2. World War I.—As a result, two types of trucks, one with a capacity of from $1\frac{1}{2}$ to 2 tons, the other capable of carrying from 3 to 5 tons, were designed. These vehicles differed from earlier military and commercial models in that they had greater ground clearance, larger engines, radiators and gasoline tanks, four-speed transmission and demountable rims. With the entry of the United States into the mar, the quartermaster general, who had responsibility for design and procurement, sought to develop an all-purpose truck that would meet various military requirements and reduce the difficulties of maintenance and repair. But since the need for large numbers of motor vehicles was immediate, the war department, unable to await their production, bought whatever usable trucks it could locate at home and abroad. The result was that the American expeditionary force in France was saddled with 216 makes requiring 445,000 parts of which only 20% were interchangeable. Thus the maintenance and repair problem, first encountered on the Mexican border, continued to plague the army with confusion and delay.

To solve the parts problem, a standardization board, composed of representatives from the main procuring and using agencies, was set up early in 1918. About the same time the war department organized the transportation service under the direction of the quartermaster general and made it responsible for procurement.

Out of the standardization board's deliberations came a decision to concentrate on a four-wheel-drive chassis designated the TT and several other chassis upon which different types of bodies could be mounted. With this accomplished, procurement and production were on a sounder basis. The military services did not obtain all the motor transport they wanted, but the progress made in motorizing ground military transport in the United States during World War I was astounding. The vehicle strength rose from about 4,000 in April 1917 to 129,154 by the end of the war, an expansion of more than 30-fold.

The rapid increase in motor vehicles was bound to affect the army profoundly. From an organizational standpoint, the most significant result was the establishment of centralized control over motor transport. This was done gradually and was not fully accomplished until Aug. 15, 1918, when the motor transport corps was created. Although abandoned after the war, it was a forerunner of the army transportation corps established early in World War II.

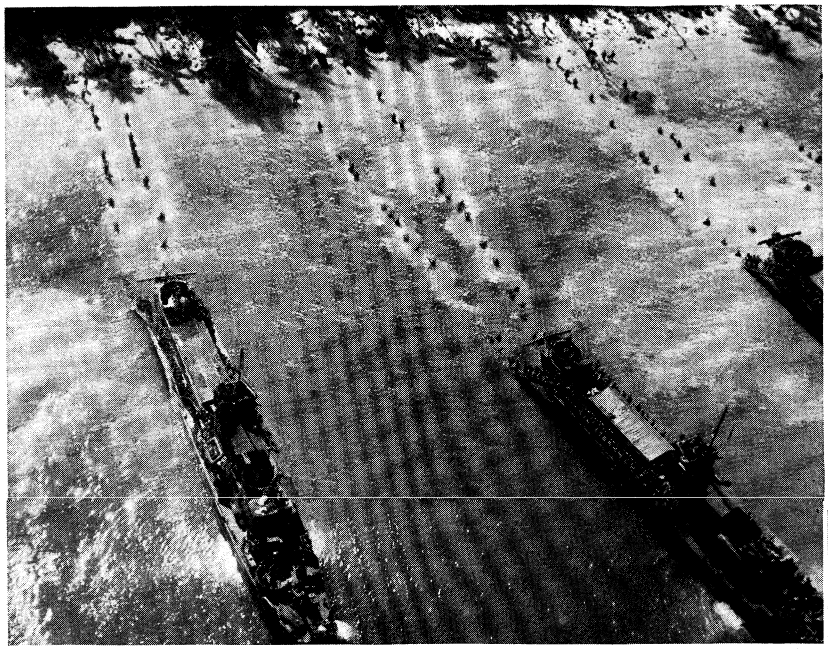
Although motor transport did not play a decisive role in World War I, it was always important and was at times critical. One instance occurred early in the struggle when the French army, in order to check the rapid advance of the Germans toward Paris, commandeered all the motor vehicles it could find in the metropolitan area to rush reserves into the fight. While the railroads moved more men into the battle on this occasion, motor vehicles, in shuttling Gen. Joseph Gallieni's so-called taxicab army to the front, were an important if not decisive factor in checking the enemy's advance.

Another instance occurred during the long, desperate Verdun campaign in 1916 when the Germans again seemed to have victory in their grasp. Their railroads in the forward area destroyed by enemy artillery, the French managed to move an entire corps in ten hours by motor trucks over a road net from Bar-le-Duc to the front which had been earmarked by Gen. Henri Pétain solely for military traffic.

Although World War I decisively proved that motor vehicles were practical in short hauls from railheads forward, it did not thoroughly test their suitability for long-distance moves. In such operations rail transport remained dominant. It was not until World War II that the motor vehicle rose to first rank in theatres of operation.

3. World War 11.—By the outbreak of World War II in 1939, trucks had all but replaced animal-drawn vehicles in the armies of France, Great Britain and the United States. In part, this rise of motor transport is attributable to the great progress made by the automotive industry in the two decades following World War I. Mass production, greater power, improved design and highway construction in this period settled whatever doubts remained that the motor vehicle could replace the horse and mule

MILITARY TRANSPORT VEHICLES OF WORLD WAR II

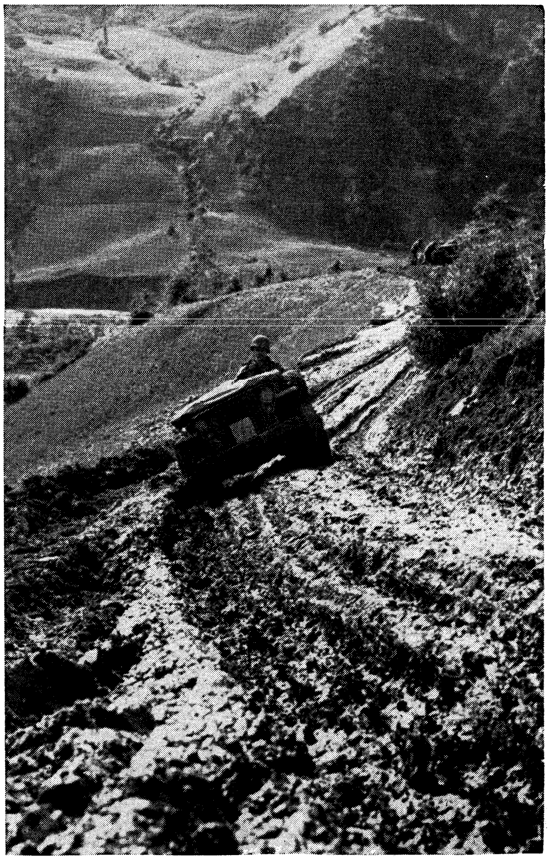


Left: LCI's (landing craft, infantry) unloading on the shore of Morotai island, southwest Pacific, in 1944. The LCI was the principal vessel used for personnel in beach landings. It held 200 men, 30 tons of cargo

Below: M29 cargo carrier, called the "Weasel," a small, tracked vehicle which was particularly effective on snow and ice. It is shown here being used to evacuate the wounded in the European theatre in 1945

Below: Unloading railway equipment from a seatrain at Cherbourg, Fr. Ships brought the equipment from England to France where it was placed directly on rails ashore, ready to operate

Below: The jeep, possibly the most famous vehicle of the war. Ruggedly constructed, with four-wheel drive, the jeep could operate on unimproved roads and trails and could ford streams 18 in. deep when fully loaded. Photograph was taken along a muddy supply road in the Apennine mountains, Italy



Below: Infantry crossing the Moselle river, Fr., in an assault boat, used frequently in Europe for river crossings where bridges had been blown up or where gasoline was not available to power larger landing craft

in the field and challenge the railroad in long-distance hauling, Among the highways built partly, if not solely, for military purposes just before World War II were the *Autobahnen* in Germany. Like the military roads of the Roman empire, they made possible the swift movement of troops to frontiers.

Tests conducted by the U.S. army in the years immediately following World War I proved that motor vehicles were practical for long as well as short hauls. Progress in solving the problem of hundreds of different types and thousands of parts was also made. By 1932 the U.S. army had designed a standardized fleet of 25 truck types mountable on five different multiwheeled chassis. This simplified maintenance and reduced the cost of spare parts to from 25% to 10% of that of the vehicle. This economy was facilitated by co-operation between the army and the automotive industry, with the latter more often than not taking the lead in developing and standardizing vehicles and pushing their use. Economy and standardization in the automotive industry were enhanced by the concentration of production in fewer and larger companies and by the tremendous development of mass-production techniques, made possible by the phenomenal growth of the industry after World War I. In 1918 the total number of automobiles and trucks on the roads of the United States amounted to 6,000,000; in 1941 it was around 32,000,000, more than in all the rest of the world.

Similar although less spectacular was the rise of the automotive industry abroad. In developing motor transport for military use the Germans stressed the half-track type in the belief that it would be more reliable in field operations than all-wheel vehicles. The Polish campaign in Sept. 1939 confirmed this and by 1940 most of German military motor vehicles were half-tracks. The British, on the other hand, clung to the wheeled vehicle while the French went in for all types, full track, half-track and wheel.

The U.S. army concentrated first on its five multiwheel-drive types. Out of this came the $\frac{1}{2}$-ton weapons carrier, the $1\frac{1}{2}$-ton cargo truck and troop carrier, the 24-ton cargo truck, forerunner of the famous 6×6 all-purpose vehicle, the 4-ton prime mover for light artillery and the 6-ton truck and prime mover. Later the ordnance department, which took over responsibility for development and procurement from the quartermaster corps in 1942, designed several other types for special purposes. The United States produced about 3,600,000 military vehicles during World War II. Of this total, 1,440,540 were light and medium trucks, 816,807 were light-heavy trucks, 155,146 were heavy trucks and 1,221,922 were trailers and miscellaneous vehicles. Most of the trucks used gasoline for fuel but some, especially prime movers, ran on diesel oil. The huge U.S. output resulted in a ratio of one vehicle to every four men in France in 1945 as compared with a 1 to 40 ratio in 1918. The ratio in the army as a whole in World War II was 1 to 5. Of the total U.S. truck production, 750,000 were sent to Allied nations under lend-lease agreements. Among them were the ubiquitous jeep, a $\frac{1}{4}$-ton, four-wheel-drive truck and the 24-ton amphibian dukw (or duck). The jeep was similar to a vehicle the Germans had developed just before the war and used with considerable success in the Balkans. Both it and the jeep could negotiate terrain that was impassable to other wheeled vehicles.

The dukw was both a boat and a 2%-ton truck, constructed so that its engine could apply power to propellers when in water and to four wheels on land. Equipped with high-flotation tires that could be inflated or deflated by the driver when traveling over submerged sand bars or beaches, the amphibian was the best vehicle yet produced to carry cargo from ship to supply dumps behind the shore line. Used in every major Allied amphibious operation from the beginning of the Sicilian campaign until the end of the war, it rendered such valuable service that it is often listed as one of the several inventions that made the Allied victory in World War II possible. Toward the close of that war its effectiveness in river crossings was demonstrated in western Europe and in the U.S.S.R. So highly regarded was the dukw that all nations, including the U.S.S.R., equipped their armies with it or with models similar to it. The United States after World War II produced a family of amphibians patterned after the dukw. The largest was the barc, a huge amphibian capable of carrying the heaviest tanks and equipment or 100 tons of cargo.

The degree to which armies had come to depend on motor vehicles for transportation during World War II can be seen in the use to which such vehicles were put after the landings in Normandy. In the late summer and fall of 1944, when the railroads were unable to handle the forward movement of supplies from beaches and ports to distant points in the amount expected of them, highway express systems for long hauls were set up. The best known of these, although not the most efficient, was the Red Ball express, organized in Aug. 1944 and operated until mid-Nov. 1944. In around-the-clock operations, it moved cargo from Cherbourg and the Normandy beaches to armies hundreds of miles distant. At its height approximately 5,400 trucks were assigned to the operation and 8,209 tons of supplies per day were moved into army areas. Other express systems organized to support the advancing armies were Red Lion, White Ball, Green Diamond, ABC and XYZ. The XYZ, organized to support the Allied drive across the Rhine into Germany in early March 1945, was operated until V-E day. Its daily average delivery to the armies was about 13,000 tons.

The experiences of World War II proved that the confidence in motor transportation was justified. In every theatre of operation trucks dominated transportation; in the interior zones they challenged the railroad even in the field of long hauls. Only in areas where adequate roads did not exist or could not be built quickly were the belligerents forced to rely on other means. The Allies in western Europe normally supplemented motor transport with rail, inland waterway and air transport. The Germans used all these and wagons as well.

4. Limitations of Motor Transport. — This heavy commitment to motor vehicles had its drawbacks, not the least of which was that it made military forces dependent on hard-surfaced roads. It meant that much energy and a tremendous amount of equipment and material had to be devoted to road construction and maintenance. Among the great road-building projects undertaken during the war, the best known were the Ledo and Burma roads in southeast Asia and the Alaska highway in Canada. So heavily did their construction draw on U.S. resources that many have questioned whether in the final analysis their building hastened or delayed victory. They certainly contributed far less than the many projects undertaken in the Persian gulf, Mediterranean, European and Pacific theatres. But whatever the final verdict of history, there can be no doubt that they widened the area of operations for motor transport.

A second drawback of motor transport is its dependence on fuel and spare parts to keep it operational. The need for fuel is so great in modern military forces that without it operations cannot be conducted. Figuratively, it is correct to label gasoline *le sang de guerre.* To provide a steady flow of this "blood of war" requires special land, sea and air transport, hence the demand for pipelines, gasoline trucks, rail tank cars, seagoing tankers, fuel resupply aircraft, storage tanks and gasoline containers. Animal-drawn vehicles to be sure also require fuel in the form of forage, but its temporary absence does not bring movement to an immediate and complete halt. Except for harnesses, horseshoes and a few wagon parts, most of which can be locally procured or met by improvisation, animal transport offers no serious maintenance and repair problems.

Largely because of this problem and climatic and highway difficulties in areas where they expected to operate, the Germans did not drop horse-drawn vehicles from their tables of organization and equipment for field units. Forward of army railheads in Poland and the U.S.S.R. they used mostly horse-drawn wagons for resupply. In the desert country of north Africa where forage was scarce, they equipped their troops entirely with motor vehicles.

The reliance of the Russians and Poles on horse-drawn vehicles was in part dictated by the same considerations, but much of it can be attributed to their industrial backwardness. Other illustrations of the extent to which fuel requirements, terrain, climatic factors and other local conditions can determine the type of transport used are to be found in Tunisia, Sicily, Italy, the Pacific islands, Norway, Finland and Greenland. Forces in the first three areas were driven to the use of horses and mules as pack animals in mountainous country. In Papua both pack animals and native porters were used. In Norway and Finland, where snow, ice, cold weather and lack of roads impeded vehicular traffic, the Germans resorted to pack animals, aerial cable tramways and sledges drawn by reindeer. On the icecap of Greenland the Americans used dog sleds.

5. Korean War.—During the Korean war, United Nations forces discovered that the native porter enabled the North Korean and Chinese armies to forward enough supplies to launch highly effective if not long-sustained offensives. Roadbound and railbound by their complete commitment to motor vehicles and railroads, the UN forces found themselves at a distinct disadvantage in coping with an enemy who could operate in terrain considered too rough and inaccessible to permit large-scale movement. Until UN troops organized their own porters to supplement conventional transport they faced constant infiltration of their lines and loss of territory. Reliable statistics on the amount of supplies carried by porters in the North Korean and Chinese armies are difficult to obtain. Some estimates place it higher than that carried by all other means. Whatever it was, it affords a striking example of how troops whose transport is adapted to local conditions can win victories over those wedded almost completely to mechanical transport. Whether or not adverse conditions will remain equalizing factors in the future depends in large part on the progress made in developing new machines to overcome them.

