typical alloys of the three types are listed below:

Type of alloy	Composition (balance titanium)	Teniile strength, p.s.i.	Elonsation %
Alpha	5% 41, 2.57, Sn	130,000	15
Alpha-beta	8% Mn	120,000	10
Alpha-beta	2% Fe, 2% Mo, 2% Cr	140,000	15
Alpha-beta	6% Al, 4% V	150,000	15
Alpha-beta (heat-treated)	6% Al, 4% V	180,000	7
Beta	13% V, 11% Cr, 3% hl	150,000	15
Beta (heat-treated)	13% V, 11% Cr, 3% Al	200,000	6

Titanium in Other Metals. — Titanium has long been used as a deoxidizer in steel where it is added as a ferrotitanium or a ferrocarbontitanium alloy. More recently, it has been used as an alloying addition to many steels to reduce grain size and control carbon content in stainless steel. In aluminum, it is used to refine the grain size, while in copper it produces a precipitation-hardening alloy. In high-temperature nickel-cobalt-chromium alloys, titanium is added to produce a precipitation-hardening reaction providing high strengths at temperatures up to 1,500° F. Titanium is used in permanent magnet alloys of the iron-cobalt-nickel-titanium type.

Uses. — The greatest use for titanium metal is in structural parts in high-speed military aircraft where high strength and low density are important. Titanium and titanium alloys can be used at temperatures up to 800° F., several hundred degrees higher than the useful temperature range for aluminum. It is used in the compressor section of jet engines, in airframe construction, aircraft skins, fire walls and as fasteners (nuts and bolts). In other military applications, it may prove useful for armour plate because of its toughness, and for structural components of equipment that may be carried by air because of its light weight. In naval applications its excellent corrosion resistance to marine atmospheres makes it suitable for special applications, such as heat exchanger tubes, superstructure parts, valves, propeller blades and armour plate.

In corrosion-resistant applications, titanium is used in valves and pumps for corrosive chemicals and in wire cloth for filtering equipment, screens and other equipment. It is used to line pulp bleaching equipment in chlorine dioxide environments. It has been used in centrifuges, condensers, filter presses and heat exchangers where corrosion is a problem. In the electroplating industry, titanium has been found to be excellent for anodizing racks, It is used in prosthetic devices because there is no reaction between titanium and fleshy tissues or bones.

A list of the potential applications for titanium would be lengthy for its combination of high strength, low density and excellent corrosion resistance would find a multitude of uses. However, the high cost of titanium ($2.75 per pound for sponge, $8 00 to $20.00 per pound for mill products) precluded its use in many applications. Continued decrease in price (the price fell steadily after 1947) to a competitive level with other metals would make it probable that large quantities of titanium would be used in transportation equipment. Such use would include not only aircraft but automobiles, trucks, busses, railroads and boats and ships.

Compounds.—The most important compound of titanium from the point of view of consumption is titanium dioxide (TiO_2), which is used extensively in the pigments industry because of its excellent hiding power or opacity. Titanium dioxide, a pure white compound having high reflectivity, is ideal for use in white paints, enamels and lacquers and can be used in conjunction with other pigment compounds in coloured paints. It is also used in pigments for rubber, paper, oilcloth, leather, textiles, inks and cosmetics. Titanium dioxide is produced from rutile or ilmenite by dissolving the ore in a sulfuric acid solution and precipitating the iron compounds. The solution is then hydrolyzed, producing a hydrous titanium oxide, which is mashed and calcined.

Titanium tetrachloride, the raw material for producing titanium metal, is the next most important compound. It is produced by chlorinating TiO_2 or titanium ores in the presence of carbon. The minor amounts of iron, silicon, oxygen and other impurities present after chlorination are removed by fractional distillation. Other uses for titanium tetrachloride are as a catalyst in many chemical reactions along with titanium dioxide and as a smoke-producing compound for skywriting or smoke screens. Titanium carbide, a compound produced by reacting carbon with a titanium compound, is used in conjunction with tungsten carbide in cutting tools and dies. Many other compounds of titanium exist, but their uses are limited. See also Index references under "Titanium" in the Index volume.

TITANOTHERE, the common name for any member of the family Brontotheriidae, extinct, hoofed, herbivorous mammals of the order Perissodactyla, which also includes the horses, tapirs and rhinoceroses. Titanotheres range from Early Eocene to Middle Oligocene in age and are known from North America, Europe and Asia. From small. hornless ancestors, the latest titanotheres became as large as elephants, with a transverse pair of great, bony, hornlike knobs above the nose (most genera) or a battering-ram extension of the nasal bones themselves (the Asiatic *Embolotherium*).

See PERISSODACTYLA. (G. G. SI.)

TITANS, in Greek mythology, the children of Uranus (Heaven) and Ge (Earth). The Greek name is Τιτᾶνες, the etymology of which is uncertain. According to Hesiod *(Theog.*, 133), the male Titans were Oceanus, Cocus, Crius, Hyperion, Iapetus and Cronus; the female, Thea, Rhea, Themis, Mnemosyne, Phoebe and Tethys. Later authors add other names. After the rebellion of Cronus and the birth of Zeus *(see* CRONUS), a struggle ensued between Zeus and Cronus in which the Titans nearly all sided with the latter but were finally defeated and imprisoned in Tartarus (Hesiod, *Theog.*, 153–210, 617 *et seq.)*.

TITCHENER, EDWARD BRADFORD (1867–1927), English-U.S. experimental and systematic psychologist and leader of the structural school, was born in Chichester, Eng., Jan. 11, 1867. He was educated in the English public schools; at Brasenose college. Oxford (A.B., 1890); and at Leipzig university, where he went to study with Wilhelm Wundt (*q.v.*). After receiving his Ph.D. degree in 1892 he returned to Oxford as an extension lecturer. In 1893 he went to the United States as an assistant professor of psychology at Cornell university, Ithaca. N.Y., and he remained there until his death, being promoted in 1895 to the Sage professorship in psychology and in 1909 to a professorship in the graduate school.

During his service at Cornell Titchener published eight books on psychology, many of which went through several revised editions and were translated into numerous languages; 11 translations of German psychological textbooks into English; and many (216) psychological articles. He edited the *American Journal of Psychology* for 31 years and founded (1904) the Society of Experimental Psychology. He died on Aug. 3, 1927.

In addition to his three elementary textbooks. Titchener's outstanding works are: *Experimental Psychology,* one of the most thorough and encyclopaedic handbooks ever published, the first two volumes covering qualitative (1901) and the last two covering quantitative psychology (1905); *Lectures on the Elementary Psychology of Feeling and Attention* (1908); *Lectures on the Experimental Psychology of the Thought Processes* (1909); *A Textbook of Psychology* (1910); and *Systematic Psychology: Prolegomena,* published posthumously in 1929.

See biographical sketch by E. G. Boring in the *American Journal of Psychology,* 38:489 ff. (1927). (K. M. D.)

TITHES, a form of tribute consisting of a tenth of a man's property or produce, connected politically with taxation, and religiously with the offering of first fruits to deity. This custom was almost universal in the ancient world, and can be traced in Babylonia, Persia, Arabia, Egypt, Greece, Rome and even in China. The tax probably originated in a tribute laid by a conqueror or ruler on his subjects; and it may be assumed that the custom of dedicating a tenth of the spoils of war to the gods led to a religious extension of the term, the original offerings to deity being first fruits. Among the early Hebrews, for example, the king could exact a tithe from cornfields, vineyards and flocks (1 Sam. viii, 15, 17); and on the religious side the oldest laws (*e.g.,* Exod. xxxiv, 26) speak of bringing the first fruits of the land to the house of Yahveh. By the 7th century (Deuteronomy) the word "tithe" had come to be used regularly for religious dues. But the analysis of tithe legislation in the books ascribed to Moses is a complicated problem, owing to the way in which strata of legislation belonging to different periods are combined in the Pentateuch as we now have it; and for detailed investigation reference should be made to the works mentioned below. Ultimately the tithe system became a means of contributing to the regular support of the priests, as ministers of the public ritual.

Tithes in Christendom. — The earliest authentic example of anything like a law of the State enforcing payment appears to occur in the capitularies of Charlemagne at the end of the 8th or beginning of the 9th century. Tithes were by that enactment to be applied to the maintenance of the bishop and clergy, the poor, and the fabric of the church. In course of time the principle of payment of tithes was extended far beyond its original intention. Thus they became transferable to laymen and saleable like ordinary property, in spite of the injunctions of the third Lateran Council; and they became payable out of sources of income not originally tithable.

The Council of Trent definitely enjoined payment of tithes, and excommunicated those who withheld them (Sessio xxv. 12). In England the earliest example of a legal recognition of tithes appears to be in a decree of a synod in 786 (quoted by Selden, *History of Tithes,* ch. viii. 2). Other examples before the conquest occur in the laws of Alfred, Athelstane, Edgar, and Canute. It was Selden's denial of the divine right of tithes which brought down the wrath of the Star Chamber upon his head (1618), and he was forced to retract his opinion.

Tithes in English Law.—Two chronological divisions may conveniently be made.

(i.) Before the Commutation Acts (1836 sqq.). Tithes were classified by origin, as "praedial," or arising immediately from the ground, *e.g.,* grain of all sorts, hay, wood and the like; "mixed," or arising from things immediately nourished by the ground, *e.g.,* colts, lambs, eggs and the like; or "personal," namely, of profits arising from the honest labour and industry of man, and being the tenth part of the clear gain, *e.g.,* fishing, mills and the like; or according to value, as great, *e.g.,* corn, hay and wood; or little, which embraced all others. Of common right tithes were only payable of such things as yield a yearly natural increase and generally only once a year. They were recoverable by a writ against the owner of the tithable property usually brought in the ecclesiastical courts, the jurisdiction of which in this respect was confirmed by the statutes *Circumspecte agatis* (13 Edw. I.), *Articuli cleri* (9 Edw. II.), and others of Henry VIII. and Edward VI.; and an act 2 and 3 Edw. VI. made any person refusing to set out tithes liable to pay double the value in the ecclesiastical court or treble in a common law court. At the time of the Commutation Acts, it was common for a tithe-owner to accept a fixed sum of money or fixed quantity of the goods tithable in place of the actual tithes, whether in respect of a whole parish or only of particular lands within it; and this could be sued for in the ecclesiastical courts. In the City of London there were customary tithes; in other towns and places there were compositions for tithes which were confirmed by local acts of parliament; and according to a return presented to the House of Commons in 1831, there were passed between 1757 and 1830 no less than 2,000 local acts containing commutation clauses.

(ii.) The principle of the Tithe Commutation Acts (1836–1860) is to make permanent and general the system which had been only partial or temporary (in most cases), and to substitute a corn rent (known as a tithe rent charge), permanent in quantity and payable in money, but fluctuating in value, for all tithes, whether payable under a *modus* or composition or not, which may have heretofore belonged either to ecclesiastical or lay persons (Phillimore, *Eccles. Law,* ii. 1161). Commissioners (now the board of agriculture) are appointed to execute the acts; a rent charge on all lands liable to tithes at the time of the passing of the first act is substituted for those tithes, of which the gross amount is ascertained either by voluntary parochial agreement. or, failing that, by compulsory award confirmed by the commissioners; and the value of the tithes is fixed in the latter case by their average value in the particular parish during the seven years preceding Christmas 1835, without deduction for parochial or county and other rates, charges and assessments falling on tithes, the rent charge being liable to all the charges to which tithes were liable. The rent charge is apportioned on all the lands liable in the parish, and such apportionment may be altered or a new one made; and the value of the rent charge is fixed at the value (at the time of confirmation of the apportionment) of the number of imperial bushels and decimal parts of bushels of wheat, barley and oats as the same would have purchased at the prices so ascertained by the advertisement (of prices of corn) to be published immediately after the passing of the act 6 and 7 Will. IV. c. 71, in case one-third part of such rent charge had been invested in the purchase of wheat, one-third part in the purchase of barley, and the remaining third part in the purchase of oats; and the respective quantities of wheat, barley, and oats so ascertained shall be stated in the draft of every apportionment. The price at which the conversion from money into corn is to be made at the time of confirmation of such apportionment, according to the provisions of the said act, are 7s. $0\frac{1}{4}$d. for a bushel of wheat, 3s. $11\frac{1}{2}$d. for a bushel of barley, and 2s. 9d. for a bushel of oats (7 Will. IV. and 1 Vict. c. 69); the average price of the bushel of each grain is now computed by substituting for the "advertisement" above the statement of the septennial average price of the imperial bushel of British corn made under the Corn Returns Act, 1882; and thus the value of the statutory amount of corn is now fixed for each year at the beginning thereof at the average price of the three components of corn for the previous seven years.

The method of recovering rent charge under the Commutation Acts was distraint where the rent charge is in arrear for 21 days after the half-yearly days of payment, and entry and possession with power of letting if it is in arrear for 40 days. This power of distress and entry extends to all lands occupied by the occupier of the land whose tithe is in arrear as owner or under the same landlord; but no action lies against the owner or occupier of the land personally. If a tenant quits leaving tithe unpaid, the landlord may pay it and recover it from him. The tithe-owner cannot recover damages from the tithe-payer for not cultivating the land. Special provision is made for the recovery of the rent charge in railway lands.

The act of 1891 shifted the responsibility from the occupier to the landowner by making the latter solely responsible. The landowner became liable to pay the rent charge in spite of any contract to the contrary between him and the occupier; the rent charge if in arrear for three months is recoverable by an order of the county court, whatever its amount may be; if the land is occupied by the owner, the order is executed by the same means as those prescribed in the Tithe Acts; but if it is not, then by a receiver being appointed for the rents and profits of the land. Appeal lies to the High Court on points of law; and a remission of rent charge may be claimed when its amount exceeds two-thirds of the annual value of the land. The act does not apply to the particular kinds of rent charges mentioned above.

The Tithe Acts do not apply to the city of London, which has always had its own peculiar customary payment regulated by episcopal constitutions of 13 Hen. III. and 13 Ric. II. and statutes of Henry VIII. confirming a decree of the privy council, under which the rate of tithes was fixed at $16\frac{1}{2}$d. for every 10s. rent, and at 2s. gd. for every 20s. rent of houses, shops and the like by the year. Provision was made by statute after the fire of London for certain annual tithes to be paid in parishes whose churches had been destroyed. Parliament in 1936 passed an **act** for the extinction of tithes.

TITHING. Formerly throughout England, except in the north and west, every man had to be enrolled in a group of ten men, called a tithing, who were responsible for his appearance in court if he were accused of any offence. This was known as the system of frankpledge (*q.v.*). If the offender was not forthcoming, inquiry was made whether he was in frankpledge; if he were not, and had no right of exemption, the township was amerced, but if he were in a tithing, then it was upon the tithing that the amercement fell. South of the Thames the tithings were districts normally identical with the township which discharged the duties of the frankpledge. Some townships, however, contained more than one tithing. There are also indications that in the ancient kingdom of Mercia the tithing was originally a district and not a mere association of persons.

TITHONUS was, in Greek legend, according to Homer, the son of Laomedon, king of Troy and husband of Eos (the Dawn). In the Homeric Hymn to *Aphrodite* Eos is said to have carried him off because of his great beauty. She entreated Zeus that he might live for ever; this was granted, but she forgot to ask for immortal youth for him. He became a hideous old man; Eos then shut him up in a chamber; his voice "flowed on unceasingly," but his limbs were helpless.

A later development is the change of Tithonus into a grasshopper, after Eos had been obliged to wrap him like a child in swaddling clothes and to put him to sleep in a kind of cradle. In some versions she is said to have carried him away to the land of Ethiopia near the ocean streams.

See O. Gruppe, *Griechische Mythologie,* i, 313, *n.* 16, who attributes a Milesian origin to the story; also the classical dictionaries.

TITI, a name properly applied to the small South American monkeys of the genus Callicebus. The titis, of which there are numerous species, inhabit the forests of Brazil and the neighbouring countries and feed on fruits, insects and even small birds. The tail is long and bushy, and is not prehensile. They are very vociferous, though less so than the howler (*q.v.*) monkeys of the same region. The name titi (also spelled teetee) is also sometimes used for the squirrel monkeys ***(Saimiri),*** small, richly coloured, largely insectivorous forms, inhabiting Central and South America. See SQUIRREL MONKEY.

TITIAN (TIZIANO VECELLI or VECELLIO) (c. 1490–1576), Italian painter universally recognized as the greatest painter of the Venetian High Renaissance. His prominence during his lifetime was acknowledged by the government of his city, by the neighbouring courts of Ferrara, Mantua and Urbino, by the pope and by Emperor Charles V and his son Philip, king of Spain. Titian's exceptionally long life enabled him to reflect the evolution of Italian art through the larger part of a century and at the same time to set a pattern according to which the lives of many creative artists were enacted. First, there were the years of apprenticeship in which the achievements of the past were absorbed. Second, with a bound, all of his contemporaries were left behind and a miraculous 'outburst of inventive power directed every branch of painting into new channels, demanding greater material size for greater spiritual expression. Third, there followed a calming-down period when the artist had reached his 40s and his interest turned to refinement and detail. Fourth, there was another crest of the wave: a return to the youthful conceptions of his heroic era, but the conception as such had lost its original importance in favour of changed interpretation. Fifth and last, in the isolation and loneliness of the old, he rejected all compromise with the demands of his period. The fame which he had gained during his earlier manhood lived on, but his direct influence on ascending contemporary artists had lessened and finally stopped. Younger patrons withdrew, and there was a rumour of decay. This art of Titian's old age, which disregarded his patrons' tastes, became the pure expression of the master's intentions. This work does not show decay. It is his fulfillment.

What is known of Titian's life is derived mainly from the writings of three contemporaries: Lodovico Dolce, Pietro Aretino and Giorgio Vasari. Dolce and Aretino lived in Venice and were intimate friends of the master. Vasari favoured Florence and Michelangelo and was thus prejudiced against Titian, although not openly inimical. Born in Arezzo and a compatriot of Pietro Aretino, Vasari was influenced by Aretino's high appreciation of Titian. Carlo Ridolfi, writing in 1648, elaborated Vasari's statements, sometimes incorrectly, and collected everything that was known about Titian in Venice in the middle of the 17th century. A source of a quite different nature is Sir Anthony Van Dyck's sketchbook (c. 1624, Chatsworth house) which in drawings preserves much of Titian's work in Italy. or rather what was believed to be by Titian in Van Dyck's time.

The year of Titian's birth is not known, but indirect evidence points to about 1490. His birthplace was high in the Alps, Pieve di Cadore, to which Titian often returned. In drawings he seems to have thoroughly studied his native mountains since he often inserted their majestic views in the background of his paintings. His family had resided in Pieve di Cadore for centuries, their male members having followed a military or a judicial career. It may be assumed that the boy had shown an inclination for painting early; otherwise he would not have been sent to Venice at the age of nine to be trained as a painter. There, probably after a short apprenticeship with Sebastiano Zuccato, a poor craftsman, he entered the workshop of the government's official painter, Gentile Bellini, and shortly afterward that of Giovanni Bellini. If a modern interpretation of Vasari's text is correct, Titian had a hand in furthering his master's important commission for Alfonzo d'Este, duke of Ferrara, the "Feast of the Gods" (National gallery, Washington). The first reliable information about Titian concerns his share in the frescoes which Giorgione was commissioned to paint on the walls of the Fondaco dei Tedeschi (the warehouse of the German merchants in Venice, 1507–08). In the damp Venetian atmosphere the frescoes soon perished except for two fragments now in the Academy in Venice; the compositions of several others are preserved in engravings dating from the 17th and 18th centuries.

Three murals representing deeds of St. Anthony, which Titian painted in the Scuola del Santo in Padua, are documented by the receipt for his fee dated Dec. 2, 1511. In the mural representing St. Anthony bringing to life a woman murdered by her jealous husband, Titian shows his independence by relegating the culminating episode of the legend to the background and making the dramatic episode of the murder the main scene.

After Giorgione's death, Titian returned to Venice. Marcanton Michiel's notes on Venetian art treasures state that Titian finished several of Giorgione's pictures. His own work was strongly influenced by Giorgione in this period which ended about 1515. The most famous examples are the "Flora" (Uffizi, Florence) and the "Sacred and Profane Love" (Borghese gallery, Rome); opinions about the authenticity of the "Concert" (Pitti, Florence) are divided.

Before 1513 Titian designed the mighty series of woodcuts, "Triumph of Faith," "Sacrifice of Abraham" and "Destruction of Pharaoh's Host in the Red Sea." They represent a revolution in the history of woodcuts, for they did not vie with miniature painting, as earlier graphic art in Venice had done, but rather with murals. In the "Destruction of Pharaoh's Host in the Red Sea" the drowning horses in their violent poses were most impressive. Titian, conscious of having achieved something that no other artist in Venice could have accomplished, let this sureness set the tone of his application to the government for the commission for the "Battle" in the Sala del Gran Consiglio (Great Council hall in the Ducal palace) in 1513, in which horses were to be the main actors. The first decoration of this hall, representing legendary themes, was replaced by a series for which Titian painted the "Battle of Spoleto." After this series was destroyed by fire in 1577, another series was begun in which the battle of Spoleto was not included as a theme, and even its name was lost; later writers referring to Titian's great work spoke of it as the "Battle of Cadore." A painted copy in the Uffizi, two engravings, a preparatory drawing of the whole composition in the Louvre and a study for one of the riders in the Uffizi are all that are preserved of Titian's greatest profane painting, which required a quarter of a century to complete. After receiving this commission, as well as the position of official government painter in 1516 after Giovanni Bellini's death, Titian accepted many other commissions.

The high altar painting "Assumption of the Virgin" for the church of Sta. Maria Gloriosa dei Frari was the sole commission which he completed on schedule (ordered in 1516, unveiled in

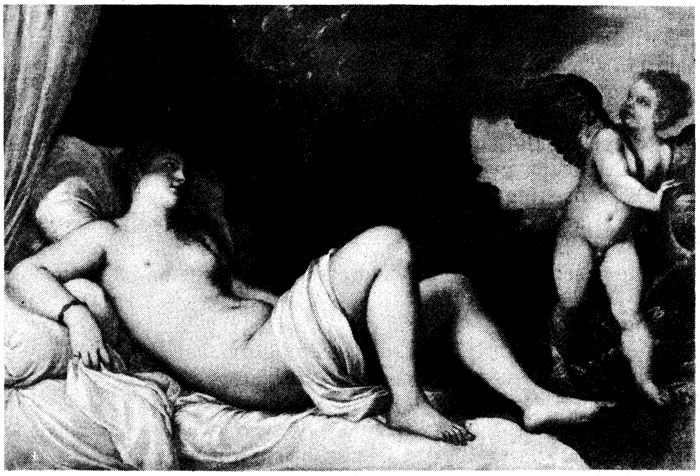
March 1518). This work, abundant with figures and bursting with vitality, was a frightening surprise for the Franciscan monks. Venice, bound by its Byzantine heritage and therefore more conservative than any other cultural centre in Italy, with this painting stepped to the front of the new movement called High Renaissance.

The second of Titian's great religious classics is the altarpiece for the Pesaro family, also found in the Frari. The payments ran from April 1519 to May 1526, and on Dec. 8, 1526, the festival of the Immaculate Conception, the painting was unveiled. This composition, although not so energetically dedicated as the "Assumption" to unprecedented arrangement, nevertheless again introduced an unprecedented scheme. Instead of the usual frontal position, the construction has been shifted to an oblique angle; furthermore the scene is set not within the usual church interior or in the open with a landscape view, but in a kind of portico with t o huge columns heightening the impression of spaciousness. The group of donors, including ancestors and living members of the family, are intermingled with the saints, so that the saints become endowed with human vitality and the humans with saintly bliss. The third of Titian's religious classics, the "Martyrdom of St. Peter Martyr," painted between 1525 and 1530 for the church of S. Giovanni e Paolo in Venice and destroyed by fire in 1867, is preserved in many copies. The union of figures and landscape, striving with all their force to the single effect of the drama of the assassination, made this work a landmark in the history of painting. This "Peter Martyr" brought to Titian the acclaim of his contemporaries as the greatest landscape painter of his time.

Alfonso d'Este commissioned three mythological paintings from Titian that are worthy parallels to the three great religious works. Executed between 1517 and around 1523, they also introduced a new style in their field. The correspondence between the duke's agent in Venice, Titian and the court of Ferrara indicates how frequently Titian was interrupted and how the duke urged the execution of these works. The themes of the "Worship of Venus" and the "Andrians" (both in the Prado. Madrid) were taken from descriptions by the late classical writer Philostratus; the one of "Bacchus and Ariadne" (National gallery, London) from Ovid's *Metamorphoses*. There are some striking analogies between the religious and mythological works (*e.g.,* in the "Assumption" and the cupids in the "Worship of Venus"); the tense movement of Bacchus and its alert reverberation in his suite find their parallel in the main figural drama of the "Peter Martyr" and its resonance in the tree trunks and swishing branches.

Titian's mood in his turbulent youth was not appropriate to portrait painting. After the few small and subdued portraits from his Giorgionesque period, Titian chose a larger format. Otherwise they resemble in their solemn rigidity the portraits of the donors in the religious paintings.

In the period of relaxation which followed Titian's first creative outburst he painted so many portraits that Aretino said in a letter of Nov. 9, 1537, that Titian was believed to have become a mere portrait painter. The large output of these portraits in the 1530s was rather uneven; outstanding were those of "Cardinal Ippolito de' Medici in Hungarian Costume" (1533; Pitti), the emperor "Charles V With Dog" (1532; Prado), "Xlfonso d'Avalos, Marquess del Vasto" (1532; private collection, Paris) and "King Francis I" (1538; Louvre). The portraits of the emperor and the French king have in common that they were not painted from nature but from models. That of the emperor is an exact copy from a painting of the Austrian court painter Jacob Seisenegger; that of the French king is from a medal. Titian s eminence as a portraitist is proved in these works: the dry work of Seisenegger has been developed into a deep and noble conception of the strange personality of this lonely man; and the medal's abstract profile has become the means of expression, the pose alone bringing to life the king's "chivalrous gaiety, his sex-appeal and exuberant vitality." The emperor appointed Titian as his court painter and promoted him to count palatine. The latter promotion enabled Titian to legitimate his two sons born before his marriage. Typical works from Titian's intimate period are the small painting in the Louvre, "Madonna With the Rabbit" ($26\frac{3}{4} \times 33$ in.) and



ALINARI

"DANAË" BY TITIAN. IN THE NATIONAL MUSEUM, NAPLES, ITALY

the somewhat larger one, "Madonna and Child With Saint John and Saint Catherine" in the National gallery, London ($39\frac{1}{8} \times 55\frac{1}{2}$ in.). Both claim the same documentation, a letter from 1530 mentioning a "Madonna With St. Catherine" for the court of Mantua. Although the Louvre painting, an "idyllic scene in format, composition and spiritual content is a little Titian, its colour scheme makes it worthy to rank among his great masterpieces."

The "Presentation of the Virgin in the Temple." painted between 1534 and 1538 for a wall in the Scuola della Carità, is still at its original location above two doors where the Accademia (the Museum of Venice) has grown around it. At first sight its composition looks traditional; but the perspective construction has been unobtrusively developed into a motif of expression. The woman with the basket of eggs against the stair wall, seemingly a mere genre figure traditional in Venetian paintings of this subject, is monumentalized by Titian to a heroic dignity which fits well with the antique torso on the other side of the door.

Titian visited Rome in 1545, at which time Paul III Farnese and his two nephews sat for a group picture. This Farnese group (Naples), a feast in flaming reds, was never finished. Titian brought with him as a present a picture of "Danae." This precious gift, now in Naples. is an evolution of the motif of the "Nude Woman Lying Down," the first version of which goes back to Giorgione. Titian had further developed this motif in the "Urbino Venus" (about 1538; Uffizi). Shortly afterward. he adapted this genrelike version, using the same youthful girl to model for a "Danae" (private collection, New York) and later for the fully blooming woman of the Naples painting. Even while in Rome Titian tried to obtain the emperor's invitation, offering him a "Venus" painting as a present. In 1547 he brought it to Augsburg where Charles V held his diet. This Venus has not been identified; it might have been a version of the two shop productions of this subject in the Prado. The most important work of Titian's first stay in Augsburg was the portrait of the emperor as victor of the battle of Miihlberg, which took place on April 24. 1547. The emperor is shown in the armour he wore that day as he rode into battle. The painting (1548; Prado) sets the pattern for all subsequent representations of princely portraits. The "Gloria" (1554; Prado), also called "Last Judgment," is the last great painting Titian delivered to Charles V. The emperor took it with him when he retired to Yuste after his abdication in 1555. After 1554, Titian began to deliver his paintings to Philip II. Charles' successor. On Dec. 22. 1574, he sent a list of those which he had shipped to Spain during the previous 25 years. Most of them represented mythological subjects—Titian called them *poesie*—and were developments of earlier conceptions. These can best be studied in the "Danae" versions of this late period (*e.g.,* in the Vienna gallery), which enhance the decorative side at the expense of the spiritual content. The woman whose passion had heightened her into a goddess became a fixture within a harmonious construction. Seen from another angle, such change denotes the wise and tenderly sad resignation of old age.

Titian's son Orazio, other members of the family and German painters who had joined the shop fulfilled the incoming orders and manufactured the goods which Orazio shipped to places where sales were likely. Titian may—or may not—have retouched them before they left the studio. The assistants based their fair copies on models kept in the studio. Titian himself had done these models, consisting of portraits from nature, final conceptions of his *poesie* and devotional pictures. Serving originally as a basis for further production as Titian developed or modernized them, they now served for reproduction by the assistants. Some of these *modelli* go back into Titian's youthful years. Vasari, when visiting Titian in 1566, found the house in the Birri full of them. After Titian's death Pomponio, his second son, had them retouched and finished to make them salable. Most of them came to the Hermitage (St. Petersburg) in the 19th century, and to the United States in the 20th century. Four were bought by Tintoretto in their original state (one of these, "Christ Crowned With Thorns," is in Munich). These *modelli* had not been conceived for sale; they anticipated the unrestrained boldness that is typical of the master's late works, with which they are often confused. The very impressive late "Pietà" (Academy, Venice), which Vasari had seen in the studio and with which Titian had planned to adorn a chapel in the Frari, was finished by Palma Giovane after Titian's death in Venice on Aug. 27, 1576.

Orazio died from the plague several weeks after his father. He had been his father's right hand for many decades, and Titian had tried to introduce him as his heir to King Philip of Spain and to the Venetian government. Since all the work of Orazio, except for a small Crucifixion that was rediscovered in 1956 in the Escorial in Spain, has been inseparably incorporated into that of his father, nothing of his own style is identifiable.

See H. Tietze, *Titian,* 2nd ed. (1950), which has a good bibliography. (E. T.-C.)

TITICACA, LAKE (LAGO TITICACA), in the Andes of South America on the border between Peru and Bolivia, is the world's highest large lake. Its area of 3,141 sq.mi. is divided into two parts by the Strait of Tiquina. The northwest part, Lake Chucuito, is the larger, 85 mi. long by 35 mi. wide; the smaller southeast part, Lake Uinamarca, is 15 mi. long by 35 mi. wide. The whole lake, including the strait, is 110 mi. long. Its northeast shore is along the base of the towering Cordillera Real with peaks 21.000 ft. or more in height. Spurs of the mountains extend into the lake as rocky promontories. There are also high mountains to the southwest. Between the promontories, and at either end of the lake, the shores are marshy. The water level is 12,497 ft. above sea level. The lake is very deep—1,214 ft. Consequently the water temperature remains quite constant at about 51° F. The lake receives its water, which is only slightly brackish, through many short streams descending from the snow-capped mountains on either side. In addition there are three larger rivers draining a wide area of the Peruvian highlands—the Río Ramis, the Río Coata and the Río Huenque. The lake's outlet to the southeast is through the Rio Desaguadero into Lake Poopó.

One of the earliest civilizations of the Americas developed around the shores of Lake Titicaca. Archaeological remains of old cities, dating back to the time before Christ, are found on Titicaca Island and Coati Island, on the Copacabana peninsula, and at Tiahuanaco southeast of the lake. The Aymara Indians who still live in the Titicaca basin are the descendants of native peoples who were conquered by the Incas from Cuzco. They maintained their language and their way of living in spite of this conquest. Later, when conquered by the Spaniards, they were able to maintain their hold on the land regardless of the superior technology of the people from Europe. The Aymaras catch fish in the lake, and plant potatoes, quinoa. barley and maize on terraced fields around the shores. Their land is generally accepted as the place where the potato was first planted as a crop. Railroads connect Puno on Lake Titicaca with Mollendo and Matarani on the Peruvian coast, and Guaqui at the southeast end of the lake with La Paz in Bolivia A regular steamer service connects these two lake ports. *See* also BOLIVIA; *PERU.* (P. E. J.)

TITLE INSURANCE COMPANY is a company that issues policies indemnifying owners, mortgagees, lessees and others having particular interests in real estate against loss by reason of defects in title. Title insurance is strictly an American institution, having originated in Philadelphia, Pa., in 1876. The only comparable system of title assurance is a method of title registration devised in 1858 by Sir Robert Torrens in Australia, under which a certificate of title is issued by a public officer. With some variations in operation, the Torrens system has been adopted in a number of British colonies, some Canadian provinces, London, England, and a few states of the U.S. In some parts of Europe land records for many years have been kept by a system of judicial registration. In some countries there is neither registration of titles nor any provision for recording deeds; title papers aye preserved and passed from one owner to another when title is transferred.

In every state of the United States there are statutes providing for recording deeds, mortgages and other instruments relating to real estate. These statutes serve the dual purpose of preserving the records and of giving notice to all persons of their contents. There are also other public records of taxes, wills, court proceedings, judgments and mechanic's liens which affect title. In the course of time these records have become so voluminous that the process of re-examining title every time it is transferred has become increasingly laborious and complicated for lawyers. The problem of improving methods of transferring interests in land has long engaged the attention of lawyers, legislators and bar associations, but despite limitation statutes barring ancient claims, curative laws correcting minor flaws in public records, and adoption of title examination standards for guidance of lawyers, no substantial progress has been made. The title insurance business has thrived in offering a solution to this complex title problem. Upon transfer of a title that has been insured, the insuring company does not re-examine the entire history of the title, but merely considers matters affecting the title since the prior policy was issued.

There are about 160 title insurance corporations in the United States. Most of these offer title service only in the state of incorporation through a home office and agents, who may be abstracters or lawyers experienced in real-estate matters, designated "approved attorneys." A few of the larger companies insure titles in many states. Title insurance is available everywhere in the United States either from a local company or through an agent of a national company. Title insurers have a trade association, the American Title association, organized in 1907, whose membership includes title insurance companies, abstracters and attorneys specializing in real-estate law. There are also 32 state title associations.

Title insurance companies are subject to regulation and supervision, the extent of which varies in different states. In most states they are governed by an insurance code, which covers also other familiar kinds of insurance—life, fire, accident and public liability. Regulation often includes minimum capital requirements, supervision of policy forms and premium rates, maintenance of loss reserves, and periodical examination of company records by state officials. Most states require a substantial deposit of securities with a state officer to protect policyholders.

Title insurers issue two basic types of policies—an owner's policy and a mortgage policy—the forms of which differ among companies. They issue also a standardized form of mortgage policy, known as the American Title Association Standard Loan policy, whose coverage is substantially broader than most mortgage policies. The cost of title insurance depends upon the amount of the policy, the scope of coverage and the work involved in searching and examining title.

Many reasons account for growth of title insurance in the United States: insurance-mindedness of Americans; preference for title insurance over other forms of title evidence because protection includes indemnity against loss and defense against adverse claims; escrow and other services rendered by title insurers in connection with closing of real-estate transactions. (C. F. GR.)

TITLE TO LAND. Title is a legal conclusion concerning the ownership of land drawn from facts which, if proved, will enable an "owner" to obtain or retain possession of it. A complete understanding of land titles requires comprehension of the number and nature of interests in land recognized by the legal system where the land is located, the rules which the system provides to determine priority among two or more claimants to the same land and the procedure for obtaining and preserving the necessary title evidence.

The Anglo-American law of real property recognizes a complicated mass of interests which may coexist in a parcel of land. Several estates, several concurrent owners of undivided interests and several persons having different rights to use and enjoyment may all exist with respect to any given parcel. Fragmentation of ownership thus complicates land titles. but the rules concerning priorities may determine how many of the fragments other than those presently created are factors in the title.

It would have been possible to have had a priority rule that anyone who buys and takes possession in good faith obtains an absolute title to land even though the possessor from whom it was obtained was not himself the owner. Gnder such a rule a thief could pass title to an innocent purchaser. Mercantile law applies this precept to certain kinds of negotiable instruments such as currency, notes or checks, so that an innocent person who purchases such property from a thief acquires a title prior to or better than the person from whom the instrument was wrongfully taken (see COMMERCIAL PAPER). This rule, however, has never been applied to land; in fact, the early common law had almost an exactly opposite rule of priority. first in time is superior in right no matter how innocent a later purchaser may be. This rule, together with the fact of land's permanence and the prevalence of many interests in land, gives land a long title history which must be proved. A buyer of land must often examine the entire history of a parcel of land in order to determine whether the present seller is the successor of an earlier person who was first in time. Thus a seller must show that he got it lawfully from someone else and the latter from someone else and so on. Except for ancient and modern statutes of limitations designed to prevent a person, however rightful he may be. from asserting his claim after the lapse of a number of years, this proof would require that title be traced back to a discoverer, conqueror, sovereign or some other "first" person (see PRESCRIPTION).

The basic problem in land titles is one of proof. How does a seller go about furnishing proof that he or his predecessors were first in time? In primitive society neighbours knew firsthand and from received tradition who owned what parcel. If ownership was to be transferred from one person to another, it was done with the utmost publicity in the neighbourhood—by a symbolic delivery of the land in the presence of neighbours. As society became more complicated such direct knowledge was not enough. and each government eventually provided procedures for preserving the evidence of title histories. In much of England this is still done by passing the accumulated instruments of title from one buyer to the next. However, on the continent of Europe, in all of the British Commonwealth and in the United States. systems of public registries where evidence of title could be publicly preserved were universally established. In the English-speaking world the registries maintained in the American colonies, from as early as 1640. are the oldest; registry in the English counties of Middlesex and York did not begin until the 18th century.

In the process of developing the systems of public registries, the old "prior in time, prior in right" rule was substantially modified. if not eliminated, and the modern system of priorities is based almost completely on statutes dating, in the Anglo-American world, from the 18th century. Two systems of public registry developed and are still in use. In one system a record of all documents affecting land title is kept in a public registry, and a competent examiner must himself draw the necessary legal conclusion as to the owner of a parcel of land. This system compels a buyer to investigate title and to draw, at his peril, a correct legal conclusion regarding the significance of all the recorded documents.

Under the other registry system, known as the Torrens system (see below), the legal conclusion as to the state of the title is itself shown by the public record.

The Title-History System.—Under the first system, which maintains a public record of the title history, the statutes, in order to compel use of the record, developed four different rules of priority: (1) In some parts of western Europe a conveyance attempting to create an interest in land is not effective at all until it is recorded in the public records, so that the first to be recorded is prior in right because it is the only recognized transfer. The Anglo-American legal system rejected this rule of priority and concluded that an unrecorded deed of conveyance was good as between grantor and grantee but that a grantee who failed to record might lose his priority or right to some other claimant. (2) In the original recording statute for York county, in Scotland, and in a few states of the U.S. a first grantee could lose his right as against a person who recorded first; he who wins the race to the public records has priority of title. (3) In the original Middlesex statute and in many parts of the United States, particularly in the northeast, a second grantee from the same grantor acquires priority or title only if at the time of the delivery to him of the second instrument he had no notice of a prior instrument. Since he had "record notice" of a recorded instrument whether or not he saw it, the second in time is entitled to priority only if the first instrument is unrecorded and only if the person receiving the second conveyance is without actual knowledge of the earlier instrument. (4) The third type of statute in the United States and in parts of the British Commonwealth combines the "race" type with the "notice" type described above and grants priority to a subsequent purchaser over an earlier purchaser of the same parcel of land only if the second purchaser lacks notice and records first.

Recording and Indexing.—The mechanics of recordation are relatively simple. In all jurisdictions a person is on notice by reason of record only if the instrument found in the record is one entitled to be there. If the instrument is of a type entitled to be recorded, it is accorded record notice in most U.S. states only if it is acknowledged or witnessed. The recipient of an instrument, of conveyance takes it to the office of the recording agency. usually a county, although sometimes a town office. together with the prescribed fees. The instrument is from that moment "recorded." The recorder transcribes the instrument by hand) typewriter or photography and returns the original instrument to its owner.

Because of the volume of such records, an index to the system is necessary. Two types of index are in use, many states of the U.S. having both types. By far the most common are alphabetic indexes of both grantors and grantees. In such an index system a prospective buyer would find his seller's name in the grantee index, which would also give in an appropriate column the name of his grantor and the volume and page where the instrument is recorded. By following the grantee index back as far as one wished, looking for each preceding grantor in the grantee index, one could determine the chain of title of the present owner. A search of the grantor index would indicate whether any grantor in the chain of title had made some other conveyance of the same parcel of land to another. Thus the grantee index would index that B had purchased from A. but only the grantor index would indicate that A previously had mortgaged the land to X.

The other index system is based on the parcel rather than the names of the owners) and all relevant instruments concerning each physical area in the county are listed by page and volume number of the official books of record. Thus each parcel has its own index page. This index system is called a "tract" index.

Other *Information Affecting* Title.—Unfortunately for a title examiner not all of the matters which affect title to a parcel of land are to be found in the recorder's office. Thus any real-property tax liens for unpaid taxes will be listed in the county treasurer's office; bankruptcies and federal tax liens may be in the United States courthouse in another county; if the parcel of land was transmitted by reason of the death of the owner, the records of the probate court must be searched; if one of two joint owners dies, the only evidence of the power of the survivor to convey is the death certificate of the other in the department of vital statistics. Some defects in title may not appear in the record at all. An instrument does not indicate whether a transferor at the time of transfer was married or single; it does not indicate whether the instrument is in fact a forgery; nor does it indicate that in spite of the description in the conveyance there is less land than agreed upon because a neighbour built his fence on the wrong location of a boundary or built his eaves and cornices to overhang the property being purchased.

England has alleviated some of these difficulties by providing, since 1925, a land charges registry in which tax liens. covenants, easements; annuities and certain public-building restrictions must be recorded in order to give the claimant to them priority. However, since entries in this system are made against the name of a previous owner and not against the land, title search is difficult.

Professional Aids.—The complicated nature of transactions under the title-history system has produced several kinds of professionals who are customarily employed in order to give a buyer full assurance as to title. For urban properties it is customary in many parts of the United States and England to employ a surveyor to run the lines of the description of the land in question in order to determine any discrepancies and encroachments on the property. A professional title searcher is employed to trace in the public records the history of the land title and to abstract the records. Sometimes this title searcher is the lawyer who also gives a title opinion, and more commonly in western United States he is a professional abstractor or reader of the records and not a lawyer. Finally, a lawyer is employed to read the abstract of the instruments found in the public records and to prepare a title opinion in which he states his conclusion as to the state of the title. No one of these professionals guarantees the title; each is obligated only to use the reasonable standards of competence of his profession, and in the case of the abstractor there is an absolute obligation not to misread or omit a document in the chain of title. Abstractors are usually bonded. In England, while a surveyor may be used, a solicitor performs all other functions.

Private Title Insurance.—Another expedient for overcoming the worst drawbacks of the private investigation system used in the United States is private title insurance. A title insurance company either investigates the history of a title itself or employs an abstractor to do so; then, on the basis of a legal examination of this history, it insures that the title is good except for certain reservations stated in the policy. The title insurance policy, purchased for a single premium and not an annual premium. insures not only against loss resulting from mistakes in the abstract of the public records but also insures that its legal conclusion regarding the title is correct, including loss resulting from forgery and other irregularities which may not show on the face of the records. Thus, if a married man in the chain of title states in his deed of conveyance that he is single, the public records will show no outstanding claim of marital property in the other spouse. If such a claim does exist because the man is married, contrary to his recital, this claim prevails against an innocent purchaser. Title insurance will insure against this possibility. (See TITLE INSURANCE COMPANY.)

The **Torrens** System.—Another system of title insurance guarantees that the title is as shown in a document maintained in a register of title. Where the older system maintains evidence of title in public records from which a conclusion may be drawn by an examiner, in the title registration system the ultimate conclusion itself is registered. This system prevails on the continent and in most of the British Commonwealth countries and is expanding in England. While it has been available in about 20 states of the U.S., it has failed to make headway. The system is called registration of title or Torrens title after its originator in the Anglo-American world! Sir Robert Torrens of Australia, who modeled it after the ancient ship-registry system in England.

Under the Torrens system each parcel of land is set up on a register in the public records. This page sets forth the name of the owners of the fee simple and also all other rights, interests and liens to which the property is subject. A copy of this page. called an "owner's duplicate certificate title," is delivered to the owner. The transfer of a registered title is accomplished by the owner delivering his certificate to the official registrar with a direction to issue a new certificate to the transferee. The old certificate is then canceled and a new one issued. Thus the system is analogous to the procedure for transfer of shares of stock —the old stock certificate is surrendered for cancellation and a new one issued in the name of the new owner. In the case of involuntary conveyances such as sales by order of creditors, there must be a court order directing the registrar to make the change in ownership.

On an application for first registration the Torrens system in the United States differs substantially from that in the rest of the world. In the commonwealth countries a government official, the registrar. inspects the title in the manner described above for the recording system, and his conclusions, guaranteed by the state, are then entered as the original registered title. In the United States it was thought, at the turn of the 20th century, that the state and federal constitutions required such conclusions to be made only by a court. Accordingly, an elaborate and expensive proceeding to "quiet title" is necessary, in which, after argument and hearing by all possible claimants. the court instructs the registrar as to the nature of the registered title.

The key to the Torrens system is the conclusiveness of the certificate. Everywhere in the United States, however, the statutes except certain encumbrances from being shown on the certificate. The usual matters are short-term leases, public highways, current taxes and claims of the United States. A purchaser of land under a Torrens title in the U.S. must therefore continue to search other records for these encumbrances.

The reasons for the failure of Torrens title in the United States is revealed by the reasons for its success elsewhere. The success of the Torrens title in western Canada and parts of Australia is due to the fact that the first registration commences with the initial transfer of land into private ownership from the sovereign. Thus no complicated earlier history has to be unraveled or considered. In the United States the initial registration is a costly judicial proceeding which will be undertaken by an owner only if the market value of his land promises, as a result, to increase sufficiently to cover the expense. Since this is rarely the case, the cost of registration must almost always be borne by the initiator and cannot be passed on to his successors. It is significant that even in countries where an administrative rather than judicial proceeding is available, registration has not occurred voluntarily. It was made compulsory in London in 1899 and is now compulsory in Middlesex, Surrey and in certain county boroughs. It is also compulsory in New Zealand and Australia, where it is substantially used.

Another reason for the failure of the Torrens system in parts of the United States was the bankruptcy of the assurance fund. Instead of making the guarantee an obligation of the state, each state provided that a portion of the fee paid at initial registration and at each transfer should be paid into an insurance fund which would guarantee the title of the holder of a certificate against loss. In California a judgment for more than the amount collected in the fund early in Torrens history destroyed the confidence in the assurance fund.

In the United States failure of the registered title system has caused renewed interest in methods of simplifying the old recordation system. Many states have statutes limiting or eliminating claims more than a specified number of years old; *e.g.,* 75 years, Bar associations have prepared title standards to which all lawyers are urged to adhere, and they have drafted statutes reducing some objections to the older system. Nowhere has the United States gone as far as England, which has eliminated many of the cumbersome features by changing many interests, such as legal future interests, into equitable interests, subject always to a trustee's power to convey the land free of the claim, and also by limiting the title which a purchaser may demand, in the absence of agreement otherwise, to a good title not more than 30 years old.

On the assumption that the title-history system would continue in the United States. many public and private groups were engaged in the early 1960s in technical research to determine whether all title information could be reduced to cards or microfilms that could be used with modern electronic .computer and other machines. *See* also LAWS OF REAL PROPERTY AND CONVEYANCING. (A. DM.)

TITMOUSE, a name used for certain of the small songbirds (*q.v.*) of the family Paridae, especially those of the genus *Parus*. In Europe "titmouse" used to be in general use but has been shortened to "tit" with a qualifying word to indicate the species, as blue tit, etc. In the United States, where the long form of the word is used, as tufted titmouse, some species which would be called tits in Europe are called chickadees (*q.v.*) from the voice of the birds. The second part of the word is from the old English bird name and has nothing to do with the mammal mouse. Scholars used to hold that "titmouses" was the proper plural but "titmice" is gaining ground. The short form. "tit." is also used for several other unrelated small songbirds of various families.

The name titmouse is used in the United States for the several crested species closely related to the tufted titmouse. *Parus bicolor*. It is about six inches long, with gray upperparts. white underparts and rufous flanks. This titmouse searches for insects among leaves and twigs and in the bark of tree trunks; in so doing it flits about actively and perches acrobatically in a variety of poses. It also feeds on thin shelled nuts which it breaks open by holding them in its feet and hammering with its bill. Its voice is a series of clear whistled phrases. It is not migratory. The nest is made in some natural cavity in a tree trunk and is often lined with fur The five or six eggs are white, finely speckled with broun. The young bear some down; both parents share in nest duties.

JOHN H WHIPPLE FROM NATIONAL AUDUBON SOCIETY

TUFTED TITMOUSE (PARUS BICOLOR) COMMON TO THE U.S.

The titmouse family Paridae contains about 45 species of typical tits, titmice and chickadees which occur in North America, Europe, Asia and Africa They are all small birds, four to eight inches long, often with black caps and black throat patches, and usually with subdued gray and white coloration although some are yellowish or bluish. In habits they are much like the tufted tit but some dig a nest cavity in a dead tree. (A. L. RD.)

TITO (JOSIP BROZ) (1892–), Yugoslav statesman, leader of the Yugoslav partisans in World War II and from Jan 14. 1953, president of the Federal People's Republic of Yugoslavia. He was born on May 25, 1892, at Kumrovec, near Zagreb. Croatia, then part of the Xustro-Hungarian empire. seventh son of a peasant. Franjo Broz. After a childhood of poverty, he earned his living as a metalworker. Soon after the outbreak of World War I, he was sent to the Carpathian front where he was wounded and captured by the Russians in March 1915. This proved to be a turning point ın his life. In 1917 he joined the Red army and also married a Russian girl, Pelagya Belousova, whom he divorced in 1935.

In 1920 Broz returned to his native country, which had meanwhile achieved independence, and joined the Yugoslav Communist party. In 1928 he was arrested and sentenced to five years' imprisonment for subversive activity. When released, he went to Moscow where he worked in the Comintern's Balkan secretariat. In 1936 he was sent to Zagreb and Paris to organize recruitment for the international brigades fighting in Spain. In 1937 he became secretary-general of the Yugoslav Communist party, making his headquarters in Zagreb. He visited Moscow in 1938 and 1939. In the autumn of 1940 he secretly convened in Zagreb the fifth party congress which resolved that Yugoslavia should be kept out of the "imperialist" war (World War II).

In April 1941 the Axis powers invaded and partitioned Yugoslavia, but it was only after the Germans attacked the U S S R. on June *22* that he hurried to Belgrade and decided, in response to Comintern appeals, to prepare an armed rising against the invaders with himself (under the *nom de guerre* of Tito) as commander in chief. Having organized sabotage groups and partisan detachments. Tito left Belgrade at the end of August to take operational command. By mid-September most of Serbia had been cleared of Germans. He negotiated with Dragoljub (Draza) Mihajlovic, a colonel in the Yugoslav army who had rallied some officers and members of the paramilitary chetnik organization, with a view to reaching a unified command and common action. Negotiations broke down, open clashes between partisans and chetniks followed, and by the beginning of December the Germans reoccupied virtually all Serbia. Tito led the remnant of his forces first into eastern Bosnia, then into Montenegro, and finally into western Bosnia. He appealed for unity between differing racial and religious groups in resistance to the occupying forces, and formed (Nov 1942) an embryonic political organization, the Anti-Fascist National Liberation committee, with the same program.

The Germans and their auxiliaries made numerous determined attempts to annihilate Tito's forces, and parachute troops once nearly trapped him in his headquarters at Drvar (May 25, 1944). He escaped to the island of Vis, which was held jointly by British and partisan troops. From there he was able to go to Italy to confer (Aug. 1944) with the Allied commander in chief in the Mediterranean and with Winston Churchill, the British prime minister. A few weeks before Tito had paid a secret visit to Moscow, where he met Stalin for the first time. After the liberation of Yugoslavia Tito, now a self-appointed marshal, became prime minister (March 7, 1945). He visited Moscow officially in April 1945.

Toward the end of the war relations with the west deteriorated owing to Tito's attempt to seize Trieste, the shooting down of a U.S aircraft and the establishment of an undisguised Communist dictatorship in Yugoslavia. At the same time Tito's relations with the U.S.S.R unexpectedly came under heavy strain. Though his forces co-operated with the Soviet army in clearing the Germans out of Yugoslavia, he resented the previous failure of the Soviet Union to help the partisans, the pretensions of Soviet officers and advisers in Yugoslavia. the lack of support for his Trieste claim, and Soviet attempts to exploit the Yugoslav economy. Though still a convinced Communist, he had acquired an independent, nationalist viewpoint. "The Yugoslav brand of Communism," he once said "had its origins in the hills and forests and was not imported ready-made from Moscow." The storm burst in June 1948 when Stalin and the other leaders of the U.S.S.R., followed by those of the people's democracies, openly attacked him. Tito, supported by the bulk of his party, stood firm against Soviet economic pressure and threats of violence. There followed a gradual *rapprochement* with the west, marked by Tito's acceptance of economic aid, a state visit to Great Britain in March 1953 and a compromise over Trieste in Oct. 1954.

Various moves were subsequently made, with fluctuating success, to draw him back into the orthodox Soviet bloc. But Tito continued to favour a neutralist position and cultivated close links with such statesmen as Jawaharlal Nehru of India and Abd-al-Nasser of Egypt. He played host to a meeting of neutralist leaders at Belgrade in Sept. 1961. His achievements are due to remarkable qualities: exceptional physical and moral toughness, coolness in danger, promptness in making difficult decisions; inflexibility over essentials, adaptability and openness to reason and fresh ideas; a ready sense of humour, friendliness (turning to ruthlessness if friends "deviated"); a great zest for life, with an occasional bent toward ostentation. By the 1960s he was living with his third wife, Jovanka Budisavljevic (a second marriage did not outlast the war), chiefly in Belgrade or on his favourite island resort of Brioni, enjoying the prestige of an elder statesman and the fame of a leader who had become a legend in his own lifetime.

See YUGOSLAVIA: *History; see* also references under "Tito" in the Index volume.

TITOGRAD (PODGORICA), the capital of the People's Republic of Montenegro. Yugos., is located 298 km. (185 mi.) S.S.W. of Belgrade at the confluence of the Moraca and Ribnica rivers.

Pop. (1961) 29,100. Under the name of Podgorica it was first mentioned in 1330. From the second half of the 15th century until 1879 it mas in Turkish hands. In 1918 the union of Montenegro with Yugoslavia was proclaimed there. During World War II the town was occupied by the Italians and heavily damaged by the Allied air forces. The old Turkish-style town still exists; the new town is built on the banks of the two rivers. Titograd (as it was named after World War II in honour of Marshal Tito) has a university as well as several schools. It is an important centre of trade and tobacco growing and has cigarette manufacturing. It is also a road centre and possesses an airfield. (V. De.)

TITRATION is a process of chemical analysis in which the quantity of some constituent of a sample is determined by adding to the measured sample a series of known quantities of another substance with which the desired constituent reacts in a definite, known proportion. The process is usually carried out by adding a standard solution of titrating reagent, or titrant, from a buret, which is essentially a long graduated measuring tube with a stopcock and a delivery tube at its lower end. The concentration of the standard solution is determined by performing a similar titration with a known quantity of the substance to be determined, or a known quantity of some other substance (a primary standard) which reacts in a similar way with the titrant.

The equivalence point of a titration is that point at which an exactly chemically equivalent amount of titrant has been added to the sample. It is a theoretical quantity, which the analyst strives to determine as nearly as possible by means of some signal. This signal can be the colour change of an indicator, a substance which has been chosen to change colour as near to the equivalence point as possible. The experimental point at which the completion of the reaction is marked by the signal is called the end point. The difference between the end point and the equivalence point is the titration error, which is kept as small as possible by proper choice of end point signal and method for detecting it.

Many physical properties of the titration system (sample plus added reagent) change gradually during the course of the titration, and then change at a different rate after the equivalence point has been passed. Among these are the density, viscosity, surface tension, colour intensity and even the temperature (owing to the heat of the titration reaction and heat of mixing). Special titrations are sometimes carried out by measuring one of these properties at various points before and after the end point, and determining by graphical means the point at which an abrupt change occurs in the rate at which the measured property changes with the addition of reagent.

Most titrations, however, are carried out either by means of visual colour indicators or by electrical methods. These two classes of titrations will be considered in more detail below.

VISUAL COLOUR TITRATION

For many titration reactions it is possible to find a suitable visual colour indicator which will signal the end point at, or very close to, the equivalence point. It is convenient to classify such reactions, according to the nature of the chemical reaction occurring between the sample and titrant.

Acid-Base Titration% — For the titration of an acid with a base, or vice versa, the indicator is a substance which can exist in two forms, an acid form and a basic form, which differ in colour. For example, litmus is blue in alkaline solution and red in acid solution. Phenolphthalein, a one-colour indicator, is colourless in acid solution and red in alkaline solution. A wide choice of acid-base indicators is available, varying not only in the colours of the two forms but also in their sensitivity toward acid or base. The indicator is not necessarily chosen to change colour in a neutral solution, but rather to exhibit its intermediate colour (equal mixture of the two forms) at the acidity corresponding to the equivalence point composition. This acidity depends upon the relative strengths of the acid and base undergoing reaction. For instance, if acetic acid (a weak acid) is titrated with sodium hydroxide (a strong base) the salt, sodium acetate, which corresponds to the equivalence point composition, gives a mildly alkaline rather than neutral solution. Therefore, an indicator (such as phenolphthalein) is chosen so that in a solution of sodium acetate it exhibits its intermediate colour.

Precipitation **Titrations.**—Several types of indicator reactions will be illustrated by the example of the determination of chloride by titration with silver nitrate, with the formation of a precipitate of silver chloride. First, the appearance of the first slight excess of silver ion can be marked by the appearance of a coloured precipitate. Potassium chromate can be used as the indicator, the coloured precipitate being red silver chromate. The concentration of the indicator ion must be properly chosen, so that its silver salt precipitates at just the right silver ion concentration. If the coloured precipitate is less soluble than the precipitate formed in the titration reaction, it is necessary to resort to an external indicator titration, in which droplets of solution are tested for excess titrant by means of a spot test. Second, an adsorption indicator can be used to detect the first excess of silver ion. The indicator action is based on the formation on the surface of the precipitate, of an adsorbed layer of silver-indicator salt, which forms only when an excess of silver ion is present. Third, a soluble coloured complex can be used as an indicator. In the Volhard titration of silver ion with thiocyanate, a small concentration of ferric iron is added as an indicator. After the precipitation of silver thiocyanate is complete, the first excess of thiocyanate is indicated by the formation of a red complex ion, $FeSCN^{++}$, formed by the combination of ferric iron, Fe^{+++}, with thiocyanate ion, SCN^-.

Complex Formation **Titrations.**—The most important titrations based upon complex formation reactions are those involving the titration of metal ions with the reagent disodium ethylenediaminetetraacetate, commonly called EDTA. The indicators are dyes which have the property of forming a coloured complex with the metal ion. As the titration proceeds, the reagent reacts first with uncomplexed metal ions, and finally at the end point it reacts with the metal-indicator complex. The colour change corresponds to the conversion of the metal-dye complex into the free dye.

Oxidation-Reduction **(Redox)** Titration% — A redox indicator is analogous in action to the other types of visual colour titrations. In the immediate vicinity of the end point, the indicator undergoes oxidation or reduction depending upon whether the titrant is an oxidizing agent or a reducing agent. The oxidized and reduced forms of the indicator have distinctly different colours.

ELECTROMETRIC TITRATIONS

Electrometric titrations are those in which the end point is detected by electrical measurements. They are classified according to the electrical quantity which is measured. Potentiometric titrations involve the measurement of the potential difference between two electrodes of a cell, conductometric titrations the electrical conductance or resistance, amperometric titrations the electric current passing during the course of the titration, and coulometric titrations the total quantity of electricity passed during the titration.

Potentiometric Titration% — The usual potentiometric titration arrangement is to have two electrodes, one an indicator electrode in the solution containing the sample being titrated, the other a reference electrode, external to the sample vessel and connected to it by means of a salt bridge. The salt bridge provides electrical contact between the sample solution and the reference electrode. The reference electrode is some convenient electrode such as a calomel electrode which maintains a constant potential during the entire titration.

The indicator electrode is chosen to respond to changes in concentration of the particular substance being titrated. For instance, if silver nitrate is titrated with sodium chloride to precipitate silver chloride, silver wire serves as an indicator electrode for silver ions. As the precipitation of silver approaches completion, the potential of the silver electrode takes a sudden jump which serves as an indication of the end point. If an acid is being titrated with a base, the indicator electrode is chosen to respond to changes in hydrogen ion concentration.

In general the potential of an indicator electrode varies linearly with the logarithm of the concentration of the substance to which it responds, or $E = A + B \log C$, where E is the electrode potential, C is the concentration and A and B are constants depending on the type of electrode and the nature of the substance being titrated. During the titration, C changes in direct proportion to the volume of reagent added. Near the end point, the rate of change of C relative to the amount still remaining becomes very large, so that log C changes very rapidly and the potential takes a sudden jump. For accurate work the end point is taken as that point at which the potential is changing most rapidly with titration volume.

Conductometric **Titrations.**—A pair of electrodes, usually platinum sheets, are introduced into a titration vessel, and the electrical resistance is measured after the addition of successive portions of reagent. The reciprocal of the resistance, or conductance, is plotted against titration volume. Generally the resulting graph consists of two straight lines intersecting at the end point. In most cases, there is a region of curvature near the end point owing to incompleteness of the titration reaction. The linear portions of the graph at some distance from the end point are extended to their point of intersection, which marks the end point.

To illustrate a conductometric titration, consider a sample of hydrochloric acid, which in dilute solution is completely ionized into hydrogen ions and chloride ions. The sample is to be titrated with potassium hydroxide solution, which contains potassium ions and hydroxyl ions. The titration reaction is

$$\underbrace{H^+ + Cl^-}_{\text{sample}} + \underbrace{K^+ + OH^-}_{\text{reagent}} \rightarrow \underbrace{H_2O + K^+ + Cl^-}_{\text{product}}$$

in which the net result up to the end point is the substitution of potassium ions for hydrogen ions. Also, some dilution occurs, because water is added together with potassium hydroxide in the reagent. However, in usual practice the reagent is made about ten or twenty times more concentrated than the sample, so that dilution is negligible. If dilution is neglected, the only reason for a change of conductance before the end point is that potassium ions move more slowly than hydrogen ions in an electric field. As a result the conductivity decreases several fold before the end point. After the end point, the conductivity rises markedly because potassium ions and hydroxyl ions are being added. A V-shaped titration curve results.

Very near the end point, the slight ionization of water contributes noticeably to the conductance and causes a slight curvature at the point of the V.

To measure the electrical conductance of solutions, it is necessary to use a Wheatstone bridge with an alternating current. If a direct current is used, Ohm's law cannot be applied because chemical reactions occur at the electrodes. As a result of the reactions, a back e.m.f. is set up which must be overcome by additional voltage before appreciable current can flow. This phenomenon, called electrode polarization, is avoided by the use of an alternating current.

Amperometric **Titrations.**—Amperometric titrations are based on the measurement of electrolysis current during the course of a titration. The current is not determined by the electrolytic resistance of the solution, because the conditions are such that Ohm's law is not obeyed. Instead, the current is determined by the rate of supply of some substance to one of the electrodes. Because of this feature, the amperometric titration does not respond to the total conductance of the solution and the electrode response is therefore more specific.

To illustrate the principle, consider a solution of potassium iodide and iodine, containing two platinum electrodes. This electrolytic cell will pass a current with the smallest conceivable applied voltage, and Ohm's law will be obeyed. At the cathode, iodine is reduced to iodide $I_2 + 2e \rightarrow 2I^-$, and just the reverse reaction occurs at the anode. No polarization, and no back e.m.f. is observed for small applied voltages. Now suppose that the concentration of iodine is very low, while that of potassium iodide is relatively high. Again, a current begins to flow when a very small voltage (say 10 mv) is applied to the cell. However, if the voltage is now increased (say to 100 mv) the current does not increase in proportion to the applied voltage because the concentration of iodine is so low that the current is limited by the rate at which iodine reaches the cathode surface by diffusion and convection. By stirring the solution the current can be increased up to a value which ultimately is limited by the resistance of the solution. However, if the concentration of iodine is low enough, the current is limited by diffusion and convection even if the solution is violently stirred.

The current is then determined by the stirring rate and iodine concentration over a relatively large range of applied voltages. Suppose that a constant voltage of 100 mv is applied, and the iodine is titrated by a suitable reagent such as sodium thiosulfate or arsenite which reduces the iodine to iodide. The current is proportional to iodine concentration, and decreases toward zero at the end point. This is an example of a "dead-stop" end point or amperometric titration with two indicator electrodes. In this example it was evident that the current was limited by the current at one of the electrodes (the cathode). It is usual practice to use only one electrode as the indicator electrode, and to use a reference electrode and salt bridge as in a potentiometric titration. The indicator electrode may respond to a metal ion or an oxidizing or reducing agent in solution. In some titrations, both the substance being titrated and the reagent produce an electrolytic current, in which case a V-shaped titration curve is obtained by plotting current against titration volume. If only the sample yields a current, the titration curve is L-shaped, while if only the reagent responds, an inverted L-shaped curve results. As in a conductometric titration, the end point is detected by the intersection of two straight lines, extended from points well removed from the end point. In the immediate vicinity of the end point, curvature due to incomplete reaction is observed.

Coulometric Titration.—According to Faraday's law, the passage of 96,500 coulombs of electricity through a solution brings about one gram equivalent of chemical reaction at each electrode. In a coulometric titration the quantity of electricity required to carry out a known reaction is measured, and from Faraday's law, the quantity of material present is calculated.

Coulometric titrations may be carried out at constant potential or at constant current. In either case it is necessary to arrange conditions so that only the desired electrode reaction can occur.

In coulometric titrations at constant potential, the potential of one of the two electrodes of an electrolytic cell is maintained at a constant value with respect to a third electrode which serves as a reference electrode of constant potential. The potential is adjusted to such a value that only the desired reaction can occur, and it is maintained at this value throughout a quantitative electrolysis. For example, if silver and copper salts are in solution, the potential is adjusted to a value which permits the deposition of silver but not of copper on the cathode. The current due to silver deposition gradually decreases to a very low value as the silver is removed. The total current, as measured by means of a coulometer, is a direct measure of the silver content of the solution. By adjusting the potential to a new value corresponding to the quantitative deposition of copper, the solution can be analyzed for copper.

To be strictly analogous to ordinary titrations, coulometric titrations should be carried out at constant current. The quantity of electricity in coulombs is equal to the product of the current in amperes and the time in seconds. The time of electrolysis is analogous to reagent volume and the current is analogous to reagent concentration in an ordinary titration. In a constant current titration it is unnecessary to use a coulometer, but simply to determine the time elapsed during the quantitative electrolysis. However, some means of indicating the end point is necessary, and also special precautions are necessary to make sure that only a single electrode reaction can occur. This is usually accomplished by adding some substance which acts as a coulometric intermediate. For example, if a quantitative oxidation of ferrous iron is to be carried out at a platinum anode, it is necessary to avoid the anodic evolution of oxygen even near the end point where the concentration of ferrous iron is very low. To do this, cerous cerium is added in relatively high concentrations. It is oxidized at the anode to ceric cerium, which oxidizes the last of the ferrous iron in solution. Another procedure is to generate the titrating reagent using an electrode in an external flowing solution which is continuously being added to the titration cell.

As an example, hydroxyl ions can be generated at a platinum cathode by electrolyzing a neutral solution of sodium sulfate. The solution flowing past the cathode surface is added to the titration vessel.

The end point can be detected either by a colour indicator or by any of the electrometric methods described above.

TITUS, SAINT, like Timothy, in the New Testament, is known from allusions in the Acts of the Apostles and the Pauline epistles. He was a convert from paganism! and St. Paul refused to allow him to be circumcised (Gal. ii. 1 ff.) at Jerusalem, when the conservative party' demanded this concession to religious feeling. He then appears in connection with the Corinthian church (see I and II Corinthians) where he won the greatest praise from the apostle for his upright and loyal services. He was specially entrusted with the business of organizing the collection for the poor Christians of Judaea, in the Achaian churches (II Cor. viii, ff.), and evidently acted as a commissioner of the apostle Paul at Corinth during the dispute that followed. According to II Tim. iv. 10 he went off subsequently on a mission to Dalmatia, but the epistle addressed to him implies a tradition that he superintended the work in the island of Crete as a delegate of his chief. Later tradition made him bishop of Crete. Titus' feast day in the Greek and Syrian churches is Aug. 25, in the Roman Catholic Church Feb. 6. (J. MoF.)

TITUS, FLAVIUS SABINUS VESPASIANUS (A.D. 40 or 41–81), Roman emperor 79–81, son of the emperor Vespasian, was born on Dec. 30. A.D. 40 (or 41). As a young man he served with credit in Germany and Britain. and had command of a legion under his father in the Jewish war. In 68 he was sent by his father to congratulate the newly proclaimed emperor Galba, but hearing of Galba's death he returned to Palestine. The next year Vespasian, having been proclaimed emperor, went to Italy, leaving Titus to carry on the siege of Jerusalem! which was captured on Sept. 8, 70. On his return to Rome he and his father celebrated a triumph! recorded by the "Arch of Titus." For the rest of Vespasian's reign he was associated with him in the government with the title of Caesar. During this time he was not popular and he outraged public opinion by his connection with Berenice, sister of Herod Agrippa; both of them came and lived in the palace for a while but Titus had to send her back. He succeeded his father in 79 and put an end to prosecutions for treason, banished the informers and became pontifex maximus to avoid shedding blood. He was notably lenient to Domitian who plotted against him. The Colosseum was finished in his reign and he built new baths in Rome. He visited Pompeii when it was destroyed in 79 and contributed to its relief; during his absence there was a three-day fire in Rome and he again gave his assistance. The only fighting during his reign was in Britain, where Agricola conquered as far as the Tay. Titus died on Sept. 13, 81.

TITUS, EPISTLE TO: see PASTORAL EPISTLES.

TITUS TATIUS, in Roman legend, the Sabine king of Cures, who waged war upon the Romans to avenge the rape of the Sabine women (see ROMULUS). After various indecisive conflicts the latter, who had become Roman matrons, intervened and prevailed upon the combatants to cease fighting. A formal treaty was then arranged between the Romans and Sabines, whereby Romulus and Tatius were to be joint and equal rulers of the Roman people. Rome was to retain its name and each citizen was to be called a Roman, but as a community they were to be called Quirites (*q.v.*); the Sabines were to be incorporated in the state and admitted into the tribes and curies. After this arrangement had lasted for five years it came to an end by the death of Tatius, who was killed out of revenge by the inhabitants of Lavinium. According to Mommsen, the story of his death (for which see Plutarch) looks like a historical version of the abolition of blood revenge. Tatius, who in some respects resembles Remus, is not a historical personage. but the eponymous hero of the religious college called *sodales Titii.* As to this body Tacitus expresses two different opinions, representing two different traditions: that it was introduced either by Tatius himself to preserve the Sabine cult in Rome; or by Romulus in honour of Tatius, at whose grave its members were bound to offer a yearly sacrifice.

TITUSVILLE, a city of Crawford county, Pa., U.S., on Oil creek. 40 mi. S.E. of Erie. It was founded in 1796 by Samuel and Jonathan Titus and prospered as a lumbering and agricultural centre. It was incorporated as a borough in 1847 and chartered as a city in 1866.

Oil seeping from the ground nearby aroused the interest of chemists and on Aug. 27, 1859, the first oil well in history was drilled just outside the city limits by "Col." Edwin L. Drake (1819–80). The oil industry began aith this 70-ft. well and the area boomed. The first oil refinery, blasting torpedo, casing-head gasoline plant and gasoline engine for pumping were at Titusville. The nation's first extensive natural gas industry was developed in the area about 1872. In 1934 the Drake well property became a state park of 229 ac. An exact replica of the Drake engine house and derrick and an extensive museum of early oil industry artifacts are at the site. A monument to Drake was erected in the city's Woodlawn cemetery in 1902.

There are no oil refineries in the city today, the annual production from the county's remaining producing wells being trucked to nearby Oil City (*q.v.*). Small plants use local oil to produce plastics and wax. Alloy steel, boilers and forgings are the city's major products. For comparative population figures see table in PENNSYLVANIA: Population.

See Hildegarde Dolson, *The Great Oildorado* (1959). (W. A. C.)

TIV, a Nigerian tribe living on both sides of the Benue river about 150 mi. upstream from its confluence aith the Niger. Their language is a separate subdivision of the Niger-Congo family of languages; it was reduced to writing about 1920 by missionaries and is taught to all who attend primary school. Tiv are subsistence farmers whose main crops are yams, millets and sorghums, all of which are eaten as staple porridge. made palatable by combination with sauces and stews consisting of meat, oils and vegetables. Tiv have no indigenous state organization, but form a series of territorially based lineages organized on the principle of segmental opposition. They see this system in terms of an agnatic genealogy running back about 17 generations; the descendants through males of each person in the genealogy, of whatever generation, form both a territorial group and a kinship group. The balance of power between equivalent segments in this system provides the basis for carrying out the political activities of law enforcement and military protection. In response to popular demand, the British administration established a paramount chief in 1948. Tiv who are not Christian are polygynous if they can afford to be so. Their complex system of exchange marriage was outlawed in 1927 and replaced by marriage with bride wealth. Women aluays move to the homes of their husbands. which in 83% of the cases are with the husband's lineage. Tiv religion, based on manipulation of forces entrusted to man by God, is still a powerful force. Missionaries have, however, worked among Tiv since 1911. A number of converts have been made; most Tiv have some knowledge of Christian principles. There is a minor Moslem infiltration.

BIBLIOGRAPHY.—Rupert East (trans.), *Akiga's Story* (1939); Laura and Paul Rnhannan, *The Tiv of Central Nigeria* (1953); Paul Bohannan, *Justice and Judgment Among the Tiv* (1957). (P. J. B.)

TIVERTON, a municipal borough in the Tiverton parliamentary division of Devon. Eng.. at the confluence of the Lowman and Exe. 14 mi. N. of Exeter by road. Pop. (1961) 12.296. Area 27.8 sq.mi. Twyfyrde (the double ford) is mentioned in Alfred's will (880–885). In Domesday Book Tiverton is the king's, but Henry I gave the great manor to the Redvers. William de Vernon, 5th earl of Devon, founded a borough between 1193 and 1217, and in 1615 it was incorporated by James I, who also established two members of parliament. New charters were granted by James II and George I. St. Peter's church contains a Norman doorway. John Greenway's chantry chapel (1517) has noteworthy external carvings of ships. The castle, founded by Richard de Redvers about 1105, was later a principal seat of the Courteney, earls of Devon. Enriched by the kersey trade, Peter Blundell founded (1604) the largest school in the west of England. Life at Blundells in the 1830s is vividly described by R. D. Blackmore in Lorna *Doone*. Externally the 17th-century buildings and grounds are well-preserved. The school continues in modern buildings near the town. The cloth trade failed in 1816; John Heathcoat (1783–1861), inventor of the bobbin net frame, then went to Tiverton. His firm now makes elastic net and woven nylon, as well as lace,

See M. Dunsfold, *Historical Memoirs of the Town and Parish of Tiverton* (Exeter, 1790); W. Harding, The *History of Tiverton*, 2 vol. (Tiverton, 1845–47); E. S. Chalk, *History of St. Peter's Church, Tiverton* (Tiverton, 1905); W. G. Hoskins. *Devon* (London, 1954).

TIVOLI, (ancient *Tibur*), a tonn and episcopal see, province of Rome, 18 mi. E.N E. of Rome by road and tramway, 24½ mi. by rail. 760 ft. above sea level. Pop. (1957 est.) 32.973 (commune). Tivoli lies on the west of the Sabine mts.. where the river Anio issues from them. upon a limestone rock above the river. The town on one side overlooks the Campagna di Roma and Rome itself, on the other the deep gorge of the Anio, with its lofty falls, and the environs are very beautiful.

Tivoli is in part built upon the extensive terraces of the temple of Hercules Victor, the chief deity of Tibur, of which some remains exist. A modern improvement is a channel, consisting of two parallel tunnels 290 and 330 yd. long, which was made to the N.E of the city in 1826–35, after a flood of the Anio led to a change in its course and threatened to carry away the town. On emerging from these tunnels, the river has a fall of 354 ft. Farther N.W. are smaller falls (the cascatelle) of that portion of the river which is carried through the town and serves for industrial purposes. Five miles W. are the sulphur baths of Acque Albule, with a temperature of 75.2° F. They were known to the ancients and are still frequented. Tivoli has numerous remains, many of them dating from ancient Roman times. Tibur was a favourite place of resort for such Romans as Augustus, Maecenas, Hadrian, Horace and Suetonius, all of whom had villas there; and Suetonius, as well as Catullus and Statius, made Tibur famous with their enthusiastic praise. The remains of villas in the district are numerous and important. particularly those of Hadrian's villa. which contained statues, marbles and fine mosaic pavements, some of the last being preserved in *situ*. The Villa d'Este, begun in 1549 by Pirro Ligorio for Cardinal Ippolito d'Este the younger, has the finest example of a Renaissance garden in Italy. The castle was built in 1460 by Pius II on the site of the amphitheatre and is now a prison. The town contains numerous old churches and houses. and there are some fine paintings of the later middle ages and early Renaissance in the cathedral.

Ancient Tibur. — Though on the edge of the Sabine mountains, Tibur was a member of the Latin league. It allied itself with the Gauls in 361 B.C., and in the war which followed the towns of Empulum and Saxula were destroyed and triumphs over Tibur were celebrated in 360 and 354 B.C., and again in 338 when its forces were defeated with those of Praeneste. It became, however, an ally of Rome. Its prosperity during the imperial period was mainly due to the favour in which it stood as a summer resort. During the siege of Rome by Narses, Belisarius occupied Tibur; it was afterwards treacherously surrendered to Totila, whose troops plundered it. but who rebuilt it in A.D. 547. (T. A.; X.)

TLAXCALA, smallest state of Mexico. Pop. (1960) 347,334; area, 1.555 sq.mi., gives it the highest density (183 persons per square mile) among Mexican states. It is bordered on three sides by the state of Puebla and is bounded west and northnest by the states of México and Hidalgo. Lying on the great Mesa Central, it has a mean altitude of 7,000 ft. that provides it with a cool, healthful climate. Railways and highways link it to the federal capital, Mexico City (66 mi. W.N.W.) and Puebla (14 mi. S.). Almost exclusively agricultural, Tlaxcala grows cereals and has numerous handicrafts, notably weaving of serapes and woolen cloth. It is the descendant of the Indian principality of Tlaxcala which refused to surrender to the Aztec confederation and joined Hernán Cortés as his principal Indian ally in the conquest of Mexico (1519–21). Continued loyalty to Spain brought the Tlaxcalans many subsequent privileges. Capital of the state is Tlaxcala (pop., 5,071), largest of numerous towns and villages. situated at an altitude of 7,500 ft. The Indians of this area are relatively prosperous because the Spaniards never let them be despoiled. The town itself is old and charming and has the oldest church in Mexico built in 1521. At Tizatlan across the river is a small temple whose painted altars depict the symbolism of the ancient religion. .Near the town Cortés built his brigantines which he transported to the Lake of Mexico in his final onslaught on the Aztec capital. (J. A. Cw.)

TLEMÇEN, a town of Algeria, the capital of an *arrondissement* in the *département* of Tlemqen, near the frontier of Morocco, 68 mi. by road and 102 by rail S.W. of Oran. Pop. (1960) 80,000 (metropolltan area). It stands 2,500 ft. above the sea, on the north slope of the Lella Setta hills 14,000 ft.). The railway from Oran runs from Tlemçen to Ujda and thence to Rabat via Fez. Another line links Tlemqen to the port of Beni-saf.

The various quarters are grouped around the principal mosque —the Jewish to the southwest, the Moorish to the southeast, that of the merchants to the northeast, while the new town with the civic buildings lies to the northwest. Of the 64 mosques which existed at the period of the French conquest, several have disappeared. The great mosque (Jamaa-el-Kebir) has a brick minaret 112 ft. high, adorned with marble columns. This mosque was built A.D. 1136 to replace a much older building. The mosque of Sidi Ahmed bel Hassan, usually called Abul Hassan, built A.D. 1298, now transformed into a museum of antiquities, has two series of arches, which rest on alabaster pillars. The courts are ornamented by sculptures of great beauty and richness; the delicately-carved cedar ceiling bears traces of polychromatic painting. The mosque of El-Halawi (the Sweetmeat Maker), dating from 1353, has eight magnificent columns of Algerian onyx. The ceiling of cedar is richly carved, and there is a fine colonnade on each side of the court. The military authorities occupy the Meshuar or citadel, built in 1145, which separates the Jewish and Moorish quarters and was formerly the palace of the rulers of Tlemçen. Only the minaret of the mosque, dating from the 14th century, and the battlemented wall, flanked by two towers, remain of its former magnificence. The vast basin (*sahrij*) under the old walls, now dry (720 ft. in length, 490 in width and 10 in depth), was apparently made for naval exhibitions. A covered market occupied the site of the Kissaria, the place of residence of European merchants from Pisa, Genoa, Catalonia and Provence. Besides the large trade carried on there are native manufactories of cloth, carpets and leather articles. A special manufacture is that of red shawls, used by Jewish women when in mourning. In the immediate neighbourhood of the modern Tlemçen are numerous remains of the fortifications of Agadir (vide infra), and the minaret of the mosque, a beautiful tower dating from the 13th century, the lower part of which is built of large hewn stones from the Roman Pornaria. More noteworthy, however, are the ruins of Sidi Bu Medin and of Mansura. Sidi Bu Medin (more properly El Eubbad) is a little over a mile southeast of Tlemçen. It was founded A.D. 1337 by Ali V, the first of the Beni-Marin (Marinide) sultans who ruled Tlemqen. The kubba or tomb of Sidi Bu Medin, near the palace, is held in great veneration by the Arabs. The adjacent mosque is a beautiful specimen of Moorish art.

Mansura, which is about 1½ mi. west of Tlemqen, owes its foundation to the attempts of the Beni-Marin rulers of Morocco to extend their sovereignty. The Amir Abu Yakub Yusef besieged Tlemqen in the early years of the 14th century. The siege lasted eight years, and Yusef turned his camp into a walled city. The siege being raised, El Mansura (the victorious), as the new city was called, was abandoned. It was reoccupied when (1335) Ali

V renewed the siege, which this time proved successful. On the expulsion of the Marinides in 1359 Mansura was finally deserted.

Besides the walls and towers, and the minaret of the mosque, little remains of Mansura, of which Ibn Khaldūn has left a contemporary and graphic sketch. The minaret was one of the finest mosque towers in Algeria. It was 125 ft. high, and was built of hewn stone. (X.; A. BE.)

The Sultanate **of Tlemçen.**—In 1248 Tlemçen was captured by Abu Yahia Yarmorasen (Ghamarasan) who was chief of the Zenata tribe of Berbers and claimed descent from the Caliph Ali. Yarmorasen, who died in 1282, founded the dynasty of the Abd-el-Wahid, who ruled the greater part of what now constitutes Algeria. Under their sway Tlemqen flourished exceedingly. The presence of Jews and Christians was encouraged and the Christians possessed a church. The bazaar of the Franks (kissaria) was a large walled enclosure, the gates of which were closed at sunset. As many as 5,000 Christians lived peaceably in Tlemçen, and the sultan included in his army a Christian bodyguard. In 1337 the power of the Abd-el-Wahid was temporarily extinguished by the Marinide sultans of Morocco. They left fine monuments of the period of their ascendancy, which lasted 22 years. Once more, under the Abd-el-Wahid, now known as the Beni-Zeiyan, from 1359 to 1553, Tlemqen enjoyed prosperity. The Spanish occupation of Oran (1509) struck a fatal blow at the European commerce of the town. The Beni-Zeiyan, after the capture of Algiers in 1516 by the corsair Barbarossa (*q.v.*), gradually lost their territory to the Turks, while Tlemçen itself for 40 years became tributary to the Spanish governor of Oran. In 1518 the town was held for a short time by Arouj Barbarossa, but Arouj was killed in a fight with the Spaniards. In 1553 the Turks under Salah Rais, pasha of Algiers, captured Tlemçen and the Sultanate of Tagrart, as it was still frequently called, came to an end. Under the Turks the town ceased to be of any importance. When the French entered Algeria, the sultans of Morocco were disputing the possession of Tlemqen with the Kuluglis, who fought first for themselves and afterward for France. In 1835 Abd-el-Kader, on whose appearance the Moors retired, sought to re-establish the ancient empire of Tlemqen, but he retreated before Marshal Bertrand Clauzel in 1836. The treaty of the Tafna (1837) gave Tlemçen to Abd-el-Kader, but, war being renewed in 1842, Tlemçen was definitely occupied by the French. (F. R. C.; X.)

TLINGIT, Indians of the southeastern Alaskan coast, northwest to Controller bay. A few also live inland on the extreme upper Yukon drainage in Canada. Progressively altered by Alaskan commercial development since the mid-19th century, the aboriginal culture was characterized by sea mammal hunting, fishing, woodworking, totemic art, emphasis on rank and wealth and slavery. The 16 major geographical groupings, or tribes, are crosscut by division into two moieties, which are further subdivided into matrilineal clans represented by localized lineages. The language may be related ultimately to Haida, Athapaskan and Eyak (Nadene family). Estimated population in the 18th century, 10.000; in the second half of the 20th century this had declined to about 4,000. See also INDIANS, NORTHWEST COAST; ATHAPASKAN.

See Aurel Krause, The *Tlingit Indians* (1956). (C. McC.)

TNT (TRINITROTOLUENE) was discovered by J. Wilbrand in 1863, but its explosive properties became known only later when detonators were adopted as the means of setting off high explosives. It was introduced into large-scale use during World War I and became the standard explosive in World War II, during which combined production of several warring nations ran into several thousand tons daily.

TNT, which has the molecular formula $C_7H_5O_6N_3$, is prepared by nitration of toluene $C_6H_5—CH_3$, which is obtained by distillation of coal tar or of crude petroleum, and is made synthetically from other components of petroleum. The nitration is usually carried out in three stages, the first yielding mononitrotoluene, the second, dinitrotoluene and the third, TNT. Mixed nitric-sulfuric acids are used for the nitration, the strength increasing from stage to stage. In the course of this preparation isomers of the desired product—alpha TNT, 2,4,6-trinitrotoluene—are formed in small quantities. Since these are less stable to heat and have the tendency to form low-melting mixtures and hence to cause exudation from loaded munitions, they are removed; this. purification is best accomplished by the washing of crude TNT with 5% sodium sulfite solution.

TNT is a pale-yellow crystalline powder; its melting point is 80.5° C. and its specific gravity is 1.65. TNT is only slightly soluble in water but is easily soluble in benzene, toluene and acetone. It is stable to heat and decomposes slowly only when heated above about 180° C.

Because of its low sensitivity to percussion, its low melting temperature (which permits it to be melted in steam-heated kettles) and its high explosive performance, TNT became the most favoured of preatomic military explosives. It is used singly and in mixtures with other explosives to load (by casting) all types of munitions.

TOAD, a name loosely used for rough-skinned tailless amphibians of several families, Hylidae (tree toads), Pelobatidae (spadefoot toads), Pipidae (Surinam toad). The true toads, genus Bufo, family Bufonidae, number about 250 species and are world-wide in distribution with the notable exceptions of Australasia and Madagascar. Among distinctive features of the family are toothless jaws and Bidder's organ (a potential ovary with no known normal function). Besides Bufo, the familv includes five small Malaysian genera of diverse habits and three African genera, one of which (Nectophrynoides) includes the only frogs, that give birth to their young.

ISABELLE HUNT CONANT

AMERICAN TOAD (BUFO TERRESTRIS AMERICANUS) COMMON TO EASTERN NORTH AMERICA

True toads, of which the American toad (Bufo *terrestris* americanus) is a common representative, are stout-bodied with short legs that limit them to hopping or walking rather than leaping. Body size ranges from three auarters of an inch to nine inches. The thick and often warty skin on the back is generally coloured a mottled brown. The smoother underside mav not be pigmented, but males usually have a dark throat. Much of the dorsal skin and its warts contain poison-secreting glands, but these are most concentrated in two raised areas behind the eyes, the parotoid glands.

The poison, which is secreted or even ejected when the toad is molested, is very irritating to the eyes and mucous membranes. It effectively inhibits some predators (occasionally dogs have been killed), but others are not deterred at all: the North American hognose snakes (Heterodon) feed almost exclusively on toads. Among the substances that have been isolated from the milky poison are bufagin, which has properties similar to digitalis, and serotonin, a substance which causes blood vessels to constrict. For centuries the Chinese have used dried toad poison to treat various ailments, but most of the medically important substances identified in the secretion can be synthesized or obtained from better sources. Contrary to a popular belief, handling toads does not cause warts on human skin.

Toads are mainly terrestrial, their thick skins allowing them to live in many habitats closed to thin-skinned frogs. They are generally nocturnal and frequently remain in fairly small feeding areas. Food is almost any insect or other animal that can be secured with the sticky tongue. For this reason some species have been introduced to control agricultural insect pests. A particular favourite is the giant toad (Bufo *marinus*), which is native to Central and South America, but now also established in the West Indies, Hawaii, Philippines, etc.

Life histories of most toads are similar. Adults are active except in winter and periods of summer drought, at which times they retire to their burrows. Breeding usually takes place in standing or slowly moving water and may involve mile-long migrations. The small dark eggs are laid in two long jelly tubes, and number from 600 to 30,000, depending on the species. The nondescript dark tadpoles hatch in a few days and transform in one to three months. Young toads mature in two or three years. *See* also AMPHIBIA. (G. B. R.)

TOADFLAX (*Linaria*), a genus of small plants of the figwort or snapdragon family (Scrophulariaceae; *q.v.*), allied to the snapdragon (*q.v.*) but distinguished by the possession of a long spur at the base of the corolla. The common toadflax (L. *vulgaris*), called also butter-and-eggs. has yellow flowers and creeping roots and is a widespread weed in grasslands.

TOADSTOOL, the popular name for poisonous or inedible mushrooms. *See* MUSHROOM.

TOALA. Early in the 20th century this small tribe, of about 100 people, was discovered in a remote valley of southnestern Celebes. Most of them lived in caves although a few had built small huts. They were dependent on hunting and the collecting of jungle produce. By 1913 the Dutch government had moved them from their mountain homes to a spot near a Buginese village. as a result of which they underwent rapid change and may vanish as a distinct people. According to Raymond Kennedy who visited them, they are of Veddoid type.

See R. Kennedy, *Bibliography of Indonesian Peoples and Cultures* (1955) ; P. and F. Sarasin, *Reisen in Celebes, 2* vol. (1905). (F.-C. CE.)

TOASTS. Toasting, defined as drinking to the health of a person or to the success of a .cause or enterprise, is a custom of ancient origin. It is related to the earlier custom of dedicating drink offerings or libations to the gods. Offered to a deity, the libation was an act of worship and of thanks for benefits. as in Psalm cxvi, 12, 13, "What shall I render to the Lord for all his bounty to me? I will lift up the cup of salvation and call on the name of the Lord." Offered to a human being. the libation betokened wishes for his good health or welfare. Centuries before the Christian era, guests at Jewish feasts drank to one another's health. often uttering the Hebrew formula *Lekhayyim* ("to your health"; literally "to lives").

Toast, a word of Latin origin, originally referred to the "sop" or morsel of bread which was browned at the fire and put into the wine cup, the idea being that it improved the flavour of the wine. An oft-quoted anecdote connecting "toast" with healths drunk to a 17th-century beauty is fictional. It is true, however, that the word toast was applied to individuals, especially to popular ladies. in or before the 17th century; from that developed the use of the word for the act of proposing a drink to the health of a person, and for the drink itself.

Martial, the 1st-century Latin poet, wrote amusing comments on the drinking customs of his time. One of these was the "drinking of names," a cupful being quaffed for each letter in the name of the person saluted, Ida three, Lyde four. Lycas five, Laevia six, Justina seven, and so to longer names and to most interesting possibilities.

An ancient Latin poem tells how the Goths. when drinking together, frequently cried out *"Eils!"*, meaning "Hail!" or "Health," and the Saxons are said to have carried the usage to Britain. According to tradition, the 5th-century Saxon princess Rowena went to the British king Vortigern bearing a golden cup filled with wine, and said to him *"Waes Hael!"* meaning "Be of good health!" The king kissed her, then gladly drank, and bade her share the contents of the cup. In time "waes hael" uas altered into "wassail" (*q.v.*). Historians are not certain that Rowena became the king's wife (or that the charming scene described above actually took place) but she is traditionally credited with introducing a new and pleasant custom to him and to his subjects. A single loving cup, token of general friendship, was used when all about the table drank in turn. In modern times it is more usual to drink to individuals from individual cups or glasses.

In Scandinavian countries, where toasting is regulated by a sort of kindly formality, good wishes are expressed in the word *skoal*, Old Norse for bowl. Germans exclaim *Gesundheit* ("good health"), or, an echo of student Latin, *Prosit* ("much good may it do you"), New Zealanders use the Maori words *Kia ora* ("be well" or "be happy"). A similar sentiment is expressed by the Hawaiian *Aloha nui* and the Japanese *Omedetō*. In 18th-century England, a popular form of toasting was with witty speeches or songs, such as "Let the toast pass," in Richard Sheridan's *School for Scandal*. In America, at Mount Vernon, George Washington usually drank to each guest in turn, with "Your health, sir," "Your health, madam," the guests responding with "Thank you, sir." In modern times the drinking of healths tends to become less formal.

Drinking customs, in times ancient and modern, in lands far and near, show many signs of universal human kinship. In England the stirrup cup, originally quaffed on horseback, was a drink at parting. In Scotland the final drink was a *deoch an' doris*, Gaelic for "drink at the door." In Germany the parting drink is an *Abschiedstrink*. In ancient Rome it was the *poculum boni genii*, to earn the favour of guardian spirits; and in the 20th century, perhaps unmindful of traffic hazards, it is "one for the road." This last example recalls the fact that in ancient times the toastmaster's duties included some supervision over the amount of liquor consumed. Hence the Greeks called him the *symposiarch* ("ruler of the drinking party"), and the Romans spoke of him as the *arbiter bibendi* ("regulator of drinking"). Nearer to our own time, the purpose of toasting was well expressed by a poet who called the drink itself "a cup of kindness." (A. McQ.)

TOBACCO Tobacco is the name given to the plant and cured leaves of several species of *Nicotiana* which may be used immediately but, commonly, after aging and processing in various ways, for the purpose of smoking, chewing, snuffing and extraction of nicotine. Nicotine and related alkaloids of tobacco furnish the habit-forming and narcotic effects which account for the general world-wide use. This article deals with the history, botany, culture and curing of tobacco and with the tobacco industry.

HISTORY

Tobacco was first cultivated by the Indians of North and South America. When Christopher Columbus and other early explorers arrived in America, they found the natives using tobacco much in the same manner as it is used today. The natives used tobacco in their ceremonials as, for example, in the smoking of the pipe of peace. It was generally supposed by the Indians to possess medicinal properties, and this was the chief reason for its early use following introduction into Europe. The extension of tobacco culture to practically all parts of the world began with its introduction to Europe: France, 1556; Portugal, 1558; Spain, 1559; and England, 1565. Jean Nicot, the French ambassador at Lisbon, Port., in whose honour the genus *Nicotiana* was named, is said to have sent seed of N. *tabacum* to the queen of France, Catherine de Medici.

The common name, tobacco, was derived from the word applied both to the tube used by the Indians for inhaling the smoke and to the cylinder of leaf prepared for smoking.

The early beginnings of tobacco culture by white settlers in colonial America took place in the following areas on the dates indicated: Santo Domingo, 1531; Cuba, 1580; Brazil, 1600; Jamestown, Va., 1612, by John Rolfe; Maryland, 1631. The tobacco grown soon furnished the chief product in demand in Europe as a commodity of exchange for the manufactured articles required by the colonists.

From the beginning overproduction was an economic problem. Following the American Revolution there was a tremendous expansion in culture from the colonial areas in Virginia and Maryland into Kentucky, Tennessee, North Carolina, Ohio and Missouri. The use of the fire-curing method in colonial days was modified in areas of Virginia and North Carolina about 1825 by the use of charcoal, which produced a different type of leaf, eliminating the effect of smoke on taste and aroma. This method was further modified follo ing the American Civil War by the use of the furnace with metal flues to accomplish the same purpose. White Burley variety appeared about this time (1864), when George Webb, a farmer in Brown county, O., found among his tobacco plants individuals that were somewhat deficient in green colouring. These plants when cured manifested a light yellowish-red colour. The leaf was porous and was found to have high absorptive capacity, which made it suitable for use in manufacturing chewing and smoking mixtures. This variety was improved by selection and became widely grown. It is extensively used in cigarette blends.

BOTANY

The tobacco of commerce is derived almost entirely from *Nicotiana tabacum,* native to South America, Mexico and the West Indies. *N. rustica* (wild tobacco) was the species cultivated by the Indians of eastern North America and is cultivated in Turkey, the U.S.S.R., India and several European countries. These two species were known to Linnaeus and described by him in 1753. Certain other species, such as *N. attenuate,* N. *trigonophylla* and *N. quadrivalvis* have been utilized for smoking by the Indians of western North America. There are numerous species of *Nicotiana* besides those mentioned, two of which are commonly used as ornamentals, namely, N. *sylvestris* and *N. alata grandiflora* (flowering tobaccos). *(See* also NICOTIANA.) The best evidence available indicates that all species of *Nicotiana* are native to America with the exception of N. *suaveolens* and the related native Australian species.

Common tobacco, *N. tabacum* (fig. 1), of which there are numerous varieties, usually reaches a height of four to six feet when not topped. The flowers, borne in a panicle, normally self-fertile, are pink as a rule, although white and carmine-red forms are known. The flower is tubular in shape with the corolla tube (fig. 2[B] and 3) greatly exceeding the calyx in length. The lobes of the corolla are distinctly pointed and separated and are five in number. The leaves, varying in number with the variety, are arranged alternately, commonly sessile (that is, without petiole or stalk) and auricled or partly clasping the stem. They vary greatly in size and shape depending upon the variety and growing conditions. The leaves of some of the larger growing varieties may reach a length of two to three feet, with a width of about one-half the length, although some of the Turkish kinds, as grown commercially are sometimes less than three inches in length. A plant may produce as many as 1,000,000 seeds, but under usual conditions produces around one-half ounce of seed (150,000 to 200,000 seeds). N. *rustics* varies in height from two to four feet and commonly shows a decided development of suckers or axillary shoots. The leaves tend to be thick, broadly ovate with a distinct naked petiole. The corolla tube (fig. 2[A]) is short, with distinctly rounded lobes. and is pale yellow to greenish. The seeds are approximately three times the size of those of N. *tabacum.* Both species have a definite epidermal covering made up of hairs, some of which are glandular and secrete a viscid gummy substance. Under favourable conditions both species may produce a high content of alkaloid; however, N. *rustica* tends to show a higher content *(see* also NICOTINE).

Types of Tobacco.—The type of leaf tobacco is determined and frequently named on the basis of (1) variety; (2) methods of curing or handling; (3) the use to which the cured leaf is adapted; and (4) the section where the tobacco is grown. There are numerous types recognized by the trade which have been assigned numbers in the official U.S. department of agriculture type classification: fire-cured (21–24), dark air-cured (35–37), flue-cured (11–14); cigar wrapper (61 and 62), cigar binder (51–56), cigar filler (41–44), Burley (31), Maryland (32) and perique (72). All these types, as well as the Turkish or oriental, Sumatra cigar wrapper produced in Indonesia. and Cuban cigar leaf, are produced from *N. tabacum,* and most are important tobaccos of world commerce. The *markhorka* (sometimes *mahorka)* type is produced from N. *rustica.* Air cured, it is grown in the U.S.S.R. and Poland. The leaf is somewhat coarse in texture and high in nicotine content, and it is largely consumed locally.

The flue-cured type, sometimes designated as bright or Virginia, is by far the most popular, largely because of its adaptability to the production of blended cigarettes.

CULTURE

The methods of culture vary somewhat in different parts of the world and with the various tobacco types, but the essential features remain much the same. The plant is grown successfully under a wide range of climatic and soil conditions; however, the commercial value of the product depends largely upon the environment in which it is produced. The variety of seed used, as well as the occurrence and control of insects and diseases, is a factor of considerable importance in determining successful culture.

The choice of the variety of seed is contingent upon the type of leaf desired. Most strains and varieties of N. *tabacum* are local in their adaptation and are not suited to the production of widely divergent leaf. The Orinoco group with its many strains is widely used for flue-curing, while the Pryor group, which was originally selected from Orinoco, is used in the production of dark air-cured and fire-cured tobaccos. Burley differs from other tobaccos in having light colour and cream-coloured stems. The seed-leaf strains, Havana seed, Sumatra and Cuban, represent outstanding varieties used in the production of cigar leaf.

The seedlings are small and are produced in cold frames covered with thin cloth in warm regions, or in hotbeds or greenhouses covered with glass in colder regions. The rate of seeding commonly used is $\frac{1}{2}$ oz. of high-quality seed to 100 sq.yd. of seedbed area. Under favourable conditions this area can be expected to furnish 15,000 to 25,000 plants for transplanting. The soil selected for the plant bed should be fertile, possess good tilth and drainage, with the site fully exposed to the sun. Sterilization of the soil by burning, steaming, chemicals such as methyl bromide to destroy weed seeds, insects, nematodes and diseases is widely practised. It is customary to apply commercial fertilizer at the rate of one-half to two pounds per square yard, to the seedbed. The seeds are usually mixed with an inert, bulky substance, such as wood ashes, white sand or air slaked lime so that a uniform distribution may be obtained. Seeds are sown on a well-pulverized, leveled area and are pressed into the soil lightly. In from eight to ten weeks the seedlings are four to seven inches in length and are ready for

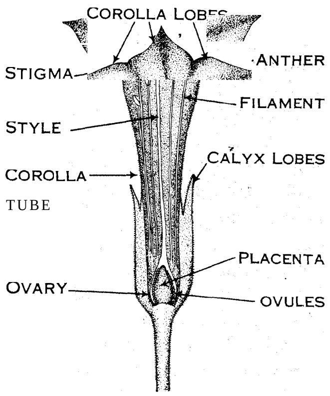
FIG. 2.—SEED PODS AND FLOWERS OF (A) NICOTIANA RUSTICA AND (B) N. TABACUM

transplanting in the field, by machine in dry weather, and by hand when the soil is wet. Watering at setting time is helpful in obtaining a stand if soil is dry. The spacing of plants in the field varies widely according to the type of tobacco grown. The rows are 3 to 4 ft. apart, with plants spaced 1 j to 48 in. in the row. Cigar and Burley tobacco are commonly spaced 3 to $3\frac{1}{2}$ ft. by 1 j to 27 in., while fire-cured and dark air-cured are planted in hills which may be as much as $3\frac{1}{2}$ ft. apart. Maryland tobacco is transplanted in hills 34 by 34 in., or closer, while flue-cured is spaced " to 24 in. by 4 ft., as a general rule. Oriental or aromatic tobacco is spaced in rows 16 to 24 in. apart with 6 to 8 in. between plants in the row. When the plant has attained the desired size, usually at or shortly after flowering, it is topped or disbudded; that is, the terminal growth is removed.



BY COURTESY OF U S DEPARTMENT OF AGRICULTURE

FIG. 3.— DIAGRAMMATIC LONGITUDINAL SECTION THROUGH TOBACCO (NICOTIANA TABACUM) FLOWER SHOWING ESSENTIAL PARTS

The number of leaves remaining varies widely. Dark air-cured and fire-cured tobaccos vary with from 10 to 16 leaves; Burley, flue-cured. Maryland and cigar types, have from 16 to 20 leaves. Following topping, the suckers, or lateral shoots, are removed at frequent intervals to increase leaf development and to provide for increased yields.

The choice of soil and its fertilization varies greatly with the kind of leaf grown. It is important that the soil is well drained and has sufficient tilth for good aeration. Much of the tobacco grown in the U.S., including flue-cured, Maryland, cigar binder and wrapper types. is produced on sandy and sandy-loam soils with a sandy or sandy-clay subsoil. Cigar filler, dark air-cured, fire-cured and Burley are produced on silt-loam and clay-loam soils with clay subsoils. Fertilization is essential in producing the desired type of leaf. The quantity of nitrogen is significantly important for the flue-cured and to a lesser extent for Maryland, and Burley types. A liberal supply of potash in the form of sulfate, carbonate or nitrate improves the over-all quality of the leaf and the fire-holding capacity of the cured tobacco. and reduces the susceptibility to leaf spot diseases. The use of chlorides in any form, such as potassium chloride or large amounts of animal manure, reduces the burning quality of cured leaf. Animal manures, when available, are used on the soil one or more years before the crop is grown. Fertilizer practices vary widely. On one acre as much as one to two tons of fertilizer containing 5% to 6% nitrogen, 5% to 8% phosphoric acid (P_2O_5) and 6% to 8% potassium oxide (K_2O) may be used for cigar tobacco, with the fertilizer applied broadcast to the soil prior to transplanting. In contrast to this, flue-cured tobacco is fertilized commonly nith 800 to 1,200 lb. per acre. of 3–9–9. or similar analysis (with the ingredients expressed in percentages in the same order as for cigar tobacco) applied in the row prior to transplanting. Burley tobacco is fertilized at the rate of 800 to 1,500 lb. of 5–10–15, 6–12–18 or similar analysis. The tobacco plant quickly develops nutritional deficiency symptoms when any of the chemical elements essential for growth is lacking in the soil. (*See* also FERTILIZERS AND MANURES.)

The preparation and cultivation of the soil consists of methods used with most cultivated crops to control weeds and maintain a well-pulverized soil-growth medium. A special method of culture employed on a limited scale in Connecticut and Florida consists of covering the field with cheesecloth or slat shade. This shading maintains a higher soil and air moisture which results in the production of a thin, elastic leaf suitable for cigar wrapper.

The culture of tobacco in Sumatra and Java suitable for cigar wrapper is limited to particular soils in regions of high rainfall, where special provisions for drainage are necessary, consisting of plantings on a mound with sufficient space for two rows of plants. These mounds are separated by definite ditches to facilitate the runoff of water to prevent water logging. It is generally recognized that in Indonesia high-quality leaf is produced for only one or two years following the clearing from the jungle. Cuban leaf, much in demand as cigar filler, is produced from special varieties grown on certain soils in the Cuban climate; this type has not been duplicated elsewhere.

The culture of oriental or aromatic tobacco in Turkey, Greece and other Mediterranean countries is unique in that the plants are not commonly topped and can be grown on soils of low productivity. The best quality oriental tobacco is grown in Mediterranean climate on upland soils during periods of little or no rainfall. There are numerous varieties which differ radically from all other known kinds.

Diseases and Pests. — The more common diseases are black root rot, fusarium wilt, mosaic, bacterial leaf spot, downy mildew or blue mold and black shank. Control may be accomplished in various ways: sanitation, crop rotation, the use of sprays and fumigants and breeding of resistant strains. Some resistant varieties of tobacco in general use have been produced by blending desired characteristics from *N. longiflora*, *N. debneyi*, *N. glutinosa* and others with some strain of N. tabacum. Resistance to bacterial leaf spot diseases, fusarium wilt, mosaic, black shank and black root rot have been accomplished in this manner.

The more common insect pests are the green June beetle larvae, cutworms and flea beetles in the plant bed; hornworms, grasshoppers, flea beetles, cutworms, budworms and aphids in the field. The cigarette, or tobacco, beetle damages stored leaf; the cigarette beetle sometimes damages the manufactured pr'oduct. The insect pests are controlled on the growing crop by the use of sprays and dusts, on the stored product by fumigation and trapping. Biological control often is effective.

Harvest. — Tobacco is harvested from 70 to 130 days after transplanting by one of two methods: (1) the entire plant is cut with the stalk split or speared and hung on a lath or tobacco stick; or (2) the leaves are removed at intervals as they mature. The leaves of cigar wrapper and Turkish tobacco are strung by means of a needle, and leaves to be flue-cured are looped. using a string tied to a lath or stick which is hung in the curing barn or shed. It is desirable for the leaf to wilt without sunburning to prevent breakage and bruising during the handling necessary in curing. To accomplish wilting, tobacco may be left in the field from a few hours to two days.

CURING

The three common methods of curing are by air, fire and flue. Sun-curing is practised with Turkish types and to a limited extent with air-cured types. Curing entails four essential steps: wilting, yellowing, colouring and drying. It consists of physical and chemical changes, and the processes are regulated to develop the desired properties of the leaf. Air-curing is accomplished primarily in buildings, equipped uith ventilators, making possible partial control of conditions. Often artificial heat provided by coke. charcoal or liquid petroleum gas is used to supplement natural conditions. The time required for air-curing varies from one to two months. Many tobaccos are cured by this process, including dark air-cured types, cigar. Maryland and Eurley.

The fire-curing process resembles air-curing except that open wood fires are kindled on the dirt floor of the barn after the tobacco has been hanging for two to six days, allowing the smoke to come in contact with the leaf, thereby imparting a characteristic creosote aroma.

The firing process may be continuous or intermittent, extending from three weeks to as long as ten weeks until curing is complete, and the leaf has the desired finish.

The barns for flue-curing are small and tightly constructed, provided with suitable ventilators and metal pipes, or flues, extending from furnaces around the floor of the barn. Fuels used are wood, coal, oil and liquid petroleum gas. Where oil or gas heaters are used, flues are not needed. Heat is applied with due attention to the chemical and physical changes in the leaf. The length of time required for flue-curing is from four to six days.

TOBACCO INDUSTRY

After curing, only during humid periods or in special moistening cellars can the leaf be handled without breakage. It is removed from the stalks or sticks and graded according to colour, size, soundness and other recognizable elements of quality. It is tied into hands, or bundles, of 15 to 30 leaves by means of a tobacco leaf wrapped securely around the stem end of the leaves. After grading, the leaf is ready for market. It may be sold directly to the purchaser who visits the farm or may be packed in bales, boxes or hogsheads and shipped to a warehouse or other centre and sold on the basis of a carefully drawn sample by private sale or auction, or it may be carried directly to the auction (loose leaf) warehouse, where it is displayed and auctioned to the highest bidder. It is a common procedure to recondition the tobacco, that is, to dry the product and then return the proper amount of moisture by "redrying" after it has been marketed and before it is packed. The purpose is to avoid damage which occurs when the leaf is packed with an excessive moisture content, and to ensure proper amount of moisture for aging. The aging period is from one to three years. This process is sometimes hastened by forced fermentation accomplished by adding moisture to the tobacco and storing it in bulk before packing and further storing.

Manufacture.—While some tobacco is consumed by the producer or sold directly for chewing and smoking, most of the leaf is aged and processed before consumption. In most cases the stems, or midribs, are first removed from the leaf. The details of certain processes of manufacture are trade secrets, but in general commonly known procedures are followed. To produce acceptable products and obtain uniformity through the years, most manufacturers blend grades of different years and from different sections and types of leaf. However, most types and grades of tobacco have rather specific uses. For example, the upper leaves on the plant are used for chewing and the lower leaves for smoking tobacco. In the U.S., cigarettes are commonly manufactured by blending flue-cured, Burley, Maryland and Turkish types. Chewing tobacco is manufactured in several different forms, such as plug, twist, fine cut and scrap. Pipe-tobacco mixtures contain considerable amounts of the Burley type. The mixture generally includes a conditioner (glycerine) and flavouring constituents. Snuff is made from fire-cured leaf and stems which are fermented before, and sometimes after, grinding, and salts and flavouring are frequently added; there are two forms—the light, containing ground stems, and the dark, made from stemmed leaf.

Composition.—Nicotine, the compound which definitely characterizes tobacco, occurs in various proportions combined with organic acids (malic, citric, etc.). Related alkaloids have been found in certain types, associated with the nicotine. Nicotine can be used as a raw material for preparation of the antipellagric vitamin, nicotinic acid (niacin). Factors governing the nicotine content of tobacco are: (1) the species, variety and strain; (2) the environment in which the plant is grown, primarily the conditions of soil and climate; (3) cultural, curing and handling methods employed (*e.g.*, time of transplanting and harvesting, spacing of plants, topping and suckering operations). The nicotine content of commercial types of tobacco varies considerably, but on the average the dark air-cured and fire-cured types contain 4% to 4.5%; cigar filler and Burley 3.5% to 4%; flue-cured 2.5% to 3%; Maryland 2%; and Turkish types 1% to 2% or more. *N. rustica* has been grown with as much as 10% nicotine in the leaf. Nicotine has long been used as an insecticide and as such is an important tobacco by-product.

The ash content of tobacco is high and ranges from 15% to 25% of the leaf on a water-free basis. The flue-cured type is notably rich in sugar, with the cigarette grades showing 15% to 20% or more. The Maryland cigarette leaf shows 90% of the total carbohydrates as cellulose, pectin and related compounds. Cigar tobaccos are especially high in nitrogenous compounds but are almost free of starch and sugars.

Among the changes in composition which take place during the fermentation or aging process is a loss in nicotine; with cigar tobaccos which are commonly subjected to a heavy fermentation, one-half or more of the nicotine may disappear.

Revenue.—Tobacco has long been one of the chief sources of revenue in many countries of the world. This revenue is derived from taxes on the stored leaf and on the manufactured products as in the U.S., from duties on imports as in the U.K. or from profits from the operation of government monopolies which have been in effect in many European countries, Japan and elsewhere. The income of the U.S. government in revenue from taxes collected on manufactured tobacco products, particularly cigarettes, greatly exceeds the sale value received by farmers for the crop. Besides the revenue collected by the federal and state governments a number of cities exact a tax on tobacco products.

Production.—World production has been estimated at about 8,000,000,000 lbs. annually. The United States is the largest producer, contributing about one-fourth of this amount, and exporting slightly more than one-fourth of its production. China, India and the U.S.S.R., respectively, rank next to the U.S. in tobacco pro-

duction. The preferential duty extended to Commonwealth tobacco by the British government has greatly stimulated production in Canada and in the Federation of Rhodesia and Nyasaland. Oriental tobacco, grown chiefly in Turkey and Greece, is exported extensively for use in the manufacture of cigarettes. In many of the principal producing countries such as China, India, the U.S.S.R. and Japan a large part of the product is consumed locally. TOBACCO PIPE. The smoking of tobacco in pipes is a custom which has prevailed in America for a period of unknown duration. The most ancient pipes of which remains exist have been found in mounds or tumuli called pipe mounds, principally in Ohio, Indiana. Illinois and Iowa. These mound pipes, which are carved in porphyry and other hard stones, are very uniform in type, consisting of a slightly convex platform or base, generally from three to four inches in length, and about one inch broad, with the bowl on the centre. A fine hole is pierced from one end of the platform to the bottom of the bowl, the opposite end being obviously for holding in the hand while the pipe is being smoked.

Among the North American Indian tribes the tobacco pipe occupies a position of peculiar symbolic significance in connection with their rites and usages. The calumet, peace pipe or medicine pipe: is an object of the most profound veneration. The introduction of the tobacco pipe into Europe is generally ascribed to Ralph Lane, first governor of Virginia, who in 1586 brought an Indian pipe to Sir Walter Raleigh and taught that courtier how to use it. The pipe makers of London became an incorporated body in 1619. By degrees pipes of special form and material have come to be definitely associated with particular peoples; *e.g.,* the elongated painted porcelain bowl and pendulous stem of the German peasantry; the red clay bowl and long cherry-wood stem of the Turk; and the very small metallic bowl and cane stem of the Japanese. Other kinds of pipe include the corncob, in which the bowl is made of the cob of maize or Indian corn, and the calabash with the bowl of a small gourd. The churchwarden is a clay pipe with a slender stem, about 16 to 20 in. long. The most luxurious and elaborate form of pipe is the Persian *kalyun,* hookah or water tobacco pipe. This consists of three pieces, the head or bowl, the water bottle or base and the snake or long flexible tube ending in the mouthpiece. The tobacco is placed in the head; a wooden stem passes from its bottom down into the water which fills the base; and the tube is fitted to a stem which ends in the bottle above the water. Thus the smoke is cooled and washed before it reaches the smoker.

TOBAGO, an island off the coast of Venezuela forms with Trinidad a British colony of the former West Indies federation. Tobago is 27 mi. long and 7½ mi. broad. with an area of 116 sq.mi. Pop. (1960) 32.963. Just off the northeast end of the island is Little Tobago. a 300-ac. islet used as a sanctuary for birds of paradise brought there in 1908. Tobago consists of a single 18-mi.-long mountain mass of volcanic origin which rises to a height of 1.800 ft. in the centre. Much of the island is clothed with a dense forest. The higher lands are set apart as "rain preserve," and felling of timber there is forbidden. The temperature averages 80° F.; the annual rainfall is 60 in. The rainy season lasts from June to December, with a short break in September. The valleys are adapted to horse and sheep raising. Cacao, copra, coconuts and limes are exported. Scarborough (pop. [1946] 908), formerly called Port Louis, is the capital, located on the south coast 8 mi. from the southwest point.

Tobago was discovered by Columbus, who called it Assumption (1498). It was first occupied by the Dutch (1632), who named it New Walcheren and held it precariously until 1662. Thereafter possession alternated between the French and English until 1814, when British title was confirmed by the treaty of Vienna. It formed part of the Windward Islands colony until 1889, when it was joined to Trinidad, though legal and fiscal arrangements were kept distinct.

In 1899 it became a ward of Trinidad; its revenue, expenditure and debt were then merged with those of the united colony (called Trinidad and Tobago), and Trinidad laws, with a few exceptions, became binding in Tobago. (L. W. BE.)

TOBIT, BOOK OF. This book of the Apocrypha is a religious novel which was for many centuries exceedingly popular both in Christian and Jewish circles in many lands. This is shown by the multiplicity of versions and editions which have survived. Moreover, it was not without influence upon some of the writers whose work is contained in the Old Testament (*e.g.,* Daniel and some of the Psalms), Jewish pseudepigraphists (*e.g.,* the authors of the Book of Jubilees, the Testament of Job), some New Testament writers (*e.g.,* the Synoptists. especially in the description of the Resurrection and Ascension. St. Paul, the author[s] of the Pastoral Epistles) and numerous postapostolic Christian writers, many of whom, as did in particular Clement of Alexandria, regarded it as "Scripture." But in one respect it has achieved a distinction shared by no other book of the Apocrypha. and by at most only one book (Jonah) of the Old Testament: it has made a remarkable appeal to the exponents of Christian art, and its hero and his dog and certain dramatic incidents in his history became, in the middle ages, a favourite theme of the workers in ecclesiastic glass and mural decorations.

Date of the Work.—F. Hitzig's relegation of the date of writing to a time subsequent to the catastrophe of A.D. 70, H. Gratz's conviction that it belongs to the reign of Hadrian, S. Rosenthal's that it is a product of the school of Rabbi Akiba. and even W. R. Smith's attempt to connect it uith the Maccabean revolt, are no longer favoured. Equally impossible is a date as early as 350 B.C., which was once favoured by writers influenced by H. Ewald. A date about 250 B.C. seems to present least difficulties.

The author wrote to inculcate respect for the dead, consanguineous marriages and practical virtues such as almsgiving. He found the ultimate sanction for these ideals in the Old Testament. but when he set out to inculcate them in his tale he drew on earlier, and even contemporary pagan models. The Egyptian Tractate of *Khons* supplied him with the idea of a maiden possessed by a demon whom the god expelled. It is also clear that the widely diffused "Fable of the Grateful Dead"—a dead man rewarding the burier of his corpse—was much in his mind nhen he set out to write his book; but in this case it may have been less a matter of consulting a literary model than of reproducing the general ideas of a class of fables known to him from boyhood. Similarly there is no reason to posit any literary source, as J. H. Moulton formerly did, to account for the alleged *Median* and more specifically Magian elements in the book—*e.g.,* the dog, the demon Asmodeus (Aēšma daēva), the seven angels. the saving heavenly visitor (Raphael). These are mostly not characteristics of the later Zoroastrian system, but belong equally to its earliest phases. and in great part even to pre-Zoroastrian Magianism, which, by 250 B.C., would be known wherever Persian traders and soldiers were to be found.

If, as is suggested, the author was an Egyptian Jew of 250 B.C., he may have written in Aramaic or in Greek. Numerous attempts, based on the theory of mistranslations in the extant Greek texts from an Aramaic original have been put forward. but on the whole the hypothesis that he was a Jew who "thought in" Hebrew or Aramaic. while writing in the Greek of his period, suffices to explain the "Semitisms" which are observable in his book. Apart from the poem in chapter 13 there seems to be no reason for not regarding the book as a literary unity.

Simpson's "Tobit" in Charles's *Apocrypha and Pseudepigrapha of the Old Testament*, vol. i, pp. 174–241 (1913), "The Chief Recensions of the Book of Tobit," *Journal of Theological Studies*, vol. xiv, pp. 516–30 (1913); *The Book of the Words of Tobit with an Introductory Essay by Ernest H. Short and Reproductions of Paintings by the Old Masters* (1927).

TOBOGGANING, the sport of sliding down snow-covered slopes and artificial ice-covered chutes on a runnerless sled called a toboggan. The toboggan was originally a primitive American Indian sled made of poles tied together with thongs. The 20th-century toboggan is usually built of thin, straight-grained boards of hickory, birch or oak fastened together by light crosspieces. Some toboggans are made of metal or laminated wood. The front end is bent up and back to form the "hood" and is braced by rope or leather thongs. The flat sliding surface is generally about 18 in. wide and from 4 to 9 ft. long. The toboggan is light in weight and will support a heavy load on soft snow. It is useful for hauling loads over wilderness trails or cross country as well as for sporting purposes.

Tobogganing, as a sport, probably originated on the slopes of Mt. Royal near Montreal, Can. During the late 1880s it spread to the United States where it had considerable popularity until the early 1930s when widespread enthusiasm for skiing brought about its decline. During the heyday of tobogganing many artificial chutes were constructed to make it easier for the inexperienced to enjoy the thrills of a fast ride. These chutes were about three feet wide with sides of ice or wood and frequently mere built with several parallel tracks to accommodate more than one toboggan at a time. The more elaborate chutes used trestlework to smooth out the contour of the slope. They were usually straight and varied in length up to several thousand feet. The chutes were quite steep at the top in order to accelerate the toboggan quickly. Speeds up to 60 m.p.h. were attained. From the bottom of the chute the toboggans coasted along an open track which occasionally extended for one to two miles.

The toboggan is well adapted to sliding down open slopes where its large surface rides easily on loose, fluffy snow. Several persons can ride at one time either lying prone or in a sitting position. The toboggan can be steered by lifting and twisting the front or by extending one's leg to the rear and dragging a foot in the snow. *See* also BOBSLEDDING; WINTER SPORTS. (A. W. TR.)

TOBOLSK, a city in the Tyumen *oblast* of the Russian Soviet Federated Socialist Republic, U.S.S.R., on the Irtysh river, below the confluence of the Tobol. Pop. 33,000. Tobolsk was founded by the Cossacks in 1587 and had an active trade in fish and furs, but Omsk rapidly superseded it. The district of Tobolsk (renamed Tyumen) became noted for *koustar* (peasant) industries, especially carpentering, the making of fishing nets, carving on ivory and the preparation of wool and skins. The Tobolsk province was the earliest to be colonized and also received the largest number of political exiles.

TOBRUK (anc. ANTIPYRGOS), a spacious and well-sheltered natural harbour in Cyrenaica, Libya, in which vessels of any size or draft may anchor, open only to the east-southeast. Pop. (1954) 4,995. It is one of the six administrative centres of the province of Cyrenaica. Water is carried to it by road from Bardia and by sea from Bengasi. It has a secondary school for boys, a primary boarding school and a hospital. For long the outlet for the oasis of Jaghbub, its export trade has become negligible. It suffered severely in World War II, changing hands five times and falling finally to the British on Nov. 13, 1942. Tobruk is the usual residence of the king of Libya. (D. G. W.)

TOCANTINS, a river rising in the Planalto Central of Brazil, in south Goiás state, a little north of Goiânia, capital of Goiás, and Brasilia, the federal capital. It flows through Goiás, and between Carolina and the junction of the Araguaia (*q.v.*) forms the boundary between Goiás and Maranhão. After meeting the Araguaia it flows through the state of Pará, finally joining the Pará river, a navigable arm of the Amazon (*q.v.*) delta, 50 mi. SW of Belém. The mouth of the Tocantins is 8 mi. wide and its total length is 1,677 mi. The river is not good for navigation, although in its mid-course above Carolina it can be navigated by small river boats. Its wide mouth is deep enough for ocean vessels which can ascend as far as Tucurui, about 200 mi. from Belém. From Tucurui a railroad, built around a succession of rapids as far as Jatobá, is being extended to São João do Araguaia at the junction with the Araguaia river. Much effort, if not much money, was expended after mid-20th century on the development of this river as an export route for the products of southern Goiás. The forests of babassu palms around Carolina could be developed to provide oil for fuel. However, the many rapids and shoals, the great length and the lack of production in the sparsely populated country through which it passes made development very costly. (P. E. J.)

TOCCATA, a musical composition — for clavichord, harpsichord or organ — of brilliant character, which originated in the 16th century. the name deriving from the Italian *toccare,* "to touch." It was thus opposed to the sonata and cantata which were works that were sounded and sung. The early examples by Andrea Gabrieli consisted of alternating sections in chords and runs. In those of Claudio Merulo fugal sections were introduced. Frescobaldi treated the form in a more elaborate manner and in later Italian examples, by Bernardo Pasquini and Alessandro Scarlatti, the toccata became a piece in rapid, unchanging tempo, resembling the *perpetuum mobile.* In Germany the toccata style of Frescobaldi was developed by J. J. Froberger, G. T. Muffat and others, while the examples of Merulo led to the large-scale toccatas for harpsichord and organ by J. S. Bach. Largely neglected during the 19th century, the toccata was revived in the 20th century, notably in piano works having the character of the *perpetuum rnobile* by Ravel, Prokofiev and others.

See E. Valentin, *Die Entwicklung der Tokkata im 17 und 18 Jarhundert* (1930).,

TOC H, an interdenominational association for Christian social service, founded as a memorial to British youth who perished in World War I. At Hooge, in the first German liquid-fire attack in July 1915, Gilbert Talbot, a lieutenant in the rifle brigade and son of the bishop of Winchester, fell. In the following December in the Flemish town of Poperinghe a soldiers' club named Talbot house was opened in his memory.

In charge of this house was a Church of England chaplain, Rev. P. B. Clayton, M.C., who created a centre of rest and recreation unique in its kind. In 1920 Clayton established in London a new Talbot house, using, since this name was already appropriated, the signalers' method of pronouncing its initials, namely, Toc H. The plan was to establish in London a house where men of all kinds would congregate, and many of them live, dedicating a reasonable proportion of their leisure time to the service of their fellowmen; membership was opened to all men of good will.

In 1922 it was incorporated by royal charter with the prince of Wales as patron. Toc H stretched with its houses, or "marks," and branches throughout the British Commonwealth. It became through the principles of service, fellowship, tolerance and honest thinking, to which its members are pledged, a great influence for good and for spiritual development and expression. Each branch was entrusted with a lamp of maintenance, lighted with simple ceremony at every meeting in remembrance of lives lived and given in service and sacrifice and in rededication to the task they left unfinished — building a "new Jerusalem." (R. C. G.; X.)

TOCHARIAN LANGUAGE. Tocharian (also called Tocharish or Tokharian) is the name commonly applied to an Indo-European language spoken in northern Chinese Turkistan (Tarim basin) during the latter half of the 1st millennium of this era. The documents date from about 500–700 A.D. There are two dialects: Tocharian A, from the area of Turfan in the east; and Tocharian B, chiefly from the region of Kucha in the west, but also from the Turfan area.

Discovery. — The first Tocharian manuscripts were discovered during the last decade of the 19th century. The bulk of the Tocharian materials, however, were brought back to Berlin by the Prussian expedition of 1903–04 and 1906–07, which explored the Turfan area; and to Paris by the French expedition of 1906–09, which investigated chiefly in the area of Kucha. Other smaller collections are those of R. Hoernle and **A.** Stein in London, M.

Berezovski in Leningrad and Otani Kozui in Japan.

Decipherment.—Tocharian is written nith a form of north Indian syllabary known as Brahmi used also in writing Sanskrit manuscripts from the same area. The first successful attempt at grammatical analysis and translation was made by the German scholars E. Sieg and W. Siegling in an article "Tocharisch, die Sprache der Indoskythen," *Sitzungsberichte,* Berlin Academy of Sciences, 1908. This article established the presence of the two dialects provisionally called A and B. The Berlin collection consisted of both, whereas all other manuscripts discovered were in B.

The name Tocharisch was proposed *(cf.* below), and the language was demonstrated to be Indo-European (IE).

Language.—Tocharian forms an independent branch of the Indo-European language family, not closely related to other neighbouring IE languages (Indic, Iranian). Rather. Tocharian shons a closer affinity with the western *(centum)* languages, *cf.* A *kant, B kante, kante* "100," Lat. *centum* v. Sans. *śatam;* A *klyos-,* B *klyaus-* "hear," Lat *clueo,* v. Sans. *śru-;* A *kus, B kuse* "who," Lat. *qui, quod,* v. Sans. *kas.* In phonology Tocharian differs greatly from the other IE languages in that all the IE stops of each series fall together, resulting in a system of three (voiceless) stops, *p, t* and *k.*

In morphology, the Tocharian verb reflects the IE verbal system both in stem formations and in personal endings. Especially note orthy is the wide development of the mediopassive in *r* (as in Italic and Celtic), *cf.* A *klyostar* "is heard." The third person preterit plural ends in *-r,* similar to Latin and Sanskrit perfects and the Hittite preterit. The noun, however, shows little trace of the original IE inflection. Instead, it has been built up by addition of postpositions to the oblique (accusative) form. This type of inflection (agglutination) has been attributed to the influence of non-IE languages (Turkish, Finno-Ugric).

The vocabulary shons a remarkable influx of loanwords, Turkish, Iranian and, later, Sanskrit. Chinese has had little influence Honever. many of the most archaic nords are retained: A *por,* B *puwar* "fire" (Gr. *πῦρ,* Hitt. *pahhur*), A B *ku* "dog" (Gr. *κύων*), A *tkaṃ,* B *keṃ* "earth" (Gr. *χθών,* Hitt. *tekan),* and especially nouns of relationship A *pdcar, mācar, pracar, ckācar,* B *pācer, mācer, procer, tkdcer* "father, mother, brother. daughter."

Literature.— Tocharian literature is Buddhistic, consisting largely of translations or free adaptations of Jatakas, avadanas and didactic, philosophical and canonical works. There exist also many commercial documents, letters, monastery records, caravan passes, medical and magical texts (translated or adapted from Sanskrit). These latter are important source materials for the social, economic and political life of central Asia.

The "Tocharian Problem."--Since the appearance of Sieg and Siegling's article "Tocharisch, die Sprache der Indoskythen," the appropriateness of the name "Tocharian" for the language has been disputed. According to the Greek and Latin historical sources, the Tochari (Gr. *τόχαροι,* Lat. *Tochari)* inhabited the basin of the upper Oxus in the 2nd century B.C. and were probably Iranians. Sieg and Siegling's identification of this language as belonging to these people was probably in error.

The proper identification of the bearers of the language among the people of central Asia is still disputed, however. Possibly the most satisfactory hypothesis identifies them with the Wo-sun, a people to the north of the Tarim basin in the first centuries B.C.

Furthermore, the name *ārśi* (*ārśiype* "Arśi-country," *ārśikāntu* "Arśi-language"), once accepted as the native name in dialect A, is probably a loanword through Iranian from Sanskrit *arya.* The question of the name is, however, of little linguistic importance. "Tocharian," even if generally accepted as a misnomer, will probably remain.

For "dialect A" and "dialect B," the substitution of Turfanian and Kuchean, or East Tocharian and West Tocharian, has been suggested.

Of greater importance is the question of the closer relationship of Tocharian to the other IE languages. Its phonology, morphology (the verb) and. to a certain extent. its vocabulary align it with the western languages. The Tochari probably once occupied a position in the IE community closely in contact with the Celtic and the Italic dialects on the one hand and the Balto-Slavonic on the other. and at the same time with some, but less significant, contacts with the Germanic and the Greek. They were, however, probably one of the earliest groups to migrate, taking a northern route to the east, as opposed to the southern route taken by the Indo-Iranians. It is possible that they were a part of that folk migration from the west which, according to archaeological evidence, appears to have invaded northeast China some time before the middle of the 1st millennium B.C. In their migration they had long contact with non-Indo-European speakers, especially Finno-Ugric and Altaic.

TOCHARISH LANGUAGE: *see* TOCHARIAN LANGUAGE.

TOCOPILLA, leading port of Chile in nitrate shipping and in cargo tonnage embarked, and a department seat of Antofagasta province. Pop. (1952) 19,353. Initial growth occurred after the 1870 silver strike at Caracoles. The open roadstead and modest port facilities serve the Maria Elena, Pedro de Valdivia and Toco nitrate fields, which are accessible by electric railway and road Approximately 65% of Chile's nitrate production is handled there. Tocopilla has a small copper concentrator and a thermoelectric plant that generates power for the Chuquicamata (q v.) copper mine. The mine and Antofagasta may be reached by road.

(J. T.)

TOCQUEVILLE, ALEXIS CHARLES HENRI MAURICE CLÉREL DE (1805–1859), was born at Verneuil on July 29, 1805. From 1827 to 1832 a junior magistrate at Versailles, he in 1831 accepted nith Gustave de Beaumont a commission to examine the prisons and penitentiaries of the United States. This journey led to the publication of his *Du système pénitentiaire aux États-Unis et de son application en France* (Paris, 1832) and provided him with material for his penetrating study of American society and politics, *De la de'mocratie en Amérique.* This work, the first part of which appeared in 1835 and the second in 1840, won him a European reputation as well as a seat in the Académie Française. Meanwhile, encouraged by P. Royer-Collard, whom he much admired, he had entered politics. After an unsuccessful contest in 1837, he became deputy for the Manche in 1839 and sat continuously as an independent, generally critical of government policy. until the fall of the July monarchy. Then, believing that monarchy had disappeared for good in France and that it behoved moderate men to ensure the success of an orderly republic, he stood for parliament again and sat in both the constituent and legislative assemblies of the second republic. From June to Oct. 1849 he was minister for foreign affairs in Odilon Barrot's second ministry. Gifted with considerable political prescience, he early suspected Louis Napoleon's ambitions, and his protest at the *coup d'état* of Dec. 2, 1851, earned him a night's arrest. Thereafter he withdrew from public life and spent his remaining years traveling and preparing his *L'Ancien Régime et la Re'volution,* the first volume of which. generally considered his masterpiece, came out in 1856. It obtained even greater success than *De la démocratie en Amérique,* but ill-health prevented him from completing the work. He died at Cannes on April 16, 1859.

Natural diffidence, a weak voice and indifferent health prevented him from making much mark in politics; but, despite his lack of sympathy with the middle classes, his writings proved him one of the shrewdest, if more pessimistic, political observers of his century. *De* la *démocratie en Amérique* was not a detailed analysis of institutions, but a speculative investigation into the effects of popular government upon a whole society and, as such, a warning of what might happen in Europe. He saw the world moving inescapably toward democracy and social equality and discerned in property the only remaining form of privilege. A passionate believer in liberty, which he considered incompatible with equality, he disliked what he saw yet believed that men must adapt themselves to the new age. His Ancien *Régime* demonstrated his historical insight; it rejected the accepted view that the Revolution marked a complete break with the past, showed a wide understanding of the broad social forces involved in change and was a landmark in the reinterpretation of the Revolution. His *Souvenirs* are a valuable source for the history of the second republic.

BIBLIOGRAPHY.—*Oeuvres complètes,* ed. by Mme. de Tocqueville (Paris, 1864–66, and, ed. by J. P. Mayer, 12 vol. (Paris, 1951 ff.). The best English edition of De la *démocratie* en *Amérique* is by Phillips Bradley, 2 vol. (New York, 1945); and the iullest English version of the *Souvenirs* is that edited by J. P. Mayer (London, 1948; New York, 1949). See also Pierre Marcel, Essai politique *sur* Alexis de *Tocqueville* (Paris, 1910); J. P. Mayer, Prophet of the *Mass* Age (London, Toronto, 1939); and G. W. Pierson, Tocqueville *and* Beaumont in America (New York, London, 1938). (J. P. T. B.)

TODA, a pastoral tribe of the Nilgiri hills of south India. Few in number (879 in 1951), they are widely known for their striking appearance and specialized culture. The culture is mainly concerned with the care and cult of their buffalo. They have a distinctive Dravidian language, a complex social system (with moieties, double descent and polyandry), an oral poetry extolling buffalo and a religion which is largely the ritual of the dairies. Programs, governmental and missionary, have long attempted to change Toda ways; one was introduced in 1954. (D. G. M.)

TODD, SIR ALEXANDER (ROBERTUS) (1907–), British chemist who was awarded the Nobel prize for chemistry in 1957 for his work on coenzymes, was born in Glasgow on Oct. 2, 1907. Educated at Glasgow university, he carried out research in organic chemistry there and at Frankfurt-on-Main, Oxford and Edinburgh. He joined the staff of the Lister institute in 1936, and became reader in biochemistry at London university in the following year. In 1938 he became professor of organic chemistry at Manchester university, and there began work on the nucleosides and their phospborylation, which he continued at Cambridge, where he m-as appointed professor of organic chemistry in 1944.

Sir Alexander Todd's researches were mainlv concerned with chemical substances of important pharmacological or biochemical interest. He was associated with the prooi of structure and the synthesis of vitamin B_1 (aneurin), vitamins E (tocopherols) and the active principles of hashish (marihuana). Other achievements were the synthesis of adenosine triphosphate in 1949 and of flavinadenine dinucleotide and uritline triphosphate in 1954, and the elucidation of the structure of vitamin B_{12} in 195j, made possible by combining the methods of organic chemistry and X-ray crystallography. His studies also included certain alkaloids from the *Erythrophleum* and *Daphnandra* genera; the plant colouring matters (anthocyanins), the insect (aphis) pigments and certain mold products, including various quinones, puberulic and stipitatic acids and penicillin. His work on the structures and syntheses of nucleosides and nucleotides made an outstanding contribution to knowledge of the structure and iunction of nucleic acids.

Todd was elected a fellow of the Royal society in 1942 and knighted in 1954. In 1952 he became chairman of the British government's advisory committee on scientific policy.

TODI (anc. TUDER), a town and episcopal see of the province of Perugia. Italy. 26 mi. S. of Perugia by rail, on a steep hill above the east bank of the Tiber, 1,348 ft. above sea level, and 866 ft. above the river. Pop. (1951) 4,648. Some portions of the ancient town walls—of two enceintes. an inner and an outer, the former attributed to the original Umbrian inhabitants, the latter to the Romans—are preserved, while the medieval walls are still more extensive, and also remains of baths. amphitheatre, theatre and a substruction wall of massive masonry with four niches. There was found the bronze statue oi Mars, which was placed in the Vatican; some line bronze objects of the 5th century B.C. were iound in tombs. Beneath the cathedral square, at the highest point of the town, is a large Roman reservoir. The Romanesque cathedral has a simple façade (partly of the 11th, partly oi the 14th century) with a fine portal and rose window. In the same square are the massive Romanesque Gothic structures, Palazzo dei Priori (1213), the Palazzo del Capitano del I'opolo (c. 1290) and the Palazzo del Podesta (1293–1337). The Gothic church of S. Fortunato, with its nave and aisles of the same height, has a splendid portal. Just outside the town on the west is the church of S. Maria della Consolazione, one of the finest buildings of the Renaissance, and often wrongly attributed to Bramante. Contemporary documents prove that the interior was begun in 1508 by Cola di Matteuccio da Caprarola and the exterior completed in 1516–24 by Ambrogio da Milano and Francesco di Vito Lombardo; the slender dome was not added till 1607.

TODLEBEN (TOTLEBEN), FRANZ EDUARD IVANOVICH, COUNT (1818–1884), Russian engineer general, was born at Mittau in Courland, on May 20, 1818. He entered the school of engineers at St. Petersburg, and passed into the army in 1836. In 1848 and the two following years he was employed, as captain of engineers, in the campaigns against Schamyl in the Caucasus. On the outbreak of war between Russia and Turkey in 1853 he served in the siege of Silistria and, after the siege was raised, was transferred to the Crimea (see CRIMEAN WAR). Sevastopol, while strongly fortified toward the sea, was almost unprotected on the land side. Todleben, though still a junior field officer, became the animating genius of the defense. By his advice the fleet was sunk, in order to blockade the mouth of the harbour, and the deficiency of fortifications on the land side was made good before the allies could take advantage of it. The construction of earthworks and redoubts was carried on with extreme rapidity, and to these was transierred, in great part, the artillery that had belonged to the fleet.

It was in the improvisation of defensive works and offensive counterworks to meet changing phases of the enemy's attack that Todleben's originality showed itself. He never commanded a large army in the open field, nor was he the creator of a great permanent system of defense. But he may justly be called the originator of the idea that a iortress is to be considered not as a walled town but as an entrenched position, intimately connected with the offensive and defensive capacities oi an army and as susceptible of alteration as the formation of troops in battle or maneuver. Until June 20, 1855, he conducted the operations of defense at Sevastopol in person; he was then incapacitated by a wound. In 1860 Todleben was appointed assistant to the grand duke Nicholas, and he became subsequently chief of the department of engineers with the full rank of general. He was given no command when war with Turkey began in 1877. It mas not until after the early reverses before Plevna (*q.v.*) that he was called to the front. Todleben saw that it would be necessary to draw works around Osman Pasha and cut him off from communication with the other Turkish cpmmanders. In due time Plevna fell. Todleben then undertook the siege of the Bulgarian fortresses. After the conclusion of preliminaries of peace, he was placed in command of the whole Russian army. When the war was over, he became governor of Odessa and hereditary count. For some time aiter 1880 he held the post of governor oi Vilna. He died at Bad Soden near Frankfurt-on-Main, on July 1, 1884.

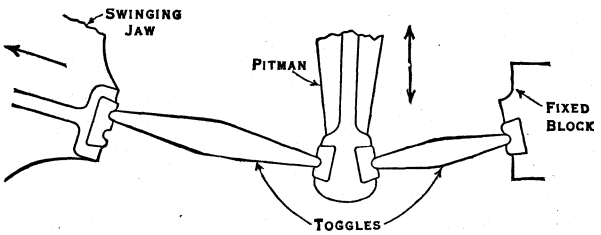
His great work on the deiense of Sevastopol appeared in Russian, French and German, 5 vol. (1864–72).

TODMORDEN, a municipal borough (1896) and market town in the Sowerby parliamentary division of the West Riding of Yorkshire. Eng., 22 mi. N.N.E. of Manchester by road. Pop. (1951) 19,074. Area 20 sq.mi. On both sides of the Calder river, at an altitude of about 500 ft., it is surrounded by high moorland. Todmorden is a railway junction for trans-Pennine routes from Manchester. Preston and Burnley to the industrial West Riding, and the Rochdale canal runs through the borough. The staple industry is the spinning and weaving of cotton, and there are also foundries and machine works. Todmorden has strong links with Lancashire, sharing its cotton industry and its county address. Until 1888 the county boundary passed through the town.

TODY, a bird (*Todus viridis*j inhabiting Jamaica, with allied species in Cuba, Haiti and Puerto Rico. A stolid bird, the tody is brightly coloured in grass green, with a crimson gorget. It feeds on insects and, like its allies the kingfishers, constructs burrows in which to lay its white eggs.

TOGGENBWRG, THE, an ancient county in the upper valley of the Thur river (Switzerland). On the death of the last count of Toggenburg (1436). Ziirich and Schwyz, in the first intercantonal war, disputed its possession. Purchased by the abbot of St. Gall in 1468. it was an area of constant strife between the abbots and the inhabitants, many among whom embraced Protestantism. The Toggenburg war between the Roman Catholic cantons and Protestant supporters of the Toggenburgers resulted in a Catholic defeat (1712) and in the restoration of the ancient liberties. Today it is a pleasant, highly prosperous part of the canton of St. Gall, inhabited by approximately equal numbers of Protestants and Catholics. Its exact limits are differently interpreted, but the entire upper valley of the Thur above the right-angled bend, near Wil, to the source near Wildhaus, is about 30 mi. long and runs mainly southeast to northwest, between steep fir-clad slopes. Near the valley head are the Churfirsten mountain (Hinterrugg, 7,566 ft.) southward and the bold peaks of the Santes (8.209 ft.) northward. The valley is well populated and has good through communications; a 20-mi. railway was built from Wil, on the Winterthur-St. Gall main line, to Nesslau. The old market centre of the valley was Lichtensteig, later surpassed in point of size and importance by several well-built towns and villages, such as Wattwil (pop., 1950, 6,336), near the entrance of the Ricken tunnel.

TOGGLE LEVER, a combination of three levers, one being at right angles to the ocher two and arranged so as to push against



A KNUCKLE FORM OF LEVER ACTION, TWO BEING STRAIGHTENED OUT BY A LATERALLY MOVING ONE

their closely set ends. One of the latter is pivoted at a fixed position, while its companion has endlong freedom. Great power is obtained by the action of the lateral lever forcing the other two into a straight line. One practical application is seen in the diagram, where the lateral lever is a rod, or pitman, given a short up and down motion from an eccentric on a shaft fitted with a heavy flywheel. As the pitman rises, it forces the toggles (which are wide pieces in this case) into line and exerts great pressure against the pivoted jaw. The latter crushes rock or stone against a fixed jaw face. Another application of toggles is in power presses for drawing hollow sheet-metal articles, such as bowls, pans, etc., from the flat sheet. This operation necessitates holding the sheet firmly around the die during the drawing. The toggle mechanism does this and transfers the great stress directly to the frame of the machine, instead of throwing it on the crankshaft.

TOGO, HEIHACHIRO, COUNT (1847–1934), Japanese admiral, was born in Kagoshima, the son of a petty retainer. He joined the navy in 1863, and his first engagement was the "Kwaiten" five years later. He studied naval science and navigation in England from 1871 to 1878 and first became a prominent figure when, in 1894, as captain of the cruiser "Naniwa," he sank the Chinese troopship "Kowshing" en route for Korea, thus precipitating war with China.

When the Russo-Japanese conflict broke out in 1904, he was appointed to the command in chief of the Japanese fleet, and under his direction various brilliant operations took place, culminating in the battle of the Sea of.Japan when the Russian fleet was annihilated. For these services he received (1907) the title of count. In 1906 he became a member of the British Order of Merit. (See RUSSO-JAPANESE WAR.)

TOGOLAND, a strip of territory in West Africa divided longitudinally into a western half, which in 1956 became united with the Gold Coast (called Ghana in 1957), and an eastern half (Togo) under French administration until it achieved full independence on April 27. 1960. To the east is Dahomey, to the north the Upper Volta and to the south the Gulf of Guinea. From north to south it extends for about 340 mi.; it is narrowest at its coast line. only 32 mi. long; its greatest width from east to west is about 140 mi. The area of the territory is approximately 35.000 sq.mi.

Physical Features. — The coastline is low and sandy: a sandbar and heavy surf impede access from the sea. A few hundred yards inland from the shore there is a line of lagoons connected by marshy creeks. Behind the lagoons lies a low plateau of lateritic clay averaging about 20 mi. in width and 200 ft. to 300 ft. in altitude. This plateau gives way to undulating plains, 1.300–1.500 ft. above sea level. The country then rises steeply to the Togo hills, which, running from south-southwest to north-northeast at an average elevation of about 2,000 ft., divide the territory into two approximately equal triangles. Mt. Agou (3.346 ft.), the highest point in the territory, is found there. To the northwest of the Togo hills is undulating savanna country drained by the River Oti, a tributary of the Volta. To the southeast of the hills the land is drained by a number of small rivers running southward, the chief of which are the Mono, which in its lower reaches forms the boundary with Dahomey, and the Haho and Sio, which terminate in the Togo lagoon, the centremost and largest of the coastal lagoons.

Climate. — Seasonal variations in climate result from the north-south oscillation of the convergence zone between the hot and dry harmattan air mass which flows from the northeast, and moist and relatively cool monsoon air from the southwest. North of the Togo hills, the harmattan is dominant except during May-October, the rainy season. Mean temperatures range from 72° F. to 92" F., while mean relative humidity lies between 45% and 67% and annual rainfall averages about 45 in. In the hills rainfall averages about 60 in. a year. South of the hills, the rainy season has two peaks, in May-June and September. and the average annual rainfall is about 30 in. Mean temperatures are low for the latitude (70° F.–85° F.), and mean relative humidity is high (around 84%). The harmattan extends to the coast for a few weeks in December–January.

Flora and Fauna. — The vegetation of Togoland has been much altered by the hand of man. True tropical forest survives only in pockets in the mountains and along the river valleys. Dense belts of reeds surround the coastal lagoons. For the rest the natural vegetation is now chiefly of the guinea-savanna type, subject to annual fires. Soils are poor and devoid of humus. Coconut palms have been planted in large numbers near the coast; oil palms, maize, cassava, yams and cotton are intensively cultivated farther inland. Cocoa and coffee are grown in the hills, while the chief crops of the northern savanna are peanuts. millet, cotton and kapok. The fauna resembles that of adjacent regions of West Africa, but, because of the relatively high density of population, the larger wild animals are now scarce, especially in the south. In the north, however, there are lions and leopards, and elephants are occasionally seen. Monkeys are common, while hippopotamuses and crocodiles live in the rivers. There are many snakes and lizards. and numerous varieties of birds and insects.

Population. — The native population is all of Negro stock, but the Togo hills divide the territory into two distinct ethnographic areas. The peoples of the north are Voltaic. subject to a degree of Hamitic influence from the Sudan e g., the Dagomba, Mamprussi and Konkomba in the west. and the Gurma, Kabre and Tem peoples in the east. South of the hills the great majority of the people are Eues, whose traditions indicate that they, or their ruling elements, migrated from southwestern Nigeria, probably about the 16th century. A number of small groups in the hill country of west central Togoland, such as the Avatime. may represent an earlier stock. In the extreme southwest are the easternmost elements of the Twi-speaking peoples. The Dagornba and Mamprussi apart, few of these peoples were organized in large or strong political units. In the north the politico-social unit was often the descent group, as among the Konkomba; in the south, the Ewes, though culturally linked with Dahomey and influenced by the Akan states to the west, were at the end of the 19th century organized into more than 100 separate tribal groups, speaking a number of different and sometimes almost mutually unintelligible dialects. The peoples of north and south alike are predominantly animists, though Christian missions have been active in the south since 1840 and the influence of Islam has been spread by immigrant Hausa and Toruba traders. The Ewes are agriculturalists and traders, the peoples of the north agriculturalists and pastoralists. Population densities are high for West Africa, the average for the territory as a whole being about 42 per square mile.

HISTORY AND ADMINISTRATION

The German Occupation. — Until 1884 what is now Togoland was merely an indeterminate zone between the predatory military states of Ashanti in the west and Dahomey in the east. (See WEST AFRICA.) Since its coastline afforded no safe landing place, the bulk of its external trade, first in slaves and then in palm oil, was conducted through the European posts in Dahomey and the Gold Coast. However. German missionaries arrived in Togoland in 1840 and 'German traders shortly followed. In July 1884, Gustav Nachtigal, sent by the German government to West Africa ostensibly to inspect German interests there, induced a number of coastal chiefs to sign treaties placing their territories under German protection. The protectorate so established was accorded international recognition at the Berlin conference of 1885, and its coastal frontiers with the adjacent colonies of Dahomey and the Gold Coast were defined by treaties with France in 1885 and with Great Britain in 1886. From 1887 to 1890 German military expeditions, penetrating into the interior and meeting with little resistance, secured a hinterland the boundaries of which were at length determined by treaties with France in 1897 and with Great Britain in 1904.

Lomé, at the western end of the coast, the only part of it which is not separated from the interior by lagoons, was selected as the political and commercial capital of the new colony. A modem town was laid out, and in 1904 a jetty was built to obviate the necessity of carrying all imports and exports through the surf. Three-metre gauge railways were constructed radiating from Lomé: one eastward through the palm-bearing coastal districts to Anécho (Little Popo), formerly the chiéf European trading centre (27 mi.) ; one north-northwest to Palimé (74 mi.) to serve the hill country; and one due north to Atakpamé (104 mi.) to open up the central area of the colony. Exploitation was practically confined to the coastal and central areas and was exclusively agricultural: no minerals were worked, and animal husbandry was hampered by the tsetse belt. Plantations were established both by the government and by private German corporations, but the greater part of agricultural development was left to the natives themselves, assisted by agriculturalists trained at a college at Nuatja. The principal products of commercial value that were developed were palm products (exports worth £239,500 in 1912), plantation and wild rubber (648,700) and cotton (625,700). Cocoa production was expanding and by 1913 exports had reached £16,600 in value. The total value of exports rose from £153,000 in 1900 to a peak of £498,000 in 1912. In the same period imports, principally cotton piece goods and hardware, increased in value from £176,000 to £572,000. In 1912 Germany took 60% of the exports and provided 42% of the imports. German administration was efficient but marred by its harsh treatment of natives and its use of forced labour. In 1912 revenue was £160,000 and expenditure £150,000.

On Aug. 7, 1914, British and French colonial troops from the Gold Coast and Dahomey respectively invaded Togoland and after a brief campaign secured the unconditional surrender of the German governor and garrison on Aug. 26. Thereafter the western part of the colony, including Lomé and the greater part of the railway system, was administered by Britain, and the eastern part by France. This division was modified by an Anglo-French agreement of July 10, 1919, by which France secured the railway system and the whole coastline. Germany having renounced her sovereignty in the treaty of Versailles, in 1922 the League of Nations issued class B mandates to Britain and France for the administration of their respective spheres.

The British Sphere.—The British sphere has an area of 13,041 sq.mi. and a population (1948) of 382,768 (51 Europeans). The northern part was administered integrally with the Northern Territories of the Gold Coast, and the southern part integrally with the Gold Coast colony. Beginning in 1951, the southern districts elected three members to the Gold Coast legislative assembly, but in the north the electoral system cannot be distinguished from that of the Northern Territories as a whole, which send 19 members to the assembly. There are no large towns in the territory, though in the north, Yendi, the Dagomba capital, has 7,694 inhabitants (1948 census), while the principal towns in the south, Ho and Hohoe, both have populations in excess of 5,000. The economy of the British sphere is exclusively agricultural. Cocoa is the principal cash crop in the south: the people of the north are mainly engaged in subsistence farming, though peanuts, yams and cattle are exported southward. Trade returns from British Togoland are not kept separately from those of the Gold Coast, but in 1953 it was estimated that the territory's exports were worth £4,345,270 (cocoa £3,646,780; maize £400,000), and its imports £4,004,200 (cotton piece goods £981,700). Although the British administration has built motor roads connecting its sphere with the road system of the Gold Coast, the bulk of its external trade passes over the railways of French Togoland. The French valuation of this transit traffic in 1951 was 66,668,000. In 1953 government revenue was £2,081,000, and expenditure £1,960,600 with an additional £585,300 on development.

The French Sphere.—The French sphere has an area of 22,008 sq.mi., and a population (1953 est.) of 1,052,318 (1,088 non-Africans). Lomé, with a population (1953 est.) of 39,200 (more than 700 Europeans), is the only town of any size. The territory is administered by a commissioner assisted by a consultative executive council of officials and by a representative assembly. The assembly has 30 members elected by more than 50,000 registered voters. Certain stipulated types of measures, including the annual budget, must receive its approval. The territory sends one representative to the French national assembly, two to the council of the republic, and one to the council of the French union. Under French administration the port facilities at Lomé have been extended and improved; the Atakpamé railway has been extended northward to Blitta, a further 68 mi.; and the mileage of roads suitable for motor traffic has been increased from 755 to 1,420. As in British Togoland, the economy is based on the peasant exploitation of cash crops, which has greatly developed. The principal exports are cocoa and coffee from the hills (worth £2,010,000 and £1,010,000 respectively in 1953), ginned cotton from the centre and north (£300.000). copra and palm kernels from the coast and centre (£510,000 and £660,000 respectively) and husked peanuts from the north. The total value of exports in 1953 was £5,580,000, and of imports £4,240,000. The principal imports were cotton piece goods) wines, spirits and beer and motor vehicles and parts. France took 64% of the exports and provided 51% of the imports in 1953. In 1953 gross revenue was £3,500,000 and gross expenditure was £3,933,000.

Modern Developments.—In 1946 the British and French governments placed their spheres of Togoland under Cnited Nations trusteeship. After 1947 Ewes in southern Togoland made a series of representations to the trusteeship council that either the territory inhabited by the Ewes or the whole of Togoland should be brought under a common administration. These proposals were difficult to implement, among other reasons, because Ewes were also inhabiting the southeast of the British colony of the Gold Coast. because of the rapid advance of the Gold Coast (including British Togoland) toward self-government, because not all the inhabitants of southern Togoland are Ewes, and because the incorporation of the northern part of the British sphere with the Sorthern Territories of the Gold Coast had satisfactorily reunited the Dagomba and Mamprussi kingdoms, both of which were cut into two by the pre-1914 boundary. However, a joint Anglo-French consultative commission for Togoland affairs was set up in 1948, frontier restrictions were relaxed, and in 1952 the Gold Coast government instituted a Trans-Volta council to deal with local problems of the Ewe areas. On Dec. 13, 1956. British Togoland was integrated with the Gold Coast (*q.v.*) which on March 6, 1957, became an independent state within the commonwealth under the name of Ghana. On April 27, 1960, Togoland under French administration became the independent Republic of Togo.

Spitz, *L'Ouest Africain français* (1947); and annual reports of the British and French governments on their administration of Togoland. (J. D. F.)

TOJO, HIDEKI (1884–1948), Japanese army officer and political leader, was born in Tokyo Dec. 30, 1884. He attended the Imperial Military academy in Tokyo and was commissioned a sublieutenant in the army upon graduation. In 1919 he served as military attaché to the Japanese embassy in Berlin. After returning to Japan he held various posts in the war office. In 1928 he was named commander of the 1st infantry regiment, which in 1936 participated in the mutiny of the Tokyo garrison. He was named commander of the gendarmery headquarters in 1937 and shortly afterward became chief of staff of the Kwangtung army. In July 1940 he was appointed minister of war in the cabinet of Premier Prince Fumimaro Konoye. Tojo succeeded Konoye as premier Oct. 16, 1941, and pledged his government to a proaxis policy as well as a "greater east Asia" program.

After the Japanese attack on Pearl Harbor, Dec. 7, 1941, Tojo officially declared war on the U.S. After prolonged Japanese military reverses in the Pacific, Tojo assumed virtual dictatorial powers, taking over the posts of minister of war and chief of the general staff. The successful U.S. invasion of the Mariana Islands so weakened his government that he was removed as chief of staff July 16, 1944. After Japan's formal surrender in 1945, Tojo shot himself in a suicide attempt but was nursed back to health to face trial as a military criminal. He was found guilty. An appeal to the U.S. supreme court was denied, and he was hanged Dec. 23, 1948.

TOKAJ, a town in Borsod-Abauj-Zemplén megye. Hungary, at the confluence of the Bodrog and the Tisza and at the foot of the Hegyalja mountains which slope from a height of 2,700 ft. to a hilly plateau of 1.500 ft. near Tokaj.

There lies the vineyard region of nearly 150 sq.mi. on a volcanic soil. The vines are believed to have been introduced by Italian colonists in the 13th century. From their grapes is produced the famous Tokay wine, the trade in which is the principal occupation. The population is (1960) 5.031 (mun.).

TOKAT, a town in Turkey. Pop. (1960) 32,725 (town); 438.439 (*il*). It is in the Sivas-Samsun *chaussée,* altitude 2.280 ft., at the mouth of a glen opening out to the valley of the Tozanli Su. a tributary of the Yeshil Irmak. It rose to importance under the Seljuks.

Industries developed there include the manufacture of copper utensils and yellow leather and the stamping of colours on white Manchester cotton.

TOKELAU ISLANDS: see PACIFIC ISLANDS.

TOKUGAWA IEYASU (1542–1616), founder of the third and last military dynasty, or shogunate, in Japan. Son of Matsudaira, a castle lord in Mikawa fief (now in Aichi prefecture), he adopted the family name of Tokugawa in 1567. At an early age he was drawn into the gigantic feudal struggles which wracked Japan in the late 16th century.

Able and ruthless, he first fought and then allied himself with the mighty Oda Nobunaga and, after Oda's death in 1582, challenged and then supported Toyotomi Hideyoshi, who became master of the land by 1590. For his efforts Ieyasu acquired extensive lands and power. Upon Hideyoshi's death in 1598, he organized a feudal coalition to support his bid for supremacy and won the historic battle of Sekigahara in 1600. Establishing his headquarters at Edo, renamed Tokyo in 1868, he obtained the title of shogun, or generalissimo, in 1603.

The Tokugawa shogunate lasted for 265 years. As the first of 15 Tokugawa shoguns, Ieyasu was a political genius. By reorganizing the system of fiefs and devising a pattern of political and military checks and balances, the almost 300 feudal lords were brought under effective control. No serious challenge to Tokugawa authority was raised for over two centuries. To ensure the power of his house, Ieyasu acquired vast wealth and estates. Though he abdicated as shogun in 1605, he dominated the Tokugawa regime until his death in 1616. *See* also JAPAN: *History.*

See A. L. Sadler, *The Maker of Modern Japan* (1937). (HN. KN.)

TOKUGAWA YOSHINOBU, PRINCE (1837–1913), Japanese statesman, was born on Sept. 29, 1837, at Tokyo. He was the last of the Tokugawa government, succeeding as shogun the 14th shogun, Iemochi. in 1866. Realizing after a year's time that the proper government of the country was impossible on the lines of feudalism. which was a bar to all progress and a source of continual internal strife, the shogun handed his resignation to the emperor on Oct. 14, 1867.

This act of sacrifice was the prelude to the enlightened Meiji era, which dates from the beginning of 1868. Tokugawa, having renounced his shogunate rights, went into a strict retirement from which he never emerged. He even renounced the succession to his title for his direct heir in favour of a collateral branch of the family, the first to inherit the title being Prince Iyesato Tokugawa, for many years president of the house of peers. The emperor Meiji accepted the renunciation, but he conferred on him another title of prince to be bequeathed to his son. He died on Nov. 21, 1913, at Tokyo.

TOKUSHIMA, a Japanese prefecture *(ken)* in eastern Shikoku. was formed from the province of Awa after the restoration of 1868. Area 1.600 sq.mi. Pop. (1960) 847.274. concentrated mainly in the Yoshino rift valley. Expansion of hydroelectric power permitted the growth of large wood-pulp and nylon and other textile industries. The prefecture is also noted for the production of tobacco and salt.

Tokushima, a historic and industrial city on the western coast of Shikoku, is the prefectural capital. Between 1940 and 1960 the city increased in area from 74 sq.mi. to 61.3 sq.mi. and in population from 119,600 to 182,782. Its present name dates from 1678. Formerly it was called Iyama and Inotsu. The chief industry is cotton textiles, notably *Awachijimi* (cotton crepe). Ferryboats connect Tokushima city with Kōbe and Awaji while a rail line, running through the Yoshino rift valley, connects the city with the rest of Shikoku. (C. A. MR.)

TOKUTOMI SOH?) (pseudonym of TOKUTOMI IICHIRŌ) (1863–1957), usually known by his pen name, Japanese historian, critic, journalist and essayist, was born at Tsumori in Kumamoto on March 13, 1863. He received an American-style education at Doshisha university, Kyoto, and immediately entered a literary career.

He was particularly concerned with Japan's future political and moral position, and his book *Shorai no Nihon* ("The Future Japan," 1886) attracted much attention. He started a periodical, *Kokumin no Tomo* (the "Nation's Friend'!): in 1887 and a newspaper, *Kokumin Shimbun* (the "Nation"), in 1890.

Of Tokutomi's numerous publications on matters relating to Japanese history and politics the most important is his *Kinsei Nihon Kokumin-shi ("A* History of the Japanese People in Modern Times"), 77 vol. (1918–46). a journalistic rather than historical work, which, despite its ultranationalistic bias, is an invaluable compendium of events in Japan from 1534 until the late 19th century. Tokutomi died on Nov. 3, 1957.

TOKYO, the capital of Japan, located at the head of Tokyo bay, is the political, economic and cultural centre of the country. Formerly called Edo or Yedo ("estuary"), it was named Tokyo, or "eastern capital," in contradistinction to Kyōto (then known as Saikyo, "western capital"), when it was proclaimed the residence of the emperor and official capital of Japan in 1868.

Greater Tokyo is claimed to be the largest city in the world. The population of the city in 1960 was 8,310,027, and the population of the urban prefecture was 9,683,802. The urban prefecture includes a number of towns around Tokyo city but not the satellite cities which extend around Tokyo bay and onto the Tokyo plain. (See *Urban Prefecture,* below.) Within 37 mi. of the centre of Tokyo there are more than 25,000,000 people. The hinterland of the city includes all of northern Japan. Tokyo is also one of the world's most modern cities, having been repeatedly rebuilt after destruction by fires, earthquakes and World War II air raids. At the beginning of the 20th century the chief means of transportation was by jinrikisha, a man-drawn carriage, but this has vanished completely except as a curiosity for tourists. The city is served by an efficient net of subways, buses, electric cars and electric or diesel trains.

The city is built on low alluvial plains, called Shitamachi, and a diluvial upland, called Tamanote. The Shitamachi lowland is less than 17 ft. above sea level and most of it has been reclaimed from the sea since 1600. This section is slowly subsiding as ground water is pumped for industrial purposes. The maximum subsidence in the mid-1950s was about $7\frac{1}{2}$ in. In general, business and industrial districts are located on the Shitamachi (downtown) and the better residential districts on the Tamanote or Yamate (uptown). Temperatures are lower on the Yamanote which has from 60 to 100 days of frost a year while in the vicinity of the delta of the Sumida river there is frost from 30 to 40 days.

The mean annual temperature for central Tokyo is about 58° F. The hottest month, August, has a mean temperature of about

79.5" while the coldest month, January, has a mean temperature of about 38°. From June through September the mean temperatures are over 68° and the relative humidity is nearly 80%. The average annual number of days of precipitation is 101.8, of which 13 are snowy. The Yamanote temperatures are often 9° cooler at night.

History **and Growth.**—While there is a questionable record of Edo as early as 1180, its real history begins in 1456 when Ōta Sukenaga (Dōkan) built the first Edo castle on the site of the present imperial palace. Toward the end of the 16th century Edo was a small fishing village with about 100 houses. The castle changed hands many times until Toyotomi Hideyoshi gave it to Tokugawa Ieyasu, along with extensive fiefs in the Kantō area in 1590. Ieyasu made Edo his principal castle because it was so located that it could control the critical land and sea communications of the Kantō plain with the west, and yet was not closely connected with the feudal family that he was displacing. When Ieyasu became shogun, he made Edo the administrative centre of the military government, *bakufu*, which in actuality made it the real capital of Japan although the emperor continued to maintain a shadowy court in Kyoto. *(See JAPAN: History.)*

The *bakufu* energetically reclaimed land from the sea and drained marshes. The Tone river: which had emptied into Edo bay, was diverted to its present course which empties directly into the Pacific ocean. The population grew rapidly. About 80,000 warriors, or samurai, who were direct retainers of the Tokugawa were soon moved to the new city. All of the *daimyō,* or feudal lords, were required to establish residences in Edo and spend part of their time there. This alternate residence in their fiefs and in the capital was called *sankinkotai*. The quarters of craftsmen, tradesmen and commoners were called the *machiya*. Numerous temples and shrines were established. The plan of the Tokugawa city resembled a spider web, a plan closely reflected in the modern Tokyo. The Tokugawa castle became the site of the imperial palace and the centre of the city plan. Parallel moats and streets encircled the castle and, with the spokelike streets which radiated out from the castle, formed the basis of the present network of streets. Some of the moats were filled to form new streets or were eventually covered with buildings. The inner circle of houses of retainers and *daimyō* was inside the outer moats; this was named the Marunouchi or "circle of houses" and is now an important business and shopping district. The tradesmen had their houses outside the moat where the Ginza, or silver shops, were located; this continues to be a main shopping district. Temples and shrines were strategically located to reinforce the defenses of the moats. Edo's population is estimated to have been 150,000 in 1613 but by 1721 it was 1,300,000. Until the end of the 18th century Edo was the largest city in the world with the exception of Peking. It probably exceeded 1,500,000 during the period 1800–50. The city became a centre of communications. Rice, fish and timber were moved to the city by sea and unloaded along the banks of the Sumida river and the net of canals. Merchants carried their goods over the five great highways that concentrated on the city. All distances on these highways were measured from a bridge in the centre of Edo, the Nihon Bashi. By the beginning of the 18th century the main features of the city were fixed and there were few changes until after the restoration of 1868. Some temples and shrines moved to the suburbs where there was more land for expansion and many *daimyd* established palaces and parks on the cooler terraces of the Yainanote section of the city. Some parks of the *daimyō* palaces later became sites of universities or public parks. Because of frequent fires some new detached *machiya* quarters were built separate from the main city. Fires were always serious in Edo and Tokyo because of the crowding of houses and the materials used in their construction. Little was left of the city after the great fires of 1657, 1668 and 1825. Smaller sections of the city were burned more frequently and it is estimated that the city was completely rebuilt on an average of every 11 years. Earthquakes, followed by fires, also took a serious toll. The most serious earthquakes have been in 1633, 1650, 1703, 1855 and 1923.

The *bakufu* was overthrown in 1868 and Edo was renamed Tokyo. Although the emperor moved to Tokyo and it continued to be the administrative centre of Japan, the restoration was accompanied by an immediate decline in the population because the dispossessed samurai and *daimyō* had owned about 60% of the city. By 1872 the population had dropped to 520,000. It was not until 1880 that the city again passed the 1,000,000 mark. The new city was an industrial, commercial and cultural centre as well as a political and administrative centre, such as it had been under the Tokugawa. The subsequent growth of the city was closely connected with the development of modern communications. A railroad built in 1872 linking Tokyo and Yokohama was the beginning of an efficient rail system which has Tokyo as its centre. A circular electrified line called the Yamate loop was completed within the city in 1910. This was the beginning of a system of electric lines, subways and buses which permit large numbers to be moved about the city quickly.

The main shopping street with its great department stores developed in the Ginza district while business concentrated in the Marunouchi district. Wherever the Yamate loop was joined by a rail line leading away from the city. a secondary shopping district developed, such as Shibuya, Shinjuku and Ikebukuro. The eastern lowland between the Sumida river and the Arakawa developed as the first industrial area. Later the entire coast line between Tokyo and Yokohama became an industrial area knoan as the Keihin.

On Sept. 1. 1923, a disastrous earthquake struck the city. The fire which followed it was fanned by strong winds and did most of the damage. The loss of life was estimated at 74,000 and 64% of the surviving population was left homeless. This disaster accelerated the move of the residential areas to the Uamanote upland which had not suffered as much damage as the Shitamachi lowland. The heavy damage in the eastern industrial area was followed by the building of new factories on reclaimed lands near the mouth of the Sumida river. in the Keihin area and to the west along the Chūō railroad. The area of the city began to expand in 1932 when neighbouring communities mere absorbed to increase the area from about 33 to 214 sq.mi. Continued expansion gave the city about 222 sq.mi. by 1958.

During the 1930s the military adventures in China were accompanied by an increase in the factories. industries and populaticn of Tokyo. In 1942 the population reached 6,916,000. During World War II, 51% of the population of the ward areas lost their homes and other people migrated, so that by Sept 1945 the population nas reduced to 2,777,000. Little was left standing in the heart of the city except some of the foreign-style buildings in the Marunouchi district. Recovery was rapid after the war with the return of refugees, rebuilding of old factories and establishment of new industries. By the mid-1950s the population was greater than before the war. The continued expansion gave rise to many problems of housing and congestion. After 1951 the government subsidized low-cost housing units. Large modern apartment houses became a feature of the city after the war.

Yokohama developed in the last half of the 19th century as Tokyo's outer port because the upper part of Tokyo bay is shallow. How-ever, in the late 1930s a channel was dredged to Tokyo which enables large ocean-going vessels to dock in the extensive Tokyo harbour area. After World War II industry expanded along the northern end of Tokyo bay. This new industrial zone, which includes the iron and steel industry of Chiba, is called Keiyō The Tokyo International airport at Haneda is the focal point of the domestic airlines and the chief Japanese airport for the international airlines

The grounds of the imperial palace form the core of the city. The palace itself mas destroyed by fire in the past and almost completely destroyed in World War II Most of the important government buildings are close to the core. The diet building nhere the Japanese legislature meets is a magnificent building nhich survived the war. Nearby are the supreme court building. the prime minister's official residence and offices and the offices of the various government ministries. The Tokyo city government and police also have their offices in the vicinity of the palace.

The greatest concentration of the government buildings is in the Kasumigaseki area to the southwest of the palace.

Culture. — A concentration of universities. libraries and museums makes Tokyo the cultural leader of Japan. The city contains 146 of the 465 universities and colleges of the country. In the early 1960s there were about 250,000 full-time college students besides those attending night school. Many of the older universities were established on the grounds of *daimyō* palaces after the restoration of 1868. The constant increase in students coupled with high land values in the vicinity of the existing campuses forced the establishment of branch or new campuses on the periphery of the city. Bookstore districts are found near the chief universities.

Tokyo contains major museums of Japanese and world art, such as the Tokyo National museum (formerly the Imperial Household museum), the National Museum of Modern Art, the Metropolitan Fine Art gallery, the Bridgestone gallery, the Okura Museum of Antiques and the Folkcraft museum. Science is represented by the Communications museum, the Electric Science museum, the National Science museum and the Transportation museum. In addition, the big department stores are famous for their special exhibits of contemporary and ancient art.

Tokyo has four types of theatres: the classical nō, the Kabuki, modern drama and moving pictures (Japanese and foreign). While the nō plays were for the upper classes of old Japan, the Kabuki were for the common people. Tokyo has continued to be the centre of Kabuki as it was in the Edo period. *(See* Nō Drama; Kabuki Theatre.)

The Tokyo dialect of Japanese was made the standard for the schools of all Japan.

Parks and Shrines. — There are more than 250 parks used for recreation. Some of these are famous gardens which were attached to *daimyō* palaces in the Tokugawa period, such as the Kiyosumi and Kōrakuen gardens. Ueno and Shiba parks, which contain the tombs of most Tokugawa shoguns, were opened to the public as parks after the restoration. The shrines and temples of Shiba park represented some of the finest Tokugawa architecture but were completely destroyed during World War II. Nearby, the third highest man-made structure in the world, a TV tower erected in 1958 and modeled on the Eiffel toner, dominates all Tokyo. Ueno park contains the Academy of Science, the Science council, the Ueno library, the Tokyo National museum, the Science museum, the Art gallery and the Ueno zoo. The Meiji park contains extensive gardens, the shrine to the memory of the Meiji emperor and athletic fields. After World War II some gardens and parks owned by the imperial family were opened to the public: Shinjuku Gyoen, Hamma Rikyii and Shiba Rikyii.

Urban Prefecture. — Tokyo-to, the prefecture, was formed after the restoration of 1868 from eight counties of Musashi province, the seven Izu Islands and the Ogasawara Islands. The prefecture covered an area of about 828 sq.mi. in 1940 but this was reduced to 780 sq.mi. with the loss of the Ogasawara Islands after World War II. In addition to the city of Tokyo, the prefecture contains other industrial and residential cities of importance which are closely tied to Tokyo. Hachiōji and Ome are textile centres. Tachikawa is a military and air base. Musashino, Fuchu and Chofu are tourist and recreational centres. Musashino is also noted for its artists' colony.

Administration. — The city is divided into 23 wards (ku), four of which (Bunkyō, Chiyoda, Shinjuka and Minato) are in the Yamanote district, and four (Chūō, Taitō, Sumida and Koto) in the Shitamachi district. Fifteen other wards were incorporated into the city in 1932, namely Katsushika, Edogawa, Arakawa, Adachi. Itabashi, Nerima, Kita, Meguro, Shinagawa, Nakano, Shibuya, Setagaya, Ota, Toshima and Suginami. Tokyo-to is administered by a governor and a metropolitan council of 120 members, who are elected to office. See also references under "Tokyo" in the Index volume. (C. A. Mr.)

TOLAND, JOHN (christened Janus Junius) (1670–1722), English deist, was born on Nov. 30, 1670, near Londonderry, Ire. Brought up a Roman Catholic, in his 16th year he became a zealous Protestant. He studied at Glasgow and then at Leiden under the famous scholar Friedrich Spanheim. He went in 1691 to Oxford, where he began the book which made him famous — his *Christianity not Mysterious* (1696. anonymous; 2nd ed. in the same year, with his name; 3rd ed.. 1702, including an *Apology for Mr. Toland*). It gave great offense, and several replies were immediately published. The author was prosecuted by the grand jury of Middlesex, and when he attempted to settle in Dublin at the beginning of 1697, he was denounced from the pulpit and elsewhere. His book having been condemned by the Irish parliament (Sept. 9, 1697) and an order issued for his arrest. Toland fled to England. The resemblance, both in title and in principles, of his book to Locke's *Reasonableness of Christianity* led to a prompt disavowal by Locke of the supposed identity of opinions and subsequently to the famous controversy between Stillingfleet and Locke. Toland's next work of importance was his *Life of Milton* (1698), in which a reference to "the numerous suppositious pieces under the name of Christ and His apostles and other great persons" provoked the charge that he had called in question the genuineness of the New Testament writings. Toland, replying in his *Amyntor, or a Defence of Milton's Life* (1699), opened up the question of the history of the scriptural canon. In 1702 he published *Vindicius Liberius*, in which he described *Christianity not Mysterious* as a youthful indiscretion.

The next year he visited Hanover and Berlin and on his return to England published (1704) his *Letters*. In two of these (*A Letter to a Gentleman in Holland* and *Motion Essential to Matter*). ostensibly an attack on Spinoza, he anticipated some of the speculations of modern materialism. The *Account of the Courts of Prussia and Hanover* (1705) was used by Carlyle in his *Life of Frederick the Great*. From 1707 to 1710 Toland lived in varying circumstances on the continent. In 1709 he published (at The Hague) *Adeisidnenzon* and *Origines Judaicae*. The last of his theological works were *Nazarenus, or Jewish, Gentile and Mahometan Christianity* (1718), in which he maintained that the early Christians were Jewish Christians observing the Mosaic law and that their successors were the Nazarenes or Ebionites. He died on March 11, 1722, in London. as he had lived, in great poverty. with his pen in his hand. The term "freethinker" was first applied to Toland, who indeed uses it himself.

See Mosheim's *Vindiciae antiquae christianorum disciplinae* (1722), containing the most exhaustive account of Toland's life and writings; a *Life of Toland* (1722), by "one of his most intimate friends"; "Memoirs of the Life and Writings of Mr. John Toland," by Des Maizeaux, prefixed to *The Miscellaneous Works of Mr. John Toland* (1747) ; also G. Berthold, *John Toland und der Monismus der Gegenwart (1876)*.

TOLBUKHIN (formerly Dobrich), a town and regional centre of northeastern Bulgaria, lies in the great fertile plain of the Dobruja. Pop. (1956) 42.661. It was part of Rumania from 1913 to 1940. when it mas known as Bazargic. The town is connected by rail to the port of Varna (Stalin) and to Medgidia, Rumania: and it is on the main road from Varna to Constanta.

Tolbukhin has many vocational and general schools. Its industries are largely connected with the agriculture of the fertile neighbouring regions and include ensilage. flour milling, baking and vegetable oil extraction. There are also factories for cotton and woolen fabrics, furniture. bricks and tiles. The city was renamed in 1949 for the Soviet marshal Fyodor Ivanovich Tolbukhin, who took it from the Germans in World War II.

(An. Be.)

TOLEDO, a province of Spain. formed in 1833 from part of New Castile. Pop. (1950) 533.654. Area 5,925 sq.mi. The surface is mountainous. Toward the centre there are extensive tablelands, but the south and east are occupied by the Montes de Toledo and the hills which separate the waters of the Tagus on the north from those of the Guadiana on the south.

Toledo is well watered by the Tagus (*q.v.*) and its affluents. Gold, silver, lead, iron, quicksilver. copper. tin and other minerals are mined; manufactures include textiles, earthenware, soap. oil. chocolates. wine, rough spirit (*aguardiente*), guitar strings and arms. There is also trade in charcoal and timber.

TOLEDO, the capital of the Spanish province of Toledo and formerly of the whole country. 47 mi. S.S.W. of Madrid, on the river Tagus, 2,400 ft. above sea level. Population (1950) 38.136 (mun.). Toledo is of immemorial antiquity; it mas a stronghold of the Carpetani and may have been a Carthaginian trading station. Captured by the Romans in 193 B.C, it became a *colonia* and the capital of Carpetania. Its ecclesiastical importance is coeval with the introduction of Christianity into Spain; there mere numerous church councils held there. notably in 396. 400 and 589. and it also was the chief battleground in the long political and religious struggle which ended (589) in the triumph of Spanish Catholicism over Arianism. From the reign of Athanagild (534–547) until the Moorish conquest in 712, Toletum was generally regarded as the capital of Visigothic Spain Tolaitola, as the city was then called, prospered under the Moors. first as a provincial capital in the caliphate of Cordova, governed by an emir (712–103.5). afterward as an independent state (1035–85). Its rulers protected the large Jenish colony, founded extensive silk and woolen industries and made their city an important centre of Arab and Hebrew culture, one of the great names associated with it being that of Rabbi ben Ezra (1119–74). Toledo was captured by Alphonso of León and Castile, aided by the Cid, in 1085, and two years later he made it his capital. It declined after Philip II moved the capital to Madrid (1560). In one of the most famous sieges of the Civil War of 1936–39, nationalists in the Toledo Alcázar held out for 70 days and were relieved on Sept. 27, 1936.

Toledo occupies a rugged promontory of granite, washed on all sides except the north by the Tagus, nhich there flows swiftly through a deep and precipitpus gorge From a distance it has the aspect of a vast fortress. The principal plaza is the arcaded Zocodover, described by Cervantes in the *Novelas ejemplares.*

The Tagus is spanned by tno fortified Moorish bridges, the Puente da Alcántara, on the northeast, which was rebuilt in the 13th and 17th centuries, and the Puente de San Martin, on the northwest, founded in 1212 and rebuilt in 1390. The Mudéjar Puerta del Sol is the finest of several ancient gateways, among nhich the Puerta Visagra (1550, restored 1575) and the Puerta del Cambron (1102, restored 1576) are also interesting The Puerta Visagra Antigua, a Moorish gateway of the 9th century, has been walled up, but its original form is preserved. The Alcázar, a huge square building with a tower at each corner and a fine arcaded patio, stands on the highest ground in Toledo, originally the site of a Roman fort and now a military academy. Its fine façade designed by Juan de Herrera, a gateway by Alonso de Covarrubias and a staircase by Herrera and Francisco de Villalpando have been preserved. The Apuntamiento, or city hall, is a 15th-century building with 17th-century alterations by Domenico Theotocopuli (El Greco).

The cathedral occupies the site of a Visigothic church. St. Ferdinand founded the present cathedral in Aug. 1227 The completion of the main fabric was delayed until 1493, while many of the chapels and other subordinate buildings mere added even later; thus Renaissance and baroque features have been introduced into a design which was originally Gothic of the 13th century. Most of the chapels date from the 15th and 16th centuries and are very magnificent in detail. The superb stained-glass windows. chiefly of Flemish work, belong to the same period and number 750. In the Mozarabic chapel, mass is still performed daily according to the Mozarabic liturgy. (See MOZARAB)

Several other churches. notably Santo Tom6 and San Vicente. contain masterpieces of El Greco. The Franciscan convent and church of San Juan de los Reyes (florid Gothic) were founded in 1476 by Ferdinand and Isabella. El Cristo de la Luz mas originally a mosque, built in 922 and incorporating some pillars from an older Visigothic church. El Cristo de la Vega, formerly known as the Basilica de Santa Leocadia, occupies the site of a Visigothic church built in the 4th century to mark the burial place of the saint. The Mudéjar Santa Maria la Blanca became successively a synagogue (in the 13th and 14th centuries), a church (1405), an asylum for women (1550), barracks (1791–98) and again a church.

Toledo's characteristic industry is the manufacture of swords Toledan blades have been famous for 2,000 years, being mentioned in the Cynegetica of Grattius (Faliscus), during the 1st century B.C. The industry throve under the Moors, especially during the 16th century; it is now practised on a smaller scale.

TOLEDO, a city of northwestern Ohio. U.S.. a port of entry and the seat of Lucas county. is on Maumee bay (the southwestern tip of Lake Erie) at the mouth of the Maumee river, 60 mi. S W. of Detroit, Mich. Toledo is at the head of modern navigation on the Maumee; bridges connect the two parts of the city but most of the land area lies on the west side of the river. The population of the city in 1960 was 318,003, an increase of 4 7% in the decade; that of the standard metropolitan statistical area (Lucas county) was 456,931. an increase of 15.5%. (For comparative population figures see table in OHIO: Population.) Suburban communities in the metropolitan area are Ottawa Hills, Maumee, Oregon, Sylvania. Perrysburg and Rossford.

History. — The Indian title to land in the Toledo area was transferred to the United States in a series of treaties negotiated from 1795 to 1817. From 1803 to 1805 there was an occasionally occupied government supply post for the Indians (Ft. Industry) at the mouth of Swan creek in what is now downtown Toledo. Settlement began about 1807, although a few French families were living in the area among the Indians prior to that time After the War of 1812 a permanent settlement was made on the northwest side of the Maumee river near the mouth of Swan creek, at a point where the river channel was close to shore. As the size of lake ships increased, the river traffic became confined to the Toledo area because of low water a few miles above Swan creek. In 1825 the opening of New York's Erie canal and the beginning of work on the Ohio canal system gave rise to expectations that the harbour would be a commercial centre. Toledo came into formal existence in 1833 with the union of two villages, Port Lawrence (founded in 1817) and Vistula (founded in 1832). It was chartered as a city in 1837. Through canal traffic was opened in 1843 to Indiana and in 1845 to Cincinnati.

Ohio's decision to include the Toledo area in the state's canal system led to the so-called Toledo war of 1835. Residents of Toledo in 1835 organized to transfer the political jurisdiction of the lower Maumee from Michigan territory to Ohio. Michigan, led by Gov. Stevens T, Mason, opposed this and sent troops. Ohio Gov. Robert Lucas called out the militia and the legislature organized most of the disputed area into Lucas county, with Toledo as the county seat and the present Ohio line as the northern boundary. The dispute was settled when the Democratic state administration sent delegates to Washington to persuade Pres. Andrew Jackson to favour Ohio, whose influence as a state was greater than Michigan's as a territory. In 1836 congress compensated Michigan for the loss by awarding it the upper peninsula and admission to statehood. Toledo's subsequent political history has been characterized by a flare for independence: in 1848 it elected a Free-Soil congressman; in 1879 a Greenback mayor; in 1899–1913 Independent Mayors Samuel M. ("Golden Rule") Jones and Brand Whitlock; and in 1950 and 1952 an Independent congressman.

Population Characteristics. — Migrants from New England and New York predominated in Toledo at first. A large German and Irish element settled prior to the American Civil War and had much influence in political. economic and cultural life. So, likewise, did the later coming of Polish, Hungarian, Balkan and near eastern elements. In 1950 the population was 87.4% native-born white, 5.9% foreign-born white and 6.7% Negro.

Government. — Toledo has a council-manager form of government, in effect since 1936. The Toledo-Lucas County Port authority was established in 1955, in anticipation of the opening of the Great Lakes-St. Lawrence seaway in 1959, with power to own, operate, develop. promote, levy taxes on and acquire property and issue revenue bonds. It is engaged in developing grain and general cargo facilities.

Commerce, Industry and Transportation. — Toledo is a major fresh-water port and is one of the largest bituminous coal shipping ports in the world. The harbour has 35 mi. of shore nith a 17-mi. long, 400–500-it. wide, 125-ft. deep straight channel leading to Lake Erie. Foreign commerce receipts consist mostly of grain. wood pulp, paper, pig iron, iron ore, stone, sand and gravel. aluminum ingots and structural steel. Exports are mostly coal, petroleum products, iron ore. scales and automobiles. Domestic receipts are largely iron ore, coal and petroleum products; domestic shipments consist mainly of coal from Ohio, Kentucky and West Virginia.

Glass, automobiles and parts, weighing machines, industrial furnaces. machinery, machine tools and shipbuilding are among the important products of Toledo's diversified manufacturing industries. Transportation facilities, in addition to the port (which has benefited from the St. Lawrence seaway), include good rail connections and service by several airlines. Toledo is on several federal highways as well as the Detroit-Toledo expressway and the Ohio turnpike. two of whose interchanges (the Maumee-Toledo and Stony-Ridge-Toledo) are within the metropolitan area.

Education and Cultural Activities.—In addition to an extensive public school system, Toledo has Roman Catholic. Lutheran and Seventh Day Adventist parochial schools. The University of Toledo is a municipal institution chartered in 1872; Mary Manse college is a Roman Catholic college for women. chartered in 1873. The city has a public library with numerous branches, a well endowed museum of art, an orchestra and a zoological park with an open-air amphitheatre. There are more than 2,000 ac. in the city park system. (R. C. Do.)

TOLEDO, COUNCILS OF. Councils of great importance for the Spanish kingdom gathered in Toledo 18 times from the 5th to the 8th century. At least 11 of these councils were considered national or plenary, the rest being provincial. The acts of each of these councils except the 18th have been preserved. The conciliar procedure is found in the acts of the fourth council. The bishops always constituted a majority of those present at the councils: however, some abbots, priests, deacons and members of the lay nobility also attended. Though ecclesiastical in nature. these councils were of considerable importance in civil and political affairs. Nearly all were convoked by kings. sometimes with the primary purpose of gaining political support.

The third council of Toledo, summoned by King Reccared in 589, is considered the most important. It was the occasion of the conversion of the king and the nobility from the Arian heresy to the Catholic faith. There followed the unification of Visigothic Spain. the establishment of Catholicism as the state religion and a strong union between the Catholic Church and the Visigothic state. The greatest theological significance is found in the 11th council. held in 675. Its Trinitarian symbol (creed) and its Christological doctrine have interested later theologians.

From the 11th to the 16th century at least ten other councils, some national, some provincial: were held in Toledo. Their importance was great for the canonical history of Spain. The last council of Toledo mas that of 1582–83.

TOLIMA, an interior department of the republic of Colombia within the drainage basin of the Magdalena river. Area 8,646 sq.mi. Pop. (1951) 712.490. Stock raising predominates on the dry lower Magdalena plains except where water is available for irrigation. On the precipitous Andean slopes, especially in the volcanic Central cordillera, coffee is the principal crop. The coffee area, which supports the largest part of the rural population, was settled by Antioqueño colonists in the 1850s. Ibagué (*q.v.*), the departmental capital, is strategically located at the foot of the Quindio pass (elevation 10,800 ft.) between the Magdalena and Cauca valleys. (J s J. P.)

TOLL, JOHAN KRISTOFFER, COUNT (1743–1817), Swedish statesman and soldier. was born at Mölleröd in Scania. He served in the Seven Years' War. In the coup *d'état* of 1772 he ranged himself on the side of Sprengtporten and mas told to capture the southern fortress of Kristianstad. By sheer bluff he won over the whole garrison. Gustavus III's *coup* d'ktat at Stockholm completed the revolution. Toll was liberally rewarded. In 1783 he was placed at the head of the secret "commission of national defense," which ruled Sweden during the king's absence abroad. In 1786 he had risen to the rank of major general and was Gustavus' principal adjutant.

After the death of Gustavus III, Toll was for a short time war minister and commander in chief in Scania. and mas sent later as ambassador to Warsaw. Unjustly involved in the "Armfelt conspiracy," he was condemned to two years' imprisonment but was reinstated in 1796 when Gustavus IV attained his majority. At the riksdag of Norrköping, 1800, he was elected marshal of the diet and was an able leader of the royalist party. He carried on the negotiations with the powers concerning Sweden's participation in the war against Napoleon. In the Pomeranian campaign of 1807 he helped to defend Stralsund, and on its surrender to Marshal Brune on Aug. 20, he persuaded the latter (Sept. 7) to make a convention by which the Swedish army was allowed to return unmolested to Sweden. and was rewarded by his marshal's baton. In 1814 Bernadotte created Toll a count. (R. N. B.)

TOLLER, ERNST (1893–1939), German dramatist, one of the exponents of the left-wing revolutionary movement after World War I, was born at Szamocin on Dec. 1, 1893. In 1914 he volunteered. but the war turned him into a pacifist. He became a radical socialist, joining the Independent Socialist party, and was imprisoned for five years for his part in the Munich rising of 1919. In prison he won fame with revolutionary plays in the expressionist style, with rousing mass scenes (Die *Wandlung*, 1919; *Masse* Mensch, 1921; Die *Maschinenstürmer*, 1929; etc.), and with two books of lyrics, *Gedichte* der *Gefangenen* (1921) and *Das Schwalbenbuch* (1923; The Swallow-Book, 1924). Toller left the Independent Socialist party in 1923 though he kept the idealism and pity that drew him into the movement. His later plays (Hoppla! wir leben, 1927; *Feuer aus* den *Kesseln*, 1930; etc.) were more realistic than the earlier work. In 1933 he emigrated to New York where he committed suicide on May 22, 1939.

Most of his plays have been translated into English. For a selection see *Seven Plays* (1935). He also wrote an autobiography, *Ein Jugend* in *Deutschland* (1933; *I Was* a German, 1934).

See P. Singer, *Ernst Toller* (1924); W. A. Willibrand, *Ernst Toller and His Ideology* (1945).

TOLMAN, EDWARD CHACE (1886–1959), U.S. psychologist identified with a form of behaviouristic psychology known as purposive behaviourism, or molar behaviourism, was born in West Newton, Mass., April 14, 1886. He studied at the Massachusetts Institute of Technology, Cambridge, and received the Ph.D. degree from Harvard in 191j, afterward teaching at Northwestern university, Evanston, Ill., until 1918 and then at the University of California, Berkeley, until his retirement in 1954.

Tolman believed that the "molecular" behaviourism of John B. Watson (*q.v.*) was too limited because it selected the conditioned reflex as the unit of habit. For him the unit of behaviour is "molar," a total goal-directed act, using varied muscular movements, organized about the purposes served and guided by cognitive (*i.e.*, perceptionlike or ideational) processes. His system remained a behaviourism (*q.v.*) by retaining an anchorage throughout on objective observations. It has acknowledged relationships with the philosophical positions of C. D. Broad and Ralph Barton Perry, and with the psychological systems of William McDougall, Wolfgang Köhler, Kurt Lewin and Egon Brunswik. Tolman's major work is *Purposive Behaviour in Animals and Men* (1932). He died Nov. 19, 1959, in Berkeley, Calif.

See *Collected Papers in Psychology* (1951), with bibliography of writings. A later biography and bibliography appear in the *American Psychologist*, 13:155–158 (1958). (*E*. R. H.)

TOLMAN, RICHARD CHACE (1881–1948), U.S. physical chemist and physicist, was one of the principal scientific figures in the first half of the 20th century. His scientific interests were broad and varied, but they centred on chemical kinetics, statistical mechanics, relativity and relativistic cosmology. Born March 4, 1881, in West Newton, Mass., he received his Ph.D. from the Massachusetts Institute of Technology, Cambridge, in 1910. He taught at the universities of Michigan, Cincinnati and California. From 1922 until his death he served as professor at the California Institute of Technology, Pasadena, and for many years was also dean of graduate studies there.

With T. D. Stewart, he was the first to measure the mass of the electric carrier in common conductors. The great part of his work was theoretical; he published two authoritative treatises on statistical mechanics in 1927 and 1938, and two on the theory of relativity in 1927 and 1934.

During World War I he was chief of the dispersoid section of the chemical warfare service. During World War II he was vice-chairman of the National Defense Research committee, chairman of its armour and ordnance division, and scientific adviser to Gen. L. R. Groves. head of the Manhattan project which developed the atomic bomb. For these services he was awarded the medal for merit and the Order of the British Empire. After the war he was principal scientific adviser to Bernard M. Baruch, United States representativeon the United Nations Atomic Energy commission, concerned with the prbblems of the international control of atomic energy.

Tolman died Sept. 5, 1948, in Pasadena, Calif. (J. R. O.)

TOLSTOY, ALEKSEY KONSTANTINOVICH, COUNT (1817–1875), Russian novelist, dramatist and poet, was a distant relation of Leo Tolstoy. Born at St. Petersburg on Sept, j. 1817, and brought up on his uncle's estate at Tchernigoff. which he inherited in 1836, he was a playmate of the emperor Alexander II. He studied at the university of Moscow, and was afterward attached to the Russian legation at Frankfurt and served in the Crimean War. He held various court appointments, and spent much time in western Europe. He died at his Tchernigoff estate, Krasni Rog, on Oct. 10, 1875. With his two cousins Zhemchuzhnikov, Tolstoy wrote between 1853 and 1863 much satirical nonsense-verse under the joint pseudonym of a fictitious civil servant, Kosma Prutkov. He also wrote some magnificent lyric poetry; one of his most famous pieces. a paraphrase of the lament for the dead in the Russian church service, is translated by Maurice Baring in the *Oxjord Book of Russian Verse.* Outside Russia, however, Aleksey Tolstoy is best known by his historical romance, *Prince Serebruny* (1863; Eng. trans. by C. A. Manning, 1927), and his dramatic trilogy: *Death of Ivan the Terrible* (1866; Eng. trans. by A. Hayes. 1926). *Tsar Feodor Ioannovich* (1868; verse trans. A. Hayes. 1924) and *Tsar Boris* (1870). Some of his poems were translated in C. T. Wilson's *Russian Lyrics* in *English Verse* (1887); Anglo-Russian Literary Society, Nos. 21, 23, 25; and J. Pollen's Rhymes *From the Russian* (1891).

TOLSTOY, LEO (LYEV) NIKOLAYEVICH, COUNT (1828–1910), Russian novelist and moral philosopher. was born on Aug. 28 (Sept. 9), 1828, at his parents' country place of Yasnaya Polyana, in the province of Tula. The Tolstoys are a family of Russian gentry dating back to the 16th century (*not* of German origin as is often affirmed. and as Tolstoy himself believed). Petr Andreyevich Tolstoy (*q.v.*) was created a count by Peter the Great. His descendant, Count Nicholas Ilyich, the novelist's father, married Princess Marie Volkonsky, who brought him a substantial fortune. They had five sons of whom Leo was the youngest but one. The surroundings in which he grew up were those of a family of the upper middle gentry of the last of the period of serfdom. This environment produced in him the "peer-and-peasant" view of life.

Early Years.—Tolstoy's mother and father died in 1831 and 1837, and he was brought up by elderly female relatives. His education was in the hands of French tutors, a state of things that was already an anachronism. So his intellectual and cultural groundwork was mainly 18th century French, and his contact with contemporary Russian culture was late and unsympathetic. In 1844 Tolstoy matriculated as a student of Kazan university, which was then probably the greatest seat of learning east of Berlin. But he worked little, and early developed an attitude of contempt for academic learning. He spent most of his time in society, Kazan being a social centre for the Russian gentry second only to St. Petersburg and Moscow. In his old age he remembered with gratitude these years of unreflecting happiness. But his questioning mind was already asserting itself, and it is to his Kazan years that he assigns the "tremendous" influence on him of the works of Rousseau. In 1847 he gave up the university and settled at Yasnaya Polyana with the intention of farming and looking after his serfs. But he found himself unprepared for the work he had undertaken, and the attempt ended in failure.

The next years were mainly passed in Moscow, where he gave himself over to the dissipated and irregular life so frequently led by the young men of his class and time. But the work of self-study and self-criticism, of which his diary, started in 1847, is such a remarkable record, went on, and the idle life could not satisfy him. In 1851 he turned a new page: he went to the Caucasus and there enlisted as a *junker* (gentleman volunteer) in an artillery unit. His time was spent in quiet garrison life in Cossack villages, diversified by hunting and occasional expeditions against the mountaineers. In 1852 he completed his first story, *Childhood*, and sent it to Nekrasov, the editor of the leading literary review, who accepted it enthusiastically and had it published at once. In 1854 Tolstoy received his commission, and was transferred (on his application) to the army that was operating against the Turks on the Danube, and a few months later to Sevastopol, where he remained till the end of the siege. After the fall of the fortress he was sent with dispatches to St. Petersburg, where he remained, frequenting society and literary circles, and much preferring the former to the latter. With the *littérateurs* he failed to get on. Their plebeian arrogance shocked him, and he had no respect for their ideal of European progress. His resounding quarrel with Turgeniev may be taken as typical of these relations. In 1857 he retired from the army.

In the same year (and again in 1860) he travelled abroad, and (like Dostoyevsky a few years later) brought back nothing but disgust with the materialistic and plutocratic civilization of the west. After his second journey abroad he settled at Yasnaya Polyana, and accepted an appointment to a magistracy introduced by the Emancipation act of 1861 for the settling of land disputes between the squires and their former serfs. He also started a school for peasant children on new and original lines, based on his belief in the superior value of their natural lights to the artificial standards of civilization, and published a journal (*Yasnaya Polyana*) devoted to the advancement of his pedagogical ideas. But before long he gave up both magistracy and school. He was on the brink of an inner crisis.

The crisis, however, did not mature till 15 years later: it was postponed by his marriage. He had been contemplating marrying for some time. His romance with Valeria Arseniev had ended in nothing. He was obsessed by grave misgivings and doubts before he proposed to Sophie Behrs, a young girl 16 years his junior, with whom he fell in love in 1861. He overcame them, however, and they were married in the following year.

Literary **Works (1852–76).** Tolstoy's literary work grew out of his diary. It was primarily an attempt to lay bare the *mechanism* of the inner life, and to give clear and verbal definition to the semi-articulate processes of the consciousness. His first literary attempt, *The Story of Yesterday* (1851, first published 1926) sets out to give an exhaustive account of his feelings and reactions during a given space of twenty-four hours. His first completed and published work, *Childhood* (1852), less exuberantly analytical and more conventional in form, reveals a greater command over the more intimate and elusive movements of the consciousness than had ever before been displayed in literature. In the stories that followed he further perfected his instruments of analysis, often to the detriment of the imaginative unity of the work. At the same time a conflict which was to remain dominant throughout his life comes to the forefront—the conflict between spontaneous, unreflecting, natural Life and the claims of reason and moral law. In *The Cossacks* (written 1854, published in what the author regarded as an unsatisfactory form in 1862) the victory rests with life: natural man, unconscious of good and evil, and consequently beyond the reach of ethical reason is glorified in the Cossacks who put to shame the reflecting and impotent hero, Olenin. The futility, meanness and vulgarity of civilized man is exposed again and again in *Two Hussars* (1856), *Lucerne* (1857), *Three Deaths*

(1859) and in *Kholstomer* (1861), a very characteristic satire on the life of the upper classes, in which the rôle of the intelligent savage of 18th-century literature is played by a racehorse. All his early work is subjective, and the reflecting and introspective character, whether his name is Olenin or Nekhlyudov (as in *Boyhood,* 1854, and *Youth,* 1857) is always Tolstoy himself. The other men whose feelings are analyzed, are merely types of "man in general"—psychological mechanisms of cause and effect, devoid of personality. Such for instance are the officers of the *Sevastopol* stories (1855) in whom Tolstoy dissects the components of fear and courage.

After his marriage Tolstoy lived at Yasnaya Polyana, passing some part of the year at Moscow and on his estate beyond the Volga. His married life was happy and prosperous. His income was increased by successful farming and the sale of his books. His wife was entirely devoted to him and to her children of which she bore him nine. His inner conflict was lulled for many years by the triumph of spontaneous life over questioning reason. His philosophy in those years was "that one should live so as to have the best for oneself and one's family;' and not try to be wiser than Life and Nature.

This philosophy found its full expression in the first of his few great novels, *War and Peace.* It was commenced in 1864 and completed in 1869. After that he turned again for a time to pedagogical writings, and made several attempts at other historical novels, including one on Peter the Great, that remained unfinished, because of the invincible repulsion aroused in him by the proposed hero. In 1873 he began *Anna Karenina*, which appeared in instalments from 1875 to 1877. Towards the end of his work on this second of his great novels he entered on the prolonged and fateful crisis that resulted in his conversion. Indications of its approach are clearly visible in the latter part of the novel.

War and Peace and *Anna Kareninu* are Tolstoy's masterpieces. They mark, in a certain sense, the highest point reached in its development by the modern realistic novel. Literary realism attains in them its goal: an adequacy of the verbal pattern to the living reality which ultimately produces the feeling, familiar to readers of Tolstoy, that his characters are to be classified with people in flesh and blood, not with other characters in fiction. This supreme achievement was largely prepared for by his previous apprenticeship, but *War and Peace* marks an enormous advance over all that had preceded it. The countless characters that fill the stage are seen not from outside only, but from the inside. The women in this respect are particularly remarkable, and among them most of all Natasha who is the centre of the novel, the embodiment of its philosophy, the quintessence of spontaneous, nature-wise mankind. Nor does the author introduce himself so crudely as he docs in his earlier work, but is transformed into the two distinct and objective characters of Prince André and of Pierre. With its world of characters, and against its vast background of Russian and European history the novel is a real piece of life, transformed by art. The novel is markedly optimistic, and has not without propriety been described as an idyll of the Russian landed gentry Not that the horrors of life are entirely absent but they are overcome by the beneficent influence of a benevolent Life-god presiding over the action. The idyllic atmosphere is preserved in the greater part of *Anna Knrenina,* which as a whole marks no advance on *War and Peace,* though each of the individual characters (and again especially the women) come up to the same level, and even, perhaps, present a greater variety of persons entirely different from the author and seen from inside.

His Conversion.—About 1876 Tolstoy began to feel uneasy about the unreflecting and prosperous life he was leading; the thought of approaching death grew into an invincible obsession; and the passionate craving for a religious justification of his life became the dominating force in him. At first he turned to the orthodox faith of the people, hoping that a religion that made sa many millions happy in the midst of their misery would save him, but the proud rationalism of his mind could not accept its rites and fasts, he renounced the Church, and out of his own reading of the Gospels gradually evolved a 'new Christianity, from which all the metaphysical and non-ethical elements were eliminated. The decisive stage in this conversion, he tells us, was the moment when he realized that the whole message of Christ was contained in the words (Matt 5, 39) "that ye resist not evil." This doctrine of non-resistance became the foundation of the creed which soon became known as Tolstoyism (tolstovstvo.)

It is necessary to distinguish two stages in this conversion: the initial pang of despair, and disgust with unjust and fleshly life, and the subsequent efforts to reduce this essentially mystical and incommunicable experience to a logical and consecutive doctrine. Tolstoy gave a complete account of his conversion in *A Confession* (written 1879, revised 1882, published 1884). It is a work of great imaginative sincerity and tremendous rhetorical power worthy to rank by the side of the *Confessions* of St. Augustine. But the initial and more essential stage of despair is recorded with even greater power in a fragment, posthumously published, The *Memoirs of a Madman* (1884). The same experience is at the base of the two greatest imaginative works of his old age—The *Death of Ivan Ilyich* (1884) and *Master and Man* (1895).

At first Tolstoy took no steps to propagate his new faith. It was not till after the revelation of social misery he had in a visit to the Moscow slums that his religion assumed a definitely social coloring, and not till his intimacy with V. G. Chertkov that "Tolstoyism" became an organized sect, and began to acquire proselytes. This happened in 1884.

Tolstoy's **Teaching.**—Tolstoy's religion expounded in *What I believe in,* and in *A Short Exposition of the Gospels,* is based on the natural light immanent in the human conscience which reveals to us the God that is the supreme Good and Reason. God is not personal, and there is no personal immortality. Jesus was a great man, whose teaching is true not because he was the Son of God, but because it coincides with the light of the human conscience. The Buddha and other men were as great, and Jesus holds no monopoly of the truth. Tolstoy advanced no metaphysics and no image of the world order. His religion is purely anthropocentric. God and the Kingdom of God are "inside us." The aim of man is to achieve happiness, which can be done only by doing right, by loving all men, and by freeing oneself from the appetites of greed, lust and anger. All forms of violence are equally wicked. Not only war but all forms of compulsion inherent in the State are criminal. The true Christian must abstain from participating in them; he must refuse conscription; he must not accept any work under the State; he must not sit on a jury. Opposing the State with violence is also wicked and cannot lead to any better forms of life. Revolutionary activity, though it may be based on the good feeling of love for the oppressed, is evil because it breeds hatred and violence. The social order can become better only when all men have learned to love each other. Still there is a great difference in Tolstoy's attitude to the State and to the Revolutionaries; he disapproves of the latter, but all the force and bitterness of his invective is kept for the former. Property, as the gratification of greed and lust and the assertion of a single man's monopoly over things that belong to all, is wicked. It is the chief source of violence and so on. The rich have built up a corrupt and artificial civilization, and created for themselves fictitious values, which must be got rid of. The poor, however demoralized by servitude, have preserved their good nature in greater purity because they have not been corrupted by the artificial culture of the rich. Love and compassion must be extended to all living things, and abstention from the flesh of slaughtered animals is a characteristic tenet of Tolstoyism. So are abstinence from intoxicants and drugs (particularly tobacco), the artificial demand for which was created by a corrupt civilization, and which dim the natural conscience of man.

Tolstoy can hardly be called a social reformer for he advanced no practical proposal for the improvement of social conditions. He did not believe in the possibility of reform in the accepted sense of the word. The first duty of the true Christian being is to abstain from living by the work of others, and from taking part in the organized violence of the State. The only practical measure he advocated was the solution of the land question by means of the land tax of Henry George. His disapproval extended to the organized violence of Western capitalistic democracy as well as of Russian autocracy.

On the whole, the direct influence of Tolstoy's teaching in Russia was not great. His disciples were never numerous (and seldom of a very high quality). He established relations with many dissenting Russian sects, but most of these (*e.g.,* the *Dukhobors, q.v.*) were essentially alien to him in spirit. His larger influence, however, was immense, and very soon crossed the frontier. In the last 15 or 20 years of his life he was probably the most venerated man in the world. His fame reached into China and India as well as Europe and America. Visitors from all ends of the world made Yasnaya Polyana a new Mecca.

From the first, the Russian Government viewed Tolstoy's new activity with hostility. But it never attempted to do anything against him. Some of his more anti-Orthodox writings, as well as some of his bitterest attacks on the Romanoff dynasty had to appear abroad. But what appeared in Russia was quite sufficient for a complete acquaintance with his teaching. In 1901 the Synod of the Russian Church excommunicated him,—an act which has been much misinterpreted and which merely registered a fact he had himself proclaimed many years earlier, viz., that he had ceased to belong to the Church. On the other hand many of Tolstoy's followers suffered imprisonment and banishment to Siberia chiefly for refusal of military service.

Tolstoy's conversion changed his attitude to his literary creation. He did not abandon it, nor did it deteriorate in quality, but it became different, so did his views of its social and moral function. They are contained in *What is Art* (1896), one of the most remarkable books ever written on the subject. Art, according to Tolstoy, is a means of emotional communion, a means by which the artist "infects" other people with feelings he has himself experienced. If this "infection" does not take place there is no art. If it is limited to a small number of persons of the same class, time or nationality as the author, it is negligible and inferior art; if the appeal extends to mankind in general, but the feelings thus communicated are evil feelings it is genuine but evil art; if the feelings are good, it is good art and if they are the highest feelings possible, the religious feelings of love and compassion, it is the highest form of all, religious art. The application of these standards led Tolstoy to reject or to minimize by far the greater part of modern art and literature, including his own early work, which had exalted the life of the rich and idle. This change of attitude went hand in hand with a change in his literary taste. He rejected the "superfluous detail" of realism not only because it limited the appeal of literature to those familiar with the society described, but because it ceased to satisfy him aesthetically. Already in 1873 he had written some stories for the people, in which everything that was not essential for the narrative development had been rigorously eliminated. From 1884 onwards he wrote a number of new stories of the same kind, masterpieces of chaste and classical narrative technique at the service of one unifying and crystallizing idea, the idea of ethical Christianity.

The same method, on a larger scale, is applied in *Father Sergius,* in *The False Coupon,* and in *Hadji-Murād* (1896–1904) which was the favourite work of his old age and which he intended as an example of good art appealing to the sense of human brotherhood, though not to the highest religious feelings.

Apart from these works stands *Resurrection* (published in 1899–1900) in which he returned to his old "superfluous-detail" and which consequently failed to satisfy him. It contains beautiful passages in the idyllic style of *War and Peace,* and pages of powerful satire on the evil social order, but it falls short of being a masterpiece.

The most important imaginative work of his last period are the stories based on his inner experience—those connected with his conversion (*The Death of Ivan Ilyich, Master and Man, The Memoirs of a Madman),* and those in which he embodied his experience of sex, the *Kreutzer Sonata* (1889) and *The Devil* (1889, pub. 1911). The former group in particular stands in importance by the side of *War and Peace.* The atmosphere pervading them is totally different: they are as grimly tragical as the earlier novel is idyllic. They are on a level with the greatest religious writings of the world.

Tolstoy's plays (with the exception of a comedy written in 1863 and published in 1926) all belong to the period after his conversion. They include *The Power of Darkness* (1889), a powerful drama of peasant life; *The Fruits of Enlightenment* (1st ed., 1891; 2nd ed., 1911), a light comedy satirizing the fads of "society," and *The Living Corpse* (pub. 1911), one of his last writings in which there is a mellowness of old age, and in which the character creator of *War and Peace* makes his last appearance.

Last Years.—Tolstoy's conversion led to his adopting a new mode of life—he dressed like a peasant, did much manual work, learned bootmaking and adopted a vegetarian diet. His wife and children (except his youngest daughter, Alexandra) remained hostile to his teaching and the Countess Tolstoy would not hear of his renouncing his worldly belongings which, she maintained, be held in trust for his children. So he made over all his property (including the copyright of his works written before 1880) to her. The paradoxical situation arose of the preacher of poverty and abstention continuing to live in affluence surrounded by a family who disapproved of his views, but adored him. The first tension between him and his wife was followed by a rapprochement, cemented by the birth in 1886 of a sixth son. But the death of the little boy at the age of seven was followed by an increasing estrangement between husband and wife. She grew increasingly hysterical, embittered and tactless, and life at Yasnaya became a hell, a constant state of war between the family and followers of Tolstoy, between Countess Tolstoy and Chertkov. Tolstoy suffered deeply from the incongruity of his position at home. At last on Oct. 28, 1910, he left home secretly at night with his daughter Alexandra.

He had no particular aim in view. His health broke down at Astapovo (gov. of Ryazan). He was laid up there in the station-master's room, and he died on Nov. 8 (21), 1910.

Tolstoy was interred at Yasnaya, without a Christian burial.

(D. S. M.)

BIBLIOGRAPHY.—An edition of the complete works of Tolstoy, translated by Louise and Aylmer Maude, was published by the Oxford University Press; versions of most of Tolstoy's works, by the same translators, were made available in the *World's Classics* series of the same press. Also: *Complete Works,* 24 vol., tr. by Leo Wiener (Boston, London, 1904–05); *Works* (incomplete), 7 vol., tr. by Constance Garnett (1901–04 and 1911–IS); *The Dramatic Works,* tr. by N. H. Dole (London, New York, 1923); posthumous works: *Hadji-Muràd, and other stories; The Forged Coupon, and other stories; Father Sergius and other stories,* ed. by C. Hagberg Wright (1911–12); *Stories and Dramas,* tr. by Lydia Turin, *et al.* (London, New York, 1926); *Tolstoy on Art,* ed. by Aylmer Maude (Boston, 1924; London, 1925).

Diaries and Letters: The Diaries of Leo Tolstoy (1852–77), tr. by C. J. Hogarth and A. Sirnis (1917); *The Private Diary of Leo Tolstoy (1853–57),* tr. by L. and A. Maude (New York, 1927); *The Journals of Leo Tolstoy* (1895–99), tr. by Rose Strunsky (1917); *Tolstoy's Love Letters,* tr. by S. S. Koteliansky and Virginia Woolf (1923).

TOLSTOY, PETR ANDREYEVICH, Count (1645–1729). Russian statesman, was the son of Andrei Vasilevich Tolstoy, an okolnichy or courtier attached to the person of the tsar. He served in 1682 as chamberlain at the court of Theodore III. Miscalculating the strength of the tsarevna Sophia, he became one of her most energetic supporters, but contrived to join the other, and winning, side just before the final catastrophe. For a long time Peter kept his latest recruit at arm's length, but nhen, in 1697, Tolstoy volunteered to go to Venice to learn Italian and shipbuilding, Peter could not resist the subtle flattery implied in such a proposal from a middle-aged Muscovite noble. In Nov. 1701 Tolstoy was appointed the first regularly accredited Russian ambassador to the Porte, and more than justified the confidence of the most exacting of masters. though his peculiar expedients (such as the procuring of the strangulation of a grand vizier and the removal by poison of an inconvenient private secretary) savoured more of the Italian than of the Russian Renaissance.

Even before Poltava, Tolstoy had the greatest difficulty in preventing the Turks from aiding the Swedes, and when Charles XII took refuge on Turkish soil he instantly demanded his extradition. This was a diplomatic blunder, as it only irritated the already alarmed Turks; and on Oct. 10 1710, Tolstoy was thrown into the Seven Towers, a proceeding tantamount to a declaration of war against Russia. On his release from "this Turkish hell," in 1714, he returned to Russia, was created a senator, and closely associated himself with the omnipotent favourite. Menshikov. In 1717 his position during Peter's reign was secured once for all by his successful mission to Naples to bring back the unfortunate tsarevitch Alexius. uhom he may be said to have literally hunted to death. For this he earned the undying hatred of the majority of the Russian people. but Peter naturally regarded it as an inestimable service and loaded Tolstoy with honours and riches, appointing him, moreover, the head of the secret chancellery, or official torture chamber.

Tolstoy materially assisted Menshikov to raise the empress consort to the throne on the decease of Peter (1725), and the new sovereign made him a count and one of the six members of the nenly instituted supreme privy council. Tolstoy was well aware that the elevation of the grand duke Peter, son of the tsarevitch Alexius, would put an end to his onn career and endanger his whole family. Thus, when Menshikov, during the last days of Catherine I declared in favour of Peter II, Tolstoy endeavoured to form a party of his own whose object it was to promote the accession of Catherine's second daughter. the tsarevna Elizabeth. But Menshikov was too strong and too quick for his ancient colleague. On the very day of the empress' death (May 11, 1727), Tolstoy, now in his 82nd year, mas banished to the Solovetsk monastery in the White sea. where he died two years later. He nas the author of a sketch of the impressions made upon him by western Europe during his tour in the years 1697–98 and also of a detailed description of the Black sea.

See R N. Bain, *Pupils of Peter the Great* (1897), *The First Romanovs* (1905). (R. N B)

TOLTEC. The Toltecs ("reed people") were a Nahua-speaking tribe of Chichimec stock who dominated the centre of Mexico betneen the 10th and 12th century A.D. The name is derived from their capital. Tollbn, which means "place of rushes or reeds." situated near the modern town of Tula, 80 km from Mexico City. They have been identified by some investigators with the Teotihuacanos and Teotihuacán itself nas considered to be the city of Tollán. Others have refused to acknowledge their actual existence, maintaining that they were an Aztec invention for the purpose of claiming a distinguished heritage. Both of these conceptions are erroneous.

The first Toltecs, arriving under the leadership of Mixcoatl, "Cloud Serpent," were responsible for the collapse and end of Teotihuacán. Mixcoatl left a posthumous son. Ce Acatl Topiltzin, who built Tollán and founded the Toltec empire, a federation of several small kingdoms of diverse ethnic and linguistic origins. Topiltzin is without doubt the most famous hero-god in Meso-American history. He is better known as Quetzalcbatl, "Feathered Serpent," the name of the god which he introduced and whose high priest he was. He is credited with being a remarkable leader and educator. and was responsible for some of the most impressive temples in Middle America. In A.D. 999 he mas compelled to leave Tollán during a religious upheaval and emigrated with some of his followers to Yucatán. There he was known as Kukulcán, which means "feathered serpent" in Maya, and exercised an important influence over the cities of Chichén Itzá and Mayapán.

The Toltecs have been credited with the invention of agriculture and the calendar system which, of course, is erroneous because these cultural traits are much earlier. But they did introduce several important innovations such as monumental porticoes, serpent columns, gigantic atlantean statues, human and animal standard bearers and the peculiar reclining Chac-Mool figures. Because of their high reputation as builders and craftsmen the term Toltec became synonymous with "artificer."

The Toltec empire came to an end in A.D. 1168, during the reign of Huemac, and Tollán was destroyed by waves of barbarous invaders known as Aztecs (*q.v.*) or Mexicas. (J. R. Ac.)

TOLUCA (Toluca de Lerdo), capital of the state of México and municipality seat; is located 45 mi. W.S.W. of Mexico City by highway on the road to Morelia and Guadalajara. Founded in 1530, renamed Toluca de Lerdo in 1861 in honour of Sebastián Lerdo de Tejada. Mexican statesman. the city (pop. [1960] 71.026) is a commercial and communications centre in the valley of Toluca. The basin. highest of the great valleys in the plateau region of central Mexico. has an elevation of about 8.500 it.: it is ringed by impressive mountains. among them the snow-capped Nevado de Toluca or Xinantecatl (15,433 ft.). Agriculture and livestock raising are of major significance. Industries include textile manufactures. brewing and distilling and food processing; commercialized household crafts include weaving and the making of baskets and pottery. The Friday market is one of Mexico's largest and most interesting. An airfield and railway facilities serve Toluca. Its oldest church was founded soon after the conquest and rebuilt in 1585; governmental buildings are post-1870. (J. T.)

TOLUENE, or Methylbenzene. is an aromatic hydrocarbon (see Chemistry: Organic *Chemistry: Reaction* to Organic *Compounds*). It is a water-white liquid which has a boiling point of 110.56" C. at 760 mm. mercury pressure, a specific gravity of 0.3665 at 20° C. compared with water at 4° C., and an index of refraction of 1.4962 at 20° C. for the D-line of sodium. It is insoluble in water hut is soluble in all common organic solvents. Two commercial grades are produced: a nitration grade: the purer grade. and an industrial grade.

Toluene is one of the important constituents of coal-tar light oil (see Coal Tar). comprising 12%–20% by volume of the light oil; it is also present in petroleum. the toluene content usually being less than 0.5%. Prior to 1917 toluene was produced almost exclusively from coal-tar light oils. During World War I toluene mas in such great demand for the manufacture of the high explosive trinitrotoluene. TNT (*q.v.*), that the production from cod-tar light oil was supplemented to a small extent by toluene isolated from petroleum. Between World Wars I and II the processes for recovering toluene from petroleum were so improved that the petroleum industry became a major source of toluene. In the United States during World War II about 30 000.000 gal. of toluene were produced from coal-tar light oils and about 60.000.000 gal. were obtained from petroleum sources.

Toluene is an important chemical raw material. It is used in the manufacture of henzoic acid (*q.v.*), saccharin (*q.v.*), dyes (see Dyes) photographic chemicals. pharmaceuticals, etc. Its principal peacetime use is as a solvent. Because TNT has remained an important ingredient of explosives, and because toluene was an important constituent of high-octane aviation gasoline, toluene was one of the strategic materials of World War II.

Toluene should be used only in well-ventilated rooms since its vapours are poisonous. (F. E. Cl.)

TOMAHAWK, the war hatchet of the North American Indians (Algonkian otomahuk, "to knock down"). The earliest tomahawks were of chipped stone, sharpened to a point at each end, something like a pickaxe, and passed through a hole bored in a stout wooden cudgel. In the more primitive types the stone head was simply tied to the handle by animal sinews, or a withe was doubled over the head and fastened below to form a handgrip. Sometimes deer antlers were used instead of stones. After the arrival of the white man, the heads were usually of iron. Where the stone head was sharpened only at one end, the blunt end was sometimes cut out into a pipe bowl, the handle, hollowed, serving as the stem.

The weapon was at once symbolical of war and peace and was ceremoniously buried at the termination of hostilities, to be as formally exhumed when the feuds revived. Hence the colloquialism "to bury the hatchet."

TOMAR, a city of Portugal on the Nabão river: a tributary of the Zezere. 4 mi. from Paialvo railway station, which is 80 mi. N.E. of Lisbon by the main line to Oporto. Population (1950) 8,063.

Tomar contains examples of the best Portuguese architecture from the 12th century to the 17th. The ruined castle of the Knights Templar, given to that order in 1159, is said to occupy the site of the ancient Nabantia. On the suppression of the Templars, King Dinis of Portugal founded the Order of Christ in 1311. The convent palace of the Knights of Christ includes a church and cloister dating from the 12th century, two cloisters and a chapter house added in the 15th century by Prince Henry the Navigator and a very fine 16th-century church built in the Manueline style by João de Castilho.

Other interesting buildings include the churches of Santa Maria do Olival, rebuilt in the Gothic style in 1450 on the site of an older Templar foundation; São João Baptista, also Gothic, built in 1490, but with Manueline additions; and Nossa Senhora da Conceição, Renaissance of 1579. The ruined palace of Prince Henry the Navigator was restored in the 16th century by Queen Catherine, the widow of John III. The city was formerly known as Thomar.

TOMASZOW, an industrial town of Poland, in the *wojewodztwo* (province) of Lodz. Pop. (1960) 49,000.

It has woolen mills, ironworks and steam flour mills and is the centre of the silk industry. Germany occupied it during World War II.

TOMATO (*Lycopersicon esculentum*), a plant and its succulent, acid fruit, of the family Solanaceae. All cultivated forms of tomato belong to this species except the tiny currant tomato (L. *pimpinellifolium*). The tomato plant is a frost-tender perennial that is cultivated as an annual. The plants are generally much branched, spreading two to six feet, and recumbent when fruiting, but a few forms are compact and upright. The leaves are more or less hairy, strongly odorous, pinnately compound, up to $1\frac{1}{2}$ ft. long. The flowers are yellow, three-quarters of an inch across, pendant and clustered. Fruits vary in diameter from one half to three inches or more, are scarlet, scarlet-red or yellow; they vary in shape from oblate through globular to oval. elongate: or pear shaped. The fruit is a soft, succulent berry containing two to many cells of small yellow seeds surrounded by jellylike pulp. Silvery hairs thickly covering the seeds become evident when they are dry and free of pulp.

Botanically the tomato is a fruit but in the U.S. it is considered a vegetable for purposes of trade. It was so classified in a decision of the U.S. supreme court in 1893 because of its common use in the main part of a meal, prepared either alone or mixed with other vegetables. Although it is extensively used in America in the form of juice as an appetizer, and in salads, as some fruits are used, it is not used as a dessert. Use in soups and in sauces and catchup for meats contribute to its classification as a vegetable. It is an excellent source of vitamins A and C.

The wild species originated in the Peru-Ecuador-Bolivia area of South America. Cultivated forms were developed before Columbus in Mexico and possibly in Central and South America. Definite records are lacking but evidence indicates that the tomato reached Europe from Mexico. The first definite description, in Italy in 1554, carried the common name *pomi* d'oro, or apple of gold. Thus the first form known to Europeans was yellow. Before the end of the 16th century it was known in the gardens of England. Spain, Italy, France and mid-Europe chiefly as a curiosity.

J. HORACE MCFARLAND CO.

TOMATO (LYCOPERSICON **ESCULENTUM**)

By the mid-1700s it was used for food in several European countries. but there is no record of its culture in the U.S. until Thomas Jefferson grew it in 1781 It was used for food in Louisiana as early as 1812 but not in the northeastern states until about 1835. Until nearly 1900 many believed it to be poisonous, possibly because some members of the family Solanaceae are poisonous.

Disease control is a major problem in producing tomatoes. The plant is susceptible to many serious disorders variously caused by fungi, bacteria, viruses. nematodes and unfavourable environment. Breeders have developed many varieties that are resistant to fusarium wilt and a few resistant to verticillium wilt. two soil-borne diseases not controllable in the field by artificial means. By the late 1950s little success had been attained in breeding varieties resistant to fungus diseases of the foliage, to viruses, bacteria and nematodes. Extensive production is not feasible in certain parts of the western U.S. because of curly top, a virus disease that is carried from infected desert plants to tomatoes by the beet leafhopper.

The tomato is a major crop in the U.S. where it is grown commercially in every state (except Alaska) for use fresh, also for canning whole or as juice or making a variety of sauces. In the winter tomatoes are grown in Florida and Texas and shipped all over the country; they are also imported from Mexico and Cuba for use fresh. They are grown under glass but in small quantities compared with field and garden cultivation. Since the plant requires relatively warm weather (and much sunlight) it is grown chiefly in hothouses in Alaska, Great Britain and northern Europe, although a few varieties are cultivated out of doors. Tomatoes are grown extensively in southern Europe', particularly in Italy, where they are used for paste and other canned products.

In most of the United States and in Europe tomato seed is sown under glass or cloth protection about six weeks before the frost-free date, when the plants can be set in the open. The seedlings are grown singly in pots and other containers or so spaced in boxes or beds of soil—from 2×2 to 4×4 in.—that sturdy plants about 8 in. tall may be produced for setting in the field. For winter crops in the south, seed is sown in open beds in the fall. Frequently in gardens, and in large fields in some areas, the tomato plants are pruned to a single stem and each tied to a stake to keep the fruits off the soil. In this system plants are set 2 to $2\frac{1}{2}$ ft. apart in rows 3 to 4 ft. apart. Most of the crop in America is grown by allowing the plants to grow naturally upon the ground, spaced 3 to 5 it. apart in rows 5 to 6 ft. apart. The fruits are highly perishable when ripe and should be harvested every three or four days. For long-distance shipment, the fruits are harvested when fully grown but still green in colour. They will ripen later only if mature. Green-harvested tomatoes never develop the high quality and high vitamin content characteristic of well-grown, vine-ripened fruit.

Most of the tomato fields of the central and northern part of the United States are set with plants grown in large "plant fields" in the southern states and shipped northward by fast motor truck or rail express at planting time. About 5,000 to 6,000 ac. in the state of Georgia are devoted to growing tomato plants for this purpose. Seed is sown in March at four pounds per acre in rows 14 to 16 in. apart, about 1j to 20 seeds per foot of row. All growing operations are done by motorized equipment; but pulling the plants from the soil. counting. wrapping in wet moss and packaging for shipment must be done by hand. About 70,000 to 100.000 plants are usually obtained per acre. In many districts having long growing seasons, tomatoes for midseason or late harvest are planted by sowing seed directly where the plants are to mature. Seed is sown at one-quarter to one-half pound per acre and the plants thinned to the desired spacing.

In the U.S. about 225,000 ac. of tomatoes are grown annually for fresh market and 300.000 to 400,000 ac. for processing. Annual production is about 1,000,000 tons for fresh market and 3,000,000 to 4,000,000 tons for processing. In a year of high production the total of processed tomatoes is as much as 30,000,000 cases of canned tomatoes. 36,000,000 of juice and 48,000,000 cases of catchup. pulp. paste and sauces.

See also HORTICULTURE; VEGETABLE; VIRUSES: Plant Viruses. (V. R. B.)

TOMB in the strict sense implies some idea of a home or house for the dead. although the term is applied loosely to all kinds of graves, funerary monuments and memorials. In many primitive cultures the dead were buried in their own houses. and the tomb form may have developed originally out of this practice, as a reproduction in permanent materials of primeval house types. Thus, prehistoric tomb barrows were usually built around an actual round hut, in which the body was placed. along with tools and other personal effects for use in the next life. With the more advanced technology of early civilizations, brick and stone tombs appeared, often of great size, but still preserving primitive house forms. They were sometimes domical and sometimes rectangular, depending on which form had come into commonest domestic use by the time tombs began to be built. Being thought of as houses. such tombs were often lavishly provided with clothes. utensils and furniture. so that they are major sources of archaeological knowledge about the cultures that built them.

In very early times, royal dead were apparently provided not only with all manner of necessary objects. but also with actual servants. who were put to death at the time of the burial. so that they might continue to serve their master in his tomb house. Typical is the tomb of Queen Shub-Ad of Ur (Early Dynastic period in Mesopotamia, *c.* 3000 B.C.), which contained the bodies of more than 60 of the queen's attendants. It became more common, however, to substitute statues or painted images for human beings; this was the practice in most Egyptian tombs, and from such painted pictures and statuettes, particularly in old and middle kingdom tombs, a vivid idea of every phase of ancient Egyptian life can be gained. Lavish furnishings continued to be placed in tombs throughout ancient Egyptian history. the most famous example being the tomb of Tutenkhamon of the 18th dynasty, discovered intact in the 1920s. (See PYRAMID.)

The use of the tomb as a house for the dead persisted into early classical times (*e.g.*, the Treasury of Atreus at Mycenae; the Etruscan tombs at Volterra and elsewhere). By the jth century B.C., however, the Greeks superseded it with monuments or memorials to the dead; the actual bodies were burned and the ashes put in funerary urns. The Romans, however. revived the use of the tomb; later emperors particularly set the example of building great tumuli of domical shape (*e.g.*, the tombs of Augustus and Hadrianj. as symbols of the divine ruler's heavenly home.

In medieval Christian thought, the tomb was considered an earthly prototype and symbol of a heavenly home. This concept appeared in the Roman catacombs. the walls of which were decorated with scenes'of the resurrected dead in paradise. The church building itself sometimes functioned as a tomb (*e.g.*, the Hagia Sophia in Istanbul was the tomb of Justinian). Throughout the middle ages it was common to inter bodies in churches, monasteries and chapels, with depictions of them on carved or painted plaques. or as life-size *gîsants* (figures lying on their backs) placed above them. The deceased were represented not as corpses. but as souls living in paradise, with their hands pressed together in adoration and the symbols of their salvation beside them.

During the 1jth century, however, it became common to represent such figures as dead (usually on biers); typical examples are the funeral cortège of Philippe Pot in the Louvre. and Donatello's tomb of the antipope John XXIII in the Florence baptistery. This foreshadowed a general revival of the Greek practice of erecting iunerary monuments, rather than tombs proper. during the 16th century. Since the Renaissance. the idea of the tomb as a home has died out, except as a faint reminiscence in the mausoleums sometimes erected above graves or serving as burial vaults in modern cemeteries.

See BARROW; CEMETERY; FUNERARY RITES AND CUSTOMS; SARCOPHAGUS; SCULPTURE, SEPULCHRAL; MONUMENTS AND MEMORIALS: SCULPTURE. See also references under "Tomb" in the Index volume. (As. G.)

TOMBIGBEE, a river formed in northeast Mississippi by the junction of Old Town creek and the East fork which arises in eastern Prentiss county. The river flows south and southeast for nearly 450 mi. to a junction with the Alabama river. to form the Mobile river, about 45 mi. N. of Mobile, hla. The chief tributary of the Tombigbee is the Black Warrior. which flows southwest through Alabama. joining it at Demopolis. Ala. The Tombigbee has a drainage basin of about 19.500 sq.mi.

During the 19th century the Tombigbee was important for navigation to and above Aberdeen, Miss.; only the 185 mi. below Demopolis were important after 1900. In 1915 the last of a series of 17 locks and dams was opened on the lower Tombigbee and Black Warrior, providing a 426-mi. nine-foot channel from Mobile to Port Birmingham, 18 mi. from Birmingham. By the second half of the 20th century, most of the original locks and dams had been, or were being, replaced by the Jackson, Demopolis, Warrior, Oliver and Bankhead locks and dams.

In 1947 congressional approval was given a Tennessee-Tombigbee waterway, though no money was appropriated. In 1958 Alabama and Mississippi signed a compact to promote the building of that waterway, which was planned to link the East fork of the Tombigbee with Yellow creek of the Tennessee by a 45-mi. canal. Tuscaloosa, Ala., is the chief city on the Black Warrior; Aberdeen and Columbus, Miss., and Demopolis are the chief cities on the Tombigbee. (M. W. M.)

TOMBSTONE, a town of Cochise county in southeastern Arizona. U.S., on a mesa between the Huachuca and Dragoon mountains: is about 30 mi. from the Mexican border. Noted for its colourful history, the town was named, as an ironic gesture. by a prospector, Ed Schiefflin, shortly after his discovery of silver deposits near the site in 1877. Schiefflin. who did not profit greatly from the discovery, reported that an acquaintance told him that all he would find in the area would be his tombstone. The strike was rich, some of the assays running as high as $5,000 a ton. By 1881 a silver rush had set in and 7,000 persons were estimated to be living in the region. Innumerable claims were staked out within a radius of eight miles of Tombstone; mining companies such as the Contention Consolidated and the Grand Central were soon making fabulous profits. In 1880 an enterprising businessman, John P. Clum, founded the Tombstone *Epitaph*, a weekly and daily journal. Along with prospectors, miners and businessmen came adventurers and outlaws, among whom were "Doc" Holliday and Johnny Ringo. Feuds were common; the most notable of them culminated in the gun battle at the O.K. corral in 1881 between the Earp and Clanton families. In 1881 Tombstone became the seat of the newly created county of Cochise.

Floodwaters in the mines, labour strikes and low prices for silver spelled the end of the boom days. In 1902 and 1916 there were short periods of renewed hope for the mines. but nhen the seat of Cochise county was removed from Tombstone to Bisbee in 1931. the colourful epic of the town was ended. With a population of about 1.000 in the second half of the 20th century, the tonn was of interest for its preserved and restored historic sites and monuments, such as Boot Hill cemetery, the Bird Cage theatre, the *Epitaph* office and the original city hall. An annual festival is held in the town in October. (R. C. E.)

TOMLINE, SIR GEORGE PRETYMAN (1750–1827). bishop of Winchester, tutor and secretary to William Pitt the younger. was born at Bury St. Edmund's, Oct. 9, 1750, the son of George Pretyman. He took the name Tomline in 1803, in accordance with the terms of a will of which he was the beneficiary. He was graduated from Pembroke hall, Cambridge, in 1772. and was made fellow and tutor of the college the following year. In 1774, when Pitt came to Pembroke, Tomline was appointed his tutor, an incident which marked the beginning of a lifelong friendship between the two men. Tomline remained at Cambridge until 1782, serving as moderator of the university in 1781. He was made rector of Corwen, Merionethshire. in 1782 and in 1783, when Pitt became first lord of the treasury, he asked Tomline to become his secretary. a position the latter held until 1787 Concurrently, Tomline was for a short time rector of Sudbourn-cum-Offord. Suffolk (1785). In 1787, probably through the intercession of Pitt, he was appointed dean of St. Paul's and bishop of Lincoln. and in 1820 he became bishop of Winchester. where he remained until his death. Pitt attempted at one time to have Tomline made archbishop of Canterbury, but without success.

Tomline was much consulted by Pitt and had, perhaps, more influence on him than any other of his friends and advisers. He was with the prime minister only a few hours before his death and was made his literary executor. He was the author of a number of works, the most important of which were *Elements of Christian Theology* (1799) and *A Refutation of Calvinism* (1811), nhich was the subject of considerable ecclesiastical controversy. He also wrote a moderately valuable biography of Pitt (1821). He died Nov. 14, 1827, at Wimborne, Dorsetshire.

TOMMASINI, VINCENZO (1880–1950), Italian composer, was born in Rome on Sept. 17, 1880. He studied at the Liceo in Rome and later became assistant director of the Accademia di S. Cecilia. His first work of importance was the string quartet of 1910; this was followed by the "Erotic Poem" for orchestra and the comic opera *Uguale fortuna* in 1911. The symphonic poem *Chiari di luna* was produced in 1916, and in 1917 he achieved his great triumph with *The Good-Humoured Ladies,* a ballet founded on Carlo Goldoni's comedy. The original performance was in Rome and it was later played in the principal music centres by Sergei Diaghilev's company with great success. Later works were: *Il beato regno* (1922); *Paesaggi Toscani* (1923); *Preludio, fanfara e fuga* (1928); *11 Carnevale di Venezia* (1929): and *Il Diavolo si Diverte* (*The Devil Has a Good Time,* New York city. 1939). He died in Rome on Dec. 24, 1950.

TOMMASEO, NICCOLÒ (1802–1874), Italian statesman and writer. was born in Sebenico. Dalmatia, Oct. 9, 1802. He studied law at Padua and then removed to Florence. where he joined the staff of the *Antologia,* a liberal periodical. One of his articles led to the suppression of the magazine in 1833 and to his own exile to Paris the following year. He returned to Italy in 1839. an amnesty having been granted, and settled in Venice. In Jan. 1848 he and Daniele Manin were arrested and imprisoned for making anti-Austrian speeches but they were set free by revolutionists in the uprising of March 17, 1848. Toinmasseo was made minister of public instruction in Manin's provisional government. When Venice fell to the Austrians in Xug. 1849, Manin's terins of surrender included exile for the leaders of the revolutionary movement in order that all the other revolutionists might be spared. Tommasseo therefore spent the years until 1554 on the island of Corfu, when he went to Turin, returning to Florence in 1861. During the last years of his life he lost his sight but continued with his writing. He died May 1, 1874, in Florence.

Of Tommasseo's numerous norks perhaps the best. and certainly the best known, are his several dictionaries of the Italian language—the *Dizionario dei sinonimi italiani* (1835), the *Dizionario estetico* (1840) and the *Dizionario universale della lingua italiana,* nhich he compiled in collaboration with B. Bellini and some of which was published after his death (1861–79). His *Supplizio d'un Italiano,* the story of his exile on Corfu, is also well thought of, and his *Canti Popolari Corsi, Toscani, Greci, e Illirici* is a valuable study. His other writings include treatises on moral and political philosophy, works of literary criticism, several volumes of poetry, a biography of Pasquale de' Paoli, a history of 16th-century France and a historical novel.

TOMPA, MIHALY (MICHAEL) (1817–1868), Hungarian lyric poet, was born in 1817 at Rima-Szombat, in the county of Gomor, his father being village bootmaker. He studied law and theology in Sáros-Patak and subsequently at Budapest. At the age of 30, after many vicissitudes, he accepted the post of Protestant minister in Beje, a small village in his native county, whence, in two years: he removed to Kelemér, and four years later to Ha-ma, in the county of Borsod, where he remained until his death in 1868. At the age of 24 Tompa published his first poems in the *Athenaeum,* which soon procured for him a high reputation. His first volume, *Népregék és Népmondák (Folk-Legends and Folk-Tales),* in 1846, met with great success, and the same may be said of the first volume of his *Poems* in 1847. In 1848 he took part in the War of Independence, acting as field chaplain to the volunteers of his county and seeing several battles, but the unfortunate close of that struggle silenced him as a poet for a considerable time and when in 1852 and 1853 he gave vent to his patriotic grief in some masterly allegories on the state of oppressed Hungary. he was twice arrested by the Austrian authorities. After being released he published his *Virágregék (Legends of Flowers);* a collection of poems showing great imagination and love of nature. Soon after this he became oppressed with melancholy and abandoned this branch of poetry. He published three volumes of sermons in addition to his poetry. His collected poetical works were first published at Budapest in 1870.

TOMPION, THOMAS (1639?–1713), English clockmaker, known as the "father of English watchmaking," was baptized at Northill, Bedfordshire, on July 25. 1639. It is thought that he first worked as a blacksmith and that in 1664 he was apprenticed to a London clockmaker. In 1671 he was admitted to the Clockmakers' company! of which he became master in 1704. In 1676 he was chosen clockmaker for the newly established royal observatory. He was responsible for a number of improvements in the construction of watches. notably for his collaboration in the invention of the cylinder escapeinent with horizontal wheel, which first made possible the construction of flat watches. He also made. with the aid of its inventor. Robert Hooke, one of the first English watches with a balance spring. Many of his clocks still exist, including several constructed to run for a year without being rewound. There is a barometer which Tompion made for William III at Hampton Court. and other examples at Windsor castle and Buckingham palace. Tompion died in London on Nov. 20, 1713.

See R. W. Symonds, *Thomas Tompion* (1951).

TOMPMINS, DANIEL D. (1774–1825). U.S. politician, was born at Scarsdale, Westchester county, N.T., on June 21, 1774. He graduated at Columbia college in 1795 and was admitted to the bar in 1797.

In 1803 he was a member of the state assembly, and in 1804 he was elected to the national house of representatives: but became a judge of the state supreme court and served as such until 1807. He was governor of New York in 1807–17; and in 1817–25, during both terms of Pres. James Monroe, was vice-president of the United States. In March 1812, under the authority of the New Tork constitution of 1777, he prorogued the legislature—the only instance of the exercise of this power.

During the War of 1812 he was active in equipping and arming the New York militia. For this purpose he borrowed much money on his personal security, and sometimes neglected to secure

DECORATIVE TOMBS

1. Exterior of the tomb of **Perneb,** Egyptian 5th dynasty, as **it** appeared at the time of its excavation
2. Tomb of Absalom at Jerusalem, a rock-cut tomb of typically Syrian Graeco-Roman style. Probably 2nd century A.D.
3. Hadrian's tomb, Rome, 2nd century A.D. Originally capped with a great dome, its present appearance results from its transformation into a fortress **(Castel** S. **Angelo)** during the Middle Ages
4. Tomb of **Itimad-ud-daula** at Agra, India. Built in 1628, **it** shows the characteristic Mogul use of pierced and inlaid marble
5. Tomb of the Mongol conaueror Timur **(Tamerlane)** at Samarkand, 1405, typical of the Persian use of polychrome tile and decorative dome form
6. Tomb of the Stuccoes, or Grotta **Bella,** Cerveteri (Caere), 5th to 7th centuries, B.C.
7. Tomb of Edmund Crouchback, earl of Lancaster (d. 1296) **;** Westminster abbey
8. Decoration in the catacomb of Calixtus, Rome, c. A.D. 300
9. Tomb of John **XXIII** (Baldassare **Cossa)** by Donatello and **Michelozzo,** 15th century. In the Baptistry, Florence

proper vouchers. Later the state comptroller announced a shortage of $120,000 in the military accounts, but Tompkins claimed that the state owed him $130,000. Later investigations disclosed that the state actually owed him more than $90,000. He died on Staten Island, N.Y., on June 11, 1825.

The *Military Papers of Daniel D. Tompkins, 1807–1817* (1898–1902) were published by the state.

TOMPKINS, SALLY LOUISA (1833–1916), U.S. hospital head and Confederate army captain, was born at Poplar Grove in Mathews, Va., Nov. 9, 1833. Before the Civil War she used her rather considerable fortune to assist worthy causes. In 1861, after the first battle of Bull Run, Jefferson Davis asked that private homes be converted into hospitals. Miss Tompkins was able to obtain Judge John Robertson's Richmond home for the purpose, and with her own funds equipped and maintained it as a hospital until 1865.

Davis shortly ordered that all nonmilitary hospitals be discontinued, but Miss Tompkins was loath to abandon her project and since Davis was anxious to retain her as head of the hospital, he commissioned her a cavalry captain (Sept. 9, 1861), a rank she retained until her death, although she would not accept pay. During the nearly four years her hospital existed, Miss Tompkins, who became known as "Captain Sally," cared for more than 1,300 patients. The Robertson hospital was maintained until April 2, 1865. Miss Tompkins died in Richmond, July 25, 1916, and was buried with military honours. She was the only woman to hold a commission in the Confederate army.

TOMSK, a town of the Tomsk *oblast* of the Russian Soviet Federated Socialist Republic. U.S.S.R., in latitude 56° 30' N., longitude 85° 12' E., on the right bank of the Tom river and on both sides of its tributary the Ushaika, at an altitude of 485 ft. above sea level. Pop. (1959) 249.000. The river is frozen from Nov. 17 to May 13. A branch line links Tomsk with Taiga on the Trans-Siberian railway.

The town was founded in 1604, but did not become important until 1824, when gold was found in the district and a gold smelting laboratory was later established in the town; the gold industry later declined rapidly. The town is an educational centre, with a university, library and museum.

TOM-TOM or TAN-TAM, a native Indian and Asiatic word, reduplicated and onomatopoeic in form, for a drum, hence often loosely applied to the various types of primitive drum used for purposes of religious excitement. war, signaling and the like by savage tribes throughout the world. The term is applied strictly to the metal gongs of the far east, which are flat disks with a shallow rim.

TONALITE, in petrology, a name originally applied by German mineralogist Gerhard vom Rath (1830–88) to a rock consisting largely of quartz, andesine, biotite and hornblende, with a little interstitial orthoclase. The name is from Mt. Tonale, in the Italian Tirol. In the type area the rock is apparently streaky and inhomogeneous, with clots and patches of intergrown green hornblende and brown biotite. The plagioclase feldspar is conspicuously zoned, the cores being sometimes spongy and irregular in outline, and usually more calcic than the mantles or rims. Pyroxene is sometimes present in the centres of hornblende crystals. Apatite, sphene and magnetite are abundant. As originally described, tonalites are ordinarily far richer in dark silicates and often far poorer in quartz than granite. The type is of worldwide occurrence, excellent examples being known from Norway, the southwest upland and Grampian Highlands of Scotland. the British Columbia and southern California batholiths and numerous other localities.

Originally defined without satisfactory quantitative limits, the name tonalite has been so differently used in different classifications as to obscure any meaning it may originally have possessed. In various rock classifications it appears as a synonym for quartz diorite, granodiorite and plagioclase granite *(see* DIORITE; GRANITE). Despite its popularity among taxonomists it has never attained wide usage in petrography; of 53 rocks listed as tonalites by the author of one well-known classification, for instance, only three are actually called tonalite in the original descriptions.

Probably the term is best reserved for rocks richer in dark silicates and poorer in quartz than granite, and in which orthoclase is low or lacking. This is suitably close to the original definition. Rocks satisfying it rarely form independent masses of batholithic dimensions. They sometimes occur in separate small plutons, but more commonly they are marginal facies of gabbro, or norite, or members of an intrusive cycle of gabbroic parentage. (F. Cs.)

TONAWANDA, a city of Erie county in western New York, U.S., on the south bank of the State Barge canal near its juncture nith the Niagara river about 8 mi. N. of Buffalo. Settlement began about 1809 on both sides of Tonawanda creek, which in 1823 was integrated into the Erie canal. The community was organized in 1836 and in 1855 mas separated from North Tonananda (*q.v.*) on the north bank of the canal and incorporated as a village. It nas chartered as a city in 1903. Manufactures include chemicals, paper and metal products, office furniture and amusement equipment. For comparative population figures *see* table in NEW YORK: *Population.* (R. T. R.)

TONBRIDGE, a market town and urban district in the Tonbridge parliamentary division of Kent, Eng., 14 mi. S.W. of Maidstone by road. Pop. (1951) 19,237. Area 7.2 sq.mi. Tonbridge stands at the navigable head of the Medway. Its castle (now town property) was built by Richard de Clare in the 11th century to guard the bridge over the river there. Tonbridge school was founded in 1553 by Sir Andrew Judd and was rebuilt in 1865. The town is an educational, residential and agricultural centre and a railway junction; its industries include printing, sawmills and the making of cricket balls, bricks and plastic goods.

TONE, THEOBALD WOLFE (1763–1798), Irish rebel, the son of Peter Tone, a Dublin coachmaker, was born in Dublin on June 20, 1763. He entered Trinity college, at 22 he married Matilda Witherington, a girl of 16, took his degree in 1786 and went to London. He was entered at the Middle Temple, and afterward read law in Dublin, being called to the Irish bar in 1789. Tone wrote two pamphlets in 1790, one of which, *A Review of the Conduct of Administration,* attracted some notice from the Whigs.

Tone made the acquaintance of Thomas Russell (1767–1803), Napper Tandy (*q.v.*) and others, and the society of the United Irishmen was formed (1791). The original purpose of this society was simply the formation of a political union between Roman Catholics and Protestants, to secure parliamentary reform; it was only when that object appeared to be unattainable by constitutional methods that the majority of the members adopted the more uncompromising opinions which Wolfe Tone held from the first, and conspired to establish an Irish republic by armed rebellion. Tone desired to root out the popular respect for Charlemont and Grattan, and to transfer to more violent leaders the conduct of the national movement. Grattan was a reformer and a patriot without a tincture of democratic ideas; Wolfe Tone was a revolutionary whose principles were drawn from the French Convention. Grattan's political philosophy was allied to that of Edmund Burke; Tone was a disciple of Danton and Thomas Paine.

In 1794 the United Irishmen, persuaded that their scheme of universal suffrage and equal electoral districts was not likely to be accepted by any party in the Irish parliament, began to found their hopes on a French invasion. An English clergyman named William Jackson, who had imbibed revolutionary opinions in France, came to Ireland to negotiate between the French committee of public safety and the United Irishmen. For this emissary Tone drew up a memorandum on the state of Ireland, which he described as ripe for revolution; the paper was betrayed to the government, and'in April 1794 Jackson was arrested on a charge of treason. Several of the leading United Irishmen, including Reynolds and Hamilton Rowan, immediately fled the country; the papers of the United Irishmen were seized; and for a time the organization was broken up. Tone, who had not attended meetings of the society since May 1793, remained in Ireland till after the trial and suicide of Jackson in April 1795. He was enabled to make terms with the government, stipulating only that he should not be called on to give evidence against Rowan and the others, and was permitted to emigrate to America, where he arrived in May 1795.

He went to Philadelphia where he met fellow exiles, and the French minister, Adet, who gave him letters of introduction to the committee of public safety in Paris. In Feb. 1796 he arrived in Paris and had interviews with De la Croix and L. N. M. Carnot, who were greatly impressed by his energy, sincerity and ability. A commission was given him as adjutant general in the French army, which he hoped might protect him from the penalty of treason in the event of capture by the English. He drew up two memorials representing that the landing of a considerable French force in Ireland would be followed by a general rising of the people, and giving a detailed account of the condition of the country. The French Directory, which possessed information from Lord Edward Fitzgerald (*q.v.*) and Arthur O'Connor confirming Tone, prepared to dispatch an expedition under Hoche. On Dec. 15, 1796, the expedition, consisting of 43 sail and carrying about 15,000 men, sailed from Brest. Tone, who accompanied it as "Adjutant General Smith," had the greatest contempt for the seamanship of the French sailors, which was amply justified by the disastrous result of the invasion. The ships were dispersed by a storm off the coast of Kerry.

But the Dutch fleet was delayed by bad weather, and before it put to sea in October! only to be crushed by Duncan in the battle of Camperdown, Tone had returned to Paris; and Hoche, the chief hope of the United Irishmen, was dead. Bonaparte, with whom Tone had several interviews about this time, was much less disposed than Hoche had been to undertake in earnest an Irish expedition; and when the rebellion broke out in Ireland in 1798 he had started for Egypt. When, therefore, Tone urged the Directory to send effective assistance to the Irish rebels, all that could be promised was a number of small raids to descend simultaneously on different points of the Irish coast. One of these under Humbert succeeded in landing a force in Killala bay, and gained some success in Connaught before it was subdued by Lake and Cornwallis, Wolfe Tone's brother Matthew being captured, tried by court-martial and hanged; a second, accompanied by Napper Tandy, came to disaster on the coast of Donegal; while Wolfe Tone took part in a third, under Admiral Bompard, with General Hardy in command of about 3,000 men, which encountered an English squadron near Lough Swilly on Oct. 12, 1798.

Tone, who was on board the "Hoche," refused Bompard's offer of escape in a frigate before the action, and was taken prisoner when the "Hoche" was forced to surrender. At his trial by court-martial in Dublin, Tone made a manly straightforward speech, avowing his determined hostility to England and his design "by fair and open war to procure the separation of the two countries," and pleading in virtue of his status as a French officer to die by the musket instead of the rope. He was, however, sentenced to be hanged on Nov. 12; but on the 11th he cut his throat with a penknife, and on Nov. 19, 1798, he died of the wound.

TONE POEM: see SYMPHONIC POEM.

TONGA, a Polynesian kingdom and archipelago in the South Pacific, lying east of Fiji and south of Samoa. It became a self-governing state under the protection of Great Britain by a treaty of friendship in 1900. Area 270 sq.mi. Pop. (1956) 56,838.

The first European contact with Tonga was made by the Dutch navigators Willem Cornelis Schouten and Jacob Lemaire who anchored off the Niuas, outlying islands of the group, in 1616. Abel Tasman landed in Tongatabu in 1643. Capt. James Cook made three visits and gave the name Friendly Island to Lifuka, an island first discovered by him during his famous voyage in 1777. This name was later applied by Europeans to the whole group. Both Tasman and Cook were struck by the peaceful conditions which prevailed during their visits, but within a few years of Cook's departure the country was embroiled in savage civil war which was finally quelled by a great chief, Taufaahau, who became king in 1845, assuming the name George Tubou I. When a young man he came under the influence of the Methodist mission which commenced its work in Tonga in 1822. His baptism in 1831 was of considerable assistance to the early missionaries and within a few years of their arrival the Tongans renounced their heathen gods and accepted Christianity.

Tonga has an interesting history. At one time it was ruled by a sacred king whose power was absolute. A list of these kings has been preserved and dates back to the 10th century. In the 15th century one of them divested himself of executive powers and set himself up as a temporal king. This delegation was repeated in the 17th century by the temporal king transferring part of his authority to a second temporal king. In the course of time the dignities and powers of the sacred and first temporal kings declined and were finally conferred upon King George Tubou I.

This king was one of the great figures of Pacific history. During his long reign (1845–93) he made treaties with France, Germany, the United States and Great Britain, all of whom recognized his sovereignty and independence. He granted parliamentary government to his people and introduced the land system, unique in the Pacific, under which every male Tongan taxpayer is entitled by law to $8\frac{1}{4}$ ac. of planting land. The king died in his 97th year. Salote Tubou (1900–), his great-great-granddaughter, succeeded as queen in 1918.

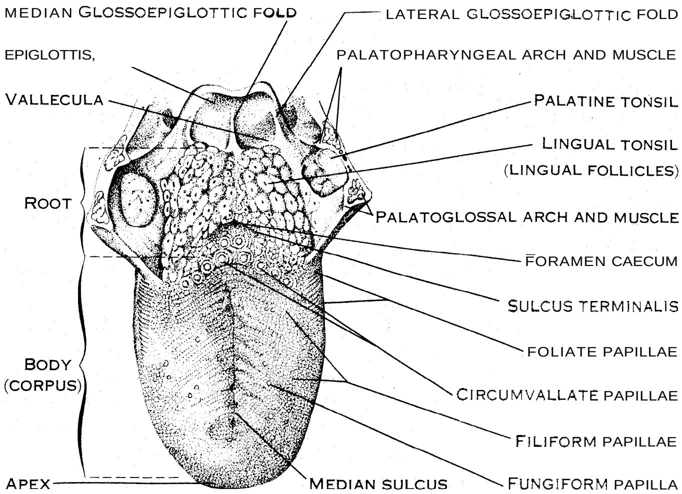
Tonga is an agricultural country. Its economy depends on copra, its main export. Tongans receive free medical and dental treatment. Primary education is free and compulsory between the ages of 6 and 14 years. Secondary education is well developed. The country has its own currency notes and its own stamp issue. British weights and measures are standard. No newspapers are published in Tonga; the government issues a news sheet daily which is distributed without charge. The climate from May to November is subtropical. From December to April the temperature rarely exceeds 90° F. but humidity is high. Rainfall in Nukualofa, the capital, averages 60 in. Though the Tongan group lies in the western hemisphere, between long. 172.5° and 177° west, it keeps eastern time, 12 hr., 20 min. ahead of Greenwich. See also PACIFIC ISLANDS. (J. S. N.)

TONGKING: see INDOCHINA; VIETNAM.

TONGUE, a movable, muscular organ, found in most vertebrates. located on the floor of the mouth. The tongue in man is a very mobile structure and is an important accessory organ in such motor functions as speech, chewing and swallowing. In conjunction with the cheeks it is able to guide and maintain food between the upper and lower teeth until mastication is completed. In persons whose tongue has been excised, speech is defective. In a mammal, such as the whale, that does not chew its food, the tongue is greatly reduced in size. Its mobility aids mammals in creating a negative pressure within the oral cavity, enabling them to suckle. In the horse this negative pressure is great enough to lift a column of water three feet, so that he can easily drink from a stream without raising his head to swallow.

The mucous membrane which covers the tongue is likewise concerned with seizing, holding and grinding food and with the reception of liquids. Its relief varies greatly. In man it is not so highly differentiated as in other mammals because he has learned to use artificial means in procuring and preparing his food. The mucous membrane is especially important as a peripheral sense organ. It contains groups of specialized epithelial cells, known as taste buds, which are the special sense organs of taste, and many nerve fibres which carry stimuli from the oral cavity to the central nervous system. The tongue informs individuals of changes which occur within the oral cavity and at times aids in locating particles of food lodged between the teeth. The central nervous system is kept informed by this membrane as to the consistency and state of salivation of the food. Furthermore, the tongue's glands produce some of the saliva necessary for swallowing (deglutition). The general appearance of the mucous membrane has interested physicians for centuries, and the custom of having the patient protrude his tongue during an examination is not without meaning since certain changes in its appearance reflect disturbances in other organs and systems. A paralysis of one-half of the tongue would also show on examination, for the tongue would deviate toward the affected side when protruded.

The mammalian tongue consists of a mass of interwoven, striated muscles covered with mucous membrane and interspaced with some glands and a variable amount of fat. By its extrinsic muscles, the tongue is attached to the mandible, the hyoid bone, the skull, the soft palate and the pharynx. It is bound to the floor



BASED ON AN ILLUSTRATION BY FRANK H. NETTER, M.D., IN "THE CIBA COLLECTION OF MEDICAL ILLUSTRATIONS"

FIG. 1.—DORSUM OF THE TONGUE

of the mouth and to the epiglottis by reflections of its mucous membrane.

The tongue presents on its upper surface a median groove, which traced posteriorly ends in a small pit, the foramen caecum linguae, which is the point of origin of the thyroid gland and forms the apex of a V-shaped groove, the sulcus terminalis linguae. The median groove and the terminal sulcus form an arrow, the tip of which is directed toward the oral pharynx. The terminal sulcus indicates the division of the tongue into two parts. The larger anterior part, or body, belongs to the floor of the mouth, while the smaller posterior, or root, forms the anterior wall of the oral pharynx.

The superior surface of the body is called the dorsum. It is separated from the inferior surface by the lateral margins, which meet anteriorly at the tip. The dorsum exhibits a rough appearance because of numerous small projections, the lingual papillae, of which five kinds are recognized. Filiform and conical papillae are slender, threadlike. cornified epithelial projections arranged in V-shaped rows, parallel with the terminal sulcus. They are numerous over the whole of the dorsum and contain an axial core of vascular fibrous tissue. Fungiform papillae are similar in structure but less numerous than the last and are easily distinguished by their larger size and reddish colour. Taste buds occur on most of the fungiform papillae. Circumvallate papillae, usually 7 to 11 in number, are found immediately in front of, and parallel to, the sulcus terminalis linguae. Each papilla consists of a flat central mound surrounded by a moat. On the sides of the moat are taste buds. and into the bottom of the fossa open ducts of the serous glands of Ebner.

Foliate papillae, rudimentary in man, are represented by a few (three to eight) vertical folds on the lateral margin of the dorsum at its hinder part. Taste buds occur on the opposite sides of these papillae.

The inferior or under surface of the body is covered in its free portion by a thin, smooth mucous membrane. It presents a prominent median fold, the fraenulum linguae, which connects rhe tongue with the mandible and the floor of the mouth; on each side of this structure is an irregular, fringed fold, the plica fimbriata, extending from near the apex, backward approximately parallel with the lateral margin of the tongue. Between the fraenulum and the plicae fimbriatae, the lingual vein on each side shines through the mucosa.

The root of the tongue differs topographically, developmentally, structurally and functionally, in innervation and in appearance, from the body.

Topographically, the root belongs to the oral pharynx, and developmentally its mucous membrane arises primarily from the second branchial arches but receives additions from the third and fourth as well, while that of the body develops from the first and second (perhaps) branchial arches. Ultimately, the sensory portions of the trigeminal and facial cranial nerves (the nerves of the first and second branchial arches) innervate the epithelium of the body of the tongue, while the glossopharyngeal and vagus nerves (the nerves of the third and fourth arches) supply chiefly the root.

In appearance the mucous membrane of the root is warty because of the underlying nodules of lymphoid tissue, the lingual follicles, which collectively are designated as the lingual tonsil. The mucosa is not firmly adherent to the underlying structures. and a loose median fold of mucous membrane passes from the root to the epiglottis and separates the valleculae, or little valleys. where foreign bodies often become lodged. The lateral boundaries of the valleculae are two folds of mucous membrane, the pharyngoepiglottic or lateral glossoepiglottic folds.

The substance of the tongue is composed chiefly of interlacing striated muscle fibres arranged symmetrically on each side of a median fibrous septum. They are derived from cervical myotomes and innervated by the hypoglossal nerve. The muscles which lie entirely within the tongue are the intrinsic muscles, four on each side—the superior and inferior longitudinal, the vertical and transverse muscles. On contracting they change the length, width and breadth of the tongue and protrude it. Moreover, when contracted on one side only, they effect a contralateral deviation of the tongue's tip. A special branch of the hypoglossal nerve, known as the end branch, innervates the intrinsic muscles. Other muscles, the hyoglossus, chondroglossus, styloglossus and genioglossus, come from skeletal parts and insert into the substance of the tongue. They are the extrinsic muscles, and there are four on each side. With the exception of the genioglossus muscle, they are retractors of the tongue. The genioglossus muscle can protrude the tongue a small amount, but its main function is to build a fulcrum around which the intrinsic muscles function. The arteries of the tongue are derived mainly from the lingual branches of the external carotid arteries (see ARTERIES). The lingual veins return the blood from the tongue to the internal jugular veins (see VEINS).

Comparative Anatomy.—The tongue in fishes is rudimentary and practically immobile since it is composed mostly of thickened epithelium. In some fishes teeth are developed on the tongue. In the tailed forms of the Amphibia the tongue resembles that of the fishes, but in frogs, toads and other tailless amphibians it contains muscles and is quite movable. In reptiles the tongue is generally very movable, though this is not true in crocodiles, alligators and turtles. Many variations of tongue form are encountered in reptiles, and the forked tongues of snakes are familiar. In birds, the tongue possesses no intrinsic muscles, and its mobility varies. When it is very protrusible. as in the woodpecker, the movement is due to the hyoid bone's moving forward.

In Mammalia the tongue, except in whales, is always movable and protrusible. In the lemurs an undertongue is found, which probably is represented by the plica fimbriata under the human tongue.

TONGUE, DISEASES OF. Diseases arising primarily in the tongue are. in order of their severity: cancer. leukoplakia. syphilis and actinomycosis. Cancer of the tongue typically begins as a firmly walled-in ulcer. Cancer. however. is so variable in appearance that inspection and observation alone do not permit a responsible distinction between serious and harmless states. Presence or absence of pain bears no relationship to the nature of a lesion of the tongue. Cancer of the tongue must be suspected whenever a lesion develops gradually and persists. Any such lesion requires medical investigation; microscopic examination of a small piece of tissue is the quickest and most reliable means for early detection or safe exclusion of cancer. In its early stage. cancer of the tongue can safely be removed by surgical treatment, possibly combined with radiation. The cause of cancer of the tongue is as unknown as that of cancer in other parts of the body; defective teeth have been suspected as one of the contributory causes, the use of tobacco seemed to account for the prevalence of tongue cancer in men until statistics proved its incidence among nonsmokers also to be twice as great in men as in women.

Leukoplakia consists in a thickening of the mucous membrane which covers the tongue and it appears as a sharply outlined uniformly whitish patch. Although it may be produced by any number of irritants (tobacco. faulty teeth. ill-fitting dentures). syphilis should be suspected as the cause and cancer anticipated as its possible outcome. It therefore requires treatment even if it should remain painless or fail to spread. Syphilitic leukoplakia often involves the entire surface of the tongue. Leukoplakia is also observed in persons without any of the above-named causes.

Syphilis of the tongue appears either as a primary lesion (chancre) or as a tumour (gumma) associated with the tertiary stage; the latter can be extensive and greatly impair the function of the tongue. Treatment is antisyphilitic or if necessary surgical.

Actinomycosis can produce a small nodule within the substance or an inflammation of part of the tongue; if preceded by complicated tooth extraction, the diagnosis is often missed because of the infrequency of this disease. Treatment with antibiotics is usually very successful.

Secondary Changes.——The tongue as part of the digestive system often reflects gastrointestinal disturbances through changes in colour, evenness of surface or degree of moisture. The well-known coating, however, provides no diagnostic clues since it also depends on diet habits and factors like breathing through the mouth or smoking. One of the earliest symptoms of systemic disease: may concern the tongue; *e.g.*, the fiery redness of pellagra, or the smoothness and burning in pernicious anaemia.

The appearance of the tongue is usually affected in febrile diseases. The various infections of the mouth often involve the tongue which may become predominantly painful because of 'the muscular efforts required for speaking, chewing and swallowing. The tongue may be abnormally small or large congenitally; largeness may result from a tumour spread diffusely through the substance of the tongue (lymphangioma) or from acromegaly. The tongue may deviate from its normal position; the tip of the outstretched tongue may point asymmetrically to either side instead of remaining in the midline. This deviation is found most often in persons who have suffered a stroke (apoplexy) but occurs occasionally in healthy persons as a result of uneven development or nerve supply of the musculature of the tongue.

The normal tongue has an evenly coloured finely granular surface. Two variations of this normal appearance may cause needless alarm: (1) the evenness of colour is disturbed by irregular grayish markings best described by the designation "geographic tongue"; (2) the surface shows deep irregular indentations and furrows (scrotal or beei tongue). The tongue can be the distressing site of allergic reactions; in some persons who are sensitive to certain drugs, the tongue can react with pain or burning or changes of appearance.

TONGUES, GIFT OF, a faculty of abnormal and inarticulate vocal utterance, under stress of religious excitement. which was widely developed in the early Christian circles, and has its parallels in other religions. It is also called Glossolalia (Gr. γλῶσσα, tongue. λαλεῖν. speak). In the New Testament such experiences are recorded in Caesarea (Acts x. 46). at Corinth (Acts xix. 6: 1 Cor. xii., xiv.), Thessalonica (1 Thess. v. 19), Ephesus (Eph. v. 18), and universally (Mark xvi. 17). From the epistles of Paul, who thanked God that he spake with tongues more than all or any of his Corinthian converts. we can gather a just idea of how he regarded this gift and what it really was.

Paul discriminates between the Spirit which during these paroxysms both talks and prays to God and the *nous* or understanding which informs a believer's psalm, teaching, revelation or prophesy, and renders them intelligible, edifying and profitable to the assembly. Accordingly Paul lays down rules which he regarded as embodying the Lord's commandment. A man "that speaketh in a tongue speaketh not unto men, but unto God; for no man understandeth"; and therefore it is expedient that he keep this gift for his private chamber and there pour out the mysteries. In church it is best that he should confine himself to prophesying, for that brings to others "edification and comfort and consolation." If, however. tongues must be heard in the public assembly, then let not more than three of the saints exhibit the gift, and they only in succession. Nor let them exhibit it at all. unless there is some one present who can interpret the tongues and tell the meeting what it all means. If the whole congregation be talking with tongues all at once, and an unbeliever or one with no experience of pneumatic gifts come in, what will he think, asks Paul. Surely that "you are mad." So at Pentecost on the occasion of the first outpouring of the Spirit the saints were by the bystanders accused of being drunk (Acts ii. 13). In the church meeting. says Paul, "I had rather speak five words with my understanding, that I might instruct others also, than ten thousand words in a tongue."

Paul on the whole discouraged glossolaly. "Desire earnestly the greater gifts," he wrote to the Corinthians. The gift of tongues was suitable rather to children in the faith than to the mature. Tongues were, he felt, to cease whenever the perfect should come; and the believer who spoke with the tongues of men and of angels, if he had not love. was no better than the sounding brass and clanging cymbal of the noisy heathen mysteries. It was clearly a gift productive of much disturbance in the Church (1 Cor. xiv. 23). He would not, however. entirely forbid and quench it (1 Thess. v. 19), so long as decency was preserved.

It is not then surprising that we hear little of it after the apostolic age. It faded away in the great Church, and probably Celsus was describing Montanist circles (though Origen assumed that they were ordinary believers) when he wrote (Origen, Contra *Celsum*, vii. 9) of the many Christians of no repute who at the least provocation. whether within or without their temples, threw themselves about like inspired persons; while others did the same in cities or among armies in order to collect alms.

Tertullian in the 3rd century testifies that glossolaly still went on in the Montanist Church which he had joined; for we must so interpret the following passage in his De *anima*, cap. ix.: "There is among us at the present time a sister who is endowed with the charismatic gift of revelations, which she suffers through ecstasy in the spirit during the Sunday service in church. She converses with angels, sometimes even with the Lord, and both hears and sees mysteries." The magical papyri teem with strings of senseless and barbaric words which probably answer to what certain of the Fathers called the language of demons. It has been suggested that we here have recorded the utterances of glossolalists.

The attitude of Paul toward glossolaly among his converts strikingly resembles Plato's opinion as expressed in the *Timaeus*, p. 72, of the enthusiastic ecstasies of the ancient *μάντις* (soothsayer). The gift of tongues and of their interpretation was not peculiar to the Christian Church, but was a repetition in it of a phase common in ancient religions. The very phrase *γλώσσαις λαλεῖν*, "to speak with tongues," was not invented by the New Testament writers, but borrowed from ordinary speech.

Virgil (*Aen.* vi. 46, 98) draws a life-like picture of the ancient prophetess "speaking with tongues." He depicts her quick changes of colour, her dishevelled hair, her panting breast, her apparent increase of stature as the god draws nigh and fills her with his divine afflatus. Then her voice loses its mortal's ring: "nec mortale sonans." The same morbid and abnormal trance utterances recur in Christian revivals in every age, *e.g.*, among the mendicant friars of the 13th century, among the Jansenists, the early Quakers, the converts of Wesley and Whitefield, the persecuted Protestants of the Cevennes, the Irvingites, and the revivalists of Wales and America.

Oracular possession of the kind above described is also common among savages and people of lower culture; and Dr. Tylor, in his Primitive Culture, ii. 14, gives examples of ecstatic utterance interpreted by the sane. Thus in the Sandwich Islands the god Oro gave his oracles through a priest who "ceased to act or speak as a voluntary agent, but with his limbs convulsed, his features distorted and terrific, his eyes wild and strained, he would roll on the ground foaming at the mouth, and reveal the will of the god in shrill cries and sounds violent and indistinct, which the attending priests duly interpreted to the people."

Cutten, *Speaking with Tongues, Historically and Psychologically Considered* (1927) (the most complete existing survey of the subject). *See* also Thouless, *Introduction to the Psychology of Religion,* chap. xi.

TONIC SOL-FA. Tonic Sol-fa has as its leading principle the relationship of sounds. The system is based on "mental effect," *i.e.* the effect on the mind of any note, chord or progression in relation to a central Tonic or key-note. The prefix "tonic" was first used by John Curwen (1816–1880). He developed his method from that of Miss Sarah Ann Glover (1785–1867) of Norwich, to whom he always acknowledged his indebtedness, but, since her system could not become popular (it was out of print), he announced a number of modifications (twenty-one are tabulated in his Teacher's *Manual*), which established the "Tonic Sol-fa Method and notation" as a national movement.

What, then, is Tonic Sol-fa? It is a letter-notation, as distinguished from a staff-notation. The initials of seven old syllables are used. They formed what was later called a "movable do" system, and Tonic Sol-fa follows this old practice. Guido d'Arezzo (995–1050) noticed that each line of a hymn to St. John began stepwise, forming his hexachord instead of the former Greek tetrachords, and he took the first syllable of each line of the hymn as a sound-name, thus ut, re, mi, fa, sol, la. The last line of the hymn was Sancte Iohannes. The initial letters; *si,* were added in the 16th century to represent the seventh of the modern major scale. In the 17th century *do* (probably from Dominus) was substitued in most countries for *ut.* In the 19th century in England *si* was changed to te to avoid confusion with the initial of *sol,* and the spelling of all the syllables was adapted to the English language, with the advantage of having an open vowel sound for every note. The higher octave was shown by a small figure on the right above the note (d^1), and the lower octave syllables had a figure below the note (s_1s_2) at the right side as shown.

Besides the signs for tune already given, a notation of time was adopted, and varied spacing represented duration pictorially. A vertical line (|) precedes the accent at the beginning of the bar (measure). A short perpendicular line (|) shows the middle or medium accent of common time (four-pulse measure). An accent mark if followed by an unfilled (un-syllabled) space indicates a rest. When a note follows the accent mark it occupies the time from that accent to the next. A long dash (—) after a note requires the sound to be continued through the next pulse or beat. A dot (full point) between two notes divides the pulse into equal parts (d.r). A dot before a continuation mark (short dash) indicates that the previous note is to be continued through half of that pulse. A comma is the sign for a quarter-pulse (d,r). A dot and comma placed together show that the preceding note is of $-pulse length, and the following note ¼-pulse length (d.,r). An inverted comma is placed after a note of one-third pulse length (d'r). A line placed below two or more notes signifies that the notes are to be sung to the single syllable or word underneath the notes (d.r). A brace binds each line of the score, and a double bar shows the end of the music. A tune may be quoted which gives within one bar five signs for rhythm:

A.	m	:m	., r	|d ,l_1	.— : l_1	.d	‖
	Oft	in	the	stilly	night,	Ere	‖

The question of key arises. At the beginning of the tune the pitch of it is indicated by the standard pitch-names (Key A, etc.). Here comes the "enlightening fact" to a beginner. A tune in Tonic Sol-fa notation has the same appearance (apart from octave marks) whether pitched high or low; it is recognized as the same tune. In the song of Moore above, for example, the same syllables would be used whether sung at a pitch suitable to tenor or bass. The Tonic Sol-faist, having a movable doh method, has not to use a fresh set of syllables with every change of pitch, in the "fixed doh" way.

In modulation (called transition) to a new key in the course of a tune, the Tonic Sol-faist finds a new signature at the point of change, and is thus prepared. If a sharp key (passing from key F to key C is a remove sharp-wards) is imminent, the new tone (the sharp) is printed over the music (for example, A.t.) on the right of the key-name. If the tune passes flat-wards, the "distinguishing tone" is placed on the left of the key-name (fah in key F, for example, f.F.). If the transition involved four removes to the right (sharp-ward progressions) the distinguishing tones would be t.m.l.r. Four flat-ward removes would have as distinguishing tones at each remove, r.s.d.f., read backwards. The latest practice is to name the number of new tones above three by a figure, as B 4, for example. In the minor key (mode) the key-note is *lah,* thus in A minor "Lah is A."

Besides having changes of key defined by fresh signature (a practice which is growing in staff notation printing), the Tonic Sol-faist is given a new syllable, forming a bridge-tone or double-name, of which, with practice, he thinks the first and sings the second, or as a beginner he will glide from one to the other, as m'lah, or as a barrister addresses m'lor. In print, this is shown thus *ml.* Explanation of the treatment of minor keys cannot be pursued here, but the "minor mode" gives the Tonic Sol-faist no trouble.

A further detail is with regard to the inflected names adopted for "accidentals" (chromatics). Doh becomes, a semitone higher, de, and the long e sound also represents re, fe, se, *le.* Depress *te* and it is named *taw,* printed *te.* Similarly down "the modulator" may be found *la, ma,* rn. Characteristic of the minor mode are *ba* (pronounced bay) and se.

First lessons in Tonic Sol-fa are begun with the aid of a chart of tune: the modulator just named. Its ladder-like appearance is a great aid to the beginner; it is the counterpart of the up-and-down picture of the staft notation. The mental image of the modulator remains; it is the answer to the objection that Tonic Sol-fa is a dead-level picture. Even before it is used. the learner hears "the sound before the sign." He learns the scale by "steps of the method." first d, *s* and *m,* second r and *t,* third *f* and 1, fourth the whole scale and transition. Such simple tools enable the ordinary teacher of an elementary school to get from small children amazing results in sight-singing. Each scale tone when sung slowly is also found to have its own character or mental effect, and this is noticed in illustrating by familiar phrases of music, which. however. must not be pressed too far; d is firm. *s* martial, *m* mild, *r* prayerful (at high, pitch, rousing). t leading upward: f leaning downward, *l* the mournful tone. The method applies other devices for teaching effect: French time-names for rhythm; hand-signs which. dispensing with printed notes. enable the teacher to give exercises rapidly. The ear is trained from the first lesson.

The value of it all is greatest in the higher stages: harmony is clarified by the tonic principle; transposition of music is easy; rhythm is analyzed and simplified by the time names; and, in addition, Tonic Sol-fa is the best introduction to the staff notation. More and more, publishers find it worth while to print the Tonic Sol-fa notation along with the staff. The facility and certainty of the Tonic Sol-faists have been admitted and praised by every conductor who has had experience of them. The story of the successful struggle to give this method a footing need not be told here. The danger now is when people in authority, or capable musicians who learned music easily, say that the notation is unnecessary, while passing compliments upon the method of teaching; and at the same time ignoring the need of giving children a good foundation in reading this notation. (J. GRA.)

TÕNISSON, JAAN (1868– ?), Estonian statesman, was the son of a farmer in the Viljandi district of Livonia. After graduating in law at the University of Dorpat (Tartu) he was for some years in the judicial service of the Russian imperial government, but left that position in 1896 to become editor of *Postimees* (The Postilion), the oldest Estonian daily newspaper, in Tartu. Tonisson's initiative and influence ranged from agricultural shows to the founding of co-operative banks and from the temperance movement to schools and literary societies. In the revolution of 1905 he was at the head of the Estonian moderate constitutional movement, which he likewise represented in the Russian duma. With the other signatories to the Viborg Appeal, he was sentenced to a term of imprisonment. From 1917 onward Tonisson, as leader of the Estonian People's party, was a member of all the parliaments and other representative assemblies. He was expelled by the Bolsheviks in Nov. 1917, but in Stockholm and in Copenhagen he carried out with the representatives of the Allied Powers the preliminaries of a de facto recognition of Estonia. From 1919 to 1920 he was prime minister, and during his period of office peace was concluded with Russia. In the second *riigikogu* (parliament) he formed a new centre party by the amalgamation of his own party, the Christian People's party, and the National Liberals and became president of the chamber. He was *Rügivanem* (president) in 1927–28, and 1933. During the suspension of parliamentary activity (1934–37), Tonisson became professor of social sciences at Tartu; but later he was elected into the constituent assembly and into the parliament, where he was a prominent member of the opposition. In 1940 he was arrested and deported by the Soviet occupation forces, after which his fate was unknown.

TONK, a town and district of Rajasthan state, India. The town (pop., 1951. 42,833), headquarters of the district, is 55 mi. S. of Jaipur, near the right bank of the Banas river.

The former princely state of TONK (pop.. 1941, 353,687) was in the Rajputana agency (Haraoti and Tonk subagency till 1936, then Jaipur residency) prior to its accession to Rajasthan on March 25, 1948. It was divided into six isolated tracts around the following cities: Tonk; Aligarh, 25 mi. S.E. of Tonk; Nimbahera, Pirawa and Chhabra (towns c. 120–130 mi. from Tonk in enclaves along the northwest fringe of Central India); and Sironj (180 mi. S.E. of Tonk and entirely within Central India); total area 2,543 sq.mi. The district of Tonk has an area of 2,754 sq.mi.; pop. (1951) 400,947. The former *nawab* was of Afghan or Pathan descent. The founder of the family was the notorious Pindari leader Amir Khan, who submitted to the British in 1817.

TONKA BEAN. The tonka, tonqua or tonquin bean, also called the coumara nut, is the seed of *Dipteryx* odorata and D. *oppositifolia,* two leguminous trees native to tropical South America. The drupelike pod contains a single almondlike black seed possessed of a fine sweet odour of new-mown hay or vanilla, due to the presence of coumarin (*q.v.*). Besides its use in perfumery, an alcoholic extract is being used more and more as a substitute for vanilla in confections.

TONKAWA, a tribe of south central Texas, usually considered as a distinct linguistic stock, belonged to the plains group of nomadic buffalo-hunting Indians. They lived in tepees and bore a reputation for cannibalism.

The Tonkawa fought, at one time or another, most of their neighbours, from the Apache to the Caddo. The original population of perhaps 1,500 decreased to a few dozen.

TONNAGE AND POUNDAGE. In England, customs duties anciently imposed upon exports and imports, the former being a duty upon all wines imported in addition to prisage and butlerage, the latter a duty imposed ad valorem at the rate of 1*s.* on the £ on all merchandise imported or exported. The duties were levied at first by agreement with merchants (poundage in 1302, tonnage in 1347), then granted by parliament in 1373, at first for a limited period only. They were considered to be imposed for the defense of the realm.