III. PREPARATION FOR FUTURE WARS

In planning for future wars, nations must consider the kinds of conflict in which they may become involved. The spectrum of possibilities includes cold war, limited nonnuclear war, limited nuclear war, general conventional war and general nuclear war. Because these types of war differ radically, the design and support of military structures to meet them must also vary. The conflicting demands of each raise the question as to where emphasis in preparation should be placed, Probably in no area does this produce more difficult problems than in transportation. That greater flexibility and strength in motor vehicles and aircraft will be required, whatever the nature of conflict, is generally assumed.

A. Land Transport

To improve land transportation, governments have stressed the improvement of highways and the development of vehicles that can be operated in all sorts of terrain and under climatic conditions ranging from the hot, sandy deserts of the tropics and semitropics to the snow, muskeg and ice of the polar regions. Because roads in these peripheral areas are few or nonexistent, off-the-road transport is needed; because commercial activity in them is limited, governments rather than private enterprise must bear the expense of development.

Note is, of course, being taken of the unconventional transport used by the mining, oil, logging and construction industries operating in such areas. In general, it is too specialized to be easily modified to fit military needs. Some characteristics, however, have been adopted. Among the most important are high-flotation tires, multiwheeled drive and power steering. All present serious technical and production problems. Costs are so high that even governments find them difficult to justify.

In the United States, where progress in off-the-road transport has been greater than elsewhere, several types were developed and tested. Among these were the marsh buggy, the sno-train and the rolling fluid transporter.

The marsh buggy, a vehicle with high-flotation tires, was designed for use in swampy areas. It was successfully tested in the muskeg of northern Canada and doubtless could with modifications be used in terrain like the Everglades of Florida or the Pripet marshes of Russia.

The sno-train, officially called the logistical cargo carrier, consists of a prime mover that pulls several trailers in trace. With three trailers, it is 175 ft. long. Equipped with tires four feet wide and ten feet high, the largest in the world, the sno-train can travel through deep snow and over the muddy terrain caused by spring thaws in the arctic and subarctic regions. That some modification of it would work equally well in desert, plain and rolling country seemed certain.

The rolling fluid transporter is a collapsible four-ply rubber container of 500 gal. capacity designed to transport liquid fuel over all but the most rugged terrain. It can be towed by truck or transported by plane to point of need and, being collapsible, quickly and easily returned to a fuel-dispensing point for refilling. Since it floats, water obstacles are no barrier to its movement.

In rail transport little progress was made after World War II. Most notable was the growth of "containerization" and the "piggyback" movement. Both represented an effort to bring rail and highway transport closer together. As for rail vehicles, a flatcar designed by the U.S. army transportation corps that could be quickly converted to either a boxcar or a gondola and a locomotive that could be operated on standard, wide- or narrow-gauge track were the chief new developments.

B. Air Transport

In military air transport, progress was considerable. Many types of fixed-wing planes and helicopters unknown in World War II came into use. In addition, advances were made in the development of convertiplanes which combined the best characteristics of the fixed-wing plane and the helicopter. In the United States, two promising convertiplanes were the XV-1 and the XV-3. The XV-1 was powered by a 550-h.p. Continental engine and a pressure jet unit located kt the tip of each of the three blades of the rotor. In forward flight the engine drove a pusher propeller and the rotor was free wheeling. To raise or lower the craft the rotors were used. The XV-3 was powered by a single 450-h.p. Pratt and Whitney engine that drove two rotors mounted on the tips of the wings. These rotors could be tilted to a vertical position by electric motors and then returned to a horizontal position by the same means, thus giving the convertiplsne vertical lift as well as forward thrust with the same propeller.

Used extensively by the United Nations in Korea to move patients and light cargo was the helicopter. This type of aircraft underwent a rapid development in all countries and there was a strong probability that it would soon be able to carry heavy loads. Some helicopters, such as the U.S.S.R. Yak-24 ("Horse"), shown in Moscow in May 1955, can carry 40 fully armed paratroopers for short distances. Fitted with a rear-loading ramp it can also load and discharge cargo with ease. Even more advanced is the Soviet MI-6 ("Hook") for which a record load was claimed. In the United States the Flying Crane, the S-60, was successfully tested. A newer model, the S-64, was designed to lift loads weighing eight tons. Another helicopter, the Hiller 17, using turbojet engines mounted on the tips of its propeller as a power unit, was also developed and was capable of lifting up to 25,000 lb. Since many of these new aircraft had commercial utility it was assumed that in the future nations would have large pools of helicopters and Flying Cranes as well as ships, railroad cars and planes on which they could draw for military transport in time of war.

In the late 1950s the U.S. army conducted tests of the Aerocyle, a unique one-man lift device powered by a two-cycle 43-h.p. outboard motor. Its weight was approximately 200 lb. and it had a payload capacity of 250 lb. To operate it the pilot took his position on a platform above the rotor blades and guided the craft by leaning in the direction in which he desired to travel. If was expected to have, when fully developed, a range of 50 mi. and a speed of 40 m.p.h. As a means of transporting a man and a small amount of compact emergency cargo over rough terrain and water hazards it appeared to have promising possibilities.

Most significant was the increase in the size, weight, speed, range and numbers of commercial planes carrying passengers and freight. The effect on preparation for future wars was startling. It will doubtless become greater and may revolutionize military transportation, particularly over long distances. It has given governments a sound industry and a large pool of aircraft on which they can draw for military purposes in case of emergency. So rapid are the developments in the aircraft industry and the air carrying field that a statement on their exact status one year would be out of date the next. Because the conversion of cargo planes to passenger service is a relatively easy matter the cargo plane is practically a dual-purpose craft.

C. Container Transporters

Since the movement of military cargo has always been hampered by huge volumes and a variety of small packages, those responsible for military transportation have constantly sought to consolidate loads so that they can be more easily handled and delivered. During World War II considerable progress was made in cargo-handling methods, especially in the U.S. army. Among these the palletization of uniform cargo was probably the most successful. It was accomplished by packing items on a sledlike wooden platform (pallet) that could be raised and moved by a fork-lift truck. With the close of the mar the practice fell into disuse and it was not until the outbreak of the Korean conflict that attention was once again directed to it. With the revival of palletization by the U.S. army, the search for new methods of simplifying and expediting cargo handling was resumed in earnest. This interest was part of the over-all effort by the military forces to increase their mobility and flexibility.

Along with the development of improved air and surface equipment and greater capability in over-the-beach and dispersed port operations, emphasis was put on the automation of cargo handling. The responsibility for research in this field in the U.S. army rested primarily with the transportation corps. Drawing on its experience with a container designed to carry household goods for military personnel on overseas assignments, it worked for years to produce a family of three standard containers that would fit the needs of all the supply services and the various types of land, sea and air carriers. This was no simple problem, for to arrive at the right specifications in regard to weight, dimensions and durability required close co-ordination with the railroad, trucking, air transportation and shipping industries as well as the several supply services in the army, navy and air force. Whatever containers were adopted would have to fit into foreign and domestic freight cars, trucks, vans, cargo ships and planes. For rail and motor vehicles it was relatively easy to design standard containers that would fit them singly or in numbers without loss of space, but to adapt the same containers to all ships without loss of space was impossible because of the great differences between their hatches. The only solution lay in designing and building vessels with hatches that could take an optimum number. Since this required the co-operation of the shipping industry, the policy of the armed services was to encourage shipping companies to consider the use of standardized containers in their future building programs.

In the belief that transport by containers will drastically reduce the cost of cargo handling, the largest single cost item in a steamship company's ledger, some shippers ordered such vessels; others plan to include them in future building. Commonly known as lift-on, lift-off ships, they load and discharge packed and sealed containers with their own gear. This not only simplifies handling and stowage but reduces the loss from damage and theft as well. Many transportation experts regard the container as the most revolutionary development in cargo-handling operations in centuries. It may be the universal catalyst that will cross the usual competitive boundaries of the various forms of sea, land and air transport.

D. Transport for Beach Operations

With the extensive use of large ports and the concentration of ships in convoys either precluded or extremely dangerous because of their vulnerability to nuclear attack, logisticians have been forced to think in terms of beach operations. For amphibious landings they visualize armies supported over numerous widely separated beaches to which vessels can be quickly dispatched and from which they can be just as quickly withdrawn in case of an approaching attack. Operations under such conditions will require, among other things, suitable equipment in large amounts. Since congested beaches would be as vulnerable as ports, transport and cargo-handling equipment would have to be of the sort that would permit rapid movement over beaches and quick delivery of men and cargo to hidden inland areas. These requirements are hard to meet. They account for the emphasis that the services are placing on special-purpose ships, vehicles and aircraft. They explain the demand for fast roll-on, roll-off vessels, families of amphibians, beach lighters that can readily tie up to vessels, aircraft that can carry supplies from ship to shore, cargo-handling equipment that can operate on soft beaches, chemicals that can harden sand quickly so that the beaches will stand up under traffic, portable docks that grip into the floor of the sea with platforms that can rise and fall with the tide, aerial tramways capable of being quickly installed between ships or docks at points where the natural shore obstacles prevent beach operations and amphibious vehicles that can move cargo from ships to points inland without a stop.

The United States made the greatest strides in most of these matters. Improved models of ships that can take on or discharge laden vehicles via ramps built into their bows have been designed and built. Among them is the U.S.N.S. "Comet," produced by the military ship transport service. Since roughly a quarter of the volume of army cargo consists of wheeled or tracked equipment the production of such ships is a matter of vital interest to the armed services. Efforts to induce the shipping industry to adopt such ships for commercial use met with little success, however, because they are considered uneconomical to operate. Until their profitability in coastwise trade can be proved, it is unlikely that many shippers will be interested.

E. Military Transport Problems in Nuclear Warfare

In operations involving nuclear weapons, it is generally agreed that armies will need a far greater capability for rapid movement and dispersal than in the past. Large fixed installations and heavy concentrations of troops in or near the combat zone will be too vulnerable to attack. Instead of fairly clear-cut lines of demarcation between the combat zone and the base areas in overseas theatres, the combat zone will probably extend back to the water's edge and possibly embrace the zone of the interior as well. Units the size of battalions must be able to remain unobserved and to move quickly, often on short notice. This means that accompanying supplies will have to be reduced to a minimum, that resupply in items normally consumed daily will have to be swift and regular and that additional supplies to meet an emergency will have to be delivered on call without fail.

Preparing logistically for general nuclear war involves, among other things, the organization of transportation and communications both within units and throughout the entire line of communication and the development of new and reliable means of transport on land, sea and in the air.

Insofar as transportation is involved, there is a strong conviction that many of the older methods of operation will be impractical for loading and discharge in theatres of combat. Because the use of railroads is likely to be strictly limited and the operation of large ports dangerous, the emphasis in preparations for nuclear warfare has been placed on the further development of motor vehicles, roll-on, roll-off ships and craft and air transport. Through their use it is hoped that balanced supplies can be provided and delivered in sufficient quantities to the forward units, thus curtailing and possibly eliminating vulnerable army depots, ports, beachheads and dumps. With warehouses on wheels, dependence on fixed installations will be reduced and armies will be able to move and disperse quickly.

To meet situations involving the destruction or denial of highways and railroads by nuclear weapons, off-the-road vehicles may be the answer. But their drawbacks are many, not the least being their size, weight, fuel requirements and cost. Since such vehicles have little commercial use, there is some doubt as to whether they can be quickly mass produced. For these reasons, increasing attention is being given to air transport, the feasibility of which was proved during the Berlin air lift. But air transport also has its limitations.

A possible solution to the problem of vulnerable airfields lies in the improvement of the air drop, begun in World War II. Considerable progress has been made in this method of delivery, and equipment weighing as much as 13 tons has been dropped by parachute. Another possible solution lies in the further development of the helicopter and the convertiplane with their ability to rise and descend vertically in limited areas.

In some regions where streams, lakes and other bodies of water with sufficient depth and straight courses exist for landings and take-offs, resupply by seaplanes appears practical. This is obviously a method that cannot be used in arid country or in the polar regions where the seas are frozen. In such areas combat forces will have to depend on conventional transport of the region, off-the-road vehicles and land-based air transport. Since no large forces are likely to be involved in such country, the transport problem is less baffling than in heavily populated areas. The difficulty of supporting large U.S. forces in western Europe in a nuclear war, for example, might place so great a strain on the transportation resources of the United States that it could not be met.

F. Trends in Transport Development

Among the possibilities in water transport not yet exploited fully is the submarine. That it can be used as a cargo carrier was first demonstrated in World War I when the German U-boat "Deutschland," loaded with dyestuffs and other scarce products, made two round trips to the United States before the latter's entry into the war without being intercepted by the British navy. In World War II the Axis powers employed submarines to shuttle supplies to north Africa. The obstacle to commercial use is the cost of construction and operation which is so high that only governments can bear it.

Much more likely to replace the surface vessel as a carrier in a nuclear war is the airplane. That it can move men and freight quickly across the seas is being demonstrated daily. That it can carry military cargo equally well was amply proved during World War II, the Berlin blockade, the Korean war, the landing in Lebanon and in peacetime military exercises. If the problems of greater carrying capacity and landing sites can be solved it may emancipate the services from dependence on surface vessels for overseas operations. When, if ever, heavy, ponderous military equipment can be exclusively moved by air transport is difficult to tell. Possibly the problem may be simplified by a drastic reduction in the weight and size of military equipment and new technical developments that will reduce the fuel requirements of aircraft and overcome their dependence on vulnerable airfields. The success achieved in powering vessels with atomic engines led to the belief that similarly powered aircraft might have a place in military transport. Nuclear power may prove to be the solution to the fuel problem that besets long-range aircraft. It may even herald the day of huge planes capable of carrying cargo of any size, weight and description, thus leaving only the problem of secure landing sites. In certain areas atomic-powered seaplanes might be usable. It may be also that fully satisfactory aircraft capable of rising and descending vertically with heavy loads will be developed. But the day of aircraft that can deliver any type of cargo in sufficient quantities anywhere has not yet dawned. Until it does armies will remain dependent on vessels and vehicles for military transport. See Index references under "Transport, Military" in the Index volume.

TRANSPORT, MINISTRY OF: see Government Departments.