From the reign of Henry VI until that of James I they were usually granted for life. They uere not granted to Charles I, and in 1628 that king took the unconstitutional course of levying them on his own authority, a course denounced a few years later by 16 Car. I c. 18 (1640), when the Long parliament granted them for two months. After the Restoration they were granted to Charles II and his two successors for life. By acts of Anne and George I, the duties were made perpetual and mortgaged for the public debt. In 1787 they were finally abolished, and other modes of obtaining revenue substituted, by 27 Geo. III c. 13 (1787).

Poundage also signified a fee paid to an officer of a court for his services; *e.g.,* to a sheriff's officer, nho is entitled by 29 Eliz. c. 4 (1586–87) to a poundage of 1*s.* in the £ on an execution up to £100, and sixpence in the £ above that sum.

TONSBERG, a seaport of Norway, Vestfold fylke ("county"), situated on the south coast. near the entrance to Oslo fjord. 72 mi. S.W. of Oslo Pop. (1950), 12,211. It is one of the most ancient towns in Norway, declined after the middle ages, but before World War II was a growing industrial town and headquarters of a sealing and whaling fleet.

TONSILLITIS is an inflammation of the tonsils; it may be acute or chronic.

Acute Tonsillitis. — This is an acute infection of the tonsils and throat caused by invasion of the mucous membrane by microorganisms, usually hemolytic streptococci. Because the tonsils contain deep folds of mucous membrane, the inflammation is greatest in these structures. On examination, the throat appears red. and the tonsils are swollen and often covered with small white patches.

The symptoms of acute tonsillitis are sore throat with difficulty in swallowing, fever, malaise and frequently enlarged lymph glands on both sides of the neck. The infection is self-limited and lasts about five days The treatment includes bed rest until the fever has subsided, isolation to protect others from the infection, and warm throat irrigations or gargles with a mild antiseptic solution. Antibiotics (penicillin) or sulfonamides or both are prescribed in severe infections to prevent complications. Throat cultures and investigations of the white blood count aid in determining the treatment.

Scarlet fever. diphtheria (*qq.v.*) and trench mouth (*see* PERIODONTAL DISEASES) may also produce acute tonsillitis. In diphtheria, the tonsils are covered with a thick whitish adherent membrane, in trench mouth with a grayish membrane that wipes off readily.

The complications of acute tonsillitis are proportional to the severity of the infection. The infection may extend upward into the nose, sinuses and ears or downward into the larynx, trachea and bronchi. Locally. virulent bacteria may spread from the infected tonsil to the adjoining tissues, resulting in a peritonsillar abscess (quinsy). More serious are two distant complications—acute nephritis and acute rheumatic fever, with or without heart involvement.

A peritonsillar abscess or quinsy may follow an acute tonsillitis; it is usually confined to one side. The massive swelling displaces the involved tonsil toward the median line. Extreme pain interferes with swallowing and talking. High fever and general prostration accompany the infection. Early administration of antibiotics may obviate the necessity of surgical incision and drainage.

Chronic Tonsillitis. — This is a chronic inflammation of the tonsils caused by repeated acute infections. Enlargement of the tonsils is accompanied by the accumulation of purulent secretions in the tonsillar crypts. In children, chronic tonsillitis may be evidenced by frequent or persistent sore throats and large lymph glands in the neck. The treatment is surgical removal (tonsillectomy).

Turnours. — Benign neoplasms of the tonsils are rare. A gradual swelling of one tonsil with or without ulceration may indicate cancer. Early diagnosis by biopsy must be followed by immediate irradiation or surgery. (H. V. v. L.)

TONSURE, a religious observance in the Roman Catholic and Orthodox Eastern Churches, consisting of the shaving or cutting of part of the hair of the head as a sign of dedication to special service. The reception of the tonsure in these churches is the initial ceremony which marks admission to orders and to clerical rights and privileges. It is administered by the bishop with an appropriate ritual. Candidates for the rite must have been confirmed, be adequately instructed in the elements of the Christian faith, and be able to read and write. Those who have received it are bound (unless in exceptional circumstances) to renew the mark, consisting of a bare circle on the crown of the head, at least once a month, otherwise they forfeit the privileges it carries. The practice is not a primitive one, Tertullian simply advises Christians to avoid vanity in dressing their hair, and Jerome deprecates both long and closely cropped hair. According to Prudentius (Περισ. xiii. 30) it was customary for the hair to be cut short at ordination. Paulinus of Nola (*c.* 490) alludes to the tonsure as in use among the (Western) monks; from them the practice quickly spread to the clergy. For Gaul about the year 500 we have the testimony of Sidonius Apollinaris (iv. 13), who says that Germanicus the bishop had his hair cut "in rotae speciem."

The earliest instance of an ecclesiastical precept on the subject occurs in can. 41 of the Council of Toledo (A.D. 633): "omnes clerici, detonso superius capite toto, inferius solam circuli coronam relinquant." Can. 33 of the Quinisext council (692) requires even singers and readers to be tonsured. Since the 8th century three tonsures have been more or less in use, known respectively as the Roman. the Greek and the Celtic. The first two are sometimes distinguished as the tonsure of Peter and the tonsure of Paul. The Roman or St. Peter's tonsure prevailed in France, Spain and Italy. It consisted in shaving the whole head, leaving only a fringe of hair supposed to symbolize the crown of thorns. Late in the middle ages this tonsure was lessened for the clergy, but retained for monks and friars. In the Eastern or St. Paul's tonsure the whole head was shaven, but when now practised in the Eastern Church this tonsure is held to be adequately shown when the hair is shorn close. In the Celtic tonsure (tonsure of St. John, or, in contempt, tonsure of Simon Magus) all the hair in front of a line drawn over the top of the head from ear to ear was shaven (a fashion common among the Hindus). The question of the Roman or Celtic tonsure was one of the points in dispute in the early British Church, settled in favour of the Roman fashion at the Council of Whitby (664). The tonsure at first was never given separately, and even children when so dedicated were appointed readers, as no one could belong to the clerical state without at least a minor order. From the 7th century, however, children were tonsured without ordination, and later on adults anxious to escape secular jurisdiction were often tonsured without ordination. Till the 10th century the tonsure could be given by priests or even by laymen, but its bestowal was gradually restricted to bishops and abbots.

TOOKE, JOHN HORNE (1736–1812), English politician and philologist, third son of John Horne, a poulterer in Newport Market, London, was born on June 2j, 1736. He was educated at Westminster school, Eton, and St. John's college, Cambridge. He had been entered at the Inner Temple, but his father wished him to take orders and he was ordained to a curacy at New Brentford in 1760. He travelled in France in 1765–67, where he met John Wilkes (*q.v.*). In 1767 he returned and became Wilkes' most energetic and ingenious supporter. In 1771, however, he quarrelled violently with his leader, to the damage of their cause. Horne's supporters took the name of the Constitutional Society.

In 1773 he was placed beyond the reach of want by the gratitude of William Tooke, of Croydon, whose rights in an enclosure case he had protected by turning attention to his case.

But Horne was now involved in serious trouble. For signing the advertisement soliciting subscriplions for the relief of the relatives of the Americans "murdered by the king's troops at Lexington and Concord," he was tried at the Guildhall on July 4, 1777, before Lord Mansfield, found guilty, and committed to the King's Bench prison in St. George's Fields, from which he only emerged after a year's durance, and after a loss in fines and costs amounting to £1,200. Soon after his deliverance he applied to be called to the bar, but his application was negatived on the ground that his orders in the Church were indelible. Horne thereupon tried his fortune, but without success, on farming some land in Huntingdonshire. He also published two influential reforming pamphlets: *Facts Addressed to Landholders,* etc. (1780), and *A Letter* on *Parliamentary Reform* (1782).

On his return from Huntingdonshire he became once more a frequent guest at Mr. Tooke's house at Purley, and in 1782 assumed the name of Horne Tooke. In 1786 Horne Tooke gave his philological treatise of Ἔπεα πτερόεντα (2 pts. 1786–1805), the sub-title of The *Diversions* of *Purley,* as *a* tribute to his friend.

Between 1782 and 1790 Tooke supported Pitt, and in the election for Westminster, in 1784, threw all his energies into opposition to Fox. After the Westminster election of 1788 Tooke depicted the rival statesmen (Lord Chatham and Lord Holland, William Pitt and C. J. Fox) in his pamphlet of *Two Pair* of *Portraits.* At the general election of 1790 he was a candidate for Westminster, in opposition to Fox and Lord Hood, but was defeated; and, at a second trial in 1796, he was again at the bottom of the poll. Meantime the excesses of the French revolution had provoked reaction in England, and the Tory ministry adopted a policy of repression. Horne Tooke was arrested early on the morning of May 16, 1794, and conveyed to the Tower. His trial for high treason lasted for six days (Nov. 17–22) and ended in his acquittal, the jury only taking eight minutes to settle their verdict. Through the influence of the second Lord Camelford, he was returned to parliament in 1801 for the pocket borough of Old Sarum. Efforts to secure his exclusion on the ground of his clerical orders failed, but an act was passed rendering all persons in holy orders ineligible, and he sat for that parliament only.

The last years of Tooke's life were spent in retirement in a house on the west side of Wimbledon Common, where he gave the Sunday parties, attended by Thurlow, Bentham, Coleridge, Paine and others, which became a legend. He died on March 18, 1812.

The *Life of Horne Tooke,* by Alexander Stephens, is written in an unattractive style and was the work of an admirer only admitted to his acquaintance at the close of his days. The notice in the *Quarterly Review,* June 1812, of W. Hamilton Reid's compilation, is by J. W. Ward, Lord Dudley. The main facts of his life are set out by Mr. J. E. Thorold Rogers, in his *Historical Gleanings,* 2nd series. Many of Horne Tooke's wittiest sayings are preserved in the *Table Talk* of Samuel Rogers and S. T. Coleridge.

TOOKE, THOMAS (1774–1858), English economist, was born at St. Petersburg in February, 1774. Entering a large Russian house in London at an early age, he acquired sound practical experience of commercial matters and became a recognized authority on finance and banking. He was one of the earliest advocates of free trade and drew up the *Merchants' Petition* presented to the House of Commons by Alexander Baring. afterwards Lord Ashburton. He gave evidence before several parliamentary committees, notably the committee of 1821, on foreign trade, and those of 1832, 1840 and 1848 on the Bank Acts. He was elected F.R.S. in 1821. He died in London on Feb. 26, 1858.

Tooke is known for his *History of Prices and of the State of the Circulation during the Years 1793–1856* (6 vols., 1838–1857). In the first four volumes he treats *(a)* of the prices of corn, and the circumstances affecting prices; (b) the prices of produce other than corn; and *(c)* the state oi the circulation. The tn-o final volumes, written in conjunction with W. Newmarch, deal with railways, free trade, banking in Europe and the effects of new discoveries of gold.

TOOL: *see* MACHINE TOOLS and articles on specific tools; for the tools of prehistoric man *see* ARCHAEOLOGY; FLINTS.

TOOLE, JOHN LAWRENCE (1832–1906), English actor, was born in London on March 12, 1832. He was educated at the

City of London school. He definitely took to the stage in 1852, appearing in Dublin as Simmons in *The Spitalfields Weaver.* In 1854 he made his first professional appearance in London at the St. James's theatre, acting Samuel Pepys in *The King's Rival* and Weazel in My *Friend the Major.* In 1857 he met Henry Irving in Edinburgh and recommended him to go to London. and their friendship remained thenceforth of the closest kind. In 1858 Toole joined Webster at the Xdelphi, and established his popularity as a comedian.

In 1868 he was engaged at the Gaiety, appearing among other pieces in *Thespis,* the first Gilbert and Sullivan collaboration.

In 1879 he took the "Folly" theatre in London, which he renamed "Toole's" in 1882. He died July 30, 1906.

TOOL STEEL. This term designates steels used for machine tools, hand tools and cutlery and. loosely, includes alloys other than of iron, and even ceramic combinations. Prior to 1870 these a-ere exclusively high-carbon steels made by crucible or cementation process; since then alloy steels have been introduced for cutting metals. Plain carbon steels of high quality are still pre-eminent for woodworking, stonecutting and cutlery. The amount of carbon ranges from 0.6% to 1.3%, the lower carbon content giving a moderate hardness but great toughness. Sledges, chisels. picks, rock drills. axes, woodworking tools, files. cutlery and razors —each item needs greater and greater hardness and more ability to maintain a cutting edge, with toughness progressively less important as the carbon content increases.

If carbon steels are worked at high rates of speed, the friction between chip and tool nose generates enough heat to draw the temper of the tool, *i.e.,* to soften it to a lesser hardness than the material being cut. This is avoided by using special alloys that temper very slowly, retain their hardness at high heats; or are intrinsically hard and thus require no heat treatment. Mushet steel (introduced by R. F. Mushet in 1871) is of the first category of low-alloy tool steels. It was a high-carbon steel containing 5% tungsten and 1% chromium. *(See* STEELS, ALLOY.) High-speed steel *(q.v.)*, which has the property of hardness at a red heat and contains much more tungsten and chromium, is widely used in machine shops for mass production of iron and steel parts. Stellite (although really not a steel) is an example of a third class of hard tool materials. Discovered by Elwood Haynes. it is one of a family of intrinsically hard alloys of tungsten, chromium and cobalt. It enjoyed wide popularity in the 1920s and 1930s for machining hard cast iron (semisteel) and for rough turning medium steels. Another material of great hardness, introduced in 1928, is a mixture of powdered tungsten (and tantalum) carbide with about 12% of metallic cobalt for binder, pressed together and sintered by processes of powder metallurgy *(q.v.)*. This idea was commercialized in Germany in 1936 and the material marketed as Widia; in the United States a well-known brand is called Carboloy. Tips of this sort are brazed to steel tool shanks. Starting with an ability to cut tough or abrasive substances like Hadfield's manganese steel and nonmetallic electrical insulation, they rapidly have expanded in their utility to almost all machine shop operations on mass-produced articles. Other hard carbides, such as boron carbide, consolidated by powder metallurgy methods, have also been introduced as cutters for special services.

This trend toward the use of nonmetallics as cutting tools has its latest example in the use of bonded. and sintered hard oxides. Artificial corundum or emery (crystallized alumina) is an example of material long used in grinding wheels or polishing cloths and it is formed into cutting tools for those uses suggested above for hard carbides.

Steel is essentially a crystalline alloy of iron and iron carbide. Iron is naturally a soft and malleable metal, primarily because the iron atoms in the microscopic crystallites are arranged in a very simple geometric space pattern. Carbide, on the other hand. is hard and brittle because of its exceedingly complex crystalline architecture. Hardening of steel consists of (1) heating the metal to a point where the carbide particles dissolve and the carbon atoms diffuse uniformly in the solid iron, then (2) quenching so rapidly that the reverse action is inhibited. What results is a highly strained (hard) iron matrix shot through with an infinite number of submicroscopic iron carbide particles. The maximum possible hardness is related to the carbon content. *See* IRON AND STEEL: *Metallography and Heat Treatment.*

A little heat relaxes the internal strain and permits carbide particles to grow by joining together, softening the hard steel. Hence properly hardened plain carbon tool steels cannot be run at high speeds because they are quickly softened by the heat generated. Mushet found that the metals tungsten and chromium combined with high-carbon steel slowed down the softening reactions, so that such alloy steel tools could be run at much higher speeds (and frictional temperatures). Research after 1900 also proved that another prime function of alloys in steel is to slow down the reversionary actions during quenching; *i.e.,* to retard the transformation from the hot solution which is soft and ductile into a hard mixture of strained iron and carbide crystals. If the optimum combination of carbon and alloying metals such as nickel, chromium and molybdenum is used, the transformation is caught midway)and the hardening effects are fairly permanent. The resulting metal resists tempering and retains its hardness even after being subjected to the heat of a tempering furnace, of friction in cutting or from contact with hot metal as in a forging die.

A great variety of tool steels have been marketed containing various combinations of alloying elements, either for economics or for the sake of special properties. For example, shortage of tungsten in World War I turned attention to the use of molybdenum (a close cousin) as a substitute, with the subsequent development of high-speed steel in which 6% to 8% of molybdenum replaces nearly all of the tungsten. Some tools—especially gauges with hard surfaces to resist normal wear—must be hardened with a minimum of size change; high manganese (1.5% to 1.75%) gives "nondeforming" tool steels. Dies for contact with hot metal, either molds in die-casting machines or forging dies, need to retain hardness at high temperatures to resist scour. The former may contain up to 7.5% chromium and an equal amount of tungsten. Tungsten in the latter formerly ran as high as 10%, but economics have forced the metallurgists to economize in alloy content. Very successful hot die steels contain 0.40% carbon, 5% chromium. 1.25% molybdenum and 0.5% vanadium.

Since there is a nearly constant relationship between hardness and strength, it may be appreciated that a steel which is hard, even when hot, will simultaneously be strong at high temperature. Hence it is that sheets rolled of hot die steel are most useful for high-speed aircraft and missile parts where working temperatures do not exceed 950° F. Its tensile strength at 800° F.. for example, is 220.000 lb. per square inch. By comparison, the best of the higher alloy stainless steels has a tensile strength of 150,000 p.s.i. at 800° F.

TOOMBS, ROBERT (1810–1885), U.S. political leader, was born near Washington, Ga., on July 2, 1510. He was educated at Franklin college (University of Georgia), at Union college, Schenectady, N.Y., from which he graduated in 1828, and at the lam school of the University of Virginia. He was admitted to the bar in 1830, served in the Georgia house of representatives (1838, 1840–41 and 1843–44), in the U.S. house of representatives (1845–53) and in the United States senate (1853–61). He supported the Compromise Measures of 1850. denounced the Nashville convention. opposed the secessionists in Georgia and helped frame the Georgia platform (1850). He and the southern unionists thought secession not wrong but inexpedient. When the Whig party dissolved, Toombs went over to the Democrats. He favoured the Kansas-Nebraska bill, the admission of Kansas under the Lecompton constitution and the English bill (1858) and on June 24, 1856, introduced in the senate the Toombs bill, which proposed a constitutional convention in Kansas under conditions acknowledged by antislavery leaders as fair and marking the greatest concessions by the proslavery senators during the Kansas struggle. The failure of the bill to provide for the submission of the constitution to popular vote was the crux of the Lecompton struggle *(see* KANSAS). On Dec. 22, after the election of Lincoln, he sent a telegram to Georgia which urged "secession by the 4th of March next." With Gov. Joseph E. Brown he led the fight for secession. His influence induced the "old-line Whigs" to support immediate secession. He was secretary of state in President Davis' cabinet and then entered the army (July 21, 1861), serving as a brigadier general in the army of northern Virginia and, after 1863, as adjutant and inspector general of Gen. G. W. Smith's division of Georgia militia. After two years in Cuba. France and England, he returned to Georgia in 1867. He died on Dec. 15. 1885.

TOOTHACHE TREE: *see* PRICKLY ASH.

TOOTHWORT, the popular name for a small British plant of curious form and growth, known botanically as *Lathraea squamaria* (family Orobanchaceae). It grows parasitically on roots, chiefly of hazel, in shady places such as hedge sides. It consists of a branched whitish underground stem closely covered with thick fleshy colourless leaves, which are bent over so as to hide the under surface; irregular cavities communicating with the exterior are formed in the thickness of the leaf. On the inner wall of these chambers are stalked hairs. The only portions that appear above ground are the short flower-bearing shoots, which bear a spike of two-lipped dull purple flowers. The scales which represent the leaves secrete water. *Lathrnea* is closely allied to broomrapes *(Orobanclze),* of which seven species occur in Great Britain; they also are parasitic. In the United States various species of *Dentaria,* family Cruciferae, are called toothwort.

TOOWOOMBA, a city in the southeast of Queensland, Austr., at an altitude of nearly 2,000 ft. on the Darling Downs, 101 mi. by rail and 84 mi. by road west of Brisbane. It is an industrial centre, pop. (1954) 43,149. It is a summer resort ("The Garden City of Queensland"), on the main Southern and Western Railway lines which connect it with Brisbane and Sydney, and a centre for much of the agricultural and pastoral produce of the Darling Downs, besides the wheat, fruit and pastoral products of the Roma and Charleville areas.

There are butter and cheese factories, one of the largest bacon factories in the southern hemisphere, engineering works and coal mines in the Toowoomba region. Milk production is on a large scale.

TOP, a toy having a body of conical. circular or oval shape. often hollow. with a point or peg. usually metal, on which it turns or is made to whirl. If given a knock. a spinning top will go round in a circle at a slant; if spun with a slant at the start. it will quickly stand upright till halted by friction. Some tops, as the common peg top, are spun by means of a cord. Whipping tops are kept spinning by whips with a lash. Other tops are spun by a twist of the hand or the action of a spring or a plunger. Some hollow tops, such as the thunder tops of Japan, have holes cut in them to produce a hum or roar.

Tops were known to the ancients. The Greek *bemble* mentioned in Aristophanes' *Eirds* was evidently a whipping top. Plato, in the *Republic,* mentions *stoblos,* a humming top spun by a string. In Homer the word *stombos* seems to point to a humming top. The Latin word *turbo* and the Greek *rhombos* are sometimes translated by "top" when they refer to the instrument used in the Dionysiac mysteries, something like a bullroarer (*q.v.*), which was whirled in the air by a string to make a booming noise. The Romans made tops out of boxwood or terra cotta. Virgil, in the *Aeneid,* compares Queen Amnta, poisoned by a Fury, to a "whip-top whirling under the twisted lash."

Tops have also long been known in the east where they were made out of such natural materials as conch shells. gourds, nuts, bamboo and stone. In Japan, top spinning or *koma asobi* has for centuries been a pastime of adults as well as children. There are street top players who earn money by making tops run along strings, etc.

Potaka, or top playing is a favourite pastime of Maori men and boys. These tops, often beautifully inlaid with shell. are sometimes pointed at both ends and made to reverse by means of a whip. *Potaku tukiri* or humming tops were made from small gourds and because of their loud wailing sound, were used in ceremonial mourning of the dead or to avenge a defeated clan. In Borneo very large wood tops often have a spindle seven inches long. In the Solomons, they are made of large hard nuts.

The top was known in Europe as early as the 14th century and in Shakespeare's day a large village top was often kept for use in cold weather as a warming-up exercise. During Napoleon's time a Chinese game known for centuries as *Koen-gen* was introduced as diabolo and became the rage. The spool or devil was whipped up by a cord, tossed up by the player and caught again on the cord. During the 18th century the hexagon *teetotum* (known to the ancient Greeks and Romans) was used in place of forbidden dice. Tops are still popular and a top of plastic and metal often plays choral reeds and changes colours while spinning.

For scientific properties of the top, *see* GYROSCOPE.

TOPAZ is a mineral used as a gem stone, and is of some industrial value as a raw material for refractories, sharing with kyanite and similar minerals the property, when heated to the proper temperature, of conversion to mullite (*q.v.*). Chemically it is a fluosilicate of aluminum in which part of the fluorine may be replaced by hydroxyl, the formula being $Al_2SiO_4(F,OH)_2$. With this range in chemical composition there is a slight variation in the specific gravity (3.5–3.6) and in the optical properties. Topaz is the standard for hardness of 8 on the Mohs' scale (*q.v.*). It is infusible and is insoluble in acids. It is formed through the agency of fluorine-bearing vapours given off during the last stages in the crystallization of igneous rocks, and typically occurs in cavities in rhyolites and granite, in pegmatite dikes and in high-temperature veins. It is often associated with the tin-bearing mineral cassiterite, and thus can be useful as an indication of the presence of tin ore.

Topaz is orthorhombic, and the crystals are usually prismatic in habit, with several dome and pyramid faces. The prism faces are striated vertically, in contradistinction to quartz in which the prism faces are striated horizontally. Usually the crystals are attached at one end in the rock cavities in which they were formed, and when detached from the matrix they often break along a flat surface parallel to the basal plane. This perfect cleavage is an important character, and enables topaz to be distinguished at sight from other minerals of similar appearance. The ,cleavage flakes when examined in convergent polarized light show a good biaxial interference figure.

The crystals are often perfectly colourless and water clear, but owing to the presence of traces of various colouring matters they may show a wide range of colours—red, yellow, brown, green, blue. Further, some of these colours are not stable. The fine brown crystals from pegmatite veins in Transbaikalia, Siberia, and the smaller wine-yellow crystals occurring in rhyolite in Colorado and Utah, fade on exposure to light; and the sherry-yellow crystals from Brazil assume a fine pink colour when they are heated.

The sherry-yellow crystals of topaz, which in the past have been cut and extensively used in jewelry, are all from the neighbourhood of Ouro Preto, in Brazil; ,and it is this material that has supplied the pink ("burnt") topaz.' Brazil also supplies colourless and pale-blue topaz. Good crystals of pale-blue and green colours have come from the Ural mountains and from Nerchinsk in Siberia. Colourless waterworn crystals and clear pebbles resembling rock crystal are abundant in the alluvial deposits of tin ore in northern Nigeria, and small colourless crystals are well known from the Cornish tin mines. Some crystals are large; one, of transparent material, weighing almost 600 Ib., from a pegmatite in Brazil. is on exhibition in the American Museum of Natural History, New York. *See* also GEM. (L. J. S.; B. H. M.; X.)

TOPE, name given to various tumuluslike structures in India, almost aluays connected with Buddhist shrines or sites and forming, undoubtedly, the most primitive type of Buddhist temple. They are usually built over, enclose one or more relics of Buddha, and consist of a low, vertical, cylindrical wall or drum surmounted by a solid conical mass of carefully built masonry. The most famous of the Indian topes is the largest of a group at Sanchi, which is generally attributed to the time of Asoka (3rd century

B.C.). In this the tope proper is surrounded by a circular walk, around which is a richly decorated stone fence, pierced by four lavishly sculptured gateways, the whole designed in forms manifestly reminiscent of wooden construction. (See INDIAN ARCHITECTURE.) The Sanskrit word for a tope, stupa (*q.v.*), is used generally of various types of sacred Buddhist structures in China, Japan, Java, etc., which all have the common characteristic of being high circular masses of solid masonry. Those of Tibet and China are often remarkable for their fantastic profiles.

TOPEKA, capital city of Kansas, and the counfy seat of Shawnee county, is in the east central part of the state 70 mi. W. of Kansas City. The name Topeka is of American Indian origin; one version meant "Smoky Hill." The present site was chosen in 1854 by a group of antislavery colonists from Lawrence, Kans., under the direction of Charles Robinson, a resident agent of the New Englancl Emigrant Aid company. Cyrus K. Holliday helped to found the city uhich later became headquarters for the building of the Atchison, Topeka and Santa Fe railway system. of nhich he was first president. Prior to the Civil War Topeka was the scene of several conflicts between the free soil and slave interests in Kansas territory, of which it was the temporary capital. The city became the permanent capital of Kansas in 1861 and was designated a first class city in 1881.

Topeka covers a land area of 12.5 sq.mi. and is known for its wide streets and avenues which are well shaded in the residential areas. The population has three main sources of income: a rich agricultural area, manufacturing and governmental services. Of the 48.000 wage and salaried personnel, over 12,000 are employed by some governmental agency. Approximately 8.000 persons are employed in over 200 manufacturing plants. Goodyear Tire and Rubber, the Dupont company and Forbes air base are leading employers and several insurance companies have home and regional offices there. The area is served by the Topeka Capital and the State Journal.

The Menninger foundation has made Topeka a national centre for the treatment of mental illness The foundation has become an important psychiatric training school for the medical profession. There are six major hospitals in the city. Washburn Municipal university, founded in 1865 and made municipal in 1941, is known for its well established law school. The Mulvane art museum is located on the Washburn campus. The state capitol, modeled after the national capitol (1866–1903) is in the centre of the business district. The J. Stewart Curry and the David Overmeyer murals are in the capitol. The Kansas State Historical society's memorial building, located east of the capitol, has an extensive historical collection for research and a modern museum. The city has many churches and is the seat of an Episcopal diocese.

Topeka maintains a year-round supervised recreational program. There are many spacious parks. Lake Shawnee is a boating and picnic area. Gage park has the Reinsch collection of over 20.000 roses. The city is the home of the Topeka Hawks. of the western baseball league, and the Kansas free fair. The municipal auditorium is used for the civic theatre and symphony concerts.

Pop. (1960) city, 119,484; standard metropolitan statistical area (Shawnee county) 141,286. For comparative city population figures see table in KANSAS: Population. (A. B SR.)

TOPETE, JUAN BAUTISTA (1821–1885), Spanish naval commander and politician, was born in Mexico on May 24, 1821. His father and grandfather were also Spanish admirals. He entered the navy at the age of 17, cut out a Carlist vessel in 1839, became a midshipman at 22, obtained the cross of naval merit for saving the life of a sailor in 1841 and became a lieutenant in 1845. He served on the West Indian station for three years, and was engaged in repressing the slave trade before he was promoted frigate captain in 1857. He was chief of staff to the fleet during the Morocco War, 1859, after which he got the crosses of San Fernando and San Hermenegildo. Having been appointed chief of the Carrara arsenal at Cádiz, he was elected deputy and joined the Union Liberal of O'Donnell and Serrano. He was sent out to the Pacific in command of the frigate "Blanca," and was present at the bombardment of Valparaiso and Callao, where he was badly wounded, and in other engagements of the war against Chile and Peru. On his return to Spain, Topete was made port captain at Cádiz, which enabled him to assume the leadership of the conspiracy in the fleet against the Bourbon monarchy. He sent the steamer "Buenaventura" to the Canary isle for Serrano and the other exiles; and when Prim and Sagasta arrived from Gibraltar, the whole fleet under the influence of Topete took such an attitude that the people, garrison and authorities of Cádiz followed suit. Topete took part in all the acts of the revolutionary government, accepted the post of marine minister, was elected a member of the *cortes* of 1869, supported the pretensions of Montpensier, opposed the election of Amadeus, sat in several cabinets of that king's reign, was prosecuted by the Federal republic of 1873 and again took charge of the marine under Serrano in 1874. After the Restoration Topete for some years held aloof, but finally accepted the presidency of a naval board in 1877, and sat in the Senate as a life peer until his death on Oct. 29, 1885 at Madrid.

TOPFFER, RODOLPHE (1799–1846), Swiss writer and artist, son of the painter Adam Topffer, was born at Geneva on Jan. 31,1799. Abandoning his art studies on account of weak eyesight, he became a teacher, eventually establishing a school of his own (1824), which attracted boys from England and America as well as from other European countries. He was the first to introduce schoolboy tramps in the Alps, and he described these in his Voyages *en* Zigzag, illustrated by clever drawings by himself. From 1832 till his death, on June 8, 1846, he was professor of belles-lettres at the university of Geneva. He wrote various novels and short stories, including the exquisite little masterpiece, La *Bibliothèque* de mon *Oncle* (1833). His tales were collected under the title Nouvelles *Génevoises* (1841), and several have been translated into English. His series of humorous drawings with explanatory text (Doctor *Festus,* Monsieur Vieux-Bois, etc.), collected under the title of Histoires en *Estampes* (1846–47), were very popular and earned the cordial approbation of Goethe.

See the lives by Relave (1886), A. Blondel (1887) and Glöckner (1891). Also E. Rambert, *Écrivains* nationaux (1874), E. Javelle, Souvenirs d'un *alpiniste* (1886; Engl. trans., 1899), and notices in Ste. Beuve's Causeries *du lundi* (1852–62), *Derniers* portraits *littéraires* (1852) and Portraits contemporains (1846).

TOPOLOGY, ALGEBRAIC. This branch of topology, also described as "combinatorial," is characterized by the extensive use of algebraic techniques for the solution of topological problems. Although isolated examples of its methods may be found in the work of various mathematicians of the 19th century, the first person to attempt to develop the subject systematically was the French mathematician Henri Poincaré in a series of papers written from 1895 to 1905. Since then the subject has grown at an increasing rate and has had important influence on the other principal branches of mathematics.

The aim of this article is to consider some typical problems in the field and then apply homology theory, the core of algebraic topology, to the solution of these problems. For a general background in the subject and an explanation of technical terms see TOPOLOGY, GENERAL.

Typical Problems. — The following examples were chosen as representative yet not too technical.

Example 1.—By a "plane domain" is meant an open, connected subset of the plane of ordinary Euclidean geometry. Given any two plane domains, one can ask whether or not they are homeomorphic, or topologically equivalent (see TOPOLOGY, GENERAL: *Homeomorphism*). Examples of plane domains are shown in fig. 1. It seems reasonable to conjecture that the domains represented in 1(A) and 1(B) are homeomorphic, as are those in 1(C) and 1(D), but that no other pair of these domains is homeomorphic. The use of homology theory to prove the last part of this statement is indicated below.

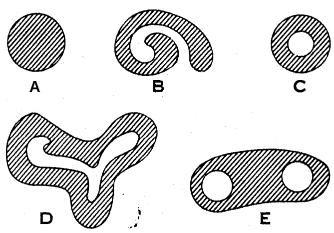

FIG I — EXAMPLES OF PLANE DOMAINS (see TEXT)

Example 2.—In a similar manner, given two closed surfaces in ordinary Euclidean three-dimensional space (3-space), we can ask whether or not they are homeomorphic. Examples of closed surfaces in 3-space are those of a sphere an egg, a cube. a torus (a doughnut-shaped surface, see fig. 2(A)) and the surfaces pictured in fig. 2(B) and 2(C). Later it will be proved that no two of the closed surfaces shown in fig. 2 are homeomorphic and that none of them is homeomorphic to the suriace of a sphere.

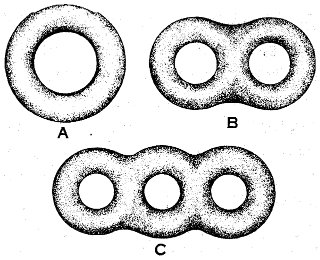

FIG. 2.— EXAMPLES OF CLOSED SURFACES (*see* TEXT)

Examples 1 and 2 both have higher-dimensional analogues. Instead of considering domains in the plane, one could consider' domains in Euclidean 3-space, or more generally, in Euclidean n-space for any integer n. Instead of closed surfaces. once could consider their three-dimensional analogues: which are called "closed three-dimensional manifolds." or even their n-dimensional analogues, called "closed n-dimensional manifolds" (see MANIFOLDS).

In order to describe the next example it is convenient to introduce some conventions of notation and terminology. Recall that a circle of unit radius with centre at the origin of a given co-ordinate system in the plane is the set of all points (x_1, x_2) which satisfy the equation $x_1^2 + x_2^2 = 1$. Similarly the unit sphere with centre at the origin of a given co-ordinate system in 3-space is the set of all points (x_1, x_2, x_3) which satisfy the equation $x_1^2 + x_2^2 + x_3^2 = 1$. In an analogous manner we define the unit n-sphere, S^n, to be the set of all points $(x_1, x_2, \ldots, x_{n+1})$ in Euclidean $(n+1)$-space which satisfy the equation $x_1^2 + x_2^2 + \ldots + x_{n+1}^2 = 1$. Thus S^1 is a unit circle and ST is the unit sphere in 3-space. The set of points in $(n+1)$-space which lie inside or on the unit n-sphere will be called the $(n+1)$-dimensional ball, E^{n+1}. To be precise, E^{n+1} is the set of all points $(x_1, x_2, \ldots, x_{n+1})$ in $(n+1)$-dimensional space which satisfy the inequality $x_1^2 + x_2^2 + \ldots + x_{n+1}^2 \leqq 1$. Thus E^2 is the disk in the plane which is bounded by the unit circle, and E^3 is the solid ball in 3-space bounded by the unit sphere. Note that according to the definitions stated above. S^n is a subset of E^{n+1}.

Example 3.—Consider the following question: Does there exist a continuous map f of the $(n+1)$-dimensional ball E^{n+1} onto the n-sphere S^n such that for any point p of S^n, $f(p) = p$? If one tries to visualize geometrically what the existence of such a continuous map would mean for $n = 1$ and $n = 2$, geometrical intuition strongly suggests that such a map cannot exist in these two cases. In fact it is a theorem of algebraic topology that such a map cannot exist for any value of n. Indications of the proof are given below.

Why should there be any interest in such a theorem of a negative nature? One reason is that it is representative of one of the most important problems of algebraic topology (see *Homotopy Theory,* below); another is that it implies one of the classical theorems of algebraic topology. the fixed-point theorem of L. E. J. Brouwer. This theorem asserts that any continuous map g of the n-dimensional ball E^n into itself has at least one fixed point. *i.e.,* a point x such that $g(x) = x$. To prove this assume the contrary: that there exists a continuous map g of E^n into itself which has no fixed points, *i.e.,* the points x and $g(x)$ are always distinct. Then define a continuous map f of E^n into the boundary sphere S^{n-1} as follows: for any point x of E^n, $f(x)$ is to be the point of intersection of the straight line through x and $g(x)$ with the sphere S^{n-1}. Moreover, $f(x)$ is to be chosen so that either x lies between $f(x)$ and g (~)or $f(x)$ and x coincide. (The situation for $n = 2$ is illustrated in fig. 3.) It can be shown that the map f is continuous and it is clear that for any point x of S^{n-1}, $f(x) = x$. But the existence of such a map f of E^n into S^{n-1} contradicts the theorem above. Thus the assumption that g has no fixed points is false and Brouwer's theorem is established. Although Brouwer's theorem is very plausible for the cases $n = 1$, 2 or 3, the advantage of the methods of algebraic topology is that it is proved for all integers n at once.

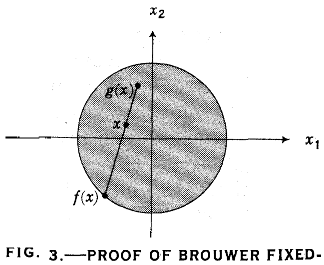

FIG. 3.—PROOF OF BROUWER FIXED-POINT THEOREM (see TEXT)

There is great mathematical interest in fixed-point theorems such as Brouwer's because they have been used in various other branches of mathematics (*e.g.,* differential equations, the theory of games) to establish fundamental existence theorems.

The Homology Groups.—In homology theory one studies closed curves, closed surfaces and similar geometric configurations in a given topological space. Simple examples show that such a study is likely to reveal important topological information about the space in question. For example. the spherical surface S^2 has the property that any simple closed curve separates it into two domains. On the other hand, on the torus there are simple closed curves which do not separate it into two domains. These are basic topological properties of the sphere and torus and show that they are not homeomorphic.

Orientation.—The curves, surfaces, etc.. which one considers in homology theory are usually "oriented." To orient a curve or line segment, place an arrow on it indicating the positive direction. To orient a surface or domain on a surface one must choose which direction of rotation (around small circles in the surface) is to be considered positive. There are two possible ways of orienting a curve or surface and the choice is purely arbitrary. The two orientations possible for a certain plane domain are indicated in fig. 4. (Nonorientable surfaces exist but are not considered here; see MANIFOLDS.) If we assign an orientation to a piece of a surface bounded by one or more curves. then the orientation of the surface in turn induces an orientation of the bounding curves in an obvious way. In fig. 3 the induced orientations of the boundary curves of the region are indicated in the two possible cases.

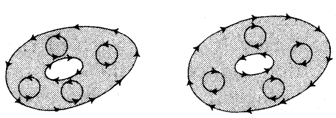

FIG. 4.— THE TWO POSSIBLE ORIENTATIONS OF A PLANE DOMAIN AND THE INDUCED ORIENTATIONS OF THE BOUNDARY CURVES

Considerations of orientation can be extended to regions in 3-space, or more generally, to three-dimensional manifolds and regions in three-dimensional manifolds. There are various ways of doing this. One way is by consideration of screw threads or spirals (like a spiral staircase) in the given region. Spirals may be right-handed or left-handed. In orienting the region one of the tno types of spirals is designated as the positive type; again the choice is entirely arbitrary.

It is easy to devise rules for specifying the induced orientation of the bounding surfaces of an oriented three-dimensional domain; we assume that this has been done. The situation is similar to that of the induced orientation of the boundary curves of an oriented tno-dimensional domain on a surface.

Questions of orientation occur in branches of mathematics other than topology—as, for example, in the discussion of line integrals, surface integrals and volume integrals in calculus. The correct staternenti of the well-known theorems of Carl Friedrich Gauss, George Green and Sir George Gabriel Stokes about these integrals require certain assumptions regarding orientation.

These definitions of orientation can be extended to n-dimensional manifolds or regions in such manifolds Naturally for values of $n > 3$ the ordinary geometric intuition is useless. The definitions are of necessity of a more formal nature. based on analogy nith the one-, tno- or three-dimensional case. It is not possible to go into this matter in the present article.

Definition of *Homology Groups:* Cycles.—The first step in the definition of the homology groups of a topological space X is the definition of a cycle in X. A one-dimensional cycle (1-cycle) in X is an expression of the form

$$z = \alpha_1 C_1 + \alpha_2 C_2 + \ldots + \alpha_k C_k$$

where $\alpha_1, \alpha_2, \ldots, \alpha_k$ are integers (positive, negative or zero) and $C_1, C_2, \ldots, C_k$ are oriented closed curves in X. A two-dimensional cycle (2-cycle) in X is an expression of the form

$$z = \alpha_1 S_1 + \alpha_2 S_2 + \ldots + \alpha_k S_k$$

where the α_1's ere integers and $S_1, S_2, \ldots, S_k$ are oriented closed surfaces in X. A three-dimensional cycle (3-cycle) in X is an expression of the form

$$z = \alpha_1 M_1 + \alpha_2 M_2 + \ldots + \alpha_k M_k$$

where once again the a's are integers and $M_1, M_2, \ldots, M_k$ are oriented closed 3-manifolds in X. One could define in an analogous manner n-dimensional cycles in X for every positive integer n.

These definitions call for tno observations. First, the curves, surfaces and 3-manifolds in the above definitions must be allowed to have self-intersections and various other singularities. Secondly, a reversal of the orientation of a curve, surface or 3-manifold occurring in the expression for a cycle is assumed to have the same effect as changing the sign of that particular term in the cycle. For example, if C_1 and C_1' denote the same curve but with opposite orientations, then

$$\alpha_1 C_1 + \alpha_2 C_2 = -\alpha_1 C_1' + \alpha_2 C_2$$

Cycles are added and subtracted in an obvious way. For example, if $z = \alpha_1 S_1 + \alpha_2 S_2 + \ldots + \alpha_k S_k$ and $z' = \alpha_1' S_1 + \alpha_2' S_2 + \ldots + \alpha_k' S_k$ are 2-cycles in X, then

$$z + z' = (\alpha_1 + \alpha_1')S_1 + (\alpha_2 + \alpha_2')S_2 + \ldots + (\alpha_k + \alpha_k')S_k$$

and

$$z - z' = (\alpha_1 - \alpha_1')S_1 + (\alpha_2 - \alpha_2')S_2 + \ldots + (\alpha_k - \alpha_k')S_k$$

With these definitions it is clear that the set of all 1-cycles in X is a commutative group (*see* GROUPS) under the operation of addition. Similarly the set of all 2-cycles in X and the set of all 3-cycles in X are commutative groups.

Note that the set of boundary curves of an oriented domain on a surface in X may be considered as a 1-cycle in X if each of the boundary curves is given the orientation induced by the orientation of the domain and assigned the coefficient $+1$. Such a cycle will be called a bounding 1-cycle in X. More generally, a cycle which is a sum of cycles of this type will also be called a bounding 1-cycle in X. Not every 1-cycle need be a bounding cycle; consider, for instance. the case in which X is a torus.

Similarly. starting with the set of bounding surfaces of an oriented three-dimensional domain in X one can define the concept of a bounding 2-cycle. One could imagine the definition of a bounding 3-cycle, although there are complications when extending this concept to higher dimensions. The remarks about bounding 1-cycles in the preceding paragraph also hold for bounding cycles of dimension 2 or 3. Note that by the very definition the set of all bounding cycles in any dimension is a subgroup of the group of all cycles in that dimension.

Homology Classes.—Two cycles z_1 and z_2 are said to be homologous (notation: $z_1 \sim z_2$) if their difference $z_1 - z_2$ is a bounding cycle. This is an equivalence relation and may be used to separate all the cycles of any given dimension into homology classes: two cycles belong to the same homology class if, and only if, they are homologous. The homology relation has the important property of being compatible with the addition of cycles. By this is meant that if $z_1 \sim z_2$ and $y_1 \sim y_2$, then $y_1 + z_1 \sim y_2 + z_2$. Because of this the addition of cycles may be used to define the addition of homology classes. To be precise, if u and v are homology classes in X, to define their sum $u + v$ one chooses representative cycles y and z from the homology classes u and v respectively and defines $u + v$ to be the homology class of $y + z$. This definition is independent of the choice of the representative cycles. It is seen that the addition between homology classes thus defined satisfies all the axioms of a group. Thus the following groups have been defined: the one-dimensional homology group of X, denoted by $H_1(X)$; the two-dimensional homology group of X, $H_2(X)$; etc. These groups are basic to all iurther developments in algebraic topology; it is hard to overestimate their importance. Actually there is not much interest in the cycles as such; it is rather the homology classes of cycles that are important.

Let us consider the homology groups of the spaces mentioned in Examples 1 and 2. In the plane domains considered in Example 1, the two-dimensional and all higher-dimensional homology groups are trivial groups (consisting of the zero element alone) because there are no bona fide two-dimensional (or higher-dimensional) cycles. Thus the main interest is in the one-dimensional homology group. In the domains illustrated in fig. 1(A) and 1(B) every 1-cycle is a bounding cycle; hence the one-dimensional homology group is trivial. This is not true of the domains illustrated in fig. 1(C) and 1(D). however. In these cases the one-dimensional homology group is infinite cyclic (*i.e.,* isomorphic to the group of integers under addition'). This situation may be described more precisely as follows: Choose an oriented closed curve C that goes around the hole in the domain exactly once; then every one-dimensional homology class contains a unique cycle a.C for some integer a.

The one-dimensional homology group of the domain shown in fig. 1(E) has a slightly more complicated structure. If one chooses oriented closed curves C_1 and C_2 in this domain such that C_1 goes around one of the holes exactly once and C_2 goes around the other hole once, then every one-dimensional homology class contains a unique 1-cycle of the form $\alpha_1 C_1 + \alpha_2 C_2$, where α_1 and α_2 ark integers.

Since spaces which are homeomorphic must obviously have isomorphic homology groups. these considerations show that the domains in fig, 1(A) and 1(C) cannot be homeomorphic. nor can the domains in fig. 1(C) and 1(E), for example.

For closed surfaces in 3-space, such as those considered in Example 2 above, the two-dimensional homology group is infinite cyclic. In each case the entire surface, when given an orientation and assigned a coefficient. is a 2-cycle which is not bounding. The three-dimensional homology group is trivial in each case because there cannot be nonzero 3-cycles in a 2-space. The one-dimensional homology groups are different in the diiferent cases, however. For the case of a spherical surface the group is trivial; every 1-cycle is a bounding cycle. In the case of a torus it is a group with two generators, isomorphic to the one-dimensional homology group of the domain shown in fig. 1(E). One may choose as generating cycles oriented circles C_1 and C_2 which lie in planes perpendicular to each other. each of which goes around the torus exactly once and which intersect in a single point. Then any 1-cycle is homologous to a unique cycle of the form $\alpha_1 C_1 + \alpha_2 C_2$.

The one-dimensional homology group of the surface in fig. 1(B) has four independent generators. and that in fig. 1(C) has six.

Note that these considerations show that no two of these surfaces are homeomorphic since their one-dimensional homology groups are nonisomorphic.

The Homomorphism Induced by a Continuous Map.— Suppose that X and Y are topological spaces and f is a continuous mapping of X into Y (notation: $f: X \to Y$). If C is a closed curve in X, then the image of C under f (denoted by $f(C)$) is a closed curve in Y. Moreover if C is oriented, this orientation is carried over to $f(C)$ by the map f in an obvious way, so we may consider $f(C)$ as an oriented closed curve. This suggests the iollowing definition: If $z = \alpha_1 C_1 + \alpha_2 C_2 + \ldots + \alpha_k C_k$ is any 1-cycle in X, then let

$$f_{\#}(z) = \alpha_1 f(C_1) + \alpha_2 f(C_2) + \ldots + \alpha_k f(C_k)$$

It is clear that $f_{\#}(z + z') = f_{\#}(z) + f_{\#}(z')$ for any 1-cycles z and z' in X. Thus $f_{\#}$ is a homomorphism of the group of 1-cycles of X into the group of 1-cycles of Y. Furthermore this homomorphism sends bounding cycles into bounding cycles. This follows from the fact that the image of an oriented piece of surface in X bounded by several curves is carried by f into an oriented piece of surface in Y bounded by the image curves. As a consequence homologous cycles are carried into homologous cycles by $f_{\#}$ and all the cycles in any homology class are mapped into a single homology class. Thus $f_{\#}$ induces a homomorphism of the homology group $H_1(X)$ into the homology group $H_1(Y)$, denoted by f_*: $H_1(X) \to H_1(Y)$.

In a similar manner the function f induces homomorphisms f_*: $H_2(X) \to H_2(Y)$, $H_3(X) \to H_3(Y)$, etc. The details are exactly the same as in the one-dimensional case.

The homomorphisms of homology groups induced by continuous maps are as important as the homology groups themselves. Applications of this concept to one of the examples given above are shown below. First, it is necessary to note that these induced homomorphisms satisfy the following two rather obvious but important conditions:

1. Let $i:X \to X$ be the identity map of the space X, *i.e.*, $i(x) = x$ for any point x in X. Then the induced homomorphism $i_*:H_n(X) \to H_n(X)$ is also the identity, *i.e.*, $i_*(u) = u$ for any homology class u.

2. Let X, Y and Z be topological spaces and $f:X \to Y$, $g: Y \to Z$ be continuous maps. Define a continuous map $h:X \to Z$ by $h(x) = g[f(x)]$ for any point x of X; for brevity one often writes $h = gf$. The map h is called the composition of f and g. Then the induced homomorphism $h_*:H_n(X) \to H_n(Z)$ is the composition of the homomorphisms $f_*:H_n(X) \to H_n(Y)$ and $g_*: H_n(Y) \to H_n(Z)$, *i.e.*, $h_*(u) = g_*f_*(u)$ for any homology class u in X, or more briefly; $h_* = g_*f_*$. The proof of these conditions can be left to the reader.

As an application of these ideas the theorem mentioned in connection with Example 3, above, can be proved. Assume that there exists a continuous map $f:E^{n+1} \to S^n$ such that $f(x) = x$ for any point x in S^n. It will be demonstrated that this assumption leads to a contradiction. thus establishing the theorem. In the course of the proof. the following facts about the homology groups of the spaces E^{n+1} and S^n are needed: (a) all the homology groups of E^{n+1} are trivial groups (*i.e.*, they contain only the zero element); (b) the homology group $H_n(S^n)$ is infinite cyclic. These two facts are certainly plausible in case $n = 1$ or $n = 2$; methods of proving facts like this are discussed below.

Now let $g:S^n \to E^{n+1}$ be the continuous map defined by $g(x) = x$ for any point x of S^n. Let $h = fg$ denote the composition of g and f. The hypothesis that $f(x) = x$ for any point x of S^n implies that $h:S^n \to S^n$ is the identity map of S^n. Then apply the two fundamental properties of induced homomorphisms mentioned above. By property (1), $h_*:H_n(S^n) \to H_n(S^n)$ is the identity homomorphisnl. By property (2), h_* is the composition of the homomorphisms $g_*:H_n(S^n) \to H_n(E^{n+1})$ and $f_*:H_n(E^{n+1}) \to H_n(S^n)$. But this is impossible since $H_n(S^n)$ has an infinite number of distinct elements, while $H_n(E^{n+1})$ consists of the zero element alone. Thus the theorem is established.

In the description of homology theory in the preceding paragraphs it may be observed that the definitions lack mathematical precision at certain points. This is especially noticeable when one tries to define n-dimensional homology groups for $n > 2$ by these methods. Although details cannot be given in the present article. there are methods of avoiding these difficulties. Completely rigourous definitions of the terms "n-dimensional cycle in X," "bounding cycle" and "n-dimensional homology group" are given in textbooks.

Determination of the Homology Groups of a Space.—In each of the preceding examples of the application of homology theory to a topological problem it was necessary to know the structure of certain homology groups. The purpose of the present section is to give brief descriptions of methods of obtaining such information.

In certain cases a topological space can be cut into small pieces of very simple type. For example, a closed surface such as that shon-n in fig. 2 could be cut into small triangular pieces. Analogously, a closed 3-manifold could be dissected into small tetrahedra. Whenever it is possible to chop a topological space into sections (line segments, triangles: tetrahedra and their higher-dimensional analogues) that fit together nicely, it is possible to determine the structure of the homology groups from the dissection by following a routine procedure. The method is of great theoretical but little practical importance because of the lengthy computations involved.

If A is a closed subset of a topological space X, and $X - A$ is the complement of A ($X - A$ is an open subset of X), then certain relations must hold between the homology groups of $A, X - A$ and X. These relations are expressed by means of something called an "exact sequence of groups and homomorphisms." which is a concept of great importance in the further development of algebraic topology.

If A and B are closed subsets of a space X such that the union of A and B is the whole space X, then certain relations must hold between the homology groups of the four spaces X, A, B and $A \cap B$ (here $A \cap B$ denotes the intersection of A and B). Once again this relation is expressed by means of an exact sequence of groups and homomorphisms, which is called the "Mayer-Vietoris sequence" in this case.

If X is the product of two spaces A and B (*i.e.*, $X = A \times B$), then the homology groups of X can be computed explicitly if the homology groups of A and B are known. The relations involved are called the "Künneth formulas."

There is a generalization of the notion of product space called a "fibre space" which is of great importance in algebraic topology, differential geometry and algebraic geometry because of its frequent occurrence and many "nice" properties. Roughly speaking, a fibre space is a twisted or a local product space. For example, the product of a circle and a segment is a cylindrical surface, like a belt. By introducing a twist one obtains the one-sided surface known as a Mobius strip (*see* MANIFOLDS: *Möbius Strip;* GEOMETRY: *Topology*).

Locally. 'a Mobius strip is the product of a segment with a piece of a circle but it is not a product space in the large because of the twist. Given two spaces A and B, there is only one way to form the product space $A \times B$, but there are usually many ways to build a fibre space from A and B. Certain relations hold between the homology groups of A and B and those of the various fibre spaces which can be constructed from A and B. These relations are much more complicated than the Kunneth formulas for product spaces.

In the preceding paragraphs we have mentioned various ways of building topological spaces out of simpler spaces and have asserted in each case that certain useful relations hold between the homology groups of the various spaces involved. This is not the only type of information available for determining homology groups, however. For example, one of the most famous theorems of algebraic topology is the Poincaré duality theorem. which asserts that for any closed, orientable, n-dimensional manifold X the homology group $H_q(X)$ is completely determined by the groups $H_{n-q}(X)$ and $H_{n-q-1}(X)$.

Homotopy Theory.—If X and Y are topological spaces, two maps f and g of X into Y are *homotopic* if there exists for each real number t such that $0 \leqq t \leqq 1$ a map $h_t:X \to Y$ such that $h_0 = f$, $h_1 = g$ and the position of the image point $h_t(x)$ depends continuously on both x and t. It is helpful to think of the variable t as representing time. At time $t = 0$, $h_t = f$; at time $t = 1$, $h_t = g$; and during the time interval $0 \leqq t \leqq 1$ the map f is continuously deformed into the map g. The relation of being homotopic is an equivalence relation between maps and it enables one to separate the set of all continuous maps from X into Y into classes, called *homotopy classes;* two maps belong to the same homotopy class if and only if they are homotopic.

Homotopic maps have many properties in common. For example, if f and g are homotopic. then the induced homomorphisms f_* and g_* of $H_n(X)$ into $H_n(Y)$ are the same. This may be seen in case $n = 1$ as follows: Let C be any oriented closed curve in X and let $h_t:X \to Y$ be defined for $0 \leqq t \leqq 1$ and have the properties listed in the preceding paragraph. Consider the various image curves $h_t(C)$. As t varies from 0 to 1, these image curves sweep out a cylindrical surface in Y bounded by the curves $h_0(C) = f(C)$ and $h_1(C) = g(C)$. Taking account of orientations. it is seen that the cycles $f(C)$ and $g(C)$ are homologous. It follows easily that if $z = \alpha_1 C_1 + \alpha_2 C_2 + \ldots + \alpha_k C_k$ is any 1-cycle in X, then $f_\#(z)$ and $g_\#(z)$ are homologous; hence if u is the homology class of z, $f_*(u) = g_*(u)$.

As an example of homotopy classification of maps, consider the case in which $X = S^1$, a circle! and Y is the plane domain shown in fig. 1(C). A continuous map $f:S^1 \to Y$ defines a closed curve in Y. Two such maps (or curves) are homotopic if, and only if, they wind around the hole in the domain the same number of times.

In general, the homotopy classification of maps of a given space X into another given space Y is one of the most difficult yet important problems of algebraic topology. Any solution of particular cases of this problem is likely to have significant implications. In some cases it has been found possible to define an "addition" or "multiplication" of homotopy classes of maps $X \to Y$ so as to obtain a group. If this can be done, the problem of describing the set of all homotopy classes of maps $X \to Y$ becomes the problem of determining the structure of the group of all homotopy classes, which is usually a more precise problem. If $X = S^n$, an n-sphere, then it is always possible to define an addition between homotopy classes of maps $X \to Y$ so as to obtain a group, denoted by $\pi_n(Y)$, and called the nth homotopy group of Y. In case $n =$ I this group is called the fundamental group, or PoincarC group, of Y. The homotopy groups for $n > 1$ were introduced by the Polish mathematician W. Hurewicz in 1935 and have played an increasingly important role in algebraic topology. Although the homotopy groups have many properties which are analogues of properties of homology groups, it is usually much more difficult to determine the homotopy groups than the homology groups.

Alongside the classification of continuous maps into homotopy classes there is a corresponding classification of topological spaces according to homotopy type. Two topological spaces X and Y are of the same homotopy type if and only if there exist continuous maps $f: X \to Y$ and $g: Y \to X$ such that the composed map gf is homotopic to the identity map of X onto itself, and the map fg is homotopic to the identity map of Y onto itself. If X and Y are homeomorphic, then they are of the same homotopy type. However. spaces may be of the same homotopy type without being homeomorphic. A simple example is the circle S^1 and the ring-shaped region in the plane shown in fig. 1(c).

Spaces which are of the same homotopy type have many similar properties. For example, if X and Y are of the same homotopy type, then their homology groups are isomorphic. In fact if $f: X \to Y$ and $g: Y \to X$ are continuous maps such that the composed maps gf and fg are homotopic to identity maps, then the induced homomorphisms $f_*: H_n(X) \to H_n(Y)$ and $g_*: H_n(Y) \to H_n(X)$ are isomorphisms. This may readily be proved on the basis of the properties already listed for the homomorphisms induced by continuous maps.

As the subject of algebraic topology developed and matured, ideas involving the homotopy classification of mappings and the classification of spaces according to homotopy type became more prominent. The re-examination of many of the more significant theorems of algebraic topology showed that they actually concerned entire homotopy classes of maps or all spaces of a certain homotopy type, and so belonged to the domain of homotopy theory. Also the classical problem of trying to find sufficient conditions for two spaces to be homeomorphic seemed impossibly difficult except in a few favourable cases. On the other hand it seemed like a much more reasonable problem to try to obtain sufficient conditions for two spaces to be of the same homotopy type: many results of this kind are known.

The *Extension Problem.*—This is another leading problem of homotopy theory, and it may be stated as follows: Suppose X and Y are topological spaces; A is a closed subset of X; and $h: A \to Y$ is a continuous map. Does there exist a continuous map $g: X \to Y$ such that g is an extension of h, *i.e.,* so that $g(x) = h(x)$ for any point x of A? Example 3, considered above, is really an extension problem. In this example $X = E^{n+1}$, $Y = S^n$, $A = S^n$, and $h: A \to Y$ is the identity map. The use of homology theory to prove the nonexistence of an extension in this example is a typical method of attacking an extension problem. By this method one can obtain necessary conditions for the existence of an extension, which in certain cases are also sufficient.

The homotopy classification problem and the extension problem are inextricably linked together. Any progress on either implies corresponding progress on the other. They are the object of much research in algebraic topology.

Other Topics.—A brief article such as this must of necessity omit many important features. One such topic is homology with coefficientsother than integers. A cycle, as defined above, is an expression of the form $\alpha_1 C_1 + \alpha_2 C_2 + \ldots + \alpha_k C_k$, where the coefficients $\alpha_1, \alpha_2, \ldots, \alpha_k$ are integers. One could equally well allow these coefficients to be rational fractions, real numbers or complex numbers and an analogous homology theory could be developed. More generally, one could choose coefficients from any ring or even from any commutative group. In certain investigations it is quite natural to do this.

Cohomology Theory.—This represents another important modification of homology theory. Although cohomology groups have properties similar to homology groups, they have several important advantages. It is possible, for instance, to define a "product" of cohomology classes (sometimes called the "cup product"). With this product and the usual addition of cohomology classes the direct sum of the cohomology groups of all dimensions becomes a ring, called the cohomology ring. This is definitely a richer algebraic structure than the homology groups and enables one to obtain finer results in many cases.

One can go still further and define various other algebraic operations on cohomology classes which have an invariant topological significance and lead to results not otherwise provable. The most important of these cohomology operations are the Steenrod squares and reduced powers (named after the U.S. mathematician Norman Steenrod) and the Pontrjagin powers (named after the Russian mathematician Leon Pontrjagin). The theory of these operations is extremely complicated. Finally, in certain situations cohomology groups definitely seem more natural than homology groups. For example, the Poincaré duality theorem mentioned earlier is easier to state precisely if cohomology groups are used.

TOPOLOGY, GENERAL. This branch of mathematics is so fundamental in nature that its influence is apparent in practically every other branch. Topology has also found uses among fields that are not integral parts of the domain of mathematics proper. Thus an intimate relation exists between some aspects of topology and symbolic logic. For applications of fixed-point theorems in mechanics *see* below. An approach to certain problems of psychology has been based on the concept of topological space. Because of its foundation in general-set theory. topology is not limited in its applications to problems of a quantitative character and it may therefore contribute to research in fields, such as the social sciences, that have not been considered susceptible to mathematical treatment.

Despite its basic character topology lacked full development until the advent of the 20th century, although its roots lie in the 19th-century researches of Georg Friedrich Bernhard Riemann, Georg Cantor and Henri PoincarC. Principally because of the geometric aspects of the topological work of Riemann and PoincarC, topology became known as a type of geometry—formerly called analysis situs, or "position analysis"—in which the shape and size of configurations are unimportant, the object of study being rather the "connectivity" of a figure. For example, that a circle is round. a triangle has corners or an ellipse is oval are not of interest from a topological point of view; what matters is that each of these figures is so constituted that (1) the omission of a single point leaves each of them connected (in a sense to be made precise below); and that (2) the omission of two points will in each case disconnect the figure. In topology all such figures—circles, triangles, ellipses, polygons, etc.—are designated by the same term, "simple closed curve."

If one imagines a circular figure made of some pliable material being subjected to stretching and bending of any sort without being torn in the process, then the figure may be said to be unaltered topologically, remaining a simple closed curve throughout the process. Similarly the surface of a sphere and the surface of a cube are topologically equivalent ("homeomorphic") but difier from the surface of the anchor ring or doughnut (torus) in the following manner: if S is the surface of a sphere or cube. then the omission of a simple closed curve in S disconnects S (this is part of the classical Jordan curve theorem); but a simple closed curve on a torus may or may not disconnect it, depending upon the particular simple closed curve chosen. Such properties of curves and surfaces as those exemplified here are topological properties.

The great advances in mathematical research made during the first few decades of the 20th century were to a rapidly increasing extent made possible by concepts which, while not geometrical in the older sense of the term. are evidently topological in nature. In topology itself a change took place which is evidenced in the dropping of the term ,'geometrical configuration" and its synonyms in favour of "point set" and ultimately "topological space." The notion of a configuration made up of a finite set of "pieces" such as straight-line intervals, triangles, etc., emphasized in the geometric combinatorial topology (see TOPOLOGY, ALGEBRAIC) of Riemann and Poincaré. gave way to the Cantorian concept of an organization of individual points, the number of points usually being infinite. It gradually became recognized that any collection of things, be it a set of numbers, algebraic entities? functions or even nonmathematical objects, can constitute a topological space in some sense or other, the degree of utility in such an interpretation being dependent upon the number of topological properties exhibited by the collection. From this realization stem the fundamental importance of topology and its use as a tool even in such investigations as those of the foundations of logic. This is not to imply that the older. geometric aspects lost their importance; it is rather the case that along with the rest of the subject their importance was enhanced by the newer concepts.

For a collection to be assigned a topological character it is sufficient that for each set M of its points the limit points of M 'be specified; then the collection may be called a topological space. The intuitive meaning of this becomes clearer: perhaps, if one returns to the well-known spaces of geometry for an illustration. Consider, for instance, the space in which the figures of ordinary plane geometry are imbedded—the Euclidean plane. denoted by E^2. Considering E^2 as a collection of points. a point p of E^2 may be called a "limit point" of a collection M of points of E^2 if it is true that every circle with centre p encloses points of M (that are different from p if p happens to belong to the collection M). For example. if M is the set of all points enclosed by a triangle T, then every point of T is a limit point of M; also every point of M is a limit point of M. On the other hand, no point exterior to T is a limit point of M, since each such point can bc enclosed in a circle whose interior contains no points of M. In three-dimensional Euclidean space. limit points may be defined similarly, but using spheres instead of circles. The intuitive concept underlying the notion of limit point then is that of nearness. or proximity, a point p being a limit point of a collection of points M if there are points of M arbitrarily near to p. However, the latter would not be an adequate definition since in some topological spaces no such notion as distance exists. In this manner. however, all the well-known spaces of the classical types of geometry become topological spaces. And an important part of topology is devoted to the study of Euclidean spaces and their subsets, as well as their counterparts in more general topological spaces.

Point Sets.—Since the configurations of topology are ultimately considered as being types of organizations of their individual points, and consequently called point sets (*q.v.*), a few of the terms and some of the symbols of set theory (see LOGIC) used in topology are given here.

The fact that a point p belongs to a point set A may be expressed by the relation $p \in A$, which is read "p is an element (or point) of A." A set which has at least two elements is called "nondegenerate": but if it has no elements it is called "empty.!' If the cardinal number of the elements of a set is not greater than that of the infinite set of positive integers. then the set is called "countable." (*See* NUMBER.) If A and B are two sets. their "sum" or "union" (in set-theoretic symbols $A + B$) is the set which consists of all elements x such that $x \in A$, $x \in B$, or both. The "product" or "intersection" of A and B ($A \cdot B$) is the set which consists of all elements x such that $x \in A$ and $x \in B$. (Thus if A and B are two nonparallel straight lines in the plane, their product is a set consisting of a single point.) By the "difference" $A - B$ is meant the set of all elements of A that are not in B; in case B is itself part of A, then B is called a "subset" of A and $A - B$ is called the "complement" of B in A. If A and B have no point in common. they are called "disjoint." See also SET THEORY (THEORY OF AGGREGATES).

Homeomorphism.—A basic notion of topology is that of topological equivalence or homeomorphism and it is this notion that makes precise the sense in which all circles, triangles, etc., in the Euclidean plane E^2 are considered topologically to be the same. Suppose that S and T are two collections in which limit points have been specified (hence topological spaces) and that between the points of S and the points of T there exists a one-to-one correspondence such that (1) if in S a point p is a limit point of a point set A, then in T the point q corresponding to p is a limit point of the point set B which corresponds to A; and conversely (2) if in T a point q is a limit point of a point set B, then in S the point p corresponding to q is a limit point of the point set A which corresponds to B; then S and T are called "topologically equivalent." or "homeomorphic," and the one-to-one correspondence just described is called a "homeomorphism" (between S and T).

The "congruences" of elementary plane geometry are particular cases of homeomorphisms; likewise. similar figures are homeomorphic. But a homeomorphism is a much larger class of correspondences than these represent. Indeed, a simple closed curve may be defined as any topological space that is homeomorphic with a circle, and since in assigning limit points for all subsets of Euclidean space every subset is itself turned into a topological space, this definition permits identification of those configurations in Euclidean space that are simple closed curves; in particular it is easy to see that every polygon is homeomorphic with a circle, and hence a simple closed curve. And similarly. to take a case in three-dimensional Euclidean space, the surface of a sphere is homeomorphic with the surface of a cube.

Topological Properties.—Any property which is definable in terms of the notion of limit point may be called topological. For example. suppose that A and B are disjoint, nonempty point sets (in a topological space) neither of which contains a limit point of the other; then A and B are called "separated." And if a space is not the sum of separated sets, it is called "connected." The property of being connected is topological and is one of the most fundamental properties in topology. All the ordinary configurations of Euclidean geometry are connected. In the second paragraph of this article, property (1) means precisely that the point set which remains when a point is removed from a circle is connected in the sense here defined: and property (2) means that when any two points are removed the resulting point set is not connected; that is. it is the union of separated sets.

One of the most important statements of topological properties of E^2 is the Jordan curve theorem: if J is a simple closed curve in E^2, then $E^2 - J$ is the sum of two separated connected sets A and B such that each point of J is a limit point of both A and B. In this theorem E^2 may be replaced by S^2 n-here S^2 denotes any homeomorph of the ordinary spherical surface (*see* items [1], [2], [10, pp. 154–155], [8], [9], [6] and [7] in bibliography).

Properties nhich relate a subset of a space to the space are often termed relative, or positional. For example. a point set M in a space S is called "closed" (relative to S) if it contains all its limit points in S. The set M of all points enclosed by a circle C in the plane E^2 is not closed (relative to E^2) but the union of M and C is closed. And a subset of a space S is "open" (relative to S) if its complement in S is closed. Such properties are affected by changes in S; a point set M which is closed in S may fail to be closed if new points are added to S, for example.

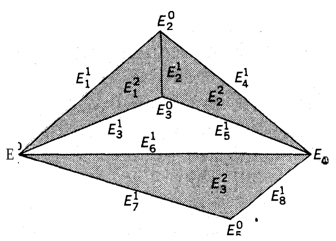
Topological properties of spaces form the basic tools and objects of study in topology. Their significance is made clearer by the concept of topological invariant. Suppose R is a class of topological spaces (see Topological Spaces, below) and consider properties that have significance for the spaces of R. Any such property which, if it holds for one space S of R, holds for every space of R that is homeomorphic with S, may be called a "topological invariant of S in R." The properties defined above, and indeed all topological properties, are topological invariants no matter what the class R of topological spaces may be. However, properties that are invariant in certain classes of spaces may cease to be invariant in larger classes and sometimes properties are investigated in topology about which it is not known for just how large a class of spaces they are invariant.

An important type of problem in topology is the recognition, by means of topological invariants, of the class of configurations to which a given point set belongs. Thus in E^2 the simple closed curve may be characterized by topological invariants as follows: every nondegenerate point set in E^2 which is (a) connected, (b) closed and (c) has properties (1) and (2) of the second paragraph of this article, is homeomorphic with a circle. Similarly, if in addition to (a) and (b) it is known of a point set in S^2 that the removal of any one of its points, with the possible exception of two, disconnects it. then it must be homeomorphic with a finite closed interval of a straight line (such a point set is called an "arc," the two special points which do not disconnect it being called its "end points").

Some invariants are of a numerical nature. Let M be a point set in a topological space and $p \in M$. Then a point x of M may be said to be connected to p in M if some connected subset of M contains both p and x. The set of all points x that are connected to p in M is called a "component" of M; any point of such a component will serve instead of the point p to determine the component. For example. if M consists of two circles having no common point, then M has two components, each of the circles constituting a component. The number of components of a point set is an excellent example of a numerical topological invariant. Numerical invariants occur frequently in algebraic topology.

Some of the aspects of topology that have proved of most importance or excited the greatest interest are described below. Because of its geometric nature and early development historically, the first topic to be considered is that of the topology of polyhedral or combinatorial topology, the beginnings of which are found in the work of Riemann. Enrico Betti and Poincaré.

Combinatorial Topology.—Let **K** denote a configuration in E^2 consisting of a finite collection of triangular-shaped pieces that meet only along entire edges or at vertices. By a "cell" of K is meant either a vertex, an edge or a triangular piece; to differentiate, the term 0-cell is used for vertex, 1-cell for edge and 2-cell for a triangular piece. An r-cell ($r = 0$, 1 or 2) is denoted by E_i^r, where i is an enumerative index. Such a figure, made up of cells. is called a "complex."



EXAMPLE OF A COMPLEX K

For each 2-cell E_k^2 there may be written a "bounding relation" of the form $\partial E_k^2 = E_1^1 + E_2^1 + E_3^1$, where E_1^1, E_2^1 and E_3^1 are the edges of E_k^2. Similar bounding relations may be written for the edges. This leads to a consideration of polynomials whose terms are 1-cells, such as $E_4^1 + E_5^1 + E_7^1 + E_8^1$ (where the coefficients are all understood to be unity as in ordinary algebra).

Such polynomials are called "r-chains" of K, where r is the dimension of the cells involved. In particular the monomial E_1^2 is a 2-chain.

The notion of "boundary chain" may be extended to arbitrary chains. Thus, if C^{r+1} denotes an $(r+1)$-chain. then the boundary chain ∂C^{r+1}, of C^{r+1} is obtained by selecting those r-cells that are present in the boundary chains of an odd number of the $(r+1)$-cells of C^{r+1}; or more concisely, by "adding modulo 2" the boundary chains of these 1-cells. For example. the boundary chain of the chain $E_1^2 + E_2^2$ of the figure is obtained thus: $\partial(E_1^2 + E_2^2) = (E_1^1 + E_2^1 + E_3^1) + (E_2^1 + E_4^1 + E_5^1) = E_1^1 + E_3^1 + E_4^1 + E_5^1$. Similarly, if $E_1^1 + E_3^1 + E_4^1 + E_5^1$ is denoted by L^1, then $\partial L^1 = (E_1^0 + E_2^0) + (E_1^0 + E_3^0) + (E_2^0 + E_4^0) + (E_3^0 + E_4^0) = 0$. If the boundary chain of a chain C^{r+1} is 0, then C^{r+1} is called a "cycle," or an $(r+1)$-cycle; thus L^1 was just shown to be a 1-cycle and it may be shown that every such boundary chain is a 1-cycle. However, usually not every cycle is a boundary chain; for example, the chains $Z_1^1 = E_3^1 + E_5^1 + E_6^1$ and $Z_2^1 = E_1^1 + E_4^1 + E_6^1$ are cycles but are not boundary chains for the complex K of the figure.

The fact that a cycle Z bounds is expressed by a relation $Z \sim 0$ on K, called a "homology relation," and read "Z is homologous to zero on K." Above, for instance, $L^1 \sim 0$ on K. Since if cycles bound, their sum must bound. homologies may be added like equations, modulo 2. And a relation $Z_1 + Z_2 \sim 0$ is also written $Z_1 \sim Z_2$; such a relation holds for the cycles Z_1^1 and Z_2^1 defined above for K. The one-dimensional "Betti number modulo 2 of K," denoted by $p^1(K,2)$ (or simply p^1 when the modulo 2 algebraic operations are understood to be used without explicit mention). is the greatest number of 1-cycles $Z_1^1, Z_2^1, \ldots, Z_{p1}^1$ of K that satisfy no homology of the form $a_1^1Z_1^1 + \ldots + a_i^1Z_i^1 + \ldots + a_{p1}^1Z_{p1}^1 \sim 0$ modulo 2, where the coefficients a_i^1 are all 0 or 1 but not all 0 (making the convention that $0 \sim 0$). It can be shown that p^1 is not dependent upon the manner in which K is fashioned from triangles so long as the two figures are homeomorphic; the value of p^1 will be the same for both, and may be considered a numerical measure of the "one-dimensional connectivity" of the figure.

The combinatorial method just exemplified may be generalized to figures of any dimension that are made up of a finite number of cells (a 3-cell is a tetrahedron, for instance) and Betti numbers of any dimension r, denoted by p^r, defined. The restriction to modulo 2 addition of chains is unnecessary if orientation is introduced: suppose $v_0, \ldots, v_i, \ldots, v_r$ are the vertices of an r-cell. To a certain order of these vertices: as for instance that just named, a symbol σ^r may be assigned, allowing σ^r to denote any order obtained from this by an even number of transpositions of the vertices (thus. if $\sigma^3 = v_0v_1v_2v_3$, then also $v_1v_2v_0v_3 = \sigma^3$); to the other orderings we assign the symbol $-\sigma^r$. By definition, $\partial\sigma^r = \Sigma_{i=0}^r\ (-1)^i v_0 \ldots v_{i-1}v_{i+1} \ldots v_r$; thus, $\partial\sigma^r$ takes the form $\Sigma_{i=0}^r (-1)^i\eta^i\sigma_i^{r-1}$, where the η^i's are -1 or 1.

Now let G be any Abelian group (for example, the additive set of integers used by Poincaré or that of the rational numbers). (See GROUPS.) Then for an "r-chain over G" of a complex K we may take a polynomial of the form $\Sigma g^i\sigma_i^r$, where the g^i's are elements of G. Chains are added by adding corresponding coefficients in G, and thereby form a group $C^r(K,G)$ called the "r-dimensional chain group of K over G." For such chains the boundary $\partial(\Sigma g^i\sigma_i^r)$ is defined to be $\Sigma g^i\partial\sigma_i^r$, where by convention $g.(-1) = -g$, $g.0 = 0$ (the identity of G), etc. It follows that for every chain c^r, $r > 1$, $\partial(\partial c^r) = 0$, and the boundary of a chain is therefore a cycle. Thus the boundary chains form a subgroup of the group of cycles and if we denote the group of cycles of dimension r by $Z^r(K,G)$ and the group of chains that bound by $B^r(K,G)$, then the factor group $Z^r(K,G)/B^r(K,G)$ is called the rth "homology group (or rth Betti group) of K over G," and is denoted by $H^r(K,G)$; it is a topological invariant of K in the class R of all complexes. If G is the group of integers I, then the rank of $H^r(K,G)$ is the rth Betti number $p^r(K,I)$. The orders of finite cyclic subgroups of $H^r(K,I)$ are the so-called "torsion numbers."

In the special case $r = 0$ the convention may be made that $\partial\sigma^0 = 0$ for all 0-cells σ^0; in this case p^0 is the number of components of K, thus forming what could be called a measure of the "0-dimensional connectivity" of K. However, frequently the convention is made that $\partial\sigma^0 = \sigma^{-1}$, where σ^{-1} is a unique "ideal" cell which is added to the complex, thereby obtaining the "augmented complex"; in this case $p^0 + 1$ is the number of components of K.

One of the most striking relations obtained by the combinatorial method. and which illustrates the power of the method in that it embodies a generalization of the classical Euler formula for polyhedral~which states that for any (nonaugmented) complex K,

$$\Sigma(-1)^r\alpha_r = \Sigma(-1)^r p^r \qquad (1)$$

where a,. denotes the number of r-cells. When K is an ordinary polyhedral, topologically equivalent to the two-dimensional sphere $p^0 = p^2 = 1$, $p^1 = 0$ and relation (1) gives the Euler polyhedral formula: a, $- \alpha_1 + \alpha_2 = 2$.

Applications.—The simplest complex of significance is the "linear graph!'; this is the one-dimensional complex obtained by piecing together straight-line segments. The 0- and 1-cells of the figure form a linear graph, for instance. The linear graph has been applied to the theory of electrical circuits, chemistry (the structure of a molecule may be represented by a linear graph in which the 0-cells denote the respective atoms and the 1-cells denote the bonds joining them), games, many topological problems such as the "four-colour map problem" (see items [1], [2] of bibliography'] and to many other parts of mathematics. For a linear graph the Euler-Poincaré formula gives $p^1 = \alpha_0 - \alpha_1 - p^0$; in the case of the linear graph representing a paraffin molecule C_nH_{2n+2}, for example, this formula gives $p^1 = 0$, so that the configuration contains no simple closed curve.

In the consideration of solutions of irreducible algebraic equations of the form $f(x,y) = 0$ and in certain integration problems a two-dimensional complex called "manifold" plays a prominent part. Its characteristic feature is that each point is contained in an open set that is homeomorphic with the Euclidean plane. Manifolds of more than two dimensions were studied by Poincaré, who showed that the Betti numbers of an orientable n-dimensional manifold (nonaugmented) satisfy the relations

$$p^r(K,I) = p^{n-r}(K,I), \qquad r = 0, 1, \ldots, n \qquad (2)$$

Relation (2) is the so-called "Poincaré duality," and allows of generalization to a certain type of duality between homology groups. In 1923 James W. Alexander stated and proved another type of duality theorem: if S^n is the Euclidean n-sphere (= ordinary n-space nith the addition of an ideal "point at infinity") and K is a point set in S^n nhich is homeomorphic with some (augmented) complex, then numbers $p^r(S^n - K,2)$ may be defined in a natural fashion for the complement of K in S^n and the following relation holds:

$$p^r(K,2) = p^{n-r-1}(S^n - K,2),\ r = 0, 1, \ldots, n-1 \qquad (3)$$

Relation (3) tells, for instance, that the complement of every topological image of an $(n-1)$-sphere in S^n has just two components. In the case $n = 2$ it readily yields the Jordan curve theorem. Relation (3) may also be extended to a duality between homology groups. and both relations (2) and (3) may be brought within the scope of the same group-theoretic considerations.

Topological Spaces.—It was stated in the introductory remarks above that all that is needed to introduce a topology into a space is that the limit points of point sets be determined and it was shown how this may be done for ordinary Euclidean spaces and their subsets. But topological spaces are not limited to a Euclidean framework since, as stated above, any collection of objects whatsoever may be converted into a topological space by assigning to each subcollection M the set of its limit points. These assignments are usually made with a definite object in view, such as an application to some particular problem either within or exterior to mathematics, and this ordinarily requires more than the mere assignment of limit points for the various point sets. Consequently in practice the term "topological space" is usually applied to a concept slightly more restricted than that indicated above, the particular concept to be employed being set forth in axiomatic form as a rule. (*See* items [4], [5], [8] and [9] of bibliography.) Some of the more important types of topological spaces are described below.

Hausdorff Spaces.—One of the favourite methods of giving the topological character of a space is by specification of its open sets. From this point of view if E is any collection of things whatsoever and one specifies quite arbitrarily that certain subsets of E are to be "open"—in such a manner! however, that (1) E itself is open and the empty set is open; (2) if A and B are open sets. then A . B is open; and (3) the sum of any number of open sets is open—then in E one has one of the most commonly employed types of topological space. A point p of E is a limit point of a subset M of E if every open set which contains p also contains at least one point of d l distinct from p (compare the definition given for limit point in E^2 in the fifth paragraph of this article). If to the axioms just given one adds (3) if p and q are distinct points of E, then there exist disjoint open sets P and Q containing p and q respectively; then the combined set (1)–(4) characterizes the so-called Hausdorff topological spaces. For example, if one calls the interior of each circle in E^2 an open set, and also calls open every set obtained by taking sums (finite and infinite) of these. then the plane becomes a Hausdorff space.

Metric Spaces.—The Euclidean spaces are also special cases of the metric spaces: a metric space is a set S together with a "distance function" $d(x,y)$ which is defined as a unique real number for each pair of points x, y ϵ S having the property that (1) $d(x,y) = 0$ if and only if x and y are the same points, and (2) for every three points x, y, z of S, distinct or not, $d(x,y) \leqq d(x,z) + d(y,z)$. These requirements imply that $d(x,y) = d(y,x)$ and that $d(x,y)$ is never negative. Condition (2) will be recognized as the "triangle inequality" of plane geometry, where $d(x,y)$ is the usual distance between the points x and y. In a metric space a "spherical neighbourhood" $U(x,r)$, where x ϵ S and r is a positive real number, is the set of all points y such that $d(x,y) < r$. Thus in E^2 the interiors of circles are spherical neighbourhoods. And if. in a metric space, each spherical neighbourhood is called open and all sums of spherical neighbourhoods are called open, then the space becomes a Hausdorfi space.

Metrizable Spaces.—A Hausdorff space is called metrizable if there exists a distance function $d(x,y)$ such that the open sets obtained as in the preceding paragraph are identical with the original open sets of the space. An interesting problem, the "metrization problem." is to determine what topological properties of a Hausdorff space, if any. render it metrizable. Not all Hausdorff spaces are metrizable; for example, if in E^2 we allow to be open any circle interior from which has been deleted a countable set of points, as well as arbitrary sums of such open sets, then the resulting space is a Hausdorff space but is not metrizable. For if it were, then any set having a limit point p would contain a countable subset having p as a limit point (this is true of all metric spaces) but this is impossible in the space just defined. (Note that the same set—that consisting of all points in the Euclidean plane—has been called a topological space in two different senses; first as the usual Euclidean plane, in nhich sense it is a metric space. and secondly as a nonmetric Hausdorff space. Thus, the same collection may be converted into many different topological spaces.)

A variety of solutions may be given of the metrization problem. One such is obtained as follows: if a space S has the property that for arbitrary disjoint closed sets A and B there exist disjoint open sets containing A and B, respectively, then S is called "normal." Using the properties of the distance function, it is not difficult to show that every metric space is normal. If. in the definition of normal, the set A consists of a single point. then the resulting (weaker) property is called "regular." Each of the properties regular. normal, is a strengthening of the axiom (4) used in defining a Hausdorff space. Now if a space contains a countable set G of open sets such that every open set in the space is the sum of elements of G, then the space is called ' perfectly separable,· or said to have a "countable base." A necessary and sufficient condition that a perfectly separable Hausdorff space be metrizable is that ıt be regular As a corollary it follons that among the perfectly separable Hausdorff spaces, metrizability is a topological invariant since regularity is a topological invariant. Thus aithough distance itself is not invariant, capability of having a distance function is invariant among such spaces. A property closely related to that of perfect separability is that of separability. a space S being separable if it contains a countable set M such that every point of S is either a point of M or a limit point of M. Every perfectly separable space is separable and every separable metric space is perfectly separable.

Complete Spaces.—An important class of metric spaces is that of complete spaces. In analogy with the Cauchy sequences of algebra and function theory, a sequence $p_1, p_2, \ldots, p_n, \ldots$ of points of a metric space is said to form a Cauchy sequence if for arbitrary positive number ϵ there exists a number $N(\epsilon)$ such that if m and n are both greater than $N(\epsilon)$, then $d(p_m,p_n) < \epsilon$. A sequence is said to "converge" if there is a point p such that $d(p_n,p)$ approaches zero as n increases, and a metric space in which every Cauchy sequence converges is called "complete." The Euclidean spaces are complete. The set of all single-valued real functions defined over the interval $[0 \leqq x \leqq 1]$ forms a complete space in which each function is a point and the distance between two functions f and g is taken to be the least upper bound of the absolute values $|f(x) - g(x)|$. Every metric space is homeomorphic with a subset of some complete space.

Compact Spaces.—If G is a collection of open sets in a space S and S is the sum of the elements of G, then G is said to "cover," or to be a "covering" of S. A "compact" (sometimes called "bicompact") space is a space which has the property that every covering of it by open sets has a finite subset forming a covering. The Euclidean spaces are not compact but every closed subset lying in a finite portion of such a space is compact. Not all compact spaces are metric; among the compact Hausdorff spaces metrizability is equivalent to perfect separability (every compact Hausdorff space is normal). A nondegenerate space which is both compact and connected is frequently called a "continuum" and the term "compactum" is used to denote a space which is both compact and metric.

Product Spaces.—If A and B are any two sets, then the "product set" $A \times B$ is the set of all pairs (a,b) where a and b are elements of A and B, respectively. Let S and T be any two topological spaces. Then by the "product space" of S and T is meant the space obtained from $S \times T$ by letting all products $U \times V$ be open, where U and V are open subsets of S and T, respectively; it is also denoted by the symbol $S \times T$. For example. the product space of two Euclidean straight lines is topologically equivalent to the plane (a fact used in Cartesian geometry); if S and T are circles, then $S \times T$ is topologically equivalent to the surface of the anchor ring. Products may also be defined for any number of spaces. They furnish an excellent source of topological configurations.

Peano Spaces.—If S and T are topological spaces, then by a "continuous mapping of S into T" is meant a function f which assigns to each point x of S a point f(x) of T, in such a manner that if A is a subset of S with limit point p, then $f(p)$ is in $f(A)$ or is a limit point of $f(A)$ in T. It may be symbolized by the expression $f:S \rightarrow T$. (If for every $y \epsilon T$ there is at least one $x \epsilon S$ such that $f(x) = y$, then f is called a mapping of S onto T.)

The concept of a mapping of one space into another has proved one of the most important tools in topology, leading to numerous important invariants, such as the homotopy classes, as well as to many interesting problems (see bibliography items [8], [11] and [12]). One of the most widely investigated types of topological spaces is obtained by mappings of the real number interval R; more precisely. if P is a Hausdorfi space and there exists a mapping $f:R \rightarrow P$ which is onto. then P is called a "continuous curve" or "Peano space." Such spaces form a much larger class than one might at first suspect; for instance, a circle together with its interior in E^2 is a Peano space (the latter name has its origin in the fact that the Italian mathematician and logician Giuseppe Peano was the first to prove [1890] the statement just made). The Euclidean 2-sphere. S^2, is completely characterized among the Peano spaces by the Jordan curve theorem: a necessary and sufficient condition that a space S be homeomorphic with S^2 is that it be a Peano space which contains at least one simple closed curve, and in which the Jordan curve theorem holds.

The investigation of the topological properties of Peano spaces forms an aesthetically satisfying and fruitful department of topology (see bibliography items [6], [8], [9] and [10]). The first successful characterization of them in terms of intrinsic topological invariants utilized the property of local connectedness: a space S is called "locally connected" if, given $x \epsilon S$ and an open set U containing x, there exists a connected open set V containing x and lying in U. A Peano space is characterized by the fact that it is a metric continuum which is locally connected.

The structure of the higher-dimensional Peano spaces, while exhibiting a large number of interesting properties, may be rendered more attractive from a geometrical point of view by the imposition of local connectedness properties of higher dimensions. The local connectedness described above is then the 0-dimensional case of an n-dimensional type of local connectedness in which the homology theory (see TOPOLOGY, ALGEBRAIC) plays a part; specifically, given $x \epsilon S$ and an open set U containing x, there exists an open set V containing x and lying in U such that every n-cycle on a compact subset of V bounds on a compact subset of U. Peano spaces that are locally connected in this sense for all dimensions up to and including a given positive integer exhibit properties of which the corresponding properties of Peano spaces are the 0-dimensional cases, and in structure they begin to approximate the n-dimensional manifolds.

(See item [9] in bibliography.)

Fixed Points.—Consider a mapping of type $f:S \rightarrow S$. If x is a point of S such that $f(x) = x$, then x is called a "fixed point" of the mapping f. For example, using the homology theory it is not difficult to show that if D is a circular disk, then every mapping $f:D \rightarrow D$ has a fixed point; and more generally, if E^n is a solid cube, then every mapping $f:E^n \rightarrow E^n$ has a fixed point. Theorems on the existence of fixed points have many applications in mathematics and mechanics. (For further details see bibliography items [1] and [15].)

Dimension Theory.—One of the most important contributions made by topology is embodied in solutions of the ancient problem concerning the nature of dimension. One may expect of such a concept that it will: (1) assign to each space a unique integer, its "dimension number"; that, in particular, it will (2) assign to Euclidean n-space the dimension number n; and that (3) if S is a subspace of a larger space T, then the dimension of S will not exceed that of T. For a wide class of spaces, including all of the ordinary spaces of mathematics and physics (indeed. all separable metric spaces) such a dimension concept has been provided. This has been done in a variety of ways, some from the standpoint of pure point-set concepts of topology and some from the standpoint of algebraic topology.

Such a "dimension function," as it might be called, may be exemplified briefly by use of the coverings mentioned above. Suppose S is a separable metric space and C is a covering of S by a finite number of open sets. **A** similar covering C' of S is called a "refinement" of C if each element of C' is contained in an element of C. Then the dimension of S is called "at most n" if every finite covering of S by its open sets has a refinement C' such that not more than $n+1$ elements of C' have common points. The dimension of S is "equal to n" if n is the smallest integer for which the dimension of S is at most n. Such a dimension function is a topological invariant and has the required properties (1) (2) and (3). listed above. The following may be cited as examples of some of the interesting theorems of dimension theory: every separable metric space is homeomorphic with a subset of a compactum of the same dimension, and every such space which is of finite dimension n is homeomorphic with a subset of the $(2n+1)$-dimensional Euclidean space.

Applications.— In addition to such applications as have been cited above, mention could be made of a wide variety of special applications to other fields of mathematics, as for instance the proof of the fundamental theorem of algebra (see EQUATIONS. THEORY OF: The *Fundamental Theorem*), which may be deduced from any of a number of theorems of plane topology; special properties of functions (*e.g.*, existence of real continuous functions having no derivative); analytic functions; algebraic geometry; calculus of variations; harmonic integrals; etc. The theory of topological groups and their applications has been extensively developed.

TORADJA (TORAJA), a group of tribes of central Celebes who, together with the closely related Sadang, are survivors of the invading Proto-Malayan people that overran the island and absorbed or exterminated the aboriginal Negrito. In later centuries they in turn have been driven back from the coasts by the more typical Malayans such as the Bugis. Their warfare and headhunting made it necessary to locate their villages on easily defended hilltops.

There the houses surrounded a square in which stone memorial slabs were erected in honour of the nobility. Painted houses with saddle roofs resembled those of the Toba Batak while the use of golden ornaments by the nobles, coffin burials in caves and strong class distinctions suggest the situation found among the Proto-Malays of Nias and Sumatra.

Under Dutch control warfare was stopped and missionary efforts led to the conversion of most of the population to Christianity. These changes led, in turn, to the abandonment of many of the hilltop strongholds and to the establishment of villages in the valleys.

Early accounts tell of the elaborate tapa garments of the women. Today their poncholike blouses of cloth are decorated with scroll designs made with shell disks. A sarong is worn but below this the woman wears short trousers. It was a custom, now going out of style, for members of both sexes to have their front teeth broken off at the gums. Face painting in dots and lines is common. Descent is reckoned bilaterally.

TORBERNITE, one of the principal uranium minerals, is a hydrous uranium and copper phosphate of secondary origin (*see* URANIUM: Occurrence). The crystals are tetragonal, thin to thick tabular; also in scaly or foliated aggregates. There is a perfect micaceous cleavage parallel to the base, and on this face the lustre is pearly; otherwise it is vitreous to subadamantine. The bright grass- to emerald-green colour is characteristic. The hardness is 2 to 2.5 and the specific gravity 3.22. The formula is $Cu(UO_2)_2(PO_4)_2.12H_2O$. The water content varies with the temperature and humidity, and is normally less than the formula indicates. When torbernite loses four molecules of water it passes over to metatorbernite, with a change in optical properties. Torbernite is found in Bohemia and Saxony and is abundant in the Katanga district of the Belgian Congo; the best specimens are from Cornwall. The name torbernite is after Torbern Bergman (1735–84), a Swedish chemist. (L. S. RL.)

TORCELLO, an island of Venetia, Italy, in the lagoons, 6 mi. N.W. of Venice. It was a flourishing city in the early middle ages, but now is thinly settled. It has two interesting churches. The former cathedral of S. Maria was founded in 641. The present building, a basilica with columns, dates from 864; the nave was restored in 1008, in which year the now ruined octagonal baptistery was built. It contains large mosaics of the 11th century, strongly under Byzantine influence; those on the west wall represent the Resurrection and Last Judgment. The seats for the priests are arranged around the semicircular apse, rising in steps with the bishop's throne in the centre—an arrangement unique in Italy. Close by is S. Fosca (c. 1011), octagonal outside, with colonnades on five sides and a rectangular interior intended for a dome which was never executed, beyond which is a three-apsed choir.

See B. Schulz, *Kirchenbauten auf der Insel Torcello* (1927).

TORCH LILY, RED-HOT POKER PLANT and FLAME FLOWER are common names for about 70 species of plants belonging to the genus *Kniphofia* of the lily family. About 40 species occur in South Africa, the remainder being native to tropical Africa and Madagascar. The plants possess a fleshy rootstock from which basal, persistent, lanceolate leaves arise, and usually a tall scape of red and yellow drooping flowers in a dense, terminal, spikelike raceme. The common names are highly appropriate because of the brilliantly coloured pokerlike spikes. Some of the species, and particularly some of the numerous hybrids available, make excellent hardy border plants that bloom from midsummer until late autumn and with a wide range of colour. (J. M. BL.)

TORDENSKJOLD, PEDER (1691–1720), Danish naval hero, son of Jan Wessel of Bergen, in Norway, was born at Trondhjem on Oct. 28, 1691. Wessel ran away from home as a stowaway in a ship bound for Copenhagen, made a voyage to the West Indies, and finally gained a cadetship. In 1712 he was promoted to a 20-gun frigate. Wessel was renowned for his audacity and his unique seamanship. The Great Northern War had now entered upon its later stage, when Sweden, beset on every side, employed its fleet principally to transport troops and stores to its distressed German provinces. The audacity of Wessel impeded it at every point. He was continually snapping up transports, dashing into the fiords where its vessels lay concealed.

When in 1715 the return of Charles XII from Turkey to Stralsund put a new life into the jaded Swedish forces, Wessel fought numerous engagements off the Pomeranian coast, and did the enemy infinite damage by cutting out their frigates and destroying their transports. On returning to Denmark in the beginning of 1716 he was ennobled under the title of Tordenskjold ("Thundershield"). When Charles XII invaded Norway and besieged Fredrikshald (1716) Tordenskjold compelled him to raise the siege and retire to Sweden by pouncing upon the Swedish transport fleet laden with ammunition and other military stores which rode at anchor in the narrow and dangerous strait of Dynekil, utterly destroying the Swedish fleet with little damage to himself. For this, his greatest exploit, he was promoted to the rank of commander.

Tordenskjold's last feat of arms (he was then rear admiral) was his capture of the Swedish fortress of Marstrand, when he partially destroyed and partially captured the Gothenburg squadron which had so long eluded him. He was rewarded with the rank of vice-admiral. Tordenskjold did not long survive the termination of the war. On Nov. 20, 1720, he was killed in a duel with a Livonian colonel, Jakob Axel Stael von Holstein. Although, Dynekil excepted, Tordenskjold's victories were of far less importance than Hannibal Sehested's at Stralsund and Ulrik Gyldenlöve's at Rügen, he is certainly, after Charles XII, the most heroic figure of the Great Northern War.

See Carstensen and Lütken, *Tordenskjold* (1887). (R. N. B.; X.)

TORDESILLAS, TREATY OF, between Spain and Portugal, was signed on June 7, 1494, to settle conflicts arising from Columbus' first voyage. In 1493 Pope Alexander VI had set up a line of demarcation from pole to pole 100 leagues west of the Cape Verde Islands. Spain was given exclusive rights to the region west of the line; Portuguese expeditions were to keep to the east. King John II of Portugal was dissatisfied because Portugal's rights were not specifically affirmed and the Portuguese would not have sufficient sea room for their African voyages. Meeting at Tordesillas in northwestern Spain, Spanish and Portuguese ambassadors reaffirmed the papal division, but the line itself was moved to 370 leagues west of the Cape Verde Islands. Papal sanction of this change was finally given on Jan. 24, 1506. Since the line now intersected the bulge of South America from the mouth of the Amazon to Santos, Portugal successfully laid claim to Brazil after its discovery by Pedro Alvares Cabral in 1500.

TORGAU, a town in the district of Leipzig, Ger.. on the left bank of the Elbe river, 30 mi. E.N.E. of the city of Leipzig and 26 mi. S.E. of Wittenberg by rail. Pop. (1950) 19.633. Torgau is said to have existed as the capital of a distinct principality in the time of the German king Henry I, but early in the 14th century it was in the possession of the margraves of Meissen and later of the electors of Saxony: In 1526 John, elector of Saxony, Philip, landgrave of Hesse, and other Protestant princes formed a league against the Roman Catholics, and the Torgau articles. drawn up there by Martin Luther and his friends in 1530, were the basis of the Confession of Augsburg. Torgau was formally ceded to Prussia in 1815. The Schloss Hartenfels, on an island in the Elbe, was built by John Frederick the Magnanimous, of Saxony.

Battle of Torgau, 1760.—This, the last great battle of Frederick the Great, and the last of his victories, was so truly Pyrrhic that it paralyzed his offensive power and left him in a gravely weakened condition to meet his gathering foes. The battle and the events which rescued him from his critical position are dealt with under Seven Years' War.

TORNADO, the violently revolving funnel cloud of small diameter that is well known in the United States east of the Rockies, in southern and middle U.S.S.R. and in southern Australia. Rotation is either clockwise or counterclockwise. In west Africa, tornado is the local name for the violent squall that blows out of the front of thunderstorms and dust storms (equivalent to the haboob of Sudan). Less commonly and in less violent form than in the U.S., tornadoes occur in nearly all other parts of Europe and America and locally in Africa and Asia. In the United States they are also popularly known as twisters or cyclones. North American tornadoes average 300–400 yd. in width, although some extend a mile or more. They often form in families of two or more in the same region at the same time. Paths are usually short, from several to 50 mi., but occasionally up to 300 mi. long; in the U.S. they generally run from southwest to northeast at 10–50 m.p.h.

The funnel cloud results from the condensation of moisture through cooling by expansion and lifting of air in the vortex. However. the air for some distance outside the funnel cloud is also part of the vortex, and near the ground this outer ring becomes visibly laden with dust and debris. The wind speed in the vortex has never been measured; but judging from the effects and from theoretical considerations, it is of the order of 100–500 m.p.h. E. M. Brooks found that some tornadoes are centred in a larger, much weaker cyclone of about a five-mile radius. which he called "the tornado cyclone." Because of centrifugal effects, very low barometric pressure occurs in the core of the vortex, creating a small "eye" that is clear and nearly calm. When observed on radar, some tornadoes are located near a distinctive hooked echo. The echo seems to revolve with the storm and may be associated with the tornado cyclone. (See Radar Meteorology.)

The whirling funnel cloud appears to grow vertically or slantingly down from a dark heavy cloud of the cumulo-nimbus or thunderstorm type and to reach the ground while twisting and bending slowly, the base of the funnel dragging because of friction. It soon dies out in reverse order.

Many tornadoes have bases elevated 50–100 ft. above the ground. in which case winds at the ground have speeds of less than 1jo m.p.h. The funnels may extend down from as high as 25,000 ft. (as reported in one instance). Rain and hail usually occur just before or after the tornado. There is considerable variation in details of appearance of individual tornadoes.

The minute or so that it takes for the storm to pass results in fantastic destruction: buildings totally flattened, exploded to bits or moved bodily for hundreds of yards; straws driven through posts; some objects left unharmed amid complete wreckage. A safe refuge during a tornado passage is a "cyclone cellar" with a stout door, such as provided on many farms in the midwestern U.S. The roar of the tornado can be heard as far as 25 mi. away.

The continental plains of North America and the U.S.S.R., reaching from polar regions to the tropics. are specially favourable for tornadoes, and no season is free from them. In spring and summer, however. tornadoes are five times as numerous as in winter and fall. They are more likely to occur during the day than at night. In the U.S., the greatest number occur in a belt along the eastern edge of the Great Plains area! extending from Iowa to northeastern Texas. The centre of maximum frequency moves north and south, in winter near the Gulf coast, in summer over Iowa.

The high speed of the revolving winds in a tornado is a result of convergence of slowly rotating air; the same principle is involved when an ice skater increases his speed of rotation by drawing in his arms. Usually tornadoes form in association with thunderstorms that are in the vicinity of either a squall line or a front which is invading a region where a layer of warm dry air overlies moist air. This sort of stratification is often rendered unstable by the lifting and convergent effects of a front, but apparently a very special combination of additional circumstances is required to produce a tornado. *See* also Squall and Squall Line; Thunderstorm.

TORNEBOHM, ALFRED ELIS (1838–1911), Swedish geologist and pioneer in mountain tectonics, was born in Stockholm on Oct. 16. 1538. Graduating from the Technological institute in 1858, he joined the geological survey of Sweden in 1859 but resigned in 1873. After travel in central Europe and a visit to Ferdinand Zirkel in Leipzig. he returned to Stockholm as professor of mineralogy and geology at the Royal Institute of Technology.

He then became director of the geological survey from 1897 to 1906. Tornebohm's researches give him high rank in the annals of mountain tectonics. He spent many years traversing the ground of his original surveys in the Scandinavian mountains and he presented in 1888 the first outlines of his theory of the overthrust of the Caledonian chain onto a foreland to the southeast. Later (1896) he demonstrated that the overthrusting applied to the entire extent of the mountain range and exceeded 80 mi. He illustrated his completed description. in which he had the assistance of A. G. Högbom, with a map covering 36,000 sq.mi. Tornebohm was an accomplished mineralogist and petrographer. He gave special attention to the iron ores of Sweden and early presented an exhaustive account of the crystalline phases of portland cement clinkers (1897).

Tornebohm died at Strangnas, near Stockholm, on April 21, 1911. (C. E. T.)

TORO, a town of Spain: in the province of Zamora. on the right bank of the Duero (Douro) river, and on the Zamora-Medina del Campo railway. Pop. (1950) 9.799 (mun.).

Toro is an ancient fortified town, with picturesque narrow streets. A fine bridge spans the river. The cathedral church is Komanesque; it dates from the 12th century but has been partially restored.

The palace of the marquesses of Santa Cruz was the meeting place of the *Cortes* of 1371, 1442 and 1505, which made Toro and its code of laws celebrated.

PHOTOGRAPH, WIDE WORLD

VIEW OF AN APPROACHING TORNADO

Tornado approaching Vulcan, Alberta, Canada. The destructive power is not in the straight wind, but in the counterclockwise rotating mass which always moves in an easterly, and generally in a north-easterly direction. Barometric pressure in the tornado falls very rapidly, causing houses to blow apart from the outward pressure of the air inside them

TORNADOES SEEN FROM THE GROUND AND BY RADARSCOPE

Top: Side view of a funnel-shaped tornado cloud sweeping in a path 50 yd. wide near Jasper, Minn. The tornado traveled only three miles

Bottom: Three radarscope photographs showing echoes from a tornado in Illinois. At 5:13 P.M. (left) the tornado developed a "hooking appendage," the projection below and at the left side of the larger cloud. At this point the tornado reached the ground and caused surface damage. The photographs taken at 5:25 and 5:36 (centre and right) show the further development and break-up of the tornado cloud as it moved eastward

TORONTO, capital of the province of Ontario and the second largest city in Canada, is situated on the northern shore of Lake Ontario. It lies on a level lake plain, bounded to the north by the 40-ft. cliff of the glacial "Lake Iroquois" shore line. The plain is traversed by the Don and Humber rivers. The city covers approximately 40 sq.mi., including Toronto bay (2 sq.mi.) and the islands stretching to the south of the city. Pop. (1961) 672,407; metropolitan Toronto 1,618,787.

History. — Toronto is the old name the Hurons gave to their country and probably means "land of plenty." In 1750–51 the French established a fortified trading post called Ft. Rouillé on the site of Toronto, but they burned it nine years later to prevent its use by the British. In 1787 the British purchased the site from the Missisauga Indians and in 1793 settlement began with its establishment as the capital for the newly formed province of Upper Canada. The site was well away from the U.S. border and possessed an easily defended natural harbour at the beginning of an overland route to the Upper Lakes. In 1797 the legislature met for the first time in the new capital, which was called York. During the War of 1812 York was captured by U.S. forces and the parliament buildings and archives were burned (1813). At first the settlement remained a small administrative and garrison town. In 1820 it numbered about 1,250 people. In the 1830s the population grew rapidly as a result of large-scale immigration, and commerce became more important than the administrative function. In 1834 York resumed its original naine and was incorporated as the city of Toronto. with a population of over 9.000. The centre of the city shifted from near the Don outlet to Yonge street. In the second half of the 19th century Toronto became the leading financial, commercial and industrial centre of the province and gradually became the focal point for the reorientated railway network. In 1885 the city included about 120,000 people and spread over most of the lake plain.

The Municipality of Metropolitan **Toronto.**—Between 1881 and 1914 the city expanded considerably by means of a number of important annexations. After that the built-up area gradually spiiied over into various municipalities, creating numerous problems in urban development. Accordingly. the provincial legislature in 1953 enacted legislation to provide for the federation of Toronto and its 12 suburban municipalities into a new municipality called metropolitan Toronto. The federated suburban municipalities have greatly contrasting economic structures. The towns of Leaside (pop. [1961] 18.579). New Toronto (13.384) and Weston (9.715) have heavy concentrations of manufacturing industries. Much larger industrial and commercial complexes are found in the townships of North York (267.705). Etobicoke (155.358), Scarborough (215.641) and York i128.521) but their industrial assessment is not so high in relation to their residential assessment as in the first three municipalities. The town of Mimico (18.212) and the village of Long Branch (11,039) also have some important industries. Of a more residential nature are the townships of East Uork (71.626). the village of Swansea (9.628) and especially the village of Forest Hill (20.489), which is almost entirely an upper-class. high-income residential district.

The formation of the new municipality attracted world-wide attention. Each of the federated municipalities retains its autonomy in local matters and is represenred in the metropolitan council. which has 25 members: a chairman. city of Toronto representatives (the mayor. two controllers. nine aldermen) and the suburban representatives (the heads of council of the 12 suburban municipalities). The chairman is elected annually by the council. which is empowered to elect him from among its membership or to elect any other person. The metropolitan corporation is responsible for assessment. water supply, sewage disposal. air pollution control, certain roads and public transportation. education, health and welfare, administration of justice. housing, licensing. police, planning, parks. civil defense and finances. The metropolitan corporation collects the revenue for its budget from the 13 municipalities by a metropolitan tax rate on the assessment of each member municipality. The corporation also issues debentures required for permanent financing in the municipalities The municipalities may appeal to the provincial government in cases of dispute.

The new municipality functioned quite successfully, an achievement which was due in large part to the energetic leadership of its first chairman. Frederick G. Gardiner. Among its accomplishments were cheaper financing for the entire area. large scale improvements in water supply and sewage disposal, equalization of the financial burden for education, the establishment of a centralized police force, improvements in parks and recreational facilities. the building of expressways and the inauguration of better welfare services.

The metropolitan Toronto planning area comprises, in addition to metropolitan Toronto, 13 other municipalities. The local planning boards retain the right to formulate or amend their local official plans, provided they receive the approval of the metropolitan planning board and the provincial minister of planning and development.

Economic Development. — Toronto is the second largest manufacturing centre of Canada; many U.S. and British branch plants are located there. In the early 1960s its 4,700 factories produced about 160 different types of products; fewer than 175 plants employed more than 200 workers and the average number of workers was 43. The resulting diversification helped to stabilize the economy. Some of the more important industries are slaughtering and meat packing. printing and publishing. agricultural implements. aircraft, heavy electrical machinery and a wide variety of iron and steel products. The city is also a leading trade and financial centre; it accounts for 19% of the wholesale trade in Canada. The Toronto stock exchange is in dollar value one of the largest on the continent. handling annually over 900.000.000 shares. Three of the nine Canadian chartered banks and about 45 life insurance companies have their head offices in Toronto.

The city has excellent transportation connections. and hence is an ideal distribution point. Within a radius of 100 mi. lies one-third of the buying power in Canada. The St. Lawrence seaway gives Toronto the additional advantage of being an ocean port. The leading commodities are coal. petroleum. grain. general cargo and cement. The Toronto Island airport accommodates non-scheduled flights; Malton airport. 13 mi. N.W. of the city, is one of the most important air terminals in Canada. A 4½-mi. subway under and near Yonge street was opened in 1954 and in the 1960s was being expanded with lines under and along University avenue and Bloor street. Road transportation was greatly improved in the 1950s and 1960s with the building of the Toronto bypass. its counterpart along the lake shore and a north-south connection via the Don valley.

The City and Its Institutions. — The central business district of Toronto is located around the intersection of Uonge and Queen streets. There are the large. department stores and farther south are Cnion station and a centre for the performing arts. Lower Bay street is the financial district and also the site of the city hall. completed in 1899 and well known for its great stained-glass window. In the 1950s a site was cleared to the —est of the old city hall for a civic square and new city hall. A fashionable shopping area extends along Bloor street between University avenue and Yonge street. Immediately east of it stands a concentration of modern buildings housing insurance offices. The seat of the provincial government is in Queen's park. It is an imposing structure of red sandstone: immediately opposite stands a large addition in blue dolomite, called the Whitney block.

Queen's park is bounded to the west by the campus of the University of Toronto, founded in 1827. It is a blend of the English college system and the faculty system. The constituent and federated colleges are University (nondenominational), Victoria (United Church). Trinity (Anglican) and St. Michael's (Roman Catholic). Also federated with the university are three theological colleges: Knox (Presbyterian). Wycliffe (Anglican) and Emmanuel (United Church). In the 1950s the university entered a period of considerable expansion, acquiring 26 ac. of land adjacent to the campus and beginning a $51.000.000 building program scheduled to he completed by 1970. The university has promoted research in many field?.and is particularly well known for the medical research conducted in the Banting and Best institutes and Connaught medical research laboratories. Near the university is the meteorological service of Canada. North of the city is the David Dunlap observatory with a 74-in. reflector, one of the largest in the world. Just to the south of Queen's park, along University avenue with its impressive array of modern office buildings. is a huge concentration of medical facilities: Toronto General hospital. Hospital for Sick Children and Mount Sinai hospital. In addition to the university, Toronto has numerous other educational institutions. Upper Canada college, a boys' school founded in 1829, in many respects resembles an English public school. Osgoode hall houses the higher courts of law and appeal and also a law school. The Royal Ontario museum is famous for its far eastern collection. Toronto has a large number of parks, totaling over 1.800 ac. Exhibition park. comprising 350 ac. with a lake frontage of $1\frac{1}{2}$ mi., is the site of the Canadian National exhibition. Fashionable residential districts are found along the ravines to the north of Bloor street in Rosedale, in the northern part of the city. and in High park and Kingsway district in the west end. Don Mills is an attractively laid out and carefully planned community about 8 mi. N.E. of downtown Toronto.

Population and Religion.— Until World War II the population of Toronto was predominantly British in origin; after the war there was a steady influx of immigrants from Europe and the city acquired a more cosmopolitan atmosphere. In the early 1960s the Anglican Church and the United Church had the largest memberships. followed by Roman Catholics. Presbyterians. Jewish congregations and Baptists. Toronto is an archiepiscopal see of the Anglican and Roman Catholic churches and the headquarters of the United Church of Canada.

TORPEDOES. The modern torpedo is a cigar-shaped. self-propelled. underwater missile designed for attacking surface vessels and submarines. It may be launched from a submarine, surface vessel or airplane. Sicknamed "tin fish," the torpedo is an underrvater guided missile with intricate devices that control its travel in depth and direction according to a preset plan or in response to signals received from an outside source. A torpedo is fitted with an exploder that detonates the explosive-filled warhead when it strikes its target or comes close to it. Against surface vessels the great value of the torpedo lies in its ahility to attack the target in the most vulnerable area—below the water line. Against submarines the torpedo possesses an uncanny ability to seek and destroy its target regardless of the evasive action the target may take.

Originally the word torpedo referred to any explosive charge, including the type of weapon known in modern times as a land or naval mine. When the modern self-propelled torpedo appeared it was called the automobile or Gsh torpedo to indicate that it contained its own source of power. Some modern underwater mines. called mobile mines, resemble torpedoes in appearance and are self-propelled but they differ in function. Aiter launching, they run for a certain distance. sink and then operate the same as any other type of naval mine. *See* MINE, NAVAL.

History.— Credit for the development of the torpedo belongs to Robert Whitehead (*q.v.*), a British engineer who was manager of a firm of engine builders in Fiume, Yugos. In 1864 an officer in the Austrian navy, Giovanni Luppis, presented Whitehead with an idea for an explosive-currying. self-propelled boat that could be steered from its launching site by means of long yoke lines. After building a model of the device Whitehead rejected the scheme as impracticable and began work on an idea of his own. By 1866 he had a successful torpedo: two years and some modifications later Whitehead was able to offer his invention for sale.

One rnodel of the Whitehead weapon measured approximately 14 ft. in length and 14 in. in diameter and weighed about 300 Ib., including an 18-lb. charge of dynamite in its nose. It was powered by a compressed-air engine driving a single propeller. Its depth was controlled by a hydrostatic valve that operated rudders on the horizontal tail surfaces; there was no provision for lateral steering. Most authorities credit this torpedo with a speed of 6 knots: its range is given variously as between 200 and 700 yd.

Modifications and adaptations of the Whitehead design mere made by various nations. The most significant of these changes were the use of heat engines and gyroscopic control. British firms achieved the most notable success with propulsion units! introducing both heat engines and contrarotating propellers. From models using the Armstrong-\\'hitworth dry-heater system of 1905, British torpedoes advanced to the high-performance, steam-driven Royal Saval Torpedo factory Mark IV weapon of 1917. Concurrently with these developments the American firm E. W. Bliss company (Brooklyn) successfully used a turbine to drive their modihcation of the Whitehead design. This torpedo, called the Bliss-Leavitt. was used extensively in the U.S. navy before World War II; the destroyers transferred to Great Britain early in that war were equipped with Bliss-Leavitts.

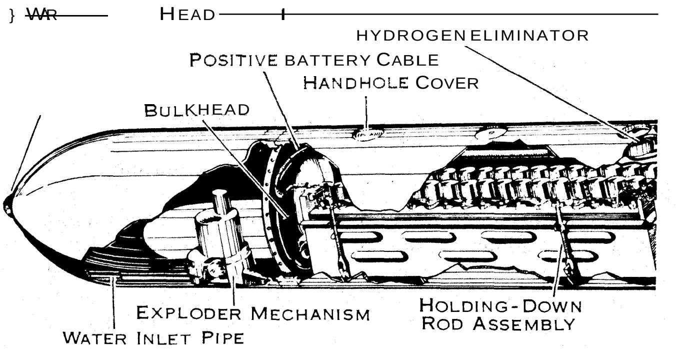
The Austrian, Ludwig Obry, is generally credited with adapting the gyroscope to use in torpedoes for directional control (1895). Any deviation from the set course caused the gyroscope to react and apply corrective movement to the vertical rudders. Further modifications to the gyroscope permitted the introduction of a set angle (up to 90°) into the torpedo's course before the steering rudders took full control. This feature allowed a ship to launch torpedoes at any point within a wide angle of heading and greatly opened up the field of torpedo tactics.

To utilize the striking power of the torpedo small, fast boats were designed to carry and launch these weapons. These torpedo boats were highly maneuverable and presented difficult targets for larger, slower cruisers and battleships. To counter them, torpedo-boat destroyers were introduced; these ships mere larger than the torpedo boats but possessed equal or greater speed. They were armed with both guns and torpedoes. From this type of ship evolved the large, heavily armed destroyer of today. See DESTROYER.

Description and Operation.— The modern torpedo differs from its predecessors in substantially increased power and reliability, and in methods of control of its underwater travel. Torpedoes may be grouped according to four general characteristics: (1) the source of propulsive power; (2) the method of control during water travel; (3) the type of target against which the torpedo will he used; and (4) the type of craft from which the torpedo is launched.

Torpedoes are driven by steam turbines or by battery-powered electric motors. Underwater travel is controlled in several ways. "Active-acoustic" torpedoes generate sound signals similar to sonar, and home on the echo received from the target. "Passive-acoustic" torpedoes home on noise generated by the target. Gyroscopic-controlled torpedoes are, as the name implies, kept on course by means of gyroscopes; this course may be straight or it may be a definite preset pattern. The pattern begins at a predetermined clistance from the launching vessel and is usually a spiral or a zigzag.

Torpedoes are intended for use against either surface vessels or submarines, or occasionally both types. Torpedoes may be launched by submarines, surface vessels, aircraft and as a com-



BY COURTESY OF U.S. BUREAU OF ORDNANCE

CUTAWAY DRAWING OF THE ELECTRIC TORPEDO MARK 18, WITH WARHEAD ATTACHED. SHOWN FROM PORT SIDE ponent of a guided missile. Frequently torpedoes are described by terms which combine the names of the launching craft and the target, *i.e.,* submarine-launched antisubmarine, or destroyer-launched antisurface vessel.

A typical n·eapon designed for above-water launching from torpedo tubes is 24 ft. long and 21 in. in diameter. The U.S. navy's Mark 15 torpedo is of these dimensions; it weighs over 3.500 lb. and carries a charge of more than 600 Ib. of the explosive torpex, which is particularly effective for underwater detonation. The Mark 15 is a three-speed, steam-driven weapon capable of traveling 15,000 yd. at a speed of 28 knots, 10,000 yd. at 33 knots or 6,000 yd. at 46 knots.

The Mark 18 torpedo (see figure) is a single-speed torpedo driven by an electric motor and designed to be launched from a submarine. It has the same diameter as the Mark 15 but is somewhat shorter. It can travel 4.000 yd. at a speed of 29 knots. Two major advantages possessed by the Mark 18 and other electric torpedoes are the absence of wake (caused by exhaust gases in the steam-driven type) and the freedom from change of weight throughout the run (steam torpedoes lose weight as their fuel is burned).

The modern torpedo is divided into four major sections: the warhead; the air flask section or, for electric torpedoes, the battery compartment; the afterbody; and the tail. The warhead carries the explosive charge and the exploder mechanism. In homing torpedoes, the homing mechanism is located in a detachable nose section, forward of the explosive-filled part of the warhead. Torpedo exploders operate either on impact with a target or on passing within a certain range of the target. Since a ship is almost never armoured on the bottom of the hull, an exploder that detonates a torpedo directly beneath the bottom is especially efiective.

An exercise head is substituted for the warhead in test and practice firings. The exercise head is a hollow shell with the same dimensions as the warhead. Liquid ballast replaces the explosive; at the end of the torpedo's run compressed gas blows the ballast out of the exercise head and the torpedo rises to the surface. A light and a smoke pot in the exercise head assist in locating the torpedo so that it may be recovered and used again.

The air-flask section of a steam torpedo is the main body of the torpedo and carries highly compressed air, water and fuel. The fuel is an alcohol-and-water mixture in some torpedoes, alcohol and Navol (a hydrogen-peroxide mixture) in others.

The afterbody is the "engine room" of the torpedo; it contains the gyroscope. the depth-regulating mechanism, the combustion flask and the turbine. The combustion flask converts the fuel-air-water mixture into steam, which drives the turbine at high speed. Reduction gears connect the turbine to the coaxial propeller shafts. The shafts pass through the tail section to the propellers. Other parts of the tail section are the tail blades and rudders.

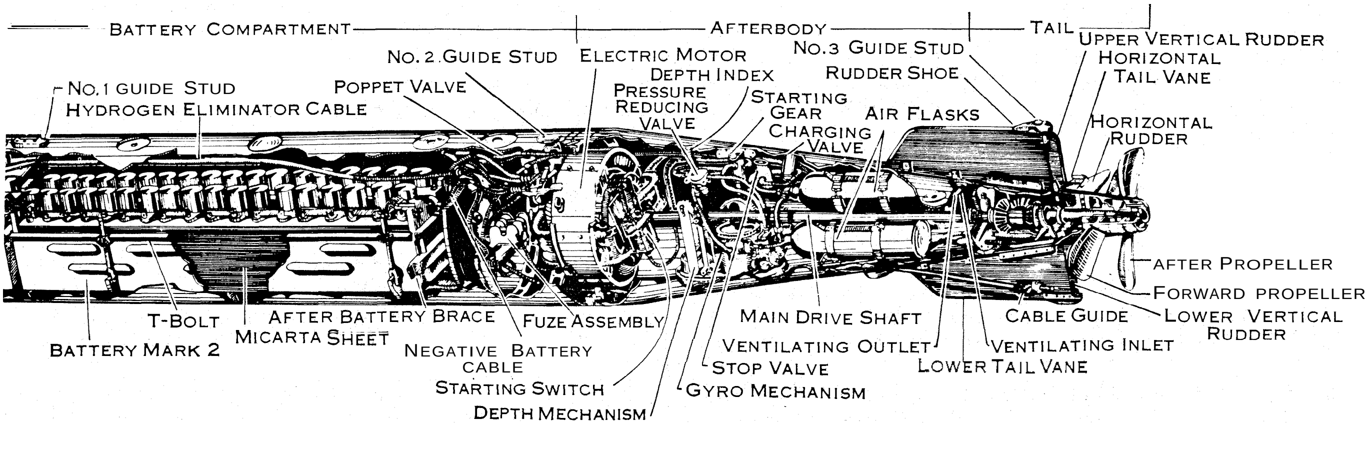
In electric torpedoes the battery compartment replaces the air-flask section. Current from the batteries drives electric motors. which in turn drive the propellers. Compressed air to power the gyroscope is stored in small air flasks in the afterbody. To minimize noise homing torpedoes are electrically powered throughout; the gyroscope is brought up to speed by an electric motor, and both vertical and horizontal rudders are electrically operated. As a further noise-reduction measure homing torpedoes are usually equipped with but a single propeller.

Most surface ships and submarines launch their torpedoes from tubes. In submarines and the most advanced surface vessels, these tubes are built into the vessel's structure. In older surface vessels. the torpedo tubes are mounted so that they can be trained to either side of the ship. Many above-water torpedo tubes are fired by means of a charge of black powder. Compounds to suppress flame and smoke are frequently added to the powder charges. and above-water tubes are often equipped with flash-hiders. Most submerged tubes and fixed, above-water tubes are discharged by means oi high-pressure air. Submarines are often equipped with devices to eliminate the air bubble caused by firing. Some submerged tubes are designed to be flooded after the torpedo is loaded: upon firing, the torpedo "swims" out of the tube. This method reduces noise and other indications of firing to a minimum. After launching, torpedoes must run for a short distance before they become "armed," or ready to explode. This provides a degree of safety for the launching vessel, particularly in the use of homing torpedoes.

Aircraft torpedoes are virtually identical to submarine and surface-ship torpedoes except in size. A typical aircraft torpedo. the C.S. navy's Mark 13, has a diameter of $22\frac{1}{2}$ in. and a length of $13\frac{1}{2}$ it. It is designed to be launched from aircraft flying at low or medium altitudes and moderate to high air speeds. .Aircraft-launched homing torpedoes are usually equipped with small parachutes designed to reduce the shock of impact with the water and thus protect the sensitive homing mechanism.

Torpedoes must be built to overcome essentially the same problems of underwater propulsion as those faced by submarines. The principal problem is to provide an adequate self-contained power supply within a vehicle of small size. This power supply must be great enough to overcome the resistance of skin friction and the drag of n·ake and propeller cavitation (*see* NAVAL ARCHITECTURE). In addition, it must drive internal mechanisms such as devices for homing. depth control and steering. Ideally torpedoes should have high speed and great endurance and should function silently but no torpedo possesses all these characteristics. Steam torpedoes with high speeds (40 knots) and long range (10.000 yd.) have been built by using a hydrogen-peroxide solution called Navol to provide the oxygen for combustion but these advantages are partially offset by the noise of the turbine and the contrarotating propellers and the telltale n·ake left on the surface. Electric torpedoes are silent but their batteries restrict either their speed or their range. New developments in marine engineering. such as the supercavitating propeller, and in electrical engineering may eventually prove adaptable to torpedo propulsion and bring about an ideal underwater weapon.

Improved performance in U.S. naval torpedoes during World War II n·as the result of intensive wartime research and development. At the outset of hostilities the U.S. navy's torpedoes were generally unsatisfactory in combat. Limited prewar funds and



excessive secrecy masked serious defects in torpedo and exploder performance. Severe criticism from the operating forces. based on dud hits, premature explosions and unaccountable misses, brought action. Efforts of the operating forces, the National Defense Research committee and the bureau of ordnance finally bore fruit but it was not until *1944* that G.S. naval forces received consistently good torpedoes.

Employment and Tactical Use.—The earliest recorded use of torpedoes in combat was in an engagement between H.M.S. "Shah," an unarmoured British frigate: and the Peruvian ironclad turret ship "Huascar." The "Huascar" had been seized by a rebellious faction and was operating in a piratical manner. In an engagement on May *29, 1377.* H.M.S. "Shah" fired a single torpedo at "Huascar." The target ship maneuvered clear with no difficulty. Authorities disagree on the earliest successful use of the automobile torpedo; it probably occurred in the war between Russis and Turkey (1877–78). It was in World War I, however. that the torpedo came of age.

During the years of the weapon's development: experiments in its tactical use were being tried. Small. fast torpedo boats, especially intended for firing torpedoes, were designed and built. As a countermeasure larger, equally fast torpedo-boat destroyers were constructed and armed with the very weapon they were intended to defeat. Large ships! up to and including battleships, were equipped with torpedo tubes. some above water and others submerged. To protect against torpedoes, armour belts were extended below the water line on major combatant vessels and anti-torpedo nets were designed for under-way use.

Maneuvering to avoid the weapon's course and to present the smallest possible target became the best means of torpedo defense. To counteract this tactic and to compensate for possible firing errors. ships usually launched several torpedoes set to run on slightly divergent courses. These "spreads!' were intended to increase chances of a hit regardless of evasive maneuvers.

The submarine was the naval vessel that used the torpedo most successfully. In the four years of World War I. German C-boats sank more than *11.000.000* tons of merchant shipping. The unrestricted submarine campaign came close to success in its attempt to deieat the Allies. (See WORLD WAR I: *Naval.*)

Between World Wars I and II, the torpedoplane (*q.v.*) was developed. An airplane carrying a torpedo extended a fleet's striking range far beyond that of its big guns. For inshore operations small. high-speed motor torpedo boats (U.S. PT's, British MTB's, German E-boats, Italian MAS-boats) were built. Submerged torpedo tubes in surface vessels fell into disuse. Cruisers and destroyers were commonly equipped with above-water tubes. Torpedo nets for under-way use disappeared. Extensive watertight compartmentation and the use of double and triple bottoms on large warships were adopted as protective measures against torpedo damage.

As in World War I, the submarine in World War II achieved its greatest success with the torpedo. In the Atlantic submarines sank more than *14.000.000* tons of Allied merchant shipping and nearly 200 naval vessels. United States submarines in the Pacific destroyed more than 5.000,000 tons of Japanese naval and merchant shipping. *(See* WORLD WAR II: *The War at Sea.)*

Torpedoplanes scored notable victories for each side in World War II. British naval aircraft sank or heavily damaged several major units of the Italian fleet in a torpedoplane attack on Taranto, It. Japanese torpedo bombers sank H.M.S. "Prince of Wales" and '.Repulse" and contributed heavily to the damage done at Pearl Harbor. U.S. torpedoplanes played a major part in sinking the world's largest battleships, "Yamato" and "Musashi."

The homing torpedo was introduced in World War II. This weapon was guided by the sound of the target ship's propellers. The German acoustic torpedo, called "Gnat" by the British and "Wren" by the Germans. was designed to home on the high-pitched sound of an escort vessel's propellers. With the escorts sunk or crippled by "Wrens," U-boats could attack a convoy with conventional torpedoes at leisure. The Allies, however, anticipated the "Wren," and were prompt in introducing a countermeasure. This was an expendable noiseniaker. called "Foxer," that was towed astern of a ship and provided a better attraction for "Wren" than the vessel's propellers.

TORPEDOPLANE. In the torpedoplane. naval science combined one of the most dangerous underwater weapons, the torpedo. with one of the most feared aerial developments, the bomber. to produce the torpedo bomber. A great tactical advantage is enjoyed by a naval force employing torpedoplanes, as the commander can launch a torpedo attack hundreds of miles from the originating ship. instead of the hundreds of yards common in destroyer or submarine attacks.

Naval experiments in aerial launching of torpedoes commenced almost as soon as experiments in the use of the plane itself. The early United States navy advocate of aerial torpedoes was Adm. Bradley Fiske, who described the advantages of such use in *1912* and finally persuaded navy technical offices to undertake the design of aircraft torpedo launching mechanisms, as well as the types of torpedoes suitable for aerial use.

By *1917* an experimental model (Bliss) torpedo of eight-inch diameter had been completed, and a successful drop was made at Huntington. L.I.. in August of that year. In May *1919* an R-6 type navy plane made the first successful drop of a live torpedo (one carrying actual explosive charge) at Hampton Roads, Va. The first navy torpedo squadron of planes was established at Yorktown. Va., in *1920* and the first carrier-based torpedoplane landed on the U.S.S. "Langley" in *1924.* In the same year, torpedoplanes helped sink the battleship "Washington" in target tests. Two years later, the new carriers "Lexington" and "Saratoga" carried torpedoplane squadrons and thereafter this type of plane played an effective part in development of naval air power. The British "Swordfish" gave yeoman service as a torpedoplane for many years, including the early phase of World War II.

In *1911* the United States entered World War II with large numbers of carrier-based Douglas Devastators. which were gradually replaced, after the battle of Midway in *1942,* with Grumman Avengers; with heavier armament and much higher speeds. Torpedoes carried by these planes were particularly designed for high-speed launchings from heights up to *100* ft. A postwar development of this type of plane was the Martin Mauler. a single-engine craft weighing more than ten tons and carrying three torpedoes. For tactical employment *see* TORPEDOES. (A. S. L.)

TORQUAY, a seaport. holiday resort and municipal borough in the Torquay parliamentary division of Devon, Eng., on Torbay, *22* mi. S. of Exeter by road. Pop. (1961) *53.915.* The beauty of its setting and the equability of its climate have gained for it a high repute as an all-year-round resort where palms and other Mediterranean plants grow. It is also a well-known conference centre.

A village existed at Torre before the foundation of the abbey for Premonstratensians by William. Lord Briwer. in *1196;* the abbey remains now house an art gallery. South of the gateway is a 13th-century building known as the Spanish harn. After the defeat of the Armada. Don Pedro's galley was brought into Torbny. and William of Orange landed there on Nov. 5. 1688. The cliff railway at Bahbacombe, to the southeast. was reconstructed. Cockington court. which is Elizabethan and later. and its fine estate. are part of the *1,330* ac. of parks and open spaces owned by the corporation.

TORQUE, the twist or torsion which a shaft undergoes n-hen transmitting power. The degree of tn-ist is very slight. but it can be measured and the horsepower that is transmitted can thus be ascertained. the method being applied particularly to steam turbines. There are several types of torsion meters for measuring horsepower, electrical, mechanical and flashlight. One of the last-named types is here described; its principle depends primarily on the straightness and very high velocity of a ray of light. Two disks are fastened to the shaft a measured distance apart. Each disk has a small slit in it, about $\frac{3}{4}$ in. by $\frac{1}{8}$ in..

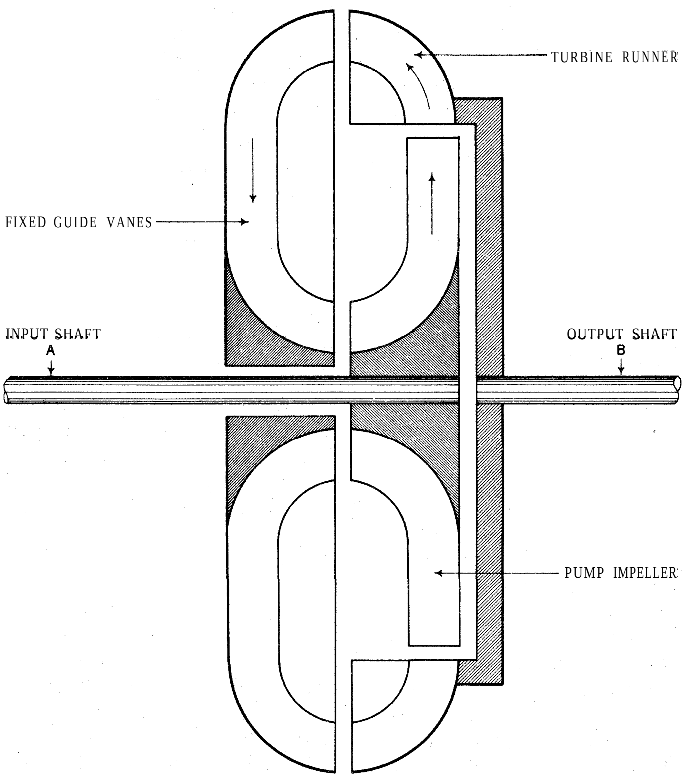
and a lamp is attached near one disk by a rigid support; the torque finder is also rigidly secured. The light from the lamp is limited by a slit of similar size to those in the disks, and the torque finder comprises a casting with a small telescopic eyepiece screwed to a brass plate which also has a slit of the same size as .the others. The plate and eyepiece can be moved circumferentially by means of a micrometer apparatus, reading to .01 of a degree. If the lamp, disks and torque finder are set so that the four slits are in line, the observer looking through the eyepiece parallel to the axis of the shaft will see the light shining in the lamp. If the shaft starts to revolve, at each rotation as the two slits in the disks pass the sight line between lamp and finder the light will be seen momentarily. The persistence of this flash with the rapidly revolving shaft makes it appear as a continuous light. When however the shaft commences to transmit power the torque throws the disk slits out of line and the light is obscured. The observer now adjusts the micrometer and the eyepiece until a sight is again taken through the disk slits. By noting the amount of the displacement thus made the degree of twist is measured, and therefrom the horsepower transmitted. See DYNAMOMETER. (F. H.)

TORQUE AMPLIFIER : see SERVOMECHANISM.

TORQUE CONVERTER. a fluid device for connecting two shafts with a change in torque (*q.v.*).

Sometimes the fluid torque converter is called a hydraulic, hydrodynamic. hydrokinetic or fluid transmission. inasmuch as power is transmitted from one shaft to another by fluid. One of the commonest applications of the fluid torque converter is in automotive transmissions as a replacement for the gearbox. The fluid torque converter pro\-ides an'automatic torque variation at different car movements and speeds and eliminates the gearshift and clutch. The converter is essentially a combination of a pump, turbine and fixed guide vanes. Oil is usually used in commercial units for the circulating fluid because of its lubricating properties, availability and stability.

Various methods can be used for joining or connecting two ro-



TCRQUE CONVERTER. SHOWING INTERNAL FLOW OF FLUID

tating shafts. such as for connecting an engine or motor to some load In many cases purely mechanical. rigid or flexible connections are most suitable: gears, chain drives and other devices can be used. In various applications, however, service requirements are best met with some form of fluid conriector.

As indicated in the figure, the input shaft A (driven, for example, by an internal-combustion engine) drives the pump impeller, which is usually a centrifugal pump runner with curved blades. Energy is transferred from the impeller to the fluid as the pump builds up speed; fluid flows from the inlet radius to the outlet radius. Leaving the impeller, the fluid enters the turbine runner. which usually has curved blades. After sufficient energy has been developed by the pump, the fluid rotates the turbine runner and turns the output shait B, which is connected to some load. Fluid leaving the turbine runner then passes through the fixed guide vanes before returning to the pump impeller. The fluid moves through a closed circuit shaped like a vortex ring. There is no rigid or mechanical connection between the input and output shafts; the connection between these shafts is solely by means of a fluid.

The fixed or stationary vanes (which are curved) change the flow direction of the fluid; thus there is a torque and speed transformation. The fixed guide vanes take some reaction; carrying it. to the fixed casing or foundation; thus the turbine torque does nor. equal the pump torque. This explains the term "torque converter." Different blade arrangements are possible. For example. the pump impeller action may be in separate stages. Similarly the turbine action or the fixed guide vane action may be in two or more stages.

The torque converter provides smooth starting of the load and absorbs torsional shocks and vibrations. If extreme loads on the output shaft of the converter stall the output shaft during operation, the input shaft will not stall but will continue running. In some converters the speed of the input shaft is almost conitant, regardless of the speed of the output shaft.

In some torque converters the starting output torque is about five times the input torque. The efficiency of a converter is defined as the ratio of the power at the output shait divided by the power at the input shaft. Converters have been built with maximum efficiencies ranging from 85% to 87%. In general. the efficiency of a torque converter is maximum at intermediate speeds. with zero efficiency at zero output shaft speed and when the input and output shafts rotate at the same speed.

Two rotating shafts could be coupled by an arrangement which includes a separate pump and a separate'turbine connected by intermediate piping. The fluid torque converter. however, provides a real saving in weight and space because of the concentric arrangement of pump impeller and turbine runner. Also, the concentric arrangement eliminates the friction loss in the intermediate piping.

A distinction should be made between a fluid coupling and a fluid torque converter. Sometimes the fluid coupling is called a fluid flywheel. If there were no fixed guide vanes in the flow circuit, then the unit would be a fluid coupling. Thus a fluid coupling is simply a combination of a centrifugal pump and a turbine. The action of the fluid coupling can be illustrated by means of two common electric fans which are set facing each other. One fan, connected to a supply of electricity, is put into motion by turning on the electric current. As the fan blades rotate, the air current turns the blades of the other fan, which is not receiving any electric current. Since there are no torque reacting elements in the fluid coupling besides the pump impeller and the turbine runner! under steady operating conditions the output torque always equals the input torque; this explains the term "fluid coupling." 'The efficiency of a fluid coupling increases from zero at zero output shaft speed to a maximum when the output and input shafts rotate at the same speed.

A torque converter can be arranged to operate as a fluid coupling if the fixed guide vanes are arranged n·ith a free wheeling device so that the vanes do not give any reaction to the fluid at certain speeds. Thus, in an automotive unit, the fluid transmission can act as a torque converter with the guide vanes fixed at low speeds; at high speeds the guide vanes can freewheel with no torque reaction, allowing the unit to operate as a fluid coupling. Thus the unit utilizes the principles of both the torque converter and the fluid coupling in their most efficient speed ranges.

See AUTOMOBILE: *Transmission System;* POWER TRANSMISSION.

(R. C. BR.)

TORQUEMADA, THOMAS (1420–1498), inquisitor-general of Spain, was born in 1420 at Valladolid. There he joined the Friars Preachers (Dominicans), took his vows, studied philosophy and received the baccalaureate in theology. About 1452 he became prior of the monastery of Santa Cruz of Segovia, a post which he held for 22 years. He retained the title, "Prior of Santa Cruz" until his death.

Torquemada was a man of strong character. His ardent love for the Catholic faith and his Spanish homeland developed in him a hatred for anything that endangered them. He was convinced that the Moors, and many of the Jews, the *Marranos* (Jewish converts to Christianity, also called *conversos* and "New Christians"), and the *Moriscos* (converts from Mohammedanism) were undermining the religious and social life of Spain. He was well thought of by contemporaries. Sebastian of Olmeda called him: "a scourge of heresy, a light of Spain, the saviour of his country and an honour to his Order." Hernando del Pulgar, secretary of Queen Isabella, referred to him as a man "of honest life, who had great zeal for the faith." Popes Sixtus IV and Alexander VI praised his zeal and wisdom, and Ferdinand and Isabella entertained a high opinion of him. Isabella may have consulted him during her frequent residences at Segovia before she became queen. She chose him as confessor on her accession to the throne. Later he was appointed confessor to Ferdinand as well.

In spite of his high station at the Spanish court, Torquemada had no desire for honours and steadfastly refused ecclesiastical preferments. He was possessed of considerable administrative ability as is witnessed by his long tenure as prior, his reorganization and direction of the inquisition and his appointment to special posts, such as visitor to the congregation of reformed Dominican priories of Aragon (1487–88). His interest in the arts is shown by his various architectural ventures, notably the construction of the monastery of St. Thomas at Avila.

The Inquisition.— In 1478 Ferdinand and Isabella decided to establish the inquisition in Castile. The motivation for this step was the problem of the *conversos* and *moriscos,* many of whom had embraced Christianity insincerely and were using the immunity and privileges thus gained to work against the Catholic faith and the unity of the Spanish nation. It is the opinion of some that the very existence of Christian Spain was at stake. A number of ecclesiastics urged the foundation of the inquisition as the only cure for these problems, and possibly Torquemada, as royal confessor, was consulted and added his voice to these representations. He and Cardinal Mendoza drafted the petition to Sixtus IV asking for authority to establish the inquisition. The pope acceded to the request in a bull of Nov. 1, 1478. Two years later, Sept. 26, 1480, the first inquisitors, Miguel Morillo and Juan de San Martin, were appointed. Mendoza and Torquemada appear to have acted as consultors. Morillo and San Martin proceeded to Seville where they established the first tribunal. The complaints of severity and injustice lodged at Rome during these early years of the inquisition were directed against the activities of these two men. On Feb, 11, 1482 Sixtus IV appointed Torquemada and seven other Dominicans as assistant inquisitors. The following year Isabella petitioned for a reorganization of the inquisition under unified control. At the suggestion of Mendoza, she recommended Torquemada as inquisitor-general and early in October he was appointed for Castile. On Oct. 17 his jurisdiction was extended to Aragon, and in Feb. 1486 to Barcelona. He was recommissioned by Pope Innocent VIII in 1485 and 1486. By virtue of his office he was appointed a member of the royal council.

As inquisitor-general Torquemada was the highest official of the Spanish inquisition. He had wide powers of appointment and dismissal of subordinate inquisitors and appellate power in cases brought before episcopal courts (1496). His jurisdiction did not extend to prelates, and Jews were tried only in cases of proselytism, sorcery, or other spiritual offenses. Torquemada reorganized the inquisition completely and promulgated standard rules of procedure. He constituted local tribunals at Seville, Jaén, Cordova, Ciudad Real (later transferred to Toledo) and at Saragossa. A supreme council of five members, including himself, was organized for the hearing of appeals.

On Nov. 29, 1484, he convoked a general assembly of all Spanish inquisitors at Seville and presented 28 articles for their guidance. New statutes were added in Dec. 1484, in 1485, 1488 and 1498. It is noteworthy that crimes other than heresy and apostasy, such as witchcraft, necromancy, bigamy, blasphemy and usury were brought under the inquisition's jurisdiction. As in the royal tribunals, torture was authorized as a means of gaining evidence. The use of irons was not allowed. Under Isabella about 2,000 persons were executed by the inquisition. Torquemada was probably responsible for one-half to two-thirds of this number. It is estimated that approximately 100,000 cases were tried during his tenure as inquisitor-general. On three occasions Torquemada sent Alphonse Badaja to Rome to represent him before the pope. In June 1494, owing to Torquemada's age and infirmity, Alexander VI appointed four assistant inquisitors. Their power was equal to Torquemada's, though he retained control until his death.

Expulsion of the Jews.—Ferdinand and Isabella had long contemplated the expulsion of the Jews, whom they considered a source of disunity for the kingdom and of contamination for the *conversos.* Thus on March 31, 1492, they signed an edict ordering the expulsion of all Jews who had not embraced Christianity. Torquemada may have been consulted before the order was issued and perhaps presented the evidence of the La Guardia trial (1490–91) as a further inducement to the sovereigns. Undoubtedly he was in thorough sympathy with the move. It is estimated that from 160,000 to 200.000 Jews left Spain. There is no adequate proof for the tale that when a ransom of 30,000 ducats was offered by the Jews, Torquemada indignantly threw his crucifix on the table and asked the king and queen if, like Judas, they would betray their Lord for money. This story seems to have become current toward the end of the 16th century.

Some critics have said that Torquemada never travelled unless accompanied by 250 armed retainers and 50 horsemen. Undoubtedly he was sufficiently protected, but there is no contemporary evidence for this statement, nor for the charge that he never ate unless the horn of a unicorn or the tongue of a scorpion lay at the side of his plate. These accusations first appeared almost a century after his death. Torquemada died at Avila, Sept. 16, 1498.

TORRANCE, an industrial and residential city on the southwestern coastal plain of Los Angeles county in southern California. U.S., 15 mi. from downtown Los Angeles (*q.v.*). It was founded in 1911 by Jared Sidney Torrance and associates, who purchased 3.500 ac. of the Rancho San Pedro for slightly more than $1,000,000. Torrance was planned as an industrial community; a tool company began operations late in 1912, with 280 employees, and was soon joined by an ironworks. By the second part of the 20th century there were more than 200 manufacturing plants in the city

Torrance was incorporated in 1921; it has a council-manager form of government, in effect since 1948. After discovery of oil in the nearby area, the city expanded rapidly. The population in 1960 was 100.991; for comparative population figures *see* table in CALIFORNIA: *Population.* Through a series of annexations after 1950, a large residential district, with modern housing, was added to the city. This stimulated construction of marketing centres, modernization of municipal facilities, including recreational areas, and the completion of a new civic centre. (R. C. GM.)

TORRE ANNUNZIATA, a seaport of Campania. Italy, in the province of Napoli, on the east of the Bay of Naples, and at the south foot of Mt. Vesuvius, 14 mi. S.E. of Naples by rail. Pop. (1951) 52,175. It is on the main line to Battipaglia, at the point of junction of a branch line from Cancello round the east of Vesuvius, and of the branch to Castellammare di Stabia and Gragnano. It has an arms factory and other ironworks, manufacture of macaroni and breeding of silkworms. There are numerous mineral springs.

TORRE DEL GRECO, a seaport of Campania, Italy, in the province of Napoli, $7\frac{1}{2}$ mi. S.E. of that city by rail. Pop. (1951) 50,099. It lies at the southwest foot of Vesuvius, on the shore of the Bay of Naples. It is built chiefly of lava, and stands on the lava stream of 1631, which destroyed two-thirds of the older town. Great damage was done by the eruption of 1737 and 1794; the earthquake of 1857 and the eruption of Dec. 8, 1861, were even more destructive.

TORRENS, SIR ROBERT RICHARD (1814–1884), British colonial statesman, was born at Cork, Ireland, in 1814, and educated at Trinity college, Dublin. He went to South Australia in 1840, and was appointed collector of customs. He was an official member of the first legislative council and in 1852 was treasurer and registrar general. When responsible government was established he was elected as a representative for Adelaide and became a member of the first ministry. In 1857 he introduced his famous Real Property act, the principle of which consists of conveyance by registration and certificate instead of deeds. The system was rapidly adopted in the other colonies and elsewhere, and was expounded by the author during a visit to the United Kingdom in 1862–64. After leaving South Australia, Torrens represented Cambridge in the house of commons from 1868–74; in 1872 he was knighted. He was the author of works on the effect of gold discoveries on currency, and other subjects. He died Aug. 31, 1884.

TORRENS, WILLIAM TORRENS McCULLAGH (1813–1894), English politician and social reformer, son of James McCullagh, was born near Dublin Oct. 13, 1813. He was called to the bar, and in 1835 became assistant commissioner on the special commission on Irish poor-relief, which resulted in the extension of the workhouse system in Ireland in 1838. In the '40s he joined the Anti-Corn Law league, and in 1846 published his *Industrial History of Free Nations*. From 1847–52 he represented Dundalk in parliament, in 1857 he was returned for Yarmouth, and from 1865–85 he represented Finsbury. Torrens devoted himself mainly to social questions in parliament. His amendment to the Education bill of 1870 established the London School board, and his Artisans' Dwellings bill in 1868 facilitated the clearing away of slums by local authorities. He wrote *Twenty Years in Parliament* (1893) and *History of Cabinets* (1894). He died in London April 26, 1894.

TORRENS, LAKE: *see* SOUTH AUSTRALIA.

TORREÓN, a modern city of Mexico in the state of Coahuila, is located on the Rio Nazas about 788 mi. N.W. of the federal capital. Pop. (1950) 128.976; (1958 est.) 142,100. Opposite is the picturesque colonial city of Gómez Palacio in the state of Durango. Torreón is an important railway juncture served by the El Paso to Mexico City line of the National Railroad of Mexico, and by branch lines to Durango and Monterrey. It is also served regularly by bus and air lines. Torreón's industries, such as cotton and flour mills, and iron and steel works, make it one of the most important manufacturing centres in northern Mexico. It is also the commercial centre for the cotton- and wheat-growing region known as La Laguna, one of the largest state-operated agricultural co-operatives in Mexico, begun in 1936 under Pres. Lázaro Cárdenas. , (R. B. McCK.)

TORRES NAHARRO, BARTOLOMÉ DE (1480–1530), Spanish dramatist. was born toward the end of the 15th century at Torres, near Badajoz. After some years of soldiering and of captivity in Algiers. Torres Naharro took orders, settled in Rome about 1511, and there devoted himself chiefly to writing plays. Although he alludes to the future pope, Clement VII, as his protector, he left Rome to enter the household of Fabrizio Colonna at Naples where his works were printed under the title of *Propaladia* 1) . He is conjectured to have returned to his native place, and to have died there shortly after 1529. His *Diálogo del nacimiento* is written in unavowed, though obvious, imitation of Encina, but in his subsequent plays he shows a much larger conception of dramatic possibilities. He classifies his pieces as *comedias á noticia* and *comedias á fantasia;* the former, of which the *Soldatesca* and *Tinellaria* are examples, present in dramatic form incidents within his personal experience; the latter, which include such plays as *Serafina, Wimenea, Calamita* and *Aquilana,* present imaginary episodes with adroitness and persuasiveness. Torres Naharro is much less dexterous in stagecraft than many inferior successors, his humour is rude and boisterous and his diction is unequal; but to a varied knowledge of human nature he adds knowledge of dramatic effect, and his rapid dialogue, his fearless realism and vivacious fancy prepared the way for the romantic drama in Spain.

TORRES VEDRAS, 43 mi. N.W. of Lisbon, Portugal, on the Lisbon-Figueira da Foz railway. Pop. (1950) 5,178. Roman inscriptions were found there, but the Latin name of the town, *Turres Veteres,* is probably mediaeval. There were "lines of Tôrres Vedras," constructed by Wellington in 1810 *(see* PENINSULAR WAR). There also in 1846 the troops of General Saldanha defeated those of the Count de Bomfim.

TORRES Y VILLAROEL, DIEGO DE (1696–1759?), Spanish writer, was born in 1696 at Salamanca, where his father was bookseller to the university. In his teens Torres escaped to Portugal where he enlisted under a false name; he next moved to Madrid, living from hand to mouth as a hawker; in 1717 he was ordained subdeacon, resumed his studies at Salamanca, and in 1726 became professor of mathematics at the university. Torres was suspected of complicity in the stabbing of a priest and fled to Portugal, where he remained until his innocence was proved. He then returned to his chair, which he resigned in 1751 to act as steward to two noblemen. Torres had so slight a knowledge of mathematics that his appointment as professor was thought scandalous even in his own scandalous age, yet he quickly acquired a store of knowledge which he displayed with serene assurance. His almanacs, his farces, his devotional and pseudoscientific writings show that he possessed the alert adaptiveness of the born adventurer; but all that remains of his 14 volumes (1745–52) is his autobiography, an amusing record of cynical effrontery and successful imposture. He was known to be alive in 1758, but the date of his death is uncertain.

TORREY, JOHN (1796–1873), U.S. botanist and chemist, originator of the monumental *Flora of North America,* was born in New York city, Aug. 15, 1796. He graduated (M.D.) in 1818 from the College of Physicians and Surgeons in New York. After holding various professorships (chemistry. geology, mineralogy and natural history), in 1836 he became New York state botanist. Torrey's *Flora of the State of New York* was produced in 1843, and from 1838 to 1843 he carried on the publication of the earlier portions of *Flora of North America,* with the assistance of his pupil Asa Gray (*q.v.*). From 1853 he was chief assayer to the U.S. assay office when it was located in New York city. In or about 1860 he gave his valuable herbarium and botanical library to Columbia college. Torrey continued to take an interest in botanical teaching until his death at New York on March 10, 1873.

See A. D. Rodgers, John *Torrey* (1942).

TORREY, REUBEN ARCHER (1856–1928), U.S. evangelist, was born in Hoboken, N.J., Jan. 28, 1856. He graduated from Yale university in 1875 and from the Yale divinity school in 1878. He became a Congregational minister in 1878, studied theology at Leipzig and Erlanger in 1882–83, joined D. L. Moody in his evangelistic work in Chicago in 1889, and became pastor of the Chicago Avenue church in 1894 and afterward superintendent of the Moody Bible institute of Chicago.

In 1902–03 he made an evangelistic tour, preaching in many parts of the world, and with Charles McCallon Alexander conducted revival services in Great Britain in 1903–05; Torrey conducted a similar campaign in U.S. and Canadian cities in 1906–07, returned to England, Scotland and Ireland in 1911 and visited

Japan and China in 1919. He was dean of the Bible institute, Los Angeles, 1912–24, and pastor of the Church of the Open Door, Los Angeles, 1915–24. Included among his many religious works are: *The Fundamental Doctrines of the Christian Faith* (1919), *The Christ of the Bible* (1923) and *Lectures on First Epistle of John* (1928). His books were translated into many languages. He died Oct. 26, 1928.

TORRICELLI, EVANGELISTA (1608–1647), Italian physicist and mathematician who discovered the principle of the barometer, was born at Faenza on Oct. 15, 1608. In 1627 he went to Rome to study science under the Benedictine Benedetto Castelli, professor of mathematics at the Collegio di Sapienza. The perusal of Galileo's third dialogue of the *Discorsi . . . a due nuove scienze* (1638) inspired him with many developments of the mechanical principles there set forth, which he embodied in the treatise *De motu* (printed among his *Opera geometrica,* 1644). In 1641 he went to Florence, where he met Galileo and acted as his amanuensis during the three remaining months of Galileo's life. After Galileo's death Torricelli was nominated grand-ducal mathematician and professor of mathematics in the Florentine academy. The discovery of the principle of the barometer (*q.v.*) which has perpetuated his fame ("Torricellian tube," "Torricellian vacuum") was made in 1643. Torricelli was brought into controversy with G. P. de Roberval as to the priority of the solution of a problem on the properties of a cycloid. Torricelli wrote on fluid motion, on the theory of projectiles and on the motion of two bodies connected by a string passing over a fixed pulley. He used and developed B. Cavalieri's method of indivisibles. He died at Florence, Oct. 25, 1647.

TORRIGIANO, PIETRO (1472–1528), Italian sculptor whose greatest achievements were the tombs he executed in England, was born and educated in Florence. For a brief period he was a professional soldier. A wanderer by nature, he carved stucco decorations (1493) in the Borgia apartments of the Vatican; later he worked in Bologna and in Siena cathedral on the Piccolomini altar (*c.* 1501). Subsequently he traveled to Antwerp, where he engaged in unspecified work for Marguerite of Austria (1509–10), and thereafter went to England. In the chapel of Henry VII in Westminster abbey, London, are his masterpieces: the double tomb of Henry VII and Elizabeth of York (1512–18), whose gilded bronze effigies lie upon a black-marble base decorated with bronze reliefs; and the tomb of the king's mother, Margaret of Richmond, in similar Renaissance style. The high altar (1517–22) of the same chapel, also commissioned of Torrigiano, was destroyed in 1643. The tomb of Henry VIII, ordered in 1518, was never begun. During 1519 and 1520 Torrigiano returned to Florence to engage other sculptors as his assistants in London. Sometime after 1522 he went from England to Spain, probably with the hope of finding important commissions there. The large terracotta statues of St. Jerome and of the Madonna with the Child in the Seville museum are the only preserved works of his Spanish sojourn. He died in July or August 1528 while in prison at Seville, held under charge of heresy by the Inquisition.

TORRINGTON, ARTHUR HERBERT, EARL OF (1647–1716), British admiral, was the son of a judge, Sir Edward Herbert (*c.* 1591–1657). He entered the navy in 1663, and served in the Dutch wars of the reign of Charles II, as well as against the Barbary pirates. From 1680 to 1683 he commanded in the Mediterranean. The known royalist sentiments of his family and his reputation as a naval officer ensured the favour of James II, who appointed him rear admiral of England and master of the robes. But Herbert refused to support the king's proposal for the repeal of the Test act, and was dismissed from his places. He now entered into communication with the agents of the prince of Orange. After the acquittal of the seven bishops in 1688 he carried the invitation to William of Orange. After the Revolution Herbert was named first lord of the admiralty, and took the command of the fleet at home. In 1689 he was at sea attempting to prevent the French admiral Château-Renault (*q.v.*) from landing the troops sent by the king of France to the aid of King James in Ireland. Though he fought an action with the French in Bantry bay May 10 he failed to baffle Château-Renault, who had a stronger force. In May 1689 he was created earl of Torrington. In 1690 he was in the channel with a fleet of 56 English and Dutch vessels, when he found himself confronted with the much more powerful French fleet. He proposed to retire to the Thames, but the council of regency, knowing that the Jacobites were preparing for a rising, and only waiting for the support of a body of French troops, ordered him not to lose sight of the enemy, but rather than do that to give battle "upon any advantage of the wind." On July 10 Torrington made a half-hearted attack on the French off Beachy Head in which his own ship was kept out of fire, and severe loss fell on his allies. Then he retired to the Thames. The French pursuit was fortunately feeble, and the loss of the allies was comparatively slight. Torrington was brought to trial before a court martial in December, and acquitted. He died April 14, 1716.

The unfavourable account of his moral character reported by Dartmouth to Pepys is confirmed by Bishop Burnet, who had seen much of him during his exile in Holland. Torrington originated the phrase "a fleet in being."

See Charnock's *Biog. Nav.,* i 258. The best account of the battle of Beachy Head is to be found in "The Account given by Sir John Ashby Vice-Admiral and Rear-Admiral Rooke, to the Lords Commissioners" (1691).

TORRINGTON, GEORGE BYNG, VISCOUNT (1663–1733), English admiral, was born at Wrotham, Kent, and entered the navy in 1678. In 1688 he helped to win the fleet over to the prince of Orange; appointed to the command of the "Nassau" in 1702 he was present at the burning of the French fleet at Vigo, and in 1703 was made rear admiral of the red. He served in the Mediterranean (1704) and at the battle of Malaga, after which he was knighted. In 1708, as admiral of the blue he prevented the Old Pretender from landing in Scotland; and ten years later defeated the Spaniards off Passaro, after which the king sent him full powers to negotiate with the princes and states of Italy. To his conduct it was owing that Sicily was subdued and the king of Spain forced to accept the terms prescribed by the Quadruple alliance. On his return to England in 1721 he was made rear admiral and a member of the privy council, and was created Baron Byng of Southill in Bedfordshire, Viscount Torrington in Devonshire and a Knight Companion of the Bath (1725). George II made him first lord of the admiralty in 1727. He died Jan. 17, 1733.

See *Memoirs relating to Lord Torrington,* Camden Soc. new series 46, and *A True Account of the Expedition of the British Fleet to Sicily, 1718–1720,* published anonymously, but known to be by Thomas Corbett of the admiralty in 1739. Forbin's *Memoirs* contain the French side of the expedition to Scotland in 1708.

TORRINGTON (GREAT TORRINGTON), a market town and municipal borough in the Torrington parliamentary division of Devon, Eng., on the Torridge, 36 mi. N.W. of Exeter by road. Pop. (1951) 2,873. Area 5.6 sq.mi. From early times Torrington, or *Toritone* as it is called in the Domesday survey, has occupied a prominent place among the borough towns of Devon, for it was a self-governing community at least three and a half centuries before it received its first royal charter of incorporation from Mary I in 1554. Some precharter mayors or *praepositi* are recorded, the first in 1183. The borough had a fair in 1221. Recognition of its early importance is shown by the fact that it had been granted a parliamentary franchise from 1295 to 1369, when the borough sent two members to parliament. On the petition of the burgesses, the town was relieved of the burden. Of Torrington castle nothing remains. It was probably first erected by the baronial owner of the manor, William de Toriton (1130–*c.* 1185). A royal mandate was issued in 1228 for its destruction, the castle having been built without a royal licence. It was rebuilt by De Toriton's successor Sir Richard de Merton, who was licensed to crenelate it in 1338–39. During the Civil Wars, the parish church suffered severely by an explosion of gunpowder on Feb. 16, 1645, when some 200 persons perished; and at the eastern end of the town the victorious parliamentarians, under Sir Thomas Fairfax, fought a battle in which several hundred royalists mere slain and the town captured. The parish register contains the names of many of those who perished and were buried in the churchyard. The chief manufactures are milk products and gloves.

See J. J. Alexander and W. R. Hooper, *The History of Great Torrington. . . .* (Sutton, Surrey, 1948).

TORRINGTON, a city of Connecticut, U.S., is located 23 mi. W. of Hartford on the Naugatuck river, surrounded by the Litchfield hills in a region of great natural beauty. First settled in 1735 as part of the town of Windsor, Torrington was organized as a town in 1740, incorporated as a borough in 1887 and chartered as a city in 1923. At the time of first settlement the community was isolated and in danger of attack by the Mohawk Indians; a fort was erected in 1744 at a cost of £70. During the American Revolution the entire male population over 20 years (169 in all) enlisted in two companies for service in the Continental army. Samuel J. Mills, Jr. (1783–1818), founder of the American Board of Commissioners for Foreign Missions (Congregational), was born in Torrington. In the 19th century Torrington was a centre of abolitionist sentiment and was, appropriately enough, the birthplace of John Brown (*q.v.*). Torrington's earliest industry was shipmast production. This was the town's industrial mainstay until the exhaustion of the pine forests about 1813 when the first textile mill was built. Abundant water power led to production of brass articles (particularly kettles and wire), German silver and other metal products. Torrington is the market and banking centre for west-central Connecticut. For comparative population figures *see* table in CONNECTICUT: *Population.* (GL. W.)

TORSTENSSON, LENNART, COUNT (1603–1651), Swedish soldier, son of Torsten Lennartsson, commandant of Elfsborg, was born at Forstena in Vestergotland. At the age of 15 he became one of the pages of the young Gustavus Adolphus and served during the Prussian campaigns of 1628–29. In 1629 he was set over the Swedish artillery, and contributed to the victories of Breitenfeld (1631) and Lech (1632). The same year he was taken prisoner at Alte Veste and shut up for nearly a year at Ingolstadt. Under Banér he rendered distinguished service at the battle of Wittstock (1636) and during the energetic defense of Pomerania in 1637–38, as well as at the battle of Chemnitz (1638) and in the raid into Bohemia in 1639. Illness compelled him to return to Sweden in 1641, when he was made a senator. The sudden death of Banér in May 1641 recalled Torstensson to Germany as generalissimo of the Swedish forces and governor-general of Pomeraniz. He was at the same time promoted to the rank of field marshal. The period of his command (1641–45) forms one of the most brilliant chapters in the millitary history of Sweden. In 1642 he marched through Brandenburg and Silesia into Moravia, taking all the principal fortresses on his way. On returning through Saxony he well nigh annihilated the imperialist army at the second battle of Breitenfeld (Oct. 23, 1642). In 1643 he invaded Moravia for the second time, but was suddenly recalled to invade Denmark, when his rapid and unexpected intervention paralysed the Danish defense on the land side, though Torstensson's own position in Jutland was for a time precarious owing to the skilful handling of the Danish fleet by Christian IV.

In 1644 he led his army for the third time into the heart of Germany and routed the imperialists at Jiiterbog (Nov. 23). At the beginning of Nov. 1645 he broke into Bohemia, and the brilliant victory of Jankow (Feb. 24, 1645) laid open before him the road to Vienna. Yet, though one end of the Danube bridge actually fell into his hands, his exhausted army was unable to penetrate any farther and, in December the same year, Torstensson, crippled by gout, was forced to resign his command and return to Sweden. In 1647 he was created a count. From 1648 to 1651 he ruled all the western provinces of Sweden, as governor-general. On his death at Stockholm (April 7, 1651) he was buried solemnly in the Riddarholmskyrka, the Pantheon of Sweden.

See J. W. de Peyster, *History of the Life of L. Torstensson* (Poughkeepsie, 1855); J. Feil, *Torstensson before Vienna* (trans. by de Peyster, New York, 1885); Gustavus III, *Eulogy of Torstensson* (trans. by de Peyster, New York, 1872). (R. N. B.)

TORT, the technical term, in the law of England, of those dominions and possessions of the British empire where the common law has been received or practically adopted in civil affairs, and of the United States, for a civil wrong, *i.e.,* the breach of a duty imposed by law, by which breach some person becomes entitled to sue for damages. A tort must, on the one hand, be an act which violates a general duty. The rule which it breaks must be one made by the law, not, as in the case of a mere breach of contract, a rule which the law protects because the parties have made it for themselves. On the other hand, a tort is essentially the source of a private right of action. An offense which is punishable, but for which no one can bring a civil action, is not a tort. It is quite possible for one and the same act to be a tort and a breach of contract, or a tort and a crime; it is even possible in one class of cases for the plaintiff to have the option—for purposes of procedural advantage—of treating a real tort as a fictitious contract; but there is no necessary or general connection. Again, it is not the case that pecuniary damages are always or necessarily the only remedy for a tort; but the right to bring an action in common law jurisdiction, as distinct from equity, matrimonial or admiralty jurisdiction, with the consequent right to damages, is invariably present where a tort was committed.

This technical use of the French word *tort* (which at one time was near becoming a synonym of *wrong* in literary English) is not very ancient, and anything like systematic treatment of the subject as a whole is very modern. From about the middle of the 19th century there was a current assumption that all civil causes of action must be founded on either contract or tort; but there is no historical foundation for this doctrine, though modified forms of the action of trespass—actions *in consimili casu,* or "on the case" in the accustomed English phrase—did in practice largely supplant other more archaic forms of action by reason of their greater convenience. The old forms were designed as penal remedies for manifest breach of the peace or corruption of justice; and traces of the penal element remained in them long after the substance of the procedure had become private and merely civil. The transition belongs to the general history of English law.

In England the general scope of the law of torts was never formulated by authority. But there is no doubt that duties enforced by the English law of torts are broadly those which the Roman institutional writers summed up in the precept *Alterum non laedere.* Every member of a civilized commonwealth is entitled to require of others a certain amount of respect for his person, reputation and property, and a certain amount of care and caution when they go about undertakings attended with risk to their neighbours. Under the modern law, it is submitted, the question arising when one man wilfully or recklessly harms another is not whether some technical form of action can be found in which he is liable, but whether he can justify or excuse himself. This view, at any rate, is countenanced by a judgment of the supreme court of the U.S. delivered in 1904. If it be right, the controverted question whether conspiracy is or is not a substantive cause of action seems to lose most of its importance. Instead of the doubtful proposition of law that some injuries become unlawful only when inflicted by concerted action, we shall have the plain proposition of fact that some kinds of injury cannot, as a rule, be inflicted by one person with such effect as to produce any damage worth suing for.

The precise amount of responsibility can be determined only by full consideration in each class of cases. But what makes the law of torts effective, especially with regard to redress for harm suffered by negligence, is the universal rule of law that every one is answerable for the acts and defaults of his servants (that is, all persons acting under his direction and taking their orders from him or some one representing him) in the course of their employment. The person actually in fault is not the less answerable, but the remedy against him is very commonly not worth pursuing. But for this rule corporations could not be liable for any negligence of their servants, however disastrous to innocent persons, except so far as it might happen to constitute a breach of some express undertaking. We have spoken of the rule as universal, but, in the case of one servant of the same employer being injured by the default of another, an unfortunate aberration of the courts, which started from small beginnings in the second quarter of the 19th century, was pushed to extreme results, and led to great hardship. A partial remedy was applied in 1880 by the Employers' Liability act; and in 1897 a much bolder step was taken by the Workmen's Compensation act (superseded by later amendment and extension now consolidated in an act of 1925). The Workmen's Compensation act includes cases of pure accident, where there is no fault at all, or none that can be proved, and therefore goes beyond the reasons of liability with which the law of torts has to do. In fact, it establishes a kind of compulsory insurance, justifiable only on wider grounds of policy.

There are kinds of cases, on the other hand, in which the law, without aid from legislation, has imposed on occupiers and other persons in analogous positions a duty stricter than that of being answerable for themselves and their servants. Duties of this kind are called "duties of insuring safety." Generally they extend to having the building, structure, or works in such order, having regard to the nature of the case, as not to create any unusual danger to persons lawfully frequenting, using or passing by them, which the occupier knows or ought to know and could prevent by reasonable care; but in some cases of "extra-hazardous" risk, even proof of all possible diligence—according to English authority, which is not unanimously accepted in America—will not suffice.

Classification.— The classification of actionable wrongs is perplexing. We may start either from the character of the defendant's act or omission, with regard to his knowledge, intention and otherwise; or from the character of the harm suffered by the plaintiff. Whichever of these we take as the primary line of distinction, the results can seldom be worked out without calling in the other. Taking first the defendant's position, the widest governing principle is that, apart from various recognized grounds of immunity, a man is answerable for the "natural and probable" consequences of his acts; *i.e.,* such consequences as a reasonable man in his place should have foreseen as probable. Still more is he answerable for what he did actually foresee and intend. Knowledge of particular facts may be necessary to make particular kinds of conduct wrongful. Such is the rule in the case of fraud and other allied wrongs, including what is rather unhappily called "slander of title," and what is now known as "unfair competition" in the matter of trade names and descriptions, short of actual piracy of trade-marks. But where an absolute right to security for a man's person, reputation or goods is interfered with, neither knowledge nor specific intention need be proved. This rule was known some time ago to apply to the exercise of rights of property, and such speculative doubt as remained was removed by the decision of the house of lords in the leading case of Allen v. Flood (1898, A.C. 1). We now know that it applies to the exercise of all common rights. The exceptions are very few, and must be explained by exceptional reasons. Indeed, only two are known to the present writer—malicious prosecution, and the misuse of a "privileged occasion" which would justify the communication of defamatory matter if made in good faith. In each case the wrong lies in the deliberate perversion of a right or privilege allowed for the public good, though the precise extent of the analogy is not certain at present. It was formerly supposed that an action by a party to a contract against a third person for procuring the other party to break his contract was within the same class, *i.e.,* that malice must be proved. But since Allen v. Flood, and the later decision of the house of lords in *Quinn* v. Leathern (1901, A.C. 495), this view ceased to be tenable. The ground of action is the intentional violation of an existing legal right; which, however, from 1906, may be practised with impunity in Great Britain "in contemplation or furtherance of a trade dispute": Trade Disputes act, sec. 3. It must be remembered, however, that the presence or absence of personal ill will, and the behaviour of the parties generally, may have an important effect, when liability is proved or admitted, in mitigating or aggravating the amount of damages awarded by juries and allowed by the court to be reasonable. It may likewise be noted, by way of caution, that some problems of criminal law, with which we are not here concerned, require more subtle consideration. However, it is hardly ever safe to assume that the bounds of civil and criminal liability will be found coextensive. Perhaps we may go so far as to say that a man is neither civilly nor criminally liable for a mere omission (not being disobedience to a lawful command which he was bound to obey), unless he has in some way assumed a special duty of doing the act omitted.

We have already had to mention the existence of grounds of immunity for acts that would otherwise be wrongful. Such grounds there must be if the law is to be enforced and justice administered at all, and if the business of life is to be carried on with any freedom. Roughly speaking, we find in these cases one of the following conditions: Either the defendant was executing a lawful authority; or he was justified by extraordinary necessity; or he was doing something permitted by legislation for reasons of superior utility, though it may produce damage to others, and either with or without special provisions for compensating damage; or he was exercising a common right in matters open to free use and competition; or the plaintiff had, by consent or otherwise. disabled himself from having any grievance. Pure accident will hardly seem to any one who is not a lawyer to be a special ground of exemption, the question being rather how it could ever be supposed to be a ground for liability. But it was supposed so by many lawyers down to recent times; the reason lying in a history of archaic ideas too long to be traced here. Exercise of common rights is the category where most difficulty arises. Here, in fact, the limits of man's freedom must be fixed by a sense of policy not capable of formal demonstration.

As Justice Holmes of the supreme court of the U.S. said, we allow unlimited trade competition (so long as it is without fraud) though we know that many traders must suffer, and some may be ruined by it, because we hold that free competition is worth more to society than its costs. A state with different economic foundations might have a different law on this, as on many other points. This freedom extends not only to the exercise of one's calling, but to choosing with whom and under what conditions one will exercise it. Also the law will not enquire with what motives a common right is exercised; and this applies to the ordinary rights of an owner in the use of his property as well as to the right of every man to carry on his business. The rule that a man's motives for exercising his common rights are not examinable involves the consequence that advising or procuring another, who is a free agent, to do an act of this kind can, a fortiori, not be an actionable wrong at the suit of a third person who is damnified by the act, and that whatever the adviser's motives may be. This appears to be included in the decision of the house of lords in Allen v. Flood. That decision, though not binding in any American court, is approved and followed in most American jurisdictions. It is otherwise where a system of coercion is exercised on a man's workmen or customers in order to injure him in his business. The extension of immunity to such conduct would destroy the value of the common right which the law protects: Quinn v. *Leathem.*

Individual Rights.--Owners and occupiers of immovable property are bound to respect one another's convenience within certain limits. The maxim or precept **Sic** utere tuo ut *alienum* non laedas does not mean that I must not use my land in any way which can possibly diminish the profit or amenity of my neighbour's. That would be false. It is a warning that both his rights and mine extend beyond being free from actual unlawful entry, and that if either of us takes too literally the more popular but even less accurate maxim, "Every man may do as he will with his own," he will find that there is such a head of the law as nuisance.

From the point of view of the plaintiff, as regards the kind of damage suffered by him, actionable wrongs may be divided into four groups. We have some of a strictly personal kind; some which affect ownership and rights analogous to ownership; some which extend to the safety, convenience and profit of life generally—in short, to a man's estate in the widest sense; and some which may, according to circumstances, result in damage to person, property or estate, any or all of them. Personal wrongs touching a man's body or honour are assault, false imprisonment, seduction or "enticing away" of members of his family. Wrongs to property are trespass to land or goods, "conversion" of goods (*i.e.,* wrongful assumption of dominion over them), disturbance of easements and other individual rights in property not amounting to exclusive possession. Trespass is essentially a wrong to possession; but with the aid of actions "on the case" the ground was practically covered. Then there are infringements of incorporeal rights which, though not the subject of trespass proper, are exclusive rights of enjoyment and have many incidents of ownership. Actions, in some cases expressly given by statute, lie for the piracy of copyright, patents and trade-marks. A wrong to a man's estate in the larger sense above noted is defamation —not a strictly personal wrong, because according to English common law the temporal damage, not the insult, is, rightly or wrongly, made the ground of action and the defendant's intention is immaterial. It is even possible to write an actionable libel without knowing that one's words can be thought to reflect on the plaintiff, or (it seems) that there is any such person: so the house of lords decided in *Hulton & Co.* v. *Jones* in 1910. Others are deceit, so-called "slander of title" and fraudulent trade competition which are really varieties of deceit; malicious prosecution; and nuisance, which, though most important as affecting the enjoyment of property, is not considered in that relation only. Finally, we have the results of negligence and omission to perform special duties regarding the safety of one's neighbours or the public, which may affect person, property, or estate.

The law of wrongs is made to do a great deal of work which, in a system less dependent on historical conditions, we should expect to find done by the law of property. We can claim or reclaim our movable goods only by complaining of a wrong done to our possession or our right to possess. There is no direct assertion of ownership like the Roman *vindicatio.* The law of negligence, with the refined discussions of the test and measure of liability which it introduced, is wholly modern; and the same may be said of the present working law of nuisance, though the term is of respectable antiquity. Most recent of all is the rubric of "unfair competition," which is fast acquiring great importance.

It will be observed that the English law of torts answers approximately in its purpose and contents to the Roman law of obligations *ex delicto* and *quasi ex delicto.* When we have allowed for the peculiar treatment of rights of property in the common law, and remembered that, according to one plausible theory, the Roman law of possession itself is closely connected in its origin with the law of delicts, we shall find the correspondence at least as close as might be expected a *priori.* Nor is the correspondence to be explained by borrowing, for this branch of the common law seems to owe less to the classical Roman or mediaeval canon law than any other. Some few misunderstood Roman maxims have done considerable harm in detail, but the principles were worked out in all but complete independence.

A list of modern books and monographs will be found at the end of the article on "Torts" by the present writer in the *Encyclopaedia of the Laws of England* (2nd ed.). Among recent editions of works on the law of torts and new publications the following may be mentioned here: Addison, by W. E. Gordon and W. H. Griffith (8th ed., 1906); Clerk and Lindsell, by Wyatt Paine (7th ed., 1921); J. W. Salmond, *The Law of Torts* (7th ed., 1928); Pollock (13th ed., 1929). In America: T. A. Street, *The Foundations of Legal Liability* (1906), 3 vols of which vol. i is on Tort; F. M. Burdick, *The Law of Torts* (4th ed., 1926). (F. Po.)

TORTOISE: *see* TURTLE.

TORTOISE SHELL. The tortoise shell of commerce consists of the epidermic plates covering the bony carapace of the hawksbill turtle, *Eretmochelys imbricata,* the smallest of the sea turtles. The plates of the back or carapace, technically called the head, are 13 in number, five occupying the centre, flanked by four on each side. These overlap each other to the extent of one-third of their whole size, and hence they attain a large size, reaching in the largest to 8x13 in., and weighing as much as 9 ounces. The carapace has also 24 marginal pieces, called hoofs or claws, forming a serrated edge round it: but these, with the plates of the plastron, or belly, are of inferior value. The plates of tortoise shell consist of horny matter, but they are harder, more brittle and less fibrous than ordinary horn. Their value depends on the rich mottled colours they display—a warm translucent yellow, dashed and spotted with rich brown tints—and on the high polish they take and retain. The finest tortoise shell is obtained from the Eastern Archipelago, particularly from the east coast of Celebes to New Guinea; large supplies come from the West Indian islands and Brazil.

Tortoise shell is worked precisely as horn; but, owing to the high value of the material, care is taken to prevent any waste in its working. The plates, as separated by heat from the bony skeleton, are keeled, curved and irregular in form. They are first flattened by heat and pressure, and superficial inequalities are rasped away. Being harder and more brittle than horn, tortoise shell requires careful treatment in moulding it into any form, and as high heat tends to darken and obscure the material it is treated at as low a heat as practicable.

For many purposes it is necessary to increase the thickness or to add to the superficial size of tortoise shell, and this is readily done by careful cleaning and rasping of the surfaces to be united, softening the plates in boiling water or sometimes by dry heat, and then pressing them tightly together by means of heated pincers or a vise. The heat softens and liquefies a superficial film of the horny material, and that with the pressure effects a perfect union of the surfaces brought together. Heat and pressure are also employed to mould the substance.

Tortoise shell was a prized ornamental material from very early times. It was one of the highly esteemed treasures of the far east brought to ancient Rome by way of Egypt, and it was eagerly sought by wealthy Romans as a veneer for their rich furniture. In modern times it is most characteristically used in the elaborate inlaying of cabinetwork known as buhl furniture, and in combination with silver for toilet articles. It is also employed as a veneer for small boxes and frames. It is cut into combs, moulded into snuffboxes and other small boxes, formed into knife handles, and worked up into many other similar minor articles. The plates from certain other tortoises, known commercially as turtle shell, possess a certain industrial value, but they are either opaque or soft and leathery, and cannot be mistaken for tortoise shell. A close imitation of tortoise shell can be made by staining translucent horn or by varieties of celluloid.

TORTONA (anc. *Dertona*), a town and episcopal see of Piedmont, Italy, in the province of Alessandria, from which it is 14 mi. E. by rail, on the right bank of the Scrivia, at the northern foot of the Apennines, 394 ft. above sea-level. Pop. (1951) 15,775. Tortona is on the main line from Milan to Genoa; from it a main line runs to Alessandria, which branches to Novi and Castelnuovo Scrivia, and a steam tramway to Sale. Its fortifications were destroyed by the French after Marengo (1800); which was fought not far off, as were the battles of Novi (1799) and Montebello (1800–1859). The cathedral contains a remarkably fine Roman sarcophagus.

Dertona is spoken of by Strabo as one of the most important towns of Liguria. It stood at the point of divergence of the Via Postumia (*see* LIGURIA) and the Via Aemilia, while a branch road ran hence to Pollentia. The local museum contains Roman antiquities found here. In the middle ages Tortona was zealously attached to the Guelphs, on which account it was twice laid waste by Frederick Barbarossa, in 1155 and 1163. In 1176 it made a treaty with Barbarossa and the people of Pavia, and was taken back into favour by Henry VI in 1193. It was the base headquarters of the British force in Italy in 1917–19.

See F. Gabotto, *Per la Storia di Tortona* (Biblioteca della Società Storica Subalpina, fasc. 96, 1922).

TORTOSA, a fortified city of Spain, in Tarragona province; 40 mi. by rail W.S.W. of Tarragona, on the Ebro 22 mi. above its mouth. Pop. (1950) 45,903 (mun.). Tortosa, the *Dertosa* of Strabo and the *Colonia Julia Augusta Dertosa* of numerous coins, was a city of the Ilercaones in Hispania Tarraconensis. Under the Moors it was of importance as the key of the Ebro valley. It was taken by Louis the Pious in 811, but was soon recaptured. Having become a haunt of pirates, it was made the object of a crusade proclaimed by Pope Eugenius III in 1148, and was captured by Ramon Berenguer IV, count of Barcelona, assisted by Templars, Pisans and Genoese. An attempt to recapture the city in 1149 was defeated by the women folk, who thenceforth received many privileges. Tortosa fell to the duke of Orleans in 1708; during the Peninsular war it surrendered in 1811 to the French under Suchet, who held it until 1814. Tortosa is a walled town with crooked and ill-paved streets, and lofty, granite-built houses. There is a modern suburb on the opposite side of the Ebro. The cathedral occupies the site of a Moorish mosque built in 914. The present structure (1347), has its Gothic character disguised by a classical façade with Ionic pillars. There are manufactures of paper, hats, leather, ropes, porcelain, majolica, soap, spirits and ornaments made of palm leaves and grasses. The river fisheries are important. Corn, wine, oil, wool, silk, fruits and iiquorice (a specialty of the district) are exported. The city is connected with Barcelona and Valencia by the coast railway, and with Saragossa by the Ebro valley line; it is also the terminus of a railway to San Carlos de la Rápita.

TORTURE, the general name for innumerable modes of inflicting pain, and especially for those employed as an incident of judicial process. From this point of view torture was always inflicted either as a means of eliciting evidence from a witness or from an accused person either before or after condemnation; or as a part of the punishment. The second was the earlier use.

Its development in mediaeval times may be traced to the decline of the ordeals and trial by battle. While the appeal to God (which is so marked a feature of the ordeals) exists, confession is unnecessary. Thus, the capitularies of Charlemagne make no provision for torture, while including the earlier modes of procedure. When the fourth Lateran council, in 1215, prohibited the clergy from participating in the ordeal, English law developed trial by jury for crime, and thus rendered the extraction of a confession of guilt from the prisoner unnecessary. Continental law, on the other hand, considered a confession the best of all evidence, and all the machinery of the law was organized to obtain it.

Even when torture was a normal incident of judicial procedure, enlightened lay opinion was overwhelmingly opposed to its employment. Cicero (Pro *Sulla*), Seneca and St. Augustine condemn it, although the latter regards it as a necessity, while Ulpian, in Justinian's Digest, declares: "Torture (quaestio) is not to be regarded as wholly deserving or wholly undeserving of confidence; indeed, it is untrustworthy, perilous and deceptive. For most men, by patience or the severity of the torture, come so to despise torture that the truth cannot be elicited from them; others are so impatient that they will lie in any direction rather than suffer torture, so it happens that they depose to contradictions and accuse not only themselves but others." Among later writers, Montaigne, Montesquieu, Bayle, Voltaire, Sonnenfels, Beccaria, Verri and Manzoni all condemn it. The influence of Beccaria in rendering the use of torture obsolete was undoubtedly greater than that of any other legal reformer. He emphasizes the unfair incidence of torture, as minds and bodies differ in strength. Moreover it is to confound all relations to expect that a man should be both accuser and accused, and that pain should be the test of truth, as though truth resided in the muscles and fibres of a wretch under torture. Apologists of torture may be found chiefly among jurists, but authors of books of practice, and notably Damhouder, von Rosbach, von Boden and Voet, are aware of its deficiencies. Muyart de Vouglans derives torture from the law of God. Other apologists are Simancas, bishop of Badajoz, Engel, Pedro de Castro, and in England Sir R. Wiseman.

Greece. — Both Aristotle and Demosthenes regard torture as the surest means of obtaining evidence. At Athens slaves, and probably at times resident aliens, were tortured, but free citizens only rarely, the practice being forbidden by a psephism passed in the archonship of Scamandrius. Torture was sometimes inflicted in open court, and the rack was employed, even for free citizens. A list of tortures is given in the Ranae of Aristophanes (V. 617) and the wheel is alluded to in Lysistrata (V. 846). Isocrates and Lysias refer to torture under the generic name of στρέβλωσις but it was generally called βάσανοι in the plural (cf. Lat. *tormenta*). Torture was frequently inflicted by Greek despots, and both Zeno and Anaxarchus are said to have been put to it.

Rome. — The Roman system was the basis of all subsequent European systems which recognized torture as a part of their procedure, and the rules attained a refinement beyond anything approached at Athens. Cicero declares that the law of torture rested originally on custom, and no existing fragment of the Twelve Tables alludes to it. It is mentioned frequently by writers both of the republic and the empire. During the republic, a master had power to torture his slaves. In the early empire, however, restrictions were imposed. A lex Petronia forbade masters to punish slaves by making them fight wild beasts, without magisterial authorization, while Antoninus Pius required a master who ill-treated his slave to sell him. Not until the later empire was the killing of a slave by excessive punishment made homicide. The law of the later empire, relating to torture, is set forth at length chiefly in the titles De quaestionibus of the Digest and the Code—the former consisting largely of opinions from the *Sententiae receptae* of Paulus, the latter being largely a repetition of constitutions contained in the Theodosian code. Both substantive law and procedure were dealt with, but a large discretion was left to the judges. Torture was used both in civil and criminal trials, but in the former only upon slaves and freedmen or infamous persons (after *Nov.* xc. ii upon *ignoti* and obscuri if they showed signs of corruption)—*e.g.,* gladiators—and in the absence of ulia *manifesta* indicia, as in cases affecting inheritance. Only slaves were tortured during the republic, but in the empire it was extended to freemen accused of crime. Certain persons were exempt by a constitution of Diocletian and Maximian from the liability to torture, *e.g.,* soldiers, nobles of high rank, and their descendants to the third generation — decuriones — and their children under 14 and pregnant women. These exemptions did not extend to accusations of treason or sorcery. A freeman could be tortured only where he had been inconsistent in his depositions, or where there was a suspicion of lying. There were detailed rules concerning the torture of slaves, and the Romans believed that this was the most efficacious means of obtaining the truth. Unlike freemen, they could be tortured as witnesses, always on behalf of their master, against him only in treason, adultery, frauds on the revenue, coining and similar offenses, attempts by a husband or wife on the life of the other, and in cases where a master had bought a slave in order that he should not give evidence against him. The exemption from accusation by a slave extended to the owner's father, mother, wife or tutor, and a former master; but a slave-owning corporation was not privileged. Where a charge of adultery was brought against the wife, her husband's, her own and her father's slaves could be tortured. Detailed rules governed" the application of torture. Other modes of proof must first be exhausted, and the evidence (*argumentum* and indicium) must have advanced so far that the slave's confession alone was required to complete it. The amount was at the discretion of the judge, but it must not injure life or limb, otherwise the judge became *infamis.* Except in treason, the unsupported testimony of a single witness was not a sufficient ground for torture. Leading questions could not be asked. The quaesitor asked the questions, the *tortores* applied the instruments. The principal forms of torture were the *equuleus,* or rack, the plumbatae, or leaden balls, the ungulae or barbed hooks, the lamina, or hot plate, the *mala* mansio (comparable with the "Little Ease" of the Tower of London) and the *fidiculae,* or cord compressing the arm. As a part of punishment, torture existed in Rome from earliest times, when it was permitted in respect of defaulting debtors. Later, crucifixion, mutilation, exposure to wild beasts in the arena, and other modes were in common use. Through the leges *barbarorum,* Roman doctrines relating to torture were transferred, with modifications, to mediaeval Europe.

The Church. — The Church, although adopting a good deal of Roman law, was at first definitely opposed to torture. Thus the synod at Rome in 384 condemned it. In 1252, a bull of Innocent IV directed the civil power to torture heretics, but the canon law had little to say upon the subject, holding that although it was no sin in the faithful to inflict torture, a priest might not do so with his own hands. In later times, torture was inflicted by the Inquisition. Torquemada's code of instructions (1484) provided that an accused might be tortured if *semiplena* probatio existed against him, *i.e.,* so much evidence as to raise a grave presumption of guilt. Confessions extracted during torture required subsequent confirmation, but retractation involved further torture or extraordinary punishment. One or two inquisitors, or a commissioner of the holy office, were bound to be present at all examinations. Following certain abuses, a decree of Philip II in 1588 forbade torture without an order from the council, but the decree was not fully observed. An edict of the Inquisitor-General Valdès, in 1561, left torture to the prudence and equity of the judges. They must consider motives and circumstances before decreeing torture, and must declare if it were to be employed in caput *proprium, i.e.,* to extort a confession, or in *caput alienum, i.e.,* to incriminate an accomplice. Torture was not to be decreed until the termination of the process and after defense heard, and the decree was subject to appeal, but only in doubtful cases, to the Council of the Supreme. It was only in doubtful cases that the inquisitors were bound to consult the council. On ratification 24 hours afterward of a confession made under torture, the accused might be reconciled, if sincerely repentant, or if convicted of bad faith he might be delivered to the secular power to be burned. Torture ceased to be inflicted before the suppression of the Inquisition, and a papal bull in 1816 decreed its abolition. The actual rules, *e.g.,* Torquemada's, were not so cruel as the construction put upon them by inquisitors. Thus Torquemada's direction that torture should only be renewed for retractation was evaded by terming renewed torture a continuation. Besides the two sets of rules already mentioned, those of Nicholas Eymenico, grand inquisitor of Aragon about 1368, and of Simancas, two centuries later, deserve mention. In 1545 and 1550, Charles V issued instructions for the guidance of inquisitors. Abuses, however, were exceedingly frequent.

England. — The English common law never recognized the legality of torture (except perhaps in the early ordeals) and Coke, commenting on Magna Carta, cap. 29, observes: "No man destroyed, etc., that is, forejudged of life or limb, disinherited, or put to torture or death" (2. *Inst.* 48. b). The Bill of Rights also provided that cruel and unusual punishments ought not to be inflicted. Judicial opinion was always in theory opposed to it, and in Felton's case (1628) a resolution of the judges declared "that he ought not by the law to be tortured by the rack, for no such punishment is known or allowed by our law." Accordingly, in only two instances was a warrant to torture issued by a common law judge, although it was an incident in criminal procedure for several centuries, being ordered either by the crown or council, or some extraordinary tribunal, and especially by the star chamber. Cases occur as early as the 13th century, and continue down to 1640. One case only is recorded after this date, three Portuguese being tortured at Plymouth during the Commonwealth. The rack was introduced in the reign of Henry VI by the duke of Exeter, and was hence known as "the duke of Exeter's daughter." Other varieties of torture were "the scavenger's daughter," or manacles, which pressed the victim's head to his feet, the iron gauntlets or bilboes, and the cell called "Little Ease." In Elizabeth's reign, the rack was in constant use. Witnesses were never tortured.

One peculiar form of torture was not unknown to the common law—the peine forte et *dure.* If a prisoner refused to plead, remaining mute of malice, he was stretched upon his back, and pressed with heavy weights, until he either consented to plead, or died. This practice was abolished by 12 Geo. III c. 20, a case having occurred so late as 1726. Tying the thumbs with whipcord was frequently used instead of the peine. Witch trials also involved incidents of torture, such as throwing the accused into a pond to discover whether she would sink or swim.

As a part of punishment, torture by mutilation appears in pre-conquest codes and in the assize of Northampton (1176). Later examples are burning to death for heresy, drawing and quartering for treason, branding in the hand for felony, the pillory, the stocks, branks and ducking stool. All these have now been abolished, although corporal punishment for robbery with violence and for juvenile offenders still exists.

Scotland. — Torture was long a recognized part of Scottish criminal procedure. Numerous instances occur in the Register of the Privy Council. The last warrant was issued in 1690, and it was finally abolished in 1708. Among the most celebrated forms employed in Scotland was the "boot." The "boot," comprising a long iron boot in which the foot was inserted, wedges being then driven between the limb and the boot, was not peculiar to Scotland for records are found in French criminal trials, and again in Ireland, where in 1583, Hurley, a priest, was tortured in Dublin by "toasting his feet against the fire with hot boots"; this species of torture was employed, not only for crime, but as an incident in religious persecution (Lecky, Rationalism in Europe, 1865, ii, p. 45), and sometimes by the nobility for their own ends. Thus in 1605, a suit was brought against the earl of Orkney, for putting a son of Sir Patrick Bellenden in the boots. Other Scottish methods of torture were the rack, the pilniewinkis (known in England as the thumbikins, and resembling the thumbscrew), the caschielaws (an instrument drawing the body and limbs together, heat being applied in some cases), the lang irnis (heavy weights, sometimes exceeding 50 stones), the harrow bore (perforations through which the teeth of harrows were inserted), the pynebankis (a variety of the rack) and the artificial prevention of sleep.

Ireland. — Torture was recognized in Ireland neither by statute nor by common law, and few cases are recorded of its infliction. In 1566, however, the president and council of Munster, or any three of them, were empowered to inflict torture "upon vehement presumption of any great offense in any party committed against the queen's majesty."

British Colonies and Dependencies. — In any British possession, the infliction of torture was usually regarded as contrary to law. In 1806, however, Sir Thomas Picton, the governor of Trinidad, was tried for subjecting Luisa Calderon to the torture of the piquet, in which the sufferer was supported only on the great toe, which rested on a sharp stake, and by a rope attached to one arm. One of the grounds for defense was that torture was authorized by the Spanish law of the island. The accused was convicted, but sentence was respited. Warren Hastings was also charged with extortion from the begums of Oude by means of the torture of their servants. The Indian penal code now expressly forbids torture. In Ceylon it was formerly allowed by the Dutch, but was abolished by royal proclamation in 1799.

United States. — In 1692, Giles Cory of Salem, accused of witchcraft, refused to plead, and was subjected to the peine forte et dure. The constitution of the U.S. forbids cruel and unusual punishments, on which there have been numerous decisions.

CONTINENTAL EUROPEAN STATES

These fall into four main groups, the Latin, Teutonic, Scandinavian and Slav states. The principles of Roman law were generally adopted in the first and second groups.

France. — In France, torture does not seem to have existed as a recognized practice before the 13th century. From then until the 17th century it was regulated by a series of royal *ordonnances,* and was applied only in the royal courts, its place in the seigneurial courts being supplied by the judicial combat. The earliest ordonnance was that of Louis IX in 1254, for the reformation of the law of Languedoc. It enacted that persons of good fame, though poor, were not to be put to the question on the evidence of one witness. In 1670, an ordonnance of Louis XIV regulated the infliction of torture for more than a century. Two kinds were recognized, the question *préparatoire* and the question *préalable.* The first was abolished by royal decree in 1780, but in 1788 the parlements refused to register a decree abolishing the *préalable.* Torture of all kinds was abolished by an ordonnance of Oct. 9, 1789, however, and the modern code *pénal* enacts that criminals employing torture to further their ends shall be guilty of assassination, while it is also an offense to torture a person under arrest.

Italy. — The law as it existed in Italy is contained in a long line of authorities chiefly supplied by the school of Bologna, beginning with the glossatores and continued by the post-glossatores until the system attained its perfection in the vast work of Farinaccius, in the early 17th century, where every possible question that could arise is treated with revolting completeness. The writings of the jurists were supplemented by a large body of legislative enactments in most of the Italian states, extending from the constitutions of the Emperor Frederick II down to the 18th century.

Farinaccius was procurator general to Pope Paul V, and the principal feature of his work is the minute and skilful analysis of *indicia, farna, praesumptio,* and other technical terms. For every infliction of torture a distinct *indicium* is required. A single witness or an accomplice constitutes an *indicium.* This rule does not apply where torture is inflicted for discovering accomplices or a crime other than that for which it mas originally inflicted. Torture may be ordered in all criminal cases, except small offenses, and in certain civil cases, such as denial of a *depositum,* bankruptcy, usury, treasure trove and fiscal cases. It may be inflicted on all Persons, unless specially exempted (*e.g.,* clergy and minors) and even those exempted may be tortured by command of the sovereign.

There are three kinds of torture, *levis, gravis* and *gravissima,* the first and second corresponding to the ordinary torture of French writers, the last to the extraordinary. This last was as much as could possibly be borne without destroying life. The judge could not begin with torture; it was only a *subsidum.* If inflicted without due course of law, it was void as a prooi.

Among other important writers was Julius Clarus of Alessandria, a member of the council of Philip II. Generally, he follows Farinaccius. He puts the questions for the consideration of the judge with great clearness. These are—whether (1) a crime was committed, (2) the charge is one in which torture is admissible, (3) the fact can be proved otherwise, (4) the crime was secret or open, (5) the object of the torture is to elicit confession of crime or discovery of accomplices. The clergy can be tortured only in charges of treason, poisoning and violation of tombs.

Other Italian writers of less eminence are Guido de Suzara, Paris de Puteo, Aegidius Bossius of Milan, Casonus of Venice, Decianus, Follerius and Tranquillus Ambrosianus. Torture was abolished in Tuscany in 1786, largely owing to the influence of Beccaria, and other states followed. The *puntale,* or piquet, however, existed in practice at Naples until 1859. Savonarola, Machiavelli, Giordano Bruno, Campenella are among those subjected to torture in Italian history. Galileo appears only to have been threatened with the *esame rigoroso.* The historical case of the greatest literary interest is that of the persons accused of bringing the plague into Milan in 1630 by smearing the walls of houses with poison.

Spain.— In Spain, Roman law was carried through the Visigothic code and the *Fuero juzgo* down to the *Siete partidas,* compiled by Alfonzo the Wise in 1243, and promulgated in 1256. Torment is defined as a manner of punishment which lovers of justice use, to scrutinize by it the truth of crimes committed secretly, and not provable in any other manner. Repetition was allowed in case of grave crimes. There were the usual provisions for the infliction of torture only by a judge having jurisdiction, and for the liability of the judge for exceeding legal limits. Subsequent codes did little more than amend the *Partidas* in matters of procedure. In Aragon, while it was an independent state, torture was not in use to the same extent as in other parts of Spain. It was abolished in the 13th century by the General Privilege of 1283, except for vagabonds charged with coining. A statute of 1335 made it unlawful to put any freeman to the torture. On the other hand, the Aragonese nobility had power to put a criminal to death by cold, hunger and thirst. The jurists dealing with the subject are not as numerous as in Italy, no doubt because Italian opinions were received as law in all countries whose systems were based on Roman law. Among them are Suarez de Paz, Antonio Gomez and Alvarez de Velasco. The Peruvian, Juan de Hevia Bolanos, who wrote at the beginning of the 19th century, should also be noted.

The principal Spanish tortures, according to Suarez de Paz, were the water and cord, the pulley or *strappado,* the hot brick, and the *tablillas,* or thumbscrew and boot combined.

Teutonic States.— Germany (including Austria) possesses the most extensive literature and legislation on the subject. The principal writers are Langer, von Rosbach, von Boden, Ulrich Tengler, Remus, Casonus and Carpzow. Legislation was partly for the empire, partly for its component states. Imperial legislation dealt with the matter in the Golden Bull (1356), the Ordinance of Bamberg (1507), the Carolina (1532) and the *Constitutio criminalis thevesiana* (1768). Torture was formally abolished in the empire in 1776. In Prussia it was practically abolished by Frederick the Great in 1740, formally in 1805. Even before its abolition it was in use only to discover accomplices after conviction. In some other states it existed longer, in Baden as late as 1831.

The Netherlands.— The principal legislative enactment was the code of Philip II, known as the *Ordonnance sur le style* (1570). One of its main objects was to assimilate the varieties of local custom, as the *Nueva recopilacion* had done in Spain three years earlier. Certain cities of Brabant, how-ever, still claimed the privilege of torturing in certain cases not permitted by the ordinance, *e.g.,* where there was only one witness. This law continued to be the basis of criminal procedure in the Austrian Netherlands until 1787, and in the United Provinces until 1798. The principal text writers are Damhouder, van Leeuwen and Voet, who took the same view as St. Augustine as to the uselessness of torture, and compared its effect with that of trial by battle.

Scandinavian Countries.— There is a notice of torture in the Icelandic code known as the Grágás (about 1119). Judicial torture is said to have been introduced into Denmark by Valdemar I in 1157. In the code of Christian V (1683) it was limited to cases of treason. It was abolished by the influence of Struensee in 1771, but notwithstanding this he was threatened with it, though it was not actually inflicted, before his execution in 1772. In Sweden torture never existed as a system, and in the code of 1734, it was expressly forbidden. It was, however, occasionally inflicted, as in England, by extrajudicial authorities, called secret committees. The "cave of roses," where reptiles were kept for the purpose of torture, was closed by Gustavus III in 1772.

Slav Countries.— The earliest mention of torture is that of the mutilation provided for certain offenses by the code of Stephen Dushan in 1349. In Russia torture does not occur in the recensions of the earlier law. It was possibly of Tatar origin, and the earliest mention of it in an official document is probably in the *Sudebnik* of Ivan the Terrible (1497). In the ordinance of 1556 there are elaborate regulations, which were not always observed in periods of political disturbance, and torture was used even as a means of enforcing payment of debts. The reaction begins with Peter the Great and culminates with Catherine II, who was largely influenced by the opinions of Beccaria and Voltaire. In the instructions to the commission for framing a criminal code (1776) it is declared that all punishments by which the body is maimed ought to be abolished, and that the rack violates the rules of equity and does not produce the end proposed by the laws. It was formally abolished by Alexander I in 1801, and in 1832 the *Svod Zakonov* subjected to penalties any judge who presumed to order it. But as late as 1847 it was inflicted in one or two exceptional cases.

ASIATIC COUNTRIES

Numerous accounts of tortures inflicted by Asiatic monarchs survive in the narratives of early travelers. Oi these, Olearius' *Voyages and Travels of the Ambassadors,* translated by John Davies (1662), is informative. From these accounts it is apparent that torture was used regularly in the east both as an incident in judicial process, and as a part of punishment, and in some countries at least there seem to have been few checks on its employment beyond the whim of the monarch. In Persia, Olearius records that such punishments as mutilation and sawing asunder were in use. In India, again, the local despots employed torture as a mode of extracting evidence.

Japan.—Japanese law was particularly severe, both procedurally and in its punishments. In trials for theft, a piece of red-hot iron was placed in the hands of the accused, who then flung it away. If his hand was unburned, he was innocent; if burned, guilty. The punishment for theft involved tying the offender to great canes in the iorm of a cross, and his body was then twice run through diagonally by a spear. Confession was usually necessary before conviction, and in order to extract it, a "boot" consisting of heavy wooden planks was employed, and also the bowstrings. As a punishment, crucifixion was in general use, and accounts of fiendish tortures inflicted on Christians in the 17th century survive. (*See* Olearius 154–155, and Murdoch's *History of Japan.*)

China.— In China, and other countries where the Chinese criminal code was accepted with local modifications (*e.g.,* Annam and Burma), some regulation of the use of torture was attempted, although abuses were frequent. As in Japan, confession by the accused was necessary before punishment. The Ta *T'sing Lu Li,* the code of the Manchu dynasty, therefore, prescribes certain forms of judicial torture. These were applicable to witnesses also, and include the "boot" (which appeared in two forms: [1] boards between which the leg of the accused was crushed, and [2] a receptacle in which the leg was placed and boiling oil poured); the finger-compressor, kneeling on chains and beating the face. Those below 15 years of age, or over 70, were exempt from torture, also those suffering from permanent disease or other infirmity.

Other forms, more cruel than those sanctioned by the code existed, although according to the code, a magistrate who applied torture wantonly or arbitrarily was liable to prosecution. Among the illegal tortures, reported by the *Chinese Repository* (vol. IV) to be in use at the beginning of the 19th century were nailing to boards, beds of iron, red-hot spikes, boiling water, knives for cutting the tendon Achilles, the beauty's bar (so named after the wife of a judge, and comprising three crossbars to which the breast, the small of the back, and the legs bent up were fastened), the parrot's beam (in which the prisoner was raised from the ground by strings round the fingers and thumbs, attached to a beam) and the refining furnace. Torture was an incident in many punishments, such as execution by slow cutting to pieces. There were Bogging (with heavy and light bamboo) and the cangue, an instrument resembling the pillory. (J. WIL.; G. W. K.)

TORY, GEOFFROY (*c.* 1480–*c.* 1533), French publisher, printer, author, orthographic reformer and prolific engraver, was born in Bourges about 1480. He was mainly responsible for the French Renaissance style of book decoration and played a leading part in popularizing in France the roman letter as against the prevailing gothic. His important publications include a number of "Books of Hours" and his famous philological work Champ *Fleury* (1529). In this work Tory put forward the idea of accents, the apostrophe, the cedilla and simple punctuation marks. He was appointed *imprimeur du roi* ("printer to the king") by Francis I in about 1530. He died in Paris about 1533. (J. C. MN.)

TORY: see WHIG AND TORY.

TOSCANINI, ARTURO (1867–1957), Italian orchestral conductor, who was unquestionably the greatest conductor of the first half of the 20th century and one of the most astonishing musical interpreters of all time, was born at Parma, Italy, on March 25, 1867. He studied at the conservatory there and at that of Milan, intending to become a violoncellist. At the age of 19. when playing in the orchestra at the opera house at Rio de Janeiro. he was called upon to deputize for the conductor at a moment's notice and conducted the whole performance of G. Verdi's Aida from memory. This feat, combined with other evidence of genius. quickly brought him fame in Italy and elsewhere. and he excelled equally in opera and in concert work. He was a strict disciplinarian, but he more readily obtained obedience from others because he most unsparingly imposed his will upon himself. His phenomenal memory stood him in good stead when he began to suffer from extremely poor eyesight and had to memorize every work he conducted. His detailed knowledge of a vast number of different works never ceased to astonish the artists who worked under him, and his incomparable insight into matters of style and interpretation inspired them with a devotion that often made them reach something like his own fervour and understanding.

Toscanini was appointed conductor in chief of the Milan Teatro alla Scala in 1898 and of the New York Metropolitan opera in 1907. He was also in charge of the New York Philharmonic Symphony orchestra during 1929–36. and conducted famous orchestras all over the world as a visiting artist, except those of Italy during the Fascist regime, of which he passionately disapproved, and of Germany after Adolf Hitler's rise to power.

Toscanini died at New York on Jan. 16, 1957.

(E. W. BM.)

TOSTIG (d. 1066), earl of Northumbria, was a son of Earl Godwine, and in 1051 married Judith, sister or daughter of Baldwin V, count of Flanders. In the year of his marriage he shared the short exile of his father, returning with him to England in 1052, and became earl of Northumbria after the death of Earl Siward in 1055. He was intimate with his brother-in-law, Edward the Confessor, and in 1061 he visited Pope Nicholas II at Rome in the company of Aldred. archbishop of York. Tostig introduced a certain amount of order into the wild northern district under his rule, but his severity made him exceedingly unpopular, and in 1065 Northumbria broke into open revolt. Declaring Tostig an outlaw and choosing Morkere in his stead, the rebels marched southward and were met at Oxford by Earl Harold, who, rather against the will of the king, granted their demands. Tostig sailed to Flanders and thence to Normandy, where he offered his services to Duke William. He harried the Isle of Wight and the Kentish and Lincolnshire coasts and later joined Harald III (Hardraha) of Norway in a descent upon York. But Harold, now king, surprised the invaders at Stamford bridge, and in the battle on Sept. 25, 1066. both Tostig and the Norwegian king were slain.

TOTEMISM. The term "totemism" is used for a feature of the religion and social organization of widespread occurrence among primitive peoples. The name *totem* is derived from an Ojibway word, but has now been generalized by anthropologists to describe an institution, the Ojibway form of which is not typical. Unfortunately, many writers have used the term totemism very loosely for any beliefs and practices dependent upon some supposed connection between animals and persons. The term should be restricted to those cases where a systematic association of groups of persons with species of animals (occasionally plants or inanimate objects) is connected with a certain element of social organization. In the widest use of the term, we may speak of totemism if: (1) the tribe said to be totemic consists of a number of groups (totem groups) comprising the whole tribe, each of which groups has a certain relationship to a species (totem), animate or inanimate; (2) the relation between each group and species is of the same general kind for each group; and (3) a member of one of these totemic groups cannot (except under special circumstances) change his membership.

By this definition one essential peculiarity of totemism is the association of groups of persons with groups of animals or objects, not of individual persons with individual animals, a common enough phenomenon, which, however, it is desirable not to include under totemism. Another peculiarity is the division of the tribe into several totemic groups, so that, while every member of the tribe has a totem, persons living in the same locality may yet differ as to their totems.

As to the determination of the membership of the totem-group, *i.e.,* the social side of totemism and the nature of the relationship between totem-group and totem, *i.e.,* the religious side of totemism, one kind of totem-group is commoner than any other, viz., the clan, an exogamous group (*i.e.,* a group within which marriage is forbidden), determined by descent, either through the father (patrilineal descent), or through the mother (matrilineal descent).

The clan (*q.v.*), is a group of great importance in primitive society, for it determines behaviour in a variety of ways, and is often of more importance than smaller groups, such as the family, or wider groups, such as the tribe. Members of a clan generally regard themselves as closely related, whether or not they can trace relationship genealogically, and frequently hold themselves and are held by others to be mutually responsible for the actions of their clan-brothers. In some parts of the world, where clans are widely dispersed, the totem serves as the only sign of clan-relationship, and a man will be welcomed, on account of his totem, as a clan-brother by distant members of his clan, whom he has never seen, and will also avoid sexual relations with the women of that group, though unable to trace relationship. The discovery of this association of totemism with the clan has given rise to one of the most interesting problems of anthropology, for it would seem that any theory of origin of totemism must also explain exogamy.

Although totemism is generally associated with the clan, the tribe is also sometimes divided into totemic groups, which are not exogamous. For example, the Arunta (*q.v.*), of central Australia are divided into totemic groups, membership of which depends upon the accident of position of the mother at the moment of realization of pregnancy, and there is no exogamic restriction on the members of these groups. There are also totemic groups in Africa and elsewhere that are more or less endogamous (*i.e.,* required to marry within the group). Furthermore, a tribe may be divided in more than one way into totemic groups; for example, in Australia we sometimes find, in addition to totemic clans, moieties (exogamous halves of the tribe, each of which includes a number of clans), and marriage-classes (groups with indirect descent, which are specially connected with the regulation of marriage), which may be more or less totemic, and even a division of totems according to sex.

Variations of the relationship between totem-group and totem,' are considerable in different parts of the world. In the first place, the totem shows extraordinary variety. While an animal-species is the most usual form of totem. plant-species are by no means uncommon, and classes of material objects are occasionally found: even abstract qualities, such as "pride," the totem of a clan of a weaver caste in Madras, and "red," the totem of an Omaha clan. A peculiar variety of totem is the split totem, in which only part of a thing is the totem; *e.g.,* instead of buffaloes, buffalo tongues occur as the totem of one Omaha sub-clan. No doubt, split totems are the result of division of a totemic group into several groups. Cross-totems, however, are less intelligible. A cross-totem consists of one part of more than one kind of thing; *e.g.,* the ends of things are the cross-totem of a certain Samoan group. the ears of animals of any species the totem of a Mahili clan, Bengal. Again, one totemic group may have a number of totems, which are then called linked totems; *e.g.,* clans in south-east New Guinea are always associated with a species of bird, of plant, of fish and of snake, the last three being subordinate to the bird totem.

Although there are considerable differences in the relation between totem-group and totem, owing to differences in the kind of totem, there are also great differences between tribes, apart from this. In one tribe we may find a strong avoidance of the totem-animal, which may neither be killed nor eaten, while in other tribes the same animal may be killed with comparative impunity. Nevertheless, this tabu on killing or eating the totem seems to be typical of totemism, and some avoidances in connection with the totem are probably present in all cases. But although these tabus may be of great severity—an offender may be severely punished by his totem-group, and, if not punished by his own totem-group, may yet be' supposed to suffer through the action of the totem itself—they apply only to the particular totem-group. For example, an Australian, whose totem is the witchetty-grub, will respect and avoid this animal, but will not hinder his friends and relations of other clans from making use of this food, and will even conduct ceremonies of which the avowed object is the increase of the totem, so as to provide food for other clans in the tribe. In some cases, the totemic tabus must be observed by persons outside the totem-group; *e.g.,* in south-east New Guinea, where a man is a member of the totem-group of his mother, the totems of the father are even more rigidly tabu than his own totems; and amongst the totemic peoples of Africa, it is common for a woman to adopt the torem-avoidances of her husband. Curiously enough, associated with severe tabus on the killing of the totem a totemic sacrifice has been reported from Australia, in which the totem-animal is cruelly killed and eaten.

The totemic tabu is usually associated with a belief in some sort of kinship between the totemic group and the totem, which makes the tabu more intelligible. In line with this is the frequent belief in descent from the totem, or of totem and totem-group from some common ancestor. Another expression of this altitude towards the totem is the performance of ceremonies, in which the totem is represented symbolically or realistically Badges, masks and mutilations may also be used to make this identification. Finally, although worship of the totem or prayer never occurs—animal worship has little in common with totemism—it is not unusual for the totemic group to believe that members of the totem species assist the group by means of omens, or in other ways. Such being the general characteristics of totemism in all those cases which it is convenient to regard as totemism, a survey of the chief areas of totemism will reveal the diversity of form which totemism takes.

Australia.—Totemism has generally been regarded as occurring in Australia in its most complete and original form, not so much on account of the elaborateness of Australian totemism, but because totemism has been regarded as the most primitive religion, and Australians are the most primitive people that we know. Both these propositions can be disputed, but Australian totemism is of exceptional interest, for the greater part of Australian religion may be brought under the heading "totemism." Australian totemism has an equally important economic and social side. Among the tribes of central Australia all those important happenings, such as the origin of man and his customs, and the recurrence of death and birth, are well explained in totemic terms, for in olden (alcheringa) days there were only totemic beings, emu, grub, and so on, half animal in form, half human. These spirits were creative and made the stock of souls, which have ever since been the souls of human beings by continual reincarnation, these souls themselves being totemic in nature. Birth is thus due to the entry of one of these spirits into the womb of a woman, death to its departure from the body. Between incarnations these spirits abide in certain centres, known as totem-centres, and tend to be associated with certain objects, which are kept in these centres, and which are used in totemic ceremonies. It might seem that such a theory of birth and death would offer difficulties, except in such cases as the Arunta, where the totem of the child is not determined by descent, but the native gets over the difficulty by supposing that these localized spirits, when their time for reincarnation arrives, wander from the totem-centre until they find a woman of the right totem, or a woman whose husband is of the right totem, according as descent is matrilineal or patrilineal. In the ceremonies of initiation into manhood, also, totemic ideas are dominant. Initiates become conversant with various sacred objects, such as those connected with the soul, and symbolic objects, constructed for particular ceremonies symbolizing in one way or another the totems of the group. Elaborate decorations of the person, dramatic representations of the activities of the totemic ancestors in *alcheringa times*, continuing often for days, and other symbolic activities, all with more or less of a totemic motive, take place on these occasions. At certain times of the year, most Australian tribes conduct elaborate rites the object of which is to increase the totem species. These appear to be mainly of the nature of sympathetic magic.

Melanesia and Polynesia.—In this region we find every degree of totemism, from an institution containing the main features mentioned above, to complete absence of all these features. For example, in the Santa Cruz islands we find exogamous clans, each possessing one or more totems, usually animals; the totem may not be killed or eaten, and there is usually a definite belief in descent from the totem. In the extreme west of Papua (where there are two moieties) and in south-east New Guinea and parts of the Solomons we find totemism of similar form, yet in other parts of the Solomons and in the New Hebrides and Banks islands totemism is absent, though there are customs which suggest survivals of an earlier totemism; in fact, the Banks islanders, while lacking totemic clans, have certain beliefs very similar to those of the Arunta of central Australia, but unsystematic. A number of men and women strictly avoid killing certain species of animals or plants on account of a supposed kinship with them. This belief is based on the belief that the mother owed her pregnancy in some way to the entry into her womb of an animal of the species avoided. This belief appears to be maintained alongside some understanding of the true nature of the process of procreation. In Polynesia we find a religious system, which in places, such as Samoa, appears to have developed out of totemism, for many totemic characters are discernible.

India.—As a social system, if little more, totemism appears in parts of India. For instance, the Santals of Bengal are divided into a number of patrilineal clans, exogamous and totemic, and each of these into a number of sub-clans, also exogamous and totemic. There is avoidance of the totem, in some form or another, by the clan or sub-clan. Totemism also occurs in Assam, in Central India and Madras, with traces elsewhere.

Africa.—Except for the region of the great lakes, totemism is sporadic in Africa. The Baganda of Uganda may be cited as an example of well-developed totemism. The Baganda are divided into some 40 patrilineal exogamous clans. Each of these has a principal and a secondary totem, usually an animal or plant, neither of which is killed or eaten by the clan. There are other avoidances, more or less connected with the totem; for example, members of the leopard clan may not eat meat which has been torn or even scratched by an animal. We do not find traditions of descent from the totem amongst the Baganda, and the belief in descent from the totem is uncommon elsewhere in Africa. A nominalistic explanation of the origin of the Baganda totems is given; for example, the lion clan of the Baganda, with the eagle as secondary totem, explain their totems as follows: Kimtu, a royal ancestor of the clan, killed a lion and an eagle, and had their skins made into royal rugs, since when the beast and the bird have been regarded as sacred. There is one curious anomaly in Baganda totemism. While a man normally takes his totem from his father, there is an exception in the case of royalty, a man taking the totem of his mother in addition, and rarely maintaining the royal totem.

North America.—Throughout the greater part of North America we find totemism in a more or less typical form, and the frequent grouping of totemic clans into moieties reminds one of the Australian variety. Other features of American totemism, however, mark it off clearly from the Australian variety. While the tie between members of the totemic group may be as strong as anywhere else in the world, the attitude towards the totem is usually quite different, and the theory of totemic souls is wanting. Often, in America, the totem is little more than a clan-badge, and the totem is often killed by the totemic clan. Nevertheless, elaborate and picturesque legends of the origin of totemic clans from the totem by some sort of descent are common enough. Totemism is not particularly associated with the less developed tribes of North America—rather the reverse; and we find both matrilineal and patrilineal descent of the totemic clans. Amongst the strongly matrilineal Iroquois of the east we find a straightforward division of the various tribes into a small number of exogamous clans, of which the totems are animal species, the clans usually being grouped into two moieties. Although a few traditions of direct matrilineal descent from an animal of the totemic species have been recorded, the clans usually aeny relationship with their totems, and show no regard whatever for them. Passing westward, some of the Siouan tribes provide examples of a more complex totemic system. For example, the Ponkas are divided into moieties, the moieties into phratries, the phratries into clans, and the clans into sub-clans, each of these classes being more or less totemic and exogamous. Here definite tabus are connected with the totems of the clans. In the west, particularly the north-west coast, totemism is not clearly distinguishable from another socio-religious institution, peculiar to North America, the cult of guardian spirits. The guardian spirit is acquired individually, sometimes quite late in life, by a process usually of fasting and religious exercise, which causes the guardian spirit to appear to the candidate in a dream or vision. Since the guardian spirit usually has an animal form, it is sometimes called an individual totem—clearly a misnomer. Sometimes the guardian spirits capable of acquirement by members of the tribe are divided out between the clans, or other social groups of the tribe, and sometimes the guardian spirit is not clearly individual in nature, but is rather of the nature of a species of animal. In so far as this is the case we have an approximation to totemism. A complication of this sort is found in the totemism of the north-west coast peoples, who make the so-called totem-poles. The student will find a mass of data on totemism arranged geographically in Sir J. G. Frazer's work *Totemism* and *Exogamy* (1910).

Prominence was given to the association of totemism with exogamy, found throughout the world with few exceptions. Where totemism is not associated with exogamy it is not difficult to suppose that exogamy has been lost. With considerably less confidence it may be supposed that tribes, containing exogamous groups, have lost their totemism. Finally there are some peoples, *e.g.,* the Andaman islanders, and the Eskimo, at a primitive level of culture, who have neither exogamous groups nor totemism. From this distribution of totemism and exogamy it follows that any theory of totemism must either be a '[psychological" theory, explaining both totemism and exogamy, or a "historical" theory, which regards totemism, wherever it occurs, as the result of a spread of cultural influence from some one centre where the totemic complex originated. By a "psychological" explanation is meant an explanation in terms of observed facts about the behaviour of groups, or by means of generalizations about the behaviour of groups deduced from known psychological principles. If, antecedently to the development of a given institution, it could be stated on psychological grounds that an institution of that sort would probably develop, then such an institution can be said to be explained psychologically. Early theories of totemism have not explained in this sense, for totemism and exogamy have only been shown to be probable, independently of the development of the one or the other, from which it follows that the distribution of totemism and exogamy, assumed above, would not occur; *e.g.,* if, owing to the nature of man and his attainment of some very simple form of society, it were probable that he should develop totemic ideas and practices, and also that he should develop exogamous groups, but for reasons other than those which lead to his developing totemism, then it would be indeed surprising that most peoples who have the one institution have the other, while those who, although in a primitive state of society, do not have the one do not have the other. The difficulty can be got over by supposing that totemism and exogamy are necessarily developed by man in the course of his evolution; but it is difficult in this case to offer a plausible explanation of the disappearance of totemism and exogamy among some very primitive peoples, and its retention by others at a more advanced stage of civilization.

Two theorists may be mentioned for their attempts to provide a psychological explanation of both totemism and exogamy; viz., Durkheim and Freud. For Durkheim the totem results from the action of the group on the individual. The group is the nearest and most powerful coercive force to which the individual is subject, particularly when the group is in violent activity and the individual is conscious of this overpowering influence, when he loses himself completely in the group. Symbolic expression alone can be given to such a force; hence the totem is a sacred symbol, symbolizing that very real force, the clan. Hence totemic symbols are sacred rather than the totem-species itself (and this, it must be admitted, is true, at least for Australia).

But why, it may be asked, should there be many clans and totems, and not one totemic group? Here Durkheim becomes obscure. If there are already several groups, then only in so far as the effective unity of each group is felt should there be more than one totemic group within the tribe. Passing over this difficulty, we have still to enquire why the totemic group is exogamous: the answer is not very convincing. It would take too long to follow the various steps which give unity and intelligibility to the scheme, but it is the tabu on the blood of the clan which is ultimately responsible for exogamy.

Freud attempted to give a single explanation of totemism and exogamy, and he appeared to have indicated the direction in which we are to seek an explanation, whatever the adequacy of his presentation.

Prior to the development of culture, man is supposed to have lived in "cyclopean" families, containing a principal male who monopolized the women, including his own daughters, and prevented his sons from having intercourse within the family. What more natural than that the sons should combine and kill the father? But the attitude of the sons is ambivalent, combining both affection and hostility. The murder committed, the sons deny themselves the fruits of the deed, owing to the operation of a psychological process familiar to psycho-analysts, and the group becomes exogamous. The affective ambivalence towards the father has also provided the beginnings of totemism. By substituting an animal for the father, a process of symbolism which psycho-analysts consider fundamental in human nature, the animal becomes a vehicle for that affective attitude towards the father which is for the moment repressed. With the killing of the father by the momentary release of this repressed *Oedipus complex,* both totemism and exogamy are born. The group with one father, and therefore one totem, is exogamous, and the totem becomes the object of observances, which are really the expression of the *Oedipus complex,* which has now become more completely repressed by means of a social mechanism. The difficulties in the way of this theory are considerable, and have been critically analysed by Profs. Kroeber and Malinowski. Doctor Freud's theory has been elaborated and modified in a comprehensive study of Australian totemism on psycho-analytic lines by Dr. Géza Roheim. While the search for a "psychological" explanation of totemism does not reward us with any convincing theory of its origin, an "historical" explanation is equally elusive, though it has been maintained by one school that the distribution of totemism can only be explained on the assumption of diffusion from a single centre, a conclusion which, as we have already seen, follows if no psychological explanation of totemism combined with exogamy can be found. No evidence for the existence of exogamy, and only the most slender evidence for totemism is provided in the Egyptian centre from which the totemic complex is supposed to have spread; in fact, on this theory totemic exogamy is derivative in the various parts of the world to which totemism spread from a kind of dual organization with marriage injunctions. The only "historical" explanation of totemism which has been elaborated is, therefore, no more, if no less, convincing than the numerous "psychological" explanations which have been offered.

Dissatisfied with this impasse that the search for explanations leads to, both in the case of totemism and in that of many other primitive institutions, many anthropologists have renounced the search for psychological or historical explanations, and confine themselves to the search for the functions of institutions. Possibly this is the only kind of explanation of totemism within our grasp, and, although there is reason to suppose that totemism without function (occurring as a survival merely) occurs in some places. it must be admitted that, until totemism is understood in this functional sense in those cases where it appears to be a significant part of the culture of the group, it is premature to attempt to account for its origin.

TOTENTANZ: see DANCE OF DEATH.

TOTILA, or BADCILA, king of the Ostrogoths (541–552), embodied the spirit of Gothic resistance to Byzantium and fought the last great battle against the reconquest of Italy by Justinian's generals. Under Theodoric (d. 526) men like Cassiodorus and the senatorial class had co-operated in the rule of the Gothic kingdom; after his death, the Roman and Gothic parties struggled for predominance. When the regent Amalasuntha, educated in the classical tradition and favouring submissive relations with Justinian, was assassinated, a Byzantine army under Belisarius was sent to invade Italy (536); the Goths fought stubbornly but, under their leaders Witigis, Hildibald and Hereric, were successively defeated. Then Eaduila, surnamed Totila, was elected king and proved an indomitable leader. Between 541 and 546 he drove the Byzantines from northern and central Italy and recovered Naples and even Rome. When he failed to win senatorial support there, he drove out the citizens and left the city desolate. By 550 he had also recovered Sardinia, Corsica and parts of Sicily and Dalmatia, provoking Justinian to send against him a very much larger army under the eunuch Narses. This force crossed the head of the Adriatic, marched through Venetia southward to Umbria, and surrourided and crushed Totila's smaller force at Taginae (*q.v.*; now Gualdo Tadino) in 552. Totila was killed and the Gothic cause lost, though resistance dragged on till 555. The earlier Ravenna mosaics, the Cesena treasure, an illuminated manuscript and a few palimpsests of the Gothic Bible survive to show the character of the civilization for which Totila fought.

TOTNES, GEORGE CAREW, or CAREY, EARL OF (1555–1629), English politician and writer, son of George Carew, dean of Windsor, and Anne, daughter of Sir Nicholas Harvey, was born on May 29, 1j55, and was educated at Broadgates hall, Oxford, where he took the degree of M.A. in 1589. After long service from 1j74 onward, chiefly as a soldier in Ireland, where he held a number of responsible offices and rose to be master of the ordnance (1588), he was appointed lieutenant general of the ordnance in England in 1592. He accompanied Essex in the expedition to Cadiz in 1596 and to the Azores in 1597. In 1598 he attended Sir Robert Cecil, the ambassador, to France. In 1600 he was appointed president of Munster, where his vigorous measures enabled the new lord deputy. Lord Mountjoy, to suppress the rebellion. He returned to England in 1603 and was well-received by James I, who gave him many honours. In 1610 he revisited Ireland to report on the state of the country; and in 1618 pleaded in vain for his friend Sir Walter Raleigh. He received his earldom in 1626. He died on March 27, 1629, leaving no issue. Besides his fame as president of Munster, Carew had a considerable reputation as an antiquary.

Carew made large collections of materials relating to Irish history and pedigrees, which he left to his secretary. Sir Thomas Stafford,author of *Pacata Hibernia* (1633) and reputed on scanty evidence to be his natural son; while some portion has disappeared, 39 volumes after coming into William Laud's possession are now at Lambeth (see *Calendar* of *the Carew* mss., 6 vol., ed. by J. S. Brewer and W. Bullen, London, 1867–73), and 4 volumes in the Bodleian library. His correspondence with Sir Robert Cecil was edited in 1864 and his letters to Sir Thomas Roe (1615–1j) in 1860. both by Sir John Maclean for the Camden society. London.

TOTNES, a market town and municipal borough in the Totnes parliamentary division of Devonshire, Eng., on the Dart, 24 mi. S.S.W. of Exeter by road. Pop. (1961) 6.064. Area 2.2 sq.mi. It stands on the west bank of the river, and is joined by a bridge to the suburb of Bridgetown. It was formerly a walled town commanding the lowest crossing of the Dart, and two of the four gates remain. Many old houses are also preserved, and in High street their overhanging upper stories, supported on pillars, form a covered way for pedestrians. The castle, founded by the Breton Juhel, lord of the manor after the Conquest, was dismantled under Henry VIII; but its keep and upper walls remain. Close by are the remains of St. Mary's priory, which comprise a large Perpendicular gatehouse, refectory, precinct wall, abbot's gate and still-house, also the Perpendicular church of St. Mary. The guildhall is formed from part of the priory. Vessels of zoo tons can lie at the wharves near the bridge. The industries include brewing, flour milling and the export of agricultural produce, chiefly corn and cider. Trout and salmon are in the river.

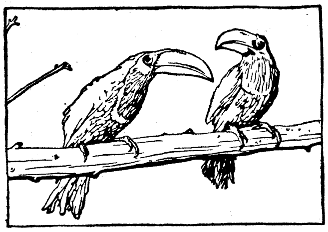
Totnes (Totanæs on Cnut coins of 979) was a place of considerable importance in Saxon times; it possessed a mint in the reign of Aethelred, and was governed by a portreeve. In the Domesday Survey it appears as a mesne borough under Juhel (Judhael) of Totnes. Its earliest charter dates from 1205.

TOTONICAPÁN, the capital of the department of Totonicapdn. Guatemala, on the same high plateau as Quezaltenango, from which it is 12 mi. E.N.E. Pop. (1957 est.) 7,380. Totonicapdn is inhabited mainly by Quiché Indians, employed in the making of cloth, furniture, pottery and wooden musical instruments. There are hot mineral springs in the neighbourhood. In 1538 Totonicapan was declared an independent republic, in which the adjoining departments of Sololá and Quezaltenango were included. This state existed for two years, and was then again merged in the republic of Guatemala. The city suffered greatly in the earthquake of April 18. 1902.

TOTTENHAM, a municipal and parliamentary borough (1934) of Middlesex, Eng., and inner suburb of London, astride the main road to Cambridge, $6\frac{1}{2}$ mi. N. of London bridge. Continuous with Stoke Newington to the south and Edmonton to the north, the eastern boundary is the river Lea. Pop. (1961) 113.126. Area 4.7 sq.mi. It is a residential and industrial area with a very large furniture factory. It has a famous football club (Tottenham Hotspurs) and at Harringay is a popular stadium and sports arena. There are in the borough 379 ac. of open space. All Hallows church, Tottenham, was given by David, king of Scotland (c. 1126), to the canons of the church of Holy Trinity, London, and parts of the old building still remain. A modern erection marks the site of the old High cross, original nucleus of Tottenham. Formerly Tottenham was noted for its "greens." In the centre of one stood the famous old elm trees called the "Seven Sisters," which were removed in 1840 and whose name is preserved in the Seven Sisters road. The manor was given by William I to Judith, wife of Waltheof, earl of Huntingdon, who built a castle which through Judith's daughter Maud and others passed to Robert Bruce. The present Bruce castle is a 16th-century mansion built on the site by Sir William Compton. In 1827 it was a boarding school founded by Rowland Hill, famous as the postmaster general who introduced the "penny post." Now public property, it houses a museum (with a proper emphasis on postal history), the grounds forming a public park.

TOTTORI, Japanese prefecture in western Honshū on the Sea of Japan, was formed from Inaba and Hōki provinces after the Restoration of 1868. It has an area of 3,489 sq.km. (1,347 sq.mi.) and in 1955 the population was 614,259. Hot springs and ski resorts are associated with the great volcanoes of this prefecture. The largest volcano, Daisen, is in Dai-sen National park. Small quantities of copper, zinc, uranium and iron ore are mined. There is some production of iron and steel. Textile and mining machinery and cotton textiles are exported. Sites of ruined castles, historic temples and famous gardens reveal the part this area played in Japanese history.

The capital of the prefecture is Tottori, which lies near the mouth of the Sendai river. Between 1940 and 1958 the city absorbed adjacent villages and increased in area from 42 to 227 sq.km. (16 to 88 sq.mi.) and in population from 49,300 to 104,880 (1955). The chief products of the city are lumber, paper and silk. (C. A. MR.)



TOUCANS, FOUND ONLY IN THE WESTERN HEMISPHERE

TOUCAN, the Brazilian name for a bird of the tropical American family *Ramphastidae,* characterized by their huge but light beaks.

The type of the family is *Ramphastes toco,* of Guiana and Brazil. The beak, 8 in. long and 3 in. high at the base, is deep orange with a large black spot near the tip. The eye is surrounded by a bare orange space; the plumage is black except for the white throat, edged beneath with red. The tail is nearly square. In many allied species, the bill is parti-coloured. R. *vitellinus* inhabits Trinidad, but all the remaining members of the family are confined to the mainland, ranging from Paraguay to Mexico. In the Andes, they reach an elevation of 10,000 ft. (K. P. S.)

TOUCH, SENSE OF. In the environment of every animal, the solid, impenetrable objects with which it may collide play an important part. Sensitiveness to touch, comparable to our own, is, therefore, generally developed. The manner in which an animal reacts to contact stimuli depends, principally, on the force of the contact. All such stimuli which exceed a certain degree act as repellants, and feeble, defenceless animals seek to escape from them. This is evident already in the simplest animals, such as the amoeba. It is sufficient to touch one of the protruded pseudopodia of an amoeba with a pointed, glass needle to bring about its immediate retraction. Already in many infusorians there are extraordinarilv developed tactile cilia; if another animal comes into contact with them, it causes the infusorian to swim hastily away (fig. 1).

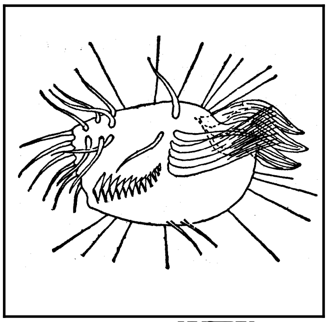


FIG. 1.—DIOPHRYS HYSTRIX, AN INFUSORIAN WITH PARTICULARLY LONG TACTILE CILIA (AFTER VON BUDDENBROCK)

In multicellular animals the reaction to mechanical impulses differs very much, in accordance with the defensive powers of the individual. This is sufficiently well known in the higher animals. Defenceless animals, such as earthworms, or gasteropads, flee, or withdraw into their protective shells; on the other hand, those capable of defending themselves, such as the large Crustacea, cuttlefishes or sea-urchins meet the assault by active defensive movements. The example last mentioned is, perhaps, of sufficient interest for it to be discussed more particularly.

If we touch a sea-urchin on any part of its surface, one of three things happens. In the first case, all the spines which are situated in the neighbourhood of the part stimulated bend towards it. If some animal were the cause of the contact it would, thus, be grievously stung by the sharp spines, and put to flight. In the second case the pedicellariae come into action (fig. 2). These are pincers consisting of three small snapping blades on a pliant stalk. They turn towards the place whence the contact stimuli proceed, and wave their gaping jaws rapidly to and fro. They bite firmly into the skin of the enemy, or into its hairs, and assist, either in putting it to flight, or in holding it fast and bringing it into contact with the tube-feet round the mouth, where it is consumed. Lastly, in a third case, the whole sea-urchin moves in a direction calculated, if possible, to take it out of the sphere of the stimulus.

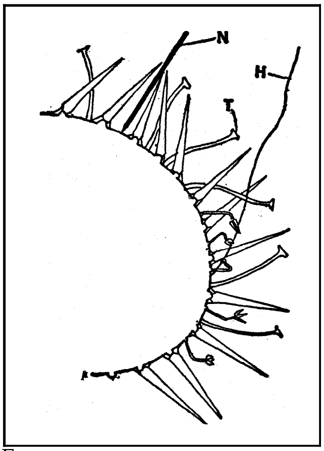

FIG. 2.—SURFACE OF SEA-URCHIN UNDER MECHANICAL STIMULATION S, NEEDLE N AND HAIR H; S A TUBE-FOOT

The common crab, particularly the male, reacts to strong contact stimuli by assuming its very characteristic defensive attitude. It turns towards its opponent and presents its widely-opened pincers. If the enemy still continues to approach, it strikes at it with great force.

Some animals are able to assume an appearance of death when attacked. The most pregnant examples of this are furnished by insects. The death-feigning reflex usually consists in the animal drawing in its legs, and remaining perfectly motionless, continuing thus even if maltreated in the most violent manner. In such a case, the assailant, a bird for example, thinks it is dealing with a dead thing instead of a food animal, and gives up the attack. Insects such as these, which feign death, usually resemble very closely some inanimate object, such as a piece of wood or a twig. The stick-insects provide the best known examples of this.

As was mentioned at the beginning, the sense of touch often serves to prevent an animal dashing itself against hard objects when moving from place to place. The whirligig beetle, *Gyrinus,* which we see skimming rapidly to and fro over the surface of the water in summer, bears eloquent witness to the degree of sensitiveness attained. The careful observer will soon perceive that these lively little creatures never collide with any object which may be floating on the surface of the water; they also do not run against one another, although, often, many may be skimming about in a restricted space. The sense organs which render this possible are situated in the feelers, as Eggers has proved. The antennary flagella are borne free in the air; their amputation does not cause alterations in the animal's conduct. On the other hand, the second basal joint rests on the water like a float (fig. 3). It contains numerous sensory cells, bearing stylets, which are

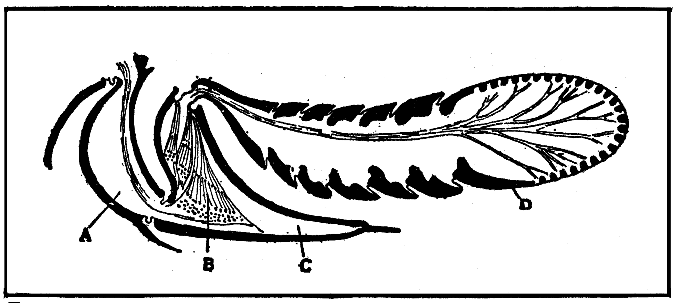

FIG. 3.—ANTENNA OF WHIRLIGIG BEETLE: (A AND C) BASAL JOINTS OF ANTENNA, (B) JOHNSTON'S ORGAN. (D) ANTENNARY FLAGELLUM

grouped together in "Johnston's organ." With the assistance of these the animal perceives in some way the proximity of solid objects; it may, perhaps, react to the waves of water reflected to it by these objects.

Among vertebrates, bats are able to perform a, perhaps, even greater feat. As was known already to the naturalists of the 18th century, even blind bats are able to avoid all obstacles which may be placed in their path.

An opposite condition to that discussed hitherto prevails in not a few cases in which the animal seeks to establish contact with a solid object, and is uneasy if it cannot do so. This phenomenon has been given a special name, and is known as "thigmotropism." In most animals the soles of the feet are usually placed in constant contact with solid bodies. The vigorous attempts at "righting" which are made by almost every animal if it falls upon its back, until it regains its feet once more, are due, in many cases, to the effort to bring the feet again into contact with solid bodies. This may be seen particularly well in insects. If we put a caterpillar upon its back it immediately rights itself. If, however, we place between its feet a twig to which it can adhere, it remains peacefully upon its back, and even eats in this position. The following experiment is easily carried out, and shows this very clearly. A thread is gummed firmly on to the back of a fly, and is then attached to a stand, the feet of the insect being allowed to hang down free. If, now, a small ball of paper is placed between them, the fly begins at once to run about upon it.

The normal running movement, therefore, follows contact of the feet with the solid object. In leeches, contact stimuli are of particular importance in locomotion. Uexkuell showed that in these animals a quite definite co-ordination exists between the action of the suckers and the contraction of the muscles of the body. When the leech is adhering by means of its posterior sucker, it stretches out its body at full length, searching thus for a suitable surface on which to fasten its anterior sucker. When the anterior sucker is attached, the posterior sucker relaxes its hold, and immediately a reflex contraction of the longitudinal muscles of the body takes place. Both phases, taken together, give rise to the characteristic looping motion of the leech. *(See* fig. 4.) If, however, we throw the leech into water without giving

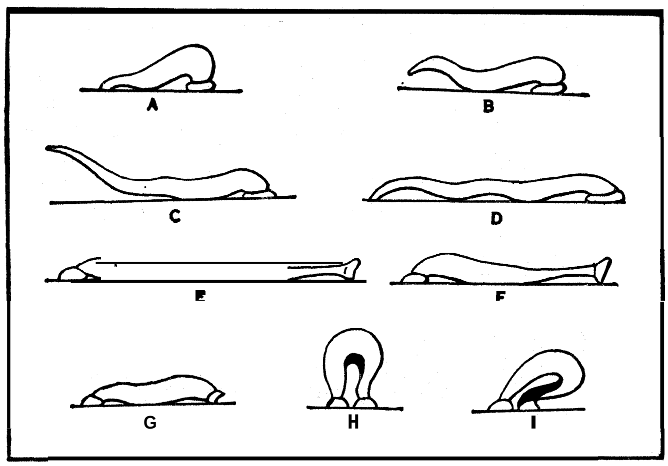

FIG. 4.—CRAWLING MOVEMENT OF A LEECH: (A–D) POSTERIOR SUCKER IS ATTACHED, AND THE WORM EXTENDED: (E–G) ANTERIOR SUCKER IS ATTACHED, POSTERIOR IS FREE, ANIMAL IS CONTRACTED: (H–I) RE-ATTACHMENT OF THE POSTERIOR SUCKER

it an opportunity of attaching itself by one of its two suckers, swimming movements at once take place.

Thigmotropism, however, appears also in quite another form. It was thought at first that many animals which are in the habit of dwelling in narrow tubes (such as many worms), or in crevices in wood, or under bark are led to seek out their hiding places through an aversion to light. The truth of the matter is that such an animal feels comfortable only if its body is in contact, as much as possible, on all sides, with solid surfaces. Thigmotropic worms will also creep into glass tubes, and some insects hide between glass slides, in spite of being fully exposed to daylight when in these retreats. Under natural conditions, the thigmotropic animal thus avoids the covetous eyes of its enemies, since in nature there are no transparent solid objects.

Sensitiveness to mechanical stimuli has a very important use in the sense which in higher animals makes them aware of the relative position of the parts of the body. To the majority of human beings it certainly appears quite as a matter of course that they are able to take hold of their noses with their hands. Science teaches, however, that this is possible only through stimulation of numerous sensory cells in the skin, which are pulled or pressed when the arm or the hand is moved. If the skin is narcotized, the power of touching any particular part of the body is lost.

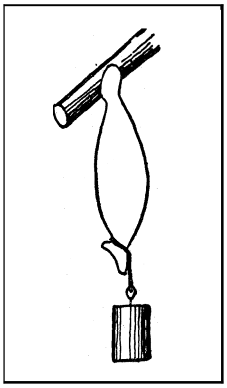

FIG. 5.—LEECH SUPPORTING WEIGHT (AFTER CAHNHEIM AND UERKÜLL)

It is of interest that some of the lower animals, particularly arthropods, possess a similar sense. Insects and Crustacea show this in the very vigorous way in which they clean the limbs and the body, making use of legs specialized for this purpose. The precision with which the decapod Crustacea, after moulting, place fresh statoliths in their statocysts is astonishing. *(See* also EQUILIBRIUM, SENSE OF.) They seize grains of sand, or similar material in their delicate pincers, and are able to introduce them into the statocyst through its minute opening.

As regards the lower animals, we do not yet know anything for certain about the localization of the sensory cells which function in these movements. In Crustacea, this faculty is distributed apparently among sensory hairs in the region of the joints; in insects we know that there are free nerve endings in the skin of the joints.

To the mechanical sense belongs also the sense of "strength." When a rnsn lifts a weight, he notices exactly if it is heavy or light, and, according to this sensation, he regulates the amount of energy to be expended. The leech shows that a similar sense is present also in the lower animals. It has been mentioned already that this animal contracts when the anterior sucker is attached and the posterior sucker is free. When the animal is in this position we can force it to lift fairly heavy weights, which, under certain circumstances, it will support for hours together. *(See* fig. 5.) If we cautiously hold up the weight with one hand, the worm experiences a sensation of considerable relief, and alters the impulse it sends to its muscles. This is clearly proved by the fact that, as soon as we withdraw our hand again, the worm is drawn out by the weight which it formerly had supported.

Stimulation of the Nervous System by Mechanical Influences.—Every organism, in order to be able to move vigorously, requires constant stimulation from without. To man this statement does not appear very credible, but it can occasionally be proved quite clearly in the lower animals. In the article on EQUILIBRIUM, ANIMAL, the statocysts of the lower organisms, which usually act as balancing organs, are described. It has been generally proved by experience, that the animals fall into an enduring state of debility-after these statocysts have been removed by an operation. They are no longer able to make powerful movements; we can express mathematically the amount of diminution in the gripping power of the chelae of a crustacean caused by the removal of the statocyst. It is not yet determined for certain how this connection between the statocysts and the muscular strength is to be explained. Apparently, the mechanical stimulation of the sensory cells of the statocyst by the statoliths affects the central nervous system of the animal, thus, as we may say, rousing it into activity in a somewhat similar manner to that in which coffee stimulates a tired man.

Flies furnish a particularly remarkable instance of this. In these insects, the posterior wings are transformed into oscillating clubs or "halteres," which, during flight, move simultaneously with the wings, with great rapidity (figs. 6a, 6b). If these clubs are removed or stuck down firmly, the insect is no longer capable of flight. It can neither rise from the ground nor maintain itself in the air. It appears from this that the active movement of the halteres is essential. Formerly, it was thought that the halteres were a kind of balancing organs, and it was believed that the fly lost its power of balance after they had been removed. This, however, is excluded by the extremely minute size of the

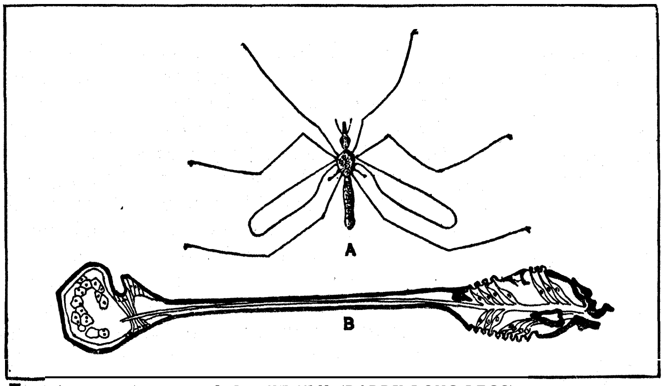

FIG. 6.—(A) TIPULA, A CRANE-FLY (DADDY-LONG-LEGS) SHOWING HALTERESES BEHIND THE WINGS; (B) LONGITUDINAL SECTION THROUGH A HALTERE, SHOWING SENSE ORGAN AT THE BASE (AFTER PFLUGSTEDT)

halteres. Now, however. numerous sensory cells affected by mechanical stimuli have been found on the basis of the halteres. These are so arranged that they must be vigorously stimulated by the movement of the halteres, which, apparently, has this stimulation as its object. We may assume that this affects the nervous system of the fly in a similar way as stimulation of the statocyst affects crustaceans. The fly is able to send the necessary impulses to the muscles of flight only if this constant stimulation is present.

Wille has recently discovered a similar, and, considered as a whole, certainly still very problematical contrivance in the Brazilian locust, *Rhipipterix chopardi*. This insect bears sense organs on the under side of its hind legs; if these are put out of action by being stuck down, the insect is prevented from springing and flying.

Structure of Tactile Organs.—There is not very much to be said on the subject of the anatomy of the sensory cells which serve for the transmission of mechanical stimuli. It has been mentioned alreadv that. even among unicellular animals (infusoria) tactile cilia are occasionally to be found. (See fig. I.) In multicellular animals there are frequently found, projecting from the surface of the body, groups of cells bearing small hairs like cilia, which are usually considered to be tactile organs (fig. 7 and 8). Several of these organs from the skin of different kinds of Echinoderms are shown in fig. 7. In fig. 8 is represented a "sensilla" from the skin of the leech. In yet other cases we find what are called free nerve-endings (fig. 9), the nerve cells, which are deeply situated beneath the skin, sending one or many fine processes up to the outer surface. Unfortunately, in no case can it be proved definitely that the groups of sensory cells mentioned really serve for the perception of mechanical stimuli. The only way in which this might be determined, namely by removing the organs by an operation and experimenting with the animals thus treated, is not practicable, owing to the large number of the organs, which usually are distributed over the whole surface of the skin. This difficulty of proof occurs also when dealing with arthropods, in which the tactile organs exhibit an astonishing

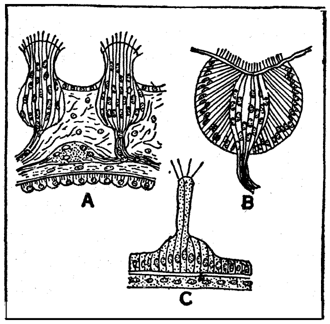

FIG. 7.— EPITHELIALSENSE-ORGANS OF ECHINODERMS
(A) Ophuroid, transverse section through the wall of an ambulacral foot; (B) Sea-cucumber, epithelial sense-organ from a tentacle; (C) Sensory papilla from an ambulacral foot of a feather-star

diversity. The rule that the cuticle is particularly thin where the sensory cells are situated (see fig. 10) applies to all these creatures (insects, crustaceans, spiders). When a sensory cell is quite separated from the exterior by a layer of chitin, it is impossible that it can perceive chemical stimuli, and we may assume, with some degree of probability, that it is an organ for the perception of mechanical stimuli.

Among Crustacea the most general form in which these occur is the sensory hair; in insects we find in addition sensory cones

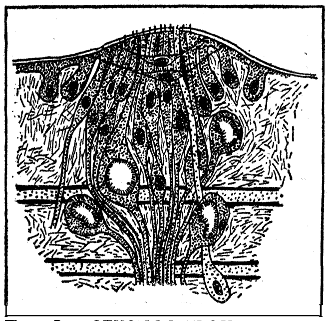

FIG. 8.—SENSILLA FROM THE SKIN OF A LEECH WITH OPTIC CELLS, AND APPARENTLY TACTILE CELLS (AFTER HACHLOFF)

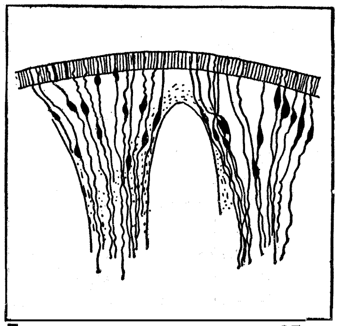

FIG. 9.— ANTERIOR END OF A SHORT HORN OF A SLUG (ARION), SHOWING FREE NERVE ENDINGS (AFTER RETZIUS)

(fig. 10 B), sensory pits (10 C), cup-shaped sense organs (fig. 10 D), and so forth. In insects only there is found also a particular kind of sense organ, the chordotonal organs. In form they are like a cord stretched between two flat surfaces of the body wall, and, doubtless, function when these surfaces are displaced in any way. The following parts may be distinguished in them:—the sensory cell with the proximal enveloping cell, the distal enveloping cell (cap cell) which connects the peculiar stylet (scolopala) with the hypodermis, and, lastly, the ligament which spans the whole apparatus. Such organs are found singly or in groups on the body and extremities of insects. The organs which most resemble them are "Johnston's organs" in the feelers. (See fig. 4.)

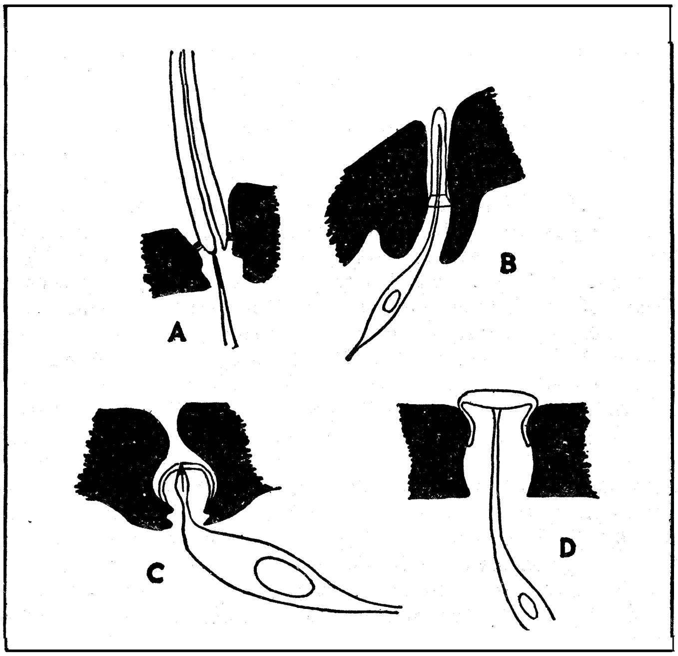

FIG. 10.— FOUR DIFFERENT KINDS OF TACTILE ORGANS FROM THE WATER-BEETLE (AFTER HOCHREUTHER)

In the auditory organs of insects the chordotonal organs certainly receive the sound waves; what purpose they serve in Johnston's organ, or in the simpler organs, is not yet known.

The Sense of Temperature.—Since heat, as is well known, consists in a mechanical vibration of molecules, the sense of temperature, also, must be included in the mechanical sense. It goes without saying that the higher animals possess a sense of temperature which is very similar to that of human beings. It is of greater interest to prove its presence in the lower animals. The simplest method of deciding whether an animal reacts to heat stimuli is by the use of the temperature organ. This consists of a narrow box, about a meter in length, the bottom of which is heated at one end, and, at the other, is cooled with ice. If a number of small animals, such as ants, are placed in the box, they avoid both the hot and the cold ends, and seek for a part in which a temperature prevails which suits them best.

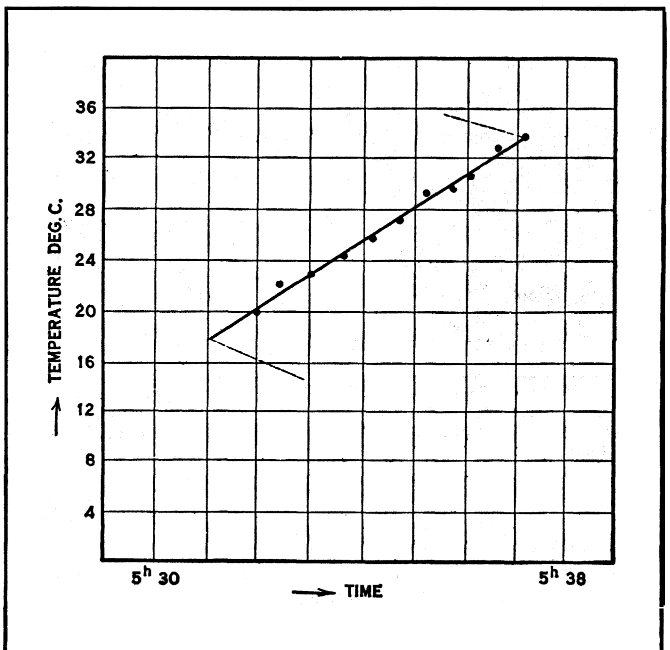

FIG. 11.—RISING OF THE TEMPERATURE OF THE BODY OF A MOTH DURING VIBRATORY MOVEMENTS OF THE WINGS (AFTER DOTTERWEICH)

Bees furnish a very fine example of an extraordinarily developed temperature sense. During the time when the eggs are hatching, they keep the interior of the hive at a very constant temperature of 35° (Hess, Himmer). The observed variations often lie within half a degree, that is to say, bees regulate the warmth of the hive just as exactly as mammals regulate the temperature of the blood.

It goes without saying that they must possess sensory cells by means of which they perceive heat. They raise the temperature of the hive apparently by muscular movements; over-heating they counteract by carrying in water and allowing it to evaporate.

Nocturnal Lepidoptera regulate the temperature of the body before flying. As a result of the heat produced by muscular activity, they attain, during flight, a temperature of about 36–40°. Before they fly off, they make very rapid, vibratory movements with their wings, buzzing or whirring. This is simply to raise the body temperature. As soon as the flight temperature is reached, they fly off. Fig. 11 represents, graphically, the raising of the body temperature during this vibration. Little is known of heat perception in the rest of the Invertebrata. (W. v. BUD.)

For the sensory function of touch in man *see* SKIN, SENSORY FUNCTIONS OF.

TOUCH-ME-NOT, any plant of the genus *Impatiens* (family Balsaminaceae), so called from the fact that the fruits burst explosively—the valves roll up inward and scatter the seeds—when touched. The genus includes about 350 species, found in tropical and north temperate regions, and especially abundant in the mountains of India and Ceylon. A few are cultivated ornamental flowers, among them garden balsam (*I. balsamina*) and sultana (*I. sultani*). Some American species are known as jewelweed. *See* IMPATIENS.

TOUL, a garrison town of northeastern France, in the *département* of Meurthe-et-Moselle, 21 mi. W. of Nancy on the Eastern railway. The population in 1954 was 11,140. Toul (*Tullum*) was originally capital of the Leuci, in the Belgic confederation, and acquired great importance under the Romans. It was evangelized by St. Mansuy in the 4th century, and became one of the leading sees of northeast Gaul. After being sacked successively by Goths, Burgundians. Vandals and Huns, Toul was conquered by the Franks in 450. Under the Merovingians it was governed by counts, assisted by elective officers. The bishops became sovereign counts in the 10th century, holding only of the emperor, and for 300 years (13th to 16th centuries) the citizens maintained a long struggle against them. Together with Verdun and Metz, the town and its domain formed the territory of the Trois-Evêchés. Toul was forced to yield for a time to the count of Vaudémont in the 12th century, and twice to the duke of Lorraine in the 15th. Charles V made a solemn entry into the town in 1544, but in 1545 it placed itself under the perpetual protection of the kings of France. Henry II took possession of the Trois-Evêchés in 1552, but the territory was not officially incorporated with France till 1648. Henry IV was received in state in 1603, and in 1637 the parlement of Metz was transferred to Toul. In 1700 Vauban rebuilt the fortifications of the town. In 1790 the bishopric was suppressed and the diocese united to that of Kancy. Toul capitulated in 1870.

The church of St. Étienne, which was formerly a cathedral, has a choir and transept of the 13th century; the nave and aisles are of the 14th, and the fine façade of the last half of the 15th. There are two western towers. The two large lateral chapels of the nave are in the Renaissance style. South of the church there is a fine cloister of the end of the 13th century which was much damaged at the Revolution. The church of St. Gengoult, chiefly late 13th- or early 14th-century, has a façade of the 15th century and a 16th-century cloister in Flamboyant Gothic. The *hôtel de ville* occupies a building of the 18th century, once the episcopal palace. Toul is the seat of a sub-prefect. The industries include the manufacture of porcelain; trade is in wine and brandy.

TOULON, a seaport and first-class fortress and naval station of France, *département* of Var, capital of the *arrondissement* of Toulon, on the Mediterranean, 42 mi. E.S.E. of Marseilles. Pop. 125,572. The Roman Telo Martius is supposed to have stood near the *lazaretto*. The town was successively sacked by Goths, Burgundians, Franks and Saracens. Until conquered by Charles of Anjou in 1259, it was under lords of its own, and entered into alliance with the republics of Marseilles and Arles. St. Louis, and especially Louis XII and Francis I strengthened its fortifications. It was seized by the emperor Charles V in 1524 and 1536. Henry IV founded there a naval arsenal which was further strengthened by Richelieu, and Vauban made the new dock, a new enceinte, and several forts and batteries.

The bay, which opens to the east, has two divisions, the Grande Rade and the Petite Rade; it is sheltered on the north and west by high hills, closed on the south by the peninsula of capes Sicié and Cépet, and protected on the east by a huge breakwater. The forts of St. Marguerite, of Cap Brun, of Lamalgue and of St. Louis to the north, and the battery of the signal station to the south, the battery of Le Salut to the east, and the forts of Balaguier and L'Aiguillette to the west protect the entrance. The bay of La Seyne lies west of the Petite Rade, and is defended by the forts of Six-Fours, Napoléon (formerly Ft. Caire), and Malbousquet, and the batteries of Les Arènes and Les Gaus. To the north of Toulon rise the defensive works of Mt. Faron and Ft. Rouge to the east the forts of Artigues and St. Catherine, to the north-east the formidable fort of Coudon, and to the south-east that of Colle Noire, respectively dominating the highway into Italy and the valley of Hyères with the Bay of Carqueiranne. The modern quarter lies to the north of the old town. The chief buildings are the former cathedral of St. Marie Majeure, the church of St. Louis, the naval and military hospital, a naval school of medicine, a school of hydrography, and large barracks. The imports are corn, wood, coal, hemp and salt provisions; the exports are salt, figs, raisins, almonds, oranges, cloth, bauxite ore, cork, soap and oils. The principal industries, apart from the arsenal, are shipbuilding, fishing and wine making. The interesting buildings and gardens of the hospital of St. Mandrier stand on the peninsula of

Cape Cépet, and near them is the *lazaretto.* Toulon is the seat of a sub-prefect, of a chamber of commerce, a board of trade-arbitrators and of a permanent maritime tribunal.

Toulon is the most important of the French dockyards, and is the headquarters of the Mediterranean fleet. The arsenal, which was created by Louis XIV, lies on the north side of the Petite Rade. This is approached from the Grande Rade by passages at the north and south ends of a long breakwater which extends from the direction of Le Mourillon towards the Cépet peninsula. Outside in the Petite Rade is a splendid protected anchorage for a great fleet, the whole being commanded by many forts and batteries. There are four great basins approached from the Petite Rade—the Vieille Darse, to the east, on the side of Le Mourillon; the Darse Vauban, next to it; and the Darse de Castigneau and the Darse Missiessy, farther to the west. Shipbuilding and its accessory trades are carried on at Toulon. (H. J. F.)

The Battle of Toulon (1744).—This battle was fought off the port from which it takes its name on February 11, 1744. An allied Franco-Spanish fleet of 28 ships was in harbour, commanded by M. de Court, and was being watched by a British fleet of similar size under Admiral Mathews.

England and Spain had been at war since 1739, but England and France, though on opposite sides, had not yet actually declared war on one another. Spain was employed at this time in sending troops to North Italy for an attack on Austria's Italian possessions, and France was helping her by placing Toulon at her disposal and also by providing about two-thirds of this fleet which was to convoy them.

Mathews felt he would be justified in attacking the French as well as the Spaniards, should the former's proffered assistance with their Mediterranean fleet materialize. The combined fleet put out of Toulon on February 9, and to Mathews' surprise, made off on a southerly course. If he were to follow them, he would uncover Toulon and the transports would slip out; on the other hand, if he waited for the transports, the enemy's fleet would not be brought to action. The English admiral decided in these circumstances to go after the fleet and bring it to action quickly, and then to double back and intercept the transports. He himself was commanding the centre, Lestock, the second-in-command, the rear, and Rowley the van.

According to the fighting instructions of the day, it was Mathews' duty first, if possible, to obtain the windward position. This he did. Then, before he bore down on the enemy to what distance he considered suitable, he was so to arrange his line that the ends would be conterminous with those of the enemy, so that, when parallel battle was finally joined, each ship would be opposed to the corresponding ship in the enemy's line. Clearly, however, Mathews' plan was hardly compatible with such instructions. If he was to wait until his whole line was covering the allies before attacking, he was the less likely to be back off Toulon in time to deal with the transports. Consequently, when Rowley's squadron was opposite the allied centre, and his own opposite the allied rear, Mathews signalled the attack. He was further influenced to this course by the fact that the British rear was far behind and to the east, owing, so its commander said, to variable breezes and adverse currents: in this connection, however, it must be noted that there was bad blood between Lestock and Mathews. Previous to the attack, Mathews had been flying the signal for the line—obviously applicable to Lestock—but when the commander-in-chief flew also the signal for battle, clearly meaning that Lestock should come up and take on the unengaged allied van before it should get about to assist the centre and rear, the second-in-command hove to and did nothing, on the grounds that Mathews was already filling his place opposite the enemy's rear and that consequently there was nothing for him to do.

The remainder of the British fleet was also puzzled at being ordered to attack before the whole enemy line was covered. The centre bore down on the enemy eventually, but in considerable confusion. Some of Rowley's squadron likewise attacked. but they were fearful of being doubled by the unoccupied allied van, and the leading ships correctly beat to windward to prevent this. Eventually M. de Court, realizing that the Spaniards who formed his rear were hard pressed, ordered his whole fleet about, and as the fresh ships came into action, Mathews' broke off the battle. The only prize was the "Poder," taken by Captain Hawke.

A record number of courts-martial followed. Lestock was acquitted on the technical grounds indicated above, but Mathews was sentenced to dismissal from the service. He had, with such ships as supported him properly, fought energetically, but was dismissed because, in trying to force a decision in difficult circumstances, he had trespassed against the fighting instructions of his day. Thanks to such measures and other reforms Great Britain's sea power was greatly increased.

The Siege of Toulon (1792).—In 1792 the royalists of the town sought the support of the English-Spanish fleet cruising in the neighbourhood under Vice-admiral Samuel Hood (*q.v.*). The Convention having replied by outlawing the town, the inhabitants opened their harbour to the English. The army of the republic at the end of Aug. 1793 laid siege to the town, and on this occasion Napoleon Bonaparte first made his name as a military expert. The forts commanding the town having been taken on Dec. 17 the English ships retired after setting fire to the arsenal and destroying a large part of the French fleet. Under the directory Toulon became the most important French military port on the Mediterranean; there Napoleon organized the Egyptian campaign. (*See* NAPOLEON I.) (G. A. R. C.; J. G. B.; X.)

World War II.—The Franco-German armistice of 1940 left the French fleet in the hands of the Vichy government, and at the time of the Anglo-American invasion of North Africa on Nov. 8, 1942, the greater part of this fleet was stationed at the Toulon naval base.

On Nov. 11 Hitler abrogated the terms of the armistice and ordered his forces to take over the unoccupied part of France, and on Nov. 27 his troops occupied Toulon and attempted to seize the French fleet.

The French were prepared for such a move, however, and under the command of Adm. Jean de la Borde scuttled or otherwise sabotaged the majority of their warships. Of more than 60 ships aggregating about 225,000 tons, only about 25,000 tons of smaller vessels remained intact.

TOULOUSE, the capital of the *département* of Haute-Garonne, France, lies at the foot of the Pyrenees in the Aquitaine basin, a natural depression which runs from the Atlantic to the Mediterranean and is formed by the valleys of the Garonne and the Aude rivers. Toulouse is 443 mi. S.S.W. of Paris, 159 S.E. of Bordeaux, 264 W. of Marseilles and 227 N.N.W. of Barcelona by rail. The area of the city is over 45 sq.mi., of which approximately one-fourth is built up. Pop. (1954) 217,667.

The City.—Toulouse is built on both banks of the Garonne (there 650 ft. wide) where it changes its course from the Pyrenees to flow northwest to the Atlantic. Three-quarters of the town's buildings, all of which are of brick, are on the right bank; one-quarter is on the left, which is 40 ft. lower and exposed to floods. The old city, on the right bank, was built entirely during the middle ages and forms the heart of the modern town. It is bounded by the Garonne and by the site of former ramparts, now the boulevards Duportal, Lascrosses, d'Arcole, de Strasbourg and Carnot, and *allées* (flower- and tree-lined avenues) François Verdier and St. Michel

Almost one-fifth of the inhabitants live on the 375 ac. of the old city, which also houses many businesses and offices. Two large streets, opened at the end of the 19th century and lined with tall houses and large stores, cross the district: the Rue d'Alsace Lorraine, becoming the Rue de Languedoc, running north-south, and the Rue de Metz running east-west. The other byways, which are left from the middle ages. are generally narrow, but often picturesque and bordered by tall houses and shops. There are numerous monuments.

The Gothic cathedral of St Étienne dates from the beginning of the 13th century, its rectangular bell tower being of the 16th century. The basilica of St. Sernin, the largest extant Romanesque church, was built between the 11th and 13th centuries.

The present boys' school was formerly the Dominican monastery; the 13th- and 14th-century church is the ancient mother church of the Dominican order. Sacked during the Revolution, the monastery was being restored in the 1950s. The old Augustinian monastery. now occupied by the Museum of Fine Arts, was built during the 14th to 16th centuries. Its main contents are medieval sculptures from destroyed Toulousian monuments, and paintings of various periods. Other notable religious buildings are the churches of Notre-Dame du Taur (14th-century), Notre-Dame la Dalbade (16th-century), St. Pierre (17th- and 18th-centuries) and Notre Dame la Daurade (18th-century).

ST. SERNIN BASILICA. TOULOUSE, THE LARGEST ROMANESQUE CHURCH EXTANT

Among the civil buildings is the Capitole, at one time the town hall and municipal theatre. It has a keep, a Renaissance courtyard and an 18th-century façade which overlooks a large square. The interior was decorated in the 20th century. The St. Raymond museum. a Renaissance building, contains antique sculpture. Approximately 100 private houses in Renaissance style, and many others dating from the 17th and 18th centuries, form one of the most complete groups of this kind in France. They are mainly in the Rues des Changes and St. Rome, de la Dalbade, Mage, Nazareth, Ninau and Ozenne. The most beautiful houses are de Bernuy. du Vieux Raisin. d'Espie, de Pierre and the Hôtel d'Assézat, finished in 1560, which now holds the Académie des Jeux Floraux. which has! since its foundation in 1323, yearly presented to poets flowers of wrought metal.

Most of the theatres and cafés are around the oval Place Wilson, built in the 19th century. The municipal library (1935) and the university library are near St. Sernin, as are also the faculties of law and letters and the three *lycées*. The school of fine arts is on the 18th-century brick embankments of the Garonne. Not far from the river is a 16th-century convent occupied by the Catholic institute.

Toulouse is an intellectual and administrative centre. The public offices of the *département* are located there, including those of the chief officer of the military region and the court of appeal. It is an archbishopric with about 40 religious houses.

The ancient *faubourgs* (suburbs incorporated into a city as it grows beyond its walls) of the right bank surround the old city between the boulevards and the Canal du Midi on the north and east to the Garonne on the south. In the southern part of this area. just beyond the walls, are the principal promenades. the *allées* François Verdier. Frédéric Mistral and St. Michel and the three gardens, Grand Rond, Jardin Royal and Jardin des Plantes, as well as the faculties of medicine and science. two university schools of engineering and the veterinary school. The houses are generally low, but! since 1950, higher ones of ten stories and more have been built. These quarters, largely residential, are interspersed with industrial areas, chiefly in the north and south. On an island on the Garonne an amusement park and municipal pool (1933–48), an exhibition hall (1948) and the residences for university students (1953) have been built.

On the left bank. the faubourg St. Cyprien, which houses one-fifth of the population of the city, is joined to the right bank by four bridges: the 17th-century Pont Neuf (New bridge) and three others built or rebuilt in the 20th century, St. Michel, St. Pierre and des Catalans. The centre of the *faubourg* contains the 17th-century Hôtel-Dieu and an 18th-century hospital, both on the edge of the river, and the 15th-century church of St. Nicolas. Farther out among the new developments, are several large factories and apartment buildings, as well as the Purpan hospital (1908–47). The city is surrounded by agricultural land where violets in particular are cultivated.

Communications and Industry.— Toulouse has land, water and air transport services. Six railways connect the town directly with Paris. Bordeaux, Pau and the Spanish frontier at Irun; Foix and the Spanish frontier at Puigcerda; Marseilles; Milan and Rome: Lyons and Geneva. The Canal du Midi and the canal to the Garonne transport nothing but hydrocarbons; the two ports are l'Embouchure and St. Sauveur. The airport is situated $5\frac{1}{2}$ mi. from Toulouse at Blagnac; it is connected by regular flights with Paris. Bordeaux, Nantes, Algeria, and Morocco.

Toulouse has become, since 1915, a large industrial city. Its principal factories produce nitrogenous fertilizer, airplanes, and cartridges and powder for the army. The minor products are confectionery, knitted goods. shoes. milled flour, paper and tobacco. It is also a centre of trade. chiefly in agricultural products. eggs and poultry, milk, grains. farinas and leather, and it is also a centre for the internal redistribution of cloth from abroad. The city has a chamber of commerce. banks and a stock exchange.

History.— The town came into being between the 4th and 3rd centuries B.C. as a stopping place on the shores of the Garonne. It became a real town after the Roman conquest and developed considerably in the 4th century A.D., the period in which it was fortified. In the 5th century it was the capital of the Visigoths, masters of southern Gaul and Spain. It was taken in 508 by Clovis, who reunited it with the French realm. In 721 the Saracens besieged the town without success.

About 850 the countship of Toulouse was secured by a family that was to rule it until the 13th century. Among these counts, Raymond IV commanded the Provençal contingent of the first crusade. It was his son, Alphonse, who gave Toulouse its communal freedom (1141). Raymond VI was a patron of the troubadours and also a protector of the Catharist heretics, and it was principally against him that Pope Innocent III declared the Albigensian crusade (*see* CATHARI), in the course of which Languedoc was devastated. Toulouse was captured by the crusaders in 1215. The countship was reunited with the crown of France in 1271.

After the crusade, numerous religious houses and the university (1229) were founded. A parliament was first opened in 1444. After the Hundred Years' War, which relatively spared the city, the Renaissance was marked by intense commercial activity based on the production of a dye (pastel) made from woad (*Isatis tinctoria*) grown locally. During the Wars of Religion, Toulouse evicted the Protestants (1562) and took the side of the Catholic league. It was ravaged by epidemics during the entire 17th century. In the 17th century the building of the Canal du Midi brought increased trade to the town. After the revolution, which took away from Toulouse its prerogatives as capital of Languedoc, Marshal Soult and the duke of Wellington fought, beneath the city walls, the last battle of the Peninsular War, April 10, 1814. The

19th and 20th centuries were, above all, characterized by industrial expansion, the increase of the population (from 50,000 in 1801 to 217.664 in 1954) and the considerable and disorderly growth of buildings. The area covered by the town increased tenfold between 1801 and 1954.

Occupied by the Germans in Nov. 1942 and liberated on Aug. 19, 1944, Toulouse came out of World War II with its population increased by 50,000 people.

See H. Ramet, *Histoire* de Toulouse (Toulouse, 1935); J. Coppolani, Toulouse, *étude* de *géographie* urbaine (Toulouse, 1954). (J. Ci.)

TOULOUSE-LAUTREC, HENRI DE (HENRI MARIE RAYMOND DE TOULOUSE-LAUTREC MONFA) (1864–1901), French painter. who vividly portrayed the character of Parisian entertainment and night life at the close of the 19th century. was born on Nov. 24, 1864. at Albi. At an early age he started to draw. When he was 15, as a result of two falls, he was left permanently crippled and deformed, and this physical disability was to influence his life, his character and his art. He worked first with René Princeteau. a painter of sporting pictures. and then studied under Fernand Cormon in Paris, where he associated with Vincent van Gogh. An eclectic, he admired Japanese drawings. Degas and El Greco. In 1886 he settled in Montmartre, whose characters and night life he painted. In large rhythmical compositions he presented a comprehensive picture.of an environment—at the dance halls of the Moulin de la Galette or of the Moulin Rouge. at bars and at the circus. In precise scenes are depicted the features and personalities of friends or star artistes: his cousin Tapié de Céleyran, the singer and song writer Aristide Bruant. the dancers La Goulue and Jane Avril, the singers Yvette Guilbert, May Belfort and May Milton and the clonn Chocolat.

LITHOGRAPH OF ARISTIDE BRUANT BY TOULOUSE-LAUTREC, 1893

His untiring curiosity led him to frequent big trials. hospitals, racecourses and sporting events where in numerous sketches he captured the gestures and attitudes of people. His very assured technique went hand in hand uith the sharpness of his vision. From his accumulated notes he extracted a linear design so expressive that often it required only a coloured drawing in which use was made of gray cardboard or of thin oil colours so placed as to avoid opposing values. In his last works he painted with a thicker palette, building up large contrasting surfaces. The influence of the theatre is evident in his canvases where faces are brought into relief under the glare of the footlights. Characteristic in his composition was an original sense of placing the central figure in the picture. His many works include essentially paintings which reveal a free-flowing line; lithographs where the stylization becomes pure arabesque; posters made powerful bv the extreme simplification in outline and movement and by the use of large areas of simple colours. Inspired by all sorts of milieus. his interest was above all in the human face. His pitiless draftsmanship produced portraits sometimes of a cruel truthfulness. their psychology being illuminated by the background.

In 1898 Toulouse-Lautrec's health started to deteriorate. He was taken to undergo a cure for alcoholism at a sanatorium. where he executed from memory a series of pastel drawings of circus subjects. He died at Malromé, Gironde, on Sept. 9. 1901. He influenced the painters of the Revue Blanche and the circle of artists of the "modern style" at Barcelona. where Picasso was beginning to paint. The Bibliothèque Nationale in Paris has a fine collection of his lithographs. The most important collection of his paintings is at the museum at Albi to which the painter's family bequeathed the works remaining in his studio. See also PAINTING: Postimpressionism.

TOUNGOO or TAUNG-NGU, a town and district of Burma, until World War II in the Tenasserim division and thereafter in the Pegu division. The town is on the right bank of the Sittang river: 166 mi. N. of Rangoon by rail. Pop. (1953) 31,589. From the 14th to the 16th centuries Toungoo was the capital of an independent kingdom.

The district of Toungoo has an area of 6,456 sq.mi.; pop. (1941) 474,858. The main Rangoon-Mandalay railway is the chief means of communication. The rainfall is between 60 and 90 in. Rice is the staple crop; there are some plantations of rubber. Large areas of forest were reserved.

TOURACO, a vernacular name applied to the birds of the family Musophagidae, also known as plantain eaters, which is the meaning of *Musophaga*, the typical genus. The most widespread genus is Tauraco. The family. with 6 genera and about 20 species, is confined to Africa south of the Sahara. Its relations are with the cuckoos.

Touracos are mainly fruit eaters but vary their diet with insects and other animal matter.

The various touracos are usually bright coloured. with short wings and a long neck. and with a striking crest (absent in one species). The red wing feathers have a peculiar pigment. containing copper, known as turacin. (K. P. S.)

TOURAINE, a French province, bounded on the north by Orléanais. west by Anjou and Maine, south by Poitou and east by Berry. and corresponding approximately to the modern *département* of Indre-et-Loire.

Touraine took its name from the Turones, the tribe by which it was inhabited at the time of Caesar's conquest of Gaul. The capital city. Caesarodunum. was made by Yalentinian the metropolis of Lugdunensis. which included roughly the later provinces of Touraine, Brittany, Maine and Anjou.

The ecclesiastical province of Tours was apparently created during the episcopate of St. Martin (fl. 375–400), who founded the abbey of bfarmoutier. near Tours, and whose tomb in the city became a celebrated shrine. Tours was included in the territory of the Visigoths. but the Tourangeaux refused to adopt the Arian heresy of their conquerors and easily accepted the conquest of the province by Clovis (*c.* 507).

The possession of Touraine was constantly in dispute between different Merovingian princes. and the province enjoyed no settled peace until the reign of Charlemagne. Charlemagne established Alcuin as abbot of St. Martin of Tours. under whom the school of Tours became one of the chief seats of learning in Caul. During the 10th century and the earlier half of the 11th, Touraine was entrusted to counts, at first appointed by the crown but later (from 940 or 941 onward) hereditary, paying homage to the kings of France only. The countship then became the object of fierce competition between the houses of Xnjou and of Blois, till in 1044 Geoffrey Martel of Anjou took hold of the region, which remained in his family till 1204. After the accession of the Angevins to the English throne. Touraine became a battieground for John Lackland and Philip Augustus; and the latter conquered it in 1204 and had it formally ceded by John in 1206. Philip had appointed William des Roches hereditary seneschal in 1204, but the dignity was ceded to the crown in 1312. Touraine was granted from time to time to princes of the blood as an appanage of the crown of France. It was held by Joan of Burgundy, queen of France, in 1328; by Philip. duke of Orléans. in 1344; and in 1360 it was made a peerage duchy on behalf of Philip the Bold. afterward duke of Burgundy. Charles YII bestowed the duchy successively on his wife Mary of Anjou. on Archibald Douglas and on Louis III of Xnjou. It was the dower of Mary Stuart as the widow of Francis II. The last duke of Touraine was Francis, duke of Alençon (d. 1584). Plessis-les-Tours had been the favourite residence of Louis XI, who granted many privileges to the town of Tours and increased its prosperity by the establishment of the silk-weaving industry.

The Reformed religion numbered many adherents in Touraine, who suffered in the massacres following on the conspiracy of Amboise. Many Huguenots emigrated after the massacre of St. Bartholomew, and after the revocation of the Edict of Nantes the silk industry, which had been mainly in the hands of the Huguenots, was almost destroyed. This migration was one of the causes of the extreme poverty of the province in the 18th century.

BIBLIOGRAPHY.—E. Pepin, *Histoire* de Touraine (1935); A. Dupin de Saint-André, *Histoire* du *protestantisme* en Touraine (1885); T. A. Cook, Old Touraine, 2 vol. (1892).

TOURCOING, a town of northern France in the *département* of Nord, less than a mile from the Belgian frontier, and 8 mi. N.N.E. of Lille on the railway to Ghent. Pop. (1954) 82,753. Famed since the 12th century for its woolen manufactures, Tourcoing was fortified by the Flemings in 1477, when Louis XI of France disputed the inheritance of Charles the Bold with Mary of Burgundy, but in the same year was taken and pillaged by the French.

In 1794 the Republican army, under Moreau and Souham, gained a decisive victory at Tourcoing over the Austrians. Tourcoing is practically one with Roubaix to the south, being united thereto by a tramway and a branch of the Canal de Roubaix. Public institutions established there include a tribunal of commerce, a board of trade arbitrators, a chamber of commerce, an exchange and a conditioning house for textiles. Together with Roubaix, Tourcoing ranks as one of the chief textile centres of France. Its chief industry is the combing, spinning and twisting of wool, spinning of cotton and the manufacture of all kinds of woolen, cotton and silk goods, notably carpets. To these industries must be added those of dyeing and the manufacture of hosiery, textile machinery and soap.