TRANSUBSTANTIATION, the term adopted by the Roman Catholic Church to express its teaching on the subject of the conversion of the Bread and Wine into the Body and Blood of Christ in the Eucharist. Its signification was authoritatively defined by the Council of Trent in the following words: "If any one shall say that, in the Holy Sacrament of the Eucharist there remains, together with the Body and Blood of Our Lord Jesus Christ, the substance of the Bread and Wine, and shall deny that wonderful and singular conversion of the whole substance of the Bread into (His) Body and of the Wine into (His) Blood, the species only of the Bread and Wine remaining—which conversion the Catholic Church most fittingly calls Transubstantiation—let him be anathema." (Sess. xiii, can. 2.) The word "transubstantiation" is not found earlier than the 12th century. But in the Eucharistic controversies of the 9th, 10th and 11th centuries the views which the term embodies were clearly expressed; as, for example, by Radbertus Paschasius (d. 865), who wrote that "the substance of the Bread and Wine is efficaciously changed interiorly into the Flesh and Blood of Christ," and that after the consecration what is there is "nothing else but Christ the Bread of Heaven." The words "substantially converted" appear in the formula which Berengarius was compelled to sign in 1079 We may take it that the first use of the word is in a passage of Hildebert de Savardin (d. 1133), who brings it into an exhortation quite informally, as if it were in common use. It is met with in a decretal of Innocent III. The fourth Lateran council fully adopted it (1215). It is clear from the treatise of Radbertus Paschasius already quoted that the word "substance" was used for reality as distinguished from outward appearance, and that the word "species" meant outward appearance as opposed to reality. The terms, therefore, were not invented by St. Thomas Aquinas and are not mere scholastic subtlety. The definition of the Council of Trent was intended both to enforce the accepted Catholic position and to exclude the teaching of Luther, who, while not professing to he certain whether the substance of the Bread and Wine could or could not be said to remain, exclaimed against the intolerance of the Roman Catholic Church in defining the question.

For a full exposition of the Catholic teaching on transubstantiation, see Ludovico Billot, S.J., De *ecclesiae* sacramentis (1896). See also the Catholic Encyclopaedia, article "Transubstantiation." (J. C. H.; X.)

TRANSURANIUM ELEMENTS. The term transuranium elements designates the chemical elements lying beyond uranium in the periodic table and hence includes all the elements with atomic numbers higher than 92, the atomic number of uranium. All transuranium elements are radioactive. They do not occur in appreciable amounts in nature, and were discovered and investigated as a result of their syntheses by transmutation reactions, starting with uranium (*q.v.*) as the primary material. All those known in the early 1960s were members of a group of chemically similar elements, the actinide series, a group that chemically resembles the rare-earth or lanthanide group of elements (see Rare Earths).

Discovery of the Transuranium Elements.—In the history of the transuranium elements, the growth of atomic science is seen as the product of an intellectual chain reaction of experiment, hypothesis and further experiment. In this process, it has been found more difficult to separate so-called practical science from pure science than to split the atom.

Ever since 1869, when D. I. Mendeléyev formulated the periodic table that showed uranium as the heaviest of the elements then known, the properties of uranium have been a challenge to chemists and physicists. In Italy in 1934, Enrico Fermi, Emilio Segrè and their co-workers, bombarding uranium with slow neutrons, obtained radioactive products that appeared to be transuranium elements. However, Otto Hahn and F. S. Strassmann and their co-workers in Germany, repeating the Fermi experiments, found that the elements so produced were lighter than uranium. Late in 1938 they discovered that one of the products of their experimental bombardment was the mediumweight element barium. The implication of this was soon realized; the uranium atom had been split into two almost equal parts (see Atomic Energy: Uranium Fission).

Among the many experiments that were stimulated by the news of atomic fission was a very simple one designed by E. M. McMillan at the University of California at Berkeley in 1940, with the object of testing the penetrating power of fission fragments. As a target in the cyclotron he used a piece of paper thinly coated with uranium oxide, backed by a stack of cigarette papers. After bombarding the uranium atoms with neutrons, he measured the radioactivity of each of the pieces of cigarette paper. He found in the uranium sample a radioactivity that evinced a different half life and different properties from those of the fission products with which the other sheets were impregnated. He realized that this radioactivity might be caused by a previously undiscovered element. In the task of identifying the new substance. he was joined by Philip H. Abelson. They succeeded in separating the first transuranium element, atomic number 93, which they named neptunium (*q.v.*).

The neptunium isotope found by McMillan and Abelson undergoes a 50% disintegration by radioactivity in 2.3 days. A study of this process indicated to McMillan that neptunium was the key to the element with atomic number 94, but his quest for this was interrupted by other duties. The search was continued by Glenn T. Seaborg, Arthur C. Wahl, Joseph W. Kennedy and Segrè. In late 1940 and early 1941, bombarding uranium first with deuterons and then with neutrons, they produced the 94-proton element, which was named plutonium (*q.v.*).

Only a very small specimen of plutonium was produced for the first experiments conducted with a weighable amount—approximately $\frac{2}{100,000,000}$ oz. However, this minute sample was sufficient to reveal that plutonium-239 was susceptible to fission by bombardment, with slow neutrons, and therefore that its production in substantial quantities was a matter of extreme importance. The implications of this to national defense became obvious, and the team of scientists, who sent communications concerning the discovery to the editor of the Physical Review in January, March and May of 1941, decided to withhold these reports from publication. In The Transuranium Elements, by Seaborg, it is pointed out that "the announcement to the world of the existence of plutonium was in the form of the nuclear bomb dropped over Nagasaki."

The task of producing and identifying neptunium had been hampered by the fact that an erroneous place had been calculated for it on the periodic table, leading the investigators to look for properties similar to those of rhenium rather than uranium. A similar obstacle was encountered at The University of Chicago in 1944 when Seaborg, Ralph James. Leon Morgan and Albert Ghiorso began the quest for the elements with atomic numbers 95 and 96. According to the periodic table then in use, these elements should evince properties similar to those of neptunium and plutonium; but experiments conducted along these lines led to a dead end.

Seaborg concluded that the elements heavier than actinium belonged in a separate group, the actinides, corresponding to the rare-earth or lanthanide elements. Experiments were planned to test this hypothesis. and they proved it correct; elements 95 and 96 were isolated, identified and named americium and curium (*qq.v.*). The actinide hypothesis was the key to the chemical identification of elements 97 and 98, berkelium and californium (*qq.v.*). These were produced at Berkeley in 1949 and 1950 by Stanley G. Thompson, Ghiorso, Kenneth Street, Jr., and Seaborg.

The next two numbers in the periodic table were filled as a result of the first hydrogen bomb test in the South Pacific in Nov. 1952. Testing planes that were flown by remote control through the vast radioactive cloud created by the explosion picked up specimens of extremely heavy isotopes that had been formed by the fission of U^{238} with neutrons. From these products, elements 99 and 100—einsteinium and fermium (*qq.v.*)—were isolated by teams of scientists working at the University of California Lawrence Radiation laboratory, the Argonne National laboratory and the Los Alamos Scientific laboratory.

The production and identification of element 101, mendelevium, are described in Elements of the Universe, by Seaborg and Evans G. Valens. In the series of experiments in which the discovery was made and validated (conducted at Berkeley early in 1955 by Ghiorso, Bernard G. Harvey, Gregory R. Choppin, Thompson and Seaborg), minute quantities of einsteinium were bombarded with helium nuclei, adding two helium protons to the 99 protons of einsteinium. Of the many problems involved, the most formidable was the chemical identification of the new 101-proton element before its radioactive decay, since mendelevium undergoes a 50% disintegration in approximately an hour. In about a dozen performances of the experiment, the team of scientists produced and identified 17 atoms of mendelevium.

The synthetic chemical element with atomic number 102 was prepared and identified by Ghiorso, T. Sikkeland, J. R. Walton and Seaborg in 1958 at the University of California, Berkeley. The first identification of this element earlier had been claimed by an international team of scientists working at the Argonne National laboratory in the U.S., the Atomic Energy Research establishment, Harwell, Eng., and the Nobel Institute for Physics, Stockholm, Swed. On the basis of the work of this team the element was given the tentative name nobelium and chemical symbol No. However, subsequent repetition of the experiment failed to confirm the discovery, and credit for the initial identification of the element passed to the research team at the University of California. Element 102 was produced there by the bombardment of Cm^{246} with C^{12} ions accelerated in a heavy-ion linear accelerator. The isotope prepared, with mass number 254, decays by alpha particle emission with a half life of 3 sec. It was identified through the chemical characteristics of its known "daughter" Fm^{250}, the atoms of the daughter element being separated from the parent element 102 by taking advantage of the recoil from alpha particle decay of the parent element.

The chemical element with atomic number 103 was synthesized in 1961 at the University of California by a research group consisting of Ghiorso, Sikkeland, A. E. Larsh and R. M. Latimer. The isotope identified of probable mass 257 was the first to be discovered solely by nuclear methods; no chemical techniques were used in its identification. The discoverers proposed that the new element be given the name lawrencium and the symbol Lw in honor of Ernest O. Lawrence, inventor of the cyclotron.

(*See* also ATOMIC ENERGY; NUCLEAR ENGINEERING.)

Properties of the Transuranium Elements.—The resemblance between the lanthanide and actinide elements suggests that their electronic structure must also be similar. An inner electron shell, consisting of 14 5f electrons in the case of the actinide elements and 14 4f electrons in the case of the lanthanide elements, is filled in progressing across the series. (See PERIODIC LAW; NUCLEUS) The evidence for this lies in the chemical properties. absorption and fluorescence spectra in aqueous solution and crystals and in the crystallographic-structure, magnetic susceptibility, atomic beam and spectroscopic data.

Plutonium early assumed the position of dominant importance among the transuranium elements because of its successful use as an explosive ingredient in the atomic weapon and the excellent prospects it offered as the base material for developing industrial uses of atomic power. In the early 1960s, plutonium was the only member of this group of synthetic elements for which methods had been developed for production in relatively large, *i.e.*, multikilogram, amounts. From a purely scientific point of view, however, the other transuranium elements are of nearly as great interest as plutonium.

Electronic Configurations (Beyond Radon) for Gaseous Atoms of Transuranium Elements

Atomic no.	Element	Configuration*
93	Neptunium	$5f^4 6d 7s^2$
94	Plutonium	$5f^6 7s^2$
95	Americium	$5f^7 7s^2$
96	Curium	$5f^7 6d 7s^2$
97	Berkelium	($5f^8 6d 7s^2$ or $5f^9 7s^2$)
98	Californium	($5f^{10} 7s^2$)
99	Einsteinium	($5f^{11} 7s^2$)
100	Fermium	($5f^{12} 7s^2$)
101	Mendelevium	($5f^{13} 7s^2$)
102	Nobelium	($5f^{14} 7s^2$)
103	Lawrencium	($5f^{14} 6d 7s^2$)

*Configurations in parentheses have not been determined experimentally.

There had been much speculation concerning the upper limit of atomic number for the existence of transuranium elements, with considerations that such a limit might arise from either atomic or nuclear (radioactivity or spontaneous fission) instability. It appeared likely that the half lives for even the longest-lived isotopes of elements with atomic number over 100 would be so short as to make tracer chemical investigations difficult.

Speculation also arose about the chemical properties of the undiscovered, higher transuranium elements. The elements through atomic number 103 should complete the rare-earthlike (actinide) transition group. The element with atomic number 104 should be chemically similar to hafnium (atomic number 72). The following 14 hypothetical elements, with atomic numbers 105 through 118, should be chemical homologues, consecutively, to the 14 known elements with atomic numbers 73 (tantalum) through 86 (emanation or radon). However, the predicted decay rates are too great to make it likely that more than a few of these elements can be synthesized and identified.

TRANSVAAL, a province of the Republic of South Africa (area 110,450 sq.mi.), occupying the northern portion of the country. It abuts on Southern Rhodesia and the Bechuanaland protectorate on the north, on the Bechuanaland protectorate and the Cape province on the west, on the Orange Free State and Natal on the south and on Swaziland and Mozambique on the east. Save on the southwest, frontiers are mostly well-defined natural features.

PHYSICAL FEATURES

More than three-quarters of the country lies on the Great Inland plateau, while the remainder is situated between the Drakensberg escarpment and the Lebombo range of mountains and forms part of the country known as the low veld. The eastern, central and northern portions of the plateau are drained by the Komati and Limpopo rivers which flow to the Indian ocean, while the southern portion is drained by the Vaal river which has its outlet through the Orange river to the Atlantic ocean. In the north the plateau is broken up by the Zoutpansberg and Blouberg mountain ranges into smaller plateaus, some of which are featureless and bush-covered, while others are characterized by isolated koppies and granite-bouldered hills. The central portion of the plateau is beset with large blocks of diversified country in which much bare rock is exposed, as a result of the presence of the mountain ranges of the Witfonteinrand, the Waterberg and the Strydpoortberg. South of these ranges is a wide expanse of flat, bush-covered country consisting of the Rustenburg bushveld, the Pretoria bushveld and the Springbok flats. From there the land rises sharply to the south and, after encountering the very broken country formed by the Magaliesberg and Witwatersrand, opens out into wide plains and rolling downs forming the high veld in the southern and southeastern portions of the province.

Four natural zones are recognized — the mist belt, the high veld, the middle veld and the low veld. The mist belt occupies the upper eastern slopes of the Drakensberg escarpment and includes the country which lies at 6,000 ft. and higher. It is the region of highest rainfall. The high veld covers the southeastern and southern portions of the province and lies between 4,000 and 6.000 ft. It extends 120 mi. from east to west, and north to south 100 mi., and consists of rolling, grass-covered downs, naturally treeless, the crests of the rolls being known as *bults* and the hollows as *laagtes.* The surface is occasionally broken by koppies, either table-shaped or pointed, rising sometimes 100 ft. above the general level. Small springs of fresh water are frequent, and the eastern portion is characterized by numerous sheets of water or "pans," as they are locally called — flat-bottomed depressions with no outlet, the water being usually brackish.

The middle veld lies between the high veld on the south and the low-lying country on the east, north and west. It is traversed by the Olifants river, and results from the denudation of the plateau, giving rise to broken country. Average altitude is 3,000–4,000 ft. It is marked by stony ridges (rands), and these and the koppies are often covered with scrub.

The low veld includes the country lying below 3,000 ft. Rands and koppies occur but the general characteristic is its uniformity. The low veld east of the Drakensberg begins at about 3.000 ft. above the sea and slopes to 1,000 ft. or less until it meets the ridge of the Lebombo hills. The lowest point is at Komatipoort, a gorge through the Lebombo hills only 476 ft. above the sea. North of the Zoutpansberg is a large salt pan. The parklike low veld is everywhere covered with dry forest. Along the river valleys the vegetation is much more luxuriant. The greater part of this is composed of thorn bush and thorn trees, especially in the dry open country. On the east the low veld is situated below the Drakensberg escarpment, on the north below the foothills of the Zoutpansberg; on the west it occupies the valleys of the Limpopo and Crocodile rivers. It is an area of low rainfall, considerable heat and high aridity.

There are four river basins in the Transvaal. Of these the Komati (*q.v.*) and the Pongola rise in the high veld and, flowing eastward to the Indian ocean, drain comparatively little of the province, of which the Pongola forms for a considerable distance the southeastern frontier. The rest of the country is divided between the drainage areas of the Vaal and Limpopo.

The destruction of wildlife has been great, but a vast area on the northeastern border, the Kruger National park, has been set aside as a reserve. (I. B. P. E.)

HISTORY

At the beginning of the 19th century, the land between the Limpopo and Vaal rivers was inhabited by native tribes. From Rhodesia there had infiltrated offshoots of the Karanga people, skilled metalworkers and builders in stone. Sotho-speaking tribes entered from Bechuanaland, and included the Barolong, also skilled metalworkers and agriculturalists. Third came the Ndebele, a group of the same stock as the Natal Nguni. They settled in the region where Pretoria now stands. Apart from odd raids by slavers from the east coast, the Transvaal tribes had no contact with Europeans until 1818 when Conrad de Buys, a refugee from Cape justice, led a swarm of coloureds and adventurers to plunder along the Marico valley. Missionaries such as J. Campbell followed. From their reports it is clear that if the Transvaal tribes were primitive by western standards, they were peaceable and skilled in many crafts. Two events violently dislocated the pattern: one was the eruption of the tribes displaced by Shaka (Chaka or Tshaka) in Zululand; the other was the arrival of the trekkers.