TOURGÉE, ALBION WINEGAR (1838–1905), U.S. judge and author, who wrote novels on the problems of the south during the reconstruction, was born in Williamsfield, O., on May 2, 1838. He attended the University of Rochester, N.Y., and during the American Civil War served as an officer in the Union army.

He was admitted to the Ohio bar in 1864 and after the war lived in Greensboro, N.C., where he practised law. Elected judge of the North Carolina superior court in 1868, Tourgée, who was an advocate of Radical reconstruction policies, was widely criticized in the south for using his post for political advantages and styled a carpetbagger. He later moved to New York and in 1881 settled in Mayville. U.S. consul at Bordeaux, France, from 1897 to 1903, he died there on May 21, 1905.

Tourgée contributed articles to various publications, edited a weekly literary magazine, lectured frequently and wrote several didactic novels. His books were romantic and sensational in plot but often accurately depicted the contemporary south in the backgrounds.

His most popular novel was *A Fool's Errand* (1879), a semi-autobiographical account of the experiences of a former Union officer in the south. *Bricks Without Straw* (1880) concerned the problems of Negro emancipation.

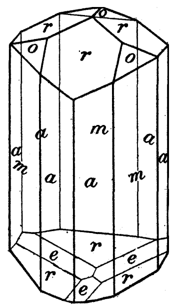
TOURJÉE, EBEN (1834–1891), U.S. musician and educator, born at Warwick, R.I., on June 1, 1834, founded with Robert Goldbeck the New England Conservatory of Music in Boston, Mass., in 1867. He introduced the class system of instruction in music and was the first dean of the College of Music of Boston university. Tourjée died in Boston on April 12, 1891.

TOURMALINE, a borosilicate mineral of complex and variable composition. The name is from the Singhalese *toramalli*, applied to brown gem stones found in Ceylon early in the 18th century.

Although sometimes occurring in granular masses, tourmaline is usually in crystals, which may be slender needles or rods, sometimes in bundles or radiating groups, but more commonly in well-formed crystals. Iron tourmalines are jet black in colour and are known as schorl. The coloured varieties when transparent and free from flaws are cut as gem stones. Tourmaline may be colourless and water clear. A pink variety is known as rubellite, a green variety as Brazilian emerald, a blue as indicolite, etc. Bicolour crystals are found, pink at one end and green at the other. Concentric colour zoning may also be found.

Composition and Crystal Forms. — X-ray studies showed that tourmaline has a structure based on a six-sided silicate ring (Si_6O_{18}) and BO_3 groups, and a basic formula may be written as $NaMg_3Al_6(OH)_4(BO_3)_3Si_6O_{18}$. Extensive replacements occur. Calcium (Ca) commonly replaces part of the sodium (Na), lithium and aluminum (Li,Al) or ferrous iron (Fe) may partially replace magnesium (Mg), and ferric iron (Fe) the aluminum (Al), and fluorine (F) the hydroxyl group (OH). Potassium, chromium and manganese may also be present. Thus rather than a single mineral species, it is actually an isomorphous series. It is common practice to recognize three types according to the predominance of certain elements: iron tourmaline, black in colour; magnesium tourmaline, brown; and alkali tourmaline, pink, green and colourless.

In spite of the wide range in composition, the crystal forms and angles are remarkably constant. The crystals belong to the ditrigonal pyramidal class of the hexagonal system. The vertical trigonal axis is polar, with different faces developed at opposite ends, and tourmaline is thus said to be hemimorphic. The illustration shows a common type, with two trigonal pyramids r and o at the upper end, and at the lower the trigonal pyramids *r* and *e*. The crystals are usually prismatic, with a hexagonal prism a and a prominent trigonal prism m, which gives a triangular aspect to the cross section. Additional narrow prism faces and conspicuous vertical striations give curving convex sides, resulting in a spherical-triangular cross section which is characteristic.



CRYSTAL OF TOURMALINE SHOWING HEMIMORPHIC DEVELOPMENT

Electrical Properties. — An interesting feature of tourmaline is the pyroelectric property, which is intimately related to the hemimorphic or polar development of the crystals mentioned above. When a crystal is heated, one end acquires a positive electrical charge and the other end a negative charge. On cooling these charges are reversed. This can be easily demonstrated by a method devised by August A. Kundt. A mixture of finely powdered red lead and sulfur is blown through a cloth screen. By friction. the sulfur particles acquire a negative charge and are attracted to the positive end of the crystal, and positively charged red lead goes to the negative end. Tourmaline also shows the related phenomenon of piezoelectricity. When a plate cut perpendicular to the vertical axis is subjected to change in pressure, it develops positive and negative charges on the opposite surfaces. This property can be used for detecting variations in pressure, as in depth-sounding apparatus. Such plates have been used to measure blast pressures, both in air and under water. For these purposes it does not need to be as free from flaws as crystals used for radio frequency control, for which purpose quartz (*q.v.*) is better suited.

Optical Properties. — The optical properties of tourmaline are of great interest. Coloured crystals are very strongly dichroic, that is, light is absorbed much more in some directions than in others. Since tourmaline is hexagonal, and therefore doubly refracting, a ray of light entering the crystals is separated into plane polarized rays, one, the ordinary ray, vibrating perpendicular to the vertical axis, and the other. the extraordinary ray, vibrating parallel to this axis. In coloured tourmaline the ordinary ray is almost completely absorbed. Plates cut parallel to the vertical axis of the crystal allow only the extraordinary ray to pass through, and if two such plates are placed in crossed position, the light is entirely cut out. A pair of such plates form a very simple polarizing apparatus known as tourmaline tongs Since the effect is limited to deeply coloured crystals, not much light is transmitted, even in the favourable direction. Thus this device is far inferior to other polarizing instruments, such as the Nicol and Ahrens prisms (see CALCITE) or polaroid.

Tourmaline is optically uniaxial and negative, and the refractive indexes vary with the chemical composition. for the ordinary ray 1.6315–1.6854, and for the extraordinary ray 1.6123–1.6515 for sodium light. The specific gravity shows a corresponding range from 3.0 to 3.2. The hardness is 7 to 7.5.

Occurrence. — Tourmaline is most abundant and has the best developed crystals in pegmatites and in metamorphosed limestones in contact with granite magmas. It appears to have originated in most cases by the interaction of boron emanations from the granite magma on the surrounding rocks. Since it is resistant to weathering processes the mineral accumulates in detrital deposits. Gem tourmaline comes from the gem gravels of Ceylon and is obtained from pegmatites in the Urals, southern California, Maine and Madagascar. See also GEM. (L. S. RL.)

TOURNAI (Flemish DOORNIK), city, province of Hainaut, Belgium, on the Scheldt. Pop. (1955 est.) 33,117. The cathedral of Notre-Dame dates from 1030, the nave is Romanesque of the middle of the 12th century, with much pointed work. The transept was added in the 13th century. The first choir was burned down in 1213, but was rebuilt in 1242 at the same time as the transept, and is a superb specimen of pointed Gothic. There are five towers with spires. There are several old pictures of merit, and the shrine of St. Eleuthère, the first bishop of Tournai in the 6th century, is a remarkable product of the silversmith's art. The belfry on the Grand Place, the oldest in Belgium, was built in 1187, partly reconstructed in 1391 and finally restored and endowed with a steeple in 1852. The church of St. Quentin in the same square as the belfry is almost as ancient as Xotre-Dame. In the church of St. Brice is the tomb of Childeric discovered in 1653. Among the relics mere 300 small golden models of bees. These were moved to Paris, and when Napoleon was crowned emperor a century and a half later he chose Childeric's bees for the decoration of his coronation mantle. In this manner the bee became associated with the Napoleonic legend just as the lilies were with the Bourbons. The Pont des Trous over the Scheldt, with towers at each end, was built in 1290, and some old houses still in occupation date back to the 13th century. On the Grand Place is the fine statue of Christine de Lalaing, princess d'Epinoy, uho defended Tournai against Parma in 1581.

The actual site was occupied under Julius Caesar and called Nerviorum or Turnacum. In the reign of Augustus, Agrippa fixed the newly mixed colony of Suevi and Menapii at Tournai. In the 5th century the Franks seized Tournai, and Merovaeus made it the capital of his dynasty. This it remained until the subdivision of the Frank monarchy among the sons of Clovis. When feudal possessions, instead of being purely personal, were vested in the families of the holder after the death of Charlemagne, Tournai was specially assigned to Baldwin of the iron Arm by Charles the Bald, whose daughter Judith he had abducted, on receiving the hereditary title of count of Flanders. During the Burgundian period it was the residence of Margaret of York, widow of Charles the Bold; and the pretender Perkin Warbeck, whom she championed, if not born there, was the reputed son of a Jew of Tournai. In the early 16th century Tournai was an English possession for a fea years and Henry VIII sold it to Francis I. It did not long remain French, for in 1521 the count of Nassau, Charles V's general, took it for Spain. Part of Tournai was destroyed in May 1940 during the German invasion. Industries include hosiery mills, weaving, tanning and cement works.

TOURNAMENT or TOURNEY. Of medieval, French origin, the term tournament described the military exercises in which knights engaged one another in order to display their skill and courage in combat. The tournament in this sense had practically died out by the end of the 16th century, by which time it had largely ceased to be a trial of arms and had become a pageant. The term is still in use somewhat in the latter sense, for instance, in the Royal Tournament, an annual naval and military display held in London, and in the Pasadena (Calif.) New Year's day Tournament of Roses.

In the early years of the 20th century the word tournament came to be applied to certain methods of conducting competition in sports events. In the most common modern tournament the contestants are matched in pairs with the losers in each test being eliminated and the winners paired anew until one remains as the champion of the tournament. In some tournaments the contestant is not eliminated until defeated a second time. These are called double-elimination tournaments. A third form of the modern tournament is called a round robbin. Each contestant opposes every other contestant and the one with the best percentage of victories (usually referred to as the best won-and-lost record) is declared the champion.

The tournament in its earliest form apparently originated in France about the middle of the 11th century. Several chroniclers credit a French baron, Geoffroi de Preulli, with having "invented tournaments " Subsequently the tournament, according to Roger of Hoveden (Charles Du Cange's *Glossarium, s.v.* "Tourneamentum"), became "military exercises carried out, not in the spirit of hostility (nullo interveniente odio), but for practice and display of prowess (pro solo exercitio, atque ostentatione *virium*)."

By the 12th century the tournament notwithstanding the condemnation of the ecclesiastical councils of Lateran in Rome had spread to England and grown so popular that Henry II found it necessary to forbid the sport which gathered in one place so many barons and knights in arms. From that age comes the famous description by William Fitz-Stephen of the martial games of the Londoners in Smithfield. He tells how on Sundays in Lent a noble train of young men would take the field well mounted, rushing out of the city with spear and shield to ape the feats of war. Divided into parties, one body would retreat, while another pursued striving to unhorse them. The younger lads, he says, bore javelins disarmed of their steel, by which it is inferred that the weapon of the elders was the headed lance. William of Newbury tells how the young knights. balked of their favourite sport by royal mandate, would pass over sea to win glory in foreign lists. Richard I relaxed his father's order, granting licences for tournaments, and Jocelin of Brakelond wrote about the great company of cavaliers who held a tournament between Thetford and Bury St. Edmund's in defiance of the abbot. From that time onward unlicensed tourneying was treated as an offense against the crown, which exacted heavy fees from all taking part in them even when a licence had been obtained.

In 1299 life and limb were declared to be forfeit in the case of those who should arrange a tourney without royal licence, and offenders were to be seized with horse and harness. As the tournament became an occasion for pageantry and feasting, new reason was given for restraint: a simple knight might beggar himself over a sport which risked costly horses and carried him far afield. Jousters traveled from land to land, offering and accepting challenges. Thus Edward I, before coming to the throne, led 80 knights to a tournament in Europe. Before the jousts at Windsor on St. George's day in 1344 heralds published in France, Scotland, Burgundy, Flanders, Hainault and Brabant (Belg.) and the domains of the emperor the king's offer of safe-conduct for competitors. At the weddings of princes and magnates and at the crowning of kings the knights gathered to the joustings — as much a part of such high ceremonies as the banquet and the minstrelsy.

Regulations. — About 1292 a "Statute of Arms for Tournaments" enacted new laws. Swords with points were not to be used. nor pointed daggers. nor club nor mace. None was to raise up a fallen knight but his own appointed squires, clad in his device. The squire who offended was to lose horse and arms and lie three years in jail. Disputes were to be settled by a court of honour of princes and earls. That such rules were needful had been shown at Rochester in 1251, when foreign knights were beaten by the English and so ill-treated that they fled to the city for refuge. On their way the strangers were faced by another company or knights who thrashed them with staves in revenge for the doings at a Brackley tournament. Even as early as the 13th century some of these tournaments were mere pageants of horsemen. For the Jousts of Peace held at Windsor park in 1278 the sword blades were of whalebone and parchment, silvered; the helms were of boiled leather and the shields of light timber. But the game could make rough sport. Many a tournament had its tale of killed and wounded in the chronicle books: how Roger of Lemburn struck Arnold de Montigny dead with a lance thrust under the helm; the first of the Montagu earls of Salisbury died of hurts taken at a Windsor jousting, and in those same lists at Windsor the earl's grandson Sir William Montagu was killed by his own father; William Longéspee in 1256 was so bruised that he never recovered his strength, and he is among many of whom the like was written. Injuries were often caused when dismounted adversaries continued the combat on foot. Blunted lance points came early into use, and by the 14th century the coronall or cronell head (crown shaped and intended to unhorse but not to wound) was often fitted in place of the point. Alter 1400 the armourers began to devise harness with defenses specially wrought for service in the lists. But the joust lost its chief perils with the invention of the tilt, which was at first a cloth stretched along the length of the lists. The cloth became a stout barrier of timber, and in the early 16th century the knight ran his course at little risk. Locked up in steel harness, he charged along one side of this barrier, seeing little more through the pierced sightholes of the helm than the head and shoulders of his adversary on the other side of the barrier. His bridle arm was on the tilt side, and thus the blunted lance struck at an angle upon the polished plates. Still mishaps might befall. At the close of the tournament which formed part of the rejoicings for the peace of Cateau-Cambrésis in 1559 Henry II of France died from the stroke of Gabriel de Montgomeri, who failed to cast up in time the truncheon of his splintered lance. The result of this tragedy was a considerable diminution in the popularity of the tournament. But the 16th-century tournament was, in the main, a bloodless meeting, as befitted a spectacle arranged as much for the delectation of women as of men. Prizes, consisting of arms and armour, rich robes and great silver vessels were presented to the victors by the Lady of the Tournament.

Pageantry. — In the 15th century the tournament had the aspect of a pageant. The great meeting at Bruges, when the jousting of the Knights of the Fleece was part of the pageant of the Golden Tree, the Giant and the Dwarf, may stand as a magnificent example of many such gay gatherings. When Henry VIII was scattering his father's treasure the pageant had become an elaborate masque. For two days after the crowning of the king at Westminster, Henry and his queen viewed from the galleries of a fantastic palace set up beside the tiltyard a play in which deer were pulled down by greyhounds in a paled park, in which the Lady Diana and the Lady Pallas came forward, embowered in moving castles, to present the champions. Such costly shows fell out of fashion after the death of Henry VIII; and in England the tournament remained, until the end, a martial sport. In France it degenerated to the carrousel, which became an unmartial display.

The tournament was, from the first, held to be a sport for men of noble birth, and in Europe, where nobility was more exactly defined than in England, the lists were jealously closed to all combatants but those of the privileged class. In the German lands, questions as to the purity of the strain of a candidate for admission to a noble chapter were often settled by appeal to the fact that this or that ancestor had taken part in a tournament. The heraldic manuscript of Konrad Griinenberg shows the *Helmschau* that came before the German tournament of the 15th century— the squires carrying each his master's crested helm, and a little scutcheon of arms hanging from it, to the hall where the king of arms stands among the ladies and judges each blazon.

Revivals. — An attempt to revive the tourney was made at Eglinton castle, Ayrshire, in 1839. Archibald, 13th earl of Eglinton, found an ideal setting for his tournament in the grounds of Eglinton castle. On Aug. 28, 1839, the lists were dressed in the park. Each knight, with his esquires and attendants, had a separate pavilion. The lists were splendidly decorated and richly hung, and temporary adornments of Westminster abbey at the then recent coronation were again used. At Lord Eglinton's request many of the ladies wore the costume of the 14th and 15th centuries. The marquess of Londonderry was King of the Tournament and Lady Seymour, afterward duchess of Somerset, was Queen of Love and Beauty. The official list contained the names of 15 knights. . The crown of victory was bestowed upon Lord Eglinton. The second day there was a series of mimic tilts between Prince Louis Napoleon, afterward Napoleon III, and Charles Lamb, both of whom were in armour. On the third day there was a series of tourneys in which eight knights, armed with swords, were engaged. A good description of the Eglinton tournament will be found in chapters 59 and 60 of Disraeli's novel *Endymion*.

When Prince Humbert, afterward Humbert I, king of Italy, was married at Turin in 1868 to Princess Margherita of Savoy, the festivities included a tournament.

TOURNEUR, CYRIL *(c.* 1575–1626), English dramatist whose reputation rests upon two plays, *The Atheist's Tragedie* and *The Revengers Tragedie,* was perhaps the son of Capt. Richard Turnor, water bailiff and subsequently lieutenant governor of Brill in the Netherlands. Cyril Tourneur also served in the Low Countries, for in 1613 there is a record made of payment to him for carrying letters to Brussels. He enjoyed a pension from the government of the United Provinces, possibly by way of compensation for a post held before Brill was handed over to the Dutch in 1616. In 1625 he was appointed by Sir Edward Cecil, whose father had been a former governor of Brill, to be secretary to the council of war. This appointment was canceled by the duke of Buckingham, but Tourneur sailed in Cecil's company to Cádiz, Spain. On the return voyage he was put ashore at Kinsale with other sick men, and died in Ireland on Feb. 28, 1626.

The first fixed date concerning Tourneur is the publication in 1600 of his poetical satire, *The Transformed Metamorphosis.* In 1609 he wrote *A Funerall Poeme on the Death of Sir Francis Vere, Knight,* who had been governor of Brill. In 1612 he joined with John Webster and Thomas Heywood in *Three Elegies on the Most Lamented Death of Prznce Henrie;* in the same year he wrote a prose *Character* of Robert Cecil, the first Lord Salisbury, which remained in manuscript until 1930.

It is however as a dramatist that he is chiefly remembered. An early play, *The Nobleman,* entered to him in the Stationer's register, Feb. 15, 1612, has disappeared. In 1611 was published *"The Atheist's Tragedie: or The Honest Man's Revenge.* As in divers places it hath often beene Acted. Written by Cyril Tourneur." Four years before, in 1607, there had appeared *"The Revengers Tragedie.* As it hath beene sundry times Acted by the Kings Majesties Servants." This play is anonymous and it was not until 1656 that the bookseller Edward Archer entered it to Tourneur on his list and was followed by Thomas Kirkman in 1661 and 1671. This later attribution is not decisive, and the internal evidence of authorship is conflicting.

In *The Atheist's Tragedie,* D'Amville, the atheist (in the Elizabethan sense of rejecting all morality), acknowledges obedience only to nature. To enrich his heirs, he stops short of no crime until he accidentally kills himself and confesses, "Nature is a fool. There is a power above her." In the other play, Vindice, the revenger, takes vengeance on the duke who had seduced his beloved, and on the members of the duke's family, until he is himself ordered to execution to which he goes boasting, "Is there one enemy left alive?" Thus the two plays differ in their attitude to private revenge and *The Revengers Tragedie,* although earlier, is more mature in its mechanical mastery and its sombre brilliance. Its authorship remains doubtful.

The *Complete Works of Cyril Tourneur* were edited by Allardyce Nicoll (1930) and *Plays and Poems of Cyril Tourneur* by J. Churton Collins, 2 vol. (1878).

TOURNON, a town of southeastern France, capital of an *arrondissement* in the *dkpartement* of Ardèche, on the right bank of the Rhône, 58 mi. S. of Lyons by rail. Pop. (1954) 5,215. Tournon preserves a gateway of the 15th century, a Renaissance college founded in 1536 by François Cardinal de Tournon and an old castle containing a Gothic chapel and museum. The church of St. Julian dates chiefly from the 14th century and contains Gothic frescoes.

Tournon had its own counts as early as the reign of Louis I.

It is the centre of a wine and fruit district.

TOURS, a town of France, capital of the dkpartement of Indre-et-Loire, 145 mi. S.W. of Paris by rail. Pop. (1954) 80,261.

Tours (see TOURAINE), under the Gauls the capital of the Turones or Turons, originally stood on the right bank of the Loire, a little above the village of St. Symphorien. At first called Altionos, the town was afterward known as Caesarodunum., The Romans moved the town from the hill to the left bank of the river.

Tours became Christian about 250 through the preaching of Gatien, who founded the bishopric. The first cathedral was built 100 years later by St. Litorius. The bishopric became an archbishopric when Valentinian I made Tours the capital of Lugdunensis Tertia, though the bishops did not adopt the title of archbishop until the 9th century. In the 5th century the official name of Caesarodunum was changed to Civitas Turonum. St. Martin, the apostle of the Gauls, was bishop of Tours in the 4th century.

Affiliated to the Armorican confederation in 435, the town fell to the Visigoths in 473. It became part of the Frankish dominions under Clovis. At the end of the 6th century the bishopric was held by St. Gregory of Tours. Tours grew rapidly in prosperity under the Merovingians, but abuse of the right of sanctuary led to great disorder. Charlemagne re-established discipline in the disorganized monastery and set over it Alcuin, who established one of the oldest public schools of philosophy and theology. The arts flourished at Tours in the middle ages and the town was the centre of the Poitevin Romanesque school of architecture. The abbey was made into a collegiate church in the 11th century and was for a time affiliated to Cluny but soon came under the direct rule of Rome. The suburb in which the monastery was situated became important under the name of Martinopolis. The Normans pillaged it in 8j3 and 903. Walls were erected from yo6 to 910, and the name was changed to that of Chbteauneuf. In the 14th century Tours was united to Chbteauneuf within a common wall, of which the Tour de Guise remains, and both towns were put under the same administration. The numerous and long-continued visits of Charles VII, Louis XI, who established the silk industry, and Charles VIII during the 15th century favoured commerce and industry. In 1562 Tours suffered from the violence of both Protestants and Catholics. In the 17th and 18th centuries it was the capital of the government of Touraine. Its manufactures, of which silk weaving was the chief, suffered from the revocation of the Edict of Kantes (1685). In 1772 its mint, whence were issued the "livres" of Tours, was suppressed. During the Revolution the town formed a base of operations of the Republicans against the Vendéans. During World War II, it was at Tours that Winston Churchill met Paul Reynaud cn June 13, 1940, and decided that Great Britain would continue the war against Germany. Tours was partly destroyed; in the postwar reconstruction an attempt was made to preserve its architectural type.

Tours lies on a flat tongue of land between the Loire and Cher just above their junction. The right bank of the Loire is bordered by hills at the foot of which lie St. Cyr and St. Symphorien. The river is crossed by one bridge and one suspension footbridge.

The cathedral of Tours is dedicated to St. Gatien. The lower portions of the west towers belong to the 12th century; the choir to the 13th; the transept and east bays of the nave to the 14th; the remaining bays. a cloister on the north and the façade, decorated in the Flamboyant style, to the 15th and 16th; the upper part of the towers to the 16th. In the choir there is fine 13th-century stained glass. The 16th-century tomb of the children of Charles VIII is attributed to the brothers Juste. The square tower of the church of St. Julien is Romanesque, the rest being in the early Gothic style of the 13th century. with the exception of two apses added in the 16th. Two towers and a Renaissance cloister are the chief remains of the celebrated basilica of St. Martin. Two other churches are Notre-Dame-la-Riche, originally built in the 13th century, rebuilt in the 16th and magnificently restored in the 19th; and St. Saturnin, of the 1jth. Of the old houses of Tours the Hôtel Gouin and that wrongly known as the house of Tristan l'Hermite (both of the 15th century) are the best known. Tours has a valuable library, including among its manuscripts a gospel of the 8th century on which the kings of France took oath as honorary canons of the church of St. Martin. Honor6 de Balzac was a native of Tours. Tours is the seat of an archbishop, of a prefect, and of a court of assizes and has tribunals of first instance and of commerce, a board of trade-arbitrators and a chamber of commerce. As a cultural centre, Tours has a faculty of medicine; schools of law and of the fine arts; an institute where foreigners can study the French language; and a musical academy. Printing and silk manufacture are important industries. The town also has steelworks and iron and tin foundries. Other products include machinery, oil, cement, stained glass, boots and shoes and porcelain. A considerable trade is carried on in the wine of the district and in brandy, dried fruits and confectionery. **(X.)**

BATTLE OF TOURS

The battle of Tours (A.D. 732), sometimes called the battle of Poitiers, marks the turning point in the northern advance of the Moors; the victory of the Franks checked once and for all the expansion of Islam in western Europe. In 711 the Arabs had crossed the Straits of Gibraltar and attacked the weak Visigothic kingdom of Spain; within seven years they had overrun most of the peninsula and crossed the Pyrenees; and in 720 they captured Narbonne, which became the base for their further progress into Gaul. The plan of extending their power to the north was rendered more possible by the political rivalry which subsisted between the dukes of Aquitaine and the Merovingian mayors of the palace. However, in 720, Eudo, duke of Aquitaine, had made his peace with Charles Martel and was therefore free to deal with the impending danger. In 721 he relieved Toulouse, which was being besieged, and won a decisive victory over the Arabs. But after a short respite the attack was renewed in 725. A strong army crossed the eastern Pyrenees, captured Carcassonne and Nîmes and occupied the greater part of Septimania. In the same year the Arabs made a raid into Burgundy and destroyed Autun. Internal dissensions among the Arabs themselves, the hostility between the Ma'ddites and the Yemenites, prevented them, however: from following these successes up; and it was only after the appointment in 731 of the popular and energetic governor of the Yernenite party, Abd ar-Rahman, that the offensive was resumed. The situation in Gaul was favourable for the enterprise, for war had again broken out between Eudo and Charles. In 732, with a large army, Abd ar-Rahman crossed the Pyrenees and captured and burned Bordeaux. Eudo, who hastened to check him, was defeated, with the loss of most of his army, between the Garonne and the Dordogne. The Arabs pressed forward, plundering as they went, along the line of the Roman road which ran northward from Bordeaux through Poitiers to Orléans. At Poitiers they destroyed the basilica of St. Hilary; their next objective was Tours, whither they were attracted by the riches of the church of St. Martin. Before they reached it they were met by Charles, to whom Eudo, despite his previous hostility, had fled for assistance after his defeat.

Charles, at the head of a large army, engaged with the enemy south of Tours, perhaps at the little town of Cenon, near the junction of the Clain and the Vienne, and not far north of Old Poitiers. For seven days the two armies stood facing each other. Then on a Saturday in October serious fighting began. Charles had taken up a defensive position in close formation; and the light Arab cavalry broke before the "immovable wall" of Frankish soldiers who stood, we are told, firm "as a rock of ice" (Isidorus Pacensis). The Arabs were hurled back with heavy loss; Abd ar-Rahman himself was killed on the field. Fighting continued until nightfall; and when, on the next morning, the Franks prepared to resume the battle, they found the Arab tents deserted.

The battle of Tours is commonly regarded as one of the decisive battles of the world's history. In a sense this is true; it dealt a check to the advance of the Arabs into Gaul. Rut there were causes other than Charles' victory which in part account for the cessation of the Arab advance. The revolt of the Berbers in North Africa was as decisive a factor as the battle of Tours in putting an end to the advance of the Arabs into western Europe.

TOURVILLE, ANNE-HILARION DE COTENTIN (or COSTANTIN), COMTE DE (1642–1701), French admiral and marshal of France, was the son of César de Cotentin, or Costantin, who held offices in the household of the king and of the prince of Condé. Destined by his family to enter the Order of Malta, he served for eleven years with the galleys of the Order against the Barbary pirates. In 1667 he was incorporated in the corps of officers of the French Royal navy and in 1689 he left the Order. In the French navy he served in the Mediterranean for some years. In 1670, Tourville commanded the "Page" (50), in the squadron of the comte d'Estrées (1624–1707) sent to co-operate with the duke of York against the Dutch. He was present at the battle of Solebay (June 7, 1672), and in the action on the coast of Holland in the following year, when Prince Rupert commanded the English fleet. When England withdrew from the alliance, the scene of the naval war was transferred to the Mediterranean, where Holland was co-operating with the Spaniards. Tourville served under Abraham Duquesne in his battles with De Ruyter. By this time he was known as one of the best officers in the service of King Louis XIV. By 1689 he had been promoted lieutenant-général des armées navales, and was named vice-admiral du Levant or of the East. In June of that year he became commander-in-chief of the French naval forces in the war against England and her continental allies.

From this time till the failure of his resources compelled King Louis XIV. to withdraw his fleets from the sea, Tourville continued to command the naval war in the Channel and the Atlantic. His conduct and example during this period were the source of the system of manoeuvring to gain an advantage by some method other than plain fighting. In 1690 he had an opportunity which might well have tempted the most cautious, and he missed it out of sheer care to keep his fleet safe against all conceivable chances, aided perhaps by a pedantic taste for formal, orderly movement. He was opposed in the channel by the allies, who had only fifty-six ships, while his own force was from seventy to eighty sail strong. He was feebly attacked by Admiral Arthur Herbert, earl of Torrington, off Beachy Head on July 10. The Dutch ships in the van were surrounded. The allies retreated in disorder, and Tourville followed in "line of battle" which limited his speed of pursuit to that of his slowest ship. In 1692 the Mediterranean fleet having failed to join him, he was faced by a vastly superior force of the allies. The French king had prepared a military force to invade England, and Tourville was expected to prepare the way. He made a resolute attack on the centre of the allies on May 29, off Cape Barfleur, and drew off before he was surrounded. This action, with the pursuit of the following days, made up what is called "the battle of La Hogue." His flagship the "Soleil Royale" and fifteen other ships were cut off and destroyed. In 1693 he was again at sea with a great fleet, and had a chance to capture the Smyrna convoy off Gibraltar. Again he kept his fleet in battle order, and a large part of the convoy escaped. Tourville was made Marshal of France in 1693. He died in Paris in 1701.

TOUSSAINT L'OUVERTURE (or LOUVERTURE), **PIERRE-DOMINIQUE** (*c.* 1746-1803), one of the liberators of Haiti, claimed to be descended from an African chief. His first surname Breda was afterwards changed to L'Ouverture in token of his valour in causing a gap in the ranks of the enemy. He obtained his master's confidence and was made superintendent of the other negroes on the plantation. After the insurrection of 1791 he joined the insurgents and acted as physician to the forces. His rapid rise aroused the jealousy of Jean François, who caused his arrest on the ground of his partiality to the whites. He was liberated by the rival insurgent chief Raissou, and a partisan war ensued, but after the death of Baissou he placed himself under the orders of Jean François. Subsequently he joined the Spaniards, but, when the French government ratified the act declaring the freedom of the slaves, he came to the aid of the French. In 1796 he was named commander in chief of the armies of St. Domingo, but, having raised and disciplined a powerful army of Negroes, he made himself master of the whole country, renounced the authority of France, and announced himself "the Buonaparte of St. Domingo." He was captured by the French and died in the prison of Joux, near Besançon, on April 7, 1803.

See Toussaint l'Ouverture's own *Mémoires,* with a life by Saint Remy (1850); Gragnon-Laconte, *Toussaint Louverture* (1887); Schölcher, *Vie de Toussaint Louverture* (1889); and J. R. Beard, *Life oj Toussaint Louverture* (1853).

TOUT, THOMAS FREDERICK (1855–1929), British historian, was born in London on Sept. 28, 1855, and educated at St. Olave's school, Southwark, and at Balliol college, Oxford. In 1881 he was appointed professor of history at St. David's college. Lampeter, and from 1890 to 1925, held a similar appointment at Manchester university. He was a fellow of Pembroke college, Oxford, from 1883 to 1890. He took a prominent part in the work of various historical societies and educational committees, and in 1911 was elected fellow of the British Academy. In 1925 he was elected president of the Royal Historical Society, and from 1927 to 1928 was messenger lecturer at Cornell university. He died in London on Oct. 23, 1929.

His works include *History of England for Schools* (with Prof. York Powell), vol. iii. (1890); vol. ii. (1898); *The Empire and the Papacy* (1898). He was first editor with H. Johnstone of *Select Trials of the Judges and Ministers, 1289–92* (Camden Series, *Royal Hist. Soc.,* 1906); and has written *Chapters in the Administrative History of Mediaeval England* (vols. i. and ii., 1920); *France and England, their Relations in the Middle Age and Now* (1922); and many school text books and articles in historical reviews.

TOVEY, SIR DONALD FRANCIS (1875–1940), English pianist, composer and writer on music, was born on July 17, 1875. at Eton, where his father, the Rev. Duncan C. Tovey, was a master. He was trained as a pianist by Sophie Weiss. In 1900 he definitely took up music as a career and began to give recitals, in which his own compositions were included, in London and on the Continent. From 1914–1940 he was Reid professor of music at Edinburgh university. The Reid orchestral concerts, which he conducted, owe their existence to his initiative. He contributed a large number of articles to the present edition of the *Encyclopædia Britannica.*

The orchestral compositions include a symphony in D, performed at Aix-la-Chapelle in 1913, a pianoforte concerto in A, prelude and entr'actes for Maeterlinck's *Aglavaine et Sklysette* (for string orchestra), and an opera, *The Bride of Dionysus* to R. C. Trevelyan's text. In chamber music he wrote two sonatas for violin alone; a sonata for two violoncellos; a pianoforte trio and a quintet; a trio in C minor for pianoforte, clarinet and horn; two string quartets; variations on a theme by Gluck for flute and strings. He also wrote three anthems and 25 rounds for equal voices. He was knighted in 1935.

TOWER, the term originally given to a tall building designed for defense. hence, any structure whose height is its most important dimension, whether isolated or forming part of another building. The two earliest uses of tall buildings were military and religious; in the one case constructed to give a raised platform from which a defending force could advantageously discharge missiles upon an attacking force. at the same time remaining protected from it; in the other case, always in connection with sun, moon or star worship, apparently in the effort to raise the worshiper or the priest as near heaven as possible.

However, towers are not iimited to either military or religious uses. Many were built in connection with town halls, others to carry clocks. The greater number of the *hôtels de ville* of France, Germany and the Netherlands had towers, serving as belfrys; the fantastic tower of the *Rathaus* at Rothenburg (13th century) is characteristic of the German examples.

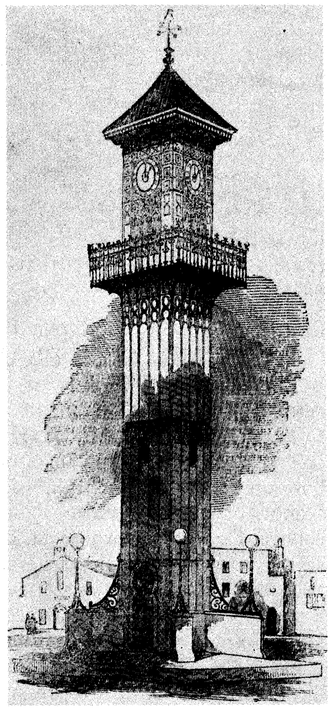
Bottom centre: Hochzeitsturm tower, Darmstadt, Germany; 20th century

Bottom right: Clock tower of the Rathaus, Stuttgart. Germany; 20th century great pylons flanking the entrance to temples were the commonest form of towers; they probably originated in mud-brick towers guarding the entrance to great chiefs' houses in primitive Egyptian times. Of Greek towers, the most famous was the Pharos, or lighthouse tower, outside Alexandria. An extensive use of military to ers began only with the Romans, however; they, and the Byzantines who followed them, made towers an integral part of every developed fortification. The Roman twin-towered city gate passed into medieval symbolism; it was with the idea of showing forth the gate of the heavenly city that Abbot Suger, for example, designed the façade of St. Denis in the early 12th century, with Roman-type twin towers and crenelations.

In the medieval period, from the 13th century on, the military tower received its greatest development in city walls (*e.g.,* Aigues Mortes and Carcassonne in southern France), in defensive keeps or donjons (*e.g.,* the White tower of the Tower of London), and sometimes as private towers of refuge (*e.g.,* S. Gimignano in Italy).

In the near east the great towers of the fortifications built on either side of the Bosporus at Rumeli Hissar and Anatol Hissar during the siege of the city (middle 15th century) are still landmarks. In China great masonry towers crown each gate of a city wall, topped with garrison buildings that give much additional height; towers of a simpler and strangely European type form the most conspicuous features of the famous Great Wall of China.

With the appearance of firearms, and particularly of large cannon, the use of towers as fortifications practically vanished. (See FORTIFICATION; MARTELLO TOWER; CASTLE.)



"THE ILLUSTRATED LONDON NEWS"
PREFABRICATED IRON AND GLAZED TERRA-COTTA CLOCK TOWER IN GEELONG, AUST.

Religious. — The tower built for religious purposes appeared in an early developed form in the ziggurat (*q.v.*) of Mesopotami — the great stepped pyramid, with stairs or inclined planes connecting the levels, and an open terrace with an altar or a shrine at the top. A ziggurat was attached to nearly every temple. Similar high buildings, the so-called pyramids, were frequently associated with temples in Middle America. The early Persians seem also to have used raised platforms on small towers in connection with their fire worship. In the classic world towers do not appear as important religious buildings, and it was not until the 8th century, and probably with the wide introduction of bells that they came to be associated with churches. (See CAMPANILE.)

By the end of the 11th century the use of church towers was almost universal. In France the earliest examples were placed at the crossing of nave and transepts. often taking the form of a lantern in several stages or levels, with a pyramidal top. In England, on the other hand. a position at the west end of the nave had become common during the Saxon period. as at Earl's Barton and Barnack. In the Norman period central towers became usual, as well as towers flanking the main entrance. Particularly picturesque were the grouped towers common in the Rhineland as in the 12th-century churches of Mainz and Speyer. Romanesque tower design was generally simple. Shallow corner buttresses were occasionally found, but the main effect was gained by a succession of stories of arcaded windows; arcaded cornices or corbeled (bracketed) cornices were much used. Interesting examples of Romanesque towers are: St. Front, Périgueux; Loches; St. Pierre, Vienne; St. Paul, Issoire; the cathedral at Le Puy en Velay; and St. Germain des-Prés, Paris, all of the 12th century, in France. In England, the west towers of Durham cathedral (lower part 1128, upper part 1220); the central tower at Tewkesbury (c. 1125) and the 12th-century church at Castor are noteworthy.

The Gothic period produced profound changes in tower design. Windows and arcades were much lengthened; buttresses increased in size and complexity; corner buttresses were much emphasized, frequently crowned with pinnacles, and offsets were arranged to vary the silhouette. Although the Gothic tower was often designed to carry a spire (*q.v.*) a large number have flat roofs with rich battlemented or traceried parapets and many pinnacles and finials. Sometimes octagonal turrets rose continuously from the ground to the top at one or more corners of the tower. The number of towers contemplated for great churches increased with their complexity. Thus in Reims, seven towers with crocketed spires were originally planned: and at Chartres, eight; Tournai cathedral (the only scheme of the three completed) in Belgium has seven. Of flat-topped towers the Tour St. Jacques, Paris (1508–22) is a graceful example. The most beautiful of English Gothic towers are Canterbury cathedral (central tower 1495); Lincoln (western towers c. 1250, completed c. 1400), central tower (lower portion 1240–50, upper portion 1307–1311); Gloucester (central tower middle 15th century); and York (central tower 1400–1423, southwest tower begun 1432, northwest tower finished 1474). Of the smaller towers, those of Wrexham church (1506) and the famous Magdalen tower at Oxford (1492–1505) are both beautiful examples of Perpendicular richness.

The best Renaissance to ers are those of comparatively late date, for it required the imaginative freedom of the baroque spirit to combine classic detail with the nonclassic verticality a rich tower requires. Of these baroque towers the most striking were those of south Germany, Austria and Italy, in all of which comparatively simple bases were crowned with several stages of rich, colonnaded detail, the whole topped with some sort of fantastic, curved roof. Spanish baroque towers differ from those already mentioned in being crowned by a lantern, usually smaller than the tower below, with frequently a low dome at the top of the entire composition; sometimes two or more stages occur, each smaller than the one below. Such towers were common, not only in Spain itself, but also in the Spanish colonies in America, existing in rich and highly developed examples in Mexico, as in the cathedral at Mexico City, and in much simplified form in the mission churches of California, as in San Luis Rey, completed 1802. English baroque towers are best exemplified in the London churches of Sir Christopher Wren; his designs came to the U.S. both directly (as at Williamsburg) and through the inedium of the Book of Architecture by his pupil J. Gibbs, and became the basis for the standard type of tower on U.S. churches well into the 19th century.

Modern. — In modern architecture, the tower has taken on new importance, as in it the structural innovations possible with new materials may be given impressive demonstration. It mas in the Eiffel tower, Paris, by Gustave Eiffel (1889; 1,056 ft. high, including a 55-ft. television antenna) that the potentialities of steel construction were first strikingly revealed; the possibilities of ferroconcrete were likewise shown in towers like that on Xuguste Perret's church of Notre Dame at Raincy (1924). In Germany, the effectiveness of pure steel and glass construction was shown particularly at the Werkbund exhibition (Cologne, 1914) in the stairway towers of Walter Gropius' model factory; the tower as an expressive shape was demonstrated by E. Mendelsohn in the Einstein tower, an observatory at Pdtsdam (1921). But more than any other modern architect, perhaps, Frank Lloyd Wright has excelled in tower design — in churches, like the Ann Pfeiffer chapel at Lakeland. Fla.; in commercial buildings, like the research laboratory tower of the Johnson Wax factory at Racine, Wis., or the Price tower at Bartlesville, Okla.; and in public buildings, like the Solomon R. Guggenheim museum of nonobjective art in New York. (See ARCHITECTURE; GOVERNMENTAL ARCHITECTURE; MONUMENTS AND MEMORIALS; RELIGIOUS ARCHITECTURE.)

Oriental. — Islamic architects rank with the greatest medieval tower designers! but except for a few examples in palaces, such as the 14th-century Comares tower in the, Alhambra at

Granada, Spain, the greater number were purely religious and served for places from which the call to prayer was given. The greatest of them all is the Giralda tower at Seville, originally a mosque minaret (1195), but in its present form it is crowned with a Renaissance top, built in the 16th century by the architect Hernan Ruiz. The Kutb Minar at Delhi (early 13th century) is the most important Indian example. *(See* MINARET.)

Towerlike structures play an important part in the Brahmin temples of India and in other religious architecture of the iar east. Thus many of the temples are entered through gateways under enormous piles of masonry which take the form of oblong pyramids. lavishly covered with tier on tier of sculptured figures, carved moldings, little projecting shrines and the like. Characteristic examples are those at Madurai (17th century) and Kanchipuram. Sometimes a square. pyramidal tower is placed over the holy of holies of a temple. as at Rfadurai.

In China the tower is chiefly developed as the pagoda (*q.v.*), whose characteristic, repeated roofs and galleries iorm an interesting silhouette, typically Chinese. Japanese pagodas are similar but for small details. *See* CHINESE ARCHITECTURE; INDIAN ARCHITECTURE ; JAPANESE ARCHITECTURE. (T. F. H.; AN. G.)

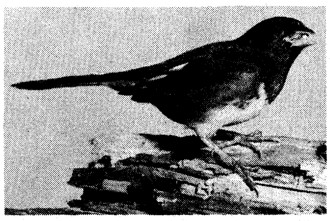
TOWER OF LONDON, THE, an ancient fortress on the east side of the City of London, on the north bank of the river Thamcs. On a slight elevation now called the Tower hill. well protected by the river and its marshes, and by woods to the north, there was a British stronghold. Tradition, however: pointed to Julius Caesar as the founder of the tower (Shakespeare. *Richard III*, iii. 1 and elsewhere), and remains of Roman fortifications have been iound beneath the present site. The tower contains barracks, and is the repository of the regalia. It covers an irregular hexagonal area, and is surrounded by a ditch, formerly fed by the Thames, but now dry. Gardens surround it on the north and west, and an embankment borders the river on the south. Two lines of fortifications enclose the inner bail. in which is the magnificent White tower or keep, flanked by four turrets. This was built by Gundulf. bishop of Rochester. about 1078. Its exterior was restored by Sir Christopher Wren, but within the Norman work is little altered. Here may be seen a collection of old armour and instruments of torture, the rooms said to have been Sir Walter Raleigh's prison, and the magnificent Norman chapel of St. John. Among the surrounding buildings are the modern barracks (1845), and the chapel of St. Peter ad Vincula, dating from the early part of the 12th century, but rebuilt in the early 14th and much altered in Tudor times. The Ballium wall, the inner of the two lines of fortification, is coeval with the keep. Thirteen towers rise from it at intervals. in a chamber of one of which, the Wakefield tower. the regalia or crown jewels (*see* CROWN AND REGALIA) are kept; this room was formerly the oratory: and it is said that it was here that Henry VI met his death (1471) while at prayers.

The chief entry to the fortress is through the Middle tower on the west (near which was a menagerie from Norman times until 1834), across the bridge over the moat, and through the Byward tower. On the south: giving entry from the river through St. Thomas's tower and the Bloody tower, is the iamous Traitors' gate, by which prisoners oi high rank were admitted. The chief historical interest of the Tower lies in its association with such prisoners. The Beauchamp tower was for long the principal place of confinement for captives of rank. but dungeons and other chambers in various parts of the buildings also have similar associations; as, for instance, the Bell tower with Queen Elizabeth when princess. Bishop Fisher and Sir Thomas More; the Bowyer tower with the duke of Clarence oi the butt of Malmsey legend; the Salt tower and Broad Arrow tower with Roman Catholic prisoners of Elizabeth's time, and the hlartin tower with Colonel Blood. who, in 1671, nearly succeeded in carrying off the crown and regalia, which were then kept there.

Executions took place both within the tower and on Tower hill, Many of those executed were buried in the chapel of St. Peter ad Vincula. such as Sir Thomas More, Henry VIII's queens Anne Boleyn and Katharine Howard. Lady Jane Grey and her husband Dudley and the duke of Monmouth. The tower was not only a prison from Norman times until the 19th century, but was a royal residence at intervals from the reign of Stephen, if not before. The royal palace was demolished by order of Cromwell. The tower is under the governorship of a constable. The attendant staff. the Yeoman Warders of His Majesty's Tower of London, familiarly called "Beeieaters," still wear Tudor costume.

See W. Hepworth Dixon, *Her Majesty's Tower* (1869); Lord Ronald Sutherland Gower, *The Tower of London* (1901); Sir George Younghusband, *The Tower Front Within* (1918) and *The Jewel House* (1920); W. G. Bell, *The Tower of London* (1921).

TOWHEE (*Pipilo erythrophthalmus*), a well-known North American bird belonging to the family of the finches. The back and breast are black, the sides chestnut, the belly white in the male, the female being brown on the back and breast. The song is loud, but scarcely musical. The towhee breeds east of the Great Plains and may often be seen on the ground near brush and in the woods, where it makes its nest. In the north of its range it is migratory.



ALLAN D. CRUICKSHANK FROM NATIONAL AUDUBON SOCIETY

TOWHEE (PIPILO ERYTHROPHTHALMUS)

The allied spurred towhee (P. *maculatus*) breeds in the western mountains and Great Plains.

TOWN AND CITY PLANNING: *see* CITY PLANNING.

TOWNSEND (family of joiners): *see* GODDARD AND TOWNSEND.

TOWNSEND, SIR JOHN SEALY EDWARD (1868–1957), Irish physicist who studied the ionization of gases, was born on June 7, 1868, at Galway, Ire. He was educated at Corrig school and Trinity college, Dublin, and in 189j he entered Trinity college, Cambridge. where he became one of J. J. Thomson's research students. In 1898 he was Clark Maxwell scholar and in 1899 he was elected a fellow oi Trinity college, Cambridge. There he made the first direct determination of the elementary ionic charge. He made early studies of the part played by electrons and positive ions in the initiation and continuation of electric discharges in gases at low pressure. In 1900 Townsend was elected to the newly founded Wykeham chair of experimental physics at Oxford, where he continued his studies on the ionization of gases until his retirement in 1941. He was elected fellow of the Royal society in 1903 and received many honours, being knighted in 1941. He died on Feb. 16, 1957, at Oxford.

Townsend's publications include *Electricity in Gases* (191j), *Motion of Electrons in Gases* (1925), *Electricity and Radio Transmission* (1943), *Electrons in Gases* (1947) and *Electromagnetic Waves* (1951). (D. McK.)

TOWNSEND PLAN: *see* PENSIONS.

TOWNSHEND, AURELIAN (*c.* 1583–*c.* 1642). English poet whose best lyrics have been justly praised for their "manly gallantry and wit wedded to manly music." mas the son of Sir John Townshend of West Dereham, Norfolk. In 1600 he attracted the notice of Sir Robert Cecil. who sent him to Paris and Italy. After getting into financial difficulties, Townshend was summoned home and was in England in April 1603. In 1608 he went to France with Sir Edward Herbert. and on his return re-entered Cecil's service; attending him in his last illness. At an unknown date he married Anne Wythies, by whom he had six children. In 1632 he appears as a composer oi two court masques in collaboration with Inigo Jones. In 1642 he was described, as "a poore and pocky poet" and on March 3, 1643, was petitioning the house of lords for protection against debt. He may be a "Mr. Townshend" who was allowed to leave England after the fall of Oxiord in 1646.

Townshend's poems, together with his two masques and extant letters, were first collected and published with a biographical introduction by Sir E. K. Chambers in *Aurelian Townshend's Poems and Masks* (1922).

See G. C. Moore Smith in *Modern Language Review*, xii (1917); *Times Literary Supplement* (Oct. 23, 1924). (V. DE S. P.)

TOWNSHEND, CHARLES (1725–1767), English politician, the second son of Charles, 3rd Viscount Townshend, was born on Aug. 29, 1725, and was educated at Leyden and Oxford. He represented Great Yarmouth in parliament from 1747 to 1761, when he found a seat for the treasury borough of Harwich. After holding minor offices he was summoned to the privy council.

With the accession of George III in 1760 Townshend transferred his support from Pitt to the young king's favourite, Bute, and in 1761, at the latter's instance, was promoted to the post of secretary-at-war, which he did not throw up until Dec. 1762. In the dying days of Grenville's cabinet, and throughout Rockingham's administrat~onhe held the post of paymaster-general, refusing to identify himself more closely with its fortunes as chancellor of the exchequer. He accepted the latter position from Pitt in 1766, and was admitted to the inner circle of the cabinet.

The defeat of his proposal to continue the land tax at four shillings in the pound, by William Dowdeswell and the landed gentry caused Lord Chatham to meditate Townshend's removal, but before this could be accomplished Chatham's mind became impaired, and Townshend, who was the must determined and influential of his colleagues, swayed the ministry as he liked, pledging himself to find a revenue in America with which to meet the deficiency caused by the reduction in the land tax. His wife was created (August 1767) baroness of Greenwich, and his elder brother George, the 4th viscount, was made lord-lieutenant of Ireland. He himself delivered in the house of commons many speeches unrivalled in parliamentary history for wit and recklessness, and one of them still lives in history as the "champagne speech."

His last official act was to carry out his intention by passing through parliament resolutions, which even his colleagues deprecated in the cabinet. for taxing several articles such as glass, paper and tea, on their importation into America, which he estimated would produce the insignificant sum of £40,000 for the English treasury. and which shrewder observers prophesied would lead to the loss of the American colonies. Soon after this event he died somewhat suddenly on Sept. 4. 1767.

The universal tribute of Townshend's colleagues allows him the possession of boundless wit and ready eloquence, marred by an unexampled lack of judgment and discretion.

A Memoir by Percy Fitzgerald was published in 1866.

TOWNSHEND, CHARLES TOWNSHEND, 2ND VISCOUNT (1674–1738), English statesman, was the eldest son of Viscount Townshend of Raynham (c. 1630–87), of an old Norfolk family descended from Sir Roger Townshend (d. 1493) of Raynham, who acted as legal adviser to the Paston family. Charles Townshend succeeded to the peerage in Dec. 1687, and was educated at Eton and King's college, Cambridge. At first a Tory when he took his seat in the house of lords, he afterwards went over to the Whigs. In Nov. 1708 he was appointed captain of the yeomen of the guard, having in the previous year been summoned to the privy council. As ambassador extraordinary and plenipotentiary to the states-general (1709–11) he took part in the negotiations preceding the treaty of Utrecht. In Sept. 1714, George I selected him as secretary of state for the northern department.

Townshend's policy, after the suppression of the Jacobite rising in 1715, was one of peace at home and abroad; he promoted defensive alliances with the emperor and with France. But in 1716 he was dismissed from his position owing to the intrigues of Sunderland, who persuaded George and Townshend's colleague, Stanhope, that Townshend and Walpole were plotting to place the prince of Wales on the throne.

Early in 1720 a partial reconciliation took place between the parties of Stanhope and Townshend, who was president of the council from June 1720 until Feb. 1721, when, after the death of Stanhope and the forced retirement of Sunderland, a result of the "South Sea Bubble," he was again appointed secretary of state for the northern department, with Walpole as first lord of the treasury and chancellor of the exchequer. The two remained in power during the remainder of the reign of George I (see ENGLISH HISTORY).

Townshend secured the dismissal of his rival, John Carteret, afterwards Earl Granville, but soon differences arose between himself and Walpole. Although disliking him, George II retained him in office, but the predominance in the ministry passed gradually from him to Walpole. Failing, owing to Walpole's interference, in his efforts to procure the dismissal of a colleague and his replacement by a personal friend, Townshend retired on May 15, 1730. His remaining years were passed at Raynham, where he interested himself in agriculture. He died at Raynham on June 21,1738.

TOWNSHIP. The civil township is a governmental subdivision of the county found in portions of the United States, principally in the northeast and north central regions. It is to be distinguished from the so-called congressional or survey township of six miles square, which is not governmentally organized but has influenced the size and configuration of the civil subdivision. Most civil townships have an area of approximately 36 sq.mi., and many have boundaries which coincide with those of congressional townships. As of 1957, according to the U.S. bureau of the census, 15,771 civil townships were in existence in 16 states. In some of these states all counties were divided into townships while in others townships were found in some counties only.

In some states a township meeting, patterned after the New England town meeting, levies township taxes, makes appropriations, enacts bylaws and serves in general as the policy-determining organ of the township. A township board, constituted on an elective or ex officio basis, ordinarily appoints certain township officers and performs other administrative duties. In addition, the board customarily acts as the township's policy-determining agency where there is no township meeting. A principal administrative officer, usually known as supervisor or trustee, is found in some states. Other township offices — elective, appointive or ex officio — commonly include those of clerk, treasurer, assessor, road commissioner and supervisor of public assistance. Justices of the peace and constables, though state rather than local officers in legal contemplation, are commonly elected from the townships.

Township functions vary widely, but the major services most commonly performed are maintenance of local roads and administration of public assistance. Property assessment is a township function in some instances; and in a few states the township serves as an area for school administration.

As a unit of local government the U.S. township was in the second half of the 20th century steadily declining in importance. Township meetings were poorly attended and township functions were gradually being transferred to the county. In some areas where once maintained, township government had been entirely eliminated.

See Clyde F. Snider, ***Local Government in Rural America*** (1957). (C. F. S.)

TOWNSVILLE, a city and port of Queensland, Austr., on the west side of Cleveland bay in the northeast of the state, 832 mi. N. of Brisbane. Pop. (1954) 40,471. It is built upon the banks and near the mouth of Ross creek and is dominated by Castle hill, a great rock mass 937 ft. high. It is the outlet for a wide area of country of varied economic potentialities and the port, which is one of the best on the Queensland coast, is the terminus for 1.308 mi. of railway which extends westward to the gold fields of Charters Towers, the sheep and cattle of Hughenden and the mines of Cloncurry and Mt. Isa. The estuary of Ross creek has been straightened and deepened and ships of 15,000 tons can berth alongside the quays. Behind Townsville lies an immense area of sheep lands which provide merino wool, one of the chief exports of the port. Others are concentrates, preserved and frozen meats, sugar. timber and silver lead. Industries include dairying, meat canning and preserving, mining, shipbuilding, the manufacture of bricks, glass, motor bodies, cement, steel and railway equipment.

Townsville was founded by Robert Towns, an English seafarer, in 1864, and became a city in 1866.

TOWTON, BATTLE OF, fought on March 29, 1461, near the Yorkshire village of that name which is 2½ mi. S. of Tadcaster and 10 mi. S.W. of York. It was remarkable among the battles of the Wars of the Roses for three reasons. First, the numbers engaged were unusually large; the best estimates are 40.000 for Lancaster and 36.000 for York. Second, the fight was prolonged and ferocious, while the casualties were immense; probably 28 000 killed. Finally it represented a supreme military effort by both sides and. as a Yorkist victory, it was decisive in securing the English kingdom for Edward IV. After failing to follow up their victory at St. Albans (Feb. 17, 1461) by seizing London. the Lancastrians had been forced slowly northward by converging Yorkist columns under the earl of Warwick, Baron Fauconberg and the newly proclaimed Edward IV. Henry VI and his queen, now at York, met this growing threat by a Lancastrian concentration around Towton under the duke of Somerset, the duke of Northumberland and Lord Dacres. Early on March 28, covering troops clashed at Ferrybridge on the river Aire, 2 mi. N. of Pontefract. Edward forded the river 4 mi. upstream at Castleford. The Lancastrians thereupon withdrew to their main body drawn up athwart a ridge between Towton and Saxton. The Yorkists closed up to the enemy on a neighbouring ridge during the day. but their movement was not completed for the duke of Norfolk's division was still at Ferrybridge. and both armies bivouacked in the open with snow in prospect. Next day. March 29, Palm Sunday, the fight was joined. Nothing definite is known of the order of battle or of the actual positions. Indeed there is surprisingly little contemporary testimony as to the course of the action. It appears that the front was short and that. after some preliminary shooting, footmen with bills and spears fought savagely at close quarters. They were hampered by mounting piles of dead and wounded, and were continually reinforced by fresh troops to fill the gaps and relieve the exhausted. Hindered by heavy snow, the battle raged all day with the Lancastrians holding a slight advantage. Then Norfolk's Yorkists arrived. They slowly turned the enemy's left flank. and suddenly Lancastrian morale broke. The flight was checked beyond Towton, where the old road to Tadcaster crosses the Aire, then probably in spate, by the great congestion of fugitives, who were slaughtered indiscriminately by the pursuing Yorkists. An attempted stand at Tadcaster was quickly overwhelmed, and by nightfall the Lancastrian army had ceased to exist. (GY. T.)

TOXICOLOGY, the name of that branch of science which deals with poisons, their chemistry, effects. antidotes and tests for detection. See POISON and MEDICAL JURISPRUDENCE.

TOXIN. Toxins are complex organic substances, protein in nature, that are produced by living organisms and are poisonous for other living organisms They are to be differentiated from the simple chemical poisons such as arsenic and the cyanides, and from the poisonous alkaloids such as strychnine. The phytotoxins are produced by higher plants; the zootoxins are the snake (*q.v.*), scorpion (*q.v.*) and spider (see BLACK WIDOW) venoms; and the bacterial toxins are the exotoxins such as those formed by the diphtheria, tetanus and botulinus bacilli. Toxins are separated roughly into two groups on the basis of their action: (1) the hemotoxins, which lyse the red blood cells, and (2) the neurotoxins, which poison nerve tissue to produce paralysis. The naturally occurring toxins are often mixtures of these two kinds, with one or the other predominating to give symptoms characteristic of the disease produced by them. The toxicity of the bacterial toxins is destroyed by treatment with formaldehyde to give formol toxoid, which may be used without further alteration (fluid toxoid) or after precipitation with alum (alum-precipitated toxoid, APT) to produce a high degree of immunity to diseases caused by the toxigenic bacteria. The venoms are not successfully detoxified by such treatment. See also ALKALOIDS; ANTITOXIN; POISON. (W. Bc.)

TOY. A toy is a plaything, often an instrument used in a game, primarily for children but also for adults. The toy may be abstract in design, as a ball, or a representation of a person, as a doll, or of animals, plants or artifacts.

Toys may be divided into two basic types: child-made toys are often not representational, but rather screens onto which the child's imagination may be projected; adult-made toys are usually instructive representations of objects of adult interest or use. A child finds or makes toys from almost any natural or man-made scrap of material or from a part of an object not originally intended as a toy. Depending upon his imagination, he will give it an individual special meaning; magically, the orange crate becomes a castle or the stick a steed. Many things not originally intended as instruments of play have been adopted by children and subsequently produced as toys by adults who realize the potential of the children's selection.

Toys. playthings and games survive from the most remote periods in the past and from a great variety of cultures. They vary from the simplest to the most complex, from the natural stick selected and imagined into a "hobbyhorse" by a child to the sophisticated and complex mechanical automata that entertained both young and old in the royal courts of 18th-century Europe. The potential range is unlimited. Museums in many countries exhibit antique objects whose original purpose may be controversial. but which children may well have used or adopted for playthings. A pre-Columbian clay animal on wheels, from an early Mexican culture where no record of the wheel has otherwise been discovered, may have been a toy. One of the most ancient toys is the ball. Near-perfect spheres found in nature may have been highly treasured by primitive man and. later, made by hand and developed into the symbolic objects of competition. Today, as apparently throughout the past, a ball plays an important role in many competitive games.

The penalties. forfeits and handicaps of play provide an introduction through enjoyment to the understanding of many facets of practical life. Childhood play continues into adult life, or may be recaptured in later life as when a father shares his son's enjoyment of an electric train. The extension of playing into adult life becomes interwoven with adult activities and preoccupations and is therefore difficult to identify as pure play; the same is true of the instruments for play.

Toys may be divided into the static and the dynamic. Play with toys follows two main directions, imitative and instructive. The earliest types of play probably developed from the instinct for self-preservation, Instinctive animal play is practice for survival: the kitten's ball of yarn is tomorrow's mouse. In many human cultures. one of the first things taught to the young was the use of weapons. The natural club or stick was the prototype of drumsticks, golf clubs, hockey sticks, billiard cues and many other instruments of play. Most physical-action games and sports derived from competition and warfare. the instruments of which were weapons. Toy soldiers and weapons dating from the middle ages are extant; the types probably originated very early in human history. The latest developments in warfare are represented among contemporary toys.

Another basic type of toy is the human or animal doll (*q.v.*) and all the related domestic activities that start with child raising and homemaking. Each epoch and culture has provided its girl children with miniatures of the artifacts used in daily living, including dollhouses and shelters. Many of the static toys are of this type: treasures to be admired and cherished rather than used.

Moving toys include a wider and more dramatic variety. It is probable that many experiments with basic physical principles were first realized in the form of toys as in Hellenistic and Islamic automata which are known through literary description. Explosive weapons and rockets developed from the early use of gunpowder for fireworks by the Chinese. Balance and counterbalance, the wheel, the swing. the pendulum, flight, centrifugal force, magnetism, the spring and a multitude of other devices appear in a great assortment of toys.

Many skills develop from cumulative childhood experiences received from the manipulation of toys—marbles, Yo-Yos and other toys requiring apt hands and bodies. Mental skills, beginning with childhood, are developed by games of position such as checkers and chess and puzzles of spatial relationships.

The element of chance has also played an important part in games. Roman children and adults threw knucklebones, the precursors of dice. Dice. in turn. are the essential tools for snakes and ladders and a host of other games. Other forms of toys probably derive from magical artifacts and fetishes that played a prominent part in primitive religions. In the Mexican festival of the Day of the Dead, elaborate and beautiful objects of sugar are made in the shapes of skulls, tombs and angels; they are essentially religious symbols, but in the hands of children they become toys which are played with and finally eaten. Christmas tree decorations, peephole Easter eggs. the Neapolitan *presepio* (crèche) with its wealth of elaborate figures. are other examples of toys of religious origin. A modern relic of primitive culture, the Hopi Indian katcina dolls, while essentially instructive sacred objects, inevitably are played with by children. Under the pressure of industrialization, folk culture and tradition are rapidly disappearing. In many countries, such as India, China, Japan, Mexico, Portugal and Peru. however, an extraordinary wealth and variety of folk toys are still to be found.

Modern western toys continue to reflect their antecedents in folk cultures; however, the machine age is fast erasing the recognizable traces.

Toys and play necessarily follow the slow or rapid changes of mores and customs. Besides representing physical environment, they express many dreams which remain in the child or adult imagination. Thus, a comprehensive collection of toys might better express the history of man's aspirations and dreams than the real objects of utilitarian culture they occasionally represent. (A. H. Gi.)

TOYAMA, a Japanese prefecture and city in central Honshu on the Sea of Japan. The prefecture (Toyama-ken) was formed from the province of Etchu after the restoration of 1868. Area 1,642 sq.mi., pop. (1960) 1,032,614. Its coastal plain is an important surplus rice area and its mountainous interior is a source of hydroelectric power and minerals. The former is the basis for the chemical. textile (synthetic fibres, cotton and wool), machinery. wood pulp and paper, and steel industries.

Toyama ([1960] pop. 207.266). the capital of Toyama-ken, is an old castle town located at the mouth of Jinzū river, which since the 17th century has been the chief centre for the production of patent medicines and drugs in Japan. The city is also an important chemical and textile centre, producing cotton, rayon and synthetic textiles. (C. A. Mr.)

TOYNBEE, ARNOLD (1852–1883), English social reformer and economist, second son of the distinguished surgeon Joseph Toynbee (1815–66), was born in London on Aug. 23, 1852. After contemplating careers in the army and the law, he ultimately devoted himself to the study of economics and economic history. He was a practical social reformer, taking part in public work and lecturing in the large industrial centres. He died on March 9, 1883.

Toynbee had a striking influence on his contemporaries, not merely through his intellectual powers but also by his strength of character, love of truth and ardent and active zeal for the public good. He was the author of some fragmentary but influential pieces. published in 1884 under the title of *The Industrial Revolution*. Toynbee's interest in the poor and his desire to be personally acquainted with them led to his close association with the district of Whitechapel in London. commemorated after his death by Toynbee hall. the first of many institutions for social betterment. *See* Social Settlements. (D. F. Do.)

TOYNBEE, ARNOLD JOSEPH (1889–). English historian, best known for his comparative study of civilizations, was born in London on April 14, 1889, the nephew of the social reformer Arnold Toynbee. Educated at Winchester and at Balliol college, Oxford, he worked for the British foreign office during World Wars I and II, and he was a member of the British delegations to peace conferences at Paris in 1919 and 1946.

Toynbee was Koraes professor of Byzantine and modern Greek language, literature and history at the University of London. 1919–24; from 1925 until his retirement 30 years later he was research professor of international history there and director of studies at the Royal Institute of International Affairs.

His major work, *A Study of History* (1934–54), was published in ten volumes; an abridgment of the first six volumes was published in 1946 and of the last four in 1957. Toynbee's thesis is that societies or civilizations (not nations or periods) are the significant units of historical study. Civilizations, 26 of which he distinguishes, including arrested societies; grow by responding successfully to challenges under the leadership of creative minorities; they decline when the leaders fail to respond creatively. *(See* also Civilization and Culture: *Concepts of Civilization and Culture.)*

Other books by Toynbee include *Greek Historical Thought* (1924), *Civilization on Trial* (1948), *The World and the West* (1953), *An Historian's Approach to Religion* (1956), *East to West: a Journey Round the World* (1958) and *Hellenism: the History of a Civilization* (1959). Toynbee also lectured widely in the United States and Canada.

TOYNBEE HALL. Founded in London by Canon S. A. Barnett (*q.v.*), then rector of St. Jude's, Whitechapel, in 1884, and named after Arnold Toynbee (*q.v.;* 1852–1883), Toynbee hall, the pioneer university settlement. inaugurated an important movement *(see* Social Settlements). In his early years at St. Jude's, Barnett had succeeded in creating interest at Oxford and Cambridge in the problems of east London and had brought undergraduates to Whitechapel to spend their holidays with him and learn about social conditions. This prepared the universities for Barnett's plan to found a settlement (that is. a house of residence for university undergraduates who might wish to live in an industrial area) which was at once warmly supported. With money collected mainly at Oxford he was able to purchase and reconstruct premises next to St. Jude's and with the help of a band of settlers to begin activities which left an enduring mark on the social history of the period. These activities were mainly concerned with the collection of social data, with social experimentation and with the amelioration of social and industrial conditions; but Barnett's underlying aim was to bring the generosity and learning of the young and the universities into effective relation with the industrial population so that both communities might come in time to serve ideals of citizenship and neighbourliness. In this stage of its existence Toynbee hall was associated with the publication of two books of profound importance — Life *and Labour of the People in London,* edited by Charles Booth, and *Unemployment*, a *Problem of Industry* by William Beveridge (later Lord Beveridge) — and with the founding of the Whitechapel Art gallery and the Workers' Educational association.

After World War I the educational activities of Toynbee hall were enlarged; the John Benn hostel and the Workers' Travel association were founded, the former for homeless boys and the latter to promote foreign travel for wage earners and the increase of friendliness between the common peoples of Europe. These two institutions, and the American seminar started in 1921 and attended every year by clergymen, educationists and social workers, had great success in their respective spheres. During World War II Toynbee hall played a prominent part in organizing food and entertainment in air raid shelters and assisting in the evacuation of the elderly and the very young. It was the centre of administration of the Anglo-American Relief Fund for Mothers and Children, and toward the end of the war, the birthplace of the Toynbee Hall and Glyndebourne Children's theatre. (J. J. M.)

TOYOHASHI, formerly called Yoshida, is a textile centre in Aichi prefecture, Honshu, Japan, on Atsumi bay. Pop. (1960) 215,515. This castle town was the scene of much fighting in the 16th century and changed hands often during the Tokugawa period. After the restoration it became one of the largest silk manufacturing centres of Japan. With the decline in silk consumption after World War II, the main production shifted from silk to cotton and synthetic textiles. (C. A. Mr.)

TOZZI, FEDERIGO (1883–1920), Italian poet and novelist who achieved international reputation with his novel *Tre croci* (1920; Eng. trans., *Three Crosses,* 1921). The son of an innkeeper, he was born at Siena, Jan. 1, 1883. His poverty-stricken, frustrated life is described in his autobiographical novels, *Bestie* (1917), *Con gli occhi chiusi* (1919) and *Ricordi di un impiegato* (1927), and in his letters, *Novale* (1925). In 1913, with D. Giuliotti, he founded the Catholic review *La Torre.* His two volumes of poetry. *La zampogna verde* (1911) and *La città della Vergine* (1913) show the influence of D'Annunzio. Of his plays only *L'incalco* (1923) was published. He died in Rome, March 21, 1920.

See P. Cesarini, *Vita di Federigo Tozzi* (1935).

TRACERY, the term given in architecture to the upright curving or intersecring bars or ribs. used in a window or other opening to give beauty and variety to its silhouette. The term is also applied to similar forms used in relief, as wall decoration (sometimes called wall tracery), and hence. figuratively, to any intricate line pattern. The word is often restricted to the elaborate system of window decoration, with its derivative forms, developed in Europe during the Gothic period, but it may, with equal validity, be applied to the pierced marble screens common in the Mogul work of India, or to the pierced plaster windows of Persia. Turkey. Syria and Egypt.

Origin of European Tracery.—Pierced marble screens, with the openings glazed, were used occasionally in Byzantine work. The Byzantines also used, commonly, groups of two, three or even more narrow, arched windows, placed close together, under a single, large, relieving arch. (See BYZANTINE ARCHITECTURE.) In this they were followed by most of the Romanesque styles. In such groups, the supports between the adjacent openings of each group usually consisted of single colonnettes; hence the arches were thin and shallow, and the tympanum (*i.e.,* section of wall filling the space between and the great enclosing or relieving arch over the whole group) was necessarily thin also. Such windows are found in the greater number of Italian campaniles and Romanesque towers, as well as in many Romanesque triforium arcades. To decorate the tympanum, piercing was an obvious and simple method. The result was the germ of tracery. (See ROMANESQUE ARCHITECTURE.)

Plate Tracery is found in early Gothic work both in France and England. In its simplest forms the tympanum is pierced with a single opening, usually circular, but occasionally taking a four-lobed or quatrefoil form. The points between the lobes, known as cusps, later became an important element in much Gothic ornament. In time, greater elaboration was sought by increasing the number and complexity of the piercings, and thus both the size and beauty of the entire unit. The climax of plate tracery appears in France in the group of magnificent windows of Chartres cathedral (1194–1212); and in England in the rose window (*q.v.*) at Lincoln cathedral (1220), known as the Dean's eye. (See GOTHIC ARCHITECTURE.)

Bar Tracery.—As skill in stonecutting and desire for complexity increased, the area of the tympanum. wall left solid grew continually smaller, finally leaving only thin bars of stone separating the adjacent openings. Moreover, in Notre Dame cathedral. Paris, certain small, interior, round windows constituting a sort of upper triforium in the original design, carried decorations of little inverted arches built of stone—a sort of rudimentary tracery. About 1220 the next ineviiable step in the development was taken, and a window was considered not as a group of lights carrying a little piece of pierced tympanum wall, but as a group of lights where arches are formed of a bar of stone similar in section to that of the mullion or support between them, with the space between these arches and the enclosing arch—the old tympanum—occupied by a pattern of similar stone bars. In early work this pattern usually consists of a circle, sometimes cusped, tangent both to the enclosing arch and to the small arches of the lights below it. The cusps are usually of the type known as soffit cusping, cut on separate pieces of stone set into grooves in the inner faces of the circle.

French **Rayonnant** Tracery.—In France. bar tracery occurred in the rebuilt clerestory of Notre Dame (between 1220 and 1230) in the simplest possible form. and in a more developed type, with cusps. in the apse chapels of Reims cathedral (prior to 1230). From about 1240 on, it became common, rapidly increasing in lightness and complexity. In general, the pattern types are restricted. There are two, three or four lights. In two-light windows, a single cusped circle is the crowning feature. In three-light windows three smaller cusped circles fill the space above. Four-light windows are formed of two 2-light windows. with an additional cusped circle above. In France the spring of the arches of the lower lights is kept far below that of the enclosing arch, so that the crowning circle is large. During the late 13th century, curved-sided triangles, and trefoil and quatrefoil forms, without enclosing circles, were occasionally used. In four-light windows, the central mullion is often heavier than the side mullions, both in depth and width, and this additional size carried around the enclosing arches of the side pairs. This heavier bar has a section or profile. part of which is a duplicate of the smaller bars or mullions. Thus tracery of two planes and two molding types was developed—one, that of the smaller bars, and the other, that of the larger. Each molding-type plane is known as an order, and such a window is said to have tracery of two orders. The climax of French Rayonnant tracery can be seen in St. Urbain at Troyes (1270), Ste. Chapelle in Paris (1246–48) and St. Nazaire at Carcassonne (early 14th century). Rose windows, such as those of Notre Dame at Paris (c. 1270). designed with radiating patterns using similar combinations of forms—arches. circles: cuspings, etc. —are perhaps the most remarkable traceried windows of this style. During the later Rayonnant period. tracery forms came to be used decoratively, for wall surfaces, pinnacles, gables, etc. Especially noteworthy is the filling of the gables of porches, above the door arches, with tracery forms. At first this was done simply, with little piercing; later, as in the Portail des Libraires, at Rouen cathedral (c. 1280), the gable became a mere decorative screen of lacelike open tracery. French Rayonnant tracery was the controlling influence in all continental tracery outside Italy. (See RAYONNANT STYLE.)

English Geometric Tracery.—Based on the same simple arch, circle and cusp forms as the French tracery, the English geometric tracery is infinitely richer and more varied. The great east end and west windows of the cathedrals allowed the development of four-. 'six- or eight-light windows, designed in two or three orders, carefully systematized, like the east window of Lincoln cathedral (c. 1280), in eight lights with three orders. But the greatest change was in single-order windows of smaller size. In these the use of cusps without circles became common, and all sorts of star-shaped, triangular and other geometric forms occurred.

English Curvilinear Tracery.—In the early years of the 14th century the English architects discovered that by the use of the ogee curve, or curve of double curvature, the occasional harsh angularities of the geometric style could be avoided, and wavy-lined tracery of great beauty produced. This gave rise to the so-called curvilinear tracery. Its simplest form is the reticulated, or network window in which the entire upper part is filled with a regular all-over pattern of waving bars, rhythmically tangent and then separating. But the introduction of the reverse curve set free the imagination of the designer, and an infinite number of varying types resulted, such as the rose window at Lincoln cathedral (1350), or the great west window at York (c. 1338). (See DECORATED PERIOD.)

Perpendicular Tracery.—By the end of the third quarter of the 14th century a reaction had set in against this flowing curvature, and the 15th century saw the new style—the so-called Perpendicular—triumphant. It was based on one controlling idea—verticality. Mullions were run through unbroken from bottom to top. At intervals they were connected by horizontal bars running across the window, supported on little arches between the mullions, thus dividing the whole window into tiers of little arch-headed lights. At the top there was great variety of treatment, but almost always the upper lights were smaller than those below; and there was frequent use of curved bars intersecting the verticals, and to some extent recalling the arched forms of the earlier styles. This new feeling appeared in the transept window of Gloucester cathedral as early as 1335, and in a more developed form in the east window of the choir, which fills the entire east end, about 1350. During the 15th century the lines became more and more rectangular and the window heads had flatter and flatter arches. The climax of this development was reached in such enormous end windows as those of the King's College chapel, Cambridge, and St. George's chapel, Windsor (c. 1525).

Wall tracery of Perpendicular character was widely used both for exterior and interior work during the 15th and early 16th

EXAMPLES OF TRACERY

1. Geometric decorated English Gothic tracery; Angel Choir, Lincoln Cathedral, 1250–80. 2. Mogul pierced marble tracery; screen in the Taj Mahal, Agra, India, 1632. 3. Rayonnant French Gothic tracery; transept rose window, Notre Dame Cathedral, Paris, c. 1270. 4. Rayonnant French Gothic tracery; rose window from St. Nazaire, Carcassonne, France, beginning of the 14th century. 5. Perpendicular English Gothic tracery; west front. St. George's Chapel, Windsor, begun 1474. 6. Early Perpendicular English Gothic tracery; east window, York Minster. 1408. 7. Curvilinear Decorated English Gothic tracery; west front, York Minster, 1338

centuries. Great areas were sometimes filled with tiers of traceried panels. as in the Henry VII chapel, Westminster abbey (begun 1502). In some cases, where flint was common, a tracery of cut stone, filled in with dark flints. was used to decorate church exteriors, as in Long Melford church and St. Laurence at Ipswich. Traceried forms were also the basis of much screen, stall and tomb design of the 1jth century; rood screens were particularly rich. Tracery was also the basis of the decorative rib treatments of fan vaulting. (See PERPENDICCLAR PERIOD.)

French Flamboyant Tracery. — In the last years of the 14th century the reverse curve came into use in French tracery, probably as the direct result of English curvilinear models. The French, however. soon gave tracery of this kind an individual spirit. In the best Flamboyant work, such as the tracery of St. Maclou, Rouen (begun 1432). and the west front of Rouen cathedral (begun 1481), all of the forms are slimmer and more flamelike than is usual in English work. Particularly interesting is the application of Flamboyant tracery to rose windows. like that of the south transept of Beauvais cathedral (1500–48). in which the radiating character of the earlier types is maintained, although combined with the reverse curve. Flamboyant tracery forms the chief decoration of many gorgeous choir stalls and screens. The screen at Albi (c. 1500) has tracery of unbelievable lacelike delicacy in its canopies, as well as larger patterns covering wall surfaces; the wood choir stalls of Amiens (1508–19) are even more delicate and the tracery is of the utmost richness and intricacy. Noteworthy, also, is the application of Flamboyant tracery forms to exterior detail. as in the porch of St. Maclou, Rouen, and the west front of St. Wulfran at Abbeville (1480). (See FLAMBOYANT STYLE.)

Italian Tracery. — The Italians lacked understanding of Gothic structural principles and tracery never achieved in Italy the logical development of the north. The nearest approach to this is in the bands of tracery of Venetian palace windows, such as those of the Ca' d'Oro (1430), by G. and B. Bon. Elsewhere, tracery was only understood as beautiful pattern, and much oi it, even when copying the forms of bar tracery, is pierced from large sheets of marble. as in the triforium of the cathedral at Lucca (c. 1400) and the cloister of Sta. Maria della Verita. at Viterbo.

Tracery in the Orient. — The Islamic designers not only followed Byzantine precedent in using pierced marble screens for windows but also, by the development of a new technique, invented a characteristic type of tracery. which combined the functions played by both leading and stone tracery in western work. This technique consisted in filling the window area with a pierced sheet of cement, each piercing being filled with a piece of coloured glass. Results of jewellike intensity and brilliance were thus obtained, and being made of a plastic material, tracery of this type could have unlimited variety of pattern. The usual types found were basically floral. with the leaf shapes in glass, carefully arranged to give a sense of flow and growth. Such cement tracery is found particularly in the later work of Cairo. such as the mosque of Barkouk (c. 1384) and in the imperial Turkish work, such as the brilliantly jeweled windows in the 17th-century mosque of Suleiman. Constantinople. In India. where ventilation is required, rather than floods of light. a different type was developed, without glass, and in a richer material—carved and pierced marble. Thus, in almost all of the great Mogul palaces, and in many of the tombs, large, pointed arch openings are filled with sheets of white marble, pierced in the most elaborate patterns, of the finest scale. The most delicate example of this pierced. marble tracery is that of the screen around the sarcophagi in the Taj Mahal (*q.v.*), at Agra (1632–4i). (See also ISLAMIC ARCHITECTURE; STALACTITE WORK; INDIAN XRCHITECTURE.)

Modern Types. — Church architects of the 20th century, working, frequently, in a modernized Gothic style, found in tracery a congenial means of free expression. Both geometric and curvilinear forms furnished inspiration, but patterns of a freshness and individuality frequently quite different from the medieval custom were developed. Foliated ornament was frequently added to the tracery basis. One modern development was the use of precast cement tiles. pierced in geometric patterns and glazed, built up into large windows, as in the church of Notre Dame at Raincy, Fr. (1924). by Perret Frères. Screens perforated with tracerylike patterns became widely admired around mid-century, notably in the work of Edward D. Stone, as in the U.S. embassy at New Delhi, India (begun in 1956). (T. F. H.; X.)

TRACHEOTOMY, the operation of opening the trachea or windpipe (*see* RESPIRATORY SYSTEM, ANATOMY OF) and inserting a tube to provide a means of breathing when the natural air passage is obstructed above this level by injury, disease or foreign bodies. The operation is not easy when performed on a small child. for the windpipe is deeply placed among important structures. The chief anxiety is in connection with hemorrhage, for the vessels are large and generally overfull because of the impairment of the respiration. Formerly. it was frequently performed in diphtheria (*q.v.*) but since the introduction of diphtheria antitoxin it has rarely become necessary.

TRACHIS, a city of ancient Greece, at the head of the Malian gulf in a small plain between the Xsopus and Melas rivers. enclosed by Mt. Oeta which there descends close to the sea and at the Trachinian cliffs commanded the main road from Thessaly. The position was well adapted as an advanced post against invaders from the north, and furthermore guarded the road up the Asopus gorge into the Cephissus valley. Its citadel, Heracleia, was a subject of dispute between the Spartans and the Thebans at the end of the jth century B.C. In Strabo's time the citadel alone was inhabited.

TRACHOMA is a chronic inflammatory disease of the eye caused by *Chlamydia trachomatis*, one of the largest viruses. The conjunctiva becomes thickened and roughened and extension of the disease to the cornea may cause scarring leading to opacity and blindness. Transmission occurs during the acute stage by infective ocular secretions transferred by personal contact or by some indirect means such as use of a common towel. Trachoma is seen especially under conditions of poverty, crowding or poor sanitation and is oiten complicated by other eye infections of bacterial origin. One of the oldest diseases known to man, trachoma is present in most areas of the world but is especially prevalent in parts of Asia and north Africa. In the United States. most cases are now seen in a few restricted localities, particularly among native Indian populations. The sulfonamide drugs, as well as some of the antibiotics. are curative provided treatment is sustained over a sufficiently long period. Efforts initiated by the World Health organization to promote mass treatment in selected areas may be expected to advance the control of this disease. Beginning in 1957 an important advance occurred when it was found possible to maintain the virus by culturing in the tissues of embryonated chicken eggs. (F. B. G.)

TRACHYTE, a light-coloured. very fine-grained to dense volcanic rock composed chiefly of alkali feldspar (*q.v.*) with minor amounts of dark (mafic) minerals such as biotite, amphibole or pyroxene (*qq.v.*). Compositionally trachyte is equivalent to the plutonic rock syenite (*q.v.*).

Rapid cooling and solidification of trachytic lava produces the fine texture of the ground mass, and cooling may be so rapid locally that small quantities of glass are formed. Most trachytes show porphyritic texture in which abundant, large, well-formed crystals (phenocrysts) of early generation are embedded in a very fine-grained matrix. The phenocrysts are usually sanidine, a glassy potash feldspar commonly rich in soda. and may range up to one or two inches across. Smaller phenocrysts of mafic minerals may also abound.

Like many volcanic rocks, trachyte shows a streaked or banded structure due to flowage of the congealing lava. This structure may be revealed by a conspicuous parallel arrangement of large tabular phenocrysts. Microscopic examination of thin slices shows the fine matrix to possess trachytic texture in which tiny lath-shaped sanidine crystals are closely packed in parallel fashion and form lines of flow more or less wrapping around the large phenocrysts. Where the tiny feldspars exhibit a stumpy or square outline, the texture is known as orthophyric.

Two types of trachyte are commonly recognized. In potash or normal trachyte, sanidine or orthoclase is the dominant feldspar, and the plagioclase is generally oligoclase. In soda or alkali trachyte the alkali feldspar and mafic minerals as well are rich in soda. As the ratio of alkali feldspar to plagioclase decreases, trachyte passes into latite. The constituent sanidine possesses peculiar optical properties which can be detected under the microscope and which mark the mineral as a high-temperature phase. Orthoclase, considered to be a sanidine partially converted to a low-temperature phase of potash feldspar, is also common in trachyte.

Brown biotite is a common mafic constituent, and the flaky grains are often observed to be so intensively resorbed that nothing remains but patches of dusty magnetite outlining the earlier crystals. Amphibole is also common and may be represented by somewhat corroded or resorbed hornblende in normal trachytes and by soda-rich varieties (arfvedsonite, barkevikite and riebeckite) in alkali trachytes. Normal trachytes may carry diopside; whereas alkali types may show pyroxene crystals with diopsidic cores surrounded by concentric shells and zones progressively enriched in sodium and iron (aegirite). Accessory minerals include zircon, apatite, sphene, ilmenite and magnetite.

Silica-rich trachyte may carry small amounts of quartz which is interstitial to feldspar; whereas tridymite and cristobalite are commonly found lining the small cavities which developed as expanding gas bubbles in the molten lava. With increase in content of free silica, trachyte passes into rhyolite (*q.v.*). Marked decrease in silica favours the formation of silica-deficient minerals (feldspathoids) such as leucite, nephelite, sodalile and analcite. As the quantity of feldspathoids increases, trachyte passes into phonolite (*q.v.*).

Trachyte is a widespread but not abundant volcanic rock and is most commonly associated with other lavas in volcanic regions. There the trachytic lava is believed to have formed from a basaltic one by the crystallization and abstraction of large quantities of minerals rich in iron, magnesium and calcium. Contamination of certain lavas by incorporation of foreign rock material may be a factor in the formation of some trachytes. Some trachytic rocks, notably certain keratophyres, may have been converted from andesitic rocks by chemical changes involving the removal of calcium and introduction of sodium. Such a substitution could increase the ratio of alkali feldspar to plagioclase.

Trachytic rocks formed in sills and dikes are generally rich in phenocrysts and are represented by various types of porphyry (*q.v.*).

An average chemical analysis (in weight per cent) of trachyte is as follows: SiO_2, 60.68; Al_2O_3, 17.74; Fe_2O_3, 2.64; FeO, 2.62; MgO, 1.12; CaO, 3.09; Na_2O, 4.43; K_2O, 5.74; H_2O, 1.26; and TiO_2, 0.38.

TRACK AND FIELD SPORTS, called athletic sports in England and other parts of the British Commonwealth, consist of competitions in running. jumping and throwing various objects.

The following article is concerned with a brief outline of the events of a track and field meet; the origins and early history of the sports and their development and organization during the 19th and 20th centuries. There is also a section dealing with women's track and field sports.

For a fuller discussion of the individual events see the separate articles RUNNING; POLE VAULTING; DISCUS THROWING; PENTATHLON; etc.

MODERN TRACK AND FIELD

Events. — Modern athletic events are best divided into eight main categories. On the track these are the sprint events up to 300 yd.; the middle distances from 400 m. (437.44 yd.) to 10,000 m. (6 mi., 376.12 yd.); the long distances, notably the marathon; the hurdling events and the steeplechase; and the relay events. In the field there are the four standard jumping events (pole vault, high jump, broad jump and hop, step and jump) and the five throwing events (shot-put, weight, discus, hammer and javelin). In a category of its own is the decathlon which comprises ten varied events in a two-day trial.

Field and Equipment. — Inmodern meets, the track events are run on a surface of cinders, clay, plain dirt or grass. The field events are usually staged on the infields of the tracks or on an adjacent grass field. Firm runways and soft landing pits are needed to avoid injury in the jumping and vaulting events. Hard-surface circles of exact measurement are used for putting the shot and throwing the weight, discus and hammer. Since running to develop momentum is permissible in javelin throwing, a hard-surfaced or grass runway is used with a line at its end serving as a base from which to measure the throws.

Indoor Track. — Indoor tracks, for other than training purposes, are featured in the U.S., France, the German Federal Republic, Great Britain and the U.S.S.R., but indoor performances are not recognized for world record consideration. During the winter months meets are held either on the dirt, cinder or clay floors of university field houses; on the hard, flat floors of armouries or on specially built oval wooden tracks, banked on the turns, in the arenas of major U.S. cities. The sizes of these indoor tracks vary from 8 to 12 laps to the mile. An eight-lap track is the minimum for U.S. indoor record consideration.

Purposes. — In addition to being used for competition, track and field sports are also used as developers of strength and stamina. The armed forces of several countries sponsor track and field sports, supplying the equipment and fields required. The U.S. armed forces conduct track and field meets at most training camps and bases, leading to annual intraservice championships.

Organization. — Amateurism rules for the most part in track and field. A few attempts to promote professional track meets in the U.S. were short lived, and only Scotland and Australia remain as havens for a handful of professional performers (see also AMATEUR).

The International Amateur Athletic federation (I.A.A.F.) is the world-wide organization for amateur track and field sports. Each country sponsoring track and field sports has its own national organization which sends representatives to the I.A.A.F. The U.S. organization is the Amateur Athletic Union of the United States (A.A.U.). The organization for the United Kingdom is the British Amateur Athletic board (B.A.A.B.).

A minimum of paid workers are employed, the majority of the organizational and officiating work necessary to conduct track and field sports, up to the international level, being done by volunteers. Most national organizations exist on registration and sanction fees, individual and group donations and net receipts from their own promotions. Government grants are used in some nations.

HISTORY

The actual movements in the various events of track and field sports go back to the efforts of primitive man to survive. With no truly effective weapons available, earliest man had to develop speed of foot, muscular power, dexterity of motion and the ability to jump and leap in order to evade his natural enemies. When not doing these things to save his own life it can be assumed that he practised with his fellow men in order to improve his skills. From such practice the idea of athletic competition may have emerged.

EARLY DEVELOPMENTS

Classical Athletics. — The first trace of track and field sports goes back to various sports cultivated before the Christian era by the Egyptians and several Asian countries. Greece played a part (see GAMES, CLASSICAL; OLYMPIC GAMES) and the Irish, too, had a great festival known as Lugnas, or the Tailtean games, celebrated several centuries B.C.

Many believe the ceremonies of the Olympic games, including some track and field events. started in the 14th century B.C. and historical records were kept from 776 B.C. The games survived the conquering of Greece by Rome and were carried on until 394 A.D., when they were abolished by order of the Roman emperor

Theodosius.

Middle Ages.—Following classical times, the next record of track and field sports is not found until A.D. 1154 when athletic practice fields were provided in London.

Affecting the development of track and field in medieval England was a ban against athletic events promulgated by Edward III because they interfered with archery. Athletics were permitted again in the following century and were generally approved from the reign of Henry VIII, who was himself proficient in throwing the hammer.

Great Britain

Early Meets.—Distance races for cash stakes flourished in England at the start of the 19th century. Amateur races were held at Uxbridge in 1825 and also at Lord's cricket ground, London. Eton college originated a 100-yd. hurdle race in 1837 and added sprints and a steeplechase in 1843 in connection with its interclass athletics.

The first regularly organized athletic meeting of modern times in England was promoted by the Royal Military academy, Woolwich, in 1849. A year later Exeter college. Oxford, inaugurated sports which continued annually. The Exeter college meeting was undoubtedly the precursor of the Cambridge sports. founded in 1857, and the Oxford sports which were begun in 1860. The Oxford and Cambridge meetings commenced in 1864 and the English championships in 1866.

The second Royal Military academy meet in 1850 brought the first perpetual trophy for the team winning the most events. It was a silver bugle presented by Captain Eardley-Wilmot. Events at the Exeter college meet that year were: 100. 330 and 440 yd., 1 mi., 140-yd. hurdles. The high jump and broad jump were added in 1851.

In 1852 Kensington grammar school began to hold regular meets. Harrow. Cheltenham college and Durham university followed a year later. and from these early meets athletics in English schools continued to grow. This reached its climax in the Public Schools Challenge cup meeting promoted annually by the London Athletic club (L.A.C.), which came into being in June 1863 under the name of the Mincing Lane Athletic club. a majority of the founders having their businesses in that centre of London trade.

The Amateur Athletic club was formed in 1866 to "supply the want of an established ground upon which competitions in amateur athletic sports might take place between gentlemen amateurs." It conducted the first English championship meet that year although the active athletes continued to ally themselves with the L.A.C. rather than the A.A.C.

The Amateur Athletic Association.—The year 1879 marked a point of cleavage and two championship meetings were held. One was promoted by the A.A.C., which had previously been in the habit of holding its championships immediately after the Oxford and Cambridge sports in the spring. The other was held later in the summer under the L.A.C. for the greater convenience of non-university athletes. In 1880. in order to overcome the difficulties of competing in two separate championships, officers of the Oxford University club and the Northern and Midlands Amateur associations called a meeting of 40 amateur clubs. This led to the formation of the Amateur Athletic association (A.A.A.) whose objectives were to organize an annual championship meeting and improve management of sports meetings.

The A.A.A. championships, open to foreigners as well as British amateur athletes, were held every year thereafter apart from war years. With the growth of athletics in Great Britain. championships came to be held in the various events on a county basis leading to the area championships, athletes reaching a specified standard being allowed to compete in the A.A.A. junior and senior championships.

Other Meets.—Annual national meetings are also held by the affiliated associations for the army, banks, civil service, hospitals, insurance, police, Royal Air Force, Royal Navy, schools of all grades. universities and various youth organizations. In addition, most athletes belong to athletic clubs whose membership is open to athletes, irrespective of trade or profession, and is drawn mainly from those living in a specific locality.

The Oxford and Cambridge sports were held regularly after their inception, apart from war years, and in 1920 there was instituted an annual relay meeting between the two universities. Relay colours instead of blues (school athletic badges) are awarded for this match, which comprises 440 and 880 yd., 1 mi., 2 mi., 4 mi., 480-yd. high hurdles (42 in.) and 880-yd. low hurdles (24 in.). Four runners, each covering a quarter of the distance, represent each university in each event.

Challenge Cups.—While championships were abandoned in Great Britain from 1914 to 1919 because of World War I, athletic meetings of a sort continued to be held. The L.A.C. contrived to carry on the Public Schools Challenge cup meeting right through the war, thus assuring Great Britain the nucleus of a fine supply of athletes of international standing when the days of war ended. This Public Schools Challenge cup meeting, which did more than anything else to induce British boys to pay more attention to athletics, commenced in 1890. in which year C. H. Mason presented a quarter-mile challenge cup to be competed for annually by public-school boys at an L.A.C. meeting. In subsequent years other cups were given, and in 1897 a number of L.A.C. members presented public schools challenge cups to commemorate the diamond jubilee of Queen Victoria. This meeting became the most important fixture in the public-schools season.

The Four-Minute Mile.—While England played host to the Olympic games in 1908 and again in 1948, perhaps the greatest day in England's impressive athletic history came on May 6, 1954. On that day Roger Bannister, a medical student who finished fourth in the 1,500-m. run at the 1952 Olympic games, achieved the long-sought goal of running the mile in four minutes or less. racing the mile around the Oxford track in 3 min. 59.4 sec. Although that mark stood as a world record for only 46 days—being reduced to 3 min. 58 sec. by Australian John Landy on June 21, 1954, at Turku, Fin.—it was England's most impressive athletic achievement to that time and was hailed throughout the world.

United States

Early Athletic Clubs.—It is taken for granted that track and field events were informally introduced into the United States by athletes migrating from Great Britain. However, the start of amateur competition is credited to the New York Athletic club (N.Y.A.C.), which was founded in 1868 and conducted the first U.S. track and field meet, indoors, on Nov. 11 of that year. A Caledonian sports program was held in New York city the previous year, but the only track and field report on it is that the pole vault was won with a vault of 9 ft. 3 in. Organized in 1860, the Olympic Club of San Francisco is considered to be the first athletic club in the U.S., but it did not enter a team in track and field competition until 1877. The year 1876 was one of significance with the first U.S. National Amateur championships, the first Intercollegiate Association of Amateur Athletes of America (I.C.4-A) meet, and with Horace H. Lee of the University of Pennsylvania becoming the first American to run 100 yd. in 10 sec.

Full credit for the birth of track and field competition in the United States is rightfully given to the New York Athletic club. The start of this club, according to its historical documents, was a meeting of three former soldiers of the Civil War on June 17, 1868. They were John C. Babcock, William B. Curtis and Harry E. Buermeyer. The club was officially organized on Sept. 8 with 14 charter members.

Only two short months after its organization, the N.Y.A.C. sponsored the first set of games open to amateurs ever held in the United States at the new Empire City skating rink at Third avenue and 63rd street. The building lacked a roof which necessitated spreading canvas as a temporary cover. Since a floor had not as yet been laid in the building, an eight-laps-to-a-mile running track was staked out on the firm ground in the centre of the rink. The first pair of spiked running shoes seen in the U.S. was worn by Bill Curtis at this meet and loaned by him to some friends competing in other events.

The N.A.A.A. and **A.A.U.**—The first meets to be considered national outdoor championships of the U.S. were sponsored by the

N.Y.A.C. at its Mott Haven grounds. 155th street and the Harlem river, in 1876, 1877 and 1878. The N.T.A.C. won the team championship in all three meets.

Early in 1879 the N.Y.A.C. decided to give up the management of the national championships and started the movement which led to the formation of the National Association of Amateur Athletes of America. The clubs forming the organization were: American A.C.. New York city; Clinton A.C., Brooklyn; Elizabeth A.C., Elizabeth, N.J., Empire City A.C., New York city; Harlem A.C., New York city; Jersey City A.C., Jersey City: N.J.; Manhattan A.C., New York city; New York A.C., New York city; Olympic A.C., San Francisco; Plainfield A.C., Plainfield, N.J.; Scottish American A.C., New York city; Short Hills A.C., Short Hills, S.J.; Staten Island A.C., New Brighton, N.Y., and Union A.C., Boston, Mass. The first championships conducted by the N.A.A.A. were at the N.Y.A.C. Mott Haven grounds on Sept. 24, 1879. The best U.S. performances on record going into those championships were: 100 yd., 10 sec.; 220 yd.. 23.75 sec.; 440 yd., 49.2 sec.; 880 yd., 2 min. 2.8 sec.; 1 mi., 4 min. 37.4 sec.; 3 mi.. 16 min. 21.5 sec.; 120-yd. hurdles, 17.25 sec.; running high jump, 5 ft. $8\frac{1}{4}$ in.; running broad jump, 21 ft. $2\frac{1}{2}$ in.; pole vault. 10 ft. $5\frac{5}{8}$ in.; shot-put, 37 ft. 10 in.; hammer throw, 87 ft. 1 in.; 56-lb. weight throw, 23 ft. $1\frac{1}{4}$ in.

The N.A.A.A. continued to conduct the national championships, all in New York city, for ten years. As a result of laxity in enforcing the amateur code, the Amateur Athletic Union of the United States (A.A.U.) took control in 1888. That brought about two championship meets that year, one by the N.A.A.A. in New York city and the second by the A.A.U. in Detroit, Mich. Annual indoor championships were started in 1906.

College Competition. — College track and field championships in the U.S. began in 1876; the pioneering body was called the Intercollegiate Association of Amateur Athletes of America. popularly abbreviated as I.C.4-A. Charter members included Amherst, Columbia. Cornell, Harvard. Princeton, Trinity, Union, Wesleyan, Williams and Yale. A month later they were joined by Bowdoin, Brown, College of the City of New York. Dartmouth and Pennsylvania. These 15 member colleges increased more than fourfold in the next 80 years and participated in outdoor collegiate track and field championships every year from 1876, except for 1917. The I.C.4-A also sponsored indoor championships every year from 1922, usually each February.

Another major national collegiate body is the National Collegiate Athletic association (known as the N.C.A.A. or N.C.2-A), with more than 300 member colleges. Though known mostly for its supervision of other sports. the N.C.A.A. plays an important role in track and field, having sponsored outdoor championships every year from 1921. Western and midmestern colleges concentrate on the S.C.A.A. annual meets rather than those of the I.C.4-A. The N.C.A.A. and the A.A.U. have an equal number of representatives on the track and field committee of the United States Olympic association.

Despite many serious attempts to standardize events in U.S. championships along the lines of the international metric system, the more cumbersome units of miles, yards, feet and inches apparently remained too deeply ingrained to be eradicated. The A.A.U. used metric measurements for the running, hurdles, steeplechase and walking events for its championships for one year in 1928 and then continuously from 1932 to 1952. The metric measurements were discontinued again beginning in 1953, with the understanding they only be used during Olympic years in order to train competitors over Olympic distances.

High School **Athletics.**—While college-trained athletes make up a high percentage of the Olympic and international U.S. track teams that have brought world domination in track and field! development in high schools has been very important. Few standout athletes were developed in colleges after 1920 without previous high school training and competition. Track and field is a national sport in U.S. high schools, teams being sponsored by schools in all states. Most of them conduct state championships in addition to local, county and sectional title competition. Bob Mathias proved an excellent example of the high grade of U.S. high school track and field performers, winning the decathlon in the 1948 Olympic games at London as a 17-year-old.

High school track and field in the U.S. is comparable to college and A.A.U. competition. The main differences are that the high hurdles are 36 in. high instead of 42. an 8-lb. shot is put instead of 16, a discus approximately a pound lighter than the college and A.A.U. implement is used and running events are limited to a maximum distance of one mile. The standard championship program includes 13 events: 100 yd., 220 yd., 440 yd.. 880 yd., 1 mi., 120-yd. high hurdles, 180-yd. low hurdles, high jump, broad jump, pole vault, discus throw, javelin throw and shot-put. Additional events held in college and A.A.U. championships are a 2-mi. run and hammer throw. National A.A.U. championships match the Olympic program with a 6-mi. run, 440-yd. medium hurdles and a 2-mi. steeplechase. These last three events are added to the annual S.C.A.A. chainpionships in Olympic years, the meet serving as semifinal trials for the U.S. Olympic team.

The National Scholastic federation, state associations and local governing groups enforce regulations to prevent coaches from using boys in too many events. Considering the physical capabilities of boys age 14 to 18, a limit of three events per entry is set in most cases. The rules are further strengthened to limit a boy to one race at 440 yd. or more or in no event more than two races by a sprinter and hurdler. The limit of three events can be reached by taking part in field events. Some organizations such as the Public Schools Athletic league (P.S.A.L.) of New York city limit boys to one race regardless of the distance. The necessity of heats in most sprints and hurdles brought this limitation.

Track and field development in the U.S. also goes below the high school age with the aid of a nationu-ide junior Olympic program sponsored by various districts of the A.A.U. and by national organizations such as the Catholic Youth organization (C.Y.O.) and the Young Men's Christian association (Y.M.C.A.).

Relay Meets. — Relay racing also holds an important place in U.S. track and field. Major relay carnivals conducted annually are the Penn relays (University of Pennsylvania), Drake relays (Drake university), Kansas relays (University of Kansas), Texas relays (University of Texas) and Florida relays (University of Florida). The first recorded relays in the U.S. were held in 1893 by Pennsylvania students. Later that year Penn and Princeton staged the first intercollegiate relay. Princeton won the 1-mi. relay in 3 min. 34 sec.

The Penn relays, inaugurated in 1895, is considered the largest relay carnival. Gradually built up through the years, this mammoth meet features eight races for colleges, four for high schools and two for prep schools. Included are a complete set of field events, a 100-yd. dash, 120-yd. high hurdles and 440-yd. medium hurdles and a 2-mi. run for college entrants. The remainder of the meet is composed of class races at a mile or less.

The Penn relay college championships are at 440 and 880 yd., 1 mi., 2 mi., 4 mi., sprint (1-mi.) medley, distance (2;-mi.) medley and 480-yd. shuttle high hurdles. Each of the four team members runs one-fourth of the distance except in the medleys. The sprint medley has legs of 440 yd., 220 yd., 220 yd. and 880 yd. in that order. In the distance medley the first man runs 880 yd., the second 440 yd., the third 1,320 yd. ($\frac{3}{4}$ mi.) and the fourth 1 mi. The shuttle hurdles are run over one strip of hurdles, with two men starting from each end. A touch off is used in the shuttle hurdles instead of a baton as in all of the other races.

The relay idea also is used in many instances in field events. Teams of four compete against each other with the total distance or height of each team deciding the winner.

INTERNATIONAL

Early Meets. — Long before annual championship meetings were instituted in any country the desire to pit athletes of one nation against those of another was clearly in evidence. England was visited in 1844 by George Seward. U.S. professional runner, who achieved some signal successes, and in 1863 by Louis Bennett, called "Deerfoot," a full-blooded Seneca Indian who established running records up to 12 mi. In 1884 a team of Irish athletes, among them W. J. M. Barry, a magnificent exponent of the heavy-

RUNNING AND THROWING EVENTS

PHOTOGRAPHS, (TOP LEFT. TOP CENTRE. TOP RIGHT. CENTRE, BOTTOM RIGHT) WIDE WORLD (BOTTOM LEFT) GUILLERMO GUZMAN WEST, MEXICO. (BOTTOM CENTRE) UNITED PRESS INTERNATIONAL weight field events, visited Canada and won several championships, In 1888 the Manhattan Athletic club sent a team to England and the Gaelic Athletic association dispatched a team to the U.S. In 1890 the Salford Harriers were the guests of the Manhattan A.C. in New York, and the following year the Manhattan athletes went again to England. The first matches of a truly international character occurred, however, in 1894 and 1895 and were arranged by the famous Yale sprinter C. H. Sherrill, who invented the crouch start. In 1894 Yale and Oxford universities met in London and the English blues proved successful by winning $5\frac{1}{2}$ of the 9 events. The following year the London A.C. took to New York almost the strongest team that could be mustered in the British Isles. They competed against the N.Y.A.C. but did not win any of the 11 events. Three world records were broken and one was equaled at this meet. Two weeks later Cambridge was defeated by Yale in the U.S. by 8 events to 3. In 1899 Oxford and Cambridge combined forces in London against Harvard and Yale, who were beaten. This match was held regularly until 1938, alternately in the U.S. and England. In 1925 Oxford and Cambridge, while in the United States for the Yale and Harvard match, held their first match against Princeton and Cornell and won by 9 points to 3. The return match in 1926 also was won by Oxford and Cambridge. The subsequent matches were held in the same year and country as the Yale and Harvard matches, Oxford and Cambridge winning three and Princeton and Cornell one. The matches were resumed in 1949 in the U.S., Princeton and Cornell beating Oxford and Cambridge, which beat Yale and Harvard. When the Oxford and Cambridge team visited the U.S. in the years 1953–57, Army (the United States Military academy), instead of Harvard, teamed with Yale and Pennsylvania teamed with Cornell in place of Princeton.

It was from the enterprise of such bodies as the Salford Harriers, Gaelic A.A., London A.C., Manhattan A.C. and the New York A.C. and the early meetings between English and U.S. universities that the series of international matches between countries throughout the world, apart from the Olympic games and Pan-American games and the European and British empire championships, grew, until no track and field season passed without each country engaging in several international matches with one or more other countries.

The Modern Olympics.—The most important of international festivals was, however, the revived or modern Olympic games, first held at Athens in 1896. They were instituted by delegates from the different nations who met in Paris in 1894, principally at the instigation of Baron Pierre de Coubertin. The result was the formation of an international Olympic games committee, with Baron de Coubertin at its head, which resolved that the games should be held every fourth year in a different country (*see* OLYMPIC GAMES).

AFTER WORLD WAR II

The improvement of track and field was so great in the decade following World War II that as the year 1956 came to a close only two prewar world records remained unbroken, the pole vault and the broad jump. Cornelius Warmerdam of the U.S., first pole vaulter to clear 15 ft., had set a record at 15 ft. $7\frac{3}{4}$ in. in 1942, but fellow Californian Bob Gutowski, the 1956 Olympic runner-up, cleared 15 ft. $8\frac{1}{4}$ in. in 1957. Jesse Owens' 1935 broad-jump record of 26 ft. $8\frac{1}{4}$ in. stood for 25 years but fell in 1960 to another U.S. athlete, Ralph Boston, who jumped 26 ft. $11\frac{1}{4}$ in. Charles Dumas, a Californian, broke the seven-foot barrier in the high jump with a leap of 7 ft. $\frac{1}{2}$ in. to qualify on the U.S. team for the Olympic high jump at Melbourne (1956), which he won. Parry O'Brien, also of California, was the first man to break the 60-ft. barrier in the shot-put.

WOMEN'S TRACK AND FIELD

Track and field for women had a natural growth. With the entrance of modern women into business and the professions, it was only a matter of time until they would find their way into athletic competition. While women, with six contestants from two countries, competed in lawn tennis at the 1900 Olympic games (Paris), women's track and field had to wait until the 1928 games at Amsterdam. By the 1952 games at Helsinki, Fin., 41 nations were entering teams in women's track and field. Thereafter, however, there was a tendency, particularly among smaller nations, to drop the women's track and field teams or reduce them. Expense was a major factor in these decisions, some countries feeling that the cost of transporting women's teams could better be applied to provide entrants for what were considered more important or popular events.

The International Amateur Athletic federation (I.A.A.F.) was organized in 1913 to govern track and field events for men, but it consistently refused to deal with women's competition although the subject was discussed at almost every federation meeting. Because the I.A.A.F. had hesitated to accept control of women's events, a women's sports federation called the Fédération Sportive Féminine Internationale (F.S.F.I.) was formed in Paris in 1921. This federation conducted world track and field championships for women in Paris in 1922, Goteborg, Swed., in 1926, Prague, Czech., in 1930 and London in 1934, which followed the plan of the women in ancient Greek times (about 600 B.C.) who held their own contests in the third year of every Olympiad, midway between the men's Olympic games. Great Britain won the 1922 event with 50 points, the U.S. was second with 31 and France third with 29. Great Britain repeated in 1926 with 50 points, France 27 and Sweden 20. In 1930 the title went to Germany with 57 points, Poland 26 and Great Britain 19; and in 1934 it went again to Germany with 95 points, Poland 33 and England 31.

When the women's federation announced its plans to hold a world championship in 1922, the Belgian Athletic association proposed that the I.A.A.F. assume control of women's athletics as well as men's. Action was delayed until 1924 when a special commission for women's sports was appointed. This commission, together with representatives from the F.S.F.I., recommended that the I.A.A.F. delegate control of women's athletics to the F.S.F.I. under rules to be drawn up by the I.A.A.F. and that the International Olympic committee be requested to include five track and field events for women in the 1928 games at Amsterdam. First it was necessary for the I.A.A.F. to determine whether or not it would have anything to do with women's athletics. It was agreed to base the decision on the issue of Olympic participation. After considerable discussion the advocates for Olympic participation won by a vote of 12 to 5.

Many countries objected to the resultant dual arrangement for the control of women's athletics and insisted that both men's and women's competition be conducted under the management of a single federation. In 1934 Germany proposed that the I.A.A.F. take full control of women's athletics, but action was deferred until 1936, at which time the agreement with the F.S.F.I. was canceled and the women's federation was dissolved. Control by the I.A.A.F. of both men's and women's competition marked the beginning of a new era for women's athletics.

Under I.A.A.F. rules the Olympic games are the only world championships recognized for both men and women, but other competitions of international character are constantly held.

TRACTORS. The term tractor is applied to a self-propelled vehicle capable of pulling a load. A vehicle which is usually powered by an internal-combustion engine, the tractor is used on highways and in factories, but its greatest use is on agricultural land. The word was not generally known until 1906, when it was used in the advertising literature of the Hart-Parr company of Charles City, Ia., although the word had been used in describing a patent in 1890. The phrase gasoline traction engine was shortened to gasoline tractor. A power vehicle driven by steam is called a steam traction engine; the term tractor does not apply to such a unit.

Tractors can be classified according to their main function, such as farm tractors, industrial tractors and highway tractors.

FARM TRACTORS

The farm tractor has revolutionized the mode of farming wherever it has been used. It has relieved farmers of arduous work and made possible great increases in production. Through the use of the tractor, farmers can control power that is equivalent to many horses and men. The average man is rated at $\frac{1}{10}$ h.p., but when he drives a 20-h.p. tractor across his fields he is doing

the work of 200 men.

Early Development.—The tractor had its birth and its greatest growth in the U.S. In 1910 there were 1,000 tractors on U.S. farms; in 1920, 246,000; in 1930, 920,000; in 1940, 1,545,000; and by 1950. 3,615,100, In 1954 there were 4,310,091.

The tractor age or era began in 1889 in the U.S. when a single-cylinder Charter engine was installed in a steam traction engine chassis in South Dakota. During the same year, the Charter Gas Engine Co. built six such gasoline tractors. The steam traction engine era began earlier, in 1876, and reached its peak in 1912, after being beaten by contemporary gasoline-kerosene tractors in the famous Winnipeg trials (*see* below). Thereafter the number of steam traction engines declined on U.S. farms, preceding the peak and decline of farm work horses by only a few years.

In 1892 the Case Threshing Machine Co. pioneered with their first gasoline tractor. It had a two-cylinder opposed-type engine. During the same year, John Froelich produced one of the first successfully operated tractors. It was the forerunner of the Waterloo Boy and the later John Deere line. Experimentation continued as N. A. Otto, the German inventor, built and sold 15 gasoline tractors from 1894 to 1896 in the U.S. In 1897 in Great Britain, tractors with oil-burning engines were being produced.

In 1901 Charles W. Hart and Charles H. Parr built a huge, oil-cooled, slow-speed, two-cycle tractor. They sold the tractor the next year and built and sold 15 more in 1903. They were so well built that one-half of them were still in service in 1920. The Hart-Parr Co. eventually became the Oliver Corp.

In 1904 the first track-type gasoline tractor was produced in the U.S., using blocks of wood on the tracks. And the large-scale tractor industry was born in 1906 when 11 companies began production almost simultaneously.

In 1907 there were 600 tractors made in the U.S. A typical tractor of that time was used for prairie plowing. It had from 90 to 100 belt horsepower, pulled 12 to 14 plow bottoms, weighed 20.000 lb., and about one-half of its horsepower was available at the drawbar. The change from a heavy, cumbersome tractor to a lighter, more versatile tractor came in 1908 when Henry Ford placed a car engine on a light, tractor chassis.

In the period from 1908 through 1912, in Winnipeg, Can., a series of annual trials or tests of steam traction engines versus gasoline tractors were made. In the first plowing demonstration, with five steam traction engines and five tractors entered, the tractors won first and second places. This 1910 demonstration signalled the final surrender of steam power and marked the emergence of kerosene and gasoline as tractor fuels.

The first frameless tractor was introduced in 1913. This unit design became popular almost immediately. Tractors up to that time were made primarily for heavy field work, but, as the result of much earlier experimentation, the first motor cultivator for corn was introduced in 1915. The weak vear for farm horses in the U.S. was in 1918. That year also marked the beginning of mass production of farm tractors. An all-purpose, nontricycle type of tractor was also introduced in that year. In 1919 Henry Ford mass-produced a tractor which was low in cost, had an air cleaner (a novelty at that time) plus enclosed transmission gears. Its sales were 75% of the industry's total. A built-in power take-off shaft was introduced on a tractor during the year, opening a new field of power application. This first power take-off shaft was used to operate the binder.

Improvements.— In 1920 mechanical tool lifts were placed on tractors, and starters and electric lights were first used. In 1923 and 1924 the International Harvester Co. introduced a tricycle all-purpose tractor which sold extensively. This tractor had adjustable tread and mounted tools, and was well-suited for cultivating corn in the central areas of the U.S. Garden tractors first became popular in the period from 1925 to 1929.

In 1930 manufacturers began using the 14-in. plow bottom rating for their tractors. This took the place of the old rating where the symbol 30/60 meant 60 h.p. on the belt and 30 h.p. at the drawbar. By 1930 tractors. because of efficient transmission systems, were developing as much as 85% of their power at the drawbar.

In 1931 the Caterpillar Tractor Co. installed a diesel engine in their crawler tractors for the first time. In 1932 rubber pneumatic tires were used. Factors such as 25% more power, 50% more speed and 25% fuel savings as compared to steel-tire tractors made rubber tires a popular feature on tractors, and many farmers converted their tractors to rubber tires.

Ford had exported some tractors to Great Britain since 1917, but in 1933 he established a factory in that country at Dagenham for production of the Fordson tractor. About the same time, in Great Britain. the David Brown Co. began making tractors with a Ferguson-type three-point implement hitch.

By 1935 high-compression engines had been introduced in the U.S. to use the high octane (73–83) fuels that became available. Hydraulic lift equipment was added to the tractors to raise and lower cultivating equipment. In 1937 the American Society of Agricultural Engineers standardized the specifications for power take-off and drawbar systems. This made it easier to adapt different tractors to different implements. Because of the extra power being used in tractors, calcium chloride and water solutions were used in tires to provide additional weight and greater pulling ability.

Later Developments.— The age of tractor-mounted equipment began in the U.S. with the introduction of the new Ford tractor in 1939. Harry Ferguson, an Englishman and one of the greatest inventors of farm machinery, designed a three-point drawbar linkage for the tractor. The linkage and the implement could be raised and louered by a hydraulically operated rockshaft by merely moving a small lever near the tractor seat. The linkage also provided automatic draught and depth control, making it possible for a relatively light tractor to do the work of heavier tractors. During the next ten years, almost 60 different implements or attachments were developed to be mounted on farm tractors. By the 1950s almost every tractor manufacturer in Great Britain, Europe and the United States was making tractors with three-point drawbar hitches.

The continuous or independent power take-off shaft was introduced on tractors in the U.S. in 1941. Battery ignition for tractors became popular, taking the place of the more expensive and

TRACTOR OPERATIONS

Top *left:* "Old No. 1" Hart-Pnrr tractor, built in 1901, the first successful gas tractor built. It developed 22–45 h.p.

Top right: Farm tractor pulling a four-furrow mounted plow

Centre left: Tractor and carry-all moving earth in highway construction

Centre *right:* Digging post-holes with tractor-powered equipment

Bottom left: Tractor with mounted loader attachment loading a manure spreader

Bottom right: Side-mounted harvester and tractor pulling a forage wagon harder-to-service magnetos. Hydraulic cylinders were used to operate trailing equipment effectively and easily. During 1941 one manufacturer produced a tractor to operate on liquid petroleum gas. a gas which had become plentiful near U.S. oil-producing areas. Fuel conversion kits were manufactured and sold to convert gasoline tractors to liquid petroleum gas tractors.

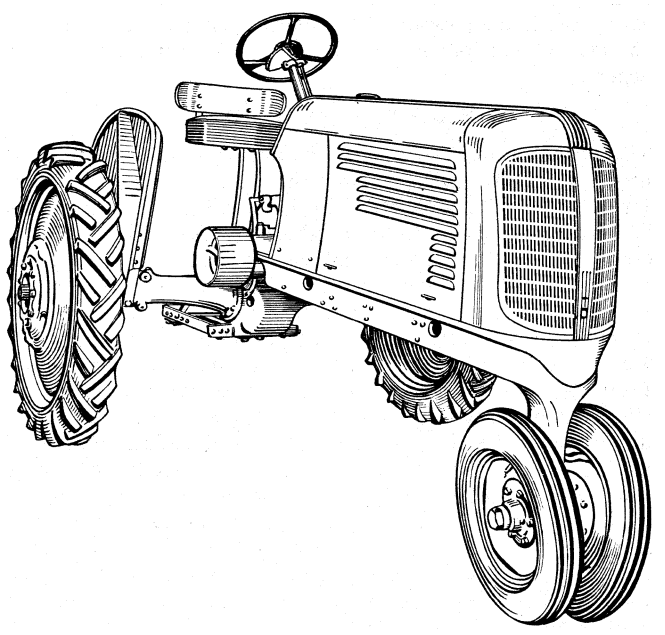
After World War II there was a tremendous increase in the use of garden tractors on U.S. farms. The year 1954 saw the introduction of trailing and mounted electrical generators on an experimental basis; the showing of an experimental tractor gasoline engine with a compression ratio of 12:1; and experimentation with tractors powered by gas-turbine engines. During that year, a British mechanized farming centre at Chelmsford, Essex, was opened to nationals of all countries. Facilities for study and discussion were provided. The great farm machinery exhibition, The Salon International de la Machine Agricole. was held in Paris, Fr.. with 130 tractor models made by 60 different manufacturers on exhibit.

The International Harvester Co. introduced a "torque amplifier" on one tractor model in 1954. This is a planetary drive unit which provides additional forward and reverse travel speeds. The tractor operator can instantly reduce travel speed 33% and at the same time increase drawbar pull up to 45% in any selected gear without stopping, declutching, shifting or touching the throttle.

Sources of Power.—An important advance in tractor farming was the introduction of mounted implements. After World War II, integral implements became popular because of greater manoeuverability, easier transportation, lower cost and ease of attachment. Mounted tools can normally be sold at lower cost since n-heels. raising and lowering devices, side. ahead and depth adjustments are largely eliminated. By the mid-1950s a mounted implement cost about 60% of the cost of a comparable trailing implement.

At first the tractor was essentially a pulling implement, delivering power by traction: But tractor pulleys have been a feature from the beginning. The X.S.X.E. standard for pulley rim speed was set at 3,100 ft. per minute. plus or minus 100. The pulley must be wide enough to accommodate a 6-in. belt.

In addition to obtaining power by traction and belt; the farmer finds the power take-off shaft desirable. In Great Britain and the C.S. the standard power take-off shaft speed n-as set at j36 r.p.m.,



COURTESY OF THE OLIVER CORPORATION

FIG. 2.—A WHEEL-TYPE TRACTOR

plus or minus 10. The shaft diameter was set at $1\frac{3}{8}$ in.. and the shaft must be located near the tractor centre at the rear. Standardization of this device permits the tractor to be used nith an assortment of machines. The independent or "live" power take-off shaft displaced the earlier transmission-operated power take-off shaft. The independent poner take-off permits the tractor operator to operate trailing power take-off implements at a constant speed while varying the tractor travel speed. This is useful in many forage harvesting operations

The fourth source of power on the farm tractor is the hydraulic cylinder operated by an oil pump located at some point in or on the tractor. The cylinder may be mounted on the tractor for operating integral equipment. or it may be located on a trailing tool and connected to the tractor system with breakaway couplings and hose. One of the most common uses of the hydraulic system is in operating a mounted attachment called the manure loader. The cylinders raise and lower the boom and tip or angle the bucket. Grader, dozer and snow blades may also be used on this attachment. The first use of the hydraulic system was to raise and control mounted plows and cultivators. The 1950s saw the application of hydraulics to the steering mechanism, by attaching a cylinder to the tractor frame and to the steering rods. This made it much easier to turn and hold the front wheels of a heavy, slow-moving tractor in loose, rough ground.

Tractor Tests.—The first tractor testing laboratory was established in Lincoln, Neb , in 1919, as the result of state legislation making it mandatory for one tractor of each make to be tested before being sold in that state. The two main features of the test are the drawbar and belt horsepower ratings made with a trailing test car and a stationary electric cradle dynamometer. The ratings are adjusted to standard atmospheric conditions. Hundreds of tests were made after the Twin City tractor was partially tested in the fall of 1919. The ratings of current tractor models were made available on one large sheet and individual ratings mere compiled by the Agricultural Engineering department of the University of Nebraska at Lincoln.

The National Institute of Agricultural Engineering. an agency of the British government, established a tractor-testing installation at Wrest Park, Siloe, Befordshire, where data comparable to the Nebraska tests could be obtained for British tractors.

Tractor Types.—Tractors can be classified by the means of obtaining traction, that is, by wheels or by tracks. In the U.S. in 1952, 96% of the total tractors on farms were of the wheel types; only 4% were crawler or track-type tractors. The same proportion existed throughout most of the other countries of the world. The crawler tractor is useful where the soil is unstable and great pulling or pushing ability is needed. Since the tracks of the crawler are not adjustable sidewise. it is difficult or impossible to use them in many row crops. It is difficult, moreover. to move the crawler tractors over roads without a carrier. The wheel tractors, although not having as much pulling ability. have adjustable treads, except on standard or orchard models, and can readily operate on highways at speeds up to 20 m.p.h.

Garden tractors became popular in the U.S. after World War II. There were 68.000 such tractors on farms in 1945 and 294,000 in 1952. The garden tractor may have an engine with a horsepower rating from 1 to 6 h.p. The engines are invariably of the air-cooled four-stroke cycle type. Some garden tractors have no n-heels, the tractor resting and operating on whirling tines. The larger. wheel models usually have a reverse gear for convenience, and many can be connected to a trailer so that the operator can ride. Among the jobs garden tractors can do are spraying. moving earth and snow, mowing grass and meeds and tilling garden plots.

Tractors throughout the world can also be classified by the fuel that they use into four categories. each requiring a special engine. These are the gasoline, the diesel, the liquid-petroleum gas and the dual-fuel tractors. In the U.S in 19j3. 3,025,jjo gasoline engines (except outboard and miniature): 117,628 diesel engines, 9,61j liquid-petroleum gas engines and 8.972 dual-fuel engines were produced. The popularity of each of the different types depends upon the availability and cost of the various fuels. In the C.S. gasoline fuel proved readily available and reasonable in price. But diesel fuel also became available at favourable cost and many farmers changed to diesel tractors when they had sufficient work to offset the higher initial tractor cost. In Great Britain and parts of Europe, diesel fuel is more plentiful than gasoline. Almost all the tractors in those areas operate on the cheaper diesel fuel.

Fuels.—In the oil-producing areas of the U.S., the gases propane and butane, by-products of gasoline refineries. have been combined to form a tractor fuel that is competitive with gasoline. Because of the low cost and desirable combustion characteristics of this fuel, farmers purchased adapter kits for their gasoline tractors, converting them to gas tractors. The gas burns cleanly, leaving no carbon residue, and has a high octane (antiknock) rating. Most of the principal tractor companies in the U.S. were making liquid-petroleum gas (LPG) tractors in 1954. In order to obtain the most efficient use of the LPG fuel it was necessary to raise the engine's compression ratio to 8:1.

The dual-fueled tractors use gasoline for starting. and kerosene, distillate or tractor fuel for operation after warming up. The engines have a lo compression ratio because of the poor ignition qualities of the fuels, which causes excessive detonation at higher ratios.

The diesel engine operates at the higher compression ratios. about 16:1, and is therefore efficient in the use of the diesel fuel. The engines do not require an ignition system because the high pressures (500 lb. per square inch) warm the incoming air to temperatures high enough (1,000° F.) to ignite the fuel as it is injected. The higher compression ratios require high-voltage starters and many diesels are equipped with 12- and 24-volt batteries. All the diesel engines used in the U.S. in the mid-1950s were of the four-stroke cycle type, except those of one manuiacturer. In Europe, however, the two-stroke cycle diesel. which gives more power per unit of engine weight than the four-stroke diesel, is more popular.

The compression ratio of tractor engines using gasoline was constantly increased, resulting in about 3% more power each year as an average. Some tractors have ratios as high as 7:1, but they go down to 4.5:1 for the dual engines. In 1954 a U.S. company placed an experimental engine in one of its regular tractors with a compression ratio of 12:1. Such a high ratio requires a fuel with an octane rating of 100 or more. In the U.S the regular gasoline antiknock qualities as indicated by Motor Method octane numbers rose from 60 in 1931 to 79 in 1951, and by 1955 it mas 82. Premium grades of gasoline run about three to four numbers higher than "regular" gasoline.

Tires.—In 1932 tractor tires gave poor traction and did not clean well. Tires were available in two typical tread patterns—a rather closely spaced nob or button type of nondirectional design and a wider-spaced lug or bar-type of directional design. In 1936 the lug height was increased as well as the space between. After World War II tractor tire manufacturers made the treads flatter and the cleats or lugs higher at the shoulders. This gave better traction. In 1938, an 84% ratio of rim width to tire diameter was standardized in the C.S. Formerly tires were on 6- or 8-in. rims. Wider rims permitted a larger volume of air in the tire and greater load capacity. By the mid-1950s there were 11 section widths and 8 rim diameters available for farm tractor tires. Special tires for rice and cane fields were also available.

Costs.—The average time of use per year of U.S. farm tractors steadily rose from less than 400 hrs. in 1930 to more than 600 hrs. in 1950. This meant a decline in operating costs as shown in the table below.

The table is based on 7,500 total hours of tractor life, allowing 15 years for the tractor to become obsolete. The repair cost is figured at 35% of the new cost. The cost per hour is based on

Cost Per Hour Per $100 New Cost

Hours used per year	Cost per hour	Hours used per year	Cost per hour
60	$ .175	750	$ .023
150	.073	1,000	.022
300	.039	1,500	.020
500	.025		

Source: American Society of Agricultural Engineers Handbook, 1954.

3.5% of the new cost as a total for such annual charges as interest, housing, taxes and insurance. From the table the cost per hour for using a tractor can be calculated if the cost of the tractor and the hours it has been used are known.

Production.—The gasoline tractor had its greatest development in the United States. Because of a scarcity of gasoline but larger quantities of fuel oil available to Great Britain, that country led the world in the percentage of tractors using diesel fuel.

The number of tractors produced in Great Britain in 1953 was 137,000. Of that number, about 85,000 were exported to Canada, Australia, New Zealand, South Africa, Denmark and Italy. The Fordson Major diesel tractor was exported in large numbers to the U.S. for the first time in 1953, competing successfully in price and quality with U.S. made diesel tractors. About 80% of the tractors produced in Great Britain in 1954 for home use were diesel-engine tractors.

In 1953, 330,091 wheel-type tractors were produced in the U.S. for domestic farm use; 12,000 crawler tractors and 164,300 garden tractors were manufactured. In the first six months of 1954, 127,655 gasoline-engine tractors were made in the U.S. In the same period, 33,107 diesel-engine tractors were produced. The figures do not include garden tractors. Also 32,666 wheel- and crawler-tractors were exported from the U.S. during the same period.

In the early 1950s the U.S. led the world in the number of tractors on farms, but the United Kingdom, Switzerland and western Germany had the greatest concentration of tractors per acre of tillable land.

INDUSTRIAL TRACTORS

These machines are similar to and often made by the same companies that manufacture agricultural tractors. Their purpose is to haul materials and products in and near industrial or manufacturing plants.

Lift arms, lift rams, front bumper, bucket and double-acting rams are carried on a frame that is heavier than the usual farm tractors. The tires are massive for good traction and easy riding, and to carry the heavy tractor and often-used heavy ballast box at the rear.

Products such as foundry sand, chemicals, fertilizer, coal, clay. sand, gravel or other loose materials are usually handled with a hydraulically operated attached material bucket. Closed cabs for the operator are provided on tractors designed to be used out-of-doors.

Backfilling and dozing operations can be done with an industrial tractor when it is equipped with a blade. They are also used for snow removal and for driving highway mowers and street rotary sweepers.

HIGHWAY TRACTORS

The highway tractor (or tractor truck, as it is often called in the United States) was developed from the truck. It differs from the latter only in having a shorter wheelbase and in that, instead of being provided with a platform or other body for carrying loads, it is fitted with a bolster on the frame over its rear axle which carries the forward end of a semitrailer through a fifth wheel. Whereas in the conventional truck nearly all of the useful load is carried on the rear wheels, in a tractor-trailer combination it can be equally divided between the rear wheels of the tractor and the two wheels of the trailer, so that a much greater load can be carried. Moreover, by far the most expensive part of the combination is the tractor, and this need not be kept idle during periods of loading and unloading, but can be kept busy all the time, providing a sufficient number of trailers is available. When the semitrailer is being loaded or unloaded its forward end rests on jacks or folding supports with caster wheels. Coupling of the semitrailer to the tractor is effected automatically by simply backing the tractor up to the trailer, and uncoupling is an equally simple operation. Highway tractors for hauling semitrailers have been built with electric, steam, gasoline and diesel power plants.

TRADE, INTERNATIONAL. International trade statistics rest on export and import records of individual countries.

Originally established for fiscal purposes, such records usually contain information on quantity and value of commodities crossing the border, often with indication of provenance of imported and destination of exported goods. Data on total value of imported and exported merchandise have been published in England (later the United Kingdom) since the end of the 17th century, in the United States since 1790 and in France since 1815. The number of countries recording their foreign trade increased in the second half of the 19th century and their records made it possible to estimate total world exports and imports.

Before World War I. systematic surveys of world trade were conducted by statistical services of different countries (for example, Germany and France). In 1910 the International Bureau of Trade Statistics (Brussels, Belg.) launched a campaign for the unification of foreign trade statistics of all countries by establishing a uniform classification of commodities. Further efforts in this direction were made by the League of Nations. It was successful in collecting and analyzing statistics of foreign trade of about 80 countries but failed in its attempts to persuade the governments to use uniform methods in classifying imported and exported commodities. The solution of the latter problem was left to the United Nations. whose Standard Industrial Trade Classification (S.I.T.C.) was widely accepted. Yet the world trade statistics compiled by the United Nations and its specialized agencies (especially the World Bank) are not inclusive. Only incomplete data are available for the U.S.S.R., its satellites and the mainland of China. There remain also some inconsistencies in records of individual countries. Some—and among them the United Kingdom and the United States—record general trade that includes in import goods designed for re-export. Others record special trade excluding re-exported goods. There is no universally accepted practice, moreover, for determining the country of destination and provenance of goods crossing the frontier. Imports are usually valued c.i.f. (cost, insurance and freight) from ship or train; exports are valued f.o.b. (free on board) of a ship or train. But the valuation is effected according to special regulations that differ widely from country to country. and the foreign trade statistics are expressed in national currency which must be converted into a universal hard currency (for example, into U.S. dollars as is the practice of the United Nations and the World Bank). The main difficulty is the handling of statistics of countries with controlled currency where special exchange rates are used for certain kinds of imports and exports and the free (black market) exchange rates may deviate from official rates.

The totals and averages in world trade statistics are therefore subject to serious reservations.

Progress of World Trade.—Ancient Times.—International trade was recorded in the monuments of the ancient world and its numerous traces have been found by archaeologists in the old burials. There was a continuous flow of exchange among the peoples of the Mediterranean basin and Red sea. Overland routes brought merchandise from the Yellow sea to India, Arabia and the shores of the Black sea. Levantine merchants met with Chinese traders in Ceylon and Java. Tyrus mas probably the main centre of international trade in the Mediterranean world. The list of merchandise brought to its markets included rare timber, metals, slaves, cattle. wheat, wine, spices, honey, oil, ivory, precious stones, embroidered fabrics, wool and many other items. As diversified was the trade between China and other areas of the far east. Large cities of antiquity could not live and grow without the continuous import of grain and building materials.

At the beginning of the Christian era, Rome was becoming the centre of trade that embraced western and central Europe, northern Africa and areas known now as the near and middle east. With the fall of the Roman empire, international trade in that area disintegrated, and the Mediterranean lost its significance as the world's busiest thoroughfare.

Middle Ages.—In the period from the 5th to the 15th century Europe was in eclipse. The chain of Moslem kingdoms had blocked the Mediterranean. The attempts of Europe to break this blockade by the direct assault of the crusaders against the stronghold of Islam in Asia Minor failed. and world trade remained in the hands of the Arabs.

In Europe the leading role in foreign trade shifted from the Mediterranean nations to those facing the open sea. Portuguese, Spanish, Dutch and British traders started the search for new routes to the east. In the 15th century Portuguese captains advanced slowly but steadily along the western coast of Africa until Vasco da Gama rounded the Cape of Good Hope and brought his ships into the Indian ocean (1497). About the same time Christopher Columbus' attempt to reach India by sailing westward from Europe brought him to the Caribbeans, the threshold of the Americas.

Modern Times.—World trade was slowly expanding along the new sea lanes—from Amsterdam, Neth.; Lisbon, Port.; Hamburg, Ger.; and London, Eng., to the Caribbean Islands and the far east. Along with spices and luxuries of the east, cotton, sugar and wool were increasing in importance. Foreign trade was essentially seaborne trade at that time and its volume could be roughly estimated from the number of ships in operation and the size of their crews. Many thousands of ships were engaged in trade, but their used carrying capacity averaged little more than 50 tons, and their crews often consisted of no more than 10 men. At the end of the 17th century the famous British economist. Sir William Petty, in the earliest attempt at international trade statistics, estimated the value of merchandise carried each year by merchant ships at £1,000 to £1,250 per ship. The estimated value of goods carried by European shipping was set at £45,000,000 a year. The Dutch were leading in European trade, followed by the British, Spaniards, Portuguese, French, Swedes and Germans.

More reliable are data for the period after the Napoleonic wars. In 1820 world exports totaled approximately £135,000,000 ($567,-000,000). Great Britain was leading (£56,000,000), France came next (£25,000,000), followed by the United States (£12,000,000), the rest (£42,000,000) being distributed among a dozen nations. With a rough correction for depreciation of all currencies in the world, it appears that the gold value of world exports in 1820 was approximately 1.5% of the value of total world exports in 1954.

Under the impact of economic growth in Europe and America, progress of industrialization and development of new means of transportation, the volume of world trade increased substantially during the 19th century and after the turn of the 20th century, until World War I. World export was estimated at $6,000,000,000

Table I.—Share of Selected Countries in Exports and Imports

*Unknown

in 1867–68, $7,000,000,000 in 1880, $7,800,000,000 in 1890, $8,-500,000,000 in 189; and $19,800,000,000 in 1913. Changes in the rate of growth in total value of exported goods were partly due to fluctuations in world prices. At constant prices, as in 1890 (adjusted by the *British* Economzst index), the value of world exports was $3 600,000,000 in 1867–68, $5,600,000,000 in 1880, $7,800,000,000 in 1890, $9,900,000,000 in 1897 and $17,000,000,-000 in 1913. The value of world imports was 10% to 15% higher because it included cost of transportation, insurance and certain other items.

From the end of the Napoleonic wars to World War I Europe predominated in world trade, and Great Britain was the mainspring and clearinghouse of the world-wide flow of merchandise. International trade consisted largely of exchange between Europe and the rest of the world and between continental Europe and Great Britain. In 1913, 40% of world exports represented intra-European trade (including trade betneen continental Europe and Great Britain); 21.5% was accounted for by European exports to other parts of the world; 15.2% by exports of non-European countries to Europe; and only 23.3% by trade among non-European countries. Moreover, the last item included transactions among European colonies and dominions largely controlled by European capital.

Great Britain lead in both exports and imports, the United States and Germany competed for second place. followed by France, the Netherlands, Russia. Belgium and Canada. These eight countries together represented nearly two-thirds of the total world trade, but the share of Great Britain and France was steadily declining while that of Germany and the Netherlands was increasing between 1880 and 1913. The share of the United States fluctuated from year to year, without showing any clear upward or downward trend

The ranking of the great commercial powers changed after World War II. The United States advanced to the leading position, followed by the United Ringdom, western Germany. Canada and France. Belgium and the Netherlands competed for sixth place. The shares of these seven countries and Russia in world exports and imports changed as shown in Table I. The disparity between the share of a country in world exports and imports reflects its position in international exchange of services (invisible exports and imports). Great Britain used to offset its import balance by earnings of its marine and profits from capital invested abroad. The export balance of the United States in the 19th century served to defray the cost of foreign—mainly British—marine for carrying its trade with Europe, interest on foreign investment in the U.S., remittances of immigrants to their families,

etc. France and the Netherlands had an import balance for the same reasons as Great Britain. Germany used its export balance for building up investments abroad. The position of Russia, Belgium and Canada changed from year to year. Most of the countries in Central and South America, Asia and Africa had an import balance.

Later Changes.—Changes in the volume of world trade after World War I are reflected in the index of export quantum that shows variations in the value of exports of different regions and the norld as a whole after correction for changing prices. Using 1929 as the basis of comparison (1929=100), the index for the world as a whole was 7j in 1913, reached the peak in 1929, went down to 74–75 during the depression in 1932–33 and climbed back to 89 before the outbreak of World War II (1938). It could not be computed during World War II. but at the end of the war the volume of world trade was hardly higher than in 1513—despite the tremendous growth in population and production. The index of quantum of world trade returned to 110 by 1949 and continued to grow thereafter. By 1955, ior example, it had climbed to 164. While in the 2j-year period from 1913 to 1938 the volume of world trade lagged behind the gronth of industrial production in the norld, in the subsequent period world exports probably outran industrial output. The fairly smooth gronth of quantum of world exports after World War II conceals deep and lasting dislocations in the volume of exports of single areas. The change in export quantum of selected regions in comparison with the prewar level is shown in Table II.

In the early phase of postwar recovery in world trade, when the quantum of world exports had returned to the prewar level, the exports of western Europe were some 40% below this level. and those from the far eastern nonsterling area (including Japan)

Table III.—*Distribution of World Trade*

1952	42.7	20.2	8.9	15.5	12.7

dwindled to less than half the prewar volume. In world totals, however, these losses were offset by the tremendous growth of exports from the United States and Canada.

In the following years exports from the United States—including shipments under foreign economic and military aid programs—fluctuated around a level more than twice the prewar volume. By the mid-1950s. exports of continental western Europe doubled. and those of the United Kingdom almost doubled in comparison with 1938.

Less conspicuous were gains in Latin America and the middle east sterling area. The slow recovery of foreign trade in the far-eastern countries (in both sterling and nonsterling areas) was partly due to unsettled political conditions.

Geographic Distribution of World Trade.—In the latter part of the 19th century and after the turn of the century, before the outbreak of World War I. Europe (excluding Russia) accounted for roughly 50% of world exports and nearly 60% of imports nhile the rest of international trade was distributed in four almost equal parts: 12.5% of exports and 10% of imports was the share of the United States, and about as large were the shares of other countries of the western hemisphere (Canada and Latin America). Asia. and the rest of the world (including Russia). The exact figures—if they could be computed—would have shown some fluctuations from year to year. but the general pattern remained fairly stable and appears clearly in the available statistics for 1913. After the outbreak of World War I, the distribution of world trade changed as shown in Table III.

World trade statistics published by the United Nations and its specialized agencies such as the World bank (International Bank for Reconstruction and Development) and International Monetary fund abandoned the traditional grouping of countries by continent for another classification that better answers the needs of analysis of international balances of payments. The United Nations experts felt that the border between continents is less significant, from the viewpoint of world trade. than the distinction between dollar and nondollar areas in Latin America, or between sterling and nonsterling areas in the middle and far east, or between continental western Europe and the United Kingdom, and so forth. Thus. the following regions (not necessarily contiguous) are considered: North America (United States and Canada); Latin America—dollar area, nondollar area; continental western Europe; European overseas territories; other Europe (Spain. Finland and Yugoslavia): middle east (nonsterling area); sterling area—United Ringdom. Ireland and Iceland. Australia. New Zealand and Rhodesia-Tyasaland, far east (independent), middle east, other;

China; other far east.

Occasionally some of these groups are further subdivided, or two or three groups are brought together into a single region. The whole classification may seem rather complicated and confusing to a layman accustomed to the old grouping of countries by continent but it serves well its purpose to form trade areas on the basis of features most significant for international transactions, such as the type of currency and association with a definite economic bloc.

It is a question of terminology whether a classification of this type should be regarded as geographic distribution of world trade. According to this classification, world trade was divided in 1956 among three broad groups of nations as shown in Table IV. The surplus of exports from the dollar area were due to the export balance characteristic of the foreign trade of the United States. One-sided transactions of that country also explain the surplus of exports to the area of uncommitted currencies over the exports from this area.

TABLE IV.—Distribution of World Trade by Currency Areas
(In millions of U.S. dollars)

	Exported from	Exported to
World	95,028	95,028
Sterling area	21,785	21,961
Dollar area	28,944	22,201
Othercurrencies	44,229	50,866

Distribution of world trade among individual nations and their ranking by value of exports and imports is fairly stable: the same countries remain at the top of the list, the same retain their position as the big ten or twelve of the aorld trade. the same two or three dozen follow them. (*See* Table V.) The U.S.S.R. is excluded from Table V because of lack of information. It would probably rank somewhere in the second dozen of countries enumerated.

The geographic distribution of world trade can be shown graphically on a world map by indicating the value of exports of each country—or each area—by dots, each one representing a definite value of exports (*see* fig. 1). The dots are densely clustered in the United States and Canada and northwestern Europe and widely dispersed in the rest of the world. Moreover, the same two North Atlantic areas represent the largest concentration of economic activities and wealth in the world. It may be desirable, therefore, to compare the distribution of world trade with distribution of national incomes in the world. Such a comparison may be made by plotting the dots showing the export value of each country on a distorted map which shows each area on the scale of its national incomes (*see* fig. 2). On a map of this type world trade appears distributed over the world more evenly than on a conventional geographic map.

Export Rate.—A closer examination of the distorted map reveals that the dots are clustered more densely in Latin America, Africa and Malaya than in northwestern Europe while in the United States they are widely scattered. The density of dots on the distorted map of national income illustrates the ratio of the value of exports to income in the respective areas (as the density of dots representing the number of inhabitants in each area on a conventional map illustrates the rate of population per square mile). The export rate depends on the type of economy rather than the level of economic development of an area. It is particularly high in areas of specialized plantation economy, especially in colonial areas and former colonies. It is equally high in such

densely populated and economically developed countries as Belgium and the Netherlands. where it has been found that production for export is more advantageous than a broadly diversified economy.

Under more or less equal or similar conditions, a larger country has a better chance for developing a diversified economy than a smaller country. This explains the fact that comparatively small industrial countries such as the Netherlands, Belgium. Denmark. Switzerland, Sweden. Austria and Norway have a higher export rate than the United Kingdom, nest Germany and France. This also explains why. in export rate. Portugal ranks higher than Spain. Mexico higher than Brazil. Pakistan higher than India, and so forth. This same advantage of bigness and diversification of the economic system is the cause of the extremely low export rate of the Cnited States: the nation that outranks all other countries in value of exports has the lowest—or one of the lowest—export rates in the world.

Direction **of** World Trade.—Barter trade presumes an approximate equilibrium in the value of goods and services exchanged between two countries. Under conditions of a free world-wide flow of foreign trade, such equilibrium is not necessary: each country may have an import balance in transactions with certain areas and export balance with others. Before World War I such multilateral exchange prevailed. This type of international trade was disrupted by the war. But the circular movement of goods was resumed in the 1920s, and by the end of the decade world trade essentially returned to the prewar pattern. The depression of the 1930s, followed by depreciation of currencies and drastic controls over imports and exchange rates, brought a profound disorganization of the world market. The conditions began to improve in the second half of the 1930s, but recovery was slow and world trade had not returned to normalcy when World War II broke out. During the war international—especially intercontinental—trade was carried out under control of the respective governments, largely in the form of barter agreements. The first attempts to restore international exchange after the war followed the same pattern. A cumbersome machinery of governmental controls and bilateral agreements had replaced the free flow of goods. The joint efforts of the Cnited Nations and its specialized agencies, the Organization for European Cooperation, European council and other international organizations succeeded in restoring relative freedom of world trade. The General Agreement on Tariff and Trade (G.A.T.T.) and trade policies of individual countries (such as those introduced under the Trade Agreement acts in the United States) resulted in substantial reductions of tariff barriers. Certain nontariff restrictions. likewise, were partly repealed, partly released. By 1954 a new pattern of direction of world trade emerged from the chaos of the early post-war years. The new direction of international trade was largely determined by the changed political and economic conditions, and current UN statistics of direction of world trade emphasized the existence of the new currency blocs—dollar and nondollar areas in Latin America, sterling and nonsterling areas in the middle and far east, etc Adjusted for comparability, these statistical series differ slightly from the original data of the respective countries, and their use by general readers is made difficult by the somewhat complicated classification of countries Table VI shows, in a condensed and simplified form, the direction of exports and provenance of imports of the 15 countries with the largest foreign trade in 1954. It suggests that more than half the imports of the United States come from Canada and Latin America and the same area absorbs some 40% of the U.S. exports. Inversely, the United States is the main source of supply and the main outlet for exports of Canada. Likewise, the foreign trade of Brazil moves mainly within the limits of the western hemisphere.

On the contrary, the foreign trade of Belgium, the Netherlands, Sweden and Switzerland rests mainly on exchange with other European countries, including the United Kingdom. Italy is a border case—it obtains nearly half of imported merchandise from European markets and sells more than half of goods it exports within Europe. The direction of foreign trade of France is affected by extensive exchange with its possessions in North Africa.

The United Kingdom is the only country in Europe whose foreign trade is not concentrated on European markets and its own colonies but is spread all over the world, including the middle east, Asia, Africa and Oceania.

Australia's foreign trade is strongly tied with the United Kingdom and continental Europe. Japan depends mainly on the United

States and the mainland of Asia for both imports and exports. India's main sources of imports and main outlets for exports are United Kingdom, Europe and Asia. Malaya largely depends on Asia for imports but exports its products to all parts of the world.

Apart from the minor short-run fluctuations caused by changes in prices and local business conditions and international competition on the disputed markets, the general pattern in direction of world trade is fairly stable. It can be represented on a world map by marking each country according to the prevailing direction of its exports (*see* fig. 3A). For this purpose, the shortcoming of a conventional map is that it shows the densely populated areas with highly developed foreign trade on the same scale as areas of little significance for world trade. It appears preferable, therefore, to use as the basis of comparison a distorted map on which each area is plotted on the scale of its exports (*see* fig. 3B).

Composition of World Trade.— Until relatively recently each country used its own classification in recording imported and exported goods. The only universally accepted classification was a rough distinction between: (1) foodstuffs and beverages; (2) crude and partly processed materials; and (3) manufactured goods. More detailed world-wide statistics of composition of international trade were made possible by the Standard International Trade Classification, mentioned previously, which the UN Economic and Social council developed. This classification is purely empirical in the sense that it rests on the classifications used in individual countries rather than on theoretical principles. It distinguishes 570 kinds of merchandise distributed in 150 groups which represent those types of commodities for which data are normally sought. The groups are further consolidated in 10 sections which are supposed to correspond to broad economic categories. Not all of these sections are equally meaningful for the purpose of economic analysis. But the groups of the S.I.T.C. were widely accepted, in some cases with minor modifications, by leading countries outside the Soviet sphere of influence

The UN *Commodity Trade Statistics* for 1954 covered 21 countries that controlled approximately two thirds of world trade. The reports of individual countries permitted expansion of this survey on approximately 90% of world imports, making possible estimates of the relative role of certain groups of commodities in international trade (*see* Table VII).

Under machinery in Table VII are three groups of the S.I.T.C.: machinery not elsewhere classified, metal-working machinery and office machinery. It does not include electrical machinery, power machinery, agricultural machinery, tractors, motor vehicles, etc. Machinery and transportation equipment together (including ships and aircraft) represented a value of nearly $10,000,000,000 in world imports in 1954.

Next are crude petroleum and petroleum products including gasoline and lubricating oils. Aggregate value of both groups. more than $5,500,000,000, dwarfs the value of coal and coke in world trade.

Coffee is fourth by far outranking all other vegetable foodstuffs. Indeed, the value of coffee in world trade is about double that of wheat and is close to the value of all cereals.

The group of iron and steel that comes next in Table *VII* is somewhat deceiving because of the difference in classification used in different countries. It includes some but not all fabricated articles made of iron and steel.

Reservation is also necessary in considering the groups of road motor vehicles. It consists mainly of motor cars, trucks and buses. Motorcycles are included in some countries but counted together with bicycles in others.

BY COURTESY OF W. S. WOYTINSKY AND THE TWENTIETH CENTURY FUND. CONVENTIONAL MAP PROJECTION BY E. RAISZ

FIG. 3.— CONVENTIONAL (TOP) AND DISTORTED (BOTTOM) MAPS SHOWING THE DISTRIBUTION OF NATIONS IN TERMS OF THE PREVAILING DIRECTION OF EXPORTS. DISTORTED MAP (B) SHOWS VALUE OF EXPORTS. THE UNITED KINGDOM IS NOT INCLUDED BECAUSE THE DIRECTION OF ITS EXPORTS IS WORLD-WIDE

In the seventh and eighth places are the natural fibres, cotton and wool. They are followed by fabrics, a fairly heterogeneous group that consists mainly of cotton and woolen fabrics but also includes fabrics of silk and rayon and some other textiles (but not all of them). The value of all textiles—fibres, yarn and fabrics including minor groups that are not listed above among the 1954 leading commodities in world imports—was probably close to $8,000,000,000.

The tenth among the big ten in world trade is wood, round and manufactured, but excluding pulp, plywood and such articles as furniture, etc.

Among other leading articles—with import value ranging between 1,000,000,000 and 1,500,000,000 U.S. dollars in 1955—are four groups of foodstuffs (fruits and nuts; wheat, sugar and meat), three groups of raw materials (coal, copper and nonferrous ores) and three groups of manufactured goods (electric machinery, paper and paperboard and manufactured metal not elsewhere classified).

FIG. 4.— COUNTRIES AND GEOGRAPHICAL AREAS WITH A NET EXPORT OF FABRICATED ARTICLES SHOWN IN BLACK ON A CONVENTIONAL MAP (TOP) AND ON A DISTORTED MAP (BOTTOM) SHOWING VALUE OF EXPORTS

They are followed by an array of other commodities: pulp and rubber; tobacco and beverages; oilseeds and minerals; dairy products; yarn; cocoa; and tea, etc.

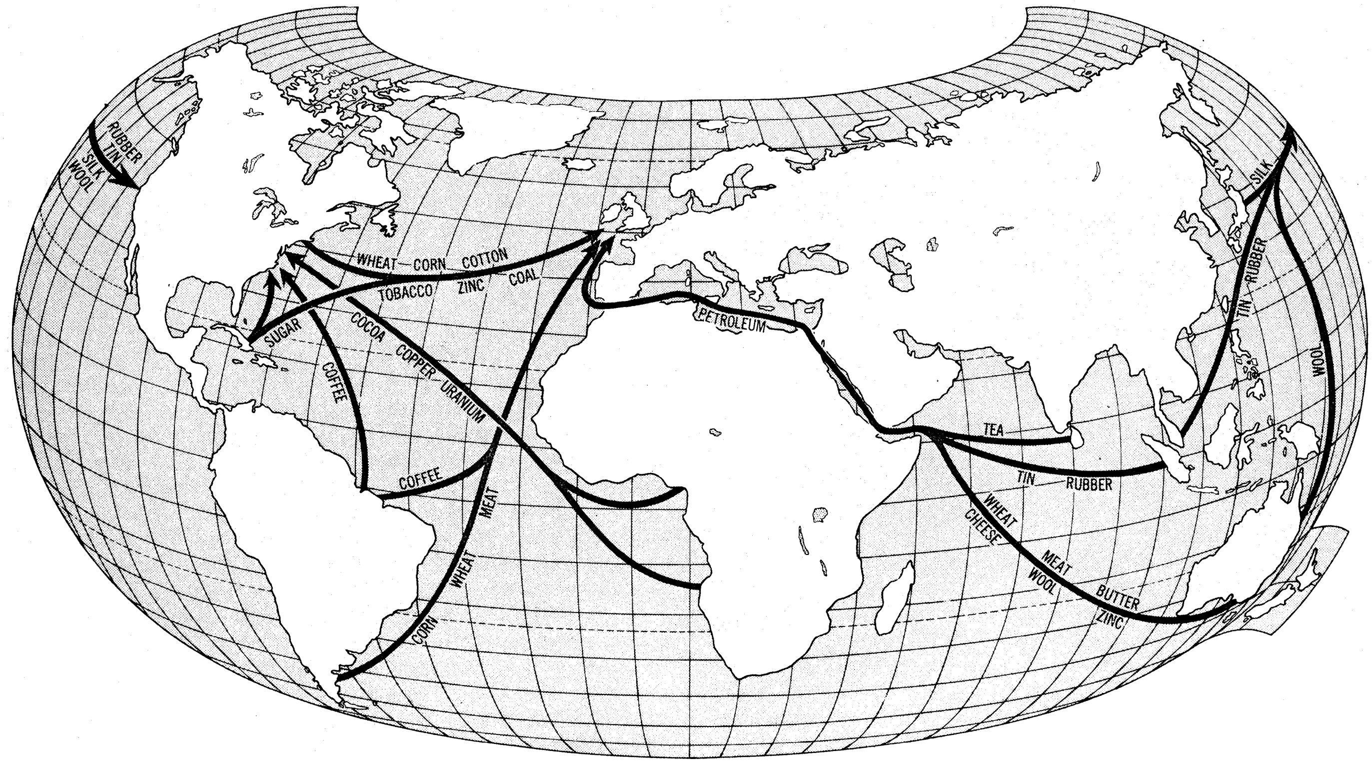
All in all, foodstuffs including sugar, tea, coffee and cocoa, spices, beverages and tobacco account for approximately 25% of the value of world imports; fuels, ores and metals, for another 25%; industrial raw materials other than fuels, ores and metals (*i.e.,* wood, fibres, oilseeds and crude minerals) represent 20% of the value; the finished goods, the remaining 30%.

Patterns of Foreign Trade.— The composition of exports and imports of each country forms what may be described as the pattern of its foreign trade. Seven patterns may be distinguished:

(1) Exchange of Foodstuffs for Fabricated Articles.—This pattern is characteristic of primarily agricultural areas on different levels of economic development. Some of them are colonies or former colonies (such as Algeria or Gold Coast [Ghana]); others, independent countries (Spain and Ireland; Cuba, Colombia, Brazil and Argentina; New Zealand).

(2) Exchange of Foodstuffs for Other *Foodstuffs* and Fabricated Articles.—This is characteristic of countries with highly specialized agriculture (*e.g.,* Denmark, Ceylon).

(3) Exchange of Raw Materials for Fabricated Articles.—This is



BY COURTESY OF W. S. WOYTINSKY AND THE TWENTIETH CENTURY FUND; MAP PROJECTION BY E. RAISZ

FIG. 5.— MAIN ROUTES OF PRINCIPAL FOODSTUFFS AND RAW MATERIALS IN INTERNATIONAL TRADE

characteristic of two groups of countries: those with agriculture specialized on production of fibres such as cotton or jute (Egypt, India and Pakistan) and those with abundant mineral resources (Venezuela, Peru, Chile, Saudi Arabia, Iran, Indonesia, Malaya, Belgian Congo, Union of South Africa and others). This group includes also the areas exporting wood (Norway. Sweden and Finland).

(4) Exchange *of Foodstuffs* and ***Raw*** *Materials for* Fabricated *Articles.*—This is the pattern of mainly agricultural areas exporting foodstuffs, for example wheat or corn, and such materials as oilseeds, cotton, wool (Rumania, Bulgaria, Yugoslavia; Morocco and Tunisia; Australia).

(5) Exchange of Fabricated Articles for Raw Materials.—This is a typical pattern of foreign trade of industrially developed countries with an agriculture powerful enough to provide their own population with food (United States, France) or with a greater deficiency in raw materials than in foodstuffs (western Germany, Belgium, Italy, Japan).

(6) Exchange *of* Fabricated Articles *for* Foodstuffs and Raw Ma-

FIG 6 — MAIN ROUTES OF ENGINEERING PRODUCTS IN INTERNATIONAL TRADE. PRODUCTS INCLUDED ARE MACHINERY, MEANS OF TRANSPORTATION, STRUCTURAL STEEL. ETC. EACH OPEN DOT REPRESENTS $100,000,000 OF EXPORTS. EACH SOLID DOT $100,000,000 OF IMPORTS. 1954–55 *terials.*—The outstanding example of this pattern of foreign trade is the United Kingdom.

(7) *Other and Shifting Patterns.*— In certain countries, exports and imports are highly diversified (the Netherlands, Austria, Switzerland). Only a few countries have a net export of fabricated articles (patterns 5 and 6 and some of the areas in the 7th group). On a conventional world map they appear as three spots—two at the shores of the North Atlantic and the third—Japan—in the north Pacific ocedn (*see* fig. 4A). The picture is different on a distorted map that shows countries on the scale of their exports on such a map the three areas are far larger than all the rest of the world; indeed, they control about three-fourths of world trade (*see* fig. 4B)

Principal Routes of World Trade.— The commodity trade statistics of the United Nations cast light on the pattern of trade routes (*q.v.*) that cross the seven seas of the world. Each commodity has its own route, usually with a limited number of exporting areas and a much larger number of importing markets. Thus, wheat moves from the surplus areas in North America and Australia to northwestern Europe and India; sugar, from the Caribbeans to North America and western Europe; tobacco, (1) from the United States. Egypt and Brazil to northwestern Europe, Japan, Canada and Australia; (2) from the United States, Brazil, India and the middle east to Europe, Japan and Australia and (3) from the Caribbeans and middle east to the United States; coffee, from Brazil to the United States and western Europe; tea, from Ceylon to Great Britain; rubber, from Indonesia and Malaya to North America and western Europe; and so on.

The principal routes of foodstuffs and raw materials in world trade are shown in' fig 5

The routes of fabricated articles form a still more intricate pattern. Industrially developed countries pay with fabricated articles for imported raw materials and foodstuffs and in addition exchange fabricated goods among themselves Such a double pattern is characteristic for example of the routes of the group of engineering products that contains structural steel. tools and machinery of all types and means of transportation, including railroad equipment, motor vehicles, ships and aircraft (*see* fig 6) *See* also COMMERCE, HISTORY OF; EXPORTS; IMPORTS; INTERNATIONAL PAYMENTS.

TRADE, PRIMITIVE. The importance of trade to' primitive peoples is seldom realized. Exchange of goods among them is certainly limited in extent; often only specified classes of objects are allowed to change hands, and many commodities are exempt from such traffic. as the land of the clan or tribe. Nevertheless trade; *i.e.*, a regular series of acts of exchange. is a distinct feature in the life of primitive peoples, even the lowest. who live by hunting and collecting forest products. The principle of reciprocal transfer of goods, of giving and taking, seems in fact to be deeprooted in human nature.

Trade has two aspects, intracommunal. between members of the same community, and extracommunal, between members of different communities. The latter is of more interest, especially since, by the widely accepted theory of Karl Bücher, those few primitive folk who have advanced beyond the pre-economic stage of existence are still in a state of closed household economy. Each little group is imagined as self-sufficient, its needs and products in equilibrium, and trade between them, being unnecessary, is therefore held to be absent. More adequate study, however, shows that this idea is quite erroneous.

Types of Trade.— Silent Trade.— Most spectacular is the institution variously described as the silent trade. "dumb barter" or depot trade. Mentioned by Herodotus. this method of exchange was practised by the Carthaginians in their traffic for gold with the African tribes beyond the Pillars of Hercules, and was noted by Fa Hien, Ibn Batuta and other early travelers. In the most general form of procedure one party goes to the customary spot. lays down goods and retires into the bush or to a distance. giving as a signal a call or a gong stroke. The other persons then come, lay down what they consider to be articles of equivalent value. and retreat in their turn. The first party then comes back and if satisfied with the bargain removes the newly deposited goods; if not, these are allowed to remain until suitable additions are made. The persons of the second party then take away the original wares and the transaction is concluded. Neither party holds any communication with the other. beyond giving the customary signal, hence the name of silent trade. This widespread institution was reported from such diverse regions as north Russia, Lapland, west Xfrica. Timor, Sumatra, India. Ceylon and north New Guinea. It is found especially where people of a fairly primitive type conduct habitual exchange with those of a somewhat higher culture. Thus the Akka pygmies obtain bananas in exchange for meat from neighboring agricultural tribes, and the Veddah obtain iron implements from Singhalese smiths in return for game. Elements of shyness and fear are obviously involved in this custom, which thus secures economic benefits for people who shun foreign contacts.

Gift Exchange.— This transaction takes the form of present and counterpresent often between host and guest. A good example is afforded by the Maori of Ken Zealand. Exchange was conducted quite in the manner of gift making; no bargaining upset the proceedings; such mas not tikn ("correct"). At the same time a strict system of reciprocity nas in force. by which the recipient of the gift was bound, as he valued his name and reputation. to make adequate repayment. This was expected by the donor. Such was the idea of *utu,* "equivalence," which ran through all Maori social life. But the recipient usually tried, if possible. to give back greater value than he received. not through generosity, but since his own prestige would thereby be enhanced. Even nhere the exchange was primarily a matter of securing necessaries of life, as food or garments, the desire to obtain fame by being liberal strove with the wish to have the economic advantage. These are the twin psychological factors lying at the root of every exchange of gifts.

Barter.— This consists in the direct transfer of goods against goods. Unlike the gift exchange, it implies agreement as to rates, with the possibility of haggling over quantities and values. A system of barter in certain commodities may co-exist with gift exchange in others of greater social import. as in the Trobriands, where, as described by Bronislaw Malinowski, the *Kula,* or exchange of valuable arm shells and necklaces is conducted along polite. strictly ceremonial lines, while the *gimwali,* the barter of fish for vegetables. is carried on with haggling as to size and quantity, and even acrimonious wrangling Barter in abstract form is often supposed to be typical of primitive peoples. But rarely in any native community is the rate of exchange for goods determined by purely economic considerations of supply and demand working on the principle of rational utility alone.

Buying and Selling.— This avoids the awkwardness of barter by the use of some medium of exchange. Much of what is often described as primitive money is wrongly so termed, but in various parts of Africa, for instance, cloth. iron, cowrie shells and salt do act as true currency. as also, apparently, do coconuts in the Nicobar islands. (See CURRENCY, PRIMITIVE.)

Occasions of trade on a large scale among primitive peoples are provided by expeditions and markets.

Trading Expeditions.— In some areas itinerant traders. as the Hausa hawkers in parts of Africa. play an important role in economic life. In others their place is taken by caravans, as those of the Arabs, regularly equipped and following recognized trade routes. Of great interest, again, as being accomplished by more primitive folk. are such group expeditions as those of the Dieri and other central Australian tribes, who will travel on foot for 400 to 500 mi. to procure red ochre and the pituri plant. Noteworthy also are the trading voyages, in unwieldy dugout canoes, of the people around the New Guinea coast, as the sailing trips of the Siassi of the North, the hiri of the Motu. in which pots are taken to the Papuan gulf and exchanged for sago, and the *Kula* of the Trobriands. the ceremonial exchange of ornaments.

Primitive Markets.— These are of varied kind and wide distribution. Their great home is Africa. but they have also been described from Guiana, old Mexico and Peru, Hawaii and various Melanesian areas. A typical example at either end of the scale will serve for illustration. The inhabitants of certain small islets off the coast of Malaita, Solomon Islands, barter fish with those of the mainland for vegetables and pigs. Almost every day, at times arranged beforehand with the bush natives, the islanders resort in their canoes to recognized places on the beach. The men then stand guard with spears, while the actual bartering is done by the women, who, thus covered, advance slowly toward one another, produce in hand. Disputes at these markets are rare, though at other times the island natives cannot venture ashore without risk. In parts of Africa this institution is more imposing. Among the Akikuyu of the east. markets in a thickly populated district are no more than two-thirds of a mile apart, and are of great importance in the life of the people. They occur frequently in the week. but are so arranged as not to clash with others in the neighbourhood, so that a person may visit them all in turn About 9 o'clock in the morning the paths begin to fill with natives carrying loads of corn, firewood, beer or iron to exchange, and between 11 A.M. and 1 P.M. business is at its height, the concourse numbering perhaps 4,000–5,000 persons. Order is maintained by special officers and no weapons are allowed within the precincts. The main characteristics of a market as a mode of conducting trade are its set time and regular recurrence, the definite place of assembly and the regulations by which order is preserved.

Psychology of the Trading Process.—The motives behind primitive trade are many sided. The central factor is undoubtedly the desire for rational gain, for securing objects of economic utility otherwise unprocurable owing to variations in natural conditions or specialized skill. But the psychological background is more complex than this. Trade is often carried on in articles charged with great social and ceremonial meaning, as in ornaments, but of no direct practical interest. Moreover, the desire for renown and prestige is often a prominent element in the exchange, while the transaction itself may assist in cementing social bonds.

The value of goods, too, is determined by a complex set of factors. Even in the case of things apparently desired merely for their practical utility there is not such an objective standard of valuation as obtains in modern society; *i.e.,* personal factors enter much into the exchange. The extent to which emotional elements lie at the root of value is shown in the case of such objects as *tiki* and other greenstone ornaments of the Maori, heirlooms of great wealth and the principal articles of ceremonial exchange. Their worth lies in their historical association with dead chiefs and ancestors of renown, in their sacredness and importance as symbols of the tribal greatness rather than in their practical use for adornment.

Theory of Primitive Trade.—The principal types of trade in primitive culture were once regarded as successive products in evolutionary development. Modern research, however, tries to study each particular system of trade in its own cultural setting. The primitive market in its various forms, for instance, cannot be understood if conceived simply as an evolutionary sequence from the customs of silent trade or as a development from previous hostile relations or as the result of a recurring assemblage of people for religious or ceremonial purposes. It is explicable only as an institution which emerges in response to certain needs, and is conditioned by the natural situation and the social structure of the community which it serves. So also with primitive trade in general. It is more than a mere matter of economic trafficking on abstract principles of national advantage; it is a complex social mechanism linked to many aspects of native life. The true problem does not lie in theorizing about its historical or evolutionary origins but in disentangling the various social and psychological factors which together determine the form of the living institution.

TRADE BOARD: see MINIMUM WAGE.

TRADE CYCLE. The phrases trade cycle, business cycle and cyclical fluctuation of trade are all convenient methods of labeling the alternating upward and downward sweeps in the volume of business activity. The most obvious manifestation of the trade cycle is a fluctuation, extending over several years, in the level of prices, the level of money profits and the level of employment. In the United States business cycles have usually taken from three to five years to run their course. In European countries the cycles have been somewhat longer and less regular. See BUSINESS CYCLE.

TRADE FORECASTS: see ECONOMIC FORECAST.

TRADE-MARKS AND NAMES. A trade-mark is a device used by a business enterprise to identify its goods and distinguish them from those made or carried by others. It may consist of fancy words and descriptive words. of pictures, figures, letters, dress labels, business equipment, etc.. and a combination of all of them; it may be a business mark, a merchandise mark or a service mark; it may be a manufacturer or a dealer mark. It is called a private brand if the dealer purchases from one or several manufacturers and causes them to place upon the article a mark selected by him. The mark may be a collective and certification mark when it is a mark reserved by an organization for the use of its members; its purpose is like that of a guild mark (see below) to preserve certain standards of quality. Such marks are standardization marks where the goods of all members have uniform peculiarities of production. Finally grade marks may be distinguished from genuine trade-marks, but the distinction may disappear where the grade mark is apt and used to indicate origin.

Trade names and other symbols such as the appearance of goods are like trade-marks if they can be registered as such. Otherwise they can be protected only if the defendant's conduct is likely to lead to "passing off" (presenting deceptively) or, especially in the United States, if there is a violation under the doctrine of unfair competition.

According to historical development. economic trends and habits of consumers. the trade-mark functions as an indication of origin or ownership, as a guarantee of the quality of goods bearing the same mark and as an advertisement. The advertising function is much more substantial than the guarantee function and the function of indicating origin is an indispensable aid to the advertising function.

In medieval times marks designating ownership were an important device; they were not trade-marks but proprietary marks. They enabled authorities and especially the guilds to control the trade and their use was compulsory. Modern parallels are the branding of horses with a proprietary mark and having the distributor's mark blown upon bottles used for the distribution of milk and other products. In the guild economy the mark was a police mark. The gold- and silversmiths in France and the Italian states, the woolen and linen weavers in England, the hammersmiths in Austria and most of the guildsmen in Germany were compelled to use a mark to enforce the guild monopoly.

Acquisition and Infringement of Trade-marks.—The trade-mark laws of the world reflect, in principle, two basically different approaches with respect to the acquisition of trade-mark rights. In the one especially dominant in the Anglo-American law and in some Roman laws, trade-mark rights arise out of appropriation and use. and the exclusive right to a particular mark belongs to the one who first appropriates and uses it in connection with a particular business; registration. being merely declaratory of title to the mark, does not affect or perfect the trade-mark right. and though it does confer certain new rights to the mark, at the outset, it grants no greater right than would have been recognized at common law without registration. Therefore, in Great Britain and the United States a claim for trade-mark protection may be founded on the common-law right to a trade-mark arising out of priority of adoption and use and the right perfected by registration based upon use in commerce. In the other approach, especially dominant in Germany, Austria and the Nordic countries. the trade-mark right is premised upon registration; use is not a condition precedent, and in principle is not even necessary, to perfecting a trade-mark right.

The English common law of trade-marks practically commences with the first years of the 19th century. The use of trade-marks was indeed of far earlier date, for in 1742 Lord Hardwicke declared that "every particular trader had some particular mark or stamp." But in the very case in which Lord Hardwicke made that statement (*Blanchard* v. Hill, 2 Atkyns. 484) he refused to protect the "Great Mogul" stamp on cards, being apparently under the influence of the notion that the legal recognition of trade-marks uould involve the creation of a new species of monopoly. But although the actual law of trade-marks cannot be traced farther back than the beginning of the 19th century, Lord Eldon repeatedly granted injunctions to restrain one trader from fraudulently passing off his goods as those of another, and thus laid a foundation on which later law has been built up. It was decided by Lord Cottenham in 1838. in the leading case of Millington v. *Fox* (3 Mylne and Craig 338). that an injunction to restrain the infringement of a trade-mark could be obtained even though the defendant had acted in ignorance and without fraudulent intent. In the common law, on the other hand, fraud was an essential ingredient in the cause of action, and remained so until the fusion of law and equity by the Judicature acts in 1873.

The theory that there may be a property right in a trade-mark and that such property may be the basis for equitable relief was first propounded in *Millington* v. Fox (see above). Equity courts have since been more favourably inclined toward the concept of a property right in trade-marks, but the precise nature of the right is still a matter of great dispute. The principle obtained from Millington v. Fox was clearly announced in three cases decided by Lord Westbury, in 1863: (Edelsten v. Edelsten, 1 De G. J. & S. 185, 10 L. T. [N.S.] 780; Hall v. Barrows, 4 De G. J. & S. 150, 32 L. J. Ch. 548; Leather Cloth Co. v. American Leather Cloth Co., 4 De G. J. & S. 137); and reaffirmed in 1882 by Lord Blackburn (Singer Mfg Co. v. Loog, L. R. S. App. Cas. 15, 33). In fact, this principle was far from well established. In 1857 it was held "now settled law that there is no property whatever in a trade-mark." (Collins Co. v. Brown, 3 K. & J. 423). In 1896, Lord Herschell, in Reddaway v. *Banham* ([1896] A. C. 199, 209) questioned the accuracy of a statement that there is a property in the common-law trade-mark, though there was no doubt that some of the rights incident to property might attach thereto, especially if it was capable of no conceivable legitimate use except by the proprietor.

In the U.S. it was still problematic in the second half of the 20th century whether the courts would recognize a property right in a trade-mark. Influenced by the function of a trade-mark as a symbol of business, most courts held that a trade-mark is not property in the ordinary sense but only a word or symbol, the owner of which acquiring the right to prevent the goods to which the mark is applied from being confused with those of others. In fact the test of infringement has been distilled out of the three functions of the trade-mark — to identify the product and its origin, to guarantee the product's unchanged quality and to advertise the product. Injury to the mark in any of these capacities would suffice to constitute an infringement thereof.

If the trade-mark owner's goods are competitive with those of the infringer, a confusion created by the infringer's use of an identical or similar mark is a confusion of goods, which means that the buyer will be caused to believe that he is buying the plaintiff's products. If the goods are noncompeting and so kindred that the maker of one might naturally be assumed to be the maker of the other (*e.g.*, electric clocks and electric razors) the implication might be, in accordance with the ordinary industrial or commercial situation, that the trade-mark owner's business has been expanded so as to include the article made or sold by the infringer. The confusion evident in such a case is a confusion of business; the deceived customer here buys the infringer's product in the belief that it originates with the trade-mark owner or that it is in some way affiliated with his business. Here, of course, the infringer is trading upon and appropriating the trade-mark owner's established reputation. Noncompeting goods may also be those which are entirely different from each other (*e.g.*, jewelry and motion pictures). There is, in all probability, no confusion in these cases at all. Here the use of the identical or very similar trade-mark by the infringer results in the dilution of the distinctiveness of the original trade-mark. (Statutes and case law against infringement by dilution exist in the U.S., Germany and other countries but not in Great Britain.)

Registration of Trade-marks. — As noted above, in the common law of England trade-mark rights originated without any registration. The development of this common law, both in England and the United States, was slow and confused. The intangible values of trade-marks, as distinguished from the tangible values of money or a house, were perplexing to the average jurist, and it was, of course, extremely difficult to prove the existence and scope of such values in a court proceeding. The businessman of both countries demanded legislative action and statutes were enacted in England, the United States and Germany, then the coming industrial centre of Europe. The English Merchandise Marks act was enacted in 1862; in the United States the first Federal Trade-Mark act was passed in 1870; and in Germany the Law for the Protection of Marks was enacted in 1874. It is extremely interesting to compare these statutes, for they proceed upon and represent three essentially different theories of trade-mark registration.

The English Merchandise Marks act of 1862 was principally concerned with the criminal law and only few provisions affected the civil law of trade-marks. It was of little practical value. In 1875, the Trade-Marks Registration act established the present register of trade-marks and revealed the English theory of protection. To facilitate, or obviate the necessity for, proof of title by use and reputation, the fact of registration was deemed prima facie evidence of the registrant's right to the exclusive use of the trade-mark in connection with goods of the class for which it was registered and used; it further provided that after five years the fact of registration is conclusive evidence of such a right, if, of course, the trade-mark has remained upon the register and the proprietor of the mark has remained the owner of the good will of the business to which it referred. As a further inducement to registration, the act provided that after a certain date no action to prevent the infringement of any trade-mark as defined by the act could be instituted unless and until that trade-mark was registered in compliance therewith. This did not, of course, defeat the possibility of a suit under the doctrine of passing off to protect an unregistered trade-mark; see *Montgomery* v. Thompson [1891] A.C. 217, 8 R. P. C. 361 (Stone Ales). Though the later statutes, including the Trade-Marks act of 1905, which repeated the whole of the statutory civil law of trade-marks, and the Trade-Marks act of 1938, introduced several significant and valuable changes, they were guided by the same principles and were primarily designed to improve the registration proceeding. The only significant change represented a deviation from a time-honoured principle in the law of unfair competition. The act expressly allowed the assignment of a trade-mark without the good will of the business to which it referred. In principle, the English law of trade-mark registration allows the first user several years in which to proceed against a registered trade-mark which allegedly invaded his common-law right; nevertheless, under the English law, the statutory rights are supplementary and similar to the common-law rights.

In the United States, the law has an entirely different history. The first Federal Trade-Mark act of 1870, like the early English laws, was characterized as "an act to revise, consolidate and amend the Statutes relating to patents and copyrights." It provided for registration of trade-marks whether or not they were used in interstate or foreign commerce. Both this act and another providing criminal penalties for counterfeiting marks registered under the act of 1870 were declared unconstitutional in the now famous Trade-Mark cases, United States v. *Steffens,* 100 U.S. 82 (1879). Congressional power with respect to trade-marks, it was held. could be derived only from the commerce clause of the constitution and not from the patent and copyright clause empowering congress "to promote the progress of science and useful arts by securing for limited times to authors and inventors the exclusive right to their respective writings and discoveries." Congress could, therefore, legislate with respect to only those trade-marks used in interstate and foreign commerce.

In 1881 a new law provided for the registration of marks used in foreign commerce, but, strangely enough, not in interstate commerce or commerce with the Indian tribes. This act, apparently, satisfied the constitutional limitation. It presupposed the existence of a valid trade-mark which could be registered on compliance with the formal requirements, and, according to established U.S. theory, registration thereunder in no wise affected the nature or function of the mark. Edison v. Thomas *A. Edison, Jr.*, Chemical Co., 128 Fed. 1013 (C. C. D. Del. [1904]).

The act of Feb. 20, 1905 was the first comprehensive trade-mark statute. Predicated upon the theory that the ownership of a trade-mark is acquired by adoption and use, registration under the act merely affected procedural rights. The most important amendment thereto was the supplemental act of March 19, 1920, which extended the substantive rights conferred by the ten-year clause. This clause permitted the registration of marks used exclusively and in good faith for more than ten years prior to the passage of the act of 1905 even though they could not be registered thereunder, *e.g.,* secondary-meaning marks. The act of 1920 was primarily designed to protect American owners of such secondary-meaning marks in those foreign countries in which the registration was contingent upon proof of registration in the home country.

The new trade-mark act, the Lanham act, of July 5, 1946, which took effect July 5, 1947, was intended to place the old trade-mark act and its numerous amendments scattered throughout the United States statutes in one statute; to eliminate judicial obscurity created by the various conflicting and confusing interpretations; to simplify and liberalize registration and to make it legally more meaningful; to dispense with mere technical prohibitions; and to provide prompt and effective relief against infringement.

On the theory that the law of trade-marks, however its protection may be secured, is part of the law of unfair competition, a close connection follows between the common law and the statutory law, and even the superiority of the former over the latter. This the German experience amply demonstrates. The German Trade-Mark act of 1894, successor to the law of 1874, as amended, provided that registration and not prior use creates the trade-mark right. However, the statute itself granted an action against the infringement of an unregistered mark which has been vested with secondary meaning; the courts recognized the priority of secondary meaning over registration and thus held the common law of unfair competition superior to the statute.

With respect to the requirement of use as a condition precedent of registrability we can distinguish the following major systems: (1) the unconditional requirement of use (represented by the United States); (2) modification of the absolute requirement of use with respect to the initial time (represented by Great Britain and Canada); (3) a combination of use and registration as interrelated factors (France, Belgium and the Netherlands); (4) Registration as the sole requirement for the creation of rights (Germany, Austria and others).

Under the United States Lanham act, sec. 1, the applicant for registration must certify to the date of his first use of the mark in commerce or otherwise and must also certify that the mark is still in use in commerce. Furthermore, the Lanham act introduced a new technique under which inactive marks can be removed from the register. It further conditions the duration of registration upon the filing by the registrant of an affidavit within the sixth year following the date of registration, attesting to the fact that the mark is either still in use or that its nonuse is excusable because of special circumstances and not because of any intention to abandon the mark (sec. 8). Similarly, when a registrant after 20 years seeks the renewal of his registration he must file an affidavit stating that the mark is still in use in commerce (sec. 9). Nonuse of a mark for two consecutive years constitutes prima facie evidence of abandonment (sec. 45[a]). Nonuse may under certain circumstances be excused (*e.g.,* scarcity of materials, lack of demand, lack of funds, bankruptcy proceedings, reorganization of business, war, accident, etc.) The commissioner of patents, acting ex officio, is directed to cancel a registration after inexcusable nonuse for six years (sec. 8).

In Great Britain as in the United States, as a matter of principle, no trade-mark right can exist without use. The requirement of use, however, has been modified and there is even a possibility of registering reserve marks and, to a certain degree, defensive marks as well. (The Trade-Marks act of 1938 has materially changed sec. 37 of the act of 1905 which gave statutory effect to the decision *Batt* v. *Dunnett* [1899] A. C. 428; 16 R. P. C. 411. See Kerly's Law of Trade Marks and Trade Names, 7th ed., p. 275 [1951]).

At the request of any person aggrieved, a registered mark can be canceled for nonuse with respect to the goods for which it was supposed to be used according to the registration, but only if one of the following situations exists:

For nonuse for a period of less than five years, the mark can be canceled on proof that the registrant, at the time of the application for registration, had no intention of using the mark and in fact has not used it in good faith. If nonuse extends over a period of five years or more, the mark will be deemed abandoned, and registration will be canceled unless the registrant's inactivity "is shown to have been due to special circumstances in the trade and not to any intention not to use or to abandon the trademark." (Trade-Marks act of 1938, sec. 26.) The decision is at the discretion of the court and is not subject to appeal.

Defensive registration of marks is permitted for the invented word mark that has become so well known with respect to certain goods that its use in connection with other goods would be likely to cause confusion. (Trade-Marks act of 1938, sec. 26 [1] [a] [b].) It may be registered for such other goods even though the registrant has no intention to use in that connection (*e.g.,* Coca-Cola for bicycles; Kodak for knives).

Another requirement is the provision that the use of a mark by a so-called registered user (one who, on the basis of a commercial relationship, uses the mark with the permission of the owner), is considered legitimate use by the owner (sec. 28). If "permitted use" of a trade-mark by a third party is desired, the registered owner of the mark and the proposed "registered user" file a joint application, accompanied by a statement which details the proposed or existing relationship between them. As distinguished from the U.S. provision, the British statute does not require control over the nature and quality of the trade-marked goods or services, being satisfied with control over the permitted use.

The concept of use in the modern English law is somewhat broader than it is in the American law. The British act of 1905 closely paralleled the present U.S. law in requiring the mark to be "applied or attached" to the goods or used in an invoice or document accompanying the goods. Use in advertising alone was not sufficient. The act of 1938 (sec. 68 [2]) changed this requirement by electing the phrase "in relation to goods," thereby qualifying use of the mark in advertisements. It should also be noted that the circulation in Great Britain of advertisements of foreign produced goods can be relied upon only if the goods are, or are intended to be, dealt with in the United Kingdom.

The use of, or the intention to use, a mark must be "bona fide." (Trade-Marks act of 1938, sec. 26 [1] [a] [b].) "Bona fide use" or "bona fide intention" to use is synonymous not with honest use or intention but with genuine use or intention to use; *i.e.,* it cannot be pretended solely to obtain registration.

As distinguished from U.S. law, in the United Kingdom there is no cancellation of a mark ex parte or ex officio, nor is it necessary that continued use of the mark be established at certain intervals.

The Canadian law deserves special consideration. Under earlier laws (Trade-Mark & Design act of 1868 as amended in 1919, 1923, 1927, 1928; Unfair Competition act of 1932), use of the mark was a condition precedent of registrability. (Standard Brands v. Staley, Ex CR 615, 6 C. P. R. 27 [1946].) The new trade-marks act, Trade-Marks act of 1953, in effect since July 1, 1954, changed the law fundamentally and the Canadian trade-mark law became one of the best with respect to the requirement of use.

Under the new law, registration can be sought if the applicant merely intends to use the mark in the future ("proposed trade-mark"). (Trade-Marks act, sec. 16 [3].) The application can be processed up to allowance if it is accompanied by a simple statement that the applicant intends to use the mark or by the application of a registered user. (Trade-Marks act, sec. 29 [e].) Registration, however, will be allowed only after the applicant uses the mark and declares accordingly. (Trade-Marks act, sec. 39 [2].) This declaration must be filed within six months of notice from the registrar that the trade-mark is allowable. Protection against infringement will be granted after the registrar has declared the registration allowable.

Similar to U.S. law, the new Canadian trade-mark law authorizes the registrar to cancel the trade-mark because of nonuse or, at his discretion, to confine it to particular goods in connection with which it is used. This authority cannot be exercised until three years after the registration, and at that time any interested party can request an investigation with respect to the actual use of the mark.

Registers of trade-marks were established in Great Britain by the act of 1875 (sec. 1 and 7) and were continued under sec. 1 of the act of 1938. The validity of previous registrations is maintained by the third schedule to the act. The main register is kept at the patent office in London, other official records are also at Manchester, so far as the marks relate to textile goods, and at Sheffield, for trade-marks of metal goods registered by traders in Hallamshire or within six miles from it. The register is under the control of the comptroller general of patents, designs. and trade-marks who is in the act of 1938 referred to as the registrar. He is appointed by, and acts under the direction of the board of trade.

By the Trade-Marks acts of 1919, the register was divided into two parts, A and B. Under the act of 1938 the register continued to be thus divided (sec. 1 [2]) and was at all convenient times to be open to the inspection of the public. subject to certain regulations (sec. 1 [3]). In order to be registrable in part **A,** the trade-mark must consist of or contain at least one of the following essential particulars: (1) the name of a company, individual or firm, represented in a particular manner; (2) the signature of the applicant for registration or some predecessor in his business; (3) one or more invented words; (4) one or more words having no direct reference to the character or quality of the goods (descriptive) and not being in its ordinary signification a geographical name or surname; (5) any other distinctive mark; however, a name, signature or words other than such as fall within the descriptions in the foregoing sections (1 thru 4) shall not be registrable under the provisions of this paragraph (sec. 9 [1]) except upon evidence of its distinctiveness. (Distinctiveness means here that the mark has lost its primary meaning as a descriptive or geographical term or as a surname and has by reason of extensive use or advertising obtained as "secondary meaning" a genuine trade-mark significance).

In order to be registrable in part B of the register the mark, though not registrable in part A, must be capable of distinguishing the goods of the registrant from those of others. Originally part B mas designed to protect trade-marks in foreign markets by providing English trade-mark owners with the domestic registration they must show to obtain protection in foreign countries. This kind of registration has. however, declined in importance since an increasing number of countries have abandoned the requirement of proof of a foreign home registration. Xevertheless, it is apparent that registration in part B mill create a public record of first use, which becomes all-important if a registration is to be transferred from part B to part A.

In the United States registration of trade-marks rests upon legislation both of the federal government and the states. Many of the state statutes were primarily designed to protect particular industries, particular articles, labour and fraternal organizations or various forms of advertisement. The most important provisions provide penal sanctions for unlawful use, imitation and counterfeiting of trade-marks, names, labels, wrappers, bottles, boxes. etc., and for using false representations or other fraudulent means to procure registration. The penalties vary: some statutes declare trade-mark infringement a misdemeanor, while others only prescribe fines in varying amounts. State registration secures state jurisdiction over trade-mark infringement and subjects the infringer to the special penalties of state law. State registration is, moreover, of evidentiary value; it is probative of the adoption of the mark, constitutes prima facie evidence of ownership and gives notice to the public, thus denying the infringer the defense of ignorance of the trade-mark owner's right.

For revenue purposes. legislation making state registration mandatory has often been advocated and such bills have suggested that registration in a given state be the sole determinant of ownership. These proposals have been rejected. Federal registration alone is important The Lanham act, similar to the English law, provides for two registers. a principal and a supplemental register; they are like part A and part B of the English law.

The effect of the registration in Great Britain is different from that in the United States. True, the general object of the registration acts was not to create new rights in addition to the right in an unregistered common-law mark, but to regulate the use of, and the means of protecting, trade-marks. Their main effects, however, have been (1) to provide a new way in which title to a trade-mark may be acquired, namely by registration; (2) to simplify infrigement actions by making registration in part A evidence, and under certain circumstances. conclusive proof of title (sec. 4–7, 13, 46 of the 1938 act); and (3) to constitute registration — in general, a condition precedent to an action for infringement, for, as distinguished from the law of the U.S., no action lies for infringement of an unregistered trade-mark (sec. 2 of 1938 act).

Registration is for a period of seven years, but may be renewed from time to time (sec. 20); under sec. 28 of the 1905 act the period of registration was 14 years. A trade-mark may be removed from the register (1) at the instance of the registered owner or by some person entitled by law to act in his name (sec. 34); (2) by the tribunal on an application to rectify the register if the registration is a wrongful act; or (3) by the registrar on non-payment of renewal fees.

In the United States registration on the principal register is equal to knowledge (constructive notice) of registrant's claim of ownership and prima facie evidence of such ownership and of the validity of the registration. Such registration may, with certain exceptions, become incontestable and entitles the registrant to have the customs authorities stop the importation into the United States of any goods bearing an infringing trade-mark and to institute all actions based on the registration in the federal courts. Registration on the supplemental register has only this jurisdictional advantage.

Assignment of Trade-marks. — "In trade-mark matters," it has been said, "the place where the most numerous and the most costly mistakes are most frequently made is in the matter of transfers." (E. S. Rogers. *Good Will, Trade Marks and Unfair Trading,* Chicago: A. W. Shaw, 1914, p. 108). It appears, however, that these errors are the result of a judicial confusion that has characterized the law on transfers in almost all countries. Early doctrine had it that a trade-mark could be transferred only with the business to which it relates, and this was almost universally accepted. With modern commercial development, the failings of this doctrine became evident, but under the orthodox rule it was extremely difficult, if not impossible, to avoid injustice. At the Rome congress of the International Association for the Protection of Industrial Property, held in 1928, the problem was not resolved and the demand for change continued. It became increasingly obvious that a more liberal approach would be more consistent with justice. and the demand for it grew more insistent. In England the law underwent a drastic change in 1938. According to sec. 22 (1) a registered trade-mark is assignable "either in connection with the goodwill of a business or not." This provision is subject to the limitation that no assignment shall be allowed if it is likely to deceive the public or cause confusion. Moreover, sec. 28 of the 1938 act provides for the entry of a "registered user" of a trade-mark. Where it is desired to provide for the "permitted use" of a trade-mark by a third party, the registered owner and the proposed permitted user may be registered if the owner of the mark has control over the manner of use of the mark by the registered user and the register is satisfied that the use of the mark by the registered user is not contrary to the public interest.

In the United States the Lanham act did not go as far as the English revision of the old lam and was adopted only after much compromise. The new sec. 10 made only the following changes. The good will of an entire business in connection with which the mark is used need no longer be assigned with the mark. It is now permitted to assign along with the mark only so much of the good will of the business as is connected with the use of and is symbolized by the mark. If an assignee uses the mark or permits it to be used in a manner that misrepresents the source of the goods or services in connection with which the mark is used, the registration will be open to cancellation proceedings. If the parties are "related companies," within the meaning of sec. 45 of the Lanham act, which means that one controls the other in respect of the nature and quality of the goods or services in connection with which the mark is used, both companies may be registered and the legitimate use of the mark by one "shall inure to the benefit" of the other. (Sec. 5 of the Lanham act.) Thus the necessity for an assignment may in many situations be deemed eliminated by this section.

Loss of Determination of Trade-mark Rights.—The right of the trade-mark owner to the exclusive use of the mark in connection with the goods of the kind in respect of which the right existed is terminated or lost: (1) When the mark ceases to be distinctive, which may happen when the owner has used the mark as the name of the goods he deals in, and the trade or the consuming public adopts the mark as the name, to the effect that the mark has become generic and *publici* juris (*e.g.*, linoleum, maizena). (2) When a mark has been assigned without the good will of a business, the assignment shall not take effect until certain requirements (see sec. 22 [7]) have been satisfied, *e.g.*, the assignee must, not later than the expiration of six months from the date of the assignment or within an extended period, apply to the registrar for directions with respect to the advertisement of the assignment. If the assignee fails to do so the registration becomes invalid. (3) When the owner has abandoned the mark. A trade-mark owner may abandon his right, or, more correctly, forfeit his right by abandonment. In other words, he consciously transfers or surrenders his claim to the mark by consenting to its use by others. He may be stopped from challenging the use of his mark by another if, because of his laches, *i.e.*, failure to voice timely objection, the junior user developed a trade-mark in the belief that his use was unobjectionable. The latter may have been unaware of the trade-mark owner's right, or may have reasonably assumed that the trade-mark owner's failure to protest connoted acquiescence. Mere lapse of time or mere disuse does not establish abandonment; it is necessary to show not only acts indicating a practical abandonment, but an actual intent to abandon. Involuntary disuse, *e.g.*, because of scarcity of raw materials, lack of demand or of funds, bankruptcy, war, fire, etc., does not constitute abandonment. Under sec. 26 of the 1938 act nonuse for five years in connection with any goods for which the mark is registered may be a cause for removal of the mark from the register and in effect will be treated as an abandonment of the mark unless such nonuse "is shown to be due to special circumstances in the trade and not to any intention not to use or to abandon the trademark." (4) When the owner has forfeited his right to be protected against infringement by using the mark deceptively or in a fraudulent trade.

International Arrangements.—Many treaties exist by which the United Kingdom agreed to give to the subjects of other countries the same right of protection, in respect of their trade-marks, as it gave to its own subjects. Sec. 2 of the 1938 act restraining actions against infringement of unregistered trade-marks applies to the trade-marks of foreigners and therefore actions for infringement could not be brought by a foreigner without his trade-mark being registered in England. A foreigner, or any resident in a British possession may obtain registration under sec. 17 of the 1938 act. The United Kingdom and the United States are parties to the International Convention for the Protection of Industrial Property, founded in Paris on March 20, 1883, revised in 1900, 1911, 1925 and 1934. The provisions of the convention pertain to patents, utility models, industrial designs, trade-mark and other trade designations and unfair competition, and are designed to assure the nationals of the member nations a certain modicum of international protection.

Neither Great Britain nor the United States has, however, acceded to the two Madrid arrangements of 1891, one of which is for the international registration of trade-marks and the other for the repression of false indications of origin.

TRADE ORGANIZATION. Whenever businessmen have been reasonably free to ply their trade, they have associated themselves together in commercial and industrial organizations of varied character and purpose. The gradation in types of organization, membership requirements, functions, activities, size, complexity of tasks performed. geographical coverage, influence and controls exercised is infinite. It varies imperceptibly from the local, sporadic informal meeting to the compactly organized national peak associations or *Spitzenverbände* that in many countries have wielded major influence on public policy and have controlled their membership through legal, financial or other sanctions implemented by the compulsory powers of government.

Three major types of trade organizations stand out: (1) The oldest and most widespread are the chambers of commerce which in commercial nations substantially match in coverage the important units of political power, national, state or provincial, and local. (2) The most important in their impact upon prices, sales, output and technology are frequently the associations of manufacturers and traders organized according to industries or products. (3) Most varied are those in the miscellaneous category of associations, the technical and research institutes, the professional organizations, the scientific bodies. the better business bureaus, the credit and cost bureaus. traffic associations, labour unions, farmers' organizations, producer and consumer co-operatives, etc.

Chambers of Commerce.—Known also by such names as commercial associations, boards of trade, development associations, prosperity boards, community leagues and the like, chambers of commerce are voluntary organizations embracing firms, public officials, professional men and public-spirited citizens of a locality or area. They are not only interested in publicizing, promoting and developing commercial, industrial and civic opportunities but also seek to improve community schools, streets, housing, public works, fire and police protection, parks. playgrounds, recreational and tourist facilities, etc.

International Chamber of Commerce.—Trade associations at times provide the basic instrumentality through which international industrial agreements are negotiated. They frequently engage in international activities such as serving in a consultative capacity to the United Nations Economic and Social council or having meetings with trade associations of similar interests in other countries. Indeed, several trade unions and trade associations bear the name "international" merely because they have members in as few as two countries; *e.g.*, the United States and Canada.

But the one organization comprehensively international in scope and most appropriately so named is the International Chamber of Commerce. Founded in 1919, it is a world federation of business organizations, business firms and businessmen. It frequently "acts as spokesman of the business community in the international field and presents the business point of view to governments and to world public opinion." It was correspondingly granted the highest consultative status with the Economic and Social council of the United Nations, that of category **A.** Its national committees "undertake appropriate action as regards their own governments." Its working committees and commissions, composed of qualified experts and expert business executives, look for practical solutions to problems in such fields as commercial and financial relations, production and distribution. transport and communications, and law and commercial practice. In addition to publishing quarterly a magazine called World Trade, it operates a court of arbitration which provides conciliation and arbitration facilities for the settlement of commercial disputes for members of disparate nationalities. In about 87% of the cases, on the average, its awards are accepted and executed.

Trade Associations.—Trade associations usually limit their membership to business firms engaged in a particular branch of industry, trade or service enterprise. Moreover, they rarely extend their activities beyond national boundaries. Indeed, in many cases a substantial portion of their effort is devoted to measures, legislative or associational, to keep foreign competition out, or to bring it satisfactorily under control.

In terms of function there are two main types of trade associations: (1) those which confine themselves to voicing the views of their members on matters of common interest; and (2) those which exercise some measure of control over their own members. The latter in many countries make extensive use of voluntary, voidable "live and let live" agreements for controlling prices, output and channels of distribution. In some instances trade association arrangements go beyond price and output stabilization and involve rationalization measures designed to control productive capacity.

In a few notable instances such trade association activities have been endorsed by government fiat with sanctions applicable not only to recalcitrant members but even to nonmembers.

The overwhelming majority of trade associations are of the first type. They prefer self-government of industry by consent rather than coercion. They avoid any attempts to stifle competition or to bar new entrants by means other than suasion and full information. Thereby they gain the advantages of good will, elasticity of operations and maximum possible membership.

Other Types of Associations. — The functions performed by miscellaneous trade associations organized on a voluntary basis are numerous According to a trade association survey by the Temporary National Economic committee, the activities most frequently reported by trade associations in 1941 as of major importance were (in order of rank): influencing governmental bodies, especially making representations concerning tariffs, taxes and other matters before administrative, executive and legislative groups; trade promotion. product advertising, commercial research and market development; standardization and simplification of nomenclature, product lines, specifications, quality and performance; holding of annual conventions and other meetings; propagation of accepted trade practices and elimination of unfair competition; collection and dissemination of trade information and statistics by means of bulletins. periodicals, handbooks and trade directories; education of members in employer-employee relations and techniques; issuance of special research monographs and statistical studies; technical assistance; public and consumer education including demonstrations. displays, exhibits, clinics. etc.; accounting and auditing aid, including cost estimating, inventory control, evaluation schedules and utilization of uniform accounting manuals; credit service; traffic and transportation assistance including provision of freight handbooks, routing information, trade customs, etc.; collecting and spreading information on members' prices and bids including open price filing with or without waiting period; commercial arbitration facilities; bill collection assistance; and information with respect to patents, trade-marks, designs and styles.

UNITED STATES

Chambers of Commerce. — The oldest chamber of commerce in the United States is that of the state of New York, formed in 1768 According to its charter. dated 1770, its object was "to carry into execution, encourage and promote by just and lawful ways and means such measures as will tend to promote and extend just and lawful commerce." The first city chamber mas formed in 1773 in Charleston, S.C.

The Chamber of Commerce of the United States. "a national federation working for good citizenship, good government and good business." was founded in 1912. In the mid-19 jos its membership comprised 21.000 business firms including more than 2,700 affiliated local chambers of commerce and approximately 450 local and national trade associations. It made the claim that directly or indirectly about 1.500,000 businessmen mere members. Its various departments provided information and advice on all items of controversy betneen business and government, notably regulatory measures, expenditures, tariffs, taxes. labour-management relations, etc. Its monthly magazine. *Nation's, Business,* enjoyed a large circulation as did its research publications, committee reports, special bulletins and annual booklet on policies advocated by it.

U.S chambers of commerce were established in several large foreign cities, notably London, Paris, Rome, Rio de Janeiro, Mexico City and other important commercial centres abroad. Their range of operations and effectiveness have varied with the regulatory measures imposed upon foreign commerce. Barriers to international trade mushroomed everywhere during the depression of the 1930s. They were multiplied by autarchic totalitarian regimes. In the U.S., they were continued during World War II by a variety of agencies including the Combined Raw Materials board, the War Food administration and agencies of the Office of Economic Warfare.

Despite the U S. reciprocal trade agreements program the barriers persisted after the mar because of changing currency and commodity control arrangements fostered by such forces as rising nationalism, the dollar shortage, austerity programs, restrictions on trade with countries beyond the "iron curtain" and military security measures. But by the mid-1950s in accordance with the provisions of the Marshall plan, re-enforced by ensuing U.S. foreign assistance programs, by the Schuman plan, and by numerous currency stabilization and trade liberalization measures taken by west Germany and other noncommunist members of the United Nations, such barriers to trade had been substantially reduced.

In addition there mere about 30 foreign chambers of commerce in the United States in the mid-1950s of which the largest, the French, founded in 1896, had approximately joo members.

Trade Associations. — Although several trade associations of modern character were founded prior to the Civil War, notably the National Association of Cotton Manufacturers in 1854 and the American Iron and Steel institute in 1855, they did not become common until the 1870s and 1880s.

The name institute instead of association is frequently used by trade organizations primarily engaged in technical tasks and headed by a career official with a contract running for three to five years; *e.g.,* the Cotton Textile institute or the Coal Mining Institute of America. It may also indicate an independent or subsidiary association engaged principally in educational services as, for example, the American Institute of Banking created in 1900 by the American Bankers association to conduct classes for employees and junior officers.

Many of the early associations were short-lived. Some of them were interested in price-fixing, in agreements to limit or divide output or sales territory or in arrangements to apportion profits. With the passage of the Sherman Anti-Trust act in 1890 and the advent of the holding company, the combine, the Gary dinners, (dinners. attended by steel executives, held at Judge Elbert H. Gary's home in New York, N.Y., from 1903 to about 1912; on such occasions economic conditions in the steel industry were discussed, and stabilization of steel prices ensued), etc., the trade association changed its focus to co-operation in product standardization, market research, statistical compilation, united lobbying for tariffs and other governmental aids, together with unified opposition against proposals considered directly or indirectly detrimental to the trade.

In the Standard Oil and tobacco cases of 1911, the supreme court held that only unreasonable restraints of trade were illegal. Certain trade association promoters, notably A. J. Eddy in his book *The New Competition,* published in 1912, devised an open-price scheme tailored to fit the new situation: Market information and statistics on production, sales prices, costs, inventories, bids, unfilled orders, etc., nere sent to the trade association and summarized there in the form of totals or averages which were published by the association. by its trade journal, and later by the department of commerce in its monthly *Survey* of *Current Business.* Thus members could compare their own operations with that of the trade.

By this type of co-operative competition, purposeless market instabilities resulting from ignorance were eliminated, an advantage promptly seized upon by the Bridge Builders society in the iron and steel industry in 1911, by the Yellow Pine association in 1912. and subsequently by many others.

Because of the active encouragement of the War Industries board during World War I, the number of trade associations increased from 800 in 1914 to 2.000 in 1919. During the next decade the role of fostering the associations was taken over by the department of commerce under Secy. Herbert Hoover and by the Federal Trade commission, especially through the technique of the fair trade practice conference.

With the passage of the National Industrial Recovery act in 1933, many trade association executives became code authorities. Fair trade practice codes written for the most part by trade association committees acquired the force of law. As a result their numbers grew in two years by more than a third. Despite the setback that came in 1935 when the act was outlawed by the supreme court their numbers increased greatly so that by 1938 there were about 1,000 national and trade associations and about 6,500 state and local associations.

Trade associations continued to grow during World War II exactly as they had during World War I. In 1956 the total number was estimated by the department of commerce to be close to 12,000, of which about 700 were regional in scope. 3,300 were state-wide and more than 7,000 were local. Even the American Trade Association Executives (ATAE) had more than 1,700 members and was putting out an imposing list of studies and publications. About 950 of these are executives for associations of manufacturers, from 300 to 400 for distributors and more than 100 for national retail groups.

In the metal products group there were. in addition to about 100 professional associations, about 450 trade associations. The largest, the National Automobile Dealers association, had 32.000 members. In the food and tobacco category the figure was 250 national, about 1,000 local and 60 professional organizations. In the textile, apparel and leather classification there were 280 national trade associations and 45 professional. In the lumber, furniture and paper industries the figures were 200 and 20, respectively.

In transport and public utilities there were about 100 national associations and 90 professional ones. The largest. the American Trucking associations. had 40.000 members, including 60 state and local associations. The Association of American Railroads had a staff of 625 handling such matters as tariffs, passenger and freight services. terminals, bridges, power supply, grade crossings, employee training, co-operative advertising and, of course, governmental relations.

In the chemical and rubber group about 100 national trade associations and 40 professional organizations were enumerated. chief among them, the Manufacturing Chemists' association with a staff of 35 to 40 persons. In the stone, clay and glass classification the figures were 100 and 20 respectively, one of the largest being the Portland Cement association which, with a staff of more than 500, for several years contested vigorously the Federal Trade commission proceedings against certain features of the basing point system.

Between 40 and 60 national trade associations and usually about 40 professional organizations uere listed in each of the following groups: printing and publishing, finance and real estate (including the National Association of Home Builders with 30,000 members disposed to co-operate with slum clearance and other government housing programs and the National Association of Real Estate Boards with 42.000 members, arch foe of rent and housing controls), advertising, insurance (the National Board of Fire Underwriters had a staff numbering more than 850 persons), petroleum, coal and gas, hotels and amusements (herein the Motion Picture Association of America with a staff of 150 and the Allied States Association of Motion Picture Exhibitors with about 5,000 theatres organized into 22 regional units).

Trade association activities have waxed and waned with governmental policy. After being supported by the War Industries board during World War I, they were set back when the supreme court ruled against the Hardwood Lumber Manufacturers association in 1921 and the Linseed Crushers' council in 1923. They recovered when the supreme court in 1925 marked out the permissible bounds of statistical, standardization and uniform cost accounting activities in the Maple Flooring Manufacturers association and Cement Manufacturers' Protective association cases.

At no time did trade associations enjoy as much leeway as the government permitted them to have under the National Recovery administration (NRA). They put into the codes of fair competition practically all the things they had wished to do for decades. Of the first 500 codes approved. 79% provided for practices tending to establish minimum prices and 72% prescribed uniform methods of cost accounting; 57% required open-price filing. many of them with a waiting or intimidation period; 45% fixed discount and credit terms; and 27% laid down basing point or other formula systems for handling delivered prices and freight charges. Those that complied were allowed to display the blue eagle emblem. Recalcitrants were punished. The codes, in short. gave the public a vivid, if brief, demonstration of monopolistic tendencies.

Governmental policy later swung toward vigorous enforcement of the antitrust laws. From June 1, 1935, to October 1, 1939, the Federal Trade commission and the department of justice brought more than 120 complaints or indictments against trade associations and secured convictions or consent decrees in all but three. During the next seven years the antitrust division initiated 100 additional suits involving trade associations. Not only were all forms of price-fixing, output allocation, market sharing, defensive combinations preventing free entry, and boycotts frowned upon, but the validity of antitrust prohibitions was asserted in new fields, notably in the cross-licensing of patents, in the use of uniform basing systems of price quotation, and in the activities of Webb-Pomerene associations.

National Association of Manufacturers.—The N.A.M., founded in 1895, had in the mid-1950s more than 20,000 member firms, or approximately 8% of all manufacturing establishments in the United States, employing about half of the industrial workers and producing more than half of total manufacturing output. Affiliated with the N.A.M. were about 200 local and national employers' associations having about 60,000 members. The purposes of the N.A.M. were stated to be threefold: (1) to develop and promote sound industrial practices; (2) to foster industrial trade both at home and abroad; and (3) to create favourable public and government support in matters relating to industrial interests.

During the period 1933 to 1941, the N.A.M. opposed as contrary to free enterprise 31 out of 38 major legislative enactments. The seven approved were: the Reconstruction Finance corporation loans to small business, the Housing Authority act making direct loans to business, the National Housing act of 1934, the Corporate Reorganization act (Chandler act) of 1938, the U.S. Housing act (Wagner-Steagall act) of 1937, the Miller-Tydings act and the 1939 reduction in capital gains tax and corporate surtax. In the post-World War II period the N.A.M. supported the termination of price controls and the passage of the Taft-Hartley law.

So far as federal fiscal policy is concerned, the N.A.M. almost from the date of its founding continuously urged balanced administrative federal and state budgets and substantial reductions in government expenditures. Internationally, while opposed to the Havana charter and the International Trade organization proposed therein as "in direct conflict with American principles of free competitive enterprise" it supported the European Recovery program, extension of multilateral trade, special protective measures for U.S. private capital invested abroad, removal of trade and travel barriers, free convertibility of currencies, elimination of quantitative trade restrictions and the abandonment of monopoly and cartel trade philosophy. It also advocated "reasonable effort to encourage international economic understanding and co-operation through the Economic and Social Council of the United Nations."

National Industrial Council.—The first predecessor of this organization was the Citizens' Industrial Association of America founded in 1903 to combat trade unionism. The second was the National Council of Industrial Defense founded in 1908 within the N.A.M., and renamed in 1919 the National Industrial Council. In 1918 the N.A.M. in conjunction with 18 national industrial associations organized the National Industrial Conference board (N.I.C.B.), a research agency which through the years issued a number of books, pamphlets and regular periodicals.

In 1936 the N.I.C. was reorganized and its members grouped into three classes. The first consisted of state industrial associations, carrying out on a state basis about the same program that the N.A.M. advocated nationally. The second class was employers' associations which had arisen in all the important manufacturing cities of the United States to present a locally united employer front to deal with trade unions in regard to wages, hours and conditions of labour. The third group was primarily national trade associations; *e.g.*, the National Metal Trades association.

Miscellaneous Associations.—Among the thousands of associations in the miscellaneous category appreciably affecting trade organization in the United States, only a few will be mentioned. There were at mid-20th century, for example, more than 100 general associations, such as the Cooperative League of the United States of America, a member of the International Co-operative alliance, which in the mid-1950s reported a membership of 100,000,000 families in 31 countries. Under the Cooperative league. six major national groups were reported. the Credit Union National association (14,152 credit unions, 7,000,000 members), the National Rural Electrical Cooperative association (1,906 R.E.A. co-ops, 4,000,000 members), the National Cooperatives, Inc., with 24 regional co-operative federations of wholesalers. the North American Student Cooperative league (300 campus co-ops, 50,000 members). and the National Cooperative-Mutual Housing association (50 co-op housing projects, 20,000 members).

Belonging in large part to these national groups there were in the mid-1950s more than 3,200 consumer retail co-operatives with 2,642,000 members, 779 service co-operatives uith 344,000 members. 3,330 farm-purchasing co-operatives with 3,100,000 members and about 6,650 farm marketing co-operatives with 4,400,000 members. There were in addition about 7,000 local building and loan associations, represented by the United States Savings and Loan league (see also CO-OPERATIVES).

Furthermore, in 1956 there were 98 better business bureau associations, the largest of which was the National Better Business bureau covering financial practices and national advertising. There were 65 commodity and stock exchanges, the oldest (1792) and the largest (1,300 employees and 1,375 members) being the New York Stock exchange. In addition, there were in the mid-1950s about 4,000 foundations, many of which such as the Battelle Memorial institute or the Mellon Institute of Industrial Research were engaged in business and technical research.

Farmers, too, were well-organized, there being about 55 farm organizations in the mid-1950s. The oldest, the National Grange, founded in 1867, had 7,200 local granges comprising roughly 860,000 members. The largest, the American Farm Bureau federation, founded in 1919, had about 2,600 county farm bureaus and represented more than 1,620,000 paid-up member families. Third in size was the National Farmers union. founded in 1902, with approximately 5,000 locals and 300,000 member families. Influencing the marketing of fruits, vegetables, nuts. sugar, livestock, etc., were such marketing organizations as the California Fruit Growers exchange with 14,500 members and 227 local affiliated organizations, the Hawaiian Sugar Planters association and the National Live Stock Producers association. (See also AGRICULTURAL ECONOMICS: *Agricultural* Co-operation.)

Influential, likewise, were the more than 200 labour associations, of which the oldest was the American Federation of Labor, founded in 1881. with a membership at mid-century of about 8,000,000 workers in 60,000–70,000 locals. Its chief publication was Labor's Monthly *Survey*. In 1935 about 40 national trade unions. including the steel and automobile unions, split off to form the Congress of Industrial Organizations. It reported a membership in 1951 of roughly 6,000,000 workers. Late in 1955 it merged with the AFL to form the AFL-CIO with about 15,000,000 members organized under five major departments: the Industrial Union Department, the Building and Construction Trades, the Railway Employees, the Metal Trades and Maritime departments. Their main house organ was the AFL-CIO *News*.

Most important among the unions outside the two large federations were the railway brotherhoods with more than 1,000,000 members, publishing the influential weekly newspaper Labor. Among other independent unions of national importance were the United Mine Workers of America, the International Ladies Garment Workers' union and the International Longshoremen's and Warehousemen's union (see also TRADE [LABOUR] UNIONS).

(T. J. K.)

THE UNITED KINGDOM AND THE BRITISH COMMONWEALTH

Chambers of Commerce.—The British chamber of commerce is a long-standing institution of an entirely independent and voluntary character having no support from government nor, indeed, even official recognition, apart from the provision that no chamber of commerce can be registered as such under the Companies acts if it pays any dividend to its members. The chamber of commerce should be distinguished from the chamber of trade whose province is rather retail trade (see also below). Although thus independent, and indeed often critical, of government policy, the relations of the chambers of commerce with government departments, especially the board of trade, have always been close, and grew closer in consultation and collaboration during World Wars I and II.

Interest in foreign trade stands out clearly in the provisions of the founding charters and in the typical activities of British chambers of commerce. The earliest ones were formed in Jersey in 1768 (the same year in which one was organized for the state of New York. as noted above), in Glasgow in 1783, in Dublin in 1785 and in Edinburgh in 1786. In 1794 the "Commercial Society" of Manchester was founded with the objects of obtaining increased safety for trade and more regular payments, and of co-operating jointly in all applications to government. After 1801 it ceased to hold meetings but was revived in 1820 as the Manchester Chamber of Commerce. Closely allied with it was the Manchester Importers and Exporters association. Other chambers were established at Belfast (1796), Birmingham (1813), Newcastle upon Tyne (1818), Liverpool (1851), Sheffield (18j7) and London (1881).

London Chamber of Commerce.—The London Chamber of Commerce is not only the largest but the most powerful chamber in the British commonwealth. In its direct membership are leaders of British overseas trade, and of manufacturing, merchandising, banking, insurance and shipping business; 46 affiliated associations are represented on the council.

The chamber's 57 trade sections are of two kinds. Some deal with a market or group of markets (*e.g.*, the Australian and New Zealand section, and the Anglo-German section), others with a commodity or trade (*e.g.*, the tobacco, bristle and the precious stone trade sections; the last has a laboratory). Eleven standing committees study such matters as transport, taxation and town planning. The London Court of Arbitration was formed in 1892 jointly with the corporation of London and consists of 12 representatives from each body; it does not itself hear cases but appoints qualified arbitrators to deal with disputes referred to it. The Commercial Education committee conducts examinations, awards certificates in commercial subjects and offers scholarships enabling students to study languages and commercial conditions abroad. The chamber's inquiry departments answer a great variety of questions from their members on day-to-day business problems, particularly in regard to import and export trade. In all, some 120,000 inquiries are dealt with each year, including many from overseas, seeking suppliers of U.K. goods.

The Association of British Chambers of Commerce was formed in 1860 to provide an organization capable of speaking for all British chambers of commerce in approaching the government on questions of common interest. Starting with only 16 chambers, by 1956 it had a membership of nearly 100 in the United Kingdom, and a number of British chambers overseas were also members. It thus forms the main national organ of commerce and as such is represented on the National Production Advisory Council on Industry (of uhich the chancellor of the exchequer is chairman), the British Productivity council and the Dollar Exports council. Thus, and by its continuous contact with the appropriate government departments. the association influences national trade policy, and also helps the government. The association is in close relationship with the British National committee of the International Chamber of Commerce, which has more than 20 chambers in the Cnited Kingdom as direct members and is the means of ensuring that the British point of view is advanced at the international level. (For the International Chamber see also above and separate article.)

Chambers of Commerce in the *Commonwealth*.—The earliest chamber of commerce in the colonies (after that of New York which as noted above was founded before the American Revolution) was the Commercial Exchange of Capetown, Cape Colony, founded in 1804 and renamed in 1861 the Capetown Chamber of Commerce. In the 1830s chambers were organized in British India—at Calcutta (1834), Bombay and Madras (1836) and Ceylon (1839). In 1840 chambers were formed in Australia (Adelaide) and Jamaica; in 1845 in Canada (Toronto).

National co-ordinating bodies exist in the principal British countries and there is also the Federation of Commonwealth and British Empire Chambers of Commerce, whose membership comprises 11 associations and 150 individual chambers. This federation came into being as a result of a series of congresses organized by the London Chamber of Commerce, the first being held in July 1885 at the time of the Colonial and Indian exhibition in London. Other congresses followed and by the time the seventh was held in Sydney they were accepted as triennial events. In 1911, to meet the wish for a more permanent link, the British Imperial Council of Commerce was formed, its name being changed to the Federation of Chambers of Commerce of the British Empire in 1926 and to the title given at the beginning of the paragraph in 1955. The constitution of the federation provides that the congresses shall be held alternately in London and elsewhere in the British commonwealth. The headquarters of the federation are at the offices of the London Chamber of Commerce and apart from congresses the work is carried on by a council to which every member chamber and association has the right to appoint a representative.

British *Chambers* of Commerce in Foreign *Countries* advise British firms concerned with the respective markets, assist British diplomatic and consular officers, and strive in general to promote British trade. They vary in membership, some being closed to non-British business representative~,others admitting them subject to varying conditions. Cp to World War II they flourished in all parts of the world, and were particularly strong in China The pressure of Communist-controlled governments, however, caused a number of British chambers of commerce abroad to cease operations, notably in the U.S.S.R. and China.

Foreign Chambers of Commerce in the United *Kingdom* are free to organize and to carry on normal activities in the United Kingdom and generally throughout the commonwealth. The United States is thus represented by the American Chamber of Commerce in London and similarly other leading commercial countries. Among similar bodies interested in the trade of special areas may be mentioned the China association and the British and Latin-American Chamber of Commerce.

Trade Associations.—There are three types of industrial association in Britain: (1) those which primarily devote themselves to technical, scientific and informational tasks; (2) those which are concerned with the regulation of prices, output and sales; and (3) those which exist almost solely for purposes of collective bargaining with their workpeople or trade-union representatives; *i.e.,* employers' associations.

Before World War I British trade associations were mostly of the first type. During World War I, however, the government actively promoted the formation of associations for equitable distribution of raw materials. etc. They grew so rapidly in number and influence that a committee on trusts was set up in 1919, which recommended, as did the Balfour Committee on Industry and Trade, ten years later, against antitrust laws. So in pursuance of the general policy of rationalization designed to secure much needed economies and the elimination of excessive internecine competition the formation of trade associations proceeded and these early found it useful to organize themselves into a joint body with authority over industry as a whole.

This was the Federation of British Industries whose membership grew steadily from the original 350 firms and 62 trade associations in 1916 to nearly 7,500 firms and 286 associations in 1955. It is thus the prime representative body for the productive industry of the United Kingdom, with a staff of 170 at headquarters and 50 at each of the 10 regional centres in the United Kingdom; there are also representatives at 140 British and foreign centres.

The range of topics dealt with by the federation both in respect of individual cases brought to its notice by member firms and in regard to questions of general policy is vast and varied; in fact no aspect of trade is excluded. The chief general subjects receiving particular attention in the mid-1950s included taxation, monopolies and restrictive practices, freight charges, commercial and technical education, exhibitions and customs tariffs at home and abroad: with particular reference to the repeated negotiations under the General Agreement on Tariffs and Trade (G.A.T.T.) referred to below.

Matters of policy of the Federation of British Industries (F.B.I.) are determined by the grand council, composed of one representative from each federation district, one from each association with 20,000 employers, one from each firm with 40,000 employees.

The federation, like the Association of British Chambers of Commerce, is represented on the National Production advisory council and it co-operates closely with the British Employers' confederation (see below). Its international activities include membership of various bodies concerned with such matters as the European Payments union and together with the Employers' confederation it represents British industry on the Council of European Industrial Federations, an advisory body to the Organization for European Economic Co-operation (O.E.E.C.). The federation is also represented on the Dollar Exports council. (*See* also FEDERATION OF BRITISH INDUSTRIES.)

The National Union of Manufacturers, formed in 1915, which by 1956 had a membership of 5,500 firms and 72 trade associations, represents the interests of, and affords a whole range of useful services for. the smaller industries. It too has representatives on the National Production Advisory council and on many government committees.

Closely akin to credit and collective bureaus elsewhere are the trade protection societies affording special facilities for the collection of debts. Their national body is the Association of Trade Protection Societies of the Cnited Kingdom. In addition there are chambers of trade, mostly local bodies made up of firms in the distributive trades. They are linked together by the National Chamber of Trade, organized in 189; and supplemented by the Incorporated Association of Retail Distributors, founded in 1920.

Furthermore, there are produce markets, some of which were established as far back as the middle of the 18th century; *e.g.,* the "Baltic" (Baltic Mercantile and Shipping Exchange Ltd.) dealing chiefly in shipping (charter parties) and grain, and the corn and coal exchanges of London. The Liverpool Corn Trade association, providing a future market for wheat and maize and controlling the wheat trade of the port, was established a century later (1853) and the London Corn Trade association in 1878. The London Produce Clearing House Ltd.. founded ten years later, handles forward contracts in coffee, sugar and many other items. The Liverpool Cotton association assumed its modern form in 1882.

Among other bodies qualified to deal authoritatively with the important aspects of industry and trade which their titles specifically indicate are the British Standards institution, the Council of Industrial Design, the Institute of Export, the British Institute of Management and the British Shippers council (see also STANDARDIZATION).

Co-operatives.—The modern consumers' co-operative movement began in Rochdale in 1844. Each stockholder was permitted only one vote, goods were sold at regular prices, and patronage refunds were made on the basis of volume of purchases. Gradually the co-operative began to produce some of the things it sold—flour, meat, shoes, preserves, vegetables, furniture. The Co-operative Wholesale society of Great Britain by mid-20th century had 11,316,000 members. (See CO-OPERATIVES.)

Employers' Organizations.—Arising out of the much changed general economic situation created by World War I the British Employers' confederation (which, as seen above, is closely connected with the Federation of British Industries) was formed in 1919 from the national groups of employers in the separate industries—trade associations of type (3) referred to above. It covers by far the greater part of all the country's industries other than those nationalized and gives powerful corporate strength and effectiveness to their members in regard to labour relations. It is thus represented on the National Joint Advisory council to the ministry of labour and on the National Production Advisory council. In the international sphere it appoints the representatives of British employers on the tripartite International Labour organization (*q.v.*).

Industrial Research.—In order that British industry should be able to take advantage of the great advances in applied science and technology, the government, again during World War I, set up the Department of Scientific and Industrial Research, the importance of which can be gathered from the fact that the estimate for its net expenditure in 1955–56 was more than £6,500,000. Its main operations include research with the building, chemical, fuel and engineering industries. (*See* also RESEARCH, INDUSTRIAL.)

The British Government and Trade Organization.--In the mercantilistic period of British history the government regulated business and trade at every turn. Against this regimentation Adam Smith's *Wealth of Nations,* published in 1776, amounted to an economic declaration of independence. British manufacturers and the activities of the Manchester school gradually accomplished the repeal of the corn laws, and changed government policy to one of *laissez faire*.

By 1880, however, the government began to take a renewed interest in foreign trade. It appointed commercial attachés to embassies and legations. By 1900 a commercial intelligence branch was set up in the board of trade. In 1908, in response to recommendations of the colonial conference, trade commissioners were appointed in Canada, Australia, New Zealand and South Africa. In 1917, partly because of the exigencies of World War I, the department of overseas trade was set up, a joint department of the foreign office and board of trade.

In the period between World Wars I and II the department grew steadily, and the number of trade commissioners multiplied. Imperial trade correspondents were set up. In foreign countries, the commercial diplomatic service was substituted for commercial attachés, mith commercial counsellors in the higher grades and commercial secretaries in the lower grades.

The main function of the department, which was later taken over by the board of trade, and of the three overseas services, was to promote export trade by providing full particulars of specific sales opportunities and of general economic and commercial affairs. The former are transmitted direct to interested manufacturers and traders; the latter are published in the *Board of Trade Journal,* a weekly established in 1886 whose files constitute an authoritative record of commercial events, regulations, tariffs, etc.. all over the world. Moreover, the reports made by the trade commissioners, commercial diplomatic officers, or consular officers are compiled for each district and published in regular annual series. British businessmen abroad ordinarily keep in close contact with government overseas officers, who are systematically called home to renew and widen their contacts in the department and in the business community.

As the financing of the export trade became more difficult in the chaotic conditions of the world and especially Europe after World War I a system of export credits was offered by the government in 1919 and government support of this kind proved so successful and necessary that later legislation created a large export credits guarantee department which, operating through a number of district and branch offices in London and other important commercial centres, covers a large proportion of British export trade—the aggregate of policies issued in the 1950s being of the order of £500,000,000.

At the same time the British Industries fair (*q.v.*) was inaugurated and was held annually in London and Birmingham (under the direction of the Birmingham Chamber of Commerce) from 1915 to 1957, when the London fair was discontinued. Responsibility for official participation in international exhibitions also rests with the board of trade.

In 1932 the Ottawa agreements and the consequent tariffs adopted in the United Kingdom confirmed the abandonment of the long-standing policy of free trade, and economic and financial crises forced the government to take over more and more control of trade and industry which during World War II became practically complete. Though there was later a natural tendency to relax control with reversion to a relatively "free" economy it had become the established principle that the government was primarily responsible for taking the necessary financial and other measures to secure both full employment at home and a proper balance of payments in overseas trade and finance. Whereas formerly the board of trade as the department of government mainly, if not solely, concerned exercised a minimum of control or influence on both home and overseas trade, its main function being the occasional negotiation of commercial treaties, it is now expected to deal actively with every aspect of trade and its concomitants. This includes distribution and general efficiency of industry, commercial relations and the promotion of exports. the administration of company law and that directed against monopolies and restrictive practices as inherent in modern business methods, a matter which received much attention in 1956 and resulted in the Restrictive Trade Practices act, 1956. In particular the board of trade had taken over the duties of the Import Duties Advisory committee established in 1932 to deal with the customs tariff, and was responsible for the participation of the United Kingdom in the proceedings of the General Agreement on Tariffs and Trade which represented the mid-century achievement of international solidarity in the matter of trade policy, the ultimate aim of which was embodied in the International Trade charter of 1948. This instrument, subscribed to by more than 50 states including both the United States and the United Kingdom. made provision for the International Trade organization to promote, among other things, the reduction of tariffs and other barriers to trade, and by these and other concerted measures to assure a balanced and expanding world economy. This step, however, had not been taken by 1956 owing to the failure of sufficient states to ratify the charter; *see* also COMMERCIAL TREATIES; FREE TRADE.

Commonwealth Associations.––After World War I, with a view to securing closer co-operation in matters of trade and communications between the several parts of the British Empire. new associations of imperial scope were created—the Imperial (later Commonwealth) Shipping committee (1920) and the Imperial (later Commonwealth) Economic committee (1925). These consist of official representatives of the United Kingdom and of the commonwealth countries supplemented in the case of the former committee by five persons experienced in shipping and commerce. The former deals with questions relating to ocean freights, facilities and conditions in the interimperial trade and reports severally to the governments concerned; it has thus dealt with such matters as terms of bills of lading, the deferred rebate system, certain harbours, rates of freight in particular trades and, in a long series of reports, with Hudson Bay insurance rates. The main function of the economic committee is to provide regular current information on the trade of the commonwealth in a wide range of raw materials and foodstuffs. Its considerable expenses are met largely by contributions from the several governments. It cooperates with the United Nations and its specialized agencies.

FRANCE

Chambers of Commerce.—From the time of their establishment. French chambers of commerce served as agencies of official administrative control and management of public commercial institutions, including inland waterways, ports, etc. In 1599 the city of Marseilles established the first *chambre de commerce* and empowered it to settle the merchant law and customs of the port, to appoint consuls and run the French consulates in the Levant, to equip expeditions against corsairs, to send embassies to the Barbaresque countries and to organize commercial missions. In 1700 Louis XIV, at the suggestion of Jean Colbert, caused an *arrêté* to be published ordering chambers of commerce to be created to nominate deputies to the royal council of commerce in Paris. Most large cities soon had them, including Lyons, Rouen, Bordeaux, Lille. Bayonne, La Rochelle, Toulouse and Amiens.

The French Revolution brought about a complete change in type of government control. Isaac Chapelier's law of 1791 forbade all types of economic association. Chambers of commerce, however, were soon legalized again. The chamber of commerce at

Rouen (which until the Revolution had been the chamber of commerce of Normandy) was officially re-established in 1802. By Napoleon's decree of 1804 (revised and codified in 1895 and 1908), chambers of commerce could be established, but only by a decree countersigned by the minister of commerce. upon the advice of the prospective municipal council. of the general council of the department, and of the existing chambers of commerce in the district. By the 1950s there was at least one chamber of commerce for each *département*. The members of these chambers, chosen from the commercial community, are appointed by official decree, there being not fewer than 12 nor more than 30, except for Paris which may have 48.

The chambers of commerce have acquired consultative as well as administrative functions. The government is bound to take their opinions regarding regulation of commercial practices, establishment of commercial exchanges and tribunals of commerce, improvement of transport and communications, application of local laws, sales prices of prison-made goods, and management of local public works together with the requisite special assessments, loans or taxes. In addition there is the usual wide range of legislative. tariff, freight rates and other matters upon which the chambers may make representations which may or may not be heeded.

The administrative functions of the French chambers of commerce are extensive. They may be authorized to establish and administer such institutions as bonded warehouses, public salesrooms, firearms testing establishments, and commercial, professional or technical schools. They may be granted concessions for public works and undertake the carrying out of public services, especially the management of ports, docks, canals and navigable rivers, under the supervision and control of the local state official. During World War I they, together with the municipalities, were even allowed to issue paper money and tokens to take the place of the fractional currency that had disappeared. Under the Stabilization law of 1928 these powers were ended.

Foreign Chambers of Conzmerce in France.—When British merchants in Paris in 1873 started what they called a chamber of commerce the French government was disturbed lest the public think that its powers were similar to those held by their own chambers. Soon. however, all the leading commercial countries of the world had chambers of commerce in Paris and elsewhere.

French Chambers of Commerce Abroad.—Beginning in 1883 the minister of commerce encouraged the establishment of French chambers abroad (which of course did not have the administrative powers they had at home). By the mid-1950s more than 50 had been founded in leading commercial centres all over the world, including several each in such countries as Spain and Belgium.

Trade Associations.—Although forbidden by the law of 1791, and not legalized until 1884, trade associations and trade unions, local, regional and national, existed in fact as early as 1821 though they were frequently disguised as friendly and benefit societies. In that year the first Federation of Industrial Associations was organized by the Carpentry association. In 1868 the National Union of Commerce and Industry was founded. It included 55 industrial associations representing industries other than the building trade. In 1896 there appeared the Commercial and Industrial alliance, in 1903 the Federation of French Manufacturers and Merchants, and in 1919 the *Confe'de'ration Générale de la Production Française* (C.G.P.F.), called into existence by Étienne Clémentel, minister of commerce, "to contribute to the development of the productive power and export trade of France, and to co-ordinate the activities of the syndicates and professional associations." The signing of the Matignon agreement of June 7, 1936, with the C.G.T. (*Confédération Générale du Travail,* national trade union organization) brought about a change in organization and leadership. The C.G.P.F. became the *Confe'de'ration Générale des Patronats Français* with a program similar to that of the N.A.M. in the United States and the F.B I. in Great Britain.

On the national level there developed four types of trade organizations. The *comptoirs* such as the *Comptoir Français des Produits Sidtrurgiques* were essentially cartels, regional, national or international in scope, usually centred about a single commodity or group of commodities. The *syndicats* such as the *Comitt des Forges* mere trade associations of specialized trades. The federations such as the *Union des Industries Chimiques* were groups formed out of syndicates and trade associations. The confederations such as the C.G.P.F. were combinations of closely allied federations and syndicates.

At the regional level there existed district associations for a wide variety of industries. In addition there existed regional federations of local associations such as the *Fédération Departmentale des Syndicats Patronauz du Bâtiment et des Travaux Publiques des Bouches du Rhône*. At the top were confederations of federations such as the *Comité d'Entente des Grands Groupements* at Marseilles. There were other groupings of specialized employer interests difficult to classify, such as the industrial societies in cities such as Nancy or Lille whose special aim was to increase efficiency.

After World War II, chambers of commerce and trade unions regained their prewar status but the powers of trade associations were drastically curtailed. The C.G.P F. was not revived; its place was taken by the *Conseil National du Patronat Français,* formed in 1946, a more comprehensive body including small, medium and large industrial and commercial enterprises in Paris and the provinces. It is regularly consulted by the government. The government itself, in response to postwar emergency problems, multiplied its controls over both foreign and domestic trade, nationalizing some industries and initiating even supranational cartelization measures in others. Thus the Schuman plan set up a high authority over production and sales of the combined coal and steel industries of France. Italy. west Germany, Belgium, the Netherlands and Luxembourg with power to allocate coal in times of shortage and to remove import quotas, tariffs, discriminatory pricing arrangements and freight rates.

GERMANY

The mediaeval merchant guilds of varied Iocal type and function were the colourful predecessors of the modern chambers of commerce and industry in Germany, The *Handelsvorstände* in Frankfurt-on-Main (1707), the *Handelszukunft* in Mannheim (1728), the *Kommerz-Deputation* in Hamburg (1765), the *Älteste der Kaufmannschaft zu Berlin* (1820) and the merchants' corporations in Stettin, Danzig and Magdeburg were typical of those that existed long before the rulers of the individual German states legalized and regulated them in the 1840s and 1850s.

In addition to voluntary duties of the usual type (*e.g.,* giving information on customs and trade, conducting commercial schools, administering exchanges. harbours, public and customs warehouses and operating arbitration courts), German chambers were required by state laws to draw up annual economic reports, nominate and swear in publicly appointed experts, weighers and assessors, and assist the courts in keeping the commercial register. To meet their expenses they were empowered in some states. such as Prussia and Bavaria, to levy a surtax on the regular income or profit taxes to which trade and industry were subject. They also obtained revenues from fees for certificates of origin, exchange and market fees, and receipts for rent of space in their buildings.

After the vicissitudes occasioned by World Wars I and II the organization of industry and commerce was fully re-established in the Federal Republic. There were in the mid-1950s about 80 chambers of commerce. and membership, where not compulsory, was very full. They were associated in the *Dcutsche Industrie und Handelstag* (first founded in 1861), at Bonn, which gave strong corporate effect to their views on all aspects of commerce. At the same time the extensive system of German chambers of commerce overseas was revived in a number of important countries though not by the mid-1950s including the United Kingdom.

Trade Associations.—Throughout German industrial history, the government has been instrumental' in promoting thorough organization and control; an outstanding example is the Potash law of 1910 which placed the industry under a cartel of the mine owners which fixed minimum export prices. During World War I such compulsory cartelization became the standard pattern. These centralizing tendencies took further shape in the *Reichsverband der Deutschen Industrie* (R.D.I.) embracing 445 national trade associations and 70 chambers of commerce and industry. The legitimate successor of this R.D.I. was the *Bundesverbund der Deutschen Industrie* (B.D.I.), established for western Germany in 1948, which became the recognized authority to speak for German industry; it embraces some 340 trade associations covering practically all German industry; among its numerous committees are those dealing with foreign trade, finance and international relations. Another important organ of German wholesale and export trade is the *Gesamtverband der Deutschen Gross und Aussen Handels.* Special aspects of commerce are dealt with by such bodies as the Association of Shipowners in Hamburg and the Insurance union in Cologne.

The interests of industrialists as employers of labour are served by the *Bundesvereinigung der Deutschen Arbeitgeberverband eintragener Verein* of Cologne, a confederation of employers' associations covering the whole field of German industry. With the B.D.I. it is a principal member of the supreme organization for the west German economy, the *Gemeinschaftsausschuss der Deutschen Gewerblichen Wirtschaft;* this body like its constituent parts is independent of the government but its influence is very great.

ITALY

The association in Italy of traders and artisans into trade guilds dates back to the middle ages. In modern times Law 680 of July 6, 1862, gave to these chambers of trades and arts, as they were then known, legal status and they became recognized as public bodies. Their functions were purely consultative. They were directed by boards whose members were freely elected by merchants and artisans, and numbered from 12 to 40 according to the importance of the locality concerned. Law 121 of March 20, 1910, more clearly defined their status and extended their functions, and the name was altered to Chamber of Commerce and Industry *(Camera di Commercio ed Industria)*; purely agricultural concerns were specifically excluded. The governing boards were still formed of 12 to 40 members, freely elected by any actively engaged in trade or industry and paying the weights and measures tax or the display window tax. The right to vote was extended to women, provided they owned or ran a business and paid the taxes named, and to commercial travellers and co-operative societies. The chambers continued to be mainly consultative but they were entrusted also with the registration of business concerns, keeping trade statistics, formulating trade usages and keeping registers of approved surveyors, receivers in bankruptcy, brokers and arbitrators. They kept lists of market prices of the principal commodities, issued certificates of value and origin for customs purposes and others in many business and official connections; provided facilities or premises for trade exchanges and museums and general information services for trade and industry. Association was voluntary and expenses were met from the fees charged for their services and a small tax levied on trade and industry. Foreigners were allowed to become full members, and to be elected to the boards, provided that they had been registered as resident traders for at least five years.

With the advent of fascism the old system of freely elected and voluntary chambers of commerce had to give way to a new regime of full government control instituted by Law 731 of April 18, 1926, and Law 1071 of June 16, 1927. These laws resulted in the setting up of provincial councils of economy (*Consigli Provinciali dell' Economia*), and of provincial offices of economy (*Uffici Provinciali di Economia*). The former councils each consisted of boards for agriculture, industry, commerce and labour (with social insurance) and where necessary a section for maritime trade; their primary function was to represent the trader, industrialist, farmer and worker. Each board had as ex-officio members a number of officials such as the district agricultural inspector, or district engineer for public works. Other members were selected by the minister for national economy from a list drawn up by trade associations. and the balance chosen by the same minister from a list of candidates nominated by the various trade and professional unions. The ministry fixed in each case the number of boards, the number of members for each board and the number of members of each category within the board and, notably, there ceased to be any form of free election. The councils continued to be consultative but became the official channel both for the representation to the government of the interests of their respective members and for the execution of government orders and enactments. They also continued all the other functions and services hitherto carried out by the chambers of commerce and industry which they replaced as stated above. The provincial offices of economy took over much of the executive work of the provincial councils of economy as agents for the government and for the economic development of each province. Under Law 875 of June 18, 1931, these councils and offices became the provincial councils or offices of corporative economy and the former in 1937 were renamed the provincial councils of the corporations.

After the fall of fascism Law No 315 of Sept. 15, 1944, finally abolished the fascist system and re-established the principle of boards chosen by free election, involving the restoration of the chambers of commerce, industry and agriculture, but retaining provincial offices of commerce and industry, the former becoming consultative organizations with certain public functions; and the latter being dependent on the ministry of commerce and industry and staffed by civil servants.

The president of the chamber of commerce is appointed by the minister and so replaces the prefect for all matters in the economic field connected with the working of the chamber. He is supported by four councillors, one each for trade, agriculture, industry and labour. The inclusion of a councillor for labour does not mean that the chambers concern themselves with questions directly related to labour but is a recognition of the importance acquired by workers in questions affecting the general economy. These councillors are assisted by consultative committees *(juntas)* formed of members chosen from the various sectors of economic activity in the province, which is the area within which the chamber also functions.

Trade Associations.— Trade associations in Italy draw their membership primarily from the handicraft trades and agriculture. They were profoundly influenced by the economic doctrines of Catholicism and consisted largely of employer and employee organizations. The first organization of national scope was the General Confederation of Agriculture, founded in 1911 with about 70,000 landed proprietors as members, dominated by the owners of the large estates in the Po valley. In 1919 the *Confederazione Generale dell' Industria Italiana (Cofindustria)* came into existence with about 100 member bodies. A third association of this kind, the *Confederazione Generale del Commercio,* was founded in 1946 and in 1954 *Cofindustria* initiated a movement to unite these three bodies into an "economic front" so as to use their considerable political influence to full advantage. In the 1950s *Cofindustria* was the most active and powerful of these employer organizations with a membership of 102 national trade associations and 114 regional associations; of the former the majority represented the food (21), engineering (19) and textile (18) industries, while the latter were naturally most numerous in the Northern Provinces, Lombardy (16), the three Venetias (15), Piedmont (13), while Tuscany (12) and Emilia (9) came next. The trade associations primarily function as employers in direct relations with the trade unions for questions of wages, hours and general conditions of employment but they also deal with production, prices, markets and the like on a national basis for their particular trade or industry.

U.S.S.R.

Trade organization in the U.S.S.R. is a matter of complete state control exercised in the main through the five-year plans which are settled, under the council of ministers as the supreme executive, by Gosplan (the state planning committee) which was established in 1921 and does its primary work through a system of subordinate planning offices. Thus the first of these plans after prolonged study and discussion was finally adopted in April 1929 for the period from Oct. 1, 1928, to Sept. 30, 1933, though eventually it was ended as completed by the end of 1932. Other such plans followed continuously until the outbreak of war in 1941 interrupted the series, which was resumed in 1946.

Gosplan is itself organized on the basis of a number of departments for each of the principal branches of industry plus one for internal and one for external trade together with a number of co-ordinating departments which have the duty of matching up production with demand, and controlling capital works and finance on a regional basis. In addition there are specialized divisions which deal with such economic factors as labour, transport and communications. Of prime importance is the Central Statistical administration. Once the plan is settled, its administration is the responsibility of the numerous ministers for the different branches of industry; there are some 30 of these covering such industries or groups as iron and steel, nonferrous metallurgy, oil, heavy and medium engineering, the chemical industry, manufactured consumer goods, also communications, railways, shipbuilding and, as indicated above, trade external and internal. Below these ministers in each case are the Glavki, or thief administrations, with control over industrial establishments producing a certain class of goods within a certain area. Under the Glavki are the trusts or combines each actually running a group of similar factories—though these may in important cases come directly under the minister. The control exercised by this official hierarchy necessarily includes not only meeting the specific requirements of the master plans as broken down for the several production units but the regulation of all matters incidental to that production such as, notably, labour training and recruitment, hours; pay and conditions, finance and office methods. Provision for the regulation of all these aspects oi the general economy is made at all levels. Because of this, the role of the trade unions in the U.S.S.R. is limited and very different irom that in countries with a free economy. *(See* TRADE (LABOUR) UNIONS.)

The foreign trade of the U.S.S.R. has of necessity to fall into line with the master plans for industry and so there is a complete state monopoly of all exports and imports. This was instituted by decree of April 22, 1918, and is vested in the ministry oi foreign trade (*Ministerstvo Vneshnyie Torgovlyi Soyuza S.S.R.)* It is administered through numerous ioreign trade corporations which deal severally with the export and import of certain groups of commodities or with trade with certain countries or with shipping (*Sovfrakht*). Contact with these bodies can be made by traders in other countries through the trade delegations of the U.S.S.R.

In view of this system it will be seen that there cannot be in the U.S.S.R. anything quite like the chamber of commerce which has become so well-established in western countries. There is however in London the Russo-British chamber of commerce, a joint Anglo-Soviet organization which was incorporated in 1916 and is affiliated to the Association of British Chambers of Commerce. It is active in the encouragement of trade between the British Commonwealth and the U.S.S R., and consists oi British firms interested in this trade. The president is British and the vice-president Soviet, whilst the executive council consists of equal numbers oi British and Soviet members.

(E. J. E.)

OTHER COUNTRIES

World War II and the resultant collapse of fascist totalitarianism brought about two major changes in trade organizations. It multiplied their number, especially in newly industrialized areas. It released them from domination by the state. In 1944 there began a restoration of freedom of association throughout the world. The emergence of free, self-governing business and labour organizations led to new legislation for trade organizations not only throughout Europe, but world-wide, as, for example, in the constitutions of Cuba (1940), Guatemala (1945), and Brazil (1946), in the labour codes oi Costa Rica (1943), and Nicaragua (1945), in the Bolivian decree of Feb. 7, 1944, in law VI of 1945 in Colombia, in the Egyptian Law of Dec. 6, 1942, in the labour codes of Iraq, Iran and Lebanon (1946), and in the Turkish law of Feb. 27, 1947.

Argentina. — At mid-20th century there were in Buenos Aires 21 merchants' and manufacturers' associations of major importance, mostly in the agricultural processing, and bullding-materials industries. They, together with similar organizations in Portugal, were the only ones that continued to be tightly supervised by government. Even *Confederacidn General del Trabajo,* including the powerful *Asociacidn Obreros y Empleados del Estado,* was not exempt.

Brazil. — At mid-20th century the *Associação Comerical de Rio de Janeiro* served as the official technical advisory board for the federal government. It published a weekly *Boletim* and a monthly *Revista do Comercio.* In addition there were 19 regional chambers of commerce and national syndicates ior 61 major industries and trades. There were five national organizations of trade unions, the largest being the *União Geral dos Trabalhadores do Brasil* with 112 member groups

Canada. — The postwar growth oi trade organizations in Canada was startling. In the early 1950s the Canadian department of trade and commerce listed 47 national agricultural and horticultural associations, 16 dairy and allied associations, 55 livestock and poultry, 24 building and construction, 14 national associations of co-operatives, 40 financial and insurance organizations, 18 national labour groups, 25 manufacturing associations in the field of food, feed and beverages, 13 for fish, 30 associations of manufacturers of textiles, clothing. and shoes, 22 of lumber and paper, 43 of miscellaneous products, 1j mining and oil, and 27 printing, publishing and advertising associations.

The Canadian Manufacturers' association had 6,400 members in 1947; The Canadian Chamber of Commerce Inc. had 400 boards of trade and chambers of commerce, 20 trade associations and approximately 1,200 business firms and corporations. The Trades and Labour congress of Canada had 400,000 members; the Canadian and Catholic Confederation of Labour had 325 unions with 80,000 members; the Canadian Congress of Labour had 28 international and national member unions with 1,039 units.

Egypt. — At mid-20th century there were 17 chambers of commerce, mostly *of* ioreign businessmen in Alexandria and Cairo. In addition there were 20 *Chambres d'Industrie,* for the most part founded during or after World War II, headed by the *Fdddration Egyptienne l'Industrie.*

India. — At mid-20th century the Federation of Indian Chambers of Commerce and Industry had 120 associations affiliated as members, including 18 regional chambers of commerce and 41 large national trade associations. The Jute Balers had more than 500 member firms; the East India Cotton Association, Ltd., 867.

In addition there were 63 important national trade unions, 27 affiliated with the Indian Federation of Labor, the remainder with the powerful All-India Trade Union congress. Among the former, the largest were the Textile Labour association with 85,000 members and the All-India Colliery Magdoor union with 48,300 members. The number of unions had grown from 29 in 1927–28 to 818 in 1943–44, and well over a thousand in 1950.

Japan.—Trade associations were founded in the 1880s, notably in the cotton spinners, textile, and silk-yarn industries. In 1931 the *Kanto Sangyo Dantai Rengokai* or National Confederation of Industrial Associations of Japan was founded with 39 member-associations. That year they became organs of the state in controlling prices, outputs, sales, capacity, exports, etc. By 1935 there were 662 such guilds covering 70 industries. In 1941 all firms and trade groups were centralized under "control associations" operated directly by the Imperial Rule Assistance association. On Nov. 3, 1946, in accordance with the policies, principles and standards laid down by the Far Eastern commission, freedom of association was declared a right in the constitution (chap. iii, paragraph 21).

By mid-20th century chambers of commerce and industry had resumed activity in Tokyo and other major cities. There also had grown up more than a dozen branches of the Japan Foreign Trade institute. But strong national trade associations except ior the *Zenkoku Kensetsugyo Kyokai* (All-Country Association of Construction Firms) had not yet emerged.

Trade unions, however, sprang up by the thousands with membership running into the millions. The top organization, the *Zen-koku Rodo Kumiai Rengo Kyogi-Kai* or National Council of Japanese Labour unions was founded in 1947. Largest of the constituent organizations, all iounded in 1946, were the *Nippon Rodo Kumiai Sodomei* with 2,892 unions and 1,247,868 members; the *Zen Nippon Sangyo-Betsu Rodo Kumiai Kaigi,* 18 unions and 1,173,782 members; and the *Nippon Nomon Kumiai* (farmers) with 4,741 unions and 906,151 members.

Mexico. — The Chambers of Commerce and Industry act of 1936 created as top organization *Confederacidn de Cdmaras Nacionales de Comercio e Industria.* Under it were organized more than zoo regional and national chambers of commerce. Every businessman and industrialist with a capital of joo or more pesos had to inscribe himself in the national register. At mid-20th century *Confederacidnde Cdmaras Industriales de los Estados Unidos Mexicanos* had 46 regional and national industry associations, the largest of them founded between 1941 and 1946. *The Cdmara* for manufactures had 10,500 members.

There were three major labour organizations. The largest, *Confederacidn de Trabajadores de México* (CTM) consisted of 13 *Sindicatos Nacionales de Industria* and 32 regional federations comprising 5,200 unions with roughly a million members. Next in size was *Confederacidn Regional Obrera Mexicana* (CROM) with 550 unions and 200,000 members.

New Zealand. — Chambers of commerce in 49 cities belonged in 1948 to the Associated Chambers of Commerce of New Zealand. Industrial Associations of Employers existed ior 22 industries, organized into iour regional manufacturers associations. That for Wellington had 670 member firms, Auckland 900, Canterhury 515, and Otiago and Southland 300. The New Zealand Federation of Labor had 34 Federations or Industrial Associations of Workers, including 53 unions each with more than 1,000 members.

South Africa. — At mid-20th century there were 20 major trade associations affiliated with the South African Chamber of Industries, the largest being the Master Printers with 455 members. There were 69 employers' associations of which only 27 were founded prior to 1941. The largest was the National Federation of Building Trade Employers with 2,195 members. In addition there were 410 registered co-operative societies with a total membership of 300,941. The South African Trades and Labour council consisted of 66 principal registered trade unions with 125,303 members, of whom roughly two-fifths belonged to the 7 Railways and Harbours unions. (T. J. K.)

TRADE **ROUTES.** The great trade routes of the world are the accustomed paths, by land, sea or air, by which goods and mails pass in exchange between Europe and Asia, between Europe and America, between America and Asia. A trade route is something more than a dotted line on the map or chart. It is a road which has to be surveyed, charted, improved. patrolled, guarded and supplied. By land it may comprise railways, canals, metalled highways and telegraph wires. It may include bridges, viaducts, stations, repair sheds, reservoirs, fuel supplies, garages, hotels, traffic lights and signposts. By sea it will comprise charts, sailing directions, ports, lighthouses, pilot vessels, tugs, cables, pipelines, naval bases and warship patrols. By air it will include runways, repair facilities, meteorological stations and radar equipment.

The dotted line in the atlas may not exist except on paper but the way is flanked and marked by installations which are real, elaborate and costly. This has always been true, in some measure, since the first trade routes were opened.

Ancient Times.—Theoretically a man may trade with goods carried on his back, but in practice the traveller, able to carry little more than he needs to eat and wear, has always sought a means of conveyance. And trade begins virtually with the domestication of such animals as can carry a load. It is probable that long-distance trade, except along rivers, developed among nomadic peoples of the steppes. People whose livelihood depends upon cattle, sheep, asses and goats must in any case move between summer and winter pastures, and it is a natural urge to load the ass with goods found to be scarcer in one place than another. By 2000 B.C. the horse too was domesticated; wheeled vehicles, drawn by oxen, were also an early invention. Knowledge of these forms of transport spread to the middle east (brought by the nomads themselves) and was the means of founding one of the earliest trade routes, that connecting Babylonia and Egypt. This ran at first across the land bridge provided by Syria and Palestine, following the fertile ground. An alternative route developed, however, across the desert itself—shorter, but involving some of the problems of an ocean voyage. The traders followed known tracks between oases and wells; and cities. comparable in function to seaports, grew up at their points of departure and arrival. This trade, the importance of which may be measured by the size and wealth of these cities, caravan termini like Baghdad, Palmyra, Baalbek and Damascus, was limited in development because the natural products of Egypt and Babylonia were not markedly different from each other. Further eastward and westward lay regions more dissimilar, and it was to them that this Syrian trade route was extended. It could not, however, be extended by land. From the mouth of the Nile to the mouth of the Euphrates the trade could pass by camel or river craft. To extend farther in either direction, it would have to go by sea, this further development depending essentially upon the evolution of the river boat (or raft) into a seagoing sailing ship. This seems to have taken place upon the Nile, which rises in Africa but points toward Europe. Once seagoing vessels had come into use it was inevitable that trade bound from Babylonia to Europe should seek a shorter route to the sea, with a place of shipment at Tyre or Antioch. Moreover, the trade of the Nile delta would as inevitably seek a shorter route to the Indian ocean, either across the isthmus of Suez or up the Nile and so to a port farther down the Red sea. Farther northward, in the original home of the nomadic peoples, there was no necessity to use a sea route. There developed instead. overland, a caravan route which extended eventually from the Black sea to the north China coast. From these earliest beginnings there evolved the great trade routes between Europe and Asia.

Routes Between Europe and Asia.—The main centres of population in Europe and Asia are almost connected with each other by a line of high mountains. Trade must pass either to the north or south of them. On the northerly route the goods will go almost entirely by land. On the southerly route they must go by sea.

Carriage by sea tends to be less costly, but, apart from that, the southern route reaches China via India or Africa and, in either event, via southeast Asia, while the northern route passes through lands less populous and, to the merchant, less attractive. The southern route has for that reason normally had preference over the other. There exists, at least in theory, a more northerly route still, connecting China with Europe via the arctic circle, but the objections to this—ignoring the technical difficulties—are of the same kind. A route traversing such relatively uninhabited country could offer only the attraction of speed. and that has not hitherto been a paramount consideration in the transport of goods.

Trade passed at first over the more northerly route, overland, and was the means whereby the Romans obtained their supply of silk. Afterward this route was interrupted by hostile trihes, and it was not until 1245 that it regained its full importance. From then until 1345 the Mongols, holding sway between China and the Danube, encouraged the reopening of the silk route. along which Marco Polo and other European travellers made their way to the far east. For about a century trade passed freely and was then checked afresh by mainly Turkish intervention. But whether passing freely or restricted, this long-distance land route could serve only a limited purpose. No heavy or bulky goods could be worth the cost of transport on pack animals over such a distance. The silk route did more to create than to satisfy the demand for luxury goods, and it fell into relative disuse as the maritime routes developed. Its place was eventually taken by the Trans-Siberian railway, but this has never been an international trade route, serving as it does only the more local purposes of the U.S.S.R. After 1345 the vast bulk of the trade went by sea.

Of the alternative southern routes, the shortest is that via the

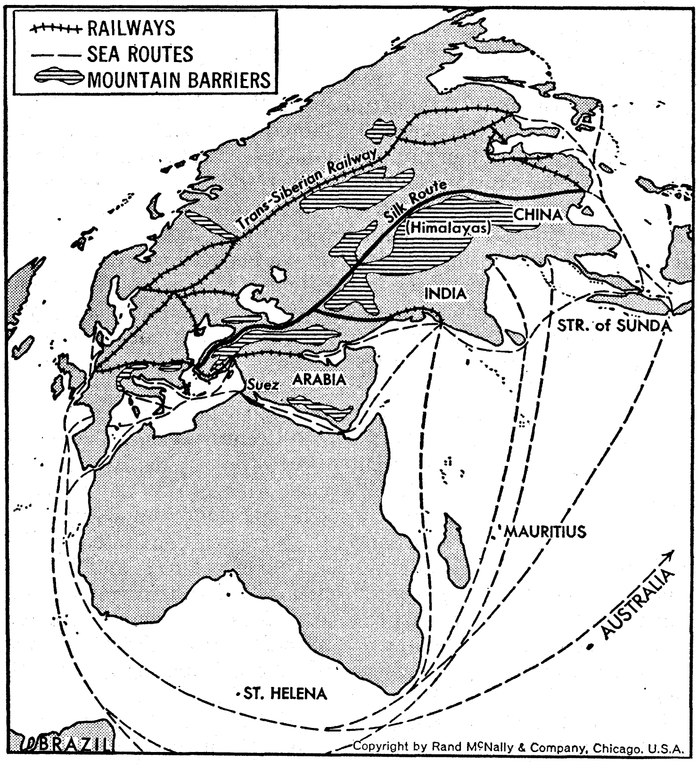

FIG. 1.—TRADE ROUTES BETWEEN EUROPE AND ASIA

isthmus of Suez, at which point the waters of the Red sea and Mediterranean are separated by barely 100 mi. of desert. In view of the cost of transshipment and the flat nature of the desert at that point, the idea of digging a canal to connect the two seas is an obvious one. Such a canal. dug by a pharaoh of Egypt, existed in 1380 B.C. Another was begun in 609 B.C.. and Darius later continued the work. If this was effectively in use it was between 285 B.C., when Ptolemy Philadelphus completed it, and 31 B.C., by which date it had ceased to be navigable. This canal connected the Red sea at Arsinoe, not nith the Mediterranean directly but with a branch of the Nile, and it was the dwindling of that branch which dried it up. The essential difficulty about this enterprise lay not so much in digging the canal as in navigating the Red sea. The project for a Suez canal was abandoned for the time being, and it is probably true to say that it was never really practicable before the introduction of the steamship.

On the other hand, there was considerable trade between Europe and Asia by other routes from about 130 B.C. This was the period during which the Persian empire stretched from the Mediterranean to the Indus and the Caspian sea, thus politically uniting much of the territory over which the trade would pass. The Persians were not themselves a seafaring people, and it had been left to the

Phoenicians, from 1500 B.C. or earlier, to extend the trade by sea from Sidon or Tyre to Carthage and Cadiz. They shipped westward the spices, silks and ivories of the east, and eastward the silver, copper and tin of the west. From the Persian gulf the trade was carried in Indian ships as far as Malabar. Goods were apparently transferred there to other Indian ships proceeding to Bengal or to the Straits of Malacca, where ships from China (as from about the 1st century B.C.) were contacted.

But this was not the only possible route. for goods could also still pass by the overland route! reaching the Black sea and so entering Europe via the Danube or the Adriatic. The wealth of Troy presumably depended upon this trade which led the Greeks and Trojans to quarrel over it. Between the Greeks (as, later, the Romans) and the Phoenicians was an essential rivalry, as between two alternative routes by which the same trade could pass. The struggle ended. for the time being, when Alexander the Great led his army to conquer Egypt and establish the new port of Alexandria with its famous lighthouse.

The Romans became heirs to this Hellenic empire and inherited from it a well-established trade with India and China. Mainly because of Parthian hostility, the Romans developed the sea route, whi'ch was notably improved by the discovery of how to sail direct from Egypt to India without following the coasts of Arabia and Baluchistan. This discovery, attributed to Hippalus, took place in about A.D. 50, leading to a vastly increased trade which did not decline until the time of Hadrian. This trade is described in detail by the author of the *Periplus of the Erythraean Sea*, written at Berenice in about A.D. 80–89, it dwindled only as the Roman empire itself declined. Direct trade by sea between the Roman empire and India almost ceased in the time of Caracalla. The foundation of Constantinople in A.D. 328 was the symptom of a revived interest in the land route via the Black sea, a route destined to be used throughout the middle ages.

The rise of Islam from A.D. 622 until about 800 marks a new phase in the history of trade between Europe and Asia. The Arabs, at the height of their success in the 8th century. controlled a territory stretching from Portugal to the Indus. This brought the whole of the southern route trade under Arab control and lessened the flow of what still passed through Trebizond and Byzantium. The Arab trade from the Atlantic to China was facilitated by the brotherhood of Islam but was based upon a Greek and Roman inheritance of knowledge, postal organization and commercial integrity. The trade of Christendom was largely confined to the northern side of the Mediterranean and led from Constantinople to Venice, Genoa or Marseilles with overland passage thence to Germany, Flanders and France.

Hostility between Christendom and Islam came to a head during the crusades (1100–1270) which temporarily recovered for the Christians the ports of the Levant and a share in the trade still passing through the Persian gulf to the Syrian coast. Concident with this was a period of Chinese enterprise in the Indian ocean, trade being active in the 10th–12th centuries. It was probably during this period that a number of important Chinese contributions to shipbuilding and navigation passed to Europe.

The chief profit from the crusades went to the Venetians who came to terms with Islam and secured a commercial supremacy in the Mediterranean which was not seriously shaken even when the Turks captured Constantinople in 1453. The commercial empire of Venice, based upon a chain of defended ports in the eastern Mediterranean, linked up with the land routes over the Alps into Germany. The German cities were connected in turn with the Netherlands, via the Rhine. and so joined up with the Hansa—an alliance of trading cities which extended from the Rhine delta up to the Baltic. England lay opposite the ports of Bruges and Antwerp but had little share, during the middle ages, in any long-distance trade. The Hansards controlled the more valuable imports and had their own establishment in London. English merchants were better able to compete on the western side of the British Isles. They could thus trade with Ireland, with Bordeaux and Portugal, making use of such ports as Bristol, Chester and Exeter. There was a change of pattern in the 13th century when the Venetians began to sail round from the Mediterranean and open trade directly at Southampton. Many of the essential techniques of modern commerce are derived from the Venetians and Hansards, although not necessarily invented by them. It was not until the 16th century that the English merchants began to be important even in northern Europe, nor until the 17th century that they began to trade as far afield as the Mediterranean.

As the European ports for eastern trade. Venice and the other Italian cities traded throughout most of the middle ages with lands under the rule of Islam. The Arabs of the Levant had proved tolerant of Christian merchants from the 12th century onward, partly because they depended upon them for arms. But long after the crusading spirit among the Italians had given place to commercial agreements with the infidel, the Spanish and Portuguese were waging bitter war to reconquer the Iberian peninsula for the Christian faith. During the period 1245–1345 Italian traders had travelled, under Mongol protection, as far as China. The Portuguese were absorbed, by contrast. in recovering Portugal, which they had no sooner done than they sought to outflank the Moors in Africa by circumnavigating that continent. It was the spirit of the crusade which led them to success in this enterprise in 1497—their actual route to the Cape being in the wake of Christopher Columbus' crossing of the Atlantic in 1492.

The new route between Europe and Asia via the Cape lasted from 1497 to 1869. Its immediate success was due less to its inherent advantages. considerable as these were. than to the vigour with which the Portuguese strangled every alternative. In a few years they built up a trade between Lisbon and Macao, with intermediate ports in east Africa, India, Ceylon and Malaya. But the Portuguese were unable to hold a monopoly for long against the stronger maritime peoples of western Europe — the Dutch. English and French. They soon lost their supremacy, the Dutch changing the route by sailing direct from the Cape to the Straits of Sunda, cutting out the ports of India when sailing to or from Java and the far east. The discovery of Australia was one by-product of this new route and the development of South Africa, in Dutch hands, was another.

During the 18th century the British established their sea power in the east, centred upon India. and built up a series of bases between Great Britain, India and China — St. Helena. Cape Town, Bombay, Madras. Calcutta and Penang. To these mere added Ceylon, Mauritius and Singapore early in the 19th century, Hong Kong in 1841, Labuan and North Borneo in about 1848. This represented the final achievement of the sailing-ship era. Already, however, from about 1840, there were signs of a revival of the older and shorter route. Napoleon had investigated its possibilities during his campaign in Egypt, being forced to realize in the end that the Red sea was no place for merchantmen under sail. New possibilities opened up, however, with the development of the steamship, and it was found possible to carry mails and passengers via Suez with a short overland journey (by rail from 1857) between one steamship and another. The logical sequel to this was to cut a ship canal across the isthmus, and this was finished in 1869 by an international company in which Great Britain acquired a controlling interest. Trade now reverted to the old route with British bases developed at Gibraltar, Malta, Cyprus, Alexandria and Aden. Cables were laid along the same route shortly afterward. For sea-borne trade this continued to be the normal communication between Europe and Asia, the longer sea route affording an alternative way of reaching Australia, via South Africa, more especially in time of war. The distance from London to Melbourne is 1,000 mi. less via Suez than the Cape but, because of canal dues and delays, there is little difference in either time or cost.

The air routes to the far east developed after 1945, being by the mid-1950s still used almost solely for passengers and mail. In general outline they duplicate the route by sea but take a shorter line over Arabia and India. British airlines use airfields at Rome and Zurich, Beirut. Cairo. Basra, Bahrein, Delhi. Calcutta. Bangkok. Singapore and Hong Kong. The airport at Bangkok has become important as the connecting link with the trans-Pacific seivices.

Routes between Europe and America. — Soon after the discovery of the new world in 1492 it was found that the wind system in the Atlantic favoured a clockwise movement of trade, the outward bound ships heading initially for South America—their course being the same as if bound for the east—and then sweeping northward through or near the West Indies, along the American coast and so homeward via the Newfoundland banks. There were modifications of this general movement, slave ships for example calling in west Africa on their outward passage, and some ships taking a more southerly route homeward. On the far side of the Atlantic the first point of commercial interest was the Spanish Main, leading to the isthmus of Panama. North of the isthmus lay Mexico, across it and southward lay Peru. These lands were conquered by the Spanish and remained a Spanish preserve until the 19th century, just as Brazil (on the route to the east) remained for long a preserve of the Portuguese. The Dutch and English. arriving later, secured footholds in the West Indies and passed on to the coasts of Virginia and New England, where the English soon predominated. The coasts on which they had settled were. from a long-term point of view, hemmed in by mountain ranges in the immediate hinterland. It was the French who outflanked that barrier by penetrating the St. Lawrence and gaining eventual access to the Great Lakes and the heart of North America.

Transatlantic trade based on Bristol and Liverpool increased

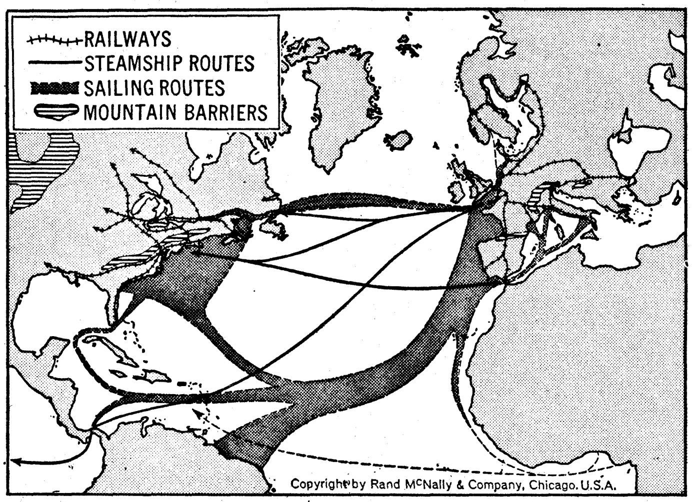

FIG. 2.— TRADE ROUTES BETWEEN EUROPE AND AMERICA

in the 17th and 18th centuries depending mainly on sugar, tobacco and slave trading. The French possessions on the St. Lawrence were conquered by Great Britain in the Seven Years' War and retained after the American colonies gained their independence in 1783. During these French Wars the trade routes in the North Atlantic were the scene of naval conflict, battles for the protection or interception of convoys taking place off the French coast, in the West Indies and near the American ports. These classic routes, upon which naval strategy was based, did not alter appreciably until the advent of the steamship. From about 1845 steamships began to prevail, soon becoming the normal means of transport for goods as well as for passengers. As they became more powerful, especially after 1870, they abandoned the more circuitous routes of the sailing ship. At the same time they had to plan their voyages in relation to fuel supply, the Atlantic crossing particularly favouring the steamship in having coal supplies at either end. As extensions of the Atlantic trade came the canals and then the railways, fanning out from the main European and American seaports. Perhaps the most important of the canals was on the American side and opened at a relatively early date. This was the Erie canal, in use from 1825 and connecting the Hudson river with the Great Lakes —a major factor in the rise to the greatness of New York as a trade centre of the world. The North Atlantic was crossed by telegraphic cables from 1866, supplementing the regular traffic of ships by the ready exchange of commercial and other news.

The paramount importance of the North Atlantic trade routes is due to the size and wealth of the centres of population which those routes connect. And, although the industries on either side of the Atlantic are partly the same, the natural products are markedly different. The vital character of this traffic is shown not only by statistics but by the elaborate and costly installations at termini such as Southampton, Liverpool, Hamburg, New York city and Montreal; as also by the vigour with which this route has been defended in time of war. During World Wars I and II attempts to intercept the trade were concentrated upon such vulnerable points as the Mersey estuary. The factors of distance and (at some periods) of neutrality averted any comparable attacks upon the U.S. end of this great trade route.

Perhaps the greatest volume of traffic in the world is that which passes through St. Mary's canal and the Great Lakes. There more than anywhere else the export traffic of a great continent is largely confined to a single outlet. Again the sea communications are largely duplicated by the air routes, which afford swift passage for mails and travellers between the great international airports of London and New York city. On the longer flights farther south from Lisbon. Port., use is made of intermediate airfields at the Azores and Bermuda.

Whereas the transatlantic trade was one in which British shipping predominated, the main interests of the United States began from an early period to turn toward the Caribbean. The first stage in this process had been the development of American trade with the Rest Indies, only slightly checked in 1783. The second stage was the Louisiana purchase of 1803 which made the Mississippi a main trade outlet instead of the western boundary of the United States. Thenceforward, as the middle west developed, its trade tended to follow the lines of least resistance, northward through the Great Lakes or southward to the Caribbean. It was the latter drive which gave the United States a growing commercial interest in Central and South America—a compensation for the extent to which the North Atlantic trade remained in European hands. As Mexico revolted against Spain in 1821, U.S. pressure south ard increased, leading to the independence of Texas in 1836 and its annexation to the U.S. in 1845. the establishment of commercial influence over Cuba and the rapid growth of the port of New Orleans, La. The Americans had great difficulty at first in breaking into the South American trade. All the historic connections of Brazil and the Argentine were with Europe, and New York is no nearer South America than is Liverpool or Hamburg.+

Where the U.S. was better placed was in relation to Peru and Chile. California had been seized from Mexico in 1846, preparing the way for the rise of San Francisco from 1849 and the first transcontinental railway of 1869. With the United States firmly established on the Pacific, the trade to the west side of South America was a legitimate field for U.S. enterprise. It was a coast well out of reach of European shipping, for the rounding of Cape Horn is a far more formidable feat than is the rounding of the Cape of Good Hope. But the pressure of exports seeking their market did not come from the narrow coastal plain of California. It came from the vast hinterland of New Orleans and pressed upon the slender barrier formed by the isthmus of Panama. There were the beginnings of a canal as early as 1880 but the French company went bankrupt and the aork was resumed by the United States in 1902. The technical and medical problems were immense, and the Panama canal was not completed until 1914.

With the opening of the Panama canal the full influence of eastern America could be brought to bear upon the west coast, not only of South America but of the United States itself. By 1930 the Panama canal had more traffic than the Suez canal. Long before that, the implications of the new route had become apparent. For nhile British traffic to Australia. Hong Kong. Manila or even Yokohama would still go via Suez—only New Zealand being nearer by Panamá—New York was now as near to Hong Kong or Manila by either route and nearer to Sydney by Panama. From the beginning the Americans were acutely aware of the need to protect the Panama canal by bases on the Atlantic side—Jamaica, for example, being potentially to the one canal what Malta is to the other. Part of the price of the U.S. intervention in World War I was the virtual British withdrawal from the Caribbean. This was a slow process, culminating in the lease of bases arranged during World War II. U.S. influence upon South America was further strengthened by the development of airlines, which shorten the distance, as for example between Belem and Rio de Janeiro, Braz.

Routes between America and Asia.—The United States has an interocean position, but with unequal opportunities as between the Atlantic and the Pacific. The Pacific has, to begin with, no potential trade comparable with that of the Atlantic. The ocean itself is wider but the lands which drain into it are less than half the area of those draining into the Atlantic. The rivers are short on the American side and those on the Asian side, if longer, are open to other objections, the Amur being frozen for half the year and the Hwang-ho changing its course too often. So the Pacific offers no limitless room for the expansion of trade. But, its potentialities had still to be fully explored by the second half of the 20th century, and some of the adjacent centres of population, in southeast Asia and Australia, for instance, were of growing importance.

The first trans-Pacific trade route was that established by the Spanish between Mexico and the Philippines. The United States, however, was the first world power to establish itself on the Pacific. This was the result, first of all, of the creation of a firm base extending from San Francisco to Alaska, acquired with the Aleutian Islands in 1867.

The next step was the acquisition of Pago-Pago in 1872, followed by the acquisition of the right to use Pearl Harbor in 1887. A growing interest in Hawaii, dating from before 1844 led to its annexation in 1898 and statehood in 1959.

At this point, United States interest in the Pacific trade routes fell very far short of control. Before the cutting of the Panama canal the eastern seaboard of North America was remote from the Pacific and the full American influence had therefore yet to develop. Nor was the United States the only power with interests in Pacific trade. The British empire straddled the Pacific with commercial bases at Vancouver (B.C.), Wellington (N.Z.) and Sydney (Austr.).

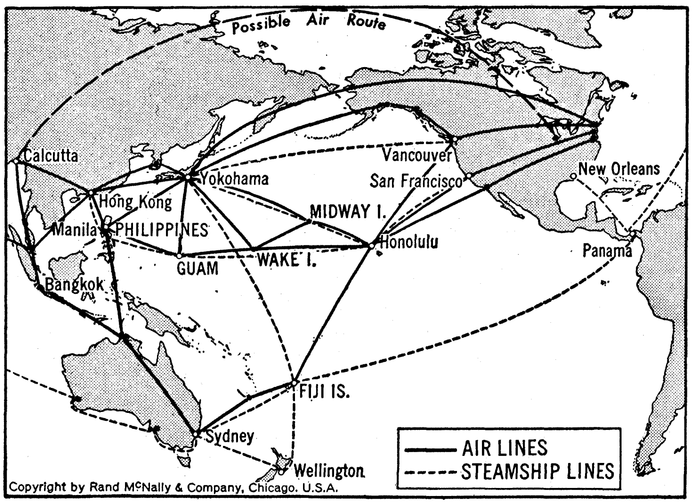

FIG. 3.— TRADE ROUTES BETWEEN AMERICA AND ASIA

The Germans, coming late on the scene, had interests in Samoa, which they showed themselves willing to defend in 1888, and Spain later sold to Germany the Carolines and the Marianas (Ladrones). But Germany was remote from the scene and far less directly interested than Russia. The completion of the Russian-leased Chinese Eastern railway and its connection with Vladivostok in 1897 had given the Russians a base in the north Pacific. The Russians' basic handicap lay, however, in the distance between their Baltic, Black sea and Pacific ports. Even the French in Indochina and the Dutch in Java were not wholly excluded. The question as to which power should succeed to this part of the Spanish empire had still to be decided.

The turning point was the Spanish-American War of 1898. A brief and unequal conflict gave the United States Puerto Rico and the entire Philippines. With a broad base on the U.S. coast, with Manila on the far side of the Pacific and with intermediate cable and coaling stations at Hawaii, Samoa, Midway and Guam, the United States was almost in a position to claim supremacy. It only remained to complete the Panama canal, the territory for which was obtained in 1903.

It was in 1903 that Pres. Theodore Roosevelt proclaimed at San Francisco that to the United States must belong the dominion of the Pacific.

Coincident, however, with the U.S. advance into the Pacific was the rise of Japan. The Japanese of the new Meiji era (1868–1912) quickly westernized their country and their forces, won victories over China in 1894 and 1895 and over Russia in 1905, acquiring Formosa, the Pescadores and (in 1910) Korea. This brought about a deterioration of U.S.-Japanese relationships, intensified during World War I when the Japanese used the occasion to capture from Germany the Marianas, Caroline and Marshall archipelagoes, simultaneously strengthening their hold over China. For a westernized Japan trade was vital, if only to dispose of the products of Japanese industry. With easier international relations, the Japanese might have secured a share, at least, of the trans-Pacific trade but the tariffs imposed during the slump of 1929–31 drove them to conquer Manchuria instead in 1931–32. This was only a partial solution to economic difficulties, and it became a Japanese ambition to open a new trade route, via Formosa and southeast Asia, to Australia. Squarely in the path of any such development stood the Philippine Islands, in U.S. hands, flanked by British Borneo, Malaya and New Guinea, and from about 1922 the British naval base of Singapore was developed with the object of preventang any such Japanese advance.

The fall of Singapore in 1942 represented a momentary triumph for the Japanese, but they held the area for only three years.

Decisively defeated in World War II, the Japanese could no longer suppose that their ambitions in this direction were practicable.

It remained true, nevertheless, that the route from Shanghai or Tokyo (or Vladivostok) to Manila and thence to Halmahera, Brisbane. Sydney, Melbourne and Hobart was still, potentially, one of the great trade routes of the world.

TRADESCANT, JOHN (1608–1662), English traveler and gardener, was born at Meopham, Kent, on Aug. 4, 1608. He inherited the museum and physic garden that had been founded at South Lambeth by his father, John Tradescant (d. 1637?). In 1637 young Tradescant traveled to Virginia to collect specimens for the museum.

His *Musaeum Tradescantianum,* a catalogue of the museum and physic garden, was published in 1656. At that time, the museum was considered to be the most extensive one in Europe. A potpourri of rarities, it reflected the universal interests of scientific men of the period and was one of the precursors of modern museums of natural history and art. After Tradescant's death on April 22, 1662, the collections were eventually absorbed into the Ashmolean museum at Oxford.

See *Dictionary of National Biography* for a fuller account; A. W. Anderson, "John Tradescant," *Gardeners' Chronicle of America,* pp. 324–325 (Dec. 1947). (J. W. Tt.)

TRADES UNION CONGRESS, THE. The Trades Union congress of Great Britain was formed at a conference of trade union organizations in Manchester, Eng., in 1868 and has had a continuous existence as a permanent association of trade unions which each year send delegates to a congress to express trade union opinion on matters of common concern and to elect a general council to act as an executive body for the movement. During its rise to a position of national and international standing, the T.U.C. established its right to speak for the organized workers of Britain. At no time has there been any rival national organization to claim the allegiance of even a substantial minority. Unlike movements in some other countries the unity of the British trade union movement has never been broken by differences of religion, politics and theories of organization. In its early years the congress was concerned mainly with legislation affecting the status of the unions and the interests of their members, although from time to time it also considered political questions. In 1899 a resolution at congress called for a special conference representing the unions, the co-operative societies and the socialist organizations to devise means of increasing the number of Labour members of parliament (see LABOUR PARTY, THE [BRITISH]).

Increased trade union membership led to a growth in the influence of the T.U.C. which was enhanced during World War I by the decision to share in national consultation on matters of national importance. During World War II regular consultation between trade union leaders, employers and the government developed on a scale that embraced all ministerial moves, bills, regulations and other actions bearing on the interests of the workers. This practice continued after the war—a welcome change from the years when the unions could do little more than lobby ministers and M.P.'s when they wanted to make proposals to the government.

Some reference should also be made to the Trade Disputes and Trade Unions act of 1927 which was passed following the general strike in support of the miners in 1926. This act, which was repealed in 1946, banned general strikes and most sympathetic strikes and imposed restrictions on picketing. It also affected the political activities of the unions.

Membership. — Starting in 1868 with 118,367 members, the T.U.C. doubled that number in one year and by 1874 totalled more than 1,000,000 members in 150 unions. Membership subsequently fluctuated between 460,000 and 800,000 until 1890 when the million mark was again reached. At the beginning of World War I there were more than 2,000,000 members in about 200 unions, and by 1918 the total had risen to 4,500,000 in 262 organizations. The highest point in affiliated membership between World Wars I and II was 1920 when 215 unions affiliated 6,500,000 members. Then came a decline mainly as a result of the economic depression which beset the country particularly in the early 1930s. After 1934, when membership was 3,200,000, there was a steady increase and after 1952 the total affiliation was more than 8,000,000 in about 180 unions.

Unions in the T.U.C.—Unions affiliating to the T.U.C. pay an annual affiliation fee of 6d. on each of their members. Any trade union may affiliate providing it satisfies the general council of its bona *fides*. The repeal in 1946 of the 1927 Trade Unions and Trade Disputes act restored to unions in the civil service the opportunity of affiliation to the T.U.C.

Affiliated unions vary in size and character and in their views on organization. The biggest is the Transport and General Workers' union with about 1,250,000 members, and this organization, together with five others, makes up half the membership of congress. Nevertheless in 1955 there were three affiliated unions with less than 100 members and 37 with less than 1,000 members each. Generally, however, after 1920 the tendency was for unions to grow bigger and fewer, with amalgamation reducing the number of organizations in the same trade or industry. Such developments took place in unions organizing in coal mining, transport, engineering, distribution, building, foundries and the furniture trades.

Another move toward closer working among unions in the same trades and industries was the setting up of federations, usually for collective negotiation and other common action within an industry. The principal federations in 1955 were the Confederation of Shipbuilding and Engineering Unions, the National Federation of Building Trades Operatives and the Printing and Kindred Trades federation. There were also federations in cotton and woollen textiles. Since their constituent unions are affiliated direct to congress, none of the federations themselves affiliate though they keep close touch with the T.U.C.

Though some of the differences between craft, industrial and general unions have become less pronounced with technical change in industry, unions affiliated to congress usually so classify themselves, apart from those nonmanual and professional bodies which have grown in strength and numbers since the 1920s. Broadly speaking the craft union bases its organization on the tool operated, the industrial union organizes workers on the basis of the commodity they produce, while the general workers' unions having evolved from the organizing of the unskilled, include many workers of different industries and skills.