The refugee tribes from Zululand and Natal crossed the Drakensberg first into the Free State and then into the Transvaal. Some of the Hlubi fell upon the Batlokwa tribe under the queen regent Mantatisi and her son Sikonyela. In their turn, Mantatisi and her tribe murdered and plundered (1822) right across the Vaal, where they dislodged Broadbent's mission station. Hard on their heels came Mzilikazi (Moselekatse), the Khumalo, dodging the vengeance of Shaka. He first attacked the Sotho peoples in the region of the Olifants river, then, with his remnants and conscripted victims, founded a new tribe, the Matabele (the name, like Ndebele, means refugee people), and devastated the whole area between the Marico and the Drakensberg. He placed his chief kraal near the junction of the Aapies and Limpopo rivers. Traders such as R. Schoon and missionaries including Robert Moffat have left reliable accounts of a despot terrorizing a ruined land. In 1832 a Zulu impi sent by Dingaan cut the Matabele to pieces and Mzilikazi withdrew from the Aapies valley, destroyed the Hurutse tribe and settled in their territory 40 mi. N. of Mosega in a paradise of wild game, on the west side of the Great Marico river. There he was visited by Andrew Smith, accompanied by the missionary Robert Moffat. Having worked havoc in the land across the Vaal, Mzilikazi was driven thence by the trekkers and settled across the Limpopo. There in Matabeleland he was visited by Moffat in 1854, 1857 and 1859. Mzilikazi admired Moffat.

Moffat had no illusion about Mzilikazi as his journals show, but he pays tribute to the way in which Mzilikazi had welded the broken remnants of tribes into a compact, disciplined and on the whole less brutal people.

THE TREICICER STATE

Trekkers in the Transvaal (**1837-52**).—In 1835 Boer frontiersmen had begun to probe beyond the borders of Cape colony with a view to organizing an exodus from British-controlled territory (see SOUTH AFRICA, UNION OF). One party, led by Louis Trichardt and Janse van Rensburg, reached the Zoutpansberg in what is now the northern Transvaal. In June 1836 Rensburg with a party of 49 Europeans moved off along the Pafuri river. He and his party were annihilated. In Sept. 1837 Trichardt set out via the Sabie river for Delagoa bay, which the fever-stricken survivors reached in April 1838. Thence they journeyed by sea to Port Natal.

A. H. Potgieter had crossed the Orange in Feb. 1836 and joined forces with Carel Cilliers and the Liebenbergs. On his return from the Zoutpansberg he found that S. Erasmus and a hunting party had been disastrously attacked, while a section of the Liebenbergs had been annihilated on the west bank of the Vaal by the Matabele. At Vegkop in Oct. 1836 he beat off the Matabele but lost most of his cattle and fell back with difficulty to Thaba Nchu. Reinforced by the party of Gert Maritz, he again advanced, destroyed Mzilikazi's kraal at Mosega and made good his retreat with all and more than the trekkers had lost at Vegkop. Throughout 1837 the number of trekkers steadily increased. In Nov. 1837 Potgieter inflicted the decisive defeat on Mzilikazi at the Marico river. The Matabele decamped beyond the Limpopo, and Potgieter claimed all the land over which Mzilikazi had ruled. South of the Vaal he also claimed the Vet river district (Winburg) in terms of a treaty with Makwana, a local Bataung chief.

There was, however, rivalry among the trekker leaders and no unanimity of council or plan once the colonial frontier had been crossed. Even after the murder of Piet Retief by Dingaan (Feb. 1838; see NATAL), though Potgieter and Jacobus Uys moved from the high veld into Natal in support of Maritz, they could not agree to an undivided command. Potgieter recrossed the Drakensberg and had no direct share in the making of the trekker republic in Natal.

The British annexation of Natal in 1843 and the resultant trekker exodus from it in 1844 and 1845 broke what had promised to be Potgieter's monopoly of the Transvaal. Some of the refugees from Natal settled at Winburg, others, among them Andries Pretorius and his son M. W. Pretorius, crossed the Vaal and were further reinforced in numbers when in Feb. 1848 Sir Harry (Henry George Wakelyn) Smith (high commissioner. 1847–52) annexed the land between the Orange and the Vaal as the Orange River sovereignty (see ORANGE FREE STATE). Inevitably the British annexation involved theattempt to assert the Vaal river as a frontier between the trans-Orange and the trans-Vaal Boers. This was not easy to achieve. In the first place the Transvaal claimed the Klip river as the source of the Vaal, while the Orange River sovereignty (which after 1854 became the Orange Free State) wanted the frontier pushed north to the Likwa Spruit so as to secure the Harrismith route into Natal. Further, the Vaal was a geographical line rather than a political frontier: Winburg constantly looked to the Transvaal for help during the British annexation of the sovereignty and thereafter was frequently at loggerheads uith the Free State raad at Bloemfontein. Conversely, first Andries Pretorius and then his son M. W. Pretorius kept alive the tradition that the Free State and the Transvaal were both legatees of Boer traditions and should therefore act together.

The thesis of trekker unity was strangely at variance with the situation across the Vaal. Groups of farmers were scattered over 100.000 sq.mi of territory, and at times each family group or personal following tended to act as a law unto itself. Potgieter settled originally at Potchefstroom in the southwest Transvaal, while Pretorius when he trekked in from Natal settled not far off in the Magaliesberg. In 1845, though, Potgieter moved anay to the northeastern Transvaal. A born leader of men, he would play second fiddle to none, least of all to Pretorius. But his main objectives in moving off from Potchefstroom were two. His new centre, Andries Ohrigstad, was just north of the limits of British jurisdiction claimed by the Cape of Good Hope Punishment act (1836). Equally important, it was well placed for trade with the Portuguese. Later Ohrigstad proved to be fever-stricken, and the capital of the eastern Transvaal was moved to Lydenburg.

Meantime Potchefstroom had become a rather more vigorous growing point in the southwestern Transvaal, and from it a steady and on the whole well-thought-out opposition to Potgieter developed. For Andries Pretorius transferred to Potchefstroom the policy of trekker unity and central control evolved at Pietermaritzburg, and he was supported by most former Natalians. In eastern Transvaal Potgieter's autocracy led there also to opposition. When challenged by the raad Potgieter appealed to Het Volk (roughly the people against parliament). In May 1849 an agreement between the eastern and western section for a united raad was contrived at Derde Poort, but only because Potgieter's faction stayed away. They did more. Incensed by criticism and thwarted in Lydenburg by the constitutionalists, Potgieter moved north to the Zoutpansberg. Thus by 1851 instead of two main groups there were three, that of Andries Pretorius at Potchefstroom (southwest Transvaal), that of W. F. Joubert at Lydenburg (southeast Transvaal) and that of Potgieter at Zoutpansberg (north Transvaal). However, in March 1852 Pretorius and Potgieter agreed together on the vital matter in hand, namely the ratification of the Sand River convention by the raad.

Sand River Convention. — The Sand River convention was signed as a result of negotiation between Andries Pretorius and special commissioners W. Hogge and C. M. Owen representing Queen Victoria. It was signed to regularize the position and to prevent the intervention of the Transvaal either to the south, in the Orange River sovereignty, or to the west, where traders had been turned back from the missionary-trader road to the north.

From one point of view the Sand River convention was a brilliant demonstration of common sense. Britain faced the fact that the Transvaal was de facto independent of British control, and since at the time British sovereignty was still exercised in what is now the Free State further intervention by the "emigrant farmers beyond the Vaal river" would be an act of aggression. But in every other respect the convention was faulty. The Boer signatories were not the accredited agents of a well-organized state (neither Potgieter nor Joubert was a signatory), and there was no administration across the Vaal to implement the undertakings. Though the convention conceded to the "emigrant farmers beyond the Vaal river the right to manage their own affairs," the undertaking of the Boers not to practise slavery was faulty. It exposed the Transvaal to missionary criticism, attracted the attention of the antislavery commissioners and led to the threatened inquiry by Sir Philip Wodehouse into allegations of slavery in the Transvaal as late as 1865. Britain was left with an implied paramountcy without legal machinery for the exercise of it. In the convention Britain foreswore alliances with native chiefs north of the Vaal river, but whereas Britain pictured the emigrant farmers as living within the arc cut by the course of the Vaal river, the Boers, as was made explicit in the grondwet of 1858, visualized a straight line drawn right across the' subcontinent. This ambiguity Hogge and Owen did not grasp. No consideration therefore was given by Britain to vital problems already existing west of Potchefstroom, although missionary stations at Kuruman antedated the Great Trek and missionaries were active along the road to the north. This neglect was to lead to the incident at Kolobeng in 1852 when David Livingstone's mission station was ransacked first by Secheli and then by the Boer commando in pursuit of him. For their part the Boers complained that the missionaries provided the natives with guns in contravention of the Sand River convention, and they invoked a power to control which in fact in 1852 Britain had neglected to assert. By a little prescience not only these difficulties but also the confused animosities of 1868–71 could have been averted. The position to the east of the Transvaal was no more satisfactory. In. 1852 Natal was a crown colony. To a great extent its tranquillity depended on the tranquillity of the three independent native states to the north and west of it. Basutoland, Zululand and Swaziland. The acquisition of the Pongola strip in 1855 by Lydenburg from the Swazi vassals of the Zulus and the acquisition of the Blood River territory by the South African republic in 1861 (see ZULULAND) sharply disturbed the position in Natal for many years.

The weakness of the Sand River convention lay then not so much in the renunciation of responsibilities as in the failure to define more precisely the frontiers of renunciation.

SOUTH AFRICAN REPUBLIC

Creation of the Republic. — When Andries Pretorius died in 1853, his son M. W. Pretorius inherited, though without conspicuous ability to implement it, the best traditions of the *voortrekker* policy. In 1856, under his guidance, the burghers of Potchefstroom, Rustenburg and newly founded Pretoria united to make the nucleus of the South African republic (S.A.R.). In practice the authority of the new republic was limited to the southwestern Transvaal, for though in 1849 at Derde Poort a united raad had been agreed upon, there were still four separate units. In the southwest was the newly founded S.A.R.; in the north Schoemansdal in the Zoutpansberg was the centre of the ivory trade and of occasional and unofficial blackbirding. Lydenburg, in the eastern Transvaal, in 1858 joined forces with the fourth unit. Utrecht, which, founded in 1848 by former Natalians, projected expansion at the expense of Zululand. The first steps of Pretorius were necessarily confined to the southwestern Transvaal.

In 185j a committee was appointed to draft a code of fundamental law, a grondwet (constitution) which would make the de jure state of the Sand River convention into a de facto sovereignty. In part, the grondwet established in 1858 reflected the accumulated experience of trekker constitutionalists who since 1837 had striven to translate Boer ideals into a political structure. But it was the society not the state which had its traditions.

The grondwet of 1858, though not so mature as that of the Orange Free State (*q.v.*), was a remarkable experiment in constitution making. The keynote was struck in article 8, which may be said substantially to measure the difference between the Afrikaner and the English approach to politics: "The people demand as much social freedom as possible and expect to obtain it by retaining their religious faith . . . by submitting to law, order and freedom and by upholding these. The people permit the spread of the Gospel among the heathen subject to definite safeguards against fault and deception." In article 12 the people are described as delegating the function of legislation to a *volksraad;* but it is also implied that ultimate sovereignty rested with the people, and a three months' delay for all save emergency legislation was stipulated; and until 1889 a 75% majority was required for the passage of all ordinary legislation. All offices and membership of the raad, until 1889, were limited to members of the Dutch Reformed congregations; at the time this proscribed none. Citizenship was limited to adult male European members of the Dutch Reformed Church, and it was expressly stated: "The people desire to permit no equality between coloured people and white inhabitants, either in church or state." Executive power was vested in a president elected for five years, assisted by an executive council wherein the commandant-general held a key position.

Progress toward implementing the grondwet, while chaotic in detail, was none the less clear. In 1860 Lydenburg, having first joined forces with Utrecht (1858), joined the S.A.R. But the attempt of M. W. Pretorius to hold simultaneously the presidency of the Free State (Feb. 1860–April 1863) and that of the S.A.R. (Jan. 1857–Sept. 1860) not only perturbed the British high commissioner but accentuated trouble nearer home. Already there was a three-cornered tussle (with Utrecht as a variable fourth factor) between the Potchefstroom district, the Zoutpansberg and Lydenburg. In 1859 this dissension was exaggerated when two new ministers from the Netherlands arrived in the Transvaal, so that more than once it looked as if religious differences would reinforce political frictions.

In 1860 Pretorius took officeas president of the Free State and, blind to political reality at home and the precarious position on his frontiers, embarked on a policy of territorial consolidation and expansion. In 1861 he supported the negotiations with Cetywayo and Mpande (Panda) which strengthened the Pongola strip by the cession to Lydenburg-Potchefstroom of the Blood River territory. In the Free State he bought up the Pniel reserves and, in 1861, the lands of Adam Kok in Griqualand. That this was done in the face of mounting opposition in the Free State and chaos in the S.A.R. was attributable less to fanatical pursuit of preconceived ends than to obstinate indifference to reality. As often as Pretorius sought to concentrate on Free State problems his opponents in the S.A.R. sabotaged the position in the Transvaal. No well-thought-out constitutional issue was at stake and theories were adapted to fit circumstances. Stephanus Schoeman took up arms against S. J. P. (Paul) Kruger, the most able of Pretorius' supporters, and fought a series of miniature battles. In Jan. 1863, Oct. 1863 and Jan. 1864 successive presidential elections were held in the S.A.R. The last one was final, partly because Pretorius was elected, chiefly because it was prefaced by a more vigorous action by Kruger against Schoeman and J. Viljoen in which five were killed and 37 wounded for a cause which all would have found difficult to define or justify. It was fantastic that, beset by enemies, the Transvaal for three years should have luxuriated in a series of irrelevant burgher tournaments.

Native **Affairs.**—At no point since the trekkers had entered the Transvaal had there been firm administration. A sparse European population was scattered over a vast area, and each place or farm was normally self-contained and under one master. It was these conditions which explained the dichotomy between what was ordered and what was done. The Transvaal settlers denied on principle any equality between black and white. Native chiefs were left in control of their tribes, and those natives who, as returned refugees from Mzilikazi's dispersal, acknowledged no chief had to have a master to vouch for them. There was a *plakkerswet* which limited the number of native families allowed to squat on European farms so that theoretically there were native areas and European areas. Substantially the domination of the white minority in the Transvaal depended on three things: superior armaments and the swift intelligent strategy of commandos; the fact that Mzilikazi had broken the initial resistance of the indigenous tribes; the fact that the two most dangerous native states, that of the Zulus and that of the Basutos, were obliquely subject to British control, while the Swazi normally looked to the Transvaal Boers as masters who could at a pinch rescue them from the Zulus.