The aim of the trade union movement is to secure a 100% membership in every place of work with every worker belonging to the appropriate union. The term "closed shop" is often wrongly used in referring to this particular trade union aim and in 1946 the T.U.C. made it clear that the closed shop in the sense of an establishment in which only members of a particular union can be employed to the exclusion of members of other unions is alien to British trade union practice.

The Annual Congress.—Affiliated unions are entitled to send one delegate for every 5,000 members or part thereof to the annual congress which is presided over by the chairman of the general council for the previous year. All delegates must, when appointed, be working at their trade or be permanent paid officials of their union.

The annual congress has three main functions. It considers the detailed report of the work done by the general council during the previous year and if necessary makes recommendations for further action. It discusses and takes decisions on the motions forwarded for the agenda by affiliated unions. Finally it elects by ballot the general council for the coming year. Decisions are taken either by voice, show of hands (when each voter is counted as one) or, at the request of delegates or the discretion of the president, by a card vote, which can be called for on any issue. The card shows the number of trade union members represented by each delegation and enables each union to cast its full affiliated strength either for or against the issue.

The General Council. — In 1869 an elected parliamentary committee was appointed to carry out the decisions of congress. This committee did little more than keep an eye on legislation and interview ministers of the crown and members of parliament when the need arose. As World War I ended the demand grew that the movement should have a more effective centralized leadership, and in 1919 proposals for the setting up of an enlarged executive body were submitted to a special congress. This executive body, first elected in 1921, was the T.U.C. general council.

The 35 members of the modern T.U.C. general council lead the British trade union movement on broad national policy. They keep up relations with the government, with employers' organizations, and with a large number of advisory and consultative bodies concerned in particular with social and economic problems. Affiliated unions are divided into 18 trade groups and seats on the general council are allocated according to the size of the group. A 19th group ensures that two women trade unionists are always elected to the council.

Any union in a group may nominate to fill places in its group but all the unions in congress vote in the election. Similarly, only unions with women members may nominate for the women's group, but all unions cast their votes in the election. The effect of this system of voting is that members of the general council sit as representatives not of individual unions or groups of unions, but of congress as a whole. It also ensures that the members bring to their deliberations opinion and experience representative of the whole range of British industrial activity. The principal executive officer of congress, the general secretary, is elected by congress and is a member of the general council.

Once elected the council appoints its chairman for the year and, subject to the rules and standing orders of congress, acts as an executive body.

Neither congress nor the general council can override the autonomy of the affiliated unions, and none of their decisions are binding. However, the moral authority of the council is strong and since it interferes as little as possible in the domestic affairs of the unions, there is a readiness among affiliated organizations to accept its decisions.

Standing orders lay down specific duties for the council during strikes, in disputes between unions and on misconduct by unions. During a strike the council does not intervene unless it is asked to do so, or unless the interests of the movement as a whole are involved. Once, however, the council has intervened in a strike it is bound to seek a just settlement of the difference and to advise the unions involved. Should a union refuse this advice it is reported to congress. Similarly, if the general council is unable to get the necessary undertakings from a union which after full investigation is found to be behaving in a way detrimental to the interests of the trade union movement or contrary to the declared principles and policy of congress. the offending union is reported to congress. In the meantime the council may suspend the affiliation of the union.

When differences arise or threaten to arise between unions (for instance, on demarcation issues), the general council seeks a settlement through its disputes committee, which exercises a triple function as a fact-finding commission, as a conciliatory body and as a judicial tribunal. Unions are expected to abide by the council's decision, and in the event of serious disobedience the council may decide to suspend affiliation until the following congress, when the matter is raised. To help keep good relations inside the movement, congress agreed in 1939 on a set of guiding-principles — the Bridlington agreement — which though not a legal code aims to eliminate competition between unions organizing in the same field.

Besides a disputes committee there are a number of other committees through which the council operates. These committees and the council are served in detailed consideration of policy by a full-time staff at T.U.C. headquarters, organized on a departmental basis. The main departments are education, organization, research, international, production and social insurance, and their senior official acts as secretary to the appropriate committee. Other departments deal with press and public relations, publications and finance.

In addition to committees which are composed exclusively of general council members there are a number of joint committees which co-opt experts or representatives elected at special conferences. These committees deal with matters affecting trade councils, women workers, nonmanual workers, scientific development and the colonies.

Trades Councils and Regional Machinery. — Inside the movement the trades councils (local representative bodies of trade union branches) have long played an important part. First formed in the middle of the 19th century. trades councils were represented separately at congress until 1895. Then, after a period of uncertainty during which there was no formal association between the trades councils and the T.U.C., they were from 1924 brought more and more into the machinery of congress and became the local agents of the T.U.C., under a system of yearly registration.

The other part of the T.U.C.'s regional machinery is the regional advisory committees of which there are 16 in Great Britain. Made up of full-time officials of unions, these committees share with the trades councils the nomination of trade union representatives to many local bodies connected with industry and the social services, are responsible for keeping the T.U.C. informed about the situation in their regions, and co-operate with employers and government departments in advising ministers of the crown on industrial development.

External and Educational Activities. — Altogether the T.U.C. is represented on more than 100 government and other bodies whose activities affect the public interest. Among the most important outside committees with which the general council is associated are the National Joint Advisory Council to the Minister of Labour which deals with a wide range of employment problems and the National Production Advisory Council on Industry which concerns itself with factors affecting output.

As an autonomous industrial body the T.U.C. does not spend money on political action, nor does it have a political fund. The general council does, however, nominate representatives to the National Council of Labour, a nonpolicy-making consultative body which also includes the nominees of the Co-operative union, the executive committee of the parliamentary Labour party and of the Labour party national executive committee.

In 1949 the T.U.C. became affiliated to the International Confederation of Free Trade Unions which was founded in London in that year and has more than 54,000,000 members in 75 countries. The T.U.C. also has close contacts with trade unions in the colonies. Another international body receiving strong support is the International Labour organization (I.L.O.). Each year the British government invites the T.U.C. to nominate the British workers' delegate and his advisers to the annual conference of the I.L.O. The T.U.C., too, makes nominations for British workers' representatives to attend the specialist committees of the I.L.O.

Among the services of the T.U.C. which expanded steadily after World War II was the provision of training courses for trade unionists. By 1955 there were an annual summer school at Oxford; a trades council summer school at Oxford; weekend and day schools for Federations of Trade Councils on the basis of at least one a year for each federation; and a wide range of courses at the T.U.C. educational centre.

The T.U.C. also advises and assists unions preparing study courses and contributes to the Workers' Educational association and the National Council of Labour Colleges.

TRADE (LABOUR) UNIONS. Trade unions are associations of employed persons for collective bargaining about their conditions of employment and also for the provision of benefits, legal defense and the promotion of their members' interests by bringing pressure to bear on governments and parliaments and, in certain cases, by political action. They undertake other functions besides these — for example, educational work and, in some cases, participation in the organization of industry through co-operative societies or by representation on control boards or in the management of productive operations; but their main work is in the field of collective bargaining, and in some countries the development of social security legislation has made their benefit activities less important than they formerly were.

The words "trade union" were originally used to mean a union of local trade clubs or societies to conduct a joint movement, the words "trade club" or "trade society" being used to describe the primary units of working class combination. Trades' union meant a combination of societies covering a number of different trades (for example, carpenters, bricklayers, etc., in a building trades' union). General combinations of societies in all trades were called trades unions or general unions. Later, as the local trade clubs amalgamated into larger bodies, the words "trade union" came to be used in their present sense, to cover any combination of workers for collective bargaining. The French equivalent is *syndicat ouvrier*, or simply *syndicat*, which still means mainly local trade union; the German word is *Gewerkschaft*, the Italian *sindacato;* Americans use mainly the term "labor union" or simply "union."

GREAT BRITAIN

No date can be assigned to the origin of trade unions; but in Great Britain they did not become numerous until the 18th century, mainly as local trade clubs of skilled workers in a particular town. There were occasional journeymen's combinations in the 16th and 17th centuries, to make demands on guild masters or other employers; but there is no basis for the attempt to treat trade unions as descendants either of the mediaeval guilds or of the bachelor or journeymen fraternities sometimes associated with them in a subordinate status.

The earliest trade societies arose among skilled workers, such as printers. tailors, saddlers, wool combers, brushmakers and weavers. They were usually small groups, often centred at a particular house of call, and they carried on friendly benefit activities as well as regulation of the conditions of employment, especially in relation to apprenticeship, hours of labour and standard wage rates.

These small trade clubs, until the 19th century, usually formed wider unions of delegates only on particular occasions, when they aished to put forward a common claim or to fight some concerted move of their employers. Such joint movements were most often limited to a single town or district and to a single industry; but in the case of weavers (and later miners) they sometimes covered considerable areas, for otherwise it was easy to defeat them by withholding work from a particular locality and transferring it elsewhere. This was especially the case in the textile trades, under the domestic system. That is why the weavers were the pioneers of trade unions covering a wide field; but their combinations of this type never lasted long and were usually broken up by the joint action of employers and the law. Spme trades, without permanent unions, had well-organized travelling arrangements whereby a journeyman seeking work outside his home district applied to the local house of call and was either found employment or helped on his way to another district (for example, wool combers, brushmakers. printers).

Mere local trade clubs were seldom interfered with by the law; but attempts to form wider unions soon brought the workers into conflict with municipal or national authority. In Great Britain, where the sections of the Elizabethan Statute of Artificers empowering the local justices to regulate wages and apprenticeship were not repealed until 1813–14, workers' combinations for the purpose of urging the justices to fix wages or to prevent the employment of illegal (that is, unapprenticed) men on skilled work were regarded as in themselves lawful up to the enactment oi the Combination acts (1799–1800) which definitely made all trade combinations unlawful.

But well before that the judges had come to regard as unla ful any combination which they regarded as being in unreasonable restraint of trade; and that was more and more held to cover all attempts to regulate wages or conditions of labour, as distinct from merely asking the justices to do so. Indeed, the Combination acts were passed less for the purpose of declaring trade unions to be criminal conspiracies — for in effect the courts had come so to regard them already — than for that of providing easier means of bringing minor offenders to book by empowering the justices to deal with cases of combination by summary jurisdiction, whereas previously such charges had involved procedure by indictment for conspiracy in a higher court. Formally, the Combination acts applied to employers' as well as to workers' combinations; but no employer was ever prosecuted under them.

In Great Britain, the name "trade union" still legally covers employers' associations, and a few such bodies are registered under the Trade Union acts. But in practice this wider sense of the term has little importance.

Early Legal Position. — Trade Unions were prohibited in France under the Le Chapelier Law of 1791, which outlawed all private associations; but in neither France nor England did the outla ry prevent their existence. though it rendered their leaders always liable to prosecution and their continuance precarious.

In Great Britain the Combination acts had been part of a series of laws passed to repress popular movements during the period of the revolutionary wars; and their enforcement was very uneven, being most severe in the mining and northern textile areas, where large numbers of potentially riotous persons were involved, and least so among the skilled urban craftsmen, whose small clubs were usually unmolested. The Combination acts were repealed, together with other acts against combinations in particular trades, in 1824, thanks mainly to the efforts of Joseph Hume and Francis Place; and the repealing act also removed the common law taint of illegality. It was replaced the next year by a much less generous government measure, which gave trade unions a bare legal right to exist, but imposed many restrictions on their actions. This act of 1825 remained in force till 1871. Other repressive statutes remained; in the famous case of the Dorchester labourers, or Tolpuddle martyrs, in 1834, the prosecution was not nominally for combining, but for "administering unlawful oaths," and the same charge figured in the indictment under Scots law of the Glasgow cotton spinners' leaders in 1837.

1825–1888.—British trade unionism after 1825 grew very fast and by 1830 attempts were being made to form a general trades union open to all kinds of workers. During these years the workers played their part in the reform agitation and, after the Reform Act of 1832 had left them voteless, turned to large-scale industrial action in the hope of improving their condition. Many unions passed under the influence of Robert Owen's ideas and launched ventures in co-operative production, including the Grand National Guild of Builders set up by the Builders' union in 1833 with the purpose of taking the entire building industry into its hands. Owen, taking the lead. tried to combine all the trade societies and unions into a Grand National Consolidated Trades' union which, after a year of bitter conflicts with the employers and the government, collapsed in 1834, its fall hastened by the sentence on the Dorchester labourers. From this point most trade unions and clubs abandoned the practice of administering oaths of secrecy to their members. The fall of the Grand National did not destroy the movement, but broke it up again into small independent local societies. with only a few unions (*e.g.,* the stonemasons) surviving as national bodies.

By 1845 recovery had gone far enough for a new central body—the National Association of United Trades for the Protection of Labour — to be set up. and for a revival of attempts at co-operative production under its auspices; but this body died away after a few years, and attention was given mainly to building up highly organized national or regional unions of skilled workers in particular trades — notably the Amalgamated Society of Engineers (1851) and the Amalgamated Society of Carpenters and Joiners (1861). The cotton operatives also reorganized strongly in local societies, federated for common action, and began to secure recognition and develop modern collective bargaining methods.

The miners, who had prematurely created a national union in the 1840s, only to have it destroyed by depression and conflict, built up a new nation-wide movement in the 1860s and began to press successfully for acts regulating safety conditions as well as for higher wages.

At this point the British unions became involved in a series of legal struggles which lasted from 1864 to 1875. Aided by the Reform Act of 1867, which enfranchised many urban workers, they not only repelled the attacks on the legality of trade unionism, but secured in the Trade Union Act of 1871 an assured legal status and, in the Master and Servant Act of 1867. the Employers and Workmen Act of 1875 and the Conspiracy and Protection of Property Act of 1875, great improvements in the workers' status at law and in the provisions regulating strikes and picketing. In 1869 the trade unions took part in forming a Labour Representation league to send workmen to parliament. and two miners mere elected M.P.s in 1874. There was a great growth of trade unionism in the late 1860s and early 1870s, including Joseph Arch's National Agricultural Labourers' union and other movements among the less skilled workers.

Many concessions were won. and many employers agreed to recognize and bargain with the unions now that their legal status had been made plain. But with the passing of the trade boom of the early 1870s and the onset of depression many of these gains were lost, and a period of stagnation followed and lasted through most of the 1880s.

New Unionism. — It was ended by the rise of the new unionism of 1888–89, largely a product oi socialist agitation during the preceding years and of disillusionment with the Liberal party after Joseph Chamberlain's secession.

The outstanding event of this period was the London dock strike of 1889, led by John Burns and Tom Mann, in which the dockers won an unexpected victory (the "docker's tanner"—6d. an hour). Workers, skilled and unskilled, flocked into the trade unions, and many new unions were formed with low contributions and few or no friendly benefits to bring in the lowest-paid workers (dockers, gas workers, workers' union, etc.). The peak reached in 1890–92 was not kept; but, after many members had been lost, the new unions established their position beside the old, which began to adopt less exclusive policies under the influence of the new ideas. The new unionists laid great stress on agitation for a legal minimum wage and eight-hour day, and on the right to work—that is, the obligation of the government to provide work or maintenance for the unemployed. These demands led straight to a revival of political action, which had languished after the movement of 1869–75. James Keir Hardie's Independent Labour party (1893) set to work to induce the trade unions to join forces with the Socialists in an independent political party; the Labour Representation committee was founded on this basis in 1900 and became the Labour party in 1906, when it won 30 seats in the general election that carried the Liberal party back to power.

Later Legal History.—Before this, the unions had become involved in a further contest with the law. In the case of the Taff Vale Railway company *v.* the Amalgamated Society of Railway Servants (1901) it was decided that a union could be sued for damages caused by its agents' actions during a strike. This decision, which threatened the right to strike, was reversed by the Trade Disputes Act of 1906—the Labour party's first important success.

Almost at once a new crisis arose. The house of lords decided in the case of W. V. Osborne *v.* the Amalgamated Society of Railway Servants that a trade union could not lawfully take political action, as unions had been doing unchallenged for many years. This decision too was reversed, by the Trade Union Act of 1913, which allowed political action by unions, on condition of a prior ballot vote in favour of an exemption ("contracting-out") for objectors. This act was temporarily altered, to substitute "contracting-in," by the act of 1927, passed after the general strike, but on the repeal of the 1927 act in 1946 the act of 1913 resumed its force.

1910–1950.—From 1910 to 1914 there was acute industrial unrest in Great Britain, signalized by many strikes, by the emergence of syndicalist and industrial unionist ideas derived from France and from the U.S., and by the creation of powerful new unions by amalgamations. This movement was cut off short by the outbreak of World War I in 1914 and the declaration of an industrial truce. During the war the unions continued to make large gains in membership, and, official trade union action being restricted under the Munitions of War Act of 1915, an unofficial leadership grew up in the shop stewards' movement, which became increasingly antiwar, especially after the Russian revolution of 1917. The shop stewards, who had previously been quite minor workshop representatives of the trade unions, where they existed at all, took up the demand for workers' control of industry voiced by syndicalists and guild socialists, but came later under the leadership of the elements which went in 1920 to the making of the Communist party.

The end of war in 1918 was followed by a further period of widespread strike action, interrupted by the depression and by the great defeat of the miners in 1921, but resumed in the general strike, called by the whole trade union movement (though not all trades were actually called out) in support of the miners in 1926. The defeat of this movement for a time seriously weakened the trade unions, which were further weakened by the depression of 1931–33, but thereafter rapidly regained strength, without resorting again to policies of mass action.

World War II brought, from 1940 onward, a further increase in membership and influence, with the unions taking a vital part in organizing the national productive effort. Trade union progress continued under the Labour government from 1945, with the unions securely entrenched on all manner of advisory and consultative bodies, both with the government departments and with the employers, and serving more and more as agencies for securing working-class compliance with the restraints rendered necessary by international economic difficulties, as well as representative bodies for forwarding working-class interests. By 1950 trade union membership (see Table I) had reached 9,235,000, organized in 704 unions, and including 1,405,000 women. (These figures excluded a few unions not making returns.) The membership was highly concentrated in a small number of larger trade unions (see Table II).

TABLE I.—*Trade Union Membership in the United Kingdom*

	Unions	Trades Union Congress		Unions	Trades Union Congress
1866	—	199,000	1925	5,522,000	4,366,000
1871	—	289,000	1930	4,839,000	3,719,000
	—	735,000	1933	4,392,000	3,295,000
1880	—	476,000	1939	6,244,000	4,867,000
1888	—	727,000	1945	7,803,000	6,671,000
		1,927,000	1948	9,301,000	7,937,000 (1949)
1892	1,501,000	1,155,000	1950	9,235,000	7,827,945
1895	1,407,000	1,000,000	1951	9,481,000	7,828,000
1900	1,972,000	1,250,000	1952	9,526,000	8,020,000
	2,565,000	1,662,000	1953	9,459,000	8,088,000
	4,145,000	2,682,000	1954	9,495,000	8,094,000
1918	6,533,000	5,284,000	1955	—	8,107,000
1920	8,334,000	6,418,000			

There were in 1955 another 14 unions with more than 50,000 members, including weavers (84), boot and shoe operatives (82), furniture workers (75), foundry workers (74), dyers, bleachers, etc. (73), locomotive engineers (69), painters (69), seamen (62), post office engineers (62), vehicle builders (57), draughtsmen (56), plumbers (56), cardroom operatives (51), typographers (51).

Negotiating functions are largely concentrated in the hands of the big unions, or in some cases of federations in which they are among the leading members—for example, National Federation of Building Trades Operatives, Confederation of Shipbuilding and Engineering Trade Unions, Printing and Kindred Trades federation, Northern Counties Textile Trades federation. In most industries national agreements have been concluded with employers' associations or federations, covering methods of negotiation, wages, hours and other conditions of labour.

Recognition of trade unions for collective bargaining has become almost universal, and in many cases trade union representatives are sitting with employers on government-sponsored control boards (*e.g.*, cotton) or development councils or voluntary joint bodies dealing with economic policy. Trade union accumulated funds amounted in 1954 to £74,000,000. In that year the income of 411 reporting unions, with 8,357,000 members, exceeded £20,000,000, and expenditure £17,750,000. The main items of expenditure were working expenses (£10,500,000), superannuation (£2,200,000), sick and accident benefit (£1,200,000). Dispute benefits cost only £483,000 and political fund expenditure was £394,000.

The British Trades Union Congress.—The central organization of the British trade unions, the Trades Union congress, was formed in 1868. It elects a general council of 3j members, representing occupational groups, to conduct its business between the annual meetings of delegates. Nearly all the big unions belong to it. For an account of the development, powers and administration of the British Trades Union congress, see the article TRADES UNION CONGRESS, THE.

The general council has no executive power to bind its affiliated unions or to engage in collective bargaining. (The general strike of 1926 was called, not by the general council or congress, but by a specially summoned conference of trade union executives.) The general council has, however, in practice great influence in formulating policy on behalf of the whole movement; its influence grew rapidly as more closely co-ordinated policies became needed. There is a separate Scottish T.U.C., made up mainly of districts of British unions but partly of separate Scottish unions; it has no great power, but is useful in airing Scottish opinion. Some British unions cover Northern Ireland, and a few extend to the Republic of Ireland; but the Republican Irish have their separate trade unions and congress as well.

Locally, trade union branches are federated in the numerous trades councils, but these have small funds and not much authority. They are mainly propagandist bodies. The general council co-ordinates their work through an annual Trades Councils' conference and a Trades Councils' Advisory committee.

(G. D. H. C.)

TABLE II.—*Great Britain: Largest Trade Unions, 1955*

Name of union	No. of members	Occupations of Members
Transport and General Workers	1,240,000	Dockers, vehicle workers, canal workers and general workers in many industries
Amalgamated Engineering union	823,000	Skilled and some unskilled throughout engineering trades
General and Municipal Workers	787,000	Municipal and public utility employees, engineering, shipyard and builders' labourers, general workers
National Union of Mineworkers	675,000	All grades of coal miners, except managerial
National Union of Railwaymen	372,000	Mainly traffic grades and less skilled shopmen
Union of Shop, Distributive and Allied Workers	344,000	Shop assistants and warehouse workers, and especially co-operative employees
National Association of Local Government Officers*	236,000	Clerical and administrative grades
Electrical Trades union	226,000	Skilled and less skilled
National Union of Teachers*	225,000	Mainly in state schools
Amalgamated Society of Woodworkers	196,000	Carpenters and joiners, cabinetmakers
National Union of Public Employees	175,000	Manual workers on road work, etc.
Union of Post Office Workers	161,000	Postmen, sorters, clerks, etc. (not engineering section)
Civil Service Clerical association	142,000	Middle and lower ranks of civil service
National Union of Printing, Bookbinding and Paper Workers	142,000	All grades in bookbinding and papermaking (*less* skilled grades in printing)
National Union of Agricultural Workers	135,000	England and Wales only
National Union of Tailors and Garment Workers	124,000	All grades
Iron and Steel Trades confederation	104,000	All grades, except blast-furnacemen and some craftsmen
Amalgamated Union of Building Trade Workers	94,000	Bricklayers, stonemasons and labourers
Transport Salaried Staffs association	90,000	Clerical and supervisory grades
United Boilermakers association	86,000	Mainly shipyard workers

*Not in Trades Union congress

UNITED STATES

Although U.S. unionism is almost as old as the nation itself, its rise to the position of a major factor in U.S. life came only mith the New Deal. It is thus proper to treat the year 1933 as the great dividing line in its development.

Early Unionism. — The first local unions, formed by craftsmen in such industries as carpentry, shoemaking and printing, were formed in the closing decades of the 18th century, when the bulk of the population was still engaged in agriculture. In the late 1820s the first labour movement on a scale larger than that of the individual craft local appeared on the American scene. The growing industrial and commercial towns along the Atlantic seaboard and also in the interior witnessed the formation of city-wide federations of local unions to discuss common problems, aid each other in strikes and organizing efforts, promote the sale of union-made goods, and represent the labour movement generally in its dealings with city authorities and the general public.

Almost immediately these local bodies turned to political action. creating local labour parties in a number of areas and urging workers to exercise their newly won franchise by voting for labour candidates. Though these parties did not federate, they advocated similar legislative proposals, including such measures as the 10-hour day, free public education, abolition of imprisonment for debt, regulation of child labour, and mechanics' liens to enforce payment of wages. The parties, though short-lived, enjoyed some degree of success, measured both by the number of candidates elected to officeand their influence in persuading the more conservative parties to champion some of their measures.

In 1834 an effort was made to form a national trade union centre by federating a number of the local central labour bodies. The National Trades' union achieved very little influence before it was wiped out, as was most of the existing labour movement, during the long depression period that followed the panic of 1837.

In the mid-19th century business expansion led to a revival of the union movement. Developing means of transportation and communication were enlarging the market and permitting the growth of enterprise on a larger scale, and these factors in turn stimulated the formation of national unions in a number of industries, beginning with the printers in 1850. Though the national union at the time mas little more than a paper organization, authority still being vested in the local unions. the growth of a national market in the decades following the Civil War was paralleled by the steady rise in power of the national union at the expense of its affiliated locals or regional councils.

The National Labor union, established in 1866, sought to unite the growing labour movement in the period that immediately followed the Civil War. The National Labor union campaigned energetically for the 8-hour day and promoted producers' co-operatives and labour political action. The political party which it sponsored in the 1872 election met with little response, and both the N.L.U. and its political arm failed to survive the year.

During the depression-ridden 1870s the unions could make little progress, though there was a series of important strikes. notably on the railroads in 1877, against wage reductions. In the anthracite coal areas of Pennsylvania a secret labour body knonn as the Molly Maguires carried on a terroristic campaign against the employers before it was broken up by the conviction of its leaders.

Knights of **Labor.**—As a continuous, more or less unified movement, with its peculiar philosophy and strategy. unionisrn in the United States cannot be said to have become established before 1880. By 1880 the Knights of Labor, organized as a secret group in 1869, had appeared in the open as a union of all workers, skilled and unskilled, manual. clerical and professional, and even of the small businessman. During the next ten years there was unfolded one of the most dramatic and significant episodes in the history of U.S. labour. Hardly known at the beginning of the period. the Knights achieved by 1886 a membership of close to 1,000,000 and an influence far transcending its size.

The Knights had set out first to organize all workers. For this slow and gigantic task, the organization had neither the financial resources nor an adequate staff of organizers. It depended on the spontaneous uprisings of men and women. Such uprisings occurred often in the few years from 1880 to 1886.

But when strikes ended in failure and strikers lost their jobs and when there was no place to turn for the sinews of war, it became more difficult to arouse enthusiasm and action. At the same time much of the attention and energy of the officers of the organization mas dissipated in carrying out the ambitious economic program of the Knights, which ran from simple trade union action over wages to vast co-operative schemes or plans for the reorganization of the currency and banking system of the country. To these sources of weakness was added the inevitable conflict for jurisdiction between the Knights and the established craft unions. The episode of the Haymarket bomb in 1886 at Chicago. Ill., brought the Knights of Labor undeservedly into disrepute and hastened its end.

Rise of the American Federation of Labor. — Even during the heyday of the Knights. a new central organization of U.S. labour was already forming under the leadership of Samuel Gompers and his associates. This organization, appearing in 1886 as the American Federation of Labor, had as its precursor the Federation of Organized Trades and Labor Unions. begun in 1881. The Knights sought to absorb the existing craft unions. to subject them to the loss of autonomy and to involve them in industrial disputes in which their own direct interests were apparently not at stake. Against this tendency craft unions revolted, organizing themselves in the loose federation which remained for a half-century the sole unifying agency of the American labour movement.

The principles on which the American Federation of Labor was founded originated in the practical experience of the leaders of this new movement and in their reaction against the practices of the times. They saw in craft unionism the solidarity and permanence which they found missing in the one big union, the Knights, and in the industrial unions, mixtures of skilled and unskilled, sponsored by the Knights.

They observed that the best chances of continuity and strength in a movement of organized labour lay in formulating narrow and attainable economic objectives instead of embracing a large and attractive program of economic reform which the trade unionists themselves had neither the interest nor the capacity to make effective. In view, finally, of the failures of past efforts to engage in independent political action, they abandoned attempts to form a labour party and sought to achieve political influence by other means.

In its beginnings, then, the American Federation of Labor was dedicated to the principles of craft unionism and autonomy, and of collective bargaining to win recognition of organized labour and advances in working conditions. To this plan the federation consistently adhered. It was a loose federation of about 100 national and international unions, each retaining full autonomy over its internal affairs. In return, each union received from the federation protection of its charter or of the workers and industrial territory over which it claimed jurisdiction. Out of this policy grew bitter jurisdictional disputes among unions affiliated with the federation.

Independent Unions. — The largest group of unions independent of the American Federation of Labor prior to the New Deal consisted mainly of the railroad brotherhoods, the unions of locomotive engineers, firemen, conductors and trainmen, with an aggregate membership of about 500,000. These railroad unions at no time affiliated with the federation. The Amalgamated Clothing Workers, for many years the most famous independent union, was admitted into the federation in 1933.

Analysis of Growth. — As an effective force in U.S. industry, organized labour hardly began to be felt before 1900. The period following the collapse of the Knights of Labor was devoted to building the foundations of the labour movement, to strengthening the few established organizations and to extending unionism into new fields. The decade 1890–1900 with its severe depression and general unemployment was not favourable to the growth of unions. With the recovery of business toward the end of the decade the growth of the labour movement began and continued with only slight recessions until 1920. From 1900 to 1914 the total membership of U.S. unions increased by nearly 2,000,000 (from 791,000 to 2,647,000) and unionism penetrated many unorganized industries, making its most notable advances in the coal industry. Among the manufacturing industries the progress of organization, while substantial. was slow.

This whole situation changed radically after the outbreak of World War I. The rapid improvement in business and rise in productive activity, the steady absorption of the unemployed in face of the cessation of immigration, the further stringency in the labour market after U.S. entry into the war, the rising levels of prices and of wages, were all factors contributing to the strength of organized labour. The membership of unions, consequently, nearly doubled from 1915 to 1920 (2,560,000 to 5,034,000), and unionism won a place for the first time in the textile industry, packing houses, machine shops, among the shop men and unskilled on the railroads, in the clothing industries and among many clerical occupations. In the iron and steel industry, however, the movement failed to make effective progress.

The war gains were not held. The liquidation of the war industries, the depression of 1921 and the revulsion in industry against organized labour caused the unions to lose 1,400,000 members by 1923. In spite of good business and employment, membership remained almost constant in the few years that followed. The severe depression following the stock market crash of 1929 further weakened the labour movement and left it in 1933 with fewer than 3,000,000 members.

With the coming of F. D. Roosevelt's New Deal administration, however, membership rose rapidly under the stimulus of legislation favourable to labour. The 1934 membership of 3,249,000 increased steadily until it reached approximately 16,000,000 at mid-century.

Handicaps to Growth Before the New Deal. — For generations U.S. industry drew a substantial part of its labour from the annual masses of immigrants from Europe. Although there was a drastic restriction of immigration after World War I, U.S. industry was still far from a condition of labour shortage. New sources of labour within the country were constantly being tapped, leading to an easy labour market:

All labour movements suffer from the internal dissension that arises out of clash of doctrine. Sooner or later the holding of a new view of the purposes of the labour movement grows into an attempt to capture the movement and to convert it to this view. Mild beginnings in this direction usually ended in bitter warfare and in the disruption of one or more unions. Such was the early history of the relations between the labour movement and the socialists; after 1905 between the Industrial Workers of the World (I.W.W.) and the American Federation of Labor; and after 1918 between the Communist movement and the established unions. In the clothing industry, for instance, the struggle for control in the years following World War I between the Communist Workers' party and the administration of several of the unions in this industry resulted in nearly destroying organizations that only a few years before were among the most effective in the country.

Before 1933 U.S. unions were handicapped by their uncertain and unfavourable legal status. The free use of injunctions in disputes, prohibitions against interference with interstate commerce and the "yellow-dog" contract were the devices which hindered union expansion, although the Norris-LaGuardia act of 1932 was a major improvement antedating the New Deal. Virtually all of the remaining legal disabilities were swept away by the legislation supported by the Roosevelt administration.

Organized labour in the United States was also handicapped by "welfare capitalism." Many industrial leaders abandoned repressive measures to engage in competition with labour unions for the loyalty of their employees. In place of the national trade unions with members recruited throughout the whole of an industry, regardless of geographical location or ownership of the business, industry created company or plant unions. These organizations, sometimes described as employee representation plans or works councils, were limited either to a single plant or to several plants under common ownership. Their number grew rapidly during the decade following World War I.

The most fundamental of the union's problems is that of adjusting its policies to changing economic conditions. Often, before World War I as well as after, strong and established unions were reduced in size and strength because they failed to gauge the probable inroads of machinery and business depression.

Sometimes the struggle betueen a union and machinery would last for a generation, but in the end the union was beaten. This was largely the history of the cigar makers' union. In general, also, nearly all of the organized industries in the United States remained partly nonunion. Unless the union is able to organize the nonunion area, or so to protect the competitive position of the union area that the nonunion firms do not grow, the union will find business being diverted to the unorganized area and control slipping from its hands. The failure of the United Mine Workers to organize the nonunion coal fields of West Virginia and at the same time to strengthen the competitive position of the union operators in Illinois. Pennsylvania and elsewhere led to temporary disruption of the union in the years after 1925.

The New Deal and the Revival of Unionism. — The 1920s were the first period of economic prosperity which did not witness an expansion of unionism. During the depression which followed the stock market collapse of 1929 and assumed catastrophic proportions in 1932 and early in 1933, labour was too benumbed to do more than engage in a few desultory desperate strikes, mostly under Communist leadership.

With the new administration of Franklin D. Roosevelt came a new dawn for labour. Now government stepped in not only to restore the most seriously deteriorated standards of employment but to pave the way directly for unionism.

New Deal labour legislation originated in the National Industrial Recovery act (NIRA) passed in June 1933. Its labour provisions included both protective labour legislation (child labour was regulated; minimum wages and maximum hours of work were to be set for each industry operating under an approved code) and labour relations legislation.

Section 7(a) of the NIRA gave employees the "right to organize and bargain collectively through representatives of their own choosing" and to be "free from the interference, restraint, or coercion of employers of labor" in their organizing and bargaining activities. Through the decisions of the National Labor board and the first National Labor Relations board interpreting section 7(a), a solid beginning was made toward a common lam of collective bargaining. The legal protection afforded by Section 7(a) and the desire by masses of workers for union representation gave U.S. unions the most favourable organizing opportunity in their history. In the period 1933–35, the United Mine Workers, the International Ladies' Garment Workers' union and the Amalgamated Clothing Workers made the most vigorous comebacks.

Prior to 1933 there was only a handful of permanent union members in the mass production industries. This can be attributed to several factors: the determined opposition of large manufacturers to unionism, the heterogeneity of the labour force, ineffectual organizing tactics and the dominance of the craft philosophy.

The new political climate, with its ascendancy of government over business and the former's patronage of unionism as a major stabilizer of the economy, gave the U.S. labour movement unprecedented opportunities to expand its numbers. To facilitate this, the A.F. of L. chartered federal (plant-wide) locals. Yet this new opportunity soon brought a characteristic difficulty. The initial organization of these previously unorganizable workers raised two crucial policy questions. How vigorously should organizing work be carried on in the mass production industries? What should be done with these newly chartered federal labour unions?

A federation minority, with the support of most of these new federal locals, demanded an aggressive organizing drive and the chartering of industrial unions in the mass production industries. The craft unionists, representing a majority of the federation's membership. argued for a more cautious policy and for the preservation of established jurisdictional rights. These "old" unionists tended to look upon industrial unions in the mass production industries as dual unions and hence disruptive of the labour movement. They held this view because the craft unions theoretically had the right to organize certain workers in these industries.

The issue came to a head in the 1935 convention of the American Federation of Labor. The industrial unionist resolution stated that "in the great mass production industries . . . industrial organization is the only solution." It was at this convention that the "older" elements in the A.F. of L. showed a lack of statesmanship.

As a result of the convention's defeat of the industrial union resolution, representatives of eight international unions announced on Nov. 9. 1935, the formation of the Committee for Industrial Organization. Its purpose was "to encourage and promote (industrial union) organizations of the workers in the mass-production industries of the nation, and affiliation with the American Federation of Labor."

Still refusing to compromise, the executive council of the A.F. of L. in Jan. 1936, ordered the immediate dissolution of the C.I.O. movement as a dual unionism move. When the C.I.O. unions refused to dissolve their organization, the council in Aug. 1936 suspended ten of them. The Tampa. Fla.. convention (1936) approved this action. In March 1937, the council ordered all city centrals and state federations of labour to expel all delegates from the ten suspended unions.

While the split stemmed originally from the conservatism of a few key A.F. of L. leaders. it was perpetuated by John L. Lewis in his capacity as head of the C.I.O. In late 1937 a tentative agreement was reached between A F. of L. and C.I.O. peace-making committees, but at the last minute Lewis rejected the plan which would have granted industrial jurisdictions to the original C.I.O. unions, with negotiations to proceed between the new "dual" unions and the A.F. of L. unions concerned, but all the C.I.O. to re-enter the portals of the A.F. of L. en bloc. After 1937 numerous attempts were made to bring the A.F. of L. and the C.I.O. together, but all failed.

In May 1938 the C.I.O. was transformed into an independent federation to be known as the Congress of Industrial Organizations.

Great Upheaval of the 1930s.—The federation's outlawing of the C.I.O. in 1936 as a dual union was overshadowed by a series of sensational victories under the latter's banner. The C.I.O., in February–March 1936, came to the aid of the rubber workers. who were on strike; the financial support. encouragement and technical advice given the strikers represented the C.I.O.'s debut as the leader and inspirer of the mass production workers.

The first concerted C.I.O organizing campaign was undertaken in the steel industry—citadel of the open shop. The chief product of the NIRA period in the steel industry was a growth of employer-sponsored organizations. The C I.O. placed $500,000 at the disposal of the Steel Workers' Organizing committee, which pursued a two-pronged attack. It not only attacked the fortress frontally but it also Infiltrated the company unions to promote independent unionism.

On Feb. 28, 1937, it was announced that the U.S. Steel corporation's chief subsidiary, the Carnegie-Illinois Steel corporation, would sign a contract with the S W.O.C. Within three months of the signing, the S lV.O.C. had reached agreements, practically without resort to strikes, with approximately 140 companies. including 14 U.S. Steel subsidiaries and the Jones and Laughlin Steel corporation. However, against "little steel" the S.W.O.C. campaign was less successful. Following the signing of the agreements with U.S. Steel's subsidiaries, the S.W.O.C. called strikes against four of the largest independents. Aided by police, national guardsmen and "citizens' committees" in the communities where strikes were called, "little steel" defeated the S.W.O.C. and succeeded in avoiding unionism and collective bargaining until 1941.

The tactics accompanying the drive in the auto industry differed appreciably from those in the steel industry. Where the S W.O.C. organizing campaign was carefully planned and centrally organized, the rank and file in the auto industry often initiated strikes in spite of the restraining influence of the union leadership.

On Dec. 28. 1936. 8,000 workers in the Cleveland Fisher Body plant of the General Motors corporation walked out, and during January sit-down strikes spread through the General Motors network of plants. Court orders to eject the strikers from the plants were issued, but the fear of serious bloodshed influenced Gov. Frank Murphy of Michigan to order the sheriff not to serve them. On Feb. 11, 1937, unionism attained its first real victory in the auto industry when the General Motors corporation signed with John L. Lewis as the spokesman of the United Automobile Workers. The signing of this agreement was followed by a sit-down strike of Chrysler employees. which mas ended on April 6, 1937 when that corporation recognized the union. Ford succeeded in holding out until the summer of 1941.

The United Electrical. Radio and Machine Workers of America was formed in March 1936 out of an amalgamation of rebelling A.F. of L. federal unions and a loosely tied group of independent local unions.

To organize the textile industry the C.I.O. created the Textile Workers Organizing committee staffed by Amalgamated Clothing R'orkers officials. Betneen 1937 and 1941 the C.I.O. was also able to make inroads in meat packing. shipbuilding, oil, metal mining and numerous other industries.

While the organizational efforts nhich made the newspaper headlines were those of the C I.O., the importance of the campaigns carried on by affiliates of the A.F. of L. and those directly under federation auspices should not be minimized. The formation of the C.I.O shook the A F. of L. internally. The original issue of craft *v.* industrial (or "horizontal" *v.* "vertical") unionism found itself blanketed by this larger issue of unionizing rivalry. To support a federation-directed organizing campaign as well as to combat the C.I.O., an assessment of one cent per member a month was voted.

The A.F. of L. international unions vigorously seconded the efforts of their parent body and the total membership of the federation increased from 3,000,000 in 1935 to approximately

7,000,000 at mid-century. In absolute numbers the following showed the greatest growth: teamsters, ladies' garment workers, carpenters. electrical workers and hod carriers. Other A.F. of L. unions such as the hotel and restaurant employees. retail clerks, meat cutters and butcher workmen and building service employees had a large percentage rate of growth. During this same period the A.F. of L. chartered many new onions.

While there was a tremendous increase in union membership during this period. to a total of about 16,000,000, it still remained true that the bulk of union members mere concentrated in a few large organizations at mid-century. About a dozen unions, each with 250,000 or more members, contained almost half of the total union membership. These giants, plus 15 or 20 medium-sized unions, formed the main body of U.S. unionism.

What factors help to explain this rapid growth in union membership after 1933? Undoubtedly the existence of a favourable governmental climate comes first, especially after the re-election of Roosevelt in 1936. With the C.I.O. a new generation of leaders and organizers entered the lists. Its campaigns were aggressive, well financed and led by capable tacticians. Probably a major factor was the air of victory radiating from the C.I.O.'s leader, John L. Lewis.

The A.F. of L.'s rejuvenation under the spur of rivalry belied the forecasts of doom by its detractors. The early strategic victories in the campaign over General Motors and U.S. Steel created the conviction of the "C.I.O. march to victory." The extended period of full employment during and after World War II enabled the new unions to become fully entrenched in their respective industries.

The La Follette investigating committee of the late 1930s brought to light the mechanism whereby employers prevented the spread of unionism prior to the New Deal. The investigation covered a variety of industries throughout the country and disclosed the existence of a widely practiced industrial militarism—arsenals, "standing armies" and espionage. These disclosures came at a time when the favourable climate of the New Deal had already been giving way to the more normal suspiciousness of unionism's intentions always present in the minds of U.S. middle groups, and thus delayed an out-and-out swing in public opinion.

National Labor Relations Act.—The upheaval derived its impulse more from the general political climate than from the specific enactment to give unions greater rights—namely, the National Labor Relations (Wagner) act of 1935, to take the place of section 7(a) of the National Industrial Recovery act which had been declared unconstitutional. Employers as a rule were convinced that it would meet with the fate of its predecessor, and the act was held in virtual suspension. Its constitutional validity rested on the authority of congress to prevent industrial strife which impeded interstate commerce. The act itself cited as its justification the objective to minimize industrial conflict through the equalization of the bargaining power of the employees and management.

The employees could achieve something nearer equality in bargaining power only if they could organize and bargain collectively without fear of employer reprisals. The promotion of collective bargaining meant that an agency—the union—had to be stimulated so that it could represent the workers in negotiations with management.

The Wagner act declared that "employees shall have the right to self organization, to form, join, or assist labor organizations, to bargain collectively through representatives of their own choosing, and to engage in concerted activities, for the purpose of collective bargaining or other mutual aid or protection."

The act stipulated two methods of protecting these rights. First, it included a list of unfair labour practices which employers must not commit. The National Labor Relations board was made responsible for the prosecution and adjudication of all unfair labour practice charges. One of the forbidden practices, employer domination of employee organization, forecast the doom of company unions. Second, the board certified the union authorized to represent the employees and could hold elections among the workers to that end. The union selected by a majority of the employees voting was the exclusive bargaining agent for the entire unit. The board also determined the election unit, whether the plant, craft or industry.

The NLRB was in no way concerned with the contents of the collective bargaining agreement nor with efforts to interpret or enforce it. In brief the settlement of disputes over the terms and conditions of employment were outside the board's province. The board intervened only to create the foundation of the collective bargaining structure and to keep it from being undermined by employer animosity.

The unexpected validation of the NLRA in the spring of 1937 nas a turning point in U S. constitutional development—a change amounting to a peaceful revolution. The U.S. Supreme Court held that congress could regulate the labour practices of employers whose operations affected interstate commerce.

Because it could be shown that most manufacturing industries substantially affect interstate commerce, the significance of these and subsequent decisions was to widen vastly the prerogative of congress over the whole field of labour problems.

Even with this broad interpretation the act did not apply to all industry. It was estimated that about 13,000,000 people, or about 40% of all nonagricultural workers in the country by mid-20th century, were subject primarily to state regulation. The bulk of these were employed in retail trade, building construction, utilities, amusements and recreation. hotels, garages, insurance and real estate, laundering and dry cleaning and miscellaneous personal services. To give to these workers Wagner act rights, several states enacted state labour relations acts.

Protective Labor Legislation.—The peaceful constitutional revolution in 1937 also made possible the Fair Labor Standards act of 1938. It established basic minimum wages and overtime payment requirements for employees engaged in interstate commerce or in the production of goods moving in interstate commerce. (The minimum straight time hourly rate was increased to 75 cents an hour in 1950 and to one dollar an hour in 19j6.) The act stipulated that one and a half times the norker's regular hourly rate of pay be paid for all hours worked over 40 a week. The act also placed restrictions on child labour by prohibiting the shipment of goods in interstate commerce if produced in any establishment employing oppressive child labour.

More stringent minimum wage and overtime pay requirements were written into the Davis-Bacon act (1931) and the Walsh-Healey Public Contracts act (1936). In combination these tno acts provided that the secretary of labour set minimum wage rates on work done under contract for the federal government. The latter act also provided for overtime payments after eight hours work a day.

The Social Security act of 1935 provided for two nationwide systems of social insurance to protect nage earners and their families against loss of income from unemployment, old age and death. First, the old age and survivors insurance program was an all-federal system operated through the Social Security administration. Covered wage earners and their employers shared equally in the cost of the program. Second, unemployment insurance was a federal-state plan under which each state would set up its own law and state administrative agency, with the federal government paying all operating costs. It was financed by a 3% federal tax levied on the payroll of employers. Prior to 1932 organized labour was hostile to compulsory unemployment insurance—an opposition founded on the basic A.F. of L. suspicion of government. The extent and duration of the 1929–33 depression, however, caused the A.F. of L. in 1932 to support unemployment compensation legislation. Like the NLRA, the Social Security act was validated in a decision in 1937.

To protect workers in industries exempt from federal regulation, many states passed minimum wage and maximum hour laws applicable to them. Nonetheless, the chief form of state protective labour legislation, mostly antedating the New Deal period, dealt with industrial injuries and accidents under workmen's compensation, with the later addition of unemployment compensation. Other state protective legislation included child labour regulations, industrial safety and sanitation codes, apprenticeship regulations, equal pay laws, fair employment practices and sickness disability compensation. The trend was toward a gradual levelling of standards in all states.

Labour Relations in World War II.—Shortly after the start of the national defense program in June 1940, the number of U.S. strikes began to increase rapidly, coinciding with a sharp rise in employment. To avoid lost production President Roosevelt on March 19, 1941, created the National Defense Mediation board. It was given jurisdiction over all labour disputes certified by the secretary of labour as threatening "to burden or obstruct the production or transportation of equipment or materials essential to national defense." The NDMB was a tripartite board composed of labour, industry and public members appointed by the president.

The NDMB endeavoured to conduct three-party collective bargaining in cases where labour and management could not work out a solution to their differences. However, the board was also authorized to institute fact-finding procedures to investigate the causes of differences between employers and employees with public recommendations for equitable settlements. The board, however, lacked any enforcement authority, and to achieve compliance with its recommendations it had to appeal to the president. The NDMB was abolished in Jan. 1942 after its C.I.O. members had earlier withdrawn as a result of the board's refusal to accept the union-shop principle for the captive coal mines.

In late Dec. 1941, after U.S. entry into World War II, an industry-labour conference was convened in Washington, D.C., to formulate a policy of wartime industrial relations. Union heads had given a no-strike pledge following the Japanese attack. The conference participants were in agreement that all industrial disputes should be settled by methods which would not hamper war production, but they could not agree on the union security question. As an outgrowth of this conference the president on Jan. 12, 1942, established the National War Labor board. It was empowered to deal with every type of dispute that "might interrupt work that contributes to the effective prosecution of the war." The NWLB was also a tripartite board whose members were appointed by the president. If the board could not gain a voluntary settlement it would act as a compulsory arbitration panel.

As a result of an executive order issued Oct. 3, 1942, the NWLB was charged with the administration of another vital wartime measure—stabilization of wages as part of the administration's anti-inflation program. Wage increases that required price rises needed the further approval of the director of economic stabilization. To cope with its great volume of work the board decentralized, setting up 12 regions, each under a regional war labour board, to handle cases arising in its area. The War Labor Disputes (Smith-Connally) act adopted in June 1943 gave statutory authority to the War Labor Board.

The Smith-Connally act also gave the president power to seize privately owned war plants and to operate them under government control, where an actual or threatened strike or lockout involved interference with war production. It forced union officials to notify the appropriate federal agencies of the existence of a labour dispute affecting war production. For 30 days thereafter, no strike could be called in such private plants. On the 30th day, the NLRB was to conduct an election among the employees directly involved, to determine whether they wished to strike.

Failure of the industry-labour conference to agree on the union security question tossed it into the lap of the NWLB. In solving this problem the board often granted both "maintenance of membership" and the checkoff. Under this type of union security, union membership was not compulsory but anyone who was a member of the union after the brief escape period had expired had to remain in the union or be discharged.

In an attempt to stabilize the general wage level the NWLB developed the "little steel" formula. Announced on July 16, 1942, it stated that wage rate increases, made because of increases in the cost of living, would be limited to 15% of the existing rate on Jan. 1, 1941. While prohibiting general wage rate increases above those set by the "little steel" formula the NWLB did sanction: (1) wage increases clearly necessary to correct substandards of living; (2) intraplant wage adjustments to create a balanced wage rate structure; (3) increases to adjust interplant wage inequalities; and (4) fringe wage issues. The latter referred to paid vacations, paid holidays, preparation time, shift differentials, sick-leave pay, dismissal or severance pay, etc.

In more than 300 cases the board directed managements and unions to negotiate the elimination of intraplant wage inequities—different rates of pay for jobs entailing the same skill and experience. To accomplish this goal the parties were required to analyze the content and character of each job in the plant, assess each job's relative standing in the production scheme and set the appropriate rate for each job classification. The board thus stimulated a rationalization of the wage rate structure.

Restrictive Labour Legislation.—The end of hostilities terminated the no-strike pledge, and the years 1946, 1947 and 1949 saw numerous large-scale strikes. The unions, especially in the newly unionized industries, still had to convince employers that they had taken root and proved it by successfully standing guard over the real wages and job control acquisitions in the collective agreements. To the latter it added a new device of "social security by contract" in the shape of pensions and other social insurance protections obtained by collective bargaining. But with these determined stands in the economic arena unionism suffered a serious loss in its legal status. The 80th congress under Republican control enacted in 1947 the restrictive labour law popularly known as the Taft-Hartley law.

As a prelude to the passage of the Labor-Management Relations act of 1947, numerous states had enacted one or more union control laws. As early as 1939 Pennsylvania had amended its state labour relations act, and Wisconsin repealed its act and passed a new one. Between 1939 and 1947, five states passed new labour relations acts of a restrictive nature. These laws dealt, among other things, with mass picketing, jurisdictional strikes, sympathetic strikes, primary and secondary boycotts, refusal to handle nonunion materials, prohibition of the closed shop and the checkoff, registration and submission of information by the unions to the state government, filing of financial statements and regulation of strikes in public employment and public utilities.

There were at least three major factors contributing to passage of the Taft-Hartley act. Employers, while no longer opposing the collective bargaining objective of the NLRA, saw themselves pilloried in the one-sided recital of "unfair practices." The public was concerned with the strike wave which followed World War II, especially the perennial coal strike threats. Lastly, the conservative middle class groups, with their suspicion of unionism on so many scores, added their influences in congress.

The Taft-Hartley act retained the Wagner act's stipulation of the rights of employees and the means for their protection, but placed a host of union activities under government surveillance. Foremost of these was the definition of certain union activities as unfair labour practices. The NLRB was to prevent their occurrence, and injunctions were relied on for enforcement.

Certain restrictions were placed on the internal administration of unions. Under a union shop contract men could be discharged only for cause or for failure to pay their union dues and initiation fees. Furthermore, the NLRB was charged with determining whether these dues and fees were excessive. In order to be able to use the services of the NLRB, unions had to file extensive information with federal authorities. Union officers had to file affidavits of nonmembership in the Communist party.

The act also defined the procedures to be followed in attempting to write a new collective agreement and in dealing with strikes or lockouts which threatened the national health or safety, giving the president the power to exact a cooling-off period of 80 days enforceable by court injunction in which an ad *hoc* board probed the dispute. The Taft-Hartley act stated that certain provisions could not be included in a collective bargaining agreement even though both parties might want them. The chief outlawed provision was the closed shop. Also prohibited were the compulsory checkoff, payment by an employer for services not performed, inclusion of plant protection workers in a bargaining unit with production workers and a one-sided union administration of health and welfare funds to which employers agreed to contribute.

Unions could be sued in the federal district courts for violation of contract. Employees of the federal government were prohibited from striking. the penalty being immediate discharge, forfeiture of civil service status and denial of re-employment for three years. Before a union could negotiate for a union shop a majority of the eligible employees in the unit had to approve it in a special election. Statutory rules were established for the NLRB to follow in defining the bargaining unit.

There was a separation of the judicial and prosecuting functions previously performed by NLRB employees. The general counsel was now given a status independent of the board and was charged with the responsibility of prosecuting all unfair labour practice charges. Another major provision of the Taft-Hartley act established the Federal Mediation and Conciliation service as an independent agency. The act further provided that union shop agreements could not be entered into in states in which they were prohibited by state law. This provision touched off a series of bitter fights over the enactment of such measures in a large number of states. By 1956 "right-to-work" laws, as they became known, had been enacted in 18 states! most of them in predominantly agricultural areas that were seeking to attract industry. Passage of the Taft-Hartley act and of "right-to-work" legislation slowed down the unionization of the south. Approximately 14,800,000 workers, or 48% of the workers in occupations in which unions had sought agreements. were employed under collective bargaining agreements in 1949, contrasting with 4,000,000 in 1935. In manufacturing industries, 7,900,000 workers. or 69% of those employed, were covered and in nonmanufacturing industries 6,900,000 workers, or 35% of those employed.

Merger of the A.F. of L. and C.I.O.—The deaths in Nov. 1952, of both William Green, long-time president of the A.F. of L., and Philip Murray, who had succeeded John L. Lewis as head of the C.I.O. in 1940, helped set the stage for the merger of the rival federations. By this time the A.F. of L. had far outstripped the younger federation. having achieved a membership of over 10,000,000. more than double that of its rival. The death of Murray, depriving the C.I.O. unions of the one leader whom all could accept willingly, led to a struggle for power between rival blocs led by the two most powerful unions, the United Automobile Workers and the United Steelworkers. Though Walter P. Reuther of the U.A.W. won the C.I.O. presidency by a close vote, he succeeded to the leadership of a divided movement which faced the danger of defections unless labour unity was achieved promptly.

By this time, moreover, the issues which earlier had divided the two federations had largely disappeared. The issue of craft as against industrial unionism no longer was a major stumbling block, since the A.F. of L. itself was organizing workers in such industries as aircraft on an industrial basis. The C.I.O. had purged itself of Communist influence, and the two federations had co-operated in fighting Communism, both on the home front and in the international field. The A.F. of L., for its part, had moved more vigorously against corruption than in the past, expelling one of its affiliates. the International Longshoremen's Association, in 1953, for failure to rid itself of racketeers. In political action, in their criticism of the Eisenhower administration, and in their general outlook on domestic and foreign issues the two federations had been moving closer together. Raids by unions upon one another's membership remained the greatest stumbling block in the path of unity.

In 1953 the federations negotiated a no-raiding agreement, which was signed in June 1954, by 65 A.F. of L. and 29 C.I.O. unions! with a combined membership of over 10,000,000. The agreement, however. was not binding on non-signers. In addition the A.F. of L. established an internal no-raiding pact, also on a voluntary basis. The C.I.O. had earlier established comparable internal machinery, so that three pacts now existed to prevent raiding and settle jurisdictional disputes.

On Feb. 9. 1955, a merger agreement was reached. All affiliates of either federation automatically became members of the combined body without change in jurisdiction. Competing unions were to be encouraged, but not forced, to merge. All workers were guaranteed rights to full union benefits, without regard to race, creed, colour or national origin. Free and democratic unionism was to be ensured, with protection from corrupt elements as well as from Communists and others opposed to democracy. The A.F. of L., by far the larger of the two bodies, was given a proportionate share of the offices. Industrial unions were to have a department of their own within the merged organization, and state and city central bodies were to merge within tao years after the merger of the federations. The names of the two bodies were combined to form the name of the new federation. The merger officially took place on Dec. j, 195j, bringing approximately 15,000,000 unionists together.

The merged labour movement, breaking sharply with the A.F. of L. tradition on national union autonomy, issued a series of ethical practices codes to govern the behaviour of officers of affiliated unions in financial and other matters; it likewise created enforcement machinery. with expulsion the ultimate penalty for unions that failed to conform. Nevertheless the entire labour movement found itself on the defensive, with the disclosure of serious financial irregularities in certain unions, notably the powerful Teamsters. The A.F. of L. also continued to be plagued nith jurisdictional disputes. the most troublesome of which concerned the conflicting claims of the building trades and some of the large industrial unions. Jurisdictional disputes and an unfavourable climate of public opinion delayed the launching of large-scale organizing drives. in the white-collar field and in the south, that had been planned to follow the merger.

Labour and Political **Action.**—With the New Deal, organized political action became an important activity of the U.S. labour movement. Politics was no new experience to the American Federation of Labor. As early as 1906 the pattern was established: "reward your friends and punish your enemies." The early investments in political action, however, were meagre. The X.F. of L.'s traditional non-partisan political policy was modified somewhat by its support of Robert La Follette's independent candidacy in 1924. Between 1924 and 1936 labour was relatively inactive politically. In 1936, however, the C.I.O. engaged in a strenuous campaign to help re-elect Roosevelt, launching Labor's Non-Partisan League for that purpose. In 1943, alarmed at the growth of conservative influence in Congress, the C.I.O. created its Political Action Committee under the able leadership of Sidney Hillman.

The A.F. of L., far less active politically until the passage of the Taft-Hartley act. thereupon established Labor's League for Political Education as its political instrument. The railroad brotherhoods also set up similar machinery. These labour political agencies co-operated to support candidates friendly to labour. for the most part working closely with the liberal wing of the Democratic party. With the merger of the A.F. of L. and the C I.O. in Dec. 1955, their political arms were combined into a Committee on Political Education; which like its predecessors was to operate within the framework of the two-party political structure.

Communism and International Labour **Relations.**—U.S. labour became concerned with Communist infiltration into positions of command as early as the 1920s. Fired by a sense of mission as the vanguard of the proletarian revolution, the Communists had sought to assume leadership over the labour movement and use it for political purposes.

Even before the passage of the Taft-Hartley act, U.S. labour mas ejecting leaders who had subordinated the interests of the trade unions to those of the Communist party. The act with its compulsory anti-Communist affidavit for union officers gave greater sweep to a spontaneous trend Communists had played a vital role in the early stages of the C.I.O mass production unions because of their indefatigable zeal as organizers. However, during 1949 and 1950 the C I.O. expelled 11 unions found to be Communist-dominated. and amended its constitution to bar Communists or their consistent followers from membership on the executive board. Prior to this drastic purge the Communists had been defeated after several years struggle in the C.I.O.'s biggest affiliate. the United Automobile Workers By the latter 1950s Communist influence in the labour movement was at its lowest point in more than 20 years, and dwindling rapidly.

While U.S. labour acted to solve this crucial internal trade union problem, it also showed novel activity on the international scene. It vigorously backed up the administration's program of rebuilding western Europe and containing Communism. A new term came into use—"labour diplomats." These "diplomats" set out to win the confidence of the non-Communist unions in western Europe and to encourage them to resist Communist encroachment. The culmination was the International Confederation of Free Trade Unions formed in Dec. 1949, to ensure "collaboration between the free and democratic trade union movements throughout the world." The World Federation of Trade Cnions set up in 1945 as labour's counterpart of the policy of continuing the "grand wartime alliance" had quickly become a soviet tool. The A.F. of L. had never joined it, but the C.I.O. did, together with the unions of Britain and western Europe. In the new trade union international (I.C.F.T.U.) the A.F. of L. and C.I.O. appeared for the first time as co-operating and equal members. U.S. labour imposed its stamp upon the new international when the traditional commitment to socialism was omitted from its platform in order to avoid raising an issue which might divide labour on opposite sides of the Atlantic ocean. *(See* also AMERICAN FEDERATION OF LABOR—CONGRESS OF INDUSTRIAL ORGANIZATIONS; CLOSED SHOP; LABOUR LAW; STRIKES AND LOCKOUTS.)

CONTINENTAL EUROPE

France.—In France trade unions became active in Paris and Lyons in the 1820s and 1830s, but had no legal recognition until 1864, when a regime of toleration began, and no assured legal position until 1884. The right of combination was still refused after this to public employees. The federation of *syndicats* formed under the act of 1884 came at the outset mainly under Socialist party (Marxist) influence: but did not make much progress until in 1894 it was absorbed into the *Fédération des Bourses du Travail,* which had been formed the previous year by the *bourses du travail* (a mixture of trades councils and local labour exchanges). The combined body came under the influence of Fernand Pelloutier, an anarchist-syndicalist, who stood for a revolution based on local working-class solidarity rather than on national organization. It opposed parliamentary action, favouring direct action by strikes to coerce both the employers and the government. In 1895 a *Confédération Générale du Travail* was founded, but was amalgamated with the F.B.T. in 1902, and passed under syndicalist leadership. The new C.G.T. remained aloof from the socialists, who were divided into a number of rival parties. Under Pelloutier's leadership it developed the theory and policy of revolutionary syndicalism—no agreements with employers, sudden strikes, sympathetic strikes, sabotage and antimilitarism—with a social general strike in the future as the means of ushering in the new era of workers' control. To Pelloutier's doctrines Georges Sorel added the notion of the general strike as an inspiring social myth and of the practice of aggressive direct action as a training in revolutionary techniques. The C.G.T., which had its period of maximum activity between 1902 and 1914, thus grew up wholly apart from French socialism, though of course many trade unionists belonged individually to socialist bodies. The C.G.T.'s policy was laid down in the Amiens Charter of 1906, which had considerable international influence on trade union developments during the following years.

The majority of the C.G.T., despite its antimilitarist philosophy, supported the war effort in 1914, and the consequent dissensions led, after the Russian revolution, to a split. The C.G.T. formulated in 1919 its doctrine of a *nationalisation industrialisée,* based on workers' participation in the control of industry, but took a nonrevolutionary line. The Communists founded in 1921–22 a rival body, the C.G.T.U. *(Unitaire),* and up to 1935 the French trade unions remained divided into hostile factions, which greatly reduced their power.

In that year, under pressure of the crisis of 1934, the two main bodies united in a new C.G.T. This was a leading element in the popular front movement, which was victorious in the general election of 1936; and the trade unions remained united, largely under Communist leadership, until 1948, when a section headed by Léon Jouhaux, long the leader of the French trade union movement, broke away to form a C.G.T.—*Force Ouvrière,* in fairly close association with the Socialist party, but up to 1957 F.O. had remained unable to shake the Communist control over the main body of manual workers, the elements supporting it being largely white-collar workers. The Catholic trade unionists (*Confédération Française des Travailleurs Chrétiens*), who had always formed a distinct element in French trade unionism, had little strength outside the textile industries and certain white-collar groups.

Germany.—In Germany workmen's associations first came to the front in the 1840s, mainly on a political basis; and the movement was renewed in the 1860s under the leadership of Ferdinand Lassalle. The Marxists also became active; but these new movements were also mainly political, and there was no considerable growth of trade unions until the 1870s. From 1878 to 1890 trade unions, as well as socialist bodies, came under the ban of Bismarck's antisocialist laws.

On their repeal the movement developed rapidly, the largest section being closely associated with the Social Democrats, though nominally independent of them. The *Freie Gewerkschaften,* organized under a *Generalkommission der Gewerkschaften Deutschlands,* had reached by 1914 a membership of 2,000,000; and there were two smaller movements, the more important under Catholic and the lesser under liberal auspices. These bodies remained separate under the Weimar republic, with the *Allgemeiner Deutscher Gewerkschaftsbund* (successor to the general commission) by far the preponderant element.

The severe depression of the 1920s hit trade unionism hard; and it was also rent asunder by dissensions between Social Democrats and Communists. The Communists formed some separatist bodies, but tried in the main to work through and capture the free trade unions, which were largely paralyzed by political dissensions until the whole movement was destroyed and transferred to a nazi-controlled *Arbeitsfront,* governed from the top, after the nazi accession to political power in 1933.

After 1945 trade unionism was gradually revived, but separately in eastern and western Germany. In 1957 there were two separate trade union movements, one associated with the Unified Socialist (Communist) party in eastern Germany and the other in western Germany, including both Christians and Social Democrats.

Western European Countries.—Rival Christian and mainly socialist free trade union movements existed in Italy, Belgium, the Netherlands and a few other countries, and the former were linked both between World Wars I and II and in 1957 in an International Federation of Christian Trade Unions. Trade unionism was strong in the Scandinavian countries, in Finland, and fairly strong in Switzerland.

In Austria it was suppressed under the nazis, but revived, especially in Vienna, after 1945. In Spain it perished after the Civil War of 1936–39; previously it had been long divided between the predominantly anarchist-syndicalist National Confederation of Labour (C.N.T.), strongest in Catalonia, and the mainly socialist

General Union of Workers (U.G.T.), strongest in central and northern Spain.

In Italy too there was a long history of dissensions between syndicalists and socialists, until the whole movement mas suppressed and replaced by *sindacati* under fascist control in the 1920s. The fascist unions, based on compulsory workers' contributions and conducted under strong party control, had no independent role, though much was made-of them as a façade under the fascist regime. After the liberation of 1944, trade unionism re-emerged, passing mainly under the control of the Communists and left-wing socialists, until in 1948–49 various groups split away to form separate federations, one under Catholic and the other under moderate socialist auspices. As in France, up to 1957 the main body (*Confederazione Generale Italiana del Lavoro*) remained predominantly under Communist influence.

Soviet Union and Eastern Europe. — In Russia trade unions first appeared on a considerable scale in the revolution of 1905, but were thereafter crushed out. They reappeared in the 1917 revolution, and speedily became highly organized in a national movement under Communist control. The Soviet trade unions were used as agents of the state in the execution of social policies, and were given a large share in the control of the commissariat of labour. When, however. they threatened in the late 1920s and early 1930s to assert their independence of Communist party control, their leadership was promptly purged, and they became more and more welfare agencies and subordinate instruments of state policy. As welfare agencies they retained very important functions in the organization of social services for their members; but industrially they became mainly instruments for helping in the drive for higher production and for Communist propaganda abroad as well as at home.

The *Vsesoyuzny Tsentralny Soviet Professionalnykh Soyuzov,* or All-Cnion Central Council of Trade Unions. took a leading part in forming the World Federation of Trade Unions in 1945, and gave particular attention to efforts to foster trade unions under Communist or near-Communist leadership in colonial countries and in the far and middle east. and also to building up their influence over the trade union movements in eastern Europe and in France and Italy. Of the countries under Soviet domination, Czechoslovakia had the most strongly organized trade union movement; but growth had been rapid elsetvhere, especially in Poland and Hungary.

OTHER COUNTRIES

Australia and New Zealand. — Outside Europe and the Americas, the strongest trade union movements are in Australia and New Zealand. These have a long history, having been started mainly by settlers from Great Britain, including, in Australia, Chartists and others transported for political offenses. The Anstralian and New Zealand unions fought their earliest battles for the eight-hour day. and subsequently for the minimum wage, and were the creators of the Labour parties nhich rose later to political power. The systems of arbitration built up in both countries at first favoured union claims. but later, when a living wage had been secured, offered fewer advantages so that strong left-wing opposition developed, accompanied by many strikes. Industrial unionist ideas. derived from the United States, became influential in the period before 1914, and retained some hold, especially among miners and dock workers, who were influenced also by Communism. The main body of trade unionists. however, supports the Labour party and works under the arbitration system.

India. — In India trade unions did not become important until the 20th century, and have been rent by many divisions. Between World Wars I and II there existed rival central bodies, the Indian Trades Union congress and the more moderate Indian Federation of Labour, besides many independent bodies, such as the Railwaymen's federation and the Gandhist Ahmedabad Labour union.

Communists made many attempts to capture control of the unions, with some success; and there were also rivalries between the Socialist party and the Indian Congress party leadership, to which the main body of the Socialists remained attached up to 1947. The split between the Socialist and the Congress parties led to new rivalries; and the position remained unsettled at the mid-1950s.

China and Japan. — In China trade unionism has been a battleground of rival political tendencies ever since its emergence as a defined movement in the 1920s. Trade unionism of a sort, in the form of guilds and clubs of workers in the same trade, has a very long history, and the basis of modern trade unionism is still in working groups of this type or in factory councils. More formally organized trade unions came into existence during the period after World War I, with Communists playing a leading part. After Chiang Kai-shek's coup of 1927, unions under Communist influence were suppressed, and the movement was driven largely underground. Later. the Kuomintang leaders began to organize government-sponsored unions under approved leadership, and the Communists in addition to carrying on their own "red" unions, adopted a policy of infiltration into these "yellow" unions and of fomenting mass strikes wherever opportunity arose—as it continually did because of the vast inflationary rise in prices. The struggle for the control of the unions was resumed after 1945; and the Communists, whenever they established control of an area, set up or consolidated unions under their own control and gave them large authority in relation to privately owned undertakings. Strikes multiplied in the areas still under Nationalist control, and the Communists were able, despite repression, greatly to increase their hold on the workers throughout the country, and thus to prepare the way for their victories of 1949.

Trade unionism in Japan, after developing fairly rapidly in the 1920s, was for the most part suppressed in the 1930s, except for benefit societies under official surveillance. It emerged again after 194j and became a point of contention between left-wing and moderate tendencies.

Malaya. — In parts of Malaya and in Hong Kong, Chinese labour organizations at mid-20th century were strong and largely under Communist influence. In Malaya Chinese guilds and associations of the traditional type were numerous: and on them were superimposed societies and clubs, largely of friendly society type, formed under the Societies Ordinances of 1889 and 1895, and on these again regular trade unions under the Trade Union ordinances which came into operation in 1946. Meanwhile the Malayan Communist party, founded in 1928, set up cells among the workers; and after 1945 these were expanded into trade unions nominally covering most industrial groups and federated into a General Labour union, which m s later divided into separate bodies for Singapore and for the rest of Malaya.

Colonial Trade **Unionism.**—Trade union movements at mid-20th century had begun to develop in other colonial areas, particularly in the British West Indies and in west Africa. They were in most cases closely connected with political movements, but had an economic basis in the low standards of living and in the conditions of mining and plantation economies in backward areas. There had been extensive strike movements in Trinidad, Jamaica and other parts of the West Indies, in Mauritius and in Nigeria and other parts of west Africa.

The policy of the British government was to recognize colonial trade unionism and to endeavour to guide it as far as possible into nonpolitical channels. As against this, the World Federation of Trade Unions, especially after it had come entirely under Communist control. tried to develop colonial trade unionism as an auxiliary to the anti-imperialist movement of the coloured peoples and to influence it toward mass strike action whenever opportunity occurred. In Jamaica William Bustamante rose to power in the 1940s mainly by organizing mass trade unions among the plantation workers and other discontented groups, though after his accession to office his policy became very different. The rival movement led by N. W. Manley had greater strength among the more skilled workers. Jamaica has its own Trade Union congress, which forms a sector of the Caribbean Labour congress, with similar bodies throughout the British West Indies.

INTERNATIONAL ORGANIZATIONS

Internationally, world trade unionism was split after 1949 between two rival organizations — the Communist-controlled World

Federation of Trade Unions, set up in 1945 on a wider basis, and the International Confederation of Free Trade Unions, founded late in 1949 mainly by the national bodies which had seceded from the W.F.T.U. in protest against its Communist direction. Trade union organization began with the International Federation of Trade Unions, set up in 1901, and centred in Germany up to 1914. The I.F.T.U. was reconstituted in 1919, with headquarters in Amsterdam. Neth.; and the Russians soon set up a rival Red International of Labour Unions as an auxiliary to the political Communist (third) international.

The contest between these bodies continued up to 1939; but after 1941 there were close contacts between the British and Soviet trade unions, and in 1945 an attempt was made to set up an inclusive international. The W.F.T.U. was intended to reconcile differences; the British T.U.C. and the U.S. Congress of Industrial Organizations, as well as the Soviet V.Ts.S.P.S. took part in its foundation, only the American Federation of Labor reiusing to join. The rift came with the strong opposition organized by the Communists against the Marshall plan. The headquarters of the W.F.T.U., under French leadership. joined in this opposition. and, after vain attempts to check this. the British T.U.C. and the C.I.O. left the organization and proceeded. with the A.F. of L. and the Dutch. Scandinavian. Belgian and other national groups. to establish a rival federation, including minority groups in France, Italy and various other countries. The bodies attending the inaugural conference of the I.C.F.T.U. included the French Christian Trade Union federation, but not the'distinctively Christian movements from other countries, to whose presence the free trade union movements of the Netherlands. Belgium, etc.. objected. During the conference it was decided to invite all the Christian federations to join, subject to their dissolving their separate international federation; this they refused, and the separation still existed in 1957, the Christian unions—chiefly, but not exclusively Roman Catholic—being organized in an International Federation of Christian Trade unions (I.F.C.T.U.) extending to Latin America as well as Europe.

While the western trade unions were forming their new international in London, the W.F.T.U. was holding a conference of trade union movements in Asia and Oceania at Peking. China. attended by delegates from China. Malaya, Burma, India. Ceylon. Indonesia. Indochina. Thailand and other areas: to draw up a common program for Communist trade union action. The two internationals were also contending for control of the international trade secretariats of trade unions in particular industries (transport workers, miners, railwaymen, metal workers. textile workers, etc.). These bodies, many dating back to the period before 1914, had refused to merge themselves in the W.F.T.U. before the split; and after the split a number of them formed a joint committee which co-operated independently in preparing for the foundation of the I.C.F.T.U.. to which they would become attached. but in such a way as to keep their independence. Other secretariats remained attached to the W.F.T.U., which regarded them as subordinate departments and set to work to form new ones in rivalry with those which rejected its control.

The W.F.T.U. claimed in 1945 to represent 67,000,000 trade unionists. including 30,000,000 members of Soviet *profsoyuzy;* the I.C.F.T.C. in 1949 claimed 48,000,000 participating in its inaugural conference and another 2,000,000 expected to join. There has been keen rivalry between the I.C.F.T.U. and the W.F.T.U. in stimulating the growth of union in the less developed countries. The I.C.F.T.U. has been particularly active in India and West Airica. and has been engaged in substantial educational and training projects in these and other areas. All these international federations are recognized by UNESCO. and there is close cooperation between UNESCO and the I.C.F.T.U. in the field of workers' education. (See also INDUSTRIAL RELATIONS.)

TRADE WIND, the name given to the regular northeasterly and southeasterly winds which blow from the subtropical belts of high pressure toward the equatorial belt of low pressure. Their regularity, especially over the oceans, explains their name, the term "trade" being used in the otherwise obsolete sense of "course" (*cf.* "tread").

The trades. broadly, extend from latitude 30° N. to 30° S. and thus cover about half of the earth's surface. They are best developed over the oceans, with the exception of the north Indian ocean where they are replaced by the monsoon. The great variety of climates included in the trade-wind belt ranges from extreme aridity with fog at the eastern margins of the oceans to copious rainfall with tropical storms along their western edges. ***See*** also CLIMATE AND CLIMATOLOGY.

See H. Riehl, *Tropical Meteorology,* ch. ii (1954). (H. RL.)

TRADING POSTS flourished in North America from earliest colonial days until late in the 19th century as places of exchange of goods and currency between Indians and the settlers and traders. In 1565 the explorer Pedro Mendenez wrote to Philip II of Spain mentioning the existence of trading areas along the Gulf of St. Lawrence to which Indians brought bison skins for trade to the French.

The first English trading post was established at the Jamestown colony in Virginia. Corn and pelts were the chief articles of exchange until beads, or wampum (*q.v.*), were established as currency.

In 1668 two French traders, Sieur des Groseilliers and Sieur de Radisson, opened a post on the shore of Hudson bay which eventually was chartered by Great Britain as the Hudson's Bay company (*q.v.*). Throughout the period of colonial expansion, the principal mother countries—Great Britain. France and Spain—set up strategic trading posts which supplied the Indians with guns and ammunition and, later, liquor. After the Revolutionary War, in an effort to control the liquor problem and to establish a fair standard of trade, a law was passed authorizing government trading posts controlled directly by the president. All border forts became trading posts.

In 1806 an office of Indian trade was created. By 1810 posts had opened in Ohio, Georgia and in the Louisiana, Indiana, Michigan, Mississippi and Orleans territories.

The government measures did not solve the problem, however, as British trading posts, handling illegal liquor and supplying the Indians with war materiel, continued to operate in the Ohio and Mississippi river areas until after 1814. Furthermore, the government posts were bitterly opposed by private traders. In 1822 the posts were abolished.

In 1811 John Jacob Astor (*q.v.*) set up a post on the Columbia river which became one of the largest fur centres in the nation. Another famous post was the one near Gardner, Kan., the town marking the beginning of the Oregon trail west. By the 1840s trading posts had been established throughout the southwest and the Pacific coast. Many of the original sites have since become large cities—Kansas City, Boise, Spokane, Winnipeg, and Vancouver among them.

The physical structure of a trading post is described by the Smithsonian Bureau of American Ethnology (*Handbook of American Indians,* 1910) as "a large square inclosed by a stockade ... within the stockade were storehouses, quarters for the men, and a room for general trade."

TRAFALGAR, THE BATTLE OF. The British naval victory over the French and Spanish fleets off Cape Trafalgar, on Oct. 21, 1805, was a sequel to the breakdown of Napoleon's scheme for invading England.

An account of the movements leading up to it, known as the Trafalgar campaign, will be found under the heading NAPOLEONIC CAMPAIGNS.

Admiral Villeneuve, returning from the West Indies, succeeded in making the port of Ferrol; thence he should have sailed for the Channel and effected a junction with the Brest fleet, but, judging that Napoleon's schemes were already defeated, he made for Cadiz instead. Nelson, after his arrival at Gibraltar from the West Indies, had fallen back on the English Channel fleet, but Collingwood was watching Cadiz with three ships. On Villeneuve's arrival, he retreated slowly towards the Straits, and the French pursued him; but they had no wish to be drawn into the Mediterranean, and after a time retreated to Cadiz, and Collingwood was able to resume his station; he was joined at the end of August by reinforcements amounting to 22 ships. The importance of defeating or effectively blockading this allied force which now numbered 33—15 of them Spaniards—was fully realised by the Admiralty, and in September they decided to send Nelson to take command of the blockading force.

Nelson in Command at Cadiz.—Nelson left Portsmouth on Sept. 15 with three sail of the line, arriving off Cadiz on the 29th of the same month—his forty-seventh birthday. He had sent ahead a frigate to forbid any hoisting of colours or firing of guns, in order not to draw the attention of the Allies to the arrival of British reinforcements. But the unofficial welcome he received was such as to put heart into any commander of a fleet. During the first fortnight of October he was reinforced by a further six ships, so that his strength was at one time 34, but at the time the battle was actually fought he had only 27 ships at his disposal; six had been sent to Gibraltar to revictual, and Admiral Calder, who was going home to face court-martial for his unsatisfactory action off Finisterre, was magnanimously allowed to return in his flagship. Nelson did not keep the bulk of his fleet close to Cadiz; only the frigates were inshore, most of the ships being some 30 to 40 miles to sea, connection being maintained by a line of signal ships.

Villeneuve Ordered to Mediterranean.—Nelson's first task was to induce Villeneuve to put to sea, and this was performed for him by Napoleon himself. A new coalition of European powers had just been formed against Imperial France, and Napoleon, unable to use his troops against England owing to the breakdown of his schemes, had marched them against Austria. He thus required naval support in the Mediterranean, and Villeneuve was ordered to leave Cadiz and enter that sea; furthermore, should he encounter an enemy fleet to which he was not inferior, he was not to hesitate to attack them. These commands reached the French Admiral at the end of September. He knew, however, that they could never be acted on successfully, and a council of war held at the beginning of October decided that, though a sortie might be possible, to give battle to the British fleet would be suicidal. At this time, too, it appears that the Allies were under-estimating the strength of the British. Later in the month Villeneuve heard that Napoleon was sending Admiral Rosily to supersede him. This he regarded as a reflection on his honour, and he decided to put to sea before his successor arrived. He did not intend to give battle to Nelson if he could get into the Mediterranean without doing so, but he fully realised that he would probably be forced into action; and he thought that, in such a case, Nelson's probable plan would be to obtain local superiority over part of his fleet. To guard against this he formed a reserve squadron of 12 ships under the Spanish Admiral Gravina, which was to keep to windward of the rest of the fleet, and thus be able to come to the assistance of any part of it that was in difficulties.

Nelson's Battle Orders.—Nelson had also drawn up orders for the guidance of his officers, and had explained to them how he intended to fight the battle. His instructions are embodied in the "Nelson Memorandum," which was drawn up at a time when he expected to have a larger force than 27. None the less the principles it contained are applicable with equal force to a smaller fleet. They were that the attack was to be made in two bodies; the larger, under Collingwood, was to obtain local superiority over the enemy's rear, while Nelson, with the smaller body, was to preserve him from the interference of the van and centre, should they attempt to go about to the assistance of the rear, as they normally would. On the day of battle Collingwood's squadron consisted of 15 ships and Nelson's of 12.

Villeneuve Puts to Sea.—It was on Saturday, Oct. 19, that the first of the Allies got to sea. Nelson knew of their movements immediately, and made sail for the south-east so as to cut them off from passing through the Straits. Only part of the allied fleet got to sea on the Saturday, and on Sunday the 20th the weather was so bad that they returned to the neighbourhood of Cadiz. Nelson, throughout, kept his main fleet out of sight, but followed them, move for move, receiving. all the information on which he based his decisions from his frigates. Monday the 21st was a fine day; the wind was light and blowing from the north-west, and at dawn the two fleets were in sight of one another. The Allies were sailing south, making for the Straits again, and the British were some 12 miles to the west of them. Nelson at once ordered his fleet to form two lines of sailing, in accordance with his plan outlined above. His own squadron was the more northerly of the two, and each admiral was leading his own squadron, Nelson in the *Victory*, and Collingwood in the *Royal Sovereign*. In this formation, they approached the allied fleet, and as they came more clearly into view, Villeneuve, for the first time, saw that he had underestimated their strength. He at once sacrificed the originality of his dispositions by ordering Gravina, with the reserve squadron, to come into the line; and, shortly afterwards, partly with a view to keeping Cadiz open as a refuge on his lee, and partly to counter what he thought was designed as an attack on his rear as he was sailing south, he ordered his whole fleet to wear and sail roughly north.

Collingwood's Attack.—Villeneuve's order to his fleet to wear was made about 8 o'clock, and it was not properly finished when Collingwood, who was to initiate the attack, ordered his squadron to change its formation from an irregular line ahead to an irregular line of bearing. This was about 8·50, some two hours after Nelson had first ordered the advance. Collingwood's object was to bring his force into a line as nearly parallel as possible with the part of the enemy line that he was to engage, and the concavity in their line was such that this manoeuvre would virtually produce that result. Nelson had given his second-in-command a free hand in deciding how to carry his line into battle, so that the credit for this movement, admirably suited as it was to the circumstances and designed to enable the British ships to use their broadsides as they got into action, must be given to Collingwood. For the rest, he carried out brilliantly the part assigned to him—namely to break through the enemy and engage the rear 12 ships. His own vessel, the *Royal Sovereign*, being a very fast sailer, was in close action just after 12 o'clock, and to her fell the duty of selecting the gap which would enable him to cut off 12 ships. Actually he cut off 15 and became engaged with 16.

Nelson's Attack.—It now remains to consider the movements of Nelson's line. The commander-in-chief it will be remembered had kept for himself the duty of preserving Collingwood from any interference from the allied centre or van. For this purpose he continued his advance in the order he had first assumed, that is to say, irregular line ahead. With the object he had before him, he naturally wished to disguise the point at which his attack was finally to be directed, and line ahead was the most flexible and easily-managed formation he could adopt. It had the drawback of exposing the head of the line, as it approached, to the concentrated fire of the enemy, but Nelson was prepared to regard this as a justifiable risk in view of the advantage of flexibility which the formation conferred, and which was peculiarly valuable in the particular circumstances. The event proved him right. He began by aiming at the van rather than the centre of the allies, whose leading ships, nervous of having their T crossed, crowded on sail to prevent this manoeuvre being executed, thus taking themselves further from that part of their line which was now being attacked by Collingwood, and which Nelson did not intend should be assisted by them. Indeed, the whole of the allied van and centre, mystified by Nelson's movements and uncertain of his aims, could do nothing but wait for him to declare his intentions, while they left the rear to look after itself. Nelson was himself leading his line, and as the "Victory" approached the allied van he turned to starboard, followed in succession by the ships in his squadron, and sailed down the allied line, looking for a suitable place at which to break through. This turn enabled him to open fire, but he preferred to hold it. Finally he found a gap astern of the "Bucentaure," 12th ship in the line and Villeneuve's flagship, and, passing through, he opened fire, raking the ships on either side with terrible effect. The majority of his line deployed to starboard and broke through the allies at various places between the points pierced by Nelson and Collingwood; but two more ships ahead of the "Bucentaure" were engaged, the Ieading ten ships finally being left without attention. Six of these, under Dumanoir, at length made some attempt to go about to the help of those behind them, but their arrival was too late to be of any use, and they made off; for, in the meantime, Nelson's 12 had been matched with 7, with the inevitable result. By this time, too, victory had declared itself for Collingwood, who had been left without interference, as Nelson had designed, to complete the destruction of the rear.

Completeness of the Victory.—In all, 20 prizes were taken —about 60% of the allied fleet. A larger percentage was taken or destroyed at the Nile, but the comparison is not a sound one, for at the latter battle the enemy was caught in a confined space. At Trafalgar they had plenty of room to manoeuvre and a friendly port on their lee; yet they could not escape. such was the paralyzing effect of Nelson's tactics—an inspired mixture of the traditional and original. Nelson had solved a problem that had puzzled British admirals for a century—namely, how to prevent the French making off while most of their fleet was still more or less intact. For this reason Trafalgar is regarded as the greatest of naval battles and Nelson as the greatest of admirals. *See* also NAPOLEONIC CAMPAIGNS.

TRAFFIC REGULATION. Prior to the end of the 19th century there was little need for traffic regulation on roads and streets. Travel was slow and road congestion did not often occur. A few basic rules of the road, such as keeping to the right (or left), were time-honoured traditions rather than regulations and were adequate for the times.

The mechanization of highway traffic greatly increased the number. size and speed of road vehicles. This revolution in the highway transportation of civilized countries produced many social and economic benefits to the public but traffic congestion and casualties became extremely critical problems. Coincident with the increase in the seriousness and scope of these problems, more rigid regulation of road traffic was demanded. Thus from an antecedent of customs and conveniences modern traffic regulations became extremely numerous and complex.

Traffic regulation includes the use of traffic controis and traffic-control devices in addition to laws. Traffic controls are applied at specific locations where their need is warranted; they consist of one-way streets. control of parking. speed limits and intersection controls. Traffic-control devices are the means by which road users are advised. directed and warned concerning the traffic controls which apply at specific places and times; they consist of traffic signs. signals and pavement markings. For the most part traffic controls and traffic-control devices are legally defined and are made enforceable by specific traffic laws. However, some traffic-control devices may be advisory or informational only, such as route markers or town destination signs.

The extensive use of the motor vehicle and its wide range of travel have placed emphasis on the need for uniformity in traffic regulations, and great progress has been made toward the unification and reciprocity of traffic regulations among the free nations of the world and their political subdivisions.

HISTQRY OF TRAFFIC LAWS

The evolution of traffic law reflects the changes in highway transportation and in public opinion throughout the years. When the motor vehicle was first introduced traffic laws favoured the horse and required motorists, when meeting a horse-drawn vehicle, to stop and lead the animal past the frightening machine. In present-day traffic horse-drawn vehicles are prohibited on some highways.

The role played by the motor vehicle in modern society is so important that nearly every aspect of highway traffic must be regulated. Modern traffic laws apply: (1) to the vehicle, as to registration, mechanical fitness, equipment, size and weight; (2) to the driver, as to age, ability to drive and financial responsibility; and (3) to the safe and expeditious use of public roads.

The authority to enact traffic laws varies considerably among different countries. In some the highest governmental authority may enact traffic legislation (such as parliament in Great Britain); in others traffic laws are enacted at lower governmental levels (such as the various states in the U.S.). In almost all countries municipal authorities have the power to establish local traffic controls (or ordinances) when enabling legislation has been provided. Where enabling legislation is not available many traffic rules are enforced under the authority of broad police powers designed to protect the safety and welfare of the public. Early traffic rules were enforced by this method.

Before 1899 no effective attempts were made to control traffic anywhere except in Great Britain, where the Highway act of 1835 provides that carriages and animals shall be driven on the left. or near, side of the road. Prior to this act the rule in Great Britain and Ireland that vehicles should keep to the left was a custom which the police enforced as a matter of common law. The act of 1835 was followed by the Town Police Clauses act of 1847, which requires the driver of a carriage meeting another to keep to the left, and when overtaking another to keep to the right except in cases of "actual necessity" or some sufficient reason for deviation. (The table lists the countries and regions where road traffic is required to keep to the left or to the right.)

The Road Traffic acts of parliament of 1930 and 1934 formed the basis of most of the traffic regulations in force in Great Britain. The act of 1930 also provided for the publication of a highway code of road manners as official advice but not a part of the traffic law. The ministry of transport and civil aviation (organized in 1919 as the ministry of transport) was empowered to make detailed regulations covered broadly by the Road Traffic acts. Under this enabling legislation local authorities in Great Britain have power to make certain traffic regulations subject to approval by the minister of transport.

In the U.S. in 1899 William Phelps Eno, organizer of the Eno Foundation for Highway Traffic Control, compiled a traffic code for New York city. He had observed that traffic in British cities operated efficiently because drivers and pedestrians obeyed without question the time-honoured rules of the road handed down through generations and that the police enforced these common-law rules. At that time in U.S. cities there were few rules for driving recognized by the public or the police and vehicles were driven in a chaotic manner. Although the automobile industry was in its infancy and motor-vehicle registrations were below 10,000, Eno envisioned the vast increase in motor-vehicle use and reasoned that the American public should be quickly educated relative to traffic rules through the issuance of a traffic code. His code was proposed ior New York city in 1900 but was not adopted until 1903. It was subsequently adopted by a number of other cities in the U.S. and by Paris in 1912. The code was revised and reissued at least five times prior to 1918. In 1919 it was again revised and adopted by the highways transport committee of the U.S. Council of National Defense.

In 1924 the National Conference on Street and Highway Safety (N.C.S.H.S.) recognized the sovereign power of individual states to regulate and control traffic. This conierence was a co-operative activity, with Herbert Hoover. then U.S. secretary of commerce, as chairman. Its membership consisted of a number of national organizations concerned with rapidly increasing traffic casualties and the need for uniiormity of traffic laws among the various states. At the first general session of the conference it was obvious that uniformity in traffic laws among the states could only be achieved through the drafting of model legislation, and a committee on uniformity of laws and regulations was created to draft the models. This committee, combined with another committee created for the same purpose by the National Conierence of Commissioners on Uniform State Laws, produced its first draft of the uniform motor-vehicle code in time for review by the second general session of the N.C.S.H.S. in 1926. At this conference the first uniform motor-vehicle code in the U.S. was adopted and recommended to state legislatures for enactment. The first model traffic ordinance recommended to cities for enactment was drafted by the committee in 1928 and reviewed by the third conference in 1930. This ordinance was designed to conform with state statutes provided through the uniform motor-vehicle code. At the next three conferences, held in 1934, 1938 and 1944, the code and ordinance were reviewed and revised.

In 1947 the N.C.S.H.S. was dissolved but the work of revising the model code and ordinance to keep them up-to-date was taken over by the National Committee on Uniiorm Traffic Laws and Ordinances (N.C.U.T.L.O.). The membership of this committee consisted of representatives of over 50 national agencies, and at least one formal meeting of the group was held each year.

Uniform Motor-Vehicle Code of the **U.S.**—The widespread ownership of motor vehicles in the U.S. placed critical emphasis on the development of sound traffic laws. Legal processes, public-road administration and traffic problems vary among different countries, but the uniform motor-vehicle code developed in the U.S. is typical of the modern traffic laws required, with modifications to meet local conditions, throughout the world. The essence of the model code, revised in 1956 by the N.C.U.T.L.O., is briefly summarized under the headings of its principal subdivisions.

The Department of *Motor* Vehicles.—This section provides for a separate motor-vehicle department in the state government, having a division of registration, a division of drivers' licences and a division of highway safety and patrol. Details pertaining to the authority to grant, refuse, revoke, cancel or suspend vehicle registration, certificate of title or drivers' licences, and to the enforcement of traffic regulations are also covered.

Certificate of Title and Registration of Vehicles.—Provisions are set forth governing issuance and renewal of a certificate of title of vehicle ownership, the validity and recording of liens or other financial encumbrances on the vehicle, vehicle-registration procedures and special registration requirements for dealers, manufacturers and transporters.

Antitheft Law.—This section deals with methods of receiving or disposing of a vehicle; penalties for unauthorized use of and tampering with a vehicle; and offenses related to title and registration.

Dealers, Wreckers and *Rebuilders*.—Requirements are established for licensing these agents, and their obligations are specified with respect to title and registration of vehicles.

Operators' and Chauffeurs' Licences.—This section includes provisions for the issuance of licences, examination of applicants and suspension or revocation of drivers' licences.

Financial Responsibility.—Legal provisions require deposit of security following an accident serious enough to be legally reportable, and specify conditions and methods under which proof of financial responsibility must be provided for future accidents.

Owners of Vehicles for Hire.—Special provisions are made for this class of owner—concerning financial responsibility, liabilities and methods of renting motor vehicles—to conform with motor-vehicle department requirements.

Civil Liability.—This section covers liability of government agencies arising from the operation of a publicly owned vehicle; liability with respect to gratuitous guest passengers in a motor vehicle; and liability imputed to the vehicle owner for negligence or willful misconduct of operator.

Accidents *and* Accident Reports.—Included are the requirements for reporting accidents; duties of persons involved in a motor-vehicle accident; responsibility of coroners and garages to report evidence of an accident; and public uses of accident reports.

Equipment of Vehicles.—Minimum requirements for vehicle equipment are specified, including lights, brakes, horns, mufflers, tires, air conditioning, safety glass and the display of flares and other warning devices when certain vehicles are disabled.

Inspection of Vehicles.—This section authorizes properly designated officials to inspect any vehicle that is believed to be unsafe or not properly equipped, and requires inspection for operating deficiencies of every motor vehicle at least once a year at either state-operated inspection stations or by officially designated inspectors.

Size, Weight and Load.—The maximum legal sizes and weights of motor vehicles are specified; official enforcement of weight limits is authorized; and provision is made for special permits ior oversize and overweight vehicles.

Powers of State *and* Local Authorities.—This section provides for co-ordination and uniformity in the enactment and enforcement of traffic laws on both state and municipal levels; requires the state highway department to adopt a manual and specifications for a uniform system of traffic-control devices consistent with national standards; requires local authorities to conform with the state manual and specifications; and authorizes education officials to adopt and enforce certain regulations governing the design and operation of school buses.

Records and Reports of Convictions.—Every magistrate or judge of a court is required to maintain records of traffic complaints and citations and to make suitable reports of these records to the motor-vehicle department.

Parties and Procedures Upon Arrest.—This section defines parties in violation of the code; establishes procedures upon arrest; and requires use of quadruplicate traffic-arrest forms in a manner designed to avoid cancellation or solicitation for cancellation of a traffic citation.

Rules of the Road.—This section pertains particularly to the operation of traffic on public highways, including regulations for driving on right side of road, overtaking and passing, right-of-way at intersections, restricted access, turning and speed change, general speed restrictions, reckless driving and driving under influence of alcohol or drugs, parking, pedestrian rights and duties and obedience to traffic laws and traffic-control devices.

Traffic Laws in the United States.—The provisions in the uniform motor-vehicle code have been adopted by most of the states in the U.S., either entirely or in part.

Driving Licences and Tests.—All states require drivers' licences and. in this connection, written and oral examinations are given on knowledge of lams, traffic-control devices, liability and driving courtesy. It is common practice to require tests of eyesight, literacy and driving skill. Drivers' licences are usually obtained through local branches or agents of the motor-vehicle department and must be renewed at intervals of from one to three years.

Registration. — Vehicles must be registered annually in all states. It is general practice to permit nonresident drivers to operate for a certain period of time without registration in a given state, Proof of vehicle ownership is required although some states do not require certificates of title; however, change of vehicle ownership must be reported in all states.

Insurance.—Three types of liability laws are in force in the U.S.: the security type, under which, following the report of an accident, the drivers (or owners) involved must show ability to pay damages; the future-proof laws, under which a similar showing of financial ability must be made after certain traffic offenses or failure to pay damage claims; and compulsory insurance laws, under nhich motorists must file proof of financial responsibility as a condition of vehicle registration.

Vehicles and Equipment. — Each state has its own size and weight regulations, and changes in these occur during state legislative sessions each year. Although there is wide variation among the states, the tendency has been toward adoption of the size and weight limitations of the uniform motor-vehicle code. Few states require official vehicle inspection.

Accident Reporting. — State laws generally require reporting of accidents by motorists. Accidents involving injury or death must usually be reported immediately to local or state police. Most states also require that these accidents, and those involving property damage over a given amount. be reported to a central state agency on forms provided for the purpose.

Additional *Regulations.*—More than half the states adopted the "Rules of the Road" recommended by the uniform motor-vehicle code or a similar set of rules.

The President's Highway Safety conference, following its inception in 1946, urged each state to compare its motor vehicle laws with the uniform motor-vehicle code and, as increasing traffic problems caused this to be done. essential conformance with the code was expected throughout the country.

Traffic Laws in Great Britain. — The traffic laws in Great Britain differ in detail from those of the uniform motor-vehicle code developed in the U.S., although in purport they are much the same. Some of the principal British traffic regulations for motor vehicles are described below.

Driving Licences and Tests. — Application for a driving licence must be made to the council of the county or county borough, and the form of application incorporates a declaration of fitness to drive. Driving licences can be endorsed by the courts for violations of lams for moving traffic (not for parking violations). Driving tests were introduced in 1935 and are conducted by examiners appointed by the ministry of transport.

Registration. — All vehicles, except those of the sovereign, must be registered with a county, county borough or burgh council, which issues a registration book. The book must be returned to the council when the licence is renewed, when the vehicle is altered. sold, destroyed or taken permanently out of the country or when the person in whose name the vehicle is registered changes his address. This person need not be the legal owner.

Insurance.—No mechanically propelled vehicle may be used on a public highway unless it is covered by insurance or a suitable security against claims arising from injury or death. A certificate of insurance must accompany each application for vehicle registration.

Vehicles and *Equipment.*—Vehicles must conform to regulations as to size and weight and must be properly equipped with respect to brakes. lights, safety glass, etc. 'The vehicle must be so maintained that no danger is likely to be caused.

Accident Reporting. — Accidents must be reported to the police as soon as practicable and within 24 hours if name, address and certificate of insurance are not made available to any person having legal reasons for requesting them.

Additional *Regulations.*—Numerous laws prohibiting certain acts when driving and when the vehicle is parked are generally similar to those of other countries.

TRAFFIC CONTROLS

Traffic controls are the means employed to insure orderly movement of vehicles and to achieve the highest practicable efficiency in using streets and roads for both travel and parking. However, such controls should be applied only when engineering studies or accident records show a need for them; overzealous use of controls may result in needless delays. with consequent impatience on the part of motorists giving rise to further hazards.

One-Way Streets. — These may be of three general types: (1) operation in the same direction at all times; (2) operations reversed in direction at different times to accommodate the predominant`flow during peak traffic hours; and (3) operations one-way and two-nay during peak and off-peak hours respectively. One-way operation increases the capacity of a street. increases speed nith safety and reduces traffic delays.

Curb Parking Controls. — Parking regulations apply to both time and space factors. Parking time limits are used to reduce the length of time a vehicle may be left at the curb. They may also be used to prohibit curb parking during peak traffic hours. Space controls of parking may prohibit curb parking at certain places at all times or they may reserve parking spaces for commercial loading zones, buses or taxis. Parking time controls increase the turnover of curb-space use and discourage illegal parking practices. Curb-parking prohibitions along sections of a street, on either or both sides, increase street capacity for moving vehicles and eliminate hazards and interference saused by parking maneuvers. Parking is generally prohibited near intersections, at entrances to public meeting places and at fire hydrants.

Speed Controls. — The common speed regulations consist of (1) the basic rule requiring motorists to travel at reasonable and prudent speeds; (2) maximum numerical limits imposed throughout a region, such as a state or urban area; and (3) speed zones suited to environmental and traffic conditions at certain locations and, occasionally, at certain times. While the severity of accidents obviously increases nith increased speed there is much controversy concerning the influence of speed on the incidence. or frequency, of accidents. Some authorities object to the inflexibility of numerical speed limits because such limits take no account of the continuously changing traffic environment. Numerical speed limits are of two types: the absolute limit. which when exceeded requires no further evidence for arrest; and the prima-facie limit. which places the burden of proof of safe driving upon the driver if he exceeds the numerical limit.

In the United States, revision of the uniform motor-vehicle code discarded prima-facie limits in favour of absolute limits of 30 m p h. in any urban district, and 60 and 55 m.p h. in other locations during day and night respectively. The code also provided for speed zoning and for altering maximum limits for certain vehicles.

In Great Britain the general speed limit was established at 20 m p.h. in 1903. During subsequent years this limit was violated so frequently and became so controversial that the general limit for passenger vehicles was abolished completely in 1930. Finally in 1934 parliament imposed a limit of 30 m.p.h. on passenger vehicles in built-up areas; lower limits for commercial vehicles were continued in all areas.

Intersection Controls. — Traffic is controlled at intersections by the establishment of "through" or "stop" streets and the prohibition of turning movements. Stop regulations are often required when minor roads intersect with major roads and automatic traffic signals are not warranted. In customary American and British practices, automatic traffic signals are warranted only (1) where the average hourly number of vehicles and pedestrians entering the intersection exceeds a specified volume; (2) where traffic hazards cannot effectively be reduced by other methods; or (3) to promote continuous flow at a given speed through a coordinated system of signals.

TRAFFIC-CONTROL DEVICES

The safety and efficiency of movement of highway traffic depend upon the drivers' immediate recognition and understanding of standardized traffic-control devices. Some semblance of uniformity in traffic-control devices in European countries was achieved at the 1926 International Convention on Motor Traffic and the European conference in 1931, although there still remained many local variations. In the U.S., need for uniformity in the design and application of traffic-control devices was first met when the secretary of agriculture, at the request of the American Association of State Highway Officials (A.A.S.H.O.), named a joint board to designate the major route systems of the country and to develop a uniform method of marking them. In 1927 the board published its manual and specifications for the manufacture, display and erection of U.S. standard road markers and signs. In 1930 the N.C.S.H.S. approved, for city use, the report of the committee of the American Engineering council on street traffic signs, signals and markings. The conflicts in these two documents were reconciled when a joint committee on uniform traffic control devices, composed of representatives of both the A.A.S.H.O and the N.C.S.H.S., was appointed in 1931, This joint committee developed and published the first *Manual on Uniform Trafic Control Devices for Streets and Highways* in 1935. In 1942 representatives of the Institute of Traffic Engineers were appointed to the joint committee, and subsequent revisions of the manual were sponsored by all three agencies.

Unfortunately the American and European traffic-sign systems have little in common. The European system utilizes distinctive symbols (pictorial or abstract) as compared with the use of word messages and few symbols in the American system. North Africa and the Middle East use the European system; Asia and the Far East (with language problems) use symbols similar to the European system; British signs combine both systems, with a symbol plate and a word-message plate on most signs; Japan uses signs from both systems; and North, Central and South America use the American sign system.

INTERNATIONAL UNIFORMITY IN TRAFFIC LAWS

With the increase in international travel, great need developed for formal agreements among nations with respect to such matters as reciprocal recognition of drivers' licences and vehicle registrations, universal vehicle-size and equipment requirements, uniform traffic laws and standardized control devices. Uniformity in the western hemisphere was initiated in 1943 by a convention held in Washington, D.C., on the regulation of inter-American automotive traffic. This convention established reciprocal agreements on motor-vehicle customs, registration, sizes, weights, equipment ownership and drivers' licences. Ho ever, no such steps were taken on a world-wide basis until the United Nations Conference on Road and Motor Transport was held in Geneva in 1949. The objects of this world-wide convention were to review all previous conventions related to road traffic, to establish broad reciprocal agreements as to traffic regulations applicable to international traffic and to develop a protocol on uniform traffic signs and controls.

The principal provisions of the 1949 United Nations conference may be summarized as follows:

1. General provisions were included to preserve the authority of the individual nations to regulate traffic but each nation agreed to admit international traffic under provisions of the convention. Individual vehicles or drivers were to be admitted for a maximum period of one year.

2. Rules of the road were provided to cover basic regulations of universal application designed to promote safety and the orderly flow of traffic. These consist of certain fundamentals found in traffic laws of many countries, such as safe and prudent operation to avoid accidents and obstruction of the way, special precautions in passing other vehicles, keeping on the proper side of the road and display of proper lights at night.

3. Provisions were made for uniform design and use of traffic signs and signals.

4. The domestic registration certificate must be recognized by all countries when the vehicle carries a registration plate and separate sign indicating country of registration (for example. "USA," United States; "GB," United Kingdom; "F," France); vehicles were required to be in safe mechanical condition; and the authority of each country to control vehicle sizes and weights was recognized.

5. Reciprocal recognition of the driving licence was authorized but any country might require an international drivers' licence; withdrawal of driving licence after certain offenses is permitted. The conference recognized the validity of provisions of the international convention (1926) and the inter-American convention (1943).

The conference, through the Transport and Communications Commission of the UN, appointed a group consisting of a traffic expert from each of the six continental areas of the world to recommend a uniform system of road signs and signals. This group met in 1950, 1951 and 1952 and submitted recommendations which were presented to the various nations of the conference for ratification.

The new traffic-sign system recommended by the UN is patterned more closely after the European system than the American. Although the United States ratified the 1949 convention with respect to traffic regulations, it did not immediately accept the protocol for unified signs and signals recommended by the UN conference.

TRAHERNE, THOMAS (1637–1674). English poet and clergyman, was the ardent exponent in prose and verse of the way of life he called "felicity." He was the son of a shoemaker at Hereford. He entered Brasenose college, Oxford, in 1653 (B.A., 1656; M.A., 1661; B.D., 1669) and was presented to the living of Credenhill, near Hereford, in 1657, but almost certainly did not hold it. He was episcopally ordained in 1660 and in 1661 was again presented to the living which he held till 1674. From 1669 to 1674 he lived in London and Teddington, Middlesex, serving as chaplain to Sir Orlando Bridgeman, who was lord keeper from 1667 to 1672. He was unmarried. He died at Teddington in 1674.

Traherne published *Roman Forgeries* (1673) and prepared *Christian Ethicks* (1675) for the press. His *Thanksgivings* in rhythmical prose were published anonymously as *A Serious and Patheticall Contemplation of the Mercies of God* (1699). Other *Meditations and Devotions* were published or republished anonymously in 1717. The chance discovery in a London street, identification by Bertram Dobell and publication by him from manuscript of the *Poetical Works* (1903) and *Centuries of Meditations* (1908) was a literary sensation. The manuscript *Poems of Felicity* were then found to have been in the British museum, London, since 1818 and were edited and published by H. I. Bell (1910). Later discoveries were a manuscript volume of meditations, etc., on occasions of the church's year, and a notebook containing early poems.

Traherne is a religious poet of great intensity and individuality. His background is Christian theology, the Bible (particularly its poetry), Renaissance Platonism and his own early ecstasies described in the third *Century* and in some of the poems. He was probably influenced to some extent by Henry Vaughan. He is not of the metaphysical school, however, though he has his own philosophy. He anticipates Wordsworth and also, though deficient in imagery, William Blake; Wordsworth especially because of the gleam irradiating his memory of childhood, Blake because of his boldness and imaginative insight. He aimed at giving an unvarnished account of mental experience, but the purity and vividness of this experience produce a poetry worthy of them. His nature was both intensely sensuous and intensely spiritual, and his greatness often consists in the fusion of these two elements. He is a conscious artist who never uses the same stanza form in two poems, and who excels in fine openings.

Poems of Felicity was prepared for the press (but not published) by his brother Philip (d. 1723). A third of its contents are also in Poetical Works (1903), but Philip made many changes in the text, some for stylistic reasons, others because he could not follow Thomas's imaginative flights or was shocked at their daring. It is therefore certain that poems known only in Philip's transcript are not all exactly as Thomas wrote them.

The Centuries, prose sections numbered in hundreds (Centuries *of* Meditations is not Traherne's title and is misleading), were written in London for Mrs. Susanna Hopton of Kington, Herefordshire, who was the centre of a small religious society. In them Traherne instructs her in the way of "felicity." Every man is "Heir of the World," to whom it is given as his paradise. He must be conscious of his happiness and must be aware that this phenomenal world is not all. Primary and infinite is Spirit, that is, God. The third Century is largely autobiographical and contains several poems, including "On News." In the fourth Century Traherne expounds the principles of "felicity," which he certainly attained himself. His childhood experience did not last, but he regained "felicity" at Credenhill, enriched by thought and fortified by a living and permanent awareness of Spirit. It was probably at Credenhill that he wrote most of the poems.

TRAILING ARBUTUS: see ARBUTUS, TRAILING.

TRAIN BANDS, a term often applied to the English militia and especially to the London militia in the 17th century. (See MILITIA.)

TRAINING, MILITARY. Military training consists of systematic. progressive education and instruction of individual soldiers and military units in the efficient performance of specific warlike duties. It is concerned basically with the inculcation of discipline, leadership, morale, initiative, teamwork, physical conditioning, and the understanding of weapon functioning and personal protective measures. including first aid and hygiene. Advanced individual training teaches the basically trained soldier to function effectively as a member of a military team. Combined training includes the employment of the weapons, tactics and teamwork between combined arms. Training for higher command includes study in strategy, tactics, staff procedures, administration, logistics (supply), personnel and industrial management.

In ancient Greece, the Spartan system of military training began with the removal of the boy from his family to the military barracks when he was seven years of age. Weapon skill and iron discipline were stressed. For the Roman, military training included marching (4 mi. an hour), leaping and running, swimming, sword practice, special drill, use of the bow, sling and javelin, vaulting and burden carrying (60 lb., less arms).

In 18th-century Europe, Frederick the Great of Prussia (see FREDERICK II) developed a method of military training based upon rigid discipline and sustained delivery of musket fire at a more rapid rate than any contemporary army. His instructions to his generals were an early effort to train individuals for high command and staff duties. Prussian discipline was predicated upon instantaneous, automatic obedience to orders. The basic concept of Prussian military training was introduced into the United States by Baron von Steuben. As inspector general and drillmaster of Washington's troops at Valley Forge; he wrote Regulations for the Order and Discipline *of* the Troops of the *U.S.*

Prior to the American Revolution. military training in the American colonies consisted of an annual muster day when able-bodied male citizens turned out on the village common and drilled under local militia officers (see MILITIA; NATIONAL GUARD). The men so trained were skilled in hunting and repelling Indian attacks but lacked formal military training and discipline, though generally they were expert marksmen. The French and Indian War trained such officers as Col. George Washington and others to lead troops. A limited number of Revolutionary War leaders were former British officers, such as Horatio Gates and Charles Lee. President Washington after the Revolution urged the establishment of a military academy. This was done in 1802 at West Point, N.Y. The naval academy was established at Annapolis, Md.. in 1845. Private schools and institutions such as the Virginia Military institute, The Citadel in South Carolina, and Norwich in Vermont were military training schools with academic instruction.

The American Civil War (1861–65) was fought initially by untrained troops. Units of volunteers (*q.v.*), under inexperienced officers, trained as they marched to the battle front. The final phase of training was received in battle.

OFFICERS' TRAINING CORPS

U.S. Reserve Officers' Training Corps.—The origin of federally sponsored military training in civil educational institutions in the U.S. rests in the Morrill act of 1862, which required that colleges and universities receiving grants of public land include in their curricula certain elementary military instruction under supervision of the secretary of war. The need for this form of instruction was emphasized by World War I, and an attempt was made to meet it in the National Defense act of 1916, wherein a Reserve Officers' Training corps (R.O.T.C.) was authorized to extend to a wider range of institutions than land grant colleges. The corps was scarcely organized before the U.S. was compelled in 1917 to supplement its work by training camps.

The R.O.T.C. as an effective force in civilian institutions for military education dates from the National Defense act of 1920. The army R.O.T.C. consisted of a senior and a junior division. The former, established at colleges, universities and selected military schools, and divided into units corresponding to the principal combat arms and specialist services, included a four-year course averaging about four hours per week and one summer camp of six weeks The junior division, established in selected high schools and equivalent institutions and including only infantry units, was confined to boys over 14 years of age. It provided a three-year course of three hours per week and was practically the equivalent of the basic infantry course in the senior division. A naval R.O.T.C. program, established in 1926 to train reserve officers for the navy, was organized along similar lines.

The term National Defense Cadet Corps schools was adopted in 1957 to designate those high schools offering military training under the National Defense act, section 55–*C*. This program required that a school have a minimum of 100 boys, 14 years of age or older and permitted the school to employ a military instructor while the government furnished the necessary equipment, not including uniforms.

Upon gaining separate and independent status under the National Security act of 1947, the air force continued the operation at 78 institutions of its R.O.T.C. units, which had been established in 1946 under the army air forces. In the mid-1950s the enrolment in air force R.O.T.C. at more than 180 institutions approximated 120,000 students annually. Enrolment in the first two years of the A.F.R.O T.C. was open to all students who met certain physical and other requirements. However, for enrolment in the last two years and appointment in the grade of second lieutenant from this program, primary emphasis was placed on those students who desired and qualified for flying training upon graduation.

The U.S air force academy was established on a temporary basis at Lowry Air Force base. Denver. Colo.. in 1955. The permanent school at Colorado Springs offers cadets a four-year academic course nith a commission, upon graduation, as second lieutenant in the regular air force.

Training Camps.—In 1916, over 12,000 men attended military instruction camps patterned after the young businessmen's military training camp held in Plattsburg. N.Y., in 1915. At these camps, used for officer training in 1917–18, thousands of civilians were trained (in 90 days) to lead troops. The introduction of such complex equipment as radio, the telephone. aircraft and motorized transport in World War I required the soldier to be trained in technical as well as conventional military subjects. Further, tactical training had to be readjusted to include the stabilized trench warfare concept. Basic or recruit training and specialist training taught basic proficiencies and skills in the operation of technical military equipment. Advanced unit training followed, or was conducted concurrently with, basic and specialist instruction. During this phase, units were taught to function as integral parts of a larger organization, or as self-sufficient, separate units. Approximately one year was required to train an infantry combat division, from the arrival of new recruits until the completion of individual basic, specialist and unit training. Manoeuvres and tactical problems designed to test co-operation between the component units and staff sections occupied the training periods prior to movement to the port of embarkation.

From 1921 to 1940 part-time military training with the U.S. army was offered to young men aged 17 to 27. Initially, the program consisted of one month's annual training without pay on a volunteer basis for three years. Later, an additional year was added.

The successful graduates of the Citizens' Military Training camps were tendered commissions as second lieutenants in the Officers' Reserve corps (now U.S. army reserve).

By World War II, military training had become even more complex. Technical skills and capabilities far removed from the earlier requirements of the battlefield had to be developed and taught. The concept was to give to each soldier basic and advanced combat training regardless of his assignment. Tests to determine the aptitude of the soldier and to determine his military occupational specialty were part of the program. Those who passed the tests were given a classification number and performed military duty in that occupational specialty. Replacement training consisted of from 13 to 17 weeks of basic combat instruction. On completion, soldiers went to advanced or specialist training or to combat divisions as individual replacements. On arrival at a replacement depot, further classification mas carried out before the replacement joined his new unit at the front. Where the combat situation permitted, he was given further training in the rear area before beginning front-line duty. Schools of the arms and services (*i.e.*, infantry, artillery, ordnance. signal. quartermaster, chemical, etc.) conducted specialized training, including the operation of schools where officer candidates, after 13 to 17 weeks training. were graduated as second lieutenants. Tactical unit training was conducted to include, generally, the regiment, division and army. Specialized area training included amphibious, desert. jungle, arctic and mountain warfare indoctrination courses for units scheduled to face combat under these climatic and geographical conditions.

During World War II, battle indoctrination courses were designed to subject the recruit to every sight, sound and sensation of battle and to train him to act calmly with sound judgment regardless of noise. confusion and surprise. Physical and mental toughness was achieved in the training cycle by the operation of strength and confidence courses. Completion of obstacle courses and the traversing of infiltration courses covered with live machine-gun fire was required of each infantry soldier before he completed basic training.

After the outbreak of the Korean war, the Universal Military Training and Service act was passed by the congress of the U.S. in 1951, but its military training provisions were implemented only on an experimental, voluntary basis. Though a model training centre for the program was organized and conducted by the U.S army at Fort Knox, Ky., certain features of the plan, especially those requiring compulsory training, met with an unfavourable public response.

The Armed Forces Reserve act of 1952, as amended by the Reserve Forces act of 1955, provided a voluntary military training program for young men between the ages of 17 and 18½ years, the period of enlistment being for eight years. Six months of active training were required on graduation from high school. While in high school the reservist under this program was deferred from active duty until he graduated or attained the age of 20 years. Upon completion of the six-months training, the individual returned to his home where he was required to participate for 3 years in weekly reserve drills and annually two-weeks camp training with pay. By fulfilling this obligation in performing his reserve duty, the reservist was granted deferment from Selective Service.

Other military training programs were offered to young men 17 to 26 years of age by the reserve; *i.e.*, a six-year enlistment with two years active duty, or with no active duty until called for service. No deferment from Selective Service was granted in connection with the six-year enlistment. Critical specialists, aged 18 to 26 years, who were engaged in critical industry or skills and classified as 1A also had the option of six-months active duty for training. Under this program the remaining 7½ years of the eight-year enlistment were spent in the reserve in a draft-deferred status.

The training of armed forces reserve units is accomplished by lectures, attendance at service schools, field training or sea training duty exercises, and unit training camps, extension courses and on-the-job training at reserve training centres. The courses parallel those given in the resident courses at service schools so far as this instruction is applicable to the wartime duties of the reserve, and is adaptable to instruction by extension course methods. With their consent, reserve personnel may be ordered to active duty in peacetime for periods in excess of 15 days during which time they are paid in the same manner as personnel of the regular establishments.

Courses are available to members of the army reserve in all army schools up to and including the National War college and the Industrial college of the armed forces. Often there is a choice for the applicant of taking either the regular course in a particular school and subject, or a shorter associate course designed especially for the civilian components. Reserve personnel may also serve on short active-duty periods in regular army units, replacement training centres, army schools, R.O.T.C. staffs and in higher headquarters. including the general staff of the department of the army. The above cited conditions obtain generally in the training of reservists of the armed services.

GREAT BRITAIN

Britain's fighting services after World War II aimed at a very high standard of training in order to compensate for lack of numbers—a factor likely to be even more evident in the future than in the past. This high standard is difficult to attain owing to the complexity of modern weapons and equipment and the advent of the short-service national serviceman. To meet these conditions, greatly improved methods of instruction have been developed.

Higher Training. — The highest level of individual instruction is given at the Imperial Defence college in London, where senior officers of all fighting services and representatives from other commonwealth countries, the civil service and industry study the higher direction of war. At a lower level instruction is given at the Joint Services Staff college at Latimer, Chesham, Bucks., and at the separate staff colleges maintained by each service. Because of world-wide dispersion of units, very large-scale exercises are rarely possible in peacetime, except in the North Atlantic Treaty organization command. Instruction in the handling of large forces — often involving combined operations by sea, land and air — is usually given at theoretical exercises in which the commanders and staffs, but not the troops. take part.

Signal exercises — in which headquarters of units and formations. and their signal communications participate — are held at lower levels, especially to practise junior staff officers.

Training of Junior Leaders. — The standard of its young officers and its noncommissioned officers is the measure of a fighting unit's efficiency, and British defense services place great emphasis on the training of junior leaders.

Potential regular officers are trained as cadets at the service colleges at Dartmouth (navy), Sandhurst, Surrey (army) and Cranwell, Lincs. (air force) usually, but not invariably, after a short period in the ranks.

The policy governing the training of the individual is based on the service schools of instruction. Taking the army as an example, the schools of infantry at Warminster, Wilts., artillery at Larkhill. Wilts., signals at Catterick, Yorks., and many others, exist to teach officers and N.C.O.'s to become instructors who, on completion of their courses, return to their units to train other officers, N.C.O.'s and men.

These schools are directly under the war office, which is thus able to control training policy throughout the army. The system is similar in the other two services.

Training in Units and Formations. — Recruits, regular and national service, on joining the services receive their first few weeks basic training at their corps or regimental depot, or its naval or air force equivalent, before being drafted to units as primarily trained men. The basis of a good unit — naval ship, army unit or air force squadron — is the individual skill of its personnel in handling their weapons, or other equipment, and performing their particular duties. In addition training in teamwork is necessary, as only by combined effort can a fleet, army or air formation fight efficiently. Training in teamwork is known as "collective training."

Also taking the army as an example, individual training is carried out in the winter and collective training in spring, summer and autumn (in the tropics this order is reversed). Collective training begins with subunit (troop and platoon) training and progresses through various stages to large-scale exercises. embracing all arms. For units stationed in Germany after World War II the climax is reached with land and air exercises on a very big scale, and in some overseas commands, such as Hong Kong, the royal navy also participates.

Nonregular Personnel Training. — Territorial army training is supervised by a small cadre of regular officers and senior N.C.O.'s in every unit. The training of territorials (volunteers and national servicemen who have completed their full-time service) is on a part-time basis in drill halls during the evenings, at week-end camps and exercises and at an annual camp which usually lasts two weeks. Its scope varies in different types of unit and is subject to modification to meet local conditions.

Regular reservists of all services are called up occasionally for short periods, mainly to train them to handle new types of equipment.

Army Emergency Reserve Personnel, consisting mostly of men whose duties in war and civil life are similar, are called up for training infrequently and for short periods only.

The Combined Cadet Force — comprising Sea Cadet corps, Junior Training corps (formerly the Officers' Training corps), Army Cadet force and Air Training corps — trains boys up to the age of 17. first basically and then for the particular branch of service which they will join as national servicemen. The purpose of this training is to develop self-reliance and powers of leadership.

(*C*. N. B.)

TRAINING, TRANSFER OF, is the exerting by one habit of some influence upon the learning of, or the memory for, another habit. In some cases one habit may influence another by making the second easier to learn or to remember; this is positive transfer of training. In other cases one habit tends to interfere mith the learning of a second; this is negative transfer of training. Negative transfer of training is one of the important causes of forgetting.

One of the simplest forms of transfer is so obvious that it is likely to escape attention: habits are not entirely specific to the environmental or stimulating conditions that pertain at the time of training. Thus a person who has learned to drive an automobile under one set of environmental circumstances may be expected to drive in a satisfactory manner under many other conditions of traffic and terrain.

Similarly, the golfer who has learned to play on one golf course can transfer his skill to other links. In such cases the change of environment is apt to produce a small loss of efficiency but if the change is not too radical, efficiency will quickly return to its accustomed level.

The fact that habits are not bound to the specific circumstances of the training situation underlies much educational theory and practice. It is not desirable to teach children habits that will operate only in school; it is expected that the habits learned will transfer to life situations that differ markedly from the classroom environment.

While transfer from school situations to subsequent life situations does occur, it would be a mistake to assume that the transfer takes place in an entirely general and comprehensive manner. This view, once widely held and usually referred to as the doctrine of formal discipline, is based upon the theory that mind can be divided into a number of relatively independent faculties or powers. The doctrine of formal discipline held that it was possible to strengthen these various powers of mind by employing relatively formal exercises, much as it is possible to strengthen the muscles of the arm by exercising mith bar bells, and school curricula were designed to provide such mental exercises rather than to teach specific factual content. At the turn of the 20th century. however. an investigation by E. L. Thorndike and R. S. Woodworth cast grave doubt on the plausibility of the theory. Subsequently Thorndike advanced the theory that transfer of training takes place in terms of identical elements existing in two training situations. According to this view the study of mathematics should transfer positively to the later learning of engineering not because the study of mathematics strengthens the analytical powers of the mind but because mathematics is used in and is a part of the latter discipline. In the same way the learning of spelling and grammar should help the student in his subsequent study of English composition.

Identical elements between two learning situations can cause negative transfer as well as positive transfer if the identical elements lead the person to make incorrect responses in the second situation. There are many identical elements involved in driving an automobile in England and in the United States, but in one respect these may cause the driver who moves from one of these countries to the other to make an incorrect response: he may find himself driving on the wrong side of the road. Negative transfer often operates to hinder new learning. For example, if a child is required to learn two equally difficult poems in succession, more effort is required to memorize the second poem than the first; this is because the material that has already been learned tends to become confused with the material being learned in the second poem. This is an example of negative transfer and is sometimes given the name of proactive inhibition. Negative transfer also can produce forgetting. In the example used above it may be shown not only that the second poem is more difficult to memorize but also that. once learned, the new habit tends to interfere with the child's memory for the first poem. This type of memory interference is known as retroactive inhibition and it is believed that a great amount of everyday forgetting may be attributed to this cause.

The theory of identical elements is capable of being refined further. This is because habits themselves are capable of being analyzed into two components: stimuli and responses. While this division is not apparent in complex habits, it is abundantly clear in simple ones. In teaching a dog to come when a whistle is blown, the whistle is the stimulus for the dog and approach is his response, If the dog has been trained to approach at the sound of a particular whistle, it should not be difficult for it to learn a second habit: approaching when a slightly different nhistle is blown. The more similar the new whistle is to the old one, the easier it will be for the dog to transfer its previous training to the new situation. If a very different whistle is used, however, the second habit will be more difficult to establish. On the other hand if the dog is to be taught a different response — to run away, for example — it would be well to use a very different type of stimulus for training the second habit. If the same or a similar whistle is used to stimulate the dog to perform in the second situation, the old habit will interfere with the new response and negative transfer will result Again the similarity between the stimuli is the important factor in determining how much transfer in this case negative, will occur

Two principles governing the amount and direction of transfer from one training situation to a second can be stated.

1. Amount of transfer of training, without regard to whether it is positive or negative, will depend upon the degree of similarity between the stimuli evoking the responses in the two training situations. The more similar the stimuli the greater will be the amount of transfer.

2. Whether transfer will be positive or negative depends upon whether or not the responses learned in the first training situation are appropriate in the second If the first learned responses are appropriate to the second training situation, transfer, if it occurs at all, will be positive; if the responses are inappropriate, transfer will be negative. See also HABIT; LEARNING.

See J. A. McGeoch, *The Psychology of Human Learning*, rev. ed. by A. L. Irion, ch. 9 (1952); C. E. Osgood, *Method and Theory in Experimental Psychology*, ch. 12 (1953). (A. L. I.)

TRAJAN (MARCUS ULPIUS TRAIANUS; A.D. 53–117), Roman emperor, was born at Italica, near Seville. His family was Spanish, possibly with some Italian blood, but his father had had a distinguished career under Vespasian, earning a consulship, patrician rank and ornamenta *triumphalia*. The son served ten years as a military tribune, partly under his father's command in Syria. In 88/89 he was commanding a legion in Spain when it was summoned to the Rhine by Domitian against Antonius Saturninus. He obeyed orders promptly and was given an eponymous consulship in 91, but Domitian did not, apparently, employ him again. On Nerva's accession he was appointed governor of Upper Germany, with three legions. About Oct. 27, 97, Nerva, faced by a mutiny of the praetorian guard in Rome and by the possibility of military uprisings elsewhere, publicly adopted Trajan as his successor; the mutineers were punished and all trouble ceased.

The nearest army commander was an effective choice in the circumstances, but Nerva had himself put Trajan in this key position, presumably with an eye to his record and character, and on all counts Trajan quickly justified his selection. It was always difficult to find a man who could fill equally well the roles of imperator for the provinces and of princeps (not *dominus*) in Rome. When Nerva died (c. Jan. 27, 98), Trajan bore out his military reputation by remaining for several months on a tour of inspection of the Rhine and Danube frontiers. But he at once swore an oath never to execute a senator, and when he returned to Rome in 99 to hold his third consulship in 100, he took care, even in the smallest details of ceremony and behaviour, to show himself a loyal servant of the constitution, at once respectful toward the senate and indulgent toward the people.

Throughout his reign relations between senate and princeps remained excellent. All important decisions were in fact still taken by the emperor, but the senate's opinion was politely consulted, and its interminable debates, often ending with a supine reference to the emperor, were a prerequisite to any action within its traditional spheres of competence. The reward of Trajan's patience and understanding was the loyal co-operation of all members of the senatorial class, and he knew how to get the best out of all types of public servant. It was this aspect of his rule that won him the title *Optimus* (with the implication that he ruled not by right of inheritance but as the best man available), though characteristically he did not accept this title officially until 114.

In Rome Trajan was particularly noted for his magnificent games and buildings. He did much for Italy, reclaiming wasteland and building roads, aqueducts and new harbours at Ostia, Centumcellae and Ancona. He tried to arrest the decline of Italian agriculture and manpower by extending the *alimenta* system of Nerva, by making senators invest in real estate in Italy and possibly by forbidding emigration. His record of provincial administration is less easy to assess. In generai it was efficient, combining firmness with humanity—witness his treatment of the Christians: they remained an illegal sect, liable to punishment; but there must be no organized persecution. Yet we hear from Pliny of several senatorial proconsuls' being tried for misgovernment (possibly a sign that Trajan's lenience toward this class was abused) and of special imperial officials' correcting irresponsible local government in provincial towns (this form of paternalism was to have a paralyzing effect later). It is also possible that his wars overstrained the manpower and economic strength of the empire, particularly of the eastern provinces.

Trajan's reign saw the last major extensions by conquest of the Roman frontiers. The Dacian Wars (101/102 and 105/106) converted an aggressive mountain kingdom into a bastion of the empire. The acquisition of Arabia Petraea (105–106) was a logical consequence of Vespasian's tidying up of the Syrian frontier. It is also arguable that Trajan's main object in going to war with Parthia in 113 was to establish a workable eastern frontier all the way from the Red sea to the Caucasus. But the evidence for all these campaigns is extremely inadequate. especially for topography. It seems likely that the First Dacian War was designed merely to bring Decebalus to heel as a controlled client king; when he surrendered he was left with a diminished kingdom and with a Roman garrison in his capital, Sarmizegethusa. Apollodorus' bridge across the Danube was thus to serve the garrisons north of the river. On Decebalus' revolt in 105, Trajan drove the Dacian raiders out of Moesia and besieged and captured Sarmizegethusa; and the war ended with Decebalus' suicide and the rounding off of Dacia, including its gold mines, as a Roman province. Further east the Tropaeum Traiani at Adamklissi indicates similar effective measures against the Bastarnae and Rhoxolani, who helped Decebalus in 101/102 and had caused continual trouble for some time. Colonies, roads, camps and patrolling river fleets now linked' the whole northern frontier from the English channel to the Black sea into one economical defensive system.

The Eastern War (113–117) started when Chosroes of Parthia violated the Neronian settlement by supplanting a Roman nominee by one of his own on the throne of Armenia. Trajan's reply was unexpectedly energetic for a man of 60 years. He rapidly overran Armenia and northern Mesopotamia, which became for a while Roman provinces. Then, either lured by these successes or seeking a decisive encounter with the Parthians, he went on to capture Ctesiphon and sailed down the Tigris to the Persian gulf, where he sighed for the youth of Alexander. At this point the Parthians counterattacked and all the newly occupied territory rose behind him. Trajan was caught with his forces hopelessly deployed, but by the end of 116 he had recovered some of the lost ground, and he fully intended to resume the struggle next year. Then he fell dangerously ill. Reluctantly he started back for Rome, presumably meaning to arrange with the senate the delicate question of his successor—delicate because the "best man" seemed to be Hadrian, a relation. But he died on the journey, at Selinus in Cilicia, c. Aug 8, 117. He would never have left Hadrian in charge of the army in Syria if he had not now decided to adopt him. But the genuineness of the deathbed adoption was doubted, Hadrian wished to be free to secure his own position, and a peace was hastily made with Parthia under which all Trajan's recent conquests were abandoned.

See R. Paribeni, *Optimus Princeps*, 2 vol. (Messina, 1926–27); B. W. Henderson, *Five Roman Emperors* (London, New York, 1927). (F. A. LR.)

TRAJECTORY. In mechanics the term trajectory denotes the path described by an object which is moving under the influence of a system of forces. For example, a projectile leaving the muzzle of a gun moves through the air under the influence of two forces. namely, gravity and air resistance; the path or curve that the projectile describes in space is termed its trajectory (see BALLISTICS). Likewise in astronomy, the trajectory of a celestial body is its path in space determined by the gravitational forces. A kno ledge of the forces acting on an object makes it possible, through Newton's second law, to compute the trajectory of the object; *i.e.*, the curve described and the object's position on that curve at any given instant.

In meteorology the term is applied to the path followed by an air particle through the atmosphere. Here the motion is determined by the pressure, Coriolis and frictional forces (see METEOROLOGY).

Since the motion of the air at all levels in the atmosphere is a prime factor in determining weather change. the meteorologist attempts to determine and predict air trajectories, Direct experimental evidence on air trajectories can be obtained by tracking gas-filled balloons: set to float at a given pressure level in the atmosphere.

A broader use of the term trajectory is found in mathematics. In addition, a trajectory may be defined as (1) a curve or a surface drawn through a set of points and (2) a curve or surface which intersects a family of curves or surfaces at a constant angle. In the latter case, if the angle of intersection is a right angle, the trajectory is called an orthogonal trajectory. (J. M. AN.)

TRALEE (*Traigh-li,* "the strand or shore of the Lee"), a seaport and the county town and administrative capital of County Kerry. Ire., lies 20 mi. N.N.W. of Killarney. 64 mi. S.W. of Limerick and 74 mi. W.N.W. of Cork by road. Pop. (1961) 10,714. It is well served with road and rail conveyances to the numerous watering places along the coast. It is connected n·ith the port of Fenit, 7 mi. W., by road and rail. Large vessels discharge at Fenit where the viaduct has been reconstructed and where coal: iron and timber are imported.

The Geraldines. who came in the Norman invasion, fortified the town and founded in it a Dominican abhey in 1243, and from this event Tralee's recorded history began. The ruins of this abhey contain the remains of many of the earls of Desmond. Tralee was incorporated by James I. (C. T. K.)

TRALLES (mod. GUZEL **HISSAR**), an ancient town of Caria, Asia Minor, situated on the Eudon, a tributary of the Maeander. It was reputedly an Argive and Thracian colony, and was long under Persian rule, of which we hear in the history of Dercyllidas' raid from Ephesus in 397 B.C. Fortified and increased by the Seleucids and Pergamenians, who renamed it successively Seleucia and Antiochia, it passed to Rome in 133. Rebuilt by Andronicus II about 1280. it was superseded a few years later, after the Seljuk conquest, by a new town. founded by the amir Aidin in a lower situation. *See* AYDIN.

TRAMWAY: see ELECTRIC TRACTION.

TRANENT, a small burgh of East Lothian, Scot.. 8 mi. E. of Edinburgh by road. Pop. (1961) 6,317. The town possesses the oldest coal-mining charter (1202–18) in Great Britain, and the mines in the neighbourhood provide the staple industry, though there is a great deal of arable farming on the very fertile soil. In 1954 the New Ross high school was opened.

In the neighbouring village of Ormiston, 2 mi. S. on the Tyne Water (pop., 1951, 1,914), Robert Moffat (1795–1883), the South African missionary and father-in-law of David Livingstone, was born.

TRANG, a *changwat* in southern Thailand on the west coast of the Malay peninsula facing the Bay of Bengal. Area, 1,909 sq.mi.; pop. (1960), 240,463; including significant minorities of Chinese and Malays. Major products are tin and rubber, both developed initially by Chinese immigrants and still produced in large part by their descendants. Trang town, pop. (1960) 17,158, the provincial capital, is a crossroads of major highways and lies on the rail spur whose southern terminus is Kantang, a small port near the mouth of the Trang river 12 mi. to the south. (G. W. SK.)

TRANI, a seaport and episcopal see of Puglia. It.. on the Adriatic. in the province of Bari and 26 mi. by rail W.N.W. of that town, 23 ft. above sea level. Pop. (1957 est.) 37.501 (commune). The cathedral (dedicated to St. Nicholas the Pilgrim. a Greek who died in 1094 and was canonized by Urban II), on an open site near the sea. was consecrated, before its completion, in 1143; it is a basilica with three apses, a large crypt and a lofty tower, the latter erected in 1230–39 by the architect whose name appears on the ambo in the cathedral of Bitonto, Nicolaus Sacerdos. It has an arch under it, being supported partly on the side wall of the church and partly on a massive pillar. The arches of the Romanesque façade are ornamented; the bronze doors, executed by Barisanus of Trani in 1175, rank among the best of their period in southern Italy. The capitals of the pillars in the crypt are fine examples of the Romanesque. The interior of the cathedral has been barbarously modernized, but the crypt is fine. Near the harbour is the Gothic palace of the doges of Venice, which is now used as a seminary. S. Giacomo and S. Francesco also have Romanesque facades, and the latter and S. Andrea have domes. The fine castle was begun by Frederick II (1233) and enlarged in the 15th and 16th centuries. The Palazzo Caccetta (1458) is a fine Gothic building. Trani produces wine (Moscato di Trani). Trani is the *Turenum* of the itineraries. It first became a flourishing place under the Normans and during the crusades, but attained the acme of its prosperity as a seat of trade with the east under the Angevin princes. Its code of maritime law (the *ordinamenta maris*) is the first of medieval codes (1063).

TRANQUILIZING DRUGS are a group of drugs that are useful in the treatment of mental disease, their chief characteristic being that they have a calming effect on disturbed patients, making those patients more accessible to psychotherapy. The tranquilizers fall into at least two different groups on the basis of their pharmacologic action, and into four different chemical classes: (1) alkaloids, of which the best known is reserpine; (2) phenothiazines, with chlorpromazine the oldest and best-known representative; (3) diphenylmethanes. including benactyzine; and (4) propanediols, typified by meprobamate.

Drugs that act on the nervous system have long been known and used, as the depressants (anesthetics and sedatives) and stimulants (convulsants). Even drugs that alter mood and behaviour more subtly. as alcohol and caffeine, are hardly new. Yet the exploitation in modern psychiatry of agents that produce or relieve hallucinations or anxiety or other attributes of mental experience had an explosive effect on many aspects of life.

Psychoactive drugs—that is. drugs that affect mental life or behaviour—may be divided into two groups: (1) those that produce symptoms seen in the mentally ill, the psychosomimetics, and (2) those that relieve these symptoms, known by the not too satisfactory name of tranquilizers. A number of tranquilizing (also called ataraxic) substances are prescribed by physicians, and several times this number are being prepared and tested. Some of these drugs have been purified from nature, as the snakeroot or *Rauwolfia* alkaloids; most have been synthesized in the laboratory, as chlorpromazine and meprobamate.

The exact locus and manner of action has not been established for any of these agents. All but the meprobamatelike group act upon the autonomic (visceral) nervous system to cause changes in heart action, blood pressure, intestinal movements, skin colour, pupil size, etc., but these actions are not essential for the action on mental condition. Reserpine liberates a substance from the brain, the amine serotonin, which has a number of physiological effects on nerve and muscle cells. Chlorpromazine, which acts much like reserpine clinically, does not release serotonin, though it does decrease the action of the related epinephrine. Bromlysergic acid, which does release the amine, is hardly active pharmacologically. Both reserpine and chlorpromazine are tranquilizers, yet they render animals more sensitive to convulsions produced by strychnine or electric shock and can even initiate "convulsive" activity in certain deep portions of the brain.

Tranquilizers, in addition to their differences in mechanism, also act differently on mood and behaviour. Reserpine and chlorpromazine render monkeys "tranquil" to handling, inactive and unresponsive to a signal of an impending shock; meprobamate does not eliminate the conditioned responses or decrease their activity but has some taming action. In man, also, chlorpromazine and reserpine quiet disturbed psychotic patients. while meprobamate has little effect; conversely, meprobamate seems more effective in relaxing neurotic tension. anxiety and muscle spasm.

Although the effective tranquilizers give relief from certain psychotic and neurotic symptoms. there is no evidence that they produce cures, and there is reason to suspect that chronic use may lead to occasional addiction. toxicity or other untoward effects. Changing disturbed mental patients to undisturbed ones, however, has made psychiatric wards more peaceful, and the use of these drugs seems to be related to a decrease in hospital population. The wide and sometimes indiscriminate use of certain tranquilizers to relieve strain and worry by persons who are not mental patients is even harder to evaluate. The effective therapeutic action and the price that must be paid in terms of dulling of drive or attention remain to be established. *See* also NEUROPHARMACOLOGY AND PSYCHOPHARMACOLOGY; PSYCHIATRY. (*R.W.* G.)

TRANSCAUCASIA. From March 12, 1922, until Dec. 5, 1936, the republics of Armenia, Georgia and Azerbaijan were combined to form the Transcaucasian Soviet Federated Socialist Republic, which on Dec. 30, 1922, became a constituent part of the Union of Soviet Socialist Republics. With the adoption of the so-called Stalin constitution, the republic was dissolved. For the geography of this region *see* CAUCASUS; for history, *see* ARMENIA, AZERBAIJAN and GEORGIA.

TRANSCENDENTALISM. "Transcendentalism" is an expression originally used to designate the philosophy of Immanuel Kant (*q.v.*), who spoke of his *Critique of Pure Reason* as laying down the plan for a complete "transcendental philosophy"; its use was later extended, perhaps because of the title of F. W. J. von Schelling's *System of Transcendental Idealism* (1800) and the influence of S. T. Coleridge, to cover the thought of the German idealists generally. In the United States the term was at one time predominantly understood as referring to the tenets of the members of the Transcendental club, founded in Boston in 1836. These "Transcendentalists," among whom *R.* W. Emerson (*q.v.*) is much the best-known, professed a form of romantic idealism whose main driving force was an antipathy to the philosophical outlook of the Enlightenment. They constitute the American equivalent of Coleridge and of Thomas Carlyle, both of whom had some influence on them.