Neither slavery, slave trading nor the market in apprentices that undoubtedly existed in the Transvaal were sanctioned by the government of Pretorius, and there are cases on record of brutality to servants, when detected, being sharply punished. But the very repetition of laws against trafficking in apprentices is evidence that the laws were repeatedly violated, especially in the northern Transvaal. There, where the writ of government barely ran, Juwawa Albasini, native commissioner of the Zoutpansberg, and others less notorious, engaged in any and every practice that was profitable. The same was true of the western Transvaal, which had no effective administrative frontier. Probably the chief weakness of the whole structure was insecurity on both sides. There were no European magistrates in the native territories to bolster or to modify tribal authority. The labour tax (*corvée*) was erratic in its incidence. Above all, not only were the natives denied individual tenure but tribal units had no communal security against European infiltration or malpractices. Missionaries, belonging to what were technically foreign powers, acted not merely as missionaries but necessarily as tribal agents; for instance, the missionary J. Ludorf fought an acrimonious battle to keep the *fonteins* (springs) of Montsioa the Molapo clear from European monopoly. European hunters either killed or drove off the game which was just as much part of the native economy as it was of the European. Since, moreover, the western frontier of the Transvaal was ill-designed, what to the missionaries was encroachment-was to the Boers the legitimate expansion of quasi-nomadic cattle farmers. Concentrated European settlement, organized advance, closer restraint, all these might have enriched trekker life and made an intelligible native policy possible. But it was to avoid these very things that the Boers had defied the policy of the Cape and the advice of their own church in the Cape, and it was not until the 1890s, when it was too late, that they found their Moses in Paul Kruger, who as a child of ten had accompanied the Boers when, beginning in 1835, they wove the epic of the Great Trek.

Second Presidency of Pretorius, 1864–71.—Effectively, M. W. Pretorius had secured his re-election as president of the S.A.R. at the price of abandoning the design to link the two Boer republics. Economically the position of the Transvaal stagnated even where it did not deteriorate. In 1863 the public debt was £10,joo; six years later it had not only grown to £74,000 but bills stood at 75% discount. The South African Mining company began in 1867 to export a little copper, and the discovery of gold at Tati on the fringe of Matabeleland brought about a promising but abortive gold rush which caused prices to rise and adventurers to stream in. The S.A.R. was now at least the mirage of El Dorado. By 1868–69 C. Mauch had discovered signs of alluvial gold in the Lydenburg district, where by 1872 there were to be more than 1.000 diggers.

Though his state was bankrupt, Pretorius became all the more a man of vision, his diplomacy sharpened by the prospects of the Tati gold fields. He made a series of bold moves. He announced the annexation of a strip a mile wide on both sides of the Maputa river to Delagoa bay. This Portugal would not accept, but in July 1869 it concluded with the S.A.R. a free trade treaty on which the subsequent negotiations for the railway from the S.A.R. to Delagoa bay were largely to depend. Second, having stationed a landdrost by Nylstroom in the newly proclaimed district of Waterberg, Pretorius asked Mzilikazi (then on his death bed) and Matsheng the Shoshong to enter at least into a treaty with the republic. Guided by his missionary, J. Mackenzie, Matsheng not only refused but appealed for British protection, while far to the south Ludorf renewed his clamour on behalf of Montsioa the Barolong. For in 1868 Pretorius had already made his third and most challenging move. He announced a western frontier for the S.A.R. which, it was clear, would put the missionary-trader road to the north within the maw of the Transvaalers so that, with a route through to Delagoa bay to the east also in his hands, Pretorius would have a monopoly of trade to and from the Tati gold fields. The 1868 frontier would also have given the S.A.R. the lion's share of the new diamond fields and much of their traffic. Pretorius proclaimed a new district along the Harts river with its centre at Bloemhof and enlarged the control of the field-cornetcy at Zeerust on the Marico river. To some of this western territory he could lay good claim, but he neither mustered nor used his evidence wisely.

In 1871 the Keate award (see SOUTH AFRICA, UNION OF), inescapable on the evidence submitted by Pretorius, designated the Makwassie Spruit as the western boundary of the Transvaal. This not only removed the missionary road from the tenuous and questionable grasp of the Transvaal but also, on paper, stripped away much which Transvaalers had unquestionably settled and developed. More dramatic, the Keate award was followed by the precipitate annexation of the diamond fields by Sir Henry Barkly (high commissioner, 1870–77). Pretorius had promised much and performed little, and the penalty of failure was enforced resignation. Yet much of his grand design was never erased from the politics of the republic.

Presidency of Burgers, 1872–77.—The successor of Pretorius was T. F. Burgers, who was invited to come from the Cape to serve the Boer republic. There can be no doubt about the integrity and vitality of Burgers, but he was handicapped from the start by three factors. He had been a leader in the liberal struggle against the rigid orthodoxy of the Cape synod and had little sympathy with the orthodox separatism of the Transvaal synod; more serious, from the first he was opposed by the Dopper Church in general and Kruger in particular. Second. the S.A.R. was a concept rather than a compact state. In 1871 it was on the defensive against tribes within its own frontier, and it was on the verge of bankruptcy. The third factor in the situation was one over which Burgers lacked control. For 1871 saw the beginnings of economic revolution as a result of the opening of the diamond fields, the rumours of greater treasure trove in the hinterland and the building of railways. In the 1870s British policy in South Africa sought to sponsor the recreation of unity which the conventions of 1852 (Sand River) and 1854 (Bloemfontein) had made fragmentary. Many in South Africa itself felt that a single framework against which the new railway and commercial economy could develop was imperative. Many realized also that the new economic developments demanded the evolution of a common native policy. But if the diamond fields were a golden apple they were also an apple of discord, and the earl of Carnarvon, secretary of state for the colonies in 1874–78, partly because of tactical blunders, partly because of colonial frictions and partly because of general scepticism as to the stability of British policy, found it impossible to win support for his policy of federation. Four years of strain (1877–81) showed that a commercial mentality tended to be a quasi-imperial mentality, while hinterland aversion to possibly premature growth sought spiritual reinforcement in the creation of an Afrikaner tradition.

It is impossible to visualize Burgers' presidency apart from this metamorphosis in South Africa as a whole. Of the changing fronts he was acutely aware, and he attempted a tour de force which, had it succeeded, would have made the Transvaal the hub and not the outwork of southern Africa. But he was alien to the idiom of Transvaal thinking. By encouraging immigrants from the Cape, Natal and the Free State as well as from the Netherlands, he sought to give a fillip to private enterprise and to find an abler type of public servant. In 1874 he used the minor discoveries of gold to order the making of a gold coinage. He tried with the help of E. J. P. Jorissen completely to reorganize the structure of education, and founded the Pretoria gymnasium, the first high school north of the Vaal. But his prohibition of doctrinal teaching was regarded as an atheistical conspiracy, the use of his own profile on coinage was regarded as idolatrous profanity, and his ill-timed attempt to alter the flag was condemned as sabotage; he provided a butt for the old school and a very uncertain beacon for progressives, whose capital ventures were just as precarious as they had been under his predecessor. In 1872 diamonds were found in the Transvaal near Christiana. In 1873 gold was discovered at Spitskop near Sabie and at Pilgrim's Rest. The year 1874 saw the beginning of gold mining in the Kaap valley and at Bloubank. This resulted in a series of local trade booms and some overspeculation. Using his personal credit, Burgers raised a loan of £60,000 from the Dutch-owned Cape Commercial bank and bought up the debased government bills.

There was one field where the "new policies" of Burgers secured a measure of common consent, the field of territorial expansion and transport development. In 1874 he denounced the Keate award, which none had observed anyway, and by negotiation with minor chiefs across the Vaal sought elbow room for expansion across the west. The farm mas still regarded as a great cattle run. and little effort was made to develop more intensive agriculture. Tobacco. but no wheat or maize, was grown for export to the Cape. When the family grew and needed provision it was to the seemingly endless veld that farmers turned. The mortgaging of public lands, quite as much as the refusal of the Venda and the Bapedi to abandon their ranges in the northeastern Transvaal, made the west the natural soft frontier for probing. Hard on the heels of this move followed another equally significant—the effort to secure a reliable route to the sea at Delagoa bay which in the MacMahon award (1875) was assigned to Portugal, not England. Delagoa bay was closer to the Transvaal than Durban; also, it was the one port which, it seemed, Britain could not control.

With momentary unanimity of opinion behind him, Burgers set out in 187j to visit three capitals, London, Amsterdam and Lisbon In London he reassured Carnarvon about confederation without committing himself. At Amsterdam he toyed with federation. but not under the British flag, and raised a heavy loan at rates approaching usury. In Lisbon he negotiated a trade and railway agreement.

Triumphant, he returned to the S.A.R. to confront disillusionment. The Lebombo Railway Co. was floated only to collapse. The railway stock he had ordered was dumped to rust at Lourenço Marques, and the Dutch artisans were dismissed as they arrived at the port. On what little of the loan was taken up the republic could not meet the interest charges. Since the Transvaal debt was secured on land the land market tightened. Drought began in 1876–77. In the Lulu mountains the Bapedi, long a sporadic nuisance, burst into open revolt under Sekukuni (Sikukuni, Secocoeni). Few of the Boers rallied to the commandos which Burgers called out, and Kruger was both ill and disaffected. When Burgers was reduced to creating a volunteer legion he could neither pay nor control them, and the so-called peace of Dec. 1877 registered thinly disguised defeat.

The S.A.R. was bankrupt financially and politically, and its bankruptcy threatened the economic and political stability of the rest of South Africa. Its plight coincided with Carnarvon's growing determination to spring federation on South Africa. In Oct. 1876 Theophilus Shepstone left the colonial office with a discretionary power to annex the Transvaal should its inhabitants desire it; subsequent instructions virtually advised that annexation take place and the desirability be demonstrated afterward. In April 1877 the *raad*, which had indignantly refused to consider reforming that with which it was satisfied, was dismissed and the Transvaal was annexed, after a formal, lukewarm and ambiguous protest by Burgers. It is thought that if Shepstone had put his cards on the table and taken a vote of approval for British action at that point he would have secured the necessary majority. As it was, Burgers' halfhearted protest became a manifesto against usurpation, which, however mishandled, at the time had at least the same merit as plucking a suicide from the edge of a precipice. Burgers retired to the Cape a broken man. He received a pension of £500 from the British government and died in 1881.

BRITISH ANNEXATION AND SUZERAINTY

From Annexation to Retrocession.—As to the necessity or the wisdom of the annexation, opinion remains divided. There were certainly many groups in the Transvaal that welcomed it, and the Transvaal's multifarious creditors in the rest of South Africa openly rejoiced; so too did many in exposed frontier districts, harassed by the Bapedi, uncertain of the Swazi and afraid that Cetywayo's impis were about to wash their spears. But the attitude of the average farmer seems to have been noncommittal rather than favourable. In his annexation speech Shepstone, on behalf of the crown, promised a separate government with its own legislature. Yet at no point was true self-government given. Partly because of this, the British officials failed to gauge Boer opposition.

From April 1877 until Jan. 1879 Shepstone administered the land he had annexed. The proposed Delagoa bay railway plan was quietly dropped in the interests of the projected Natal line from Durban, yet Natal consistently refused to consider a rebate of customs dues on goods in transit to the Transvaal. The imperial treasury made a grant of £100,000 to the Transvaal administration and subsequently agreed to be responsible for the military expense of the war against Sekukuni. The grant was not ungenerous but it was not adequate. The public debt was £300,000 and in a community notoriously averse to direct taxation, accustomed to hoard rather than to invest its savings, taxation was regarded as tyranny and any administration was an infringement of privacy. The defeat of Sekukuni followed by the tardy triumph over the Zulu at Ulundi in July 1879 gave that frontier security which by its existence made the continuous presence of British troops superfluous. The beginning of the Natal system of taxing the natives settled in defined locations helped substantially to restore solvency. Gradually, and at the cost of increasing estrangement of the Boers, security and solvency returned to the Transvaal. Sir Owen Lanyon, who succeeded Shepstone (March 1879–Aug. 1881), was more efficient but even more remote from Transvaal opinion.

In 1877 Kruger headed a deputation which interviewed Carnarvon at the colonial office. He was promised local autonomy for the Transvaal and the retention of the Dutch language, but little else, for the colonial office professed to be assured that the occupation was desired by the inhabitants. Less than a year later, after £3,000 had been collected for his expenses, Kruger returned to the colonial office, this time with convincing evidence of the attitude of the republicans. But Sir Michael Hicks Beach (later Earl St. Aldwyn), the new colonial secretary (1878–80), while renewing protestations of Britain's good intentions insisted that there could be no retrocession of sovereignty. However, by this time both Hicks Beach and Sir Henry Bartle Frere (high commissioner March 1877–Sept. 1880) were convinced of the need for making constitutional concessions. In April 1879 Frere undertook to forward a Boer petition to the colonial office, but in June the appointment of Sir Garnet Wolseley to a separate high commissionership for southeast Africa limited Frere's field to the Cape. Wolseley was an excellent soldier and administrator of occupied territories, but he was impatient of politicians and was himself no statesman. By 1879 Pretorius, Kruger and P. J. Joubert were organizing an independence movement, for Wolseley failed to convince anyone that the council which he created in July 1879 was any different from the legislative council of the old Cape from which the trekkers had fled.

Meanwhile there was much to encourage the Boer opposition. To the north and east the frontier was secure. For the first time in Transvaal history the finances were sound. Both facts steeled waverers to rally to the patriots. In Britain Gladstone's exuberant attack on Disraeli's Balkan policy lured him into defending oppressed nationalities in general and the Transvaal in particular. Kruger and the independence party had grounds then for expecting a total reversal of British policy in South Africa when, in April 1880, Gladstone displaced Disraeli as prime minister. Yet once in office Gladstone faltered and fumbled. There is evidence that he intended to move very much along the lines etched later at the convention of Pretoria (see below), but dissensions in the cabinet and obstruction in the commons led to postponement. In the transvaal Lanyon underestimated the swelling tide of Boer patriotism, gave Gladstone no warning and the Boers no reassurance. But in fact the ubiquity and efficiency of British administration had created a national temper in the Transvaal of such a calibre that had it existed in the previous decade annexation would have been unnecessary.

At the close of 1880 the Transvaal sprang to arms. The republic was proclaimed at Paardekraal on Dingaan's day, 1880. Lanyon was besieged in Pretoria and the 94th regiment, hastening to his relief, was cut to pieces in ambush, while the Boers advanced on Natal. Without waiting for reinforcements G. P. Colley moved to intercept, was worsted at Laing's Nek and Ingogo (Feb. 8, 1881) and overwhelmed at Majuba on Feb. 27. There can be little doubt that the Boers would have been defeated had Britain decided on a major military move to restore the status quo before negotiating. But already, before Majuba, Gladstone's policy had belatedly crystallized, and on Feb. 7 (the day before Ingogo) Colley had received notice of Britain's intention to negotiate with the Boers. But Colley delayed getting in touch with Kruger and the crucial dispatch was, ironically, not delivered until after Majuba. Victory or defeat, Gladstone was resolved on principle to proceed with negotiations wherein he sought to reconcile Transvaal liberty with imperial responsibility for a beneficent native policy. But after Majuba negotiation to the Afrikaner spelled weakness and to the English-speaking colonials betrayal. Gladstone's policy failed to correct either impression.

Conventions of Pretoria and London.—From Aug. 1881 until May 1883 the Transvaal was administered by the triumvirate, Kruger, Pretorius and Joubert. In 1883, by an overwhelming majority, Kruger was elected president and was thereafter re-elected cntil the second annexation of the Transvaal in Sept. 1900. In Aug. 1881 a convention was concluded at Pretoria by direct negotiation between a royal commission and the triumvirate. The convention of Pretoria established a *modus* vivendi which as late as 1879 might have worked fruitfully but which after Majuba was ratified only with difficulty by the volksraad. But Kruger, if not the volksraad, had learned to grasp the substance which was de facto independence, with a view to dispelling the shadow of suzerainty at some more convenient point. The Transvaal took over about half the debt incurred by the British administration and secured the Harts river as its western boundary in place of the Makwassie Spruit specified in the Keate award. Britain retained a crown veto on native legislation and the right to appoint a British resident with a seat on the Native Locations commission; no treaties, either with foreign powers or with native chiefs beyond the frontiers, were to be concluded without British consent.

The immediate reaction in the Transvaal was an economic slump. In little more than a year the Transvaal had defaulted in its debt to Britain; it had crippled free enterprise by the sale of monopolies; it had estranged many in South Africa by the imposition of customs barriers; and it regarded as traitors those both in the Free State and the Cape who realized that, repugnant though British blunders often were, the security of South Africa and much of its economic stability depended on the insurance of the British connection. Many Transvaalers trekked in search of fresh pastures. In 1882 the new republics of Stellaland and Goshen, west of the Harts river between Taungs and Mafeking, were founded, and Boers from the Cape and the Free State as well as the Transvaal pushed back the Batlapin and the Barolong. The colonial office expressed concern over the fate of the native peoples whose chiefs, without forethought or scruple, sought alternately British and Boer protection. Whether victor or vanquished in intertribal conflicts, the natives invariably forfeited much of their land to European speculators. Cecil Rhodes grasped that the issue was one of territories not peoples, vital territory, since once again the only route to the north between the Kalahari and the republics was in peril. He urged the Cape to annex, but the Cape, having annexed much of the Transkei in 1879 and paralyzed to the point of defeatism in Basutoland, was chary of the responsibility of further annexations.

In 1884 accordingly, at London, Kruger on behalf of the Transvaal, Sir H. G. Robinson (high commissioner, 1881–89) on behalf of the Cape and the earl of Derby (colonial secretary, 1882–85) signed what was at once a revision and an amplification of the convention of Pretoria. All mention of the suzerainty categorically asserted in 1881 was tacitly dropped, and the republic secured acknowledgment of the title of the South African republic. On the west the frontier was rectified. The lands of Massouw and Mashete, both of whom were pro-Boer, were recognized as belonging to the republic, which thus secured a part of Stellaland and Goshen. Article 12 reiterated the independence of the Swazi to the east. Article 4 prohibited the conclusion of treaties with foreign powers or with native chiefs outside the borders of the S.A.R. without crown sanction. Article 14 guaranteed that no discriminatory regulations should be imposed on immigrants into the Transvaal. But by dropping the claim to appoint a resident to sit on the Native Locations commission and dropping the veto on native legislation, Britain no longer retained reasonable grounds for interfering in the internal affairs of the Transvaal.

The convention of London was ratified by the volksraad in Aug. 1884. But already new causes of dissension, made more tense by the German annexation of South-West Africa, had arisen. In April 1884 a group of Transvaal Boers moved into Zululand to join Lukas Meyer of Utrecht, who was officially in alliance with Dinizulu. For services rendered, they claimed what was in effect a drastic extension of the Blood River territory and Pongola strip—a new republic thrust down to the Indian ocean between the Umhlatusi and White Umfolosi to secure the littoral of St. Lucia bay. Zulus, displaced by tribal war and dislocated by Boer surveyors, poured into the Natal reserves, while the colonial office, perturbed by German policy in the Pacific as well as in Africa, claimed St. Lucia bay in terms of the 1843 treaty with Mpande (Panda), and in Jan. 1885 claimed a protectorate over the whole of the Pondoland coast. The new republicans claimed to have divested themselves of their former citizenship so that the letter of the convention was not technically broken. In 1886 Britain recognized the new republic. now shorn of its coastal territories, and in 1887 annexed Zululand as logically it should have done in 1879. In 1888 the new republic joined the Transvaal and was incorporated as the district of Vryheid, so that the boundaries of the S.A.R. in 1888 were effectively not those agreed upon in 1884.

To the west of the Transvaal the position was at first no more stable. Bechuanaland was a tribal chaos, but the colonial office, which in 1884 had reluctantly resumed responsibility for Basutoland, hesitated to intervene. In the confusion one resolute action might turn the issue. Kruger annexed Goshen. His action goaded Britain into action already overdue. In 1885 Bechuanaland south of the Molapo river became a crown colony, and north of the river a protectorate was declared and policed. In brief, the road to the north forged mainly by hunters and British missionaries was kept open, a highway for all, the sealed monopoly of none.

Kruger was by no means unaware of the exigencies of British diplomacy. For instance, Berlin as well as Pretoria protested at the annexation of St. Lucia bay, and the new republic had openly sought the aid of three continental powers. From London, Kruger in 1884 had journeyed to the Netherlands, Belgium, France, Portugal, Spain and Germany. In the Netherlands the Netherlands South Africa Railway Co. was given valuable concessions and the monopoly of railway construction in the S.A.R. In Lisbon Kruger discussed the recent concession of the Portuguese government to the American Col. E. McMurdo, who had undertaken to build a railway up to the Transvaal frontier from Delagoa bay. This was Burgers redivivus; but Kruger was a natural politician, persuasive, evasive, studying the art of the possible without ever losing sight of the desirable. He sought a free-growing and prosperous Transvaal with its own route to the sea. The Transvaal in the early days under Kruger was as near bankruptcy as it had ever been under Burgers; no part of South Africa had been so hardly hit by the recent slump; yet his diplomacy was still firm and his confidence unshaken. On paper his plans were the plans of Pretorius and of Burgers before him. But, though the discovery of gold played its part, what differed was the calibre of the man.

Discovery of the Witwatersrand Gold Fields.—When the economic collapse of the Transvaal seemed imminent. the discovery of the Sheba mine in the Barberton area and the more important gold-bearing complex of the Witwatersrand started an industrial revolution which was to metamorphose not only the republic but the whole of South Africa. At the same time the concentration of urban population was a great stimulus to agriculture. Hitherto, apart from tobacco, most farmers had been content with little above a subsistence economy. Henceforward maize, wheat, fruit, etc., were grown as a commercial proposition made more attractive by the development of railway transport. As a result a kind of imperialism beckoned to all the Dutch-speaking people of southern Africa, to make the now wealthy Transvaal the centrepiece of a revival of the trekker pattern of life.

External Relations, 1886–95.—Externaliy the policy of the Transvaal continued to be a logical extension of trekker politics. From 1886 onward Kruger. whose tentative overtures for a customs union in 1884 and 1885 had been rebuffed by the Cape, concentrated on forging a path to the sea, independent of British control and untrammelled by colonial tariffs. In particular he regarded the Netherlands Railway Co. with its preponderance of Dutch and German shareholders as his special creation. When in Jan. 1895 he officially opened the completed Pretoria-Delagoa Bay railway, the tenacity of Transvaal policy seemed justified. Having declined to enter the projected customs union of 1889, Kruger nevertheless concluded a belated railway convention with Natal. In this way the Transvaal sought the best of both worlds.

At Kosi bay, which the Transvaal could reach by driving through Swaziland, was the one port not yet covered either by Portuguese or by British claims. Since the independence of Swaziland had been expressly guaranteed by the conventions of Pretoria and London, a railway concession through Swaziland could be achieved only with British connivance. But though the London convention had defined both the eastern and the western frontiers of the Transvaal, the northern limit had not been so precisely fixed. In 1887 a concession was secured by the Boers from the Matabele north of the Limpopo. Kruger sought to barter forbearance in the north against privilege to the east in Swaziland and the development of Kosi bay. Three Swazi conventions were signed (1890, 1893 and 1894), and in the third Britain finally visualized the rule of the republic in Swaziland subject to safeguards for the natives.

By 1894 the high commissioner, Sir Henry (later Baron) Loch (1889–95), had been prepared to raise the question of the *Uitlander* franchise on a *quid pro quo* basis had German protests not prevented it. The German government regarded the commercial federation of South Africa, which was Rhodes's minimum objective, as a menace to German commerce in the Transvaal. In Jan. 1895 Kruger openly boasted of German protection, and to discreet British remonstrance at Berlin, Baron von Marschall replied that "interests demanded the maintenance of the Transvaal as a state economically independent and the safety of the *status quo* regarding railways and Delagoa bay." British reaction was sharp and legitimate. In response to the appeal of Queen Sambili, Britain in Feb. 1888 had pronounced Tongaland a British sphere of influence. In May 1895 the coast, including Kosi bay, was annexed.

The Transvaal was in fact surrounded. But it was not surrounded by foes. Railway agreements could be made with the Cape and the Free State, as they had been with Natal. But within the Transvaal, railway transport was the monopoly of the Netherlands Railway Co., which placed differential rates on goods in transit from colonial ports. Consequently merchants from the south unloaded at the border and reverted to wagon transport for the rest of the journey to the Rand. In Oct. 1895 Kruger closed the Drifts (ford across the Vaal). An ultimatum from Joseph Chamberlain (colonial secretary, 1895–1903), sent with the backing of the Cape government, forced Kruger to withdraw in November. If Kruger's policy within the Transvaal had been the most liberal in the world, his external relations would have provoked criticism.

Effects of the Discovery of Gold.—From being the poorest, the Transvaal had become the wealthiest of the South African communities. Inevitably a flood of immigrants of all nationalities (British and German preponderating) invaded the republic and their numbers soon exceeded that of the burghers. Their whole economy and social habits were the product of urban life overseas, whereas the burghers cleaved, at least officially, to the habits of life engendered by a diffuse rural economy. The immigrants (dubbed *Uitlanders)* threatened to overwhelm the old order and to metamorphose the state. Given time, social fusion and political readjustment could have been brought about, for the leaven of a money economy was altering the structure of Boer society; Kruger did not face a simple issue of a burgher community of the elect ranged against the servants of mammon, though many of his supporters visualized it as such. From the first he perceived that the *Uitlanders* were not a solid bloc. Some came to settle and would make permanent contributions to the country. Many came to make fortunes and depart. Further, joint-stock undertakings rapidly displaced the private enterprise of the digger. That meant that there was not one but, broadly, three classes, the mining capitalist, the commercial class and the skilled artisans. A third factor was that without native labour the mines could not be worked. Hitherto the natives had been blocked on tribal land, where since the British occupation of 1877–81 they had, if cramped, enjoyed increasing security of tenure. Now the simple territorial approach to the native problem no longer sufficed.

Kruger had a shrewd insight into realities. But his memory and burgher traditions were long and bitter. The new wealth seemed to provide the opportunity to thrust against the geographical encirclement dictated by British policy and the more insidious commercial suction which Rhodes sought to apply to bring back the trekkers into the vortex of the Cape. In the second place Kruger's presidency was subject to re-election every five years, and the rivalry of P. J. Joubert and later of Schalk Burger was formidable.

Franchise Issue.—Unfortunately neither the burghers nor the Hollanders whom Kruger imported had the ability and scruples necessary to make administration fit the needs of the *Uitlanders.* The monopolies and other concessions, including the dynamite monopoly, were vested interests developed before the Rand was discovered. The Netherlands Railway Co. provided a harvest of contracts for Hollanders and charged excessive and discriminating rates. Though in 1882 Dutch had been recognized as the official language in the Cape, English was not so recognized in the Transvaal. The provision of schools and municipal services was hopelessly inadequate. When petitions to the *volksraad* failed, malcontent *Uitlanders,* many of whom were colonials, pressed for the franchise which alone could give them political expression. On this point neither the president nor the *volksraad* would budge. To the contrary, as *Uitlander* pressure increased, the franchise, which in 1882 had been reasonably limited to burghers and to settlers of five years' standing, was made more limited. In 1891 a significant pointer was given. All who had fought for the republic at Majuba were enfranchised. A year earlier a second *raad* (for which a vote was obtainable after two years' registration) was established to deal with the concerns of the mining areas, but since it had no taxing powers, and its decisions were subject to review by the first *mad*, it could never be more than a talking shop. A minimum of 14 years' residence was required to qualify for the franchise for the first *raad* and for presidential elections. Moreover, the status of the child born in the Transvaal depended on the status of his parent, so that the franchise was entailed. Since the first *raad* could legislate in a self-diagnosed emergency by *ad hoc* resolution or *besluit,* there was no guarantee that the residence qualification would not be indefinitely extended by this means. This situation consolidated a discordant opposition which Kruger might otherwise have divided.

In 1892 there was a slump on the Rand; drought hit the farms; customs and railway rates kept up the cost of living. Charles Leonard, an attorney who had come from the Cape, founded the National Reform union, to agitate for better administration and an extension of the franchise. This was a popular and, it should be noted, an indigenous, even local, South African movement; and the prime objectives seem to have been neither imperial nor Cape-federal. As the spirit of the Transvaal became more obdurate in its attitude to reform, so British policy hardened. In 1894, encouraged, and in part misled, by German diplomacy, Kruger began to arm. Over Swaziland, over customs rates, wherever the Transvaal encountered either the high commissioner or the Cape (where Rhodes was now prime minister) there was deadlock. Increasingly it seemed to many that only by solving the franchise issue across the Vaal could South African, not to mention Transvaal, problems be solved.

Jameson Raid.—On Dec. 29, 1895, L. S. Jameson, friend and agent of Rhodes, invaded the Transvaal from his base at Pitsani in Bechuanaland, where he had been stationed in Rhodes's railway concession strip, theoretically to police the route to the north, in practice to watch events at Johannesburg. It had been anticipated that the *Uitlanders* would rise in revolt in the cause of reform. In that case Jameson's task force was to intervene and hold the position for Rhodes. But proceedings in Johannesburg and Pretoria had moved slowly and clumsily, so much so that Kruger had paced their every move. Some favoured reform only with no change of status; some favoured a republican revolt with complete independence as the goal; some favoured revolt and federation with the Cape; some favoured revolt and the hoisting of the British flag. Rhodes advised that the decision about the flag could be taken afterward by plebiscite, but that meantime the projected revolt should be postponed. However, Rhodes's message did not reach Jameson, who attempted a coup aimed as much against the critics of Rhodes as against Kruger. The raid was a fiasco. On Jan. 2 Jameson, surrounded at Doomkop, surrendered to the Boers, while the leaders of the feeble revolt that had followed his advance were likewise arrested and imprisoned. Jameson and his men were handed over to Sir Hercules Robinson (later Baron Rosmead; high commissioner, 1895–97). The Johannesburg leaders, Lionel Phillips, Frank Rhodes, J. H. Hammond, George Farrar and others were condemned to death for high treason. Sentence was commuted to fine and imprisonment, the latter in most cases being also commuted. Rhodes paid the fines.

The high commissioner acted promptly and correctly, and the peaceful surrender of Johannesburg on Jan. 7 was attributable in part to his efforts. There was resentment against the raid among both the British and the Afrikaners, but the edge was blunted somewhat outside the Transvaal, when the kaiser congratulated Kruger in an open telegram on breaking the raid "without appealing to the help of friendly powers." For the time being Rhodes's power in the Cape was broken. He withdrew to Rhodesia. The commission of inquiry in Britain which reported in 1897 censured him but proved no complicity on the part of the colonial office. Joseph Chamberlain, in the house of communs, emphasized that the raid as such had been countermanded by Rhodes and (it is thought under pressure) whitewashed Rhodes in a general defense of his policy. Modern research, though some vital documents are destroyed, has shown that both the high commissioner and the colonial office were, at the very least, in a position to know and therefore to have condemned what was being planned.

WAR AND THE UNION

From the **Raid** to War.—Tension in South Africa had been marked before the raid; after the raid the position became increasingly grave, for the fruitful partnership in the Cape which Rhodes had maintained with J. H. Hofmeyr, and through Hofmeyr with the Afrikaner Bond, was snapped. Throughout South Africa Kruger, who to many at the time of the Drifts crisis had seemed an obstacle to progress, now to the Afrikaners everywhere appeared as the bulwark against chauvinist imperialism. Unfortunately, legitimate resentment was translated by Kruger into four moves which aggravated the position. The Transvaal moved into closer touch with Germany and accelerated its armaments; it built on to the defensive alliance with the Free State and worked for a federal link between the two republics; Kruger pursued with redoubled skill the drive to absorb Swaziland in defiance of the conventions; and in the republic he was forced to yield increasingly to the implacables in the volksraad. His own views also had hardened. In 1896 a new press law crippled the English press in the Transvaal. More serious, since by implication they raised the suzerainty issue, laws providing for the expulsion of aliens and a drastic tightening of immigration laws were passed. The executive was given increasingly autocratic powers. Only a military demonstration at Ladysmith and the dispatch of warships to Delagoa bay secured the repeal of the immigration laws. In 1897 Judge J. G. Kotze (in R. E. Brown v. Dr. Leyds) ruled that legislation by *besluit* was contrary to the constitution and claimed for the courts a testing power analogous to that of the U.S. supreme court; then Kruger, with an election in the offing, secured from the volksraad the right to dismiss any judge who claimed the testing power, but, on the intervention of Chief Justice de Villiers of the Cape, did not exert the right pending some amendment of the *grondwet*. At the election the rival candidature of Joubert and Burger split the opposition vote and Kruger was returned in triumph.

After the election Kotze was dismissed (Feb. 1898) and opposition against Kruger hardened again. Concentration on franchise reform seemed the only rational procedure. In Feb. 1899 a petition to Queen Victoria signed by 21,000 British subjects was drawn up. This was supported by a dispatch (May 4, 1899) telegraphed to London by Sir Alfred (later Viscount) Milner (high commissioner, 1897–1905). In June a conference took place at Bloemfontein. Some of Kruger's delegation, among them Schalk Burger, opposed any change. Kruger offered an equivocal seven-year franchise but insisted that it be bartered against the incorporation of Swaziland in the Transvaal and the submission of future disputes to an arbitration procedure which would carry the implication that the conventions were a dead letter. The feeling was that if the issue broadened into the general issue of suzerainty, and if Britain yielded on that point, in the existing constitutional confusion in the Transvaal there would be no guarantee of the permanency of any concessions Kruger might make. In July 1899 the Transvaal executive resolved to increase the number of seats in both raads and, eschewing Milner's stipulated five-year franchise, proposed to substitute, albeit in simplified form, a seven-year franchise, which Milner had already rejected at Bloemfontein. Though feeling on both sides was mounting, Chamberlain sanctioned a new joint inquiry in August, wherein Conyngham Greene acted for Britain and J. C. Smuts for the republic. Before the end of the month Smuts had agreed on the five-year franchise but again at a price which he left discreetly vague but which F. W. Reitz hardened, namely the dropping of the suzerainty claim. Chamberlain therefore could make only a qualified acceptance. Kruger's answer to Chamberlain's reservations on the suzerainty issue was to revert to the seven-year franchise. Thereupon Chamberlain claimed that if his reservations were ignored, he must consider the whole question anew. Parallel with the adoption of this stiffer tone went the drafting of troops from India and the Mediterranean. On Oct. 9 the Transvaal presented an ultimatum to Conyngham Greene in Pretoria, demanding the withdrawal of all reinforcements and cancellation of the troop movements. Throughout, the Free State had striven to avert the war, in which, in terms of its alliance with the Transvaal, it was bound to be involved. But when, as was inevitable, Britain declared war, the Free State moved loyally if belatedly to support the Transvaal. If there was justice on both sides so too was there bigotry and arrogance, and the war was an index of failure on both sides. In the event it solved nothing.

From War to Union.—For the events of the war itself *see* SOUTH AFRICAN WAR. Peace proposals were rejected by the Boer leaders at Middelburg in March 1901, and the treaty of Vereeniging, May 31, 1902, was signed only when the resources of the Boers had been broken by unceasing strain against superior forces.

Already in March 1901 Milner had arrived at Pretoria to inaugurate a civil administration, for the rate of South African recovery would depend in part on the rapidity with which gold production could be resumed, in part on the skill with which men were resettled on the derelict farms. Farming, hit seriously by rinderpest in 1895–96, had suffered severely during the war period, and it was estimated that half the livestock in the republics had perished. As high commissioner and governor of the Transvaal and Orange River colony (the former Free State), Milner treated the problem of rehabilitation as involving a single unit and this went far to complete the links between the two Boer states which Kruger and Pretorius before him had striven to forge.

Milner created an efficient four-judge supreme court and made no attempt to substitute British for Roman-Dutch law. Municipal government was organized, the Rand Water board was created by ordinance in 1903, and improvement little short of spectacular was made in the provision of schools and teachers. Some blocks of land were bought and earmarked for British settlers (596 immigrants were settled under this scheme), but the main effort was made to restore the rural economy by the prompt granting of relief. the assessment of war damage, the provision of seed and the loan of agricultural equipment. More than £10,000,000 in grants and loans was spent on development projects. As an emergency measure labour difficulties in the mines were met by the importation of Chinese coolie labour. It served its purpose and by 1908 the mines were producing £30,000,000. Parallel with the most brilliant piece of administrative reconstruction that to that time had been attempted anywhere by Britain went Milner's moves to set the points right for federation. He bought out the Netherlands Railway Co. and placed the railway system of the Transvaal and the Orange River colony under joint administration. Between 1903 and 1905 an intercolonial Commission on Native Affairs met under the chairmanship of Sir Godfrey Lagden and examined in detail the structure of native administration in each colony. The problems of railway rates, customs and tariffs were studied, and each deadlock emphasized the need for union.

Meanwhile Louis Botha and J. C. Smuts, neither of them Transvaalers by birth, began the political education of the Afrikaner in the Transvaal. In Jan. 1904, having deliberately declined to participate in Milner's nominated legislative council, Botha formed Het Volk, a party with two objectives, conciliation and self-government. The latter was also the objective of the former *Uitlanders*, and Milner and his council became the target of both. In April 1905 Milner was replaced by another Tory peer, Lord Selborne (high commissioner, 1905–10), who was empowered by letters patent to institute representative government. But largely as the result of Smuts's unofficial visit to London soon after the Liberal ministry of Sir Henry Campbell-Bannerman took office, the Liberal cabinet advised the immediate granting of responsible government. New letters patent were issued in Dec. 1906. The first election was held at the beginning of 1907 and Het Volk secured 37 of the 69 seats in the new legislative assembly. Selborne therefore asked Louis Botha to form a ministry and Botha included Smuts in his team. Between 1907 and 1910, when the Transvaal was merged in the union, the ministry displayed great ability. Smuts's Education act, which provided for mother-tongue education in the primary years with English instruction thereafter and five hours of Dutch per week, though it annoyed extremists on both sides, was a much more tolerant approach to a difficult problem than that of J. B. M. Hertzog in the Orange River colony. There was no blind panic about the Chinese coolies, though all were agreed they must go. They were repatriated as their indentures expired, and by 1910 the exodus was completed. A firm but inconclusive approach was made to the Indian problem. In 1907 Smuts supported a stringent immigration and registration law which was met by the first passive resistance campaign of Mohandas K. Gandhi, who secured for the moment the repeal of the laws in question without any improvement otherwise in the position of Asians.

But the major problem was the one the ministry had inherited from Milner; namely, the problem of federation. Intercolonial conferences on such vital matters as a common appeal court, a common native policy and railway rates and customs proved sterile in spite of repeated efforts. Failure of the Customs conference of May 1908 provided the occasion for Smuts to move six resolutions in favour of taking concrete steps toward attaining political union.

At the national convention which met in Durban in Oct. 1908 Smuts proved his mettle. He broke the Natal move to substitute federation for a closer union, and whenever rupture threatened he smoothed away objections or found a compromise formula. Botha's more sober approach was equally impressive and did more probably to convince the Afrikaners than the mental agility of Smuts. Together they made a perfect team, and the result was that Pretoria became the axis of political gravity.

Transvaal After the Union. — The structure and powers of the Transvaal provincial council as established by the South Africa act. 1909 (see SOUTH AFRICA, UNION OF), were precisely those of the other provinces; but the wealth and resources of the Transvaal, the problems created by its rapid industrialization, and the fact that the union was substantially made and moulded by Botha and Smuts, all conspired to make the Transvaal province the touchstone of South African politics. The first prime minister of the Union was Botha (1910–19), and for 29 of the first 40 years of union his successor, Smuts, was a member of the Union cabinet and for 14 years prime minister.

The economic development of the Transvaal after union was phenomenal: stable government, a stronger diplomatic position vis-à-vis Portugal and a national approach to customs and transport provided a framework for growth. In 1910 Johannesburg was already the largest town in the union, and it retained its primacy. In 1951, of 16 South African towns with populations of more than 20,000, 9 were in the Transvaal. The weight of the population shifted from the Cape to the Transvaal, and by periodic redistribution of seats, the Transvaal representation in the assembly increased to 68—14 more than the Cape. In the 1946 census, 397,497 of the Europeans in the Transvaal were English-speaking, 621.035 were Afrikaans-speaking and 16,056 were bilingual. A provincial education ordinance required children to attend the school whose medium of instruction was the certified home language of the parent, irrespective of the parent's stated wishes. This evoked bitter controversy in the Transvaal and in the Union.

Developments in the Transvaal which at first sight seem to be merely provincial have reacted, because of its economic importance, on the Union as a whole. It was on the Rand that the three main problems which haunted the Union government after 1910 first crystallized: the relations between capital and European labour; the relations between European and both native and coloured labour; and the problem of trying to maintain the territorial *apartheid,* or segregation of races, traditional in the Transvaal, while at the same time feeding the labour market.

In 1913 a labour dispute at Kleinfontein gold mine at Benoni developed into an armed clash with the troops in which 27 were killed and 47 wounded. If the Rand were paralyzed the Union would be crippled, and renewed strikes in 1914 were answered by the deportation of the leaders. The victory of Labour in the Transvaal provincial election made it impossible for the central government to evade legislation. In 1914 workmen's compensation was improved; it was extended to cover benefit for miners' phthisis and marked the beginning of an industrial code. As industrialization developed to the point of economic revolution, so the labour legislation of the Union government increased in scope.

It was on the Rand, moreover, that the question of the relation between European and non-European workers presented itself in its most acute form. Fear of unemployment and low wages when the Chamber of Mines sought economy by reducing the proportion of European labour, and when wage rates in the coal mines fell, led to the great miners' strike of 1922. It was suppressed only after a loss of life greater than that in the South-West Africa campaign of 1915. In the 1924 election Transvaal labour voted either Labour or Nationalist, and Hertzog in quasi-coalition with F. H. P. Creswell secured and extended the colour bar which in practice already existed in the mines. There was temporary identity of interest rather than of theory between the two parties, and the pressure of Afrikaner nationalism alienated a section of the Labour council. Native trade unions were not recognized by the Industrial Conciliation act of 1936, but by 1942 more than 30 unofficialnative unions existed on the Rand and the example was followed elsewhere. The Native Labour Settlement of Disputes act, 1953, prohibited strikes and lockouts but provided new machinery for settling native industrial disputes. Some native unions are affiliated to the European unions in the respective trades, so that yet another experiment that may affect the Union as a whole has emanated from the Transvaal.

Just as the Transvaal by its precocious industrial development provided the spearhead of a labour thrust, so too it seems that the Transvaal attitude toward both rural and urban natives has increasingly influenced the native policy of the Union government. The Group Areas act of 1950 was one of a series of acts which sought to implement Smuts's Natives Land act of 1913, which checked the penetration of natives into European areas and vice versa as firmly as Boer commandos had held the frontiers in the old Transvaal. The Native Resettlement bill, 1954, proposed an arbitrary clearance of native townships over the heads of the johannesburg city council, where the Native Trust and Land Amendment bill, 1953, removed the necessity, hitherto incumbent on the authorities, to provide alternative accommodation for natives evicted under the Natives (Urban Areas) Consolidation act, 1945. Many of the devices of the old Transvaal system — the pass laws, the segregation, the colour, as distinct from the civilization, test of the old Cape franchise--mutatis mutandis passed into the national structure of native policy. The half century which opened with the British annexation of the Transvaal in 1900 saw not merely the triumph of a policy of union sponsored by Transvaal statesmen who were opposed on principle to a liberal franchise. but also the triumph within the Union of the trekker spirit translated into the idiom of a commercial society. (W. A. ML.)

SOCIAL AND ECONOMIC CONDITIONS

Population. — The population in 1951 numbered 4,801,708, including 1,204,712 whites. The largest proportion of these latter is centred in gold and uranium production areas, in coal mining and iron and steel industrial areas. The natives in 1951 numbered 3,472,640. Apart from the large numbers employed in the gold and coal mines and in the iron and steel industry, they are concentrated chiefly in the native reserves. These are mainly in the Pietersburg, Potgietersrust, Zoutpansberg, Letaba, Rustenburg, Brits, Pretoria, Middelburg, Lydenburg, Pilgrim's Rest, Nelspruit and Barberton areas. Basutos are numerous in the Zoutpansberg and Lydenburg districts, Bechuana are largely confined to the west and southwest, Amazulu are found principally in the Wakkerstroom and Standerton districts and Amaswazi in the Barberton, Ermelo and Wakkerstroom districts. Shangaan and other east coast tribes form an appreciable element in Barberton, Lydenburg and Zoutpansberg. Asians numbered 49,342 in 1951. They are largely engaged in trade and are settled on the Witwatersrand, in Pretoria and in Barberton. Other nonwhites numbered 75,014.

Towns.—Pretoria (*q.v.*) is the administrative capital of the Transvaal and of the Union of South Africa. Johannesburg is the largest city. Other towns of more than 50,000 inhabitants are Germiston, Springs, Brakpan, Roodeport-Maraisburg, Benoni, Krugersdorp, Boksburg and Vereeniging. Further towns of importance are Pietersburg, Barberton, Witbank, Lydenburg, Blyvooruitzicht.

Education.—Primary and secondary education for Europeans and non-Europeans (other than Africans) and the training of teachers are administered by the province. University, technical and vocational, agricultural and special education and, since 1954, the preuniversity education of Africans is administered by the Union. European primary and secondary education (785 schools in 1951) is mainly public education and is financed by the province. Private schools (111 in 1951) cater for only a small percentage of the children. Non-European primary and secondary education (1,406 schools in 1951) is mainly state-aided (before 1954 through the provincial administration; in and after 1954 by the Union government), and is partly financed and controlled by mission enterprise. The relative contribution of the state (Union and province combined) to non-European education is small in comparison with that for European education—in 1954 approximately £2,500,000 as against nearly £10,000,000. Segregation of the races in primary and secondary education is complete. From 1950 every white child in the Transvaal was taught through the medium of his home language. There are two technical colleges, Witwatersrand and Pretoria. Agricultural education is available in farm schools, at the Agricultural college (Potchefstroom) and at two universities (Pretoria and Potchefstroom). There are three universities, Witwatersrand, Pretoria and Potchefstroom.

Provincial Government.—At the head of the executive is a provincial administrator, appointed by the governor general in council. He holds office for five years and is assisted by an executive committee of four members elected by the provincial council consisting of 50 members, elected for the same constituencies and by the same electorate as are the members of the house of assembly. The provincial council, which has strictly local powers, sits for a statutory period of three years.

Provincial expenditure in 1949 was £19,965,081, of which £9,019,930 was for education.

Agriculture.—Next to mining, agriculture is the most important occupation in the Transvaal. Mixed farming is practised by most of the white farmers. Good summer grazing is available on the high veld, but during the winter months stock loses condition and requires supplementary feed. In the low veld good pastures are found but low rainfall is a limiting factor. Much stock is moved from the high veld to the bushveld and the low veld for winter grazing. The low veld and middle veld are unsuited in summer for horses and sheep because of horse sickness, blue tongue, etc. The tsetse fly used to be deadly to cattle in the low veld, but it disappeared naturally in 1898 after the rinderpest outbreak. The prevalence of ticks is one of the main drawbacks to stock farming. In 1951 there were 2,232,008 cattle owned by whites and 3,386,972 owned by natives, 2,747,776 sheep owned by whites and 3,047,940 owned by natives and 71,747 goats owned by whites and 803,817 owned by natives.

The amount of land under cultivation is small in comparison with the area of the province, chiefly because, for physical reasons, it cannot be plowed. Moreover, while large areas on the high veld are suitable for the raising of crops of a very varied character, in other districts, including a great part of the low veld, arable farming is impossible or unprofitable. Many regions suffer permanently from deficient rainfall; in others, because of the absence of irrigation works, the water supply is lost, while the burning of the grass at the end of summer, a practice adopted by many farmers, tends to impoverish the soil and render it arid. The country suffers also from periods of excessive heat and general drought, and formerly was often devastated by locusts. After 1950, however. there was no invasion of the province by these pests, largely as a result of successful methods of destruction, in which chemicals are used. The districts with the greatest area under cultivation are Heidelberg, Witwatersrand, Pretoria, Standerton and Krugersdorp. The chief crops grown for grain are maize (mealie), kafir and wheat. Maize is the staple food of the natives. Oats, barley and millet are largely grown for forage. The chief vegetables grown are potatoes, pumpkins, carrots, onions and tomatoes. Fruit farming is a large industry on the slopes of the plateaus and in the warmer valleys, where citrus and other subtropical fruits thrive where irrigation is available; *e.g.*, about Rustenburg, Waterberg, etc. Citrus production (all varieties) was 10,850,000 pockets in 1950, 9,600,000 in 1951, 8,600,000 in 1952, one pocket being equal to 30 lb. of fruit. In 1950 there were 582,000 nonbearing trees and 2,023,000 bearing trees. Considerable expansion, however, took place and brought the number of nonbearing trees up to about 706,000 by the mid-1950s. Apples, deciduous fruits and grapes are also grown.

In 1950 cotton was grown, by whites only, chiefly in the Barberton, Rustenburg, Piet Retief, Nelspruit, Waterberg, Pilgrim's Rest and Letaba areas. The yield varied from 2,390,756 lb. at Barberton to 80,970 lb. at Letaba. Tobacco is grown chiefly in the Brits, Marico, Rustenburg, Waterberg, Piet Retief, Letaba, Pietersburg, Potgietersrust and Zoutpansberg districts. The Transvaal produces about four-fifths of the total tobacco crop of the Union, which in 1951–52 amounted to more than 53,000,000 lb.

Mineral Resources.—The Transvaal, the principal gold-producing country in the world, is noted for the abundance and variety of its mineral resources. Besides gold, the minerals chiefly mined are diamonds and coal, but the province also possesses platinum, asbestos, silver, iron, copper, lead, tin, cobalt, sulphur, saltpetre and many other mineral deposits. The production of uranium was being undertaken in three of the gold mines in the 1950s, and great expansion was expected.

Gold.—The principal gold-bearing reefs are found along the Witwatersrand (the "Rand"). Probably connected with the Rand reefs are the gold-bearing rocks in the Potchefstroom and Venterskroon districts. Other auriferous reefs are found all along the eastern escarpment of the Drakensberg and are worked in the Barberton district, on the Swaziland frontier in the Lydenburg district, in the Murchison range and in other places in the Zoutpansberg. Gold fields also exist in the Waterberg and on the western frontier in the Marico district. Production of gold in 1952 amounted to 11,594,271 oz. with a value of £143,913,888.

Diamonds.—The chief diamond fields are in the Pretoria district. The ground was discovered to be diamantiferous in 1897, but it was not until 1903, when mining began on the Premier mine, 20 mi. N.E. of Pretoria, that the wealth of the fields was proved. In June 1903 mining began, and the diamonds found in the first five months realized more than £90,000. On Jan. 27, 1905, the largest diamond in the world, weighing 3,106 carats, or about $1\frac{1}{3}$ lb., was found in the mine and named the Cullinan. The Premier mine is of the same character as the diamond mines at Kimberley (see DIAMOND) and is considerably larger. The area of the "pipe" containing blue ground is estimated at 350,000 sq.yd. Besides the Pretoria fields there are diamantiferous areas (alluvial diggings) in the Bloemhof district on the Vaal river northeast of Kimberley and in other regions. In 1951 alluvial diamonds to the value of 6727,669, weighing 111,429.85 carats, were produced; from mines diamonds weighing 1,134,942 carats were produced, at an average price of 47*s*. 3d. per metric carat.

Platinum.—Platinum is produced in the Rustenburg district. In 1952, 172,766 oz. were exported and were valued at 64,135,866.

Coal and Other Minerals.—There are extensive beds of good coal including thick seams of steam coal near the Rand and other gold fields. Coal appears to have been first discovered in the neighbourhood of Bronkhorst Spruit between the Wilge and Olifants rivers, where it was so near the surface that farmers dug it up for their own use.

In 1887 coal was found at Boksburg in the east Rand, and a mine was at once started. The principal collieries are those at Boksburg and at Brakpan and on the east Rand, at Vereeniging, at Klerksdorp, at Watervaal north of Pretoria and in the Middelburg district, which in 1945 supplied most of the coal used by the gold mines. Like that of Natal, the Transvaal coal burns with a clear flame and leaves little ash. The mines are free from gas and fire damp. In 1952 the output was 20,869,087 tons valued at £8,951,-409.

Iron and copper are widely distributed. The Yzerberg near Marabastad in the Zoutpansberg consists of exceedingly rich iron ore which has been smelted by the natives for many centuries. An important iron and steel industry has been established. During 1952, 1,612,211 tons of iron ore were produced, valued at £875,402. In that year also, 1,158,700 fine oz. of silver were produced. valued at E358,905; 997 tons of tin valued at £868,805; and 12,660 tons of copper valued at £3,626,012. (I. B. P. E.)

TRANSYLVANIA, a large region of distinct geographical identity which from the 11th century until 1918 formed the easternmost part of Hungary, but was then ceded to Rumania. The Latin name, which appears in the 12th century, signifies "beyond the forest" (*i.e.,* from Hungary); the Hungarian name. Erdély, means "the land at the foot of the forest," and from this the Rumanian Ardeal is taken. The German name, Siebenbiirgen, is usually derived from the seven principal fortified towns founded by German colonists.

Transylvania proper is a D-shaped area of 23,324 sq.mi. contained on the north and east by the Carpathians, on the south by their continuation, the Transylvanian Alps, and on the west by the lower and more broken Bihar mountains. The name of Transylvania is used, however, to include the neighbouring regions of Maramures and Crisana (10,133 sq.mi.) and part of the Banat (*q.v.;* 7,228 sq.mi.), also transferred after 1918 from Hungary to Rumania; *i.e.,* a total area of 40.685 sq.mi. with a total population (1910 census) of 5,216,000, including 2,826,000 Rumanians, 1,550,000 Magyars and 520,000 Germans.

HISTORY

Transylvania formed the nucleus of the extensive Dacian (Getic) kingdom, which can be traced back to the 3rd century B.C. and was to become the Roman province of Dacia (*q.v.*) following the final victory of Trajan over the Dacian king Decebalus in A.D. 105.

After the withdrawal of the legions by Aurelian (A.D. 271) the history of the region remains a blank for many centuries. It was overrun by successive barbarian tribes: Germanic (Goths, Gepidae), Ural-Altaic (Huns. Avars and probably Bulgars and Petchenegs) and Slavonic. The debated question whether a Daco-Roman (Vlach) population survived these storms is discussed elsewhere (see VLACHS).

Magyar Conquest.— The Magyars did not fully establish their rule until A.D. 1003, when their newly crowned King Stephen made himself master of the country, defeating, tradition has it, a native prince, Gyula, variously claimed as Vlach or Bulgarian by race. The local rulers were not strong enough to exact concessions from their new masters, but the remote and mountainous character of the country hindered complete integration with Hungary. The administration was, however, consolidated soon after the conquest by the settlement, probably as frontier guards, of the Szeklers (*q.v.*), a tribe akin to the Magyars, in the east and southeast. and of the "Saxons" (Germans from Luxembourg and the Rhineland) on the southern and northeastern passes. Both Saxons and Szeklers were free! self-governing communities under the king; the former proved a great civilizing influence. The chief of the many privileges of the Saxons was the charter (Goldener *Freibrief*) granted them in 1224 by Andrew II. They formed the communities of the sieben *Stühle* round Hermannstadt (Sibiu), the *zwei Stühle* (Medias), the Burzenland (Kronstadt or Brasov) and the Ndsnerland (Bistrita). Very few early documents on Transylvania survive, so no conclusion can be drawn from the fact that there is no mention of the Vlachs before 1222, when they appear as shepherds. Soon afterward they figure as settled peasants and in the 13th and 14th centuries Vlach nobles are mentioned, but these were shortly to be Magyarized.

The great Mongol invasion of 1241 checked Transylvanian development and hindered Magyar immigration, while the local Vlach peasant population increased. At first a prince of the Hungarian royal house usually acted as governor, but from the 13th century onward the province was under a special voivode. A diet met as early as 1229, but the dominant communities, nobles (Magyars), Szeklers and Saxons, did not combine to develop strong local institutions until the 15th century, when the power of Hungary began to decline under Turkish pressure. Exactions to meet the Turkish danger caused unrest among the Magyar and Vlach peasants, which burst out in a serious uprising in 1437. To counter this the nobles, Szeklers and Saxons concluded at Kapolna on Sept. 14 of that year a "brotherly union" whereby they swore fealty to the king of Hungary, promised to support each other against the peasants and the Turks and agreed to settle internal disputes by arbitration. This union was renewed in 1438 and 1459, and in 1506 a supreme court of justice was established for all the communities, then referred to as "nations." This third union formed thenceforward the basis of the Transylvanian local constitution. relations with the serfs being regulated by the codex tripartitus introduced in Hungary in 1514 after the peasant uprising of that year

Transylvania a **Principality.**—With the subjugation of Hungary by the Turks after the battle of Mohacs (1526), Transylvania became de *facto* independent under local Magyar princes. The voivode John Zapolya, who arrived too late for the battle, aas left the strongest power in Hungary and was elected king by the anti-Habsburg party (Oct 14 and Nov 10, 1526) For the next 12 years, however, Ferdinand of Habsburg disputed his claim, the matter being settled by the secret treaty of Nagyvarad (Oradea Mare) (1538), which confirmed Zapolya as king of Transylvania and part of Hungary on condition that on his death these territories should revert to the Austrian crown. This stipulation was violated by the estates when he died in 1540; electing his son as prince, they cut themselves loose from Hungary and became tributary to the sultan. Under the dynasties of Zapolya and Bathory Transylvania preserved its independence by the playing off of sultan against emperor and took an important part in international affairs, especially under Stephen Bathory (see STEPHEN [ISTVAN] BATHORY), who was also king of Poland (1575–86).

The chief internal event of the 16th century was the triumph, after a severe struggle, of the Reformation. The Saxons were converted to Lutheranism, the majority of the Magyars to Calvinism, while many of the Szeklers went farther and became Unitarians; in 1556 the most famous Unitarian community of the continent, with its own bishop, was founded at Kolozsvar (Cluj). A certain party, usually identified with the Habsburg cause, remained in the Roman obedience. At a time of bitter religious controversy Transylvania set Europe a notable example of tolerance; the diet in a series of resolutions declared the Calvinist, Lutheran. Roman Catholic and Unitarian religions to be "received" and entitled to free exercise and equal rights for all time. A flaw in this enlightened settlement was the exclusion of the Orthodox Church to which the Vlach (Rumanian) peasants belonged and which had more adherents than any one of the "received" creeds. The Orthodox, subject to the metropolitan of Walachia, were impeded in contacts with their ecclesiastical superiors; Calvinist pressure was exerted on them with the unintended result of fostering national consciousness by the translation of scriptures and liturgy into the Rumanian language. The various Protestant groups formed the backbone of Transylvanian nationalism; the efforts of the Catholic Bathorys to carry through the Counter-Reformation with Jesuit aid were the main cause of the confused wars which filled the last years of the century. It was in the course of these campaigns that Michael the Brave, voivode of Walachia, intervened and for a year

(1600) actually united Moldavia, Walachia and Transylvania in a single state, for which he did homage to the emperor. This brief episode was later to fire Rumanian national aspirations. Michael was murdered in 1601 by order of the imperial commissioner Gen. George Basta. and in 1604 the emperor Rudolph secured Transylvania: but the prosecutions indulged in by Basta's troops and the proselytizing fury of the Jesuits speedily provoked a rebellion.

On April 5, 1605, the diet elected as prince Stephen Bocskay (*q.v.*), who by the peace of Vienna (June 23, 1606) forced the emperor to recognize him as prince of an enlarged Transylvania and secured the confirmation of all traditional liberties; while by the treaty of Zsitvatorok (Nov. 1606) he negotiated a 20 years' truce between the emperor and the sultan. Unfortunately. Bocskay died on Dec. 29. 1606. Gabriel Bathory (1608–13) was the most tyrannical ruler Transylvania ever had, but the reign of Gabriel Bethlen (1613–29) restored the principality's former glories and is generally regarded as its golden age.

Under Bethlen and George Rakoczy I (1630–48; *see* RAKOCZY) Transylvania was again a power of international importance and the chief bulwark of Protestantism in eastern Europe. The emperor, distracted by the Thirty Years' War, was obliged to treat with the princes of Transylvania as equals. while the Ottoman empire, for the time, was unable to interfere with its nominal vassal. Only when George Rakoczy II (1648–60) was defeated in an unlucky campaign against Poland did the reviving Porte again intervene. depose Rakoczy, and, after six princes had died violent deaths within three years, appoint a Szekler. Michael Apafi (1661), who ruled as a mere vassal of the Turks; and Transylvania sank again into extreme misery.

When the Turks were defeated before Vienna by John III Sobieski (1683), and their power again declined, the estates opened secret negotiations with the emperor Leopold I. whose suzerainty they recognized under the treaties of Vienna (1686) and Blasendorf (Blaj; 1687). Apafi died in 1690. being succeeded by his son, Apafi II. On Dec. 4. 1691, the emperor Leopold, after long negotiations, issued the diploma which regulated relations between him and his subjects.

Period of **