Kant gave a special meaning of his own to the term "transcendental," but he did not coin the word. Medieval philosophers grouped together under the title *transcendentia* or *transcendentalia* those concepts, such as "being," "unity" and "goodness," which cut across the Aristotelian division of categories, in the sense of not being predicable under any single category; Aristotle himself (cf. *Metaphysics* Γ, 2; *Nicomachean Ethics,* i, *6)* had recognized their special characteristics without giving them a special name. The doctrine of transcendentals is already present in Albertus Magnus, author of the dictum *quodlibet ens est unum, verum, bonum,* and in St. Thomas Aquinas; but it was left to Duns Scotus to work it out in detail. Besides being (the most general of all concepts), Duns in his *Opus Oxoniense,* book i, distinction 8, question 3, recognizes two important classes of transcendental attributes: those, such as "one," "true," "good," which are simple, coextensive with being *(passiones convertibiles)*; and those, such as "contingent" and "necessary," "actual" and "potential," which are disjunctive *(disjunctae)*. *(See* A. B. Wolter, *The Transcendentals and their Function in the Metaphysics* of *Duns Scotus,* Washington, 1946.)

Although Kant mentions the "transcendental philosophy of the ancients" in one passage in the *Critique of Pure Reason* (2nd ed., p. 113, 1787), his own understanding of the term seems, on the surface at least, to have little to do with the doctrines just mentioned. Transcendental philosophy, for him, comprises first an inquiry into the nature and extent of the a *priori* elements in knowledge and second a complete enumeration of those elements, together with analyses of the concepts involved and a full review of what can be deduced from them *(ibid.,* p. 27). Behind this program, which Kant did not claim to be carrying out in full but for whose execution he thought his own work provided a firm foundation, lay Kant's own special philosophical conceptions. The first task of philosophy, in Kant's view, was to conduct a critique or critical examination of the powers of speculative reason. The extent of these powers had, he believed, been much exaggerated by earlier philosophers when they claimed to be able to arrive on the basis of pure reason at conclusions about the fundamental nature of things. Metaphysicians had thought it possible to begin from premises which were alleged to be self-evident and from them to deduce what looked like important truths of fact (*e.g.,* that God exists and that the human soul is immortal); and though no one of these "proofs" had escaped criticism, attempts to construct them continued. It was Kant's aim at once to explain these metaphysical pretensions and to show them to be baseless. To explain why they were made we must take account of what for Kant was a fact, namely that pure reason has some knowledge of its own, or, in his own language, that there are some valid synthetic *a priori* judgments. But an examination of the logical status of these judgments and of the conditions under which they were possible showed that their existence afforded no real encouragement to metaphysicians. for they turned out to be not so much material truths as propositions concerning the form of experience. Their function was to express the necessary conditions of experience as such. and they were accordingly empty in themselves, gaining significance only when brought to bear on concrete data. Thus the principle that every event has a cause. to take Kant's best-known example of a synthetic *a priori* truth, may be treated as an injunction to seek causal connections throughout experience; in this sense it may be said to prescribe the form of possible experience. But it is an empty truth except when used in conjunction with empirical data; in advance of experience we can say on the strength of it only that an event will have some cause or other, not what its cause must be. It follow-ed that the kind of use of the causal principle which metaphysicians had attempted to make (*e.g.,* in the "First Cause" argument for God's existence) was illegitimate, since in passing beyond the bounds of the experienceable they automatically deprived themselves of the data without which pure concepts of the understanding were so much idle machinery.

This general sketch should serve to throw light on Kant's peculiar definition of "transcendental" and his distinction between "transcendental" and "transcendent." "I entitle *transcendental,"* he writes, "all knowledge which is occupied not so much with objects as with the mode of our knowledge of ohjects'in so far as this mode of knowledge is to be possible *a priori" (op. cit.,* p. 25). The term "transcendental." that is to say, is in place only when epistemological questions are being asked, and then only when the hypothesis that some of our knowledge is *a priori* is being considered. Thus the "Transcendental Aesthetic," the first main division of the *Critique,* is an examination of whether there are any *a priori* elements in human sensibility and an attempt to establish that the ideas of space and time answer this description; while the celebrated "Transcendental Deduction of the Categories," which constitutes the centre of Kant's whole argument, seeks to show both that there are concepts of this nature *(a priori* concepts) and what their role in knowledge is. Similarly the "transcendental idealism" to which Kant commits himself gets its name from his belief that what we know is conditioned by factors in our cognitive apparatus. To have drawn attention to these factors was, in Kant's own view, among his main philosophical achievements. But he was equally insistent that to show that a concept or principle functions *transcendentally* will not justify our making a *transcendent* use of it. We attempt such a use when we seek to apply an *a priori* concept such as cause or substance, not to the ordinary objects of experience, which Kant called "appearances," but to "things in themselves," which by definition lie beyond the sphere of experience. It was characteristic of philosophical dogmatism, Kant thought, to make such attempts; why he believed they must fail has already been indicated.

In later philosophical terminology, Kant's principal merit in this part of his work may be said to be his having initiated an inquiry into the precise status and nature of principles which function as ultimate presuppositions. He saw that a dictum such as "every event has a cause" neither expresses a truth of reason in the Leibnizian sense (since it is not analytically true), nor yet is a simple truth of fact, as empiricists had supposed; and he realized that the establishing of presuppositions of this kind constitutes a special problem, since neither deduction from the self-evident nor induction from experience can form their basis. His appeal to the argument "from the possibility of experience." sometimes known as "transcendental proof," was his own way of solving this problem. But the careful limitations that he sought to place on the powers of pure reason had little appeal to his immediate successors. The "transcendental idealism" of Schelling is entirely different from the "transcendental idealism" of Kant, in so far as it seeks to establish truths about the reality which lies behind the phenomena of nature and mind; *i.e.,* just such a thesis as Kant had argued to be inadmissible. It was because of its use by Schelling and others like him that "transcendentalism" acquired the pejorative overtones which it retains in many philosophical circles.

(W. H. W.)

TRANSCRIPTION, in music, is the arrangement of a composition written for one instrument (or group of instruments) for performance by one of another kind. as of an organ work for the piano, of an orchestral work for the organ and so on.

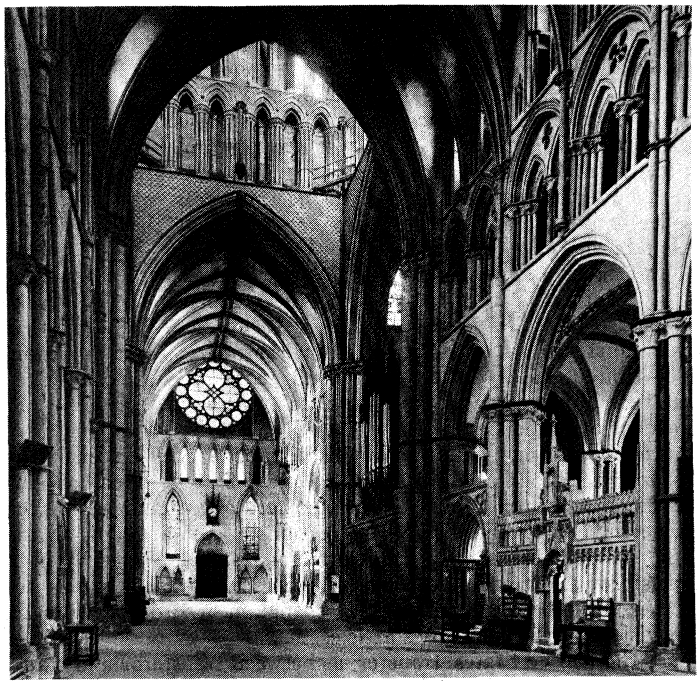
TRANSEPT, in architecture, is a transverse section or portion of a hall or building, of considerable relative size. whose main dimension is at right angles to the long dimension of the building proper. thus developing a plan of either cruciform or T shape. In ecclesiastical architecture, it is the arms of the church, at right angles to the nave.· At least two early Christian basilicas in Rome, St. Peter's and St. Paul's, were from the beginning provided'with transepts, each taking the shape of a long, unbroken transverse hall whose length was equal to or extended beyond the combined width of nave and aisles and was separated from the nave by a great arch known as the triumphal arch. In the opposite wall an arch of similar size led into the apse.

The transept, however, constitutes no essential part of the architecture of the basilica (*q.v.*); it never occurred in the civil basilicas of ancient Rome. Though hardly a Christian invention, its origin and original purpose remain conjectural. Conceived as an extension of the sanctuary proper, rather than of the nave and aisles where the congregation assembled, the transept may have been adopted in order to accommodate a large number of clergy or in order to provide space for the tables on which the faithful deposited their offerings. A more plausible interpretation is suggested by the early use and conspicuous development of transepts in the ecclesiastical architecture of the Christian east.

In Palestine, Asia Minor, Egypt and Greece the transept was either combined with basilical structures or incorporated in churches of central plan, forming two arms of an equilateral cross. Invariably these eastern transept churches were dedicated to a martyr who was buried there (St. John's, Ephesus; the Menas basilica in Egypt; St. Demetrius' at Salonika) or to the memory of a sacred event believed to have occurred at the place where the sanctuary was built (Church of the Multiplication of Loaves, Palestine). The transept facilitated the circulation of large numbers of pilgrims past or around the place of worship. The connection of the transept with the cult of the Christian dead is all the more noteworthy because of antecedents of transept architecture that occur in funerary structures of Greek and Roman antiquity.

Eastern influences or the cult of relics may account for the reintroductioq of the transeptal basilica in the west during and since the 8th century (St. Praxedis at Rome; St. Denis, near Paris; abbey at Centula [St. Riquier]). The great development of the transept began in the 11th century. Among the great basilical churches of the Romanesque period there is hardly one without a transept. Liturgical requirements of the Benedictine order and the increasing number of clergy that had to officiate in monastic and cathedral churches account for this development. In the churches of the congregations of Cluny and Citeaux additional altars were placed along the eastern walls of the transepts or in chapels opening out of these walls. In the abbey of Cluny (begun 1089) there even were two transepts in the eastern part of the basilica.

German Romanesque basilicas, which were often provided with t o apses, one at each end of the nave, occasionally also have two transepts inserted between nave and apses, as in St. Michael's at Hildesheim. In this church each transept arm terminated in two superimposed galleries dedicated to the cult of the angels. Romanesque transepts tend to be large and are frequently designed like the naves, with triforia, clerestories and even side aisles. In several churches (St. Maria im Kapitol, Cologne; St. Lucien at Beauvais) transept arms ended hemispherically like the main apse and thus described a trefoil ground plan. This pattern, derived from Christian antiquity (6th-century additions to the Nativity basilica at Bethlehem), was adopted once more in the early Gothic cathedrals of Tournai, Noyon and Soissons. (See ROMANESQUE ARCHITECTURE.)



A F. KERSTING

NORTH TRANSEPT OF LINCOLN CATHEDRAL. ENGLAND

The transept loses its importance in Frehch Gothic architecture, which provided space for subsidiary altars in chapels radiating from the ambulatory. In the cathedrals of Paris and Bourges the transept does not project at all beyond the outer walls of the church; in Chartres, Reims and Amiens it extends beyond the nave but merges with the contour of ambulatory and chapels.

In England, where even the cathedral clergy often lived under the Benedictine rule, large churches continued to be provided, even in Gothic times, with large transepts, often with two of them. In Durham the Nine Altars transept was added in the 13th century. These English transepts tend to be large, the west transept of Lincoln (c. 1200) being almost 225 ft. long, the transepts of York (c. 1216–56) about 220 ft. and .those of Lichfield (1220–40) about 145 ft. The most beautiful of all are the double transepts of Salisbury (begun 1220). (See GOTHIC ARCHITECTURE.)

In Renaissance architecture and baroque architecture (*qq.v.*), transepts, often with hemispherical endings, continue to be frequent. Bramante planned St. Peter's at Rome as an equilateral cross. each arm of which was to be apse ended. In modern church architecture the transept seems to be less common.

In the U.S., transept cathedrals have for the most part followed European precedents. The Cathedral of St. John the Divine in New York city was designed in the Gothic style. with a transept 320 ft. long; the Cathedral of St. Peter and St. Paul in Washington, D.C., with a transept 135 ft. long, was patterned after English Gothic cathedrals.

Attempts to interpret cruciform churches symbolically and to see in the arms of the transept the arms of the cross or crucifix appeared at an early date and continued through the middle ages and even the Renaissance. Such interpretations, however, do not indicate the source of transeptal architecture but rather were inspired by it.

(O V. S.; X.)

TRANSFER, in law, means the extinguishing of an interest in an object of property in one person and the creation of such interest in another person. For the form or method by which a transfer of land is effectedsee LAWS OF REAL PROPERTY AND CONVEYANCING; for personal property generally see PERSONAL PROPERTY.

This article describes the procedure for transfer of securities that are called in the U S stocks and bonds and for which the corresponding terms in England are shares and stocks or debentures. Stocks (U.S.) or shares (Eng.) define the extent of an investor's holding in the capital of a company or corporation. Bonds (U.S.) and stocks or debentures (Eng.) represent the investor's holdings or participation in a loan to a company, municipality or government (see STOCK). In the transfer of these securities three persons are concerned: the transferee, who may be a buyer or recipient of a gift; the transferor, who may be a seller or donor; and the company or other body that has issued the security.

In English and commonwealth law shares are regarded as essentially contractual relations between the company and the stockholder so that the power to transfer, if any, and the form that the transfer must take are based on the articles of association. The United States, on the other hand, tends to look upon shares of stock as property so that power to transfer is regarded as an incident of property.

An outward manifestation of this difference may be seen in the form of the stock certificate in the United States, which contains on its back a form for endorsing transfers or assignments by the owner named on the face of the certificate. In England, on the other hand, there is a separate form for transfer, signed by both transferor and transferee, which is then sent to the company together with the old certificate for change in accordance with the provisions of the company's articles.

In the United States, transfer, as between transferor and transferee, is effected by delivery to the transferee of the stock certificate properly endorsed or assigned on the back. If the endorsement or assignment omits the name of any transferee, any person possessing the certificate, even wrongfully, may claim it as his own and further transfer it to innocent persons. The Uniform Stock Transfer act in force in most states tends to make a stock certificate a negotiable instrument.

As betneen owner of the stock and the company, however, transfer is not complete by delivery of the certificate from transferor to transferee but only on change of registration on the books of the company, usually kept by a professional transfer agent or registrar. In England the transfer agent is entitled to treat the registered owner as absolute owner and has no duty to inquire as to his power to transfer. In the United States transfer agents have considerable responsibilities to see that wrongful transfers do not occur. It is for this reason that they refuse to register stocks in the name of children and, more importantly, require that the signature of the owner endorsing a transfer be guaranteed by a bank or person known to the transfer agent. If the stock is owned by an executor or trustee even more onerous duties are imposed on transfer agents. To avoid these complications many trustees and large traders keep their securities registered in the names of nominees, that is, individuals whose names and signatures are on file with the transfer agent.

Bonds or debentures are usually negotiable securities that may be issued in registered form (*e.g.*, U.S. savings bonds) or bearer form. Where transfer is permitted, as it usually is, it too is effected by delivery or delivery and endorsement.

In England and some states of-the U.S. there is a tax imposed on the transfer of securities based on the market or sometimes par value of the security. (A. DM.)

TRANSFORMATION GROUPS: see GROUPS.

TRANSFORMER, an electric device for stepping up or stepping down voltage, depending on which is desired. Transformers are employed for widely varied purposes; *e.g.*, to operate toy electric trains, increase the effectiveness of telephone transmitters and transmit electric power at high voltages for long distances. Transformers change voltage through electromagnetic induction and without any continuously moving parts. As they change voltage transformers also change current, although the frequency of the current is unchanged. In a step-up transformer the voltage delivered is greater than the voltage received and the current is less. In a step-down transformer the voltage delivered is less than the voltage received and the current is greater.

General Principles of Operation.—In the simple transformer shown in fig. 1 two windings of insulated wire surround the central portion of a magnetic core that consists of thin sections, or laminations, of steel stacked side by side. A lamination thickness of .014 in. is common for transformers that operate at 60 cycles (cy.) per second. The core represented may consist of E- and I-shaped laminations stamped from steel sheets having the desired thickness and magnetic properties. The sheets are usually given a heat treatment known as annealing to improve their magnetic properties. An oxide that forms on the lamination surfaces during the annealing process is a poor electrical conductor and provides some insulation between adjacent laminations. If more insulation is necessary the laminations may be dipped in an enamel that yields a hard finish when baked.

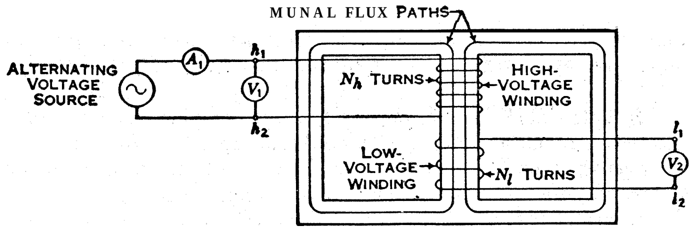

FIG. 1.—WINDINGS AND CONNECTIONS OF A SIMPLE TRANSFORMER

In fig. 1 an alternating voltage source is connected between the terminals h_1 and h_2 of a high-voltage winding having N_h turns. This causes the winding to become a primary. A voltmeter V_1 connected between h_1 and h_2 registers the effective voltage. A graphical representation of the time variations of the voltage is the voltage wave form. With what is known as a sine wave form the maximum instantaneous voltage is 1.41 times as great as the reading on V_1.

The application of voltage to the high-voltage winding establishes an alternating current. The current in the N_h turns causes an alternating magnetomotive force that in turn establishes alternating magnetic flux in the core. In fig. 1 two flux paths are represented. Since the flux passes through both windings, it is common to them and is called the mutual flux. Usually either air, an insulating vapour or oil surround the windings and the core. These materials are poor magnetic conductors compared with the core and so most, but not all, of the flux is confined to the core. For the present, assume that all the flux is in the core. The alternating flux induces an electromotive force of self-induction in the high-voltage winding nearly equal at every instant to the voltage applied to the winding. This electromotive force acts as a throttle or choke and causes the current to be much less than if the winding had resistance only and no self-inductance. The current drawn is called the exciting current. Its effective value is registered on the ammeter A_1 in fig. *1.* The value of the exciting current drawn by a winding with a given number of turns when operated at a given voltage and frequency depends upon the cross section of the core normal to the flux and the magnetic properties of the steel. Because of surface irregularities the contact of an E lamination with an I lamination is never complete. As a result the exciting current is greater than it would have been with no separation between laminations.

With a sine wave form of voltage the voltage equation of a transformer is

$$V = 4.44 N f B_m A \times 10^{-8}$$

where V root-mean-square (effective) volts (v.) are applied to the N turns of a winding, f cy. per second is the frequency, B_m lines, or maxwells, per square inch is the maximum instantaneous flux density in the core of A sq. in. cross section. For transformer steel a typical value for B_m is 70,000, a value that may be used in the above equation to design a winding for use at a given voltage and frequency on a given core.

In fig. 1 the mutual flux set up by the exciting current in the high-voltage winding induces an electromotive force of mutual induction in the low-voltage winding. Assuming that all the flux is confined to the core, the voltage induced in each turn of the low-voltage winding is equal to that in each turn of the high-voltage winding. As a result the voltage across the high-voltage winding as registered on voltmeter V_1 is to the voltage across the low-voltage winding as registered on voltmeter V_2 as the number of turns N, is to the number of turns N_l. The transformer is operating to step down the voltage since N_l is less than N_h.

If a load such as a lamp is connected between terminals l_1 and l_2 in fig. 1, an alternating current flows in it. One action of this current is to reduce the amount of mutual flux. This action in turn causes a proportional reduction in the electromotive force induced in the high-voltage winding and permits more current to flow in that winding A component of current appears in the high-voltage winding that is equal to the current in the low-voltage winding divided by the inverse ratio of turns. That is, if a transformer has $N_h = 1{,}000$ and $N_l = 100$, the ratio of turns is $1{,}000 \div 100 = 10$. If the low-voltage winding is delivering 20 amp., a component of $20 \div 10 = 2$ amp. appears in the high-voltage ninding. In general, the reading on the ammeter A_1 would not increase exactly two amperes since the two-ampere component would add vectorially and not numerically to the current that existed in the high-voltage winding with no current drawn from the low-voltage winding.

The flow of current through the winding resistances causes a heat loss that raises the winding temperature. The rated. or full-load, current of a ninding is the value which, when carried continuously, causes the specified temperature rise. The design of 60-cycle transformers is such that the exciting current is likely to be 5% of the rated current.

If the rated current of the low-voltage winding of a 10-to-1 ratio step-down transformer is 20 amp. then, when the low-voltage winding is delivering 20 amp., a component of 2 amp. is required in the high-voltage winding. If the load were disconnected from the low-voltage winding the current in the high-voltage winding would drop to the exciting value, or about 5% of 2 amp., which is .1 amp. The vectorial addition of 2-amp. and .1-amp. components could not be more than 2.1 amp. and would have that value only nhen the nature of the load is such that the components are in time phase. Usually the resultant current is just over 2 amp. Hence when the windings are carrying their rated currents the ratio of the currents is very nearly equal to the inverse ratio of turns. The cross section of the wire required in the high-voltage winding would be about one-tenth that in the low-voltage winding. The volume of copper in the high-voltage winding is roughly equal to that in the low-voltage winding, since the winding with the greater number of turns has the wire of smaller cross section.

Assume that 1,000 v. at rated frequency are applied to the high-voltage winding of a transformer that has a turn ratio of 10 to 1. With no load connected to the low-voltage winding the voltage across it is 100 v. Further assume that the exciting current is .1 amp. Now assume that when enough lamps are connected across the low-voltage winding to cause it to deliver its rated current of 20 amp., the current in the high-voltage winding increases to 2.01 amp. The voltage delivered will decrease. usually by a small percentage. Assume that the decrease here is from 100 to 98 v.

Part of the decrease occurs because of resistance in the windings. The remainder occurs because of what are called the leakage reactances of the windings. Flux that links one winding and not the other is called the leakage flux of the winding that it links. The voltage induced in a winding by its leakage flux divided by the minding current is the leakage reactance of the winding. The leakage reactances depend upon the distance between the windings. With a core such as in fig. 1 it is common to have one minding completely surround the centre portion and the second winding surround the first.

The capacity of a transformer is specified in volt-amperes (va.) or kilovolt-amperes (kva.). If a winding is rated at 100 v. and 20 amp., the transformer capacity is 100 v. $\times$ 20 amp. = 2.000 va. or 2 kva. In the example considered above the transformer was delivering 98 v. $\times$ 20 amp. = 1,960 va. with an input of 1,000 v. $\times$ 2.01 amp. = 2.010 va. Hence the volt-ampere input and output are nearly equal.

The steel in a transformer core is an electric as well as a magnetic conductor. The alternating flux induces electromotive forces in the steel. These produce eddy currents in the steel, which in turn produce heat, known as the eddy current loss. For frequencies up to a few thousand cycles per second the eddy current loss can be kept to a value that can be tolerated by building the core of laminations rather than using a core of solid steel. Just how thin the lamination should be for a given frequency is determined by economic considerations. As laminations are made thinner the eddy current loss is reduced, but the cost of making and handling a greater number of laminations is increased. The thickness of the insulation needed is the same on thin as on thick laminations. As a result, with extremely thin laminations the insulation occupies an objectionably large percentage of the gross cross section of a core.

Hysteresis (*q.v.*) loss also takes place in the steel of a transformer core, occurring when the steel is carried through magnetic cycles represented by the alternating flux. This loss is not reduced by laminating the core. The hysteresis loss at a given frequency and flux density can be reduced only by improving the magnetic properties of the steel.

The sum of the eddy current loss and the hysteresis loss is called the iron or core loss.

Another loss occurs in the solid material that insulates the windings from each other and from the core. The alternating electric field in the solid material causes what is known as a dielectric loss.

Performance Characteristics. — The core loss and dielectric loss of a given transformer depend upon the voltage and frequency. For power circuit transformers that operate at nearly constant voltage and frequency, these losses are nearly constant regardless of the value of current being delivered. The loss in the windings, known as the copper loss, varies in proportion to the square of the current. When no current is being delivered there is no loss in the secondary winding but there is a loss in the primary winding caused by the exciting current there. This loss is usually insignificant compared with the core loss and the dielectric loss. Hence, when rated voltage at rated frequency is applied to one minding and the other winding is open-circuited, the power input to the transformer is considered equal to the core loss plus the dielectric loss. The combination of the core loss and the dielectric loss in kilowatts in commercial 60-cycle transformers is likely to be from .25% to 1% of the kva. rating of the transformer.

The resistances of the windings of a transformer can be measured with direct current when no alternating voltage is being applied. Then in normal operation the copper loss in a winding is equal approximately to the resistance times the square of the alternating current. The losses in both windings are added to obtain the total copper loss. Actually, because of what is called skin effect, the resistance of a winding for an alternating current is greater than that for a direct current having an equal effective value. The copper loss in kilowatts with rated current in each winding of a commercial 60-cycle transformer is likely to be from .5% to 3% of the transformer kva. rating.

The losses in a transformer depend only upon the voltages across and the currents in the windings. The power output of a transformer depends not only upon the voltage output and the current output but also upon the load power factor, which may range from zero to one. If a transformer is delivering rated current at rated voltage to a load whose power factor is one, its efficiency is likely to be from 96% to 99%.

The losses in a transformer appear as heat which should be removed as rapidly as it is produced after the winding temperature has reached the highest permissible value. Dry-type transformers are cooled by the natural movement of air or by air blown by fans through ducts near the windings. Transformers that are insulated by oil or a synthetic liquid may be water-cooled, in which case cool water is circulated in sealed tubes immersed in the liquid, or they may be cooled by pumping the hot liquid out of the transformer case into radiators where it is cooled and then returned to the case.

With rated voltage at rated frequency maintained across the primary winding. the change in voltage across the secondary winding that occurs as the output current is changed from rated value to zero is a measure of what is called the voltage regulation of the transformer. If 120 v. are delivered with rated current and 123 v. when no current is delivered, the voltage change is 3 v. The voltage regulation is the percentage change in terms of the voltage at rated current, or $(3 \div 120) \times 100 = 2.5\%$. The voltage regulation of a given transformer depends upon the load power factor. Usually, load power factors are such that the output voltage increases when the load is removed. However, with a load of leading power factor it may be that the voltage will decrease or perhaps not change.

Power transformers with ratings as large as 360.000 kva, have been built. Large transformers are often constructed as three-phase units in which the magnetic and electric circuits of three phases are combined. For a given kva. rating the weight and volume of a three-phase transformer are less than would be the combined total for three single-phase transformers each having one-third that kva. rating. A three-phase transformer is shown in fig. 2. Here the three high-voltage bushings through which the currents flow to and from the transformer windings are prominent in the upper centre portion of the figure. On each side of the transformer may be seen a radiator through which cooling oil circulates.

FIG. 2.— THREE-PHASE TRANSFORMER RATED 25,000 KVA. AT 132,000 TO 34,500 V. AND 60 CY.

In a communication circuit a transformer may be used for what is called impedance transformation. Assume that a 1.000-ohm resistor, a transformer having 200 turns in one winding and 100 turns in the other, and a source of 10 v. at 1,000 cy. per second are available. If the 100-turn winding is connected to the source and the resistor connected across the 200-turn winding, there will be approximately 20 v. across the resistor. The resistor will draw 20 v. $\div$ 1,000 ohms = .02 amp. The transformer will be delivering 20 v. $\times$ .02 amp. = .4 va. Since the input volt-amperes to the transformer will equal approximately the output, the transformer will draw .4 va. $\div$ 10 v. = .04 amp. from the source, a value equal to that which would be drann by a resistor of 10 v. $\div$ .04 amp = 250 ohms connected directly to the source. Hence the combination of the 1.000-ohm resistor and the transformer is equivalent to a 250-ohm resistor.

By a similar analysis it can be shown that if the 200-turn winding were connected to the source and the resistor were connected across the 100-turn minding, the volt-amperes drawn from the source would be equal to that drawn by a 4,000-ohm resistor connected directly.

Audio transformers, intended for use in circuits in which the frequencies are in the audible range, have a core of steel or other magnetic material. Very thin laminations or powdered materials are sometimes required to limit the eddy current loss to a tolerable value.

Radio-frequency transformers for use in circuits in which the frequencies are above the audible range consist of coils supported near each other by insulating material. If metallic cores were used the eddy current loss in them would be objectionably great.

Transformers may have the same number of turns in each winding. These are used to isolate electrically one circuit from another. Some transformers have two or more coils on either or both sides. The coils may be connected in series for operation at one voltage or in parallel for another.

History of **the** Transformer.— The principles of electromagnetic induction were discovered in 1831 at the Royal Institution in London by Michael Faraday (*q.v.*), an English chemist and physicist. Utilizing these principles various experimenters built induction coils consisting of two coils of wire close to but insulated from each other. When a battery is connected to one coil the current in that coil soon attains a value fixed by the coil resistance. Then if the circuit is interrupted the sudden decrease in current induces an electromotive force of self-induction in that coil and one of mutual induction in the other. By using more turns in the second coil than in the first, the momentary surge of electromotive force in the second coil can be made to be much greater than the battery electromotive force.

An early demonstration of the use of an induction coil to step donn voltage and increase current was made by Elihu Thomson (*q.v.*) at a Franklin institute lecture in 1879. He used two pairs of induction coils with their primary nindings in parallel. The secondary windings in parallel supplied current to a small arc lamp. Apparently this was the first recorded case in which induction coil windings were used in parallel. These coils had a closed magnetic circuit of steel instead of the more common one containing a large proportion of air.

In 1883 Lucien Gaulard, a Frenchman, and John Dixon Gibbs, an Englishman, developed an induction coil system using primary windings in series. In 1885 George Westinghouse secured options on the Gaulard and Gibbs system patents and in 1886 purchased the patent rights for use in the United States. William Stanley, a young inventor employed by Westinghouse, was assigned the project of improving the transformer and developing the alternating current system for distributing electrical energy. Stanley discarded the Gaulard and Gibbs plan of operating primary windings in series and connected them in parallel to a constant voltage supply. He was convinced that it was permissible to connect a coil of only a few ohms resistance across several thousand volts if a good magnetic circuit was provided so that only a small current was required to produce a self-induced electromotive force equal to the applied voltage.

In the Gaulard and Gibbs transformer the core was composed of iron wires. Sometimes these were straight and did not form a complete ring. Stanley made some cores with the iron wires formed into a ring and others with continuous and laminated cores. At first iron plates about $\frac{1}{8}$ in. thick were tried. Later the iron plates then used by photographers were found to be even better. The plates were separated by thin sheets of paper. One improved method of construction suggested by Westinghouse was to wind the coils about the middle section of a stack of H-shaped punchings. Then the magnetic circuit was closed by placing two stacks of I-shaped punchings across the open ends of the H stack.

In 1885 Stanley established a laboratory in Great Barrington, Mass., and by March 1886 had in operation a system that supplied current directly from a 500-v. generator to customers 4.000 ft. distant. Transformers stepped down the voltage to 100 v. for lighting at the customers' premises.

The first plant for distributing alternating current energy in the United States was built by Westinghouse in Buffalo, N.Y.. and put in operation on Nov. 30. 1886. It was supplied from 133-cycle, 1,000-v. generators. *See* ELECTRICITY: *Transformers and Alternating Currents;* ELECTRIC POWER; *see* also references under "Transformer" in the Index volume.

TRANSISTOR, a device able to amplify electrical signals by the action of electronic charge carriers within a semiconducting crystalline solid. Since transistors can be made very small, long-lived and efficient, they are finding extensive use in electronic systems for such purposes as communication, automatic control and high-speed computation.

One form of transistor (the point-contact type) was invented by John Bardeen and Walter Brattain in the course of a research program at the Bell Telephone laboratories, Murray Hill, N.J., initiated after radar experience in World War II showed a need for better understanding of semiconductor devices. The program was directed by William Shockley, who as theorist, device analyst and inventor made outstanding contributions to the field of semiconductor electronics. In the first five years after its announcement in 1948, the transistor was shown to be useful for many communications functions in radio and television receivers, sound and high-frequency amplifiers, electronic computers, control systems, etc. It is a device comparable in flexibility with the thermionic electron tube. Its range of application supplements that of tubes by making feasible operation of electronic equipment in smaller sizes, consuming less power and with improved reliability, especially under conditions of high vibration or shock.

FIG. 1.—P-N JUNCTION DIODE

DEVICE STRUCTURE AND BEHAVIOUR; CHARGE CARRIERS

In describing how amplification takes place by means of these devices, it is useful first to explain that for both tubes and transistors it is essential to generate and control a stream of electric charge carriers. Under suitable conditions, it is then possible to derive from the stream a greater amount of power than was expended in controlling it. As a result, weak control signals can be amplified through successive stages to produce useful output.

The basic stream of charge carriers may be produced in a variety of ways. In a typical vacuum tube, a stream of electrons released from a source (cathode) is controlled by a small input signal applied betneen cathode and control grid. These controlled electrons are then accelerated and collected by a positively charged electrode (anode). The energy gained from the anode appears as a larger power facsimile of the input signal in the output load.

Transistors, on the other hand, achieve their amplification functions by controlling the flow of electrons within specially treated solid materials called semiconductors. In a typical transistor, described below, the charge carriers are released from a source (emitter) and controlled by a signal between the emitter and a control electrode (base). The controlled stream is then accelerated and collected by a relatively high-potential electrode (collector), and, again, the energy gained from the collector appears as an amplified replica of the input signal in the output load.

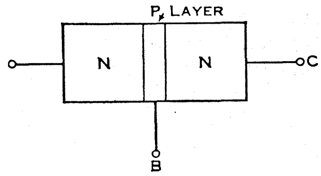
FIG. 2.—P-N-P JUNCTION TRIODE

Operation of usual transistors depends on the fact that semiconductors, such as germanium or silicon, can conduct electricity by the motion of either or both of two kinds of charge carriers. One kind. which carries a negative charge, is called a "conduction electron"; it is an electron of such an energy that it can wander through the crystal with relative freedom. The other kind, which carries a positive charge, is called a "hole," because it is actually a deficiency of one electron in the valence bond structure of the crystal. Under proper conditions, this deficiency may be filled from another valence bond by an electron which. in doing so, leaves another deficiency behind; thus in effect the hole moves through the crystal, carrying a positive charge. By incorporating in the crystal appropriate chemical impurities or other deviations from lattice perfection, either type of charge carrier can be caused to predominate, with the other type being in the minority. Thus, according to whether the negative or positive carriers are in the majority. a specimen of semiconductor is classified as N type or P type.

Most transistors are constructed by juxtaposing regions of different conductivity types within a single crystal of semiconductor, so as to produce the useful controlled current of charge carriers. The following broad descriptions of some of the principal structures is based on Shockley's classic paper on P-N junction published in 1949 (see Bibliography).

P-N Junction Diode.—This simple semiconductor structure is of interest not only because it is a useful device in itself but also because it can be regarded as a building block with which to construct other semiconductor devices. When suitable regions of P- and N-type conductivity adjoin in the same semiconductor, as in fig. 1, the magnitude of current flow depends markedly on the direction of the potential applied. For example, if the P region is made positive, then some of the positive charges (holes) it contains are impelled across the P-N boundary into the negatively polarized N region. Concurrently, some negatively charged conduction electrons from the N region are attracted across the boundary into the P region. In general, both flows of holes and of electrons may contribute appreciably to the electric current which flows in this direction of applied potential, called "forward bias." On the other hand, if the applied potential is reversed, then both types of majority carriers—both holes in the P side and electrons in the N side—are repelled from the boundary. Only the minority carriers, both electrons in the P side and holes in the N side, are attracted across the boundary; since normally these minority carriers are very small in number, the junction draws comparatively little current under reverse bias conditions.



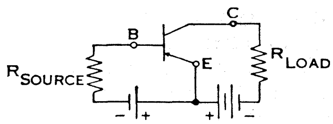
BY COURTESY OF BELL TELEPHONE LABORATORIES

FIG. 3.—N-P-N JUNCTION TRIODE

Because of these properties, the P-N iunction diode is widely used as a rectifier; *i.e.,* a device which permits current to flow essentially in one direction only when alternating voltage' is applied. In connection with ordinary radio receivers, for example, rectification is used in developing direct power supply voltage from the alternating current supply mains. Other rectifiers (detectors) recover the sound signal from an amplitude-modulated radio broadcast wave, while still others (mixers) are used to shift the frequency of the radio wave to a value desired for amplification purposes.

The P-N junction is also an important feature of the action of many transistors in that the junction can act as a source or as a collector of charge carriers. Under forward bias, the current which flows consists of the injection or emission of minority carriers, both holes into the N region and electrons into the P region. The concentration of minority carriers can thus be greatly increased over what is normally present in the material. Moreover, if the semiconductor is a nearly perfect single crystal, the injected minority carriers may remain above the normal concentration an appreciable length of time; lifetimes of 100 microseconds or more are commonly used in transistor material. However, if too long a time elapses, the minority carriers will each "recombine" with a majority carrier, thus tending to reduce the minority carrier concentration toward its equilibrium value.

Similarly, the P-N junction under reverse bias acts as a collector of minority carriers, since any which may arrive at the junction are attracted across it. Under normal diode conditions this reverse current of collected minority carriers is low, reflecting the low equilibrium concentration of such carriers. However, if the minority carrier concentration is increased through the action of a nearby emitter, the collector current correspondingly increases.

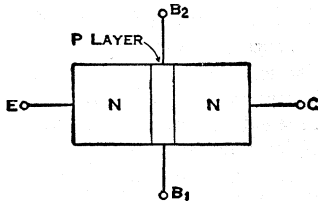


BY COURTESY OF BELL TELEPHONE LABORATORIES

FIG. 4.— BASIC AMPLIFIER CIRCUIT

A P-N junction also contains a layer of space charge whose magnitude depends upon the voltage drop across the junction. The need to charge and discharge this layer limits the speed with which the junction potential can change.

P-N-P Junction Triode.—By combining an emitting junction and a collecting junction in the same unit, it is possible to cause a controlled stream of minority charge carriers to flow from one to the other, as diagrammed in the P-N-P junction transistor of fig. 2. In normal operation, the emitter junction E is biased in the forward direction (emitter positive) so that it injects minority carriers (holes) into the base region. When the base region is thin and its crystal perfection is good enough to provide an adequately large lifetime for the minority carriers, nearly all of them live long enough to flow to the collector junction. The latter is normally biased in the reverse direction (collector negative), so that it collects the minority carriers which the emitter has injected, together with a small number which may also be present from other sources.



BY COURTESY OF BELL TELEPHONE LABORATORIES

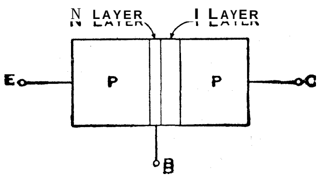
FIG. 5.—TETRODE

The triode amplifying properties derive from the fact that the collector current depends mainly on the small control voltage between emitter and base. Since the collector current, in flowing through an external load, can develop much more power output than is required to control the base-to-emitter voltage, the device can be built into a circuit which amplifies. A basic circuit is shown in fig. 4. In practical cases, the gain. or ratio of power at the output to power at the input, sometimes can be as much as 10,000 times (40 decibels).

Amplifying devices are widely used in electrical communications wherever it is desired to bring weak signals up to higher power levels. In addition, they can be used to generate alternating currents, or to act as very fast electronic switches or electronic computing devices.

N-P-N Junction Triode.—By arranging two N-P diodes as diagrammed in fig. 3, it is possible to make an N-P-N junction transistor. Its action is analogous to that of the P-N-P junction unit described above. However, since in the N-P-N the stream of minority carriers which is emitted, controlled and collected is composed of negative electrons rather than positive holes, it follows that in normal operation the electrode potentials are all opposite in polarity to the P-N-P. The availability of similar devices with opposite polarities makes possible certain symmetrical amplifiers and specially efficient low-frequency amplifiers which have no counterpart in the electron tube art.

Extension of Performance to Very High Frequencies.—With the structures just described in principle, it is feasible with available semiconductors such as germanium to build amplifiers for frequencies up to a few score megacycles per second; that is, somewhat beyond the commercial broadcast range but rather short of such uses as walkie-talkies, mobile radio or the frequency modulation band. Attempts to extend the range to encompass these additional uses encounter both fundamental and practical difficulties, which make necessary resort to new principles of operation.



BY COURTESY OF BELL TELEPHONE LABORATORIES

FIG. 6.—INTRINSIC BARRIER TRANSISTOR

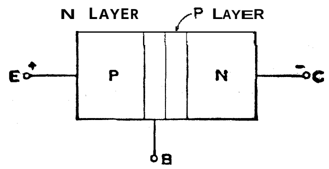
Two phenomena conspire to limit the range of the simple triodes. The first is connected with the time taken for the charge carriers to travel from emitter to collector across the base layer of thickness w. Even though the input current pulse at the emitter might be infinitely sharp, by the time it has reached the collector the pulse has spread out by diffusion; *i.e.*, because of random motion of the individual charge carriers within the semiconductor crystal. This effect therefore limits the speed with which the transistor can respond to fast signals or to high frequencies. The effect is measured in terms of the current amplification factor, alpha, which is the ratio of A.C. collector current to A.C. emitter current under constant collector voltage. The speed of response then depends upon the "alpha cutoff frequency," f_α, which is that frequency where α^2 is down to one-half its low-frequency value. For transistors in which the carriers travel entirely by diffusion, this frequency depends on their diffusion constant D in the material and on the inverse square of the base thickness w: $f_\alpha = 0.8\ D/w^2$. With a base layer $\frac{1}{1{,}000}$ in thick, for electrons in germanium this frequency is about five megacycles; in silicon, with a smaller electron mobility, it is about two megacycles.

The other factor limiting speed or frequency of operation is the time taken to charge the junctions, mainly the collector junction. There is present at each P-N junction a layer of electrical charge whose magnitude varies with the applied potentiai. Consequently, the junction has an electrical capacitance C_c. When the potential changes, the charge distribution can respond at only a finite rate because the current to the junction capacitance must flow in through the effective resistance r_b' of the base layer. This charging rate corresponds to a second characteristic frequency of the transistor; namely, $f_o = \frac{1}{2} r_b' C_c$.

A useful measure. or figure of merit, showing frequency capability is the frequency at which the gain has fallen to unity. It is closely related to the maximum frequency at which the device can generate electrical oscillations of alternating current, and is given approximately by one-half the geometric mean of the two limiting frequencies above; namely,

$$f_{\max} = \frac{\sqrt{f_\alpha f_o}}{2} = \left(\frac{f_\alpha}{8\pi r_b' C_o}\right)^{\frac{1}{2}}.$$

If an attempt is made to improve frequency response by decreasing the base layer width w, the base resistance r_b' also increases. If an attempt is made to decrease r_b' by reducing the base laver resistivity, the maximum voltage $V_{\max}$ at which the collector can operate is reduced. Thus in an optimally designed triode there is a minimum base width below which it is not profitable to go without further modifications of the structure. In germanium. at base widths of the order of 0.0005 in., maximum frequencies of the order of 150 megacycles result, but at the cost of greatly reduced area, lower maximum voltage and therefore lower power output.

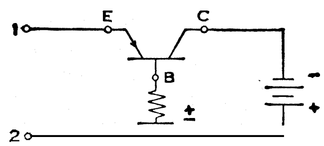


BY COURTESY OF BELL TELEPHONE LABORATORIES

FIG. 7.—CONJUGATE-EMITTER STRUCTURE

Tetrode.—One means for overcoming this speed limitation of conventional junction triodes is the tetrode structure invented by R. L. Wallace and diagrammed in fig. 5. A second base connection is made to the opposite side of the triode base layer of fig. 3. In operation, with the second base B_2 biased more negatively than the eniitter, charge carriers can be injected only very close to the first base connection. Consequently, the base resistance r_b' between the electron stream and B_1 is reduced to very low values even for base widths w as small as 0.0001 in., and it becomes advantageous to further increase the speed of current response f, by reducing w and to further decrease junction capacity by reducing area. In the laboratory such microtetrodes were pushed to maximum oscillation frequencies above 1,500 megacycles.

Intrinsic-Barrier Triode.—Another structure for improving frequency performance of transistors, which also improves the power-handling capability, is the four-conductivity-zone structure invented by J. M. Early, of which a particular version is diagrammed in fig. 6. By inserting between the collector and the base a layer of semiconductor of comparatively high purity ("intrinsic" or I type), the space-charge layer of the base-collector junction is greatly thickened, with a corresponding reduction of collector capacitance C_c by a factor which may be as large as 50 or more. Since the rise in voltage between collector and base is thus distributed over a longer distance, there is also a corresponding increase in the maximum collector voltage, $V_{\max}$. Further, the base layer resistivity can be greatly reduced without increasing C_c or reducing $V_{\max}$, since these are now controlled principally



BY COURTESY OF BELL TELEPHONE LABORATORIES

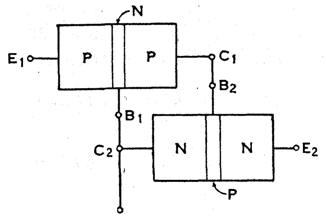
FIG. 8.—NEGATIVE-RESISTANCE CIRCUIT USING A TRANSISTOR WITH MULTIPLYING COLLECTOR

by the thickness of the intrinsic barrier region. The combination of all these features means that the time needed to charge the collector junction is greatly reduced.

The structure also promotes high speed of collector current response, since the base layer can be made very thin to keep down the diffusion time taken by carriers crossing the base region. The time taken for carriers to be collected across the intrinsic layer is also very short, since the layer is pervaded by the high electric field of the collector-base junction.

In summary, the intrinsic barrier principle favours the characteristic frequencies f_0 and f_α of the transistor so much as to increase frequency response by a factor of 30 or more over what is feasible with a conventional triode.

Even though by the mid-1950s this structure was relatively new, experimental models oscillated above 600 megacycles. Furthermore, the maximum power was about 100 times greater than the capabilities of the older structures.



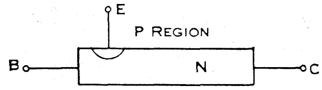
BY COURTESY OF BELL TELEPHONE LABORATORIES

FIG 9.—PAIR OF TRIODES NEARLY EQUIVALENT TO THE CONJUGATE-EMITTER STRUCTURE OF FIG.

Current-Multiplying Triodes.—In all the junction triodes and tetrodes mentioned up to this point, the collector does not collect more current than the emitter emits; or, in transistor terminology, the current amplification factor alpha is limited to unity. However, one of the useful properties of some types of transistors is their ability to have alphas greater than unity, of the order of two to five. For pulse-type circuitry such as is widely used in electronic computers, such high alpha can lead to a negative-resistance property which permits considerable circuit simplification and reduction of the number of transistors needed.

Conjugate Emitter *Structure—Shockley's "P-N* Hook."—One way in which current amplification factors greater than unity can be obtained is by means of the four-conductivity-zone structure of fig 7. Here the emitter and base are a conventional P-N structure, but the collector is a compound structure consisting of a thin P layer backed up by an N-type region to which the collector contact is made. As will be explained, such a compound collector can do more than collect minority carriers which have come from the emitter; under the influence of the minority carriers, the compound collector may also release majority carriers, so that the total collector current becomes greater than the incident minority carrier current.

In normal operation, the biases of the P-N-P-N structure of fig. 7 are like the P-N-P triode of fig 2, and the emission of holes into the base region under the control of the emitter-to-base potential is as before. Likewise, the collection of holes into the second P region across the reverse-biased N-P junction is similar. However, the final P-N junction is designed to be a good emitter of electrons from the N region into the P region, and it may be noted that with the biases as given this final junction is biased in the forward direction. Consequently, any current which flows across it must be, in major part, electrons flowing into the second P region. Alternatively, it may be said that under the influence of the primary current of holes, the compound collector not only collects the holes but also emits a secondary current of electrons which can be much larger than the hole current. By suitable design, current gains as large as 50 can be obtained.



BY COURTESY OF BELL TELEPHONE LABORATORIES

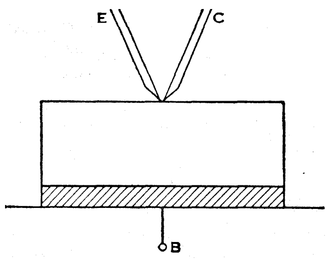
FIG. 10.— FILAMENTARY TRANSISTOR

If the two-terminal characteristics of such a transistor, for example in the schematic circuit of fig. 8, are examined, it is found that in regions where, because alpha is greater than unity, the collector current increment is large enough to override the emitter current increment, the device exhibits a negative resistance; *i.e.*, the incremental current which flows at terminals 1–2 is opposite in direction to the incremental voltage applied. Such negative resistance circuits are often useful, as in computer service.

The name "conjugate emitter" comes from the fact that the final P-N junction emits carriers of opposite sign to those supplied by the emitter. The entire composite P-N collector is also often called a "P-N hook" from the appearance of the electron energy diagrams.

An effect almost exactly equivalent to the P-N-P-N conjugate emitter triode can be obtained by the use of a conjugate pair of triodes, one P-N-P, one N-P-N, connected as in fig. 9. The leads E_1, B_1 and E_2, when biased in the same way as the emitter, base and collector of fig. 7, behave in very nearly the same way, although the "conjugate" emitter E_2 and the flow of electrons are in a separate transistor unit.

Filamentary Transistor; Conductivity Modulation.—Another way of obtaining collector multiplication is illustrated by the filamentary transistor of fig. 10. So-called because of its shape, the filamentary transistor consists of a thin rod of semiconductor with an emitter attached on one side. In normal operation, when the rod is biased by a potential applied between B and C, any minority carriers injected by the emitter are swept down the rod. The end toward which the minority carriers are swept is the collector, the other end the base. Since the current of minority carriers is electrically charged, it attracts an equal charge of majority carriers from the collector in order to leave the filament electrically neutral. Consequently, the conductivity of the filament has been increased, an effect entitled "conductivity modulation." The total collector current is greater than the current of minority carriers. A somewhat different version of this transistor in which the emitter junction is near the centre can be regarded as an emitter diode in which alternatively either end of the rod can be used as a base; consequently, it is also called the double-base diode. These units as usually built have much lower gains than the junction triodes previously described, but have utility in negative-resistance circuits.



BY COURTESY OF BELL TELEPHONE LABORATORIES

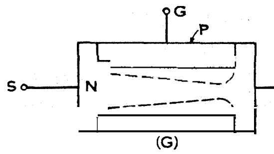
FIG. 11.—POINT-CONTACT TRANSISTOR

Point-Contact Transistor.—The form of transistor invented by Bardeen and Brattain, the point-contact type, also exhibits collector multiplication as a major feature. Here the emitter and collector are made by pointed wires close together on the surface of the semiconductor, while the base contact is a large-area low-resistance contact to the semiconductor (fig. 11). The mechanism of operation is similar to that of the other units; the emitter under forward bias injects minority carriers into the body of the semiconductor (base). These minority carriers are collected by the collector, with multiplication; *i.e.*, the collector also releases majority carriers. Just how the collector multiplication works is obscure and somewhat controversial; it appears probable that in some versions of the point-contact transistor the collector acts like a conjugate emitter, while in other versions probably the mechanism is conductivity modulation as in the filamentary transistor.

For most amplification purposes the point-contact transistor has been superseded by the junction units, because rectifying junctions made by placing points on a semiconductor surface are inferior to those called "junctions" made by other methods, described below. However, for some purposes the point-contact unit is still useful. Since a negative resistance is simply and economically obtainable, it finds employment in pulse-type computer circuitry. Since the unit has very small area and therefore very low collector capacitance, it is fast and especially useful for high-speed computers.

Besides the three structures just described, there are also other ways of obtaining the effect of a multiplying collector, and it is possible that some of these may become important.

Majority Carrier Transistors.— To this point the discussion has concerned transistors which operate by injecting, controlling and collecting a stream of minority charge carriers within a semiconductor. However, it is also possible to obtain useful effects with a stream of majority carriers. In order to avoid confusion, a different terminology is used. The stream of majority carriers comes from an electrode called the "source," is controlled by a "gate" and terminated in a "drain." These electrodes have functions analogous to those of the emitter, base and collector of the minority carrier transistors; the functions are also analogous to those of the cathode, control grid and anode of an electron tube.



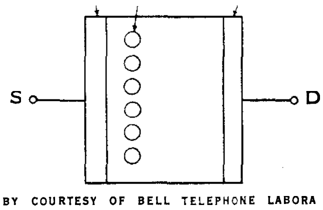
BY COURTESY OF BELL TELEPHONE LABORATORIES

FIG. 12.— FIELD-EFFECT TRANSISTOR

In normal operation the space-charge region, between the gate G and the dotted lines, is swept almost free of holes and electrons

Field-Effect Transistor. — The structure diagrammed in fig. 12 represents a particular version, due to Shockley, of the field-effect transistor. A rod of N-type semiconductor has nonrectifying contacts S and D at the two ends. Circumferentially disposed around the middle is a P-type region to which the gate contact G is made. In normal operation, the drain D is positively biased with respect to the source S, so that a current of electrons (*i.e.*, majority carriers in the N-type material) tends to flow from S to D. The gate G is negatively biased; since this is the reverse direction of the P-N junction, little current flows to the gate. Ho ever, as in any P-N junction, there is a space-charge region between the P- and N-type materials; when the reverse bias is large enough, this space charge region has the effect for a finite distance beyond the junction of repelling or "sweeping out" the conduction electrons which would normally be present in the N-type material. Depending upon the numbers of carriers present (*i.e.*, upon the electrical conductivity of the N-type material), such a reverse-biased junction may be capable of sweeping out carriers for a distance of as much as several thousandths of an inch.

With the normal carriers thus swept away, the conductivity of the rod between source and drain and consequently the drain current is reduced. As the reverse bias of the gate is further increased, the space-charge region increases in extent until at a particular point the entire cross-sectional area of the rod is swept clean of carriers, an effect known as "pinch-off." Further increase of gate voltage thenceforth has little effect on the drain current. Since the control of the drain current by the gate voltage requires very little power, the replica of the gate signal, obtained by passing the drain current through an external load resistor, has been amplified. Furthermore, the control electrode (gate) draws very little current, an advantage which the field-effect transistor shares with the vacuum tube.



BY COURTESY OF BELL TELEPHONE LABORATORIES

FIG. 13.—ANALOG TRANSISTOR. THE GATE CONNECTION IS MADE TO THE ROW OF RODS

W

Enough field-effect transistors have been made to show that the action is well understood. However, for many specific purposes their over-all performance appears to be less attractive than that of the minority carrier transistors.

"Analog" Transistor. — In fig. 13 is diagrammed the cross section of a planar version of a device whose structure and method of operation is so analogous to a vacuum tube that it has been called the analog transistor by its inventor, William Shockley. Here the source S and drain D of the charge carrier stream are area contacts on opposite faces of a slab of low-conductivity semiconductor, while the control electrode (grid) consists of a set of rod-shaped inclusions which have conductivity type opposite to the source and drain. Like the anode of a triode vacuum tube, the drain D is biased so as to attract majority charge carriers from the source, while the control electrode, like the grid of the tube, is biased in the reverse direction. Under these conditions, if the drain voltage is sufficiently large it will draw a current from the source which can be controlled by the grid voltage. At the same time, very little power is required for the grid since the current'is small.

Summary of Transistor Structures. — By the use of the basic prototypes just described, a large number of useful devices can be constructed. In each case, for a particular purpose the design variables, such as resistivity, geometry, etc., can be varied to produce the best practical result. Furthermore, the possibility of still other principles of operation, leading to additional prototypes, cannot be excluded. In the face of such a large number of possibilities, this article will not attempt to catalogue exhaustively the properties of all possible transistors. Rather, the rest of the article will describe some semiconductor materials usable for transistors, and some fabrication techniques.

MATERIALS FOR TRANSISTORS

In order to support a useful, controlled flow of minority charge carriers in the structures covered in the preceding section, a semiconductor material -must meet a number of requirements: (1) It must support the two kinds of charge carriers; (2) when minority carriers have been injected. they must have a lifetime long enough to enable them to reach their destination; (3) for the device to operate with a desired speed, the carriers must reach their destination with a corresponding speed (*i.e.*, they must have an adequate mobility); (4) the desired stream must not be obscured by undesired carriers arising from other causes, especially from the thermal energy uhich the material always has because of its temperature; (5) the number of carriers must be suitably controllable to make the material N or P type in the necessary amount.

Crystal Structure. — A crystalline solid consists of an ordered array of atoms. Each atomic nucleus, positively charged, is surrounded by the number of electrons corresponding to its atomic number, or position in the periodic table of the elements. The electrons, negatively charged. move in orbits which are arranged in groups or "shells" around the nuclei. The innermost shells of electrons are so tightly bound to their own nucleus that they do not interact with neighbouring nuclei; they can be torn loose only by relatively large amounts of energy such as are associated with X-rays, alpha particles or other nuclear radiations. However, the outermost electrons are more loosely bound and do interact with their neighbours; that is, they travel back and forth in the lattice. These interactions result in the binding forces which hold the crystal together. It is these same outer electrons, acting in the same way, which also create the binding forces which hold together ordinary chemical compounds and which are responsible for the chemical valences of the elements; for this reason, the outermost electrons which bind the crystal together are called valence electrons (see VALENCE).

Electrical Conduction by Charge Carriers. — A perfect crystal in equilibrium at absolute zero temperature is an insulator[1]. There can be no net flow of electric current, because for each electron travelling in a certain direction through the valence structure, there is a symmetrically placed electron travelling in the opposite direction. For each electron travelling back, another travels forth. In order for a current to flow, there must be some unpaired electrons. These electrons can appear in several ways. In particular, when the material is heated or illuminated, some electrons can acquire energy and be broken loose from the valence bonds. For every valence bond broken, there result two units of electronic charge which can contribute to the electrical conductivity when an electric field is applied. First, the free electron, because of its negative charge, experiences a force which causes it to drift through the lattice, thus carrying a current. Second, after the electron has left, the formerly neutral region where there is now a "hole" in the valence structure has a net positive charge because one electron is missing. Under the influence of the field, another valence electron can move into the hole in the same direction as the free electron; of course, this event leaves a hole where the second electron came from, into which still another valence electron can move, and so on. It may be said, therefore, that the hole

[1] statement assumes the crystal is a nonmetal in which the energy bands and do not overlap. *See* C. Kittel, *Introduction to Solid State Physics*, p. 261 (New York, 1953).

has moved in the direction opposite to the free electron.

The two kinds of charge carriers needed for minority carrier transistors are thus supplied by the negatively charged electrons and the positively charged holes.

Just as two charge carriers are created when an electron leaves a valence bond, so also the opposite process can occur; a free electron can drop into a valence bond, thus destroying two charge carriers. Consequently, the minority carriers are said to have a lifetime, which is the average length of time before the minority carrier is lost by recombination with one of the majority carriers.

For moderate applied electric fields, both electrons and holes move with velocity proportional to the field. However, in general, holes are a little harder to move than electrons. The holes are said to have a lower mobility, the mobility being the average velocity imparted by a unit electric field (one volt per centimetre).

Control of Conductivity and Carrier Lifetime.—To have adequate mobility and minority carrier lifetime for transistors, the semiconductor usually must be a carefully prepared single crystal. Any defects in the crystal contribute to the recombination rate, thus impairing the lifetime. If the crystal is polycrystalline (*i.e.*, consists of a number of small single crystal grains), the measured mobility may also be greatly lowered because the material in the boundaries between the grains may have a greatly disordered crystal lattice which interferes with the orderly motion of the charge carriers. The grain boundaries may also have different properties because they tend to contain more chemical impurities than the rest of the crystal. Because these requirements are so stringent, it is a long and difficult task to give an adequate and fair evaluation of even a single material for transistor purposes.

To control the majority carrier concentration, chemical impurities are included in the semiconductor crystal lattice. For example, to produce N-type conductivity in germanium, arsenic is often added as an impurity. Germanium, a member of Group IV of the periodic table, has four valence electrons. When arsenic, which has five valence electrons, is substituted into the germanium lattice, four of the electrons play the role of their germanium counterparts. The extra fifth electron is not needed to complete the lattice and is very loosely bound to the arsenic atom, so that only very little energy is required to activate it as a conduction electron. Consequently, germanium, when "doped" with a small amount of arsenic as an impurity, acquires (at room temperature) approximately one conduction electron per arsenic atom and becomes N-type.

Similarly, to produce P-type conductivity in germanium, gallium may be added. Since gallium has only three valence electrons, the valence structure is one electron short in the neighbourhood of each gallium atom. It is said that each gallium atom has added a hole to the valence structure. This hole also is very loosely bound to the gallium impurity which caused it, and accordingly very little energy is required to activate it and cause it to move through the lattice as a positively charged hole. Consequently, germanium doped with a small amount of gallium as an impurity becomes a P-type or hole conductor, with (at room temperature) approximately one hole present for each atom of the Group III chemical impurity. This type of conduction is called extrinsic because it depends on the impurities, to contrast it with the intrinsic conductivity which exists in the pure material.

The properties of transistors, as described above, depend on the extrinsic conductivity of the semiconductor. Accordingly, the intrinsic conductivity, which arises in the following way, must be relatively small. Because of the heat energy which the crystal possesses by virtue of its temperature, the atoms of the lattice are in continual vibration; and as the temperature increases, these thermal vibrations also increase, tending more and more to excite valence electrons into conduction electrons, and thus to produce intrinsic conductivity which is characteristic of the pure crystal itself. This intrinsic conductivity tends to be inhibited when a large amount of energy is required to activate a valence electron into the conduction band. Consequently, to keep down the number of undesired charge carriers from sources other than the controlled stream, the semiconductor should have an adequately large energy gap between the band of energies corresponding to the valence electrons and the band of the free conduction electrons. Even so, the intrinsic conductivity increases sharply (exponentially) with temperature, and eventually produces so many carriers that the transistor effects are swamped. The larger the energy gap, the higher the temperature at which the transistor will still work.

It is basically for this reason that a metal cannot be used as a vehicle for a controlled stream of minority carriers in the transistor sense; for in a metal, where there is no energy gap above the valence band, the valence electrons are too easily lured from their bonds.

To obtain the needed extrinsic conductivity, ordinarily the number of impurities used is extremely small—perhaps 1 part in 1,000,000, or even 1 part in 10,000,000. By ordinary standards transistor materials are extremely pure, yet their electrical properties depend on the accurately controlled residual impurity. Totally new levels of purity and control were made available through the brilliantly simple zone-melting processes invented by W. G. Pfann. By this means, germanium was prepared in which impurities constituted less than 1 part in 10^{10}—probably the purest substance known.

Impurity atoms of the type which contribute conduction electrons to the lattice are for that reason called donor atoms, like the Group V elements phosphorus, arsenic and antimony in germanium. Impurities of the other type, which accept valence electrons from the lattice and thereby produce hole conduction, are called acceptor atoms, like the Group III elements boron, aluminum, gallium and indium in germanium.

Other effects can also result from impurities. Some impurities degrade the minority carrier lifetime? acting as centres for generation or for recombination of charge carriers. Others may produce "traps" which can hold a charge carrier temporarily and release it at a later time.

FABRICATION TECHNIQUES

Various mechanical, electrical, chemical and metallurgical techniques have been used to make transistors and other semiconductor devices. Some of the principal ones are listed here. By combining these or other suitable techniques as building blocks in various ways, the transistor structures may be made. Since in each of these structures the dimensions and the semiconductor may be varied, the number of possible combinations is legion.

P-N Junctions.—One basic problem common to many of the structures is the fabrication of a P-N junction, which may be made by various methods as outlined below.

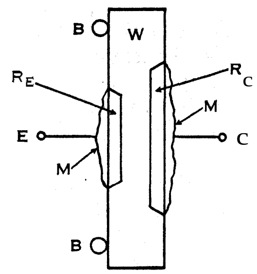
Point Contact.—The mere placing of a clean metal point in contact with etched N-type germanium, for example, gives the effect of a P-N junction inside the semiconductor. Why this junction should occur was for a long time a mystery; its explanation by John Bardeen in terms of surface energy states was an important step on the road to understanding transistors. On etched P-type germanium a rectifying point contact may be made if the point is of a particular material (*e.g.*, phosphor bronze, which contains the donor impurity phosphorus) and if the point is momentarily heated by passage of a pulse of current, a process known as forming. Such point contacts are relatively simple to fabricate, but their properties are, of course, sensitive to the surface condition of both point and semiconductor. Moreover, much better rectifiers can be made by some of the other methods.

Grown P-N Junction.—This is so-called because it is made by controlling the impurity concentration in a single crystal while it is being grown from a melt. A seed crystal is dipped into the molten semiconductor and then withdrawn, being gradually cooled so that it serves as a nucleus upon which additional material crystallizes. The impurity concentration and hence the conductivity is controllable either by adding impurities to the melt while the growing proceeds or by varying the rate of growth of the crystal.

Alloy P-N Junction.—This is so-called because it is made by melting together (*i.e.*, alloying) the semiconductor with a desired impurity. For example, a small button of indium may be heated in contact with N-type germanium until the indium melts and dissolves a portion of the semiconductor. On cooling, the germanium which recrystallizes or regrows from the melt is, of course, P type (because contaminated with indium, an acceptor impurity): so that a P-N junction has been formed. Two such junctions, which may be formed simultaneously on opposite sides of a thin wafer, compose a P-N-P alloy junction transistor, sketched in principle in fig. 14. An N-P-N alloy junction transistor can be made by the analogous method of melting suitable N-type buttons into a P-type semiconductor. The alloy junction is also sometimes called a fused or bonded junction.

Diffused P-N Junction.—This is so-called because it is made by diffusing a suitable impurity into the semiconductor. For example, when N-type silicon is exposed to boron chloride at a high temperature, some of the boron diffuses in and converts the silicon surface to P type. Although some slight diffusion also occurs during the alloying process, it seems better terminology to reserve the term "diffused" for those cases in which the dominant process does not involve melting of the semiconductor.

Surface Barrier Junction.—This may be made and contacted by an ingenious chemical process of etching and plating. The surface of the semiconductor is first etched electrolytically, with the etching electrolyte being a fine jet directed at the surface; consequently, the area etched may be very small. Second, by reversing the polarity of the current flow while the jet is still present, a metallic electrode is plated onto the freshly etched surface. The surface barrier is a rectifier, evidently for the same reason as a point contact; namely, because of the charge in the surface energy states. A particular advantage of the jet-etch-plating technique is the possibility it affords of making high-frequency transistors. Etching simultaneously on both sides of a wafer can be precisely controlled to give a very thin web (0.0002 in.), consequently a very small distance between the emitter and collector junctions. The consequent high alpha cutoff frequency, coupled with the low capacitance of the small junctions, can result in a frequency response up to 300 megacycles or more.



BY COURTESY OF BELL TELEPHONE LABORATORIES

FIG. 14 —P-N-P ALLOY GERMANIUM JUNCTION TRIODE:

(B) Base contact ring; (C) collector contact; (E) emitter contact: (R_E) regrown emitter region, P-type; (R_c) regrown collector region, P-type; (M) solidified indium-germanium mixture; (W) germanium water

Ohmic Contacts.—In contrast with the fabrication of a P-N junction, another generic problem is the fabrication of a low-resistance ohmic contact. In this case it is desired to get rid of all traces of rectifying action at the contact, a matter which is not always simple but which may be done in a number of ways.

Alloying.—The process is similar to the making of an alloy P-N junction except that the type of impurity used is the same as the substrate rather than opposite; so that instead of a rectifying junction, a low-resistance contact results.

Plating a Metal Onto an Abraded or Sand-Blasted Semiconductor Surface.—Here the mechanical working of the material so reduces the minority carrier lifetime that rectification is destroyed.

Welding, Bonding or Soldering.—Since these methods involve formation of a liquid phase during the process, they are closely related to alloying.

Point Contact to an Abraded Surface.—This method is often unsatisfactory because the resistance is too high. However, if the current is kept small, a point contact may be used for test purposes even on etched surfaces.

Surfaces.—A third general problem is the preparation of a suitable surface. The action of the various structures was described above in terms of bulk properties inside the semiconductor, such as lifetime, conductivity, etc. However, an unsuitable surface may impair or destroy the desired action. For instance, commonly the surface, even when carefully prepared, has such a high tendency to recombine carriers that it may seriously interfere with the number which succeed in reaching the collector. When the surface is abraded or sand-blasted, it may cause the complete disappearance of minority carriers, rectifying or injection action.

To obtain a surface with adequately high lifetime, it is conventional to etch in order to remove material whose crystal structure may have been impaired by previous mechanical treatment, such as sawing, grinding or lapping to make a flat surface. The etching may be by chemical or by electrochemical means. Even after a high-quality surface has been obtained, if stable and reliable properties lasting many years are desired, the maintenance of the surface in a good condition is a serious problem. Extremely minute quantities of contaminants, such as water or oxygen, amounting to far less than a single layer of atoms, may cause appreciable changes; even in a high vacuum the avoidance of such small quantities is difficult. In the mid-1950s it was possible to make transistors that were probably satisfactorily stable for periods of the order of about ten years, if their temperature was not allowed to rise much above room temperature. The stability obtained was comparable with the best obtainable with electronic equipment.

USEFUL RANGE OF TRANSISTORS

By combinations of these fabrication techniques and others not mentioned, it is possible to make a great variety of semiconductor devices, including all those mentioned in the first section of this article. Among these possibilities are low-level amplifiers suitable for receiving weak signals up to several hundreds of millions of cycles per second; oscillators up to more than 1,000,000,000 cycles per second; and detectors up to the highest radio frequencies now usable, about 100,000,000,000 cycles per second. Power in the range of 1 to 50 w., sufficient to drive electromechanical devices such as relays, loud-speakers and small motors, can be obtained. With such devices it is possible to build an enormous variety of communication and control equipment, such as voice-frequency systems, telephone amplifiers, radio receivers, data transmitters, automatic control systems and complex, high-speed electronic switching and mathematical computing equipment. Such apparatus features miniature size, portability, minimum power requirements, ruggedness and long life. While a number of such applications had .already been carried through by the 1950s, a much greater number remained to be developed in the future.

TRANSIT CIRCLE (*MERIDIAN CIRCLE*), a telescope for measuring the time when a star passes across the meridian and at the same time measuring its altitude. These two measurements determine respectively the right ascension and the declination (*qq.v.*), hence the place of the star on the celestial sphere. Because of its fundamental importance in positional astronomy, and as the source of standard time furnished to the community, the transit circle is traditionally regarded as the leading instrument, at least in the great national observatories; but in modern times important observatories have grown up whose work lies wholly in other directions. The transit circle looks rather like a big gun on a gun carriage, and to the stranger the surprising thing about this kind of telescope is that it cannot be turned to all parts of the sky; it only moves up and down in the north and south line. looking out through a slit in the walls and roof. Nor can it be used for prolonged study; the observation is a snapshot as the object passes rapidly across the field of view.

Suppose that the exact position of some star is to be remeasured. From the catalogues a star is chosen that is due to pass across the north-south line in a minute or so; and by means of a setting circle the telescope is elevated to the proper angle to catch it. The aperture of the object glass is probably eight or nine inches, and it mill easily show stars to the ninth magnitude. While waiting, the field of view can be examined. A faint artificial illumination shows stretched across the field a number of wires that are actually made of spiderweb; there is one horizontal wire which can be moved up or down by turning a micrometer screw, and a considerable number of vertical wires (perhaps ten). The star now enters the field—at the extreme right since the telescope inverts—and is seen traveling rapidly toward the left. The telescope is shifted slightly so as to bring the star almost onto the horizontal wire and then the instrument is clamped at that altitude. Now the star is approaching the series of vertical wires; as it passes each, the pressing of a key records the instant on a chronograph on which the standard sidereal clock is recording the seconds.

Near the centre of the field there is an intermission which gives a few moments for making the altitude observation. Turning the micrometer screw, the horizontal wire is made to bisect the star, an action repeated two or three times to reduce accidental errors. There is no time for the micrometer head to be read, but it is furnished with some printing or recording device which keeps a record of settings. Tapping off the passage over the vertical wires is now finished, and the star disappears from view. Next, at the side of the instrument four long microscopes are read which are viewing a graduated circle attached to the telescope. Their combined reading will ultimately tell at what elevation the telescope was clamped; to that must be added the reading of the micrometer head so as to include the extra displacement given to the wire to bring it onto the star.

The whole observation takes two minutes or less, but there is a great deal of work in store for the computer. He must sort out the taps on the chronograph belonging to this star and also the records of the micrometer head. The error and rate of the standard clock must be worked up from the clock stars observed during the night. The large correction for refraction must be computed and applied to the altitude. Various observations for adjustment will have been taken, and from these the collimation, azimuth, level and zenith point corrections must be deduced and applied. There will be further corrections, not specially connected with the instrument, to be included before the final place of the star is obtained in the form of mean right ascension and declination. This typical procedure may be varied somewhat. The most importaht modification is the use of the traveling-wire micrometer (see MICROMETER), which is generally employed in first-rate work. Attempts have been made to substitute some photographic or photoelectric method for visual observation.

Formerly the altitude observation and the time observation were made with different instruments, called, respectively, the mural circle and the transit instrument. The mural circle is obsolete, but the transit instrument survives as a small portable instrument used for determining longitudes and for the most accurate determinations of time. The transit instrument is virtually a transit circle shorn of its graduated circles and microscopes.

The transit circle is used for determining the positions day by day of the sun, moon and planets. For stellar work its scope is limited to the brighter stars, roughly those brighter than magnitude 9 (there are more than 100,000 of these). There is no advantage in observing fainter stars with it, since the work can be done more speedily and accurately by photography; but photographic measures are relative, and the positions can be made absolute only if the photograph contains some reference stars whose absolute positions are already known from meridian work. Thus transit-circle observation is extended only so far as to provide accurate positions of a reasonable number of reference stars on all photographs.

TRANSKEI, THE, the name given to the part of Cape province, U. of S. Af., lying between the Kei river and Natal, excluding Elliot and Maclean. It covers Tembuland, Griqualand East and Pondoland. Area 16,329 sq.mi. Pop. (1951) 1,300,920, including 18,481 Europeans. These territories form mainly a native reserve, although there are many European farms in Mt. Currie and Matatiele.

The undulating country is fertile and well watered and the climate is healthful. Wool is produced and there are small deposits of iron

TRANSMITTER: see MICROPHONE.

TRANSMUTATION OF THE ELEMENTS. The transmutation of one metallic element into another was one of the chief objects of the earliest chemists, or alchemists, and was notably unsuccessful. Today, under the influence of modern views on the constitution of matter, transmutation into nearby elements in the periodic table has been successfully accomplished with respect to practically every one of the chemical elements.

See ALCHEMY; ACCELERATORS, PARTICLE; NUCLEUS; RADIOACTIVITY, ARTIFICIAL; RADIOACTIVITY; NATURAL.

TRANSPLANTS, TISSUE AND ORGAN. Transplants (grafts) are classified as autotransplants, homotransplants or heterotransplants, according as the tissue is obtained from the recipient himself, from another member of the same species or from a member of another species.

The fate of a living autotransplant depends on whether its nutritional requirements are adequately met and thus, with most tissues, on the early re-establishment of a blood supply. Pieces of skin (either whole thickness or partial thickness) or small pieces of other tissues may be transplanted freely to suitable sites and soon become permeated by new vessels. Autotransplants of skin and subcutaneous tissue are left connected by a pedicle containing blood vessels, at least until they acquire a new blood supply, and transplants of organs are made similarly or by vascular anastomosis; *i.e.,* by connecting the artery and vein to suitable vessels in the new site.

Homotransplants, as a rule, evoke a state of immunity in the recipient and in consequence are destroyed after a few days or weeks. The immunological nature of the process was suggested by the discovery that a second transplant from the same donor is destroyed more quickly than the first, and was confirmed by the subsequent discovery that increased resistance to a transplant could be transferred to an animal of the same inbred strain as the recipient by transplanting cells from the lymph nodes draining the region in which the transplant was located. The antigens concerned are located in the cell nuclei, are genetically determined and appear to be common to all the nucleated cells of an individual. There is evidence that they are complex mucopolysaccharides. Antibodies can sometimes be demonstrated in the recipient's serum, but those concerned in the destruction of homotransplants appear to be transported by cells (probably lymphocytes) (see IMMUNITY). The survival of homotransplants may be prolonged temporarily by experimental and therapeutic procedures; *e.g.,* administration of cortisone.

Exceptionally, homotransplants may survive permanently, notably (1) when the donor and recipient are identical twins or animals of a closely inbred strain; (2) when the tissue, such as cornea and cartilage, is devoid of blood vessels; (3) when the recipient before birth (or in some species soon after birth) has been injected with living cells from the prospective transplant donor and has in consequence become specifically tolerant of his tissues; (4) when the recipient has been exposed to whole body irradiation; and (5) when the transplant is isolated by a porous membrane which allows the passage of fluids and nutritive substances but not cells. Homotransplants between nonidentical twins normally survive only temporarily. In cattle, however! and very occasionally in man, nonidentical twins may exchange blood-forming tissue during intrauterine life, following which the blood of each contains red cells of two different blood groups, and homotransplants interchanged between them survive permanently.

Homotransplantation of adult blood-forming tissue to an immature recipient may cause runt disease, characterized by retardation of growth, diarrhea and sometimes death; a similar condition, termed secondary disease, may develop after transplantation to an irradiated adult. Both conditions appear to be due to an immunological action of some of the transplanted cells against the recipient.

Heterotransplants are normally rapidly destroyed. They too evoke a state of immunity, and cytotoxic antibodies usually can be demonstrated in the recipient's serum. Tumour heterotransplants may survive, however, in certain special sites.

In surgery, free autotransplants of skin, bone and cartilage are used extensively. Skin transplants are of special importance in the treatment of deep burns. They usually consist of only part of the thickness of the skin. and in this event the donor site will heal spontaneously. Free nerve transplants also are used, sometimes in the form of multistrand or cable grafts made from small sensory nerves which can conveniently be sacrificed. Attempts have been made to increase the permissible dose of radiation in cancer patients by removing bone marrow before treatment and replacing it afterward as an autotransplant. Pedicled autotransplants of stomach or bowel are used in reconstruction of the alimentary tract after resection for cancer and other disorders, and pedicled transplants of bowel are used also in reconstruction of the urinary tract.

Homotransplants of cornea are used to restore sight in patients with corneal opacities and conical cornea. They may be partial or full thickness and will remain clear provided that blood vessels do not enter them. Homotransplants of skin survive for only a few weeks but may be lifesaving in patients with extensive burns. They are replaced by autotransplants when the patient's general condition is satisfactory. Homotransplants of bone are used in orthopedic surgery. They are often dead and, even if living, do not survive permanently, but they provide a scaffolding which facilitates repair by the recipient's own tissue. Homotransplants of arteries are used in vascular surgery, and they too act as scaffolding for regenerating recipient tissue, but the tendency is to prefer substitutes of woven synthetic materials. Homotransplantation of a whole kidney is unjustified unless an identical twin is available as donor, because the transplant is unlikely to function for more than a few weeks and a patient can be maintained on an artificial kidney for this period. Several instances of successful transplantation of a kidney from an identical twin, however, have been reported. Homotransplantation of blood-forming tissue has been tried in conjunction with X-ray therapy in leukemia and cancer, but by the early 1960s had succeeded only in experimental animals.

For storage, transplants of blood and bone blood vessels, which need not remain alive, are frozen, freeze-dried or kept in antiseptics. Skin transplants survive for a few weeks at 4° C. and for months after being soaked in glycerol and frozen to −79" C.. but the problem of storing whole organs by freezing or by continuous perfusion remains unsolved. *See* also PLASTIC SURGERY.

See M. F. A. Woodruff, *The* Transplantation *of* Tissues and Organs (1960). (M. F. A. W.)

TRANSPORT. For separate articles dealing with this subject, *see:* for land transport: AUTOMOBILE; ELECTRIC TRACTION; MOTOR TRANSPORT. COMMERCIAL; RAILWAY; ROADS AND STREETS; SUBWAY (UNDERGROUND RAILWAY); TRAFFIC REGULATION; TUNNEL. The following articles cover transport at sea: SHIP; SHIPBUILDING (MERCHANT AND NAVAL); SHIPPING, HISTORY OF; SHIPPING INDUSTRY. Inland waterways are dealt with in BARGES AND CANAL CRAFT; WATERWAYS, INLAND; INLAND WATER TRANSPORT; LOCK: RIVER AND RIVER ENGINEERING; WEIR. *See* also PANAMA CANAL; SUEZ CANAL. Subjects connected with coast and port protection are treated under BREAKWATER; BUOY; DOCK; HARBOURS; JETTY; LIGHTHOUSES; PIER; PORT OPERATION. For air transport, *see* AERONAUTICS and AVIATION, CIVIL.

General Characteristics. — This article deals with the history and organization of the chief forms of transport. Transport is a personal activity, a social service and an industry. There are two sharply defined stages: the period up to the Industrial Revolution, before which only the power of human porters, draft animals and the winds could be used; the period beginning with the Industrial Revolution, which brought steam, electricity and internal combustion as prime movers.

Basic conditions have greatly influenced both the techniques used and the forms of organization and ownership; *e.g.*, inland transport always involves both a vehicle and a specialized way, whether road, railway or waterway. A road is a much less specialized way than a railway, being used by many kinds of traffic; and the community has thus generally accepted the responsibility for providing the roads. The construction of railways has generally been undertaken by private capital, except where it has been necessary, for political or economic reasons, for the state to take the initiative. On roads there is usually no connection between the provision of the track and the ownership of vehicles. On railways, though, it was early recognized that the provision of the track should be under the same control as the provision and operation of the trains.

Sea and air transport are fundamentally different. Nature provides the track, and conducting transport is confined to the provision and operation of the vehicles and of the terminal facilities. Ships are generally privately owned; docks and harbours are owned by local authorities, public corporations and private companies.

Inland transport by water is an intermediate case. Where rivers are used, operations are similar to sea transport. Where an artificial waterway has been made, it is like both road and rail. Canal boats may be owned by the authority owning and maintaining the canal, or by common carriers or private traders. The canal may be provided by the state or be privately owned with tolls charged for passage.

Air transport differs economically from both land and water. Airline operation needs first to expend power and money merely to keep the vehicle air-borne. The cost of operation is very high. Terminal facilities are generally provided by the state, while operation is by corporations owned either privately or by the state.

LAND TRANSPORT

Pack Animals. — Women were the first porters and remain so in primitive societies. The use of animals for transport — dog, ox, horse, reindeer, camel and elephant — marked a great advance.

The dog was possibly the earliest animal to be used in transport. Because of its small size and limited strength, it was trained only when no better animal was available. Throughout the arctic and in parts of the old world the dog is still used.

The ox was the most widely distributed of all transport animals, species existing in a wild state in North America, Africa, Europe and Asia. The domestic ox was common in Europe and Asia in the Stone Age. The ox wagon was common transport in Mesopotamia and Egypt in early times; it is still seen round the Mediterranean, and has spread to South Africa and South America.

The domestic horse, presumably derived from the wild horse of the central Asian plains, seems to have been the earliest domesticated animal in Japan, though used for riding, not for draft. Its westward spread altered the history of Europe. Stray horses running wild over the plains and horses deliberately let loose in America soon produced wild herds in both North and South America. These wild horses profoundly influenced the life of the Indians. The horse is rarely used by African natives, except those in close contact with the Arabs. Human carriers (men, not women) are the usual means of transport in Africa south of the equator as far as the cattle areas, where oxen are used.

The reindeer provides not only transport but milk, flesh and skins. A herd of them constitutes wealth in Siberia and among the Lapps of northwestern Europe.

The camel, with its thirst-defying stomach, its capacity for thriving on desert herbage and its flat feet, which spread out instead of sinking into the soft sand, has made life and wealth possible in the Sahara. The camel rivals the horse in the drier districts of Asia from the near east to China, and has been invaluable in the exploration of the deserts of Australia. A good riding camel will cover 150 mi. in a day, and the Bactrian or two-humped baggage camel can carry more than 1,000 lb.

The domestication of the African elephant came late, but the Indian elephant was early trained for transport. Its great strength and intelligence can be used in pathless jungle and for road and bridge building, but because of its enormous appetite, which must be satisfied off vegetation where it works, and its delicate constitution, compared with other animals, its usefulness is definitely and narrowly limited.

Draft. — Man can drag more than he can carry on his back. Where the surface of the country is suitable some contrivance is made for hauling. The American Indians developed a type of sledge and also dragged skins sewn into bags along the frozen ground. Though over the whole of the arctic packs are carried on the back (human and canine), as the ground hardens sledges are made, on which far heavier loads can be transported. South of the frozen land, the toboggan takes the place of the sledge, and farther south a special method of packing led to the travois, a V-shaped framework formed by tent poles with a skin tent cover tied on and household goods piled on the top, the whole being dragged by dog or, later, horse. Such primitive constructions preceded the wheel cart, and survive in farm sleds, the sledge on runners and slide car. The wheel is not a primitive invention; though wheeled vehicles were familiar in early time in Assyria and Egypt, there was no wheeled vehicle in the Americas before Columbus.

Early Roads. — Porterage by human beings or pack animals needs only rough tracks trodden down by traffic. The first step toward more efficient overland transport of heavy loads was the use of tree trunks as rollers placed under the load to move it for a short distance. With the transformation of the roller into a wheel, a specialized track and vehicle were needed. Efficient transport over long distances was possible. The Romans, invading Britain in the 1st century B.C., found war chariots in use; doubtless some primitive carts were then also employed. The invading Romans built a network of paved roads constructed on sound engineering principles which, while primarily intended to provide for the rapid movement of troops, could also be used for wheeled traffic. There is evidence of the use of chariots and carts in other early civilizations.

Evidence of the existence of roads in the ancient world is generally evidence of a strong central government interested in military transport. Even as late as the 19th century the most spectacular road developments were in France under Napoleon, and in the 20th century under the fascist government in Italy and under the Nazi regime in Germany.

With the breakup of the Roman empire, the road system of Europe declined. The free movement of persons and goods was restricted, and travel was virtually confined to knights, nobles, priests and a few itinerant merchants.

The medieval monarchy recognized no special responsibilities for road construction and maintenance, but the church here and there attempted to fill the gap, assuming responsibility for the provision of bridges or certain stretches of road.

The first tentative move toward a modern road system began with the Tudor period and the beginnings of a system of local government based on the parish. Road maintenance became a duty of each parish under an act of 1555, and highway surveyors were appointed under an act of 1662 to levy rates for road upkeep. This system persisted, with modifications, until modern times. It has always led to disputes as to how far the roads are used by local people (and are thus a proper charge to the local community) and how far they are used by through traffic and should be charged to the nation or to the users of the roads.

Road Building in the **17th** and 18th Centuries. — France led among European countries in developing a modern inland transport system. Near the end of the 16th century the duc de Sully started creating a national system of roads surfaced with broken stones. The great road builder of France, however, was Jean Baptiste Colbert, who became comptroller in 1665. By enforcing the feudal system of compulsory labour, he brought about the surfacing of 15,000 mi. of road. In 1775 P. Tresaguet, by making provision for drainage of the roadway, began the construction of better roads and substituted a continuing force of paid workers for the earlier system. Two Scotsmen, however, Thomas Telford (1757–1834) and John Loudon McAdam (1756–1836), first built roads according to scientific methods. Telford laid a base of large stone on which smaller stones were placed, the surface being of finely broken rock. McAdam omitted the foundation of large stone and laid crushed rock for a few inches. The McAdam road was lighter and cheaper to build than Telford's. The McAdam foundation, with a binding of cement and a surface of asphalt or concrete, continued in use into the 20th century.

Roads in the Modern World. — Great Britain. — Both the technical knowledge and the forms of organization needed for a modern system of roads came into being in the 18th century. The principle that the parish should pay for the roads was largely replaced by one that the roads should be paid for on the basis of use. Though the first recorded levy of road tolls was in 1346, no real progress on these lines was made until early in the 18th century. Then the turnpike system began to be widely adopted. Sections of main roads were turned over to turnpike trusts, usually made up of local landowners. The trusts raised loans for road building and improvements and met costs of upkeep and charges for interest and repayment of capital out of tolls collected. Although some turnpike trusts actually did the work, many farmed out both the work and the collection of tolls to contractors.

With the development of fast stage coaches, the turnpike system reached its peak — just before railway competition began, about 1830. The turnpike trusts were not always efficient, nor had they the foresight to encourage steam power by road. Their levying of prohibitive tolls on the early experimental steam carriages, such as Gurney's, virtually ensured the future of steam traction on the railways. As the railway steadily superseded the roads for through traffic in the second quarter of the 19th century, the revenues of turnpike trusts declined and the system fell into desuetude.

Toward the end of the century, also, the growth of a modern system of local government made it easier to lay upon it the duties of a highway authority.

This system survived into the 20th century, though the growth of motor transport and the return of traffic to the roads began to raise the expenditures on roads and the question of national versus local responsibility. A road fund was established in 1909, with all proceeds of motor taxation to go for road expenditures. This system broke down because successive chancellors of the exchequer could not resist drawing upon the road fund for general government purposes.

The permanent principle that road maintenance, while being carried out mainly by local authorities, should be financially assisted by grants from the central government was, however, firmly established.

At mid-20th century there were about 8,000 mi. of trunk roads financially charged to the minister of transport, though the highway authorities maintained them as his agents and at his cost. The remaining roads were "classified" and "unclassified," the former comprising about 86,000 mi., or slightly less than the total road mileage in Great Britain in 1955. The unclassified roads were considered of purely local importance and were unsupported by grants

Other Countries. — The movement for good public roads began in western Europe 11 years before it started in the U.S. There the early and widespread development of railways, in a country sparsely populated, provided facilities for other than local transport that were fairly adequate until near the end of the 19th century. It then became manifest in the more thickly populated northeastern states that improved county and state roads were necessary. New Jersey acted in 1890, and Massachusetts, New Tork and other states soon followed.

In certain countries the growth of motor traffic caused a reversion to the turnpike system. In the 1920s Italy constructed *autostrade,* motor roads for high-speed traffic only between important centres, free from sharp curves. junctions and steep gradients. In the 1930s Germany also built Autobahnen, partly for military reasons. to provide an alternative to railways. Perhaps the widest development of the turnpike system took place in the U.S. where, especially after World War II, turnpikes provided unrivalled facilities for high-speed motor traffic. (See ROADS AND STREETS.)

Organization of Passenger Road Transport. — Road passenger transport has developed in three main forms — private, hackney and stage carriages. Use of private carriages presupposed the existence of a wealthy class and a reasonably good road system. By the 17th century not merely the aristocracy but also officials (such as the diarist Samuel Pepys) and merchants of the new middle classes began to own their own carriages in London. But for long journeys horseback remained the commonest form of travel until in the late 18th and early 19th century main roads were provided upon which a carriage could maintain a good average speed.

From the private carriage it was an easy transition to the hackney coach. The hackney was a device for sharing the overhead costs of a carriage among a number of persons, each of whom was prepared to pay part of the running costs and a contribution toward the overhead costs in return for the exclusive use of the vehick for a limited time. In London and in Paris the hackney vehicle appeared in the 17th century, and as soon as it had become common in London it began to compete with a much older form of public transport, the boats of the Thames watermen.

The stage carriage was later in appearing on a large scale, and its full development had to await the construction of a modern road network. It carried the principle of sharing expenses a good deal farther than the hackney, since the running and overhead costs of the vehicle were shared among a number of passengers simultaneously.

Whereas in the 17th century it was still an adventure to travel, most journeys being made on horseback, by the end of the 18th century stage coaches covered the country with a network of services that on the whole were well maintained. The mail coaches operated under contract with the postmaster general and kept to strict timetables, under penalty. By 1836 there were more than 3,000 coaches on the road; from one London tavern alone no fewer than 80 coaches departed every day. But this rapid development was followed by an even more rapid decline; as the railways came into operation, the coaches disappeared from one main road after another.

One of the institutions that also vanished was the posting house, the office, often also an inn, at which horses could be hired for a stage of a journey to draw the traveller's own chaise, or at which both a chaise and horses could be hired for the journey to the next posting house. Costs were high, and after the rise of railways a reserved railway coach or compartment met the needs of the wealthy traveller better.

The carrier's cart was a recognized institution in country districts for many years. It survived the arrival of the railway in many country districts as a purely local facility, until the advent of motor transport. In fact, while long-distance services by road vanished, a new network of road services connecting with railway stations appeared.

Street tramways were pioneered by the American George Francis Train, who introduced short lines of horse tramway in both the United States and Great Britain in the middle of the 19th century. These lines had, however, no statutory authority and in Great Britain lasted only a short time, large-scale development having to wait until the passing of the Tramways act of 1870. Between 1870 and the end of the century numerous horse tramways were laid down. In many cases, upon the expiry of the initial concession, the local authorities exercised their rights of purchase and a second stage of development followed which coincided with the general application of electricity to tramways.

The electrified tramways were extended for considerably longer distances than the old horse tramways, and generally proved successful competitors of the railways for suburban traffic. In some cases they were extended outside the city boundary to run over reserved tracks apart from the road. The end of the tramway era came in sight when the growth of motor traffic had increased street congestion to such a point that the presence of rail-bound vehicles could no longer be tolerated in the busiest streets. Many tramways were converted to trolley buses (electrically propelled, steerable vehicles on rubber tires, designed like omnibuses, which draw their power from overhead wires). The general trend however was toward the replacement of tramways by motorbuses, in view of their greater flexibility.

The horse bus started in London with George Shillibeer's pioneer service from Paddington to the City in 1829. Throughout the 19th century horse buses were increasingly used in the principal cities, but their development was checked for a time when electric trams took the lead. Soon afterward, however, the internal-combustion engine proved that it could provide a reliable and satisfactory form of motive power for the omnibus, and by World War I the horse bus had been generally superseded by the motorbus. This developed steadily; the modern vehicle differs from its predecessors principally in burning diesel oil instead of gasoline.

The growth of the motor-coach lines connecting important towns and holiday resorts stemmed from the old horse-drawn wagonette or charabanc. In the early 20th century the first motor charabanc was designed; from providing occasional joy rides it developed steadily into a nation-wide network of passenger coach services, in many cases highly competitive with the railways.

The Railway: Its Economic Significance.—The technical aspects of railways are fully covered in other articles. Attention is drawn here to the place of the railway in general economic history.

In the first quarter of the 19th century the flanged wheel on the iron rail offered the most promising scope for the application of steam power, because of the limitations of the then-existing road system, the absence of efficient vehicle suspension systems and of pneumatic tires, and the excessive tolls imposed by the turnpike trusts on steam road carriages. The engineer who made the greatest single contribution to steam locomotive design, George Stephenson, happened also to be a great designer of railway systems. A powerful advocate of the steam locomotive, he was commissioned to lay out lines of railway upon which the locomotive could show to the best advantage its capacity for both heavy haulage and high speed.

At the same time as Stephenson and other engineers were demonstrating the technical abilities of the new form of transport, the growing industrial wealth of Great Britain was making available the flood of new capital required for the construction of a vast network of railways. This was accomplished, in the main, over a period of no more than 40 years, from 1830 to 1870.

The revolution achieved by the railway in the economic condition of many countries during the 19th century was paralleled only by the further revolution wrought during the 20th century by the advent of motor transport. For the first time cheap and rapid travel to all parts of a country became widely available; the markets for raw materials and manufactured goods widened enormously, and costs of production fell as output increased.

Before the nationalization of railways in 1948 (Transport act, 1947), the state took no part in railway construction in Great Britain; government intervention was directed almost exclusively at the protection of the public safety, at the control of rates and fares and at ensuring the control of monopoly in the public interest. The fierce intercompany competition of the mid-19th century tended. however, constantly to dwindle by voluntary amalgamations, agreements for pooling schemes and agreements on rates and fares. Finally, after World War I, the British government by the Railways act of 1921 amalgamated all the principal railways into four groups, which in turn were unified under public ownership under the Transport act of 1947.

In the United States, also, private enterprise of a competitive character was the mainspring of railway development, and well into the 20th century it continued its traditional role. In most continental European countries, however, the state had early accepted the duty not merely of regulating but of participating in railway construction-especially in the economically less advanced countries, where private capital was not sufficiently abundant or sufficiently enterprising to cover the needs for railway construction. Development of transcontinental railways also demanded state action, and in some cases also became a measure of political expansion and influence, as, for example, the development of the Baghdad railway (*q.v.*) and the Trans-Siberian railway, which led to the further opening up of the vast resources of Siberia and closer relations between Russia and China. In Europe, especially, the need to use railways for the'movements of troops led to the development of strong state control.

Both in Great Britain and in the United States railways during the 19th century were not subject to the stimulus of much external competition from other forms of transport. Consequently, when road motor competition arose in the first quarter of the 20th century the railways were often slow at first to meet the challenge and adjust their traditional ways of doing business. A consequence was that while the railways continued to carry something like the same volume of traffic as 50 years previously, this represented a greatly reduced proportion of a greatly increased total volume of traffic offering. The ever-increasing balance of traffic was mainly carried by road. The problem of road-rail competition is further discussed in the following section.

The most effective technical answer by the railways to road competition was the abandonment of steam traction and the adoption of either electric or diesel power. Electrification proved indispensable for handling dense volumes of passenger traffic, as in suburban services; while by the middle of the century diesel traction was ousting steam rapidly in North America and many other parts of the world.

Organization of Freight Road Transport. — It was during World War I that the potentialities of road motor transport as a serious commercial rival to the railways were first demonstrated. The production of motor vehicles on a large scale for military purposes was combined with their use for the conveyance of men and supplies in various theatres of war, including the mobilization of the Paris taxicabs to rush troops to the battle of the Marne and the dispatch to the front of large numbers of London buses.

During the first quarter of the 20th century the railways had already experienced successful competition from electric trams and motorbuses for short-distance passenger traffic, which in most cases they had not attempted to meet. The rapid growth in the use of private cars, however, made inroads upon the previous railway monopoly of long-distance passenger traffic, and a third party to the competition entered when motor-coach lines were opened on roads which covered the same ground as the railways. So far as passenger traffic was concerned the competition was of a straightforward character, and in certain cases the railways found it possible to make concessions in their fares which enabled them to retain a substantial volume of traffic. As regards freight traffic, however, the problem was complicated by the existence of different systems of charging.

After World War I, large numbers of army surplus trucks (lorries) were offered for sale and many demobilized men invested their war gratuities in the purchase of vehicles. A period of rapid development and keen competition in road haulage followed, during which serious inroads were made into many railway traffics. Road transport generally concentrated upon those traffics which were highly rated under the railway classification and for which it was therefore easy for the road operators to offer lower rates.

The railways, in the days when they held a virtual monopoly of inland transport, had evolved a system of differential charges based mainly upon the assumed liability of different types of goods to bear different levels of transport costs. Thus coal and minerals, being relatively cheap in relation to their weight, were charged a much lower rate per mile than manufactured articles, textiles, etc. The theory was that, "taking the rough with the smooth," this system would encourage the maximum volume of traffic to pass, even though it might involve some element of subsidy as between the consignors of different types of goods. The road haulage operators, however, charged more or less uniform scales irrespective of the nature of the articles carried. Their charges were designed simply to cover the costs of operating the vehicle, with a margin of profit. The railways claimed that this competition was unfair in the sense that their road competitors were only carrying the "cream" of the traffic and were leaving them with the relatively unprofitable parts, which nevertheless in the national interest must continue to be transported and which could not bear a higher charge.

Between World Wars I and II this transport problem arose in practically every highly industrialized nation. The attitude of governments was generally that they desired to keep the railways in being and efficient, since they remained essential for heavy industrial traffic and would also be vital in time of war. At the same time, they did not wish to strangle or restrict unduly the development of a new and progressive service, which in many respects had advantages over the railways since it could give door-to-door deliveries without intermediate handling and for certain forms of transport was also cheaper.

In most countries a partial solution was found through some form of licensing of road vehicles. In Great Britain licensing of passenger services began with the Road Traffic act of 1930 and of goods vehicles with the Road and Rail Traffic act of 1933. In the United States the principal statute was the Motor Carrier act of 1935. These measures introduced a licensing system for vehicles. Existing operators were generally entitled to licences in respect of their existing services, but were obliged to submit proof of need for extensions. In Great Britain proof of need applied merely to the acquisition of further vehicles, but in the United States it also applied to the routes to be served.

In Great Britain the Labour government of 1945–51 decided that this system had failed to produce adequate co-ordination of transport facilities, and it nationalized long-distance road haulage under the Transport act of 1947; the subsequent Conservative government repealed these provisions and embarked upon denationalization. In the United States competition continued to be regarded as the best safeguard of efficiency, subject only to the principles of licensing and public control laid down in the Motor Carrier act. It became clear, however, that the Motor Carrier act had not operated to prevent the expansion of motor-truck lines, which took place on a spectacular scale after the end of World War II.

WATER TRANSPORT

Primitive Boats. — Water transport usually requires less effort than transport by land, and is often more highly developed among primitive peoples. The earliest type of boat is the raft, made of grass, logs of wood, bundles of reeds or other light materials tied together, on which man can float. Such was the raft of the Tasmanians, made of eucalyptus bark tied in cigar-shaped bundles nine or ten feet long, thinning at either end. Similar floating rafts of varying materials were used by early Egyptians on the Nile and by the Incas on Lake Titicaca. Inflated skins are used among the pastoral people of western Asia and North Africa, and inverted pots are used to support rafts for ferrying across the Nile river. The coracles of the ancient Britons, described by Pliny and still used in modern times in Wales and round the coasts of Ireland, the skin-covered canoes used by hunters in British Columbia and the bullskin boats in the western states of the Cnited States are varying developments of the same type.

The finest examples of skin boats are the Eskimo umiak and kayak. The umiak is the boat commonly used for hunting large game. The kayak is seldom used for transport but is essentially hunting and fishing equipment. Skin boats are mostly fitted for temporary use; great care has to be taken in beaching them, while, if they are left in the water, the skins soon rot. Both kayak and umiak, though still important, were less widely used than formerly in the 20th century.

FROM WISSLER, "THE AMERICAN INDIAN" (OXFORD UNIVERSITY PRESS)

ESKIMO KAYAK, MADE OF SKIN STRETCHED OVER A TIGHT FRAME. WORK WITH A HOLE FITTING THE HUNTER'S WAIST

Where suitable trees of good size are found, a simple type of boat is made of a sheet of bark. The Lillooet canoes of British Columbia were formerly always of bark, poplar, cottonwood, spruce, cedar or birch. In the spring two rings were cut around the tree trunk, with a line connecting them, and the bark was pried off in one piece. This was fixed to a wooden framework by sewing with root fibres, and all the crevices were caulked with moss and gum. The Australian bark canoes are of eucalyptus. A large sheet is peeled off, the ends are turned up and either tied or sewed, and the joints are caulked with resin.

The boat made out of a solid tree trunk has many advantages. Ancient dugout canoes, sometimes 50 to 60 ft. long, are found in British peat bogs, but it is not possible to date them with any precision.

The finest and most varied boats are found among the islands of Polynesia. where there are relics of primitive types, rafts of poles lashed together or bundles of bulrushes. The Moriori of the Chatham Islands used to venture out to sea, 60 at a time, on a raft of flax flower stems (Phormium *tenax*) floating on sea kelp bladders. Beautifully balanced dugout canoes, with or without outriggers, and carvel-built plank boats ingeniously lashed together with cord are universal. and in these long voyages of hundreds of miles from island to island are undertaken.

Early Ocean Shipping.—The Phoenicians, Greeks and Romans were able to navigate the ocean in vessels equipped with sails and with one to three banks of oars, and it was by means of these craft that they established and maintained their colonies. The Roman armies and their equipment and supplies were transported to Carthage and Gaul in these boats. The early civilizations developed in river regions, with special opportunities of production and transport, and about the Mediterranean, an inland sea providing a navigable highway.

The mariner's compass, though the properties of the lodestone were known in China and India long before they were in Europe, did not have much influence in the east because the orientals were not maritime people; but in Europe, from the 14th century on, mariners could sail by the compass whither they uould. and by the end of the 1jth century the sailing vessel had carried men to America and around Africa to India.

Shipping From the Middle Ages Onward.—The principal shipping routes were concentrated in the Mediterranean until trade developed with the new world, with West and South Africa and the far east. Genoa and Venice were the most important trading powers in the Mediterranean. The Mediterranean ships were of two distinct types, the sailing vessel and the galley. The sailing vessel had a considerable beam in relation to its length, and consequently a good cargo-carrying capacity. The galley was narrow and built for speed; a vessel of war: it could also carry a limited amount of cargo, generally articles of high value, and it was the principal means of communication between Venice and its trading outposts.

The galley was unsuited for the great oceans, where the sailing ship pioneered the main trading routes. But the broad distinction between the wide-beamed cargo vessel and the narrow, faster galley was repeated in later centuries when British trade was largely carried on by two types of ships, the East Indiaman and the free trader. The East Indiaman was the large sea transport, up to 1,500 tons, belonging to the East India company; it was armed to repel attacks by pirates and operated a "liner" type of service. The free trader on the other hand was a lighter, faster vessel which was developed in the West India trade but which eventually penetrated wherever a profitable cargo could be found. It was the forerunner of the cargo tramp of today.

As late as the 17th and 18th centuries it was common for a merchant engaged in overseas trade to own his own ships. A voyage was a single trading venture. The amount of capital required for such ventures was of course considerable; but, until it became legally possible to set up limited liability companies, the risks could be shared only by taking in partners. It became customary for the ownership of a vessel and its cargo to be divided into 64 shares, of which the various partners took up as many as they could afford.

With the growth of specialization that followed the Industrial Revolution. and the increasing supply of capital for investment, it became less common for a merchant also to be a shipowner. Shipping services then developed in two main directions—the establishment of liner services giving regular sailings and carrying both goods and passengers at fixed charges, and the provision of tramps which had no fixed itinerary and would sail to any port in the world if a profitable cargo could be obtained.

The differences in organization between liner and tramp services were reflected in different systems of charging. The liner companies organized themselves in shipping conferences, which agreed on the rates to be charged and published schedules of fares and rates to which all the member companies adhered. Traders were induced to leave their traffic with the conference lines by the offering of rebates, which were forfeited if a trader employed other shipping lines. Tramp steamers, on the other hand, were frequently owned by small companies, and their rates fluctuated in accordance with the world demand for shipping.

The wooden sailing vessel gradually gave way to the steel steamship during the first three-quarters of the 19th century. Robert Fulton's "Clermont" inaugurated steamboat navigation on inland waterways in 1807; the "Savannah" made an early transatlantic crossing with steam power in 1819; the screw propeller was invented in 1836; and the iron hull dated from about 1840. The Inman line adopted the propeller in 1850 and the Cunard line did so in 1862. The "Great Eastern," the giant of its time (floated 1858). had not only a screw propeller but also paddle wheels and six masts for sails. Twin screws were first used on warships in 1880 and came into use on merchant vessels in 1881. Steel began to replace iron in hull construction about 1880.

The relatively slow technical development of the ocean vessel was largely the result of the limitations of the marine engine. Engines with low steam pressure and consequently long, slow piston stroke could be used to drive paddle wheels by direct crankshaft action, uhereas gearing and loss of power were involved in giving the propeller the requisite speed. While direct-acting engines were used to drive propellers as early as 1854, it was not until after 1870 that the compound steam engine came to be exclusively used; then the ocean vessel developed rapidly in speed, size and economy of service.

The turbine. which had been invented in 1884, was introduced in warships and large, high-speed ocean vessels about 1900; but while the turbine uas superior to the reciprocating engine for some purposes, its use did not involve a fundamental change such as accompanied the introduction of the internal-combustion engine named after its inventor. Rudolf Diesel. The diesel engine did away with boilers and furnaces, it occupied less space than steam equipment and thus added to available cargo capacity. It consumed much less fuel, gave a vessel a much greater sailing range and was more economical to operate. For these reasons it was largely adopted for vessels of moderate size and speeds. One check upon the general dieselization of shipping was the higher cost of installation and the weight of the diesel engine and its auxiliaries, but these handicaps have been largely overcome.

During the 19th century the Cnited Kingdom had slightly more than 50% of the world's shipping tonnage. During World War I a large part of this was sunk and the United States appeared as a large-scale operator of shipping. Between World Wars I and II the British share declined to less than one-third of the total, and after World War II it was between one-fifth and one-quarter.

Air competition after World War II seriously affected the volume of high-class passenger traffic upon the main ocean routes; but its effect was masked for a time by the shortage of shipping that prevailed immediately after the war and the consequent pressure upon shipping space. Air transport did not, however, generally affect the demand for freight except in the case of articles of high value in relation to weight, especially perishables. There seemed a good prospect that a reasonable equilibrium would in fact be achieved between air and shipping services. under which each could play its proper part.

Canals and Inland Waterways.—The first modern British canal was promoted by the duke of Bridgewater to connect Worsley, and thus Liverpool, with Manchester. It was opened in 1761.

On the continent of Europe and in North America, inland water communication generally developed through the improvement of existing natural waterways, with the addition of some artificial waterways—often built and owned by the state; but in Great Britain the canals were generally built by private enterprise. The distances to be covered were not great but, because of the undulating countryside. the canals suffered from the drawback of frequent changes of level and consequent interruption of traffic at locks. They were also generally constructed to a narrow gauge, and even this was not standard throughout the country. Most of the canals could accommodate only the "narrow boat" of seven-foot beam. The wider canals could generally accommodate barges of broader beam, but on some wide canals the locks were too short for the narrow boat. Thus, while Great Britain was foremost in the development of a network of canals, through working was difficult and the system was less well-equipped to survive railway competition than were other systems elsewhere.

The long inland waterways of the continent, such as the Rhine and the Danube, and in America the Mississippi, on the other hand, continued despite the rise of railways to play an important part in the life of the communities they serve. A special place in world transport is also held by ship canals, which, like the Riel canal connecting the North sea with the Baltic, may also have considerable strategic value in time of war. The Suez and Panama canals are equally of great international importance, and free passage through them is safeguarded by international agreements.

The original conception of canals in Great Britain was that the canal company would merely provide a track open to all comers on payment of the appropriate tolls. Canal boats or barges, serving as common carriers, were operated in some cases by boatmen who owned a single vessel, in others by companies that maintained fleets of boats. Traders with premises adjacent to the canals often provided boats for the carriage of their own goods. Lastly, in some cases the canal company operated boats or barges itself, through a subsidiary company.

In Great Britain during the 19th century many canals were bought up by the railways in order to eliminate their actual or potential opposition to the parliamentary powers which the railways were seeking. Some canals, however, such as the Aire and Calder Navigation, which connects an important coal field with a port, continued to play a useful part and remained financially solvent. But despite various attempts to rehabilitate the canal system, no substantial capital investment could be attracted for this purpose. Eventually the Transport act of 1947 brought practically all the canals in Great Britain under state ownership, their management being entrusted to the British Transport commission. The commission undertook a careful survey of the whole of the canal system and reached the conclusion that. out of a total of 2,101 route-mi., only 336 route-mi. offered prospects of a satisfactory return from substantial improvements. while 994 route-mi. should be maintained without substantial expenditure's being justified, and 771 route-mi. should be abandoned as soon as opportunity offered. An important exception to the general nationalization of the canals was the Manchester Ship canal (*q.v.*).

AIR TRANSPORT

General Characteristics. — The economics of commercial air transport are dominated by the need to expend considerable energy merely to keep the vehicle on its "track"—in other words, airborne. Fuel consumption must therefore always be high in transporting a given load from place to place. Another feature of air transport is the high cost of safety precautions. On the other hand, the high speeds achieved mean that a regular and frequent service can be maintained over long distances with a small number of operating units.

Like shipping, air transport undertakings do not generally own the terminals from which they operate; most are publicly owned. Dues are charged to air-line operators for the services provided.

Between World Wars I and II commercial air transport generally required to be subsidized. This was done either by direct payments from the state, as in the case of the subsidy which the United Kingdom government paid to Imperial Airways Limited, or through the placing of mail contracts on a subsidy basis, as in the case of the United States air lines. Private flying developed more sloivly than was at one time expected. Charter transport, providing a taxi service of the air, steadily developed, however, and had become an important factor at peak holiday periods in carrying the overflow from the regular air lines.

In Great Britain the first civil air lines started, financed by private capital, shortly after World War I. They led a precarious existence. and eventually the four principal operators were amalgamated in 1924, under government pressure, to constitute Imperial Airways Limited. The government held some shares in this company and appointed two directors to the board, undertaking to give it a decreasing annual subsidy for a period of years. The main task of the new company was to develop a system of air communications throughout the British empire, in addition to maintaining the services to the continent and the Channel Isles that had been provided by its predecessors. The air service from Cairo to Basra, Iraq, was opened in 1927, and the first through service between England and India started in 1929. This was extended to Singapore in 1933, and the first London-to-Australia through service opened in 1935. Air routes reached Cape Town in 1932.

Shortly before the outbreak of war. under an act passed in 1939, Imperial Airways was amalgamated with British Airways, an organization formed in 1935 which operated various continental routes, to form the British Overseas Airways corporation (B.O.A.C.). This was a nationalized public corporation, whose board was appointed by the government and whose general policy was subject to government approval. After the war, British European Airways (B.E.A.) was set up to take over the services between Great Britain and the continent, so that B.O.A.C. serves the long-distance ocean routes while B.E.A. links Great Britain with the European continent. The two public corporations are complementary to each other and do not compete.

For a full account of the development of passenger travel by air, see the article AVIATION, CIVIL.

Cargo Transport by Air.—The first notable event in the evolution of the air cargo carrier was the Zeppelin airship launched in Germany in 1900. Although passenger business was paramount, valuable papers and small packages of relatively large unit value were also transported—essentially the beginning of air express. The Hamburg-American line, acting as agents for the German Zeppelin company, announced in 1932 the first regular transoceanic sailing schedule for the "Graf Zeppelin." The service was expanded later to include both North Atlantic and South Atlantic crossings, until World War II forced its abandonment.

While interest in lighter-than-air vehicles grew apace in Europe, the United States turned its attention to the possibilities of heavier-than-air craft. World War I created a great demand among European nations for aeroplanes and stimulated C.S. manufacturers to focus more of their energies upon their development. By the end of the war sufficient progress had been made to bring about the establishment of the first regular airmail service. A line began operation May 15, 1918, between New York city and Washington, D.C., and gradually the service mas extended until July 1, 1924, when the transcontinental mail service was formally inaugurated. While this activity was in progress, the Universal Postal union was alert to international airmail possibilities. As early as 1920 at the congress of the Universal Postal union at Madrid an international airmail service was discussed! and in 1924 such service was made the subject of official regulation.

Ocean steamship lines sought permission to operate air-cargo services. Although they were not given this privilege, some lines held financial interests in air lines and also entered into special contracts with air-line companies for cargo services between stipulated ports.

During World War II the great possibilities of the plane for transporting heavy loads were first realized. However, such use of the plane was not commercial. The post-World War II years marked the beginning of a rapid growth in scheduled freight and express services and in the use of planes exclusively for such purposes. The Railway Express agency handled nearly all the cargo hauled by the air lines. This was a matter of convenience, because the air lines had not developed a transportation service between the airports and the points of origin or destination of their cargo.

Another aerial device tested as a carrier as early as 1939 was the helicopter, employed for short-haul duty, particularly the carriage of mail. It has also been widely utilized for rescue work at sea and on land. involving the dropping of foodstuffs and other emergency supplies as well as the transference of persons from hazardous locations to places of safety.

TRANSPORT AND THE STATE

Public and Private Ownership and Forms **of** Organization — In 1955 there was a large variety in the forms of organization and ownership in transport, extending from the British Transport commission with nearly 900,000 employees to one-man businesses operating a single motor truck or bus. Both private capital and the state provide important transport services.

Individuals, through their ownership of private cars, possess a degree of mobility unknown in any previous age. Trading firms can provide motor vehicles to carry their own goods with, in most countries, a wide degree of freedom. They also sometimes operate canal barges for the same purpose; and some large corporations even own oceangoing steamers, particularly for the carriage of oil, iron ore and fruit. Traders also in many countries own specialized railway cars (*e.g.*, refrigerator cars) for the transport of their own goods, although in such cases they do not of course perform the haulage.

Public transport services are provided on the roads and on canals by large and small firms and by individuals. The character of railway operation however requires investment of large amounts of capital, and railway ownership is therefore confined to corporations, either privately or publicly owned, or to the state.

Air lines are generally operated by companies or corporations, which may be either privately or publicly owned. The operation of urban passenger transport, whether trams, trolley buses or motorbuses, is divided between privately owned companies, public corporations and municipalities. Shipping is generally carried on by private capital, though in some cases the state has itself entered this field, generally setting up a publicly owned corporation for the purpose rather than entrusting the management to a department of state. The director-general of the French National Railway company has pointed out that two main trends can be discerned in transport organization. The first is the tendency toward consolidation and centralization.

The 19th century was the steam age. Steam was the chief source of power both for manufacturing and for transport. In factories, central enginehouses provided, by means of shafting and belts, the power for large numbers of machines. Centralization of the power supply was accompanied by a trend toward consolidation and enlargement of individual business firms. This trend was particularly marked in railways, where amalgamation tended to produce a continually larger scale of operation. At sea the same tendency was apparent; shipping companies consolidated and grew in size, just as the size of their vessels increased.

The culminating point of this process of consolidation was probably reached in Great Britain when the Transport act of 1947 amalgamated the four railway companies into a single state-owned system and brought under the same control the canals, a large part of the docks system of the country, the London passenger transport services and also long-distance road haulage. Although a subsequent government enacted that road haulage should to a large extent be returned to private ownership, the British Transport commission remained probably the largest transport undertaking in the world, apart, possibly, from the Russian state railway system. Its railway system is approached in magnitude by the state railways of various European countries; but it is unique as a single public body providing so many diverse forms of transport.

A contrary tendency, however, began with the advent of the internal-combustion engine and electric power. The main effect of using these prime movers is greatly to reduce the scale upon which power can be economically applied to particular tasks. Instead of a steam locomotive hauling a railway train weighing several hundred tons, a truck or lorry will carry anything from half a ton to 20 tons of goods directly to any point to which the road system penetrates. Equally, in factories, small electric motors can be employed to give power to each individual machine.

Accordingly, it is now much easier both for the individual to have unlimited rapid personal transport and for the trader to meet his own transport requirements through the employment of trucks. There has thus been remarked on the one hand a tendency for public transport to grow in size and (since competition within the industry always tends to become less effective) for the state to step in to protect the interests of the public. On the other hand, transport of the most flexible kind has become increasingly available in private hands, and represents probably the most effective safeguard of the consumer. The main clash in fact is not, as in the 19th century, between rival common carriers, operating different forms of public transport, but between public transport and private transport.

TRANSPORT, MILITARY. This is a broad term that includes all forms of ground, water and air transport employed in preparing for or prosecuting war. Most of it is conventional transportation put to military use but some is specially designed to meet peculiar military requirements. So basic is military transport in the conduct of war that without it the organization and utilization of large bodies of men as armies would be impossible. It is transportation that makes it possible for military units of size to take to the field, to maneuver over wide areas, to wage wars in distant lands. In the absence of transport, warfare would be primitive indeed, confined to short raids by small groups armed only with light, simple weapons.

This article is organized according to the following outline:

I. CLASSIFICATION OF VEHICLES

A. GROUND TRANSPORT

Ground transport, the most varied and important item in military transport, ranges from the individual porter. equipped with gear devised to assist him in carrying burdens, to vehicles mounted on wheels, tracks, runners, rollers or combinations thereof and propelled by animals or self-contained power units. It includes the one-man cart, the animal-drawn wagon, the railroad locomotive and car and innumerable types of motor vehicles and trailers designed to roll over highways or operate across country. In the military forces of the western nations the motor vehicle became, during the first half of the 20th century, the dominant form of ground transport in the field. Military vehicles can be distinguished from each other in a number of ways. Usually they are classified according to assignment. use and purpose.

1. Organic and **Nonorganic.**—When classified on the basis of assignment they are listed as organic and nonorganic vehicles. The first are those assigned to military units according to their tables of organization and equipment; nonorganic vehicles are not assigned to specific units but may be temporarily attached to them.

2. Administrative and Tactical. — When classified according to use, the general terms that apply to military vehicles are administrative and tactical. Administrative vehicles are normally commercial-type vehicles suitable for routine military transportation not directly related to combat operations. Tactical vehicles are those employed in the field in connection with combat and tactical movements. Since many vehicles in this category also meet the requirements for routine operations, they are often employed as substitutes in administrative service. When this is done they are classified as administrative vehicles.

3. General and Special Purpose. — General-purpose vehicles are conventional types modified to meet a variety of military transportation needs. Included in this group are trucks, trailers, semitrailers, special-equipment vehicles mounted on a standard chassis, passenger cars and buses. The term special-purpose vehicle embraces all those built to meet requirements which cannot be met by modifying the chassis of a general-purpose vehicle. It comprises fire trucks, tractors, amphibious trucks and combat vehicles. The latter is by far the largest category, including such types as armoured cars, artillery carriages and tanks. Combat vehicles are not usually considered military transports since movement of men and supplies is not their main purpose. How effective they can be in emergencies as cargo carriers, however, has been demonstrated in warfare many times. A classic instance was the use that Field Marshal Erwin Rommel made of tanks in towing trucks and trailers when faced with a shortage of fuel during his long retreat across the Libyan desert following the battle of El Alamein in World War II.

B. Water Transport

Water transport used for military purposes includes all types of floating equipment ranging from barges, lighters and small craft to huge ocean-going freighters and passenger liners converted to troop carriers. Since most of the vessels employed for military purposes are taken from the carrying trade, their military classification follows that of the shipping industry. In general they are grouped as harbour craft, passenger. combination passenger and cargo, cargo and special-purpose vessels.

1. Main Types.—Harbour craft include all floating equipment such as tugs, lighters, barges and boats normally used in ports to handle ships or move men and things from ship to shore or from shore to ships at anchorage.

Passenger ships are personnel carriers ranging from small coastwise vessels to huge ocean liners like the "Queen Mary" and "Queen Elizabeth." Although designed to transport people they can carry some light, compact freight.

Combination passenger and cargo vessels can lift both men and freight. Normally they ply their trade between ports where full-fledged passenger service would be unprofitable.

Cargo vessels are designed to lift freight of every description. To get the most economical use out of them requires careful prestowage, loading and discharge planning. They are fitted with large hatches and booms that enable some to handle weights up to 60 tons. Known in the trade as freighters, they usually contain a few spaces for passengers.

The special-purpose class comprises a variety of ships designed to carry special types of cargo. On the whole they are unsuited for transporting general cargo but often they can lift cargo similar to that for which they were built. In this group are tankers, colliers and seatrains. Tankers are used primarily for transporting bulk petroleum products, colliers for coal and ore and seatrains for railroad rolling stock. Easily loaded and discharged, the latter proved invaluable during World War II in speeding tanks, vehicles and locomotives to overseas theatres of operation.

2. Landing Craft and Ships.—Because the assumption of the offensive in World War II required the western Allies to undertake amphibious operations, the world witnessed the appearance of a host of novel vessels for military transport. The development of some, mainly small boats and craft for ship-to-shore operations, antedated the war. Among them the Higgins boat, a craft of shallow draft that could be beached and retracted easily, was the most promising. Tested by the U.S. marine corps in 1941 in maneuvers, it proved satisfactory in moving men, tanks and artillery ashore.

After the entrance of the United States into World War II, the emphasis in both that country and Great Britain switched to the design and production of landing craft and ships needed for the extensive amphibious operations that the U.S. and British military leaders agreed would have to be undertaken if victory over the Axis powers was to be won. Only with thousands of craft and vessels, capable of landing large bodies of men quickly and sustaining them by over-the-beach supply operations until ports could be acquired and worked, could Germany and Japan be dislodged from the areas they had overrun. Because the amphibious landings often involved long voyages and prolonged operations, some of the types of vessels in the building program had to be entirely seaworthy. In the development and production of many types the Americans and British participated jointly.

Since the vessels were designed to meet peculiar military needs, they can be placed in the special-purpose class. Most important among them were the landing craft, infantry (LCI), the landing ship, tank (LST), the landing ship, medium (LSM), the landing ship, dock (LSD), the landing craft, medium (LCM), the landing craft. tank (LCT) and the landing craft, vehicle, personnel (LCVP). The majority of these ships and craft were shallow-draft roll-on, roll-off vessels that could be beached under favourable hydrographic conditions. This enabled them to discharge their loads quickly without first transferring them to small boats, lighters and craft, thus reducing the hazards of transfer at sea and the turnaround time.

Chief among the personnel carriers in this group was the LCI. It was powered by a diesel engine and had accommodations for 200 men plus space for 30 tons of cargo. The ship was equipped with twin ladders on both sides of the bow and troops could be disembarked into shallow water or directly onto beaches. Among the vehicle carriers developed during World War II were the LST and the LSM. Both had ramps built into their bows and flat bottoms that permitted them to disgorge vehicles directly to docks or beachheads. When track was installed on the LST's and rail ramps were erected on the beach to bridge the water gap between shore and ship, they could handle railroad rolling stock equally well. Completely seaworthy, the LST and LSM could navigate oceans with sufficient speed to permit them to sail in slow convoys.

The LSD was similar to the LST but larger. Its main purpose was to carry amphibious vehicles long distances over rough waters. The effectiveness of the ship was demonstrated in the Pacific campaigns of World War II and during 1958 in the resupply of the Chinese Nationalist garrisons on Quemoy.

The LCT and the LCM were smaller in size than the LSM. Built to carry a few tanks or motor trucks, they could operate efficiently in calm seas over short distances. The LCVP was both a vehicle- and a personnel-carrying craft. Its normal use was in ship-to-shore operations.

Although all the above vessels were designed to serve as assault shipping they could be used equally well in resupply operations. Produced by the hundreds during World War II in U.S. and British shipyards, they accounted for much of the success attained in amphibious operations. If one type were to be picked above the others for effectiveness, the laurels would probably go to the LST, a vessel first developed by Great Britain and later modified by the United States. Without doubt it was one of the best of the vessels originally designed for beach landing. So valuable was it that after World War II both the U.S. army and the U.S. navy encouraged the shipping industry to build similar but larger and faster models for commercial use in order to establish a pool of roll-on, roll-off vessels on which they could draw in an emergency.

C. Air Transport

Air transport is the most recent addition to military transport. Used but slightly in World War I, it underwent a rapid development between World Wars I and II in all western nations. From small planes capable of lifting only a few hundred pounds of mail, aircraft reached the stage where they could carry tons of cargo and scores of passengers. Startling progress in increasing capacity and speed was made during World War II and equally startling advances were made in the postwar years. Because of the growth of commercial air transportation their exists a vast pool of aircraft in most modern nations that could be converted to military use in time of war. In addition, most nations and particularly the U.S. and the U.S.S.R. have developed both planes and helicopters primarily to lift troops and supplies. Some of the new types are capable of lifting over 100 men and many tons of supply and equipment. Among those specifically designed by the United States to carry troops or cargo, the C-119 (Boxcar), the C-123 (Provider), the C-124 (Globemaster) and the C-130 (Hercules) are the most important.

Known carriers produced by the U.S.S.R. after World War II were the 11-14 ("Crate"), the "Camp," the Ukrainia ("Cat") and the Tu-104A ("Camel"). One large plane, the Tu-114 (Rossiya), had a double-deck fuselage. It was capable of flying between 170 and 180 passengers from Moscow to Peking or Vladivostok at a speed of 570 m.p.h.

II. HISTORICAL DEVELOPMENT

Throughout history, military men have been dependent on some form of transport to enable them to carry the supplies and equipment needed to sustain their operations, More often than not the transport they employed was conventional, typical of the period and region in which they fought. As society developed and the conduct of war became more complicated, the need for transport to fit special military requirements grew. To a large extent it was met by modifying existing transport; in most of man's long history the differences between conventional and military transport have been few. It is only in recent times that military and commercial transports have tended to diverge more sharply, but even so few basic differences exist and the great mass of military transport is still conventional transport adapted to military purposes.

Before the dawn of civilization, primitive man in making war on land carried his supplies and equipment strapped on his back or loaded them on beasts of burden. When traveling over water he used a raft, canoe or crude boat. The invention of the wheel revolutionized land transportation. It brought first the two-wheeled cart and then the four-wheeled wagon into existence. When new sources of power were discovered it made possible the railroad, the steamboat, the motor vehicle and the land-based airplane.

Second only to the wheel in its effect on society was the invention of the sail, which enabled man to harness the power of the wind to propel craft over water. From the days of the Phoenicians, who were among the earliest peoples to equip ships with sails, until the mid-19th century the sailing vessel was the dominant form of water transport. Supplemented at first by man-powered oars, it permitted easy and rapid movement to distant lands. Without it none of the vast overseas colonial empires of the ancient and modern world could have been established and maintained.

A. Men and Animals

Until the early 19th century land transport was simple, and not until the U.S. Civil War, when the railroad was used, was there any great change in military transport. What equipment and supplies man did not carry on his person or load on an animal, he moved in one-man carts or animal-drawn wagons. As military transport, the use of men, animals and animal-drawn vehicles had both advantages and drawbacks. Men, being more agile and intelligent, could operate as porters in rougher terrain and with less care and direction than animals. Horses, camels, donkeys and elephants could carry far heavier and bulkier loads, but they could not operate in all the areas where men could. When harnessed to vehicles, as many were after the wheel was invented, the weight and bulk of the load they moved were greatly increased, but their ability to move over difficult terrain declined.

Which animal was first used to haul carts will probably never be known. It may have been the ox. Slower but stronger and tougher than horses, oxen yoked in pairs could haul much heavier burdens over more primitive roads than could an equal number of horses. It is not surprising, therefore, that for centuries the ox was a leading beast of burden in both military and commercial transportation. Only with the improvement of roads did he give ground to the horse and mule. His decline in military transport was gradual and it varied in time and location. In the United States, for example, ox-drawn vehicles were used by the army until late in the 19th century, long after they had been discarded by the armies of western Europe. The reason was that western Europe had better roads than did the American frontier where most of the U.S. army was stationed. In parts of Asia and Africa carts drawn by oxen and water buffalo served as military transport in the 20th century. Both the Boers and the British used oxen in the South African War and the water buffalo was widely used in the Pacific theatre during World War II.

The use of men and animals as carriers of military supplies is still important despite the development of vehicles driven by steam and internal-combustion engines. That they will continue to be employed for some time to come is probable because they can operate in areas where mechanized vehicles cannot, and because they do not break down or run out of fuel as do machines.

The importance of manpower and animal power in military transportation in the future will, of course, vary greatly with conditions. In Asia, for example, where manpower is abundant and cheap, it is reasonable to believe that porters will continue to be employed. How effective man can be as a carrier was demonstrated in the Korean conflict where, with the aid of an A frame on his back, he probably carried more tonnage than was moved by vehicles. The individual soldier is unlikely ever to escape from being a transporter for the simple reason that he must carry on his person not only weapons and equipment but enough food, water and ammunition to sustain himself in the field for a short time. His burden may be reduced but it cannot be eliminated entirely. Animals, on the other hand, will probably continue to give way gradually to machines in western nations, but it is impossible to predict when they will disappear entirely. Under certain conditions there is still no substitute for them. Even modern armies like those of the United States and England, which had given up their use before World War II, were forced to procure mules and horses during the war to supply forces moving over the rough and difficult mountain areas of north Africa, Sicily and Italy. In Burma the British employed water buffaloes and elephants in addition to mules and horses; in the Philippines the Americans, Filipinos and Japanese frequently resorted to the use of water buffaloes in flooded areas. Water buffaloes will doubtless still be required to haul military supplies through the rice paddies of southeast Asia in time of war, for enough roads to permit resupply by other methods of laqd transport do not exist.

The trend in modern armies after World War II was to lighten the load placed on the soldier and to decrease the time he must carry it so that he could enter battle stripped of nonessentials and untired by grueling approach marches under heavy pack. The American and European infantryman formerly carried between 70 and 80 lb. on his person and often more; the modem soldier usually carries about 40 lb. This reduction in the soldier's burden was bought at the expense of self-containment, though the loss was partially offset by a cut in the weight of certain items of equipment and by improvement in the means of regular resupply. The latter was largely the result of the greater flexibility that came from newly developed motor vehicles and aircraft, the increase in the numbers of both, better communications and improved control of transportation.

B. The Rise of Steam Transport

With the invention of the steam engine in the late 18th century, man for the first time had at his disposal a form of power other than animal and wind that he could apply to transport. By attaching the steam engine to wheels that could run on track, he produced the railroad; by putting it in the hull of a ship and harnessing it to a water wheel he produced the steamboat.

Before the advent of the railroad, which brought new velocity to land transport, wind-propelled sea transport could often outrace animal-drawn vehicles in long-distance movements. Napoleon recognized this fact but could do little about it, for the British navy controlled the seas and could halt the growth of a rival merchant marine at will. With the extensive building of railroads in Europe during the 19th century, making movement by land easy and rapid, the advantage in transportation for waging war passed temporarily to the continental powers. Had it not been for the fact that sailing ships gave way to steamboats about the same time that railroads came into being, the balance in transportation would have swung more sharply than it did in favour of nations that could utilize railways most effectively to move armies to distant points.

By mid-19th century enough railroads had been built in Europe and America to warrant the keen interest taken by strategic planners in their use for military movements. It was not long after that governments, with strategic purposes in mind, began to encourage railroad construction. While more emphasis was placed on this factor by European nations, it was considered by others as well. The role the U.S. war department played in surveying routes for transcontinental railroads is evidence of its existence in the United States.

The first major conflict in which both railroads and steamboats were used extensively was the U.S. Civil War. The supremacy of the North in both, many historians maintain, was a determining factor in the outcome. Because the North had more rail capacity in strategic areas the Federal government was able to move men, equipment and supplies quickly from one front to another. Because it could outproduce the Confederacy in ironclad river boats propelled by steam, it was able to break through the defense barriers along the Tennessee and Mississippi rivers and strike at the heart of the South.

In Europe the first impressive use of rail transport was made by Prussia in mobilizing for war against Austria in 1866. A few years later, in the Franco-German War, railroads proved to be even more effective in moving military forces. The next extensive use of the railroad was during the Russo-Japanese War (1904–05). To sustain their armies in Manchuria, the Russians moved equipment, supplies and reinforcements thousands of miles over their broad-gauged Trans-Siberian railroad. The Japanese, in turn, depended on the South Manchuria railroad to move men and supplies from Port Arthur to Mukden, where the final battle was fought. The Russo-Japanese War was the first war in history in which railroads clearly played a decisive role, although before the end of the 19th century they had been accepted by military leaders as the main means for handling large-scale movements in areas where they existed.

The rise of railroads affected army organization as well as strategic planning in all western nations. So completely did railroads dominate military thinking that few leaders would have disagreed with the head of the French bureau of transportation, when he stated on the eve of World War I that it would be impossible to move an army corps by any other means. Though true at the time, the validity of the concept was soon challenged by highway transportation. Yet it remains a fact that railroads played a dominant role in land transportation throughout World War I and remained the best means for moving large forces in rear areas.

The steamboat gained recognition as a means of military transport somewhat later than the railroad, primarily because of the nature of the major wars fought in the 19th century. Although steamboats were used in the Crimean War by the British and French, it was not until the end of the century, during the Spanish-American and the South African wars, that their effectiveness was fully demonstrated. By this time the steamboat had supplanted the sailing vessel as thoroughly as the railroad had supplanted the wagon train.

C. Ships in Modern Wars

After 1898 the United States, Great Britain, Japan and, to a lesser extent, France all required sea transport in their wars. Endowed in its early history with a strong merchant marine, the United States, when it became a world power, was woefully lacking in ships that could serve as military transports. The famous clipper ships of the pre-Civil War era had long since relinquished their supremacy as fast cargo carriers to steamboats. With their decline went American interest in merchant shipping. By 1870, despite the growth of external trade, most American exports and imports were being carried in foreign bottoms, mainly British. A short-lived revival of interest in shipping around 1880 faded quickly. When the nation went to war with Spain it could barely scrape together enough vessels to transport its armies to the areas of conflict in Cuba, Puerto Rico and the Philippines. During the same period Great Britain, because of its dominant merchant marine, was never at a loss for ships to move troops and supplies to overseas garrisons. Although the lessons of the Spanish-American War were immediately recognized, the United States made no progress in rebuilding a merchant fleet until World War I. It entered that war without a merchant marine worthy of the name. Britain, Germany, France, Japan and even small countries such as Norway and the Netherlands had more vessels flying their flags than did the United States. Strenuous efforts were made to build a merchant fleet during the war, but they came too late to make the United States fully self-sufficient in water transport. Without ships flying foreign flags, and the German and neutral ships seized while interned in U.S. ports, the United States could not have transported and maintained its expeditionary force in France. Notable among the German liners appropriated and converted to transport duty was the "Vaterland," the largest vessel of its day. As the "Leviathan," it carried about 12,000 men each trip.

The cargo-ship construction program inaugurated during World War I would in time have produced enough bottoms to meet the military requirements of the United States. Houever, with the end of the war in 1918 the program was abandoned and with its passing went the plans to make the United States self-sufficient in merchant ships. What vessels had been built were in large part tied up and, years later, sold as scrap. As a result the United States entered World War II little better endowed with a merchant marine than it had been in 1917. As in World War I it leaned heavily at first on foreign vessels, mostly British, Norwegian and Dutch. Fortunately, during World War I U.S. industry had mastered many of the problems of producing ships rapidly; the country also had a ship-construction program set up under the Marine act of 1936 which called for the building of 500 vessels within ten years. This program was quite inadequate to meet the full needs of global war, but it served to pave the way for the mass production of ships.

By concentrating on standard designs, the United States was able to produce vessels quickly on an unprecedented scale. The two chief types became known as the Liberty and Victory ships. Over 2,600 Liberties were built, enough to earn them the reputation of being the leading carriers of World War II. Their main drawback was their slow speed of 11 knots. In this respect, the Victory with its 17-knot speed was far superior to the Liberty and therefore tended to replace it as the standard U.S. ship. Between 1943, when the first Victory slid down the ways, and the end of the war a total of 531 were built. Like the Liberty, the Victory was primarily a cargo vessel, but many were converted to other purposes from time to time as the need arose, particularly to troopships and aircraft carriers.

Great Britain, too, went into a heavy ship-construction program during World War II. In addition, it took over and operated many of the cargo and passenger ships flying the flags of countries overrun by the Germans. Among them were the French liners "Ile de France" and "Pasteur" and the Dutch "Nieuw Amsterdam." To get the greatest possible military use out of the tonnage produced, the shipbuilding program in both the United States and Britain was accompanied by the development and production of new cargo-handling equipment such as fork lifts and heavy cranes. Also stressed was the enlargement of port facilities and the building of harbour craft. One tremendous project, undertaken to facilitate the handling of ships and cargo for the 1944 cross-channel invasion, was the construction in England of two huge artificial ports known as Mulberry A and B. When towed to the far shore in sections shortly after D-day by ocean-going tugs and then assembled, they served to relieve the strain on the Normandy beaches over which the bulk of men and supplies were being moved.

The belligerents constructed thousands of craft and lighters to meet the needs of greatly increased port, offshore and inland waterway activities during World War II. These vessels ranged in size from small launches to huge seagoing tugs, barges and ferries. As water transport they deserve to rank in significance with ocean-going cargo and passenger ships. Among the new types of craft produced were the sea mule, a powerful little harbour craft used to push lighters and small barges short distances; the rhino ferry, a self-propelled barge developed by the British for use off the

Normandy beaches and in navigating inland waterways; and the ocean-going tug. Only three of the latter were built, but they rendered remarkable service, first in towing strings of barges across the Atlantic and later in moving ponderous components of the artificial ports from England to the Normandy beaches. Among the most used transports were the steel and wooden lighters and barges built for port, river and canal operations. Hundreds were shipped in parts to the British Isles from the United States and Canada. After the Korean conflict a unique craft called the beach lighter was developed in the United States. Married to a large vessel of the roll-on, roll-off type, it can take on vehicles at sea and move them from ship to shore.

When World War II ended, many of the vessels produced by the United States during the emergency were placed in the reserve fleet. Some were sold to shipping companies; some were turned over to other countries. During the Korean crisis, many ships in the reserve fleet, mostly of the Victory class, were temporarily restored to service. Meanwhile the shipbuilding program did not stand still as it had after World War I. New types of vessels, similar in design to the Liberty and Victory ships but considerably improved, were constructed. Known as the C types, they developed speeds of from 11 to 20 knots and had gross tonnages varying from 5,100 to 13,000 tons. Construction of a type called the Mariner was begun in 1951. By mid-1958, 35 had been completed. Although built to carry vehicles and cargo, these vessels could quickly be converted to troop transports or hospital ships.

D. The Rise of Motor Transport

Following the railroad and the steamship, the next type of transport to appear was the automobile. It was made possible by the invention of the internal-combustion engine and the pneumatic rubber tire. First designed to carry passengers, it was soon adapted to cargo as well. In the early part of the 20th century the motor vehicle was added to the list of military transports in most western nations. From shaky beginnings in Great Britain, Germany and France, it became the major means for moving modern armies on land. With its capacity to travel quickly on ordinary roads for short distances, it soon challenged the supremacy of animal-drawn wagons as military transport for short hauls. Before World War II it had practically replaced animal transport in several modern armies and was in a position to compete with railroads in long hauls. That it could do this successfully was conclusively proved during that conflict.

The transition from animal-drawn to motorized vehicles in the United States can be said to have begun in 1904 when a few trucks were tested at the United States Military academy. This experiment and a subsequent one a few years later failed to attract favourable attention and by 1914, when World War I broke out, whatever plans the army may have had to supplement animal-drawn with motor vehicles had been abandoned. The western European countries, particularly England, France and Germany, were not so easily discouraged and all three of these powers overcame early obstacles and entered World War I equipped with motor vehicles that soon proved their value.

1. Mexican Expedition. — Profiting by the successful use the belligerents were making of motor transport, the U.S. war department immediately enlisted the co-operation of the Society of Automotive Engineers in designing a $1\frac{1}{2}$-ton and a 3-ton truck suitable for military use. By 1916 enough were available to permit Brig. Gen. John J. Pershing to employ them, with civilian drivers, on his expedition into Mexico in pursuit of Pancho Villa. This marked the first effective use of motor trucks in a military operation by a U.S. force.

By the time the troops were withdrawn from the border, the army had acquired about 2,000 motor vehicles, most of which were commercial types. Their various sizes and makes gave the army its first introduction to the perplexing problem of maintaining and repairing mechanized transport in the field. So serious was this problem that a strong demand arose for standard models that would meet military requirements and simplify the replacement of worn-out parts.
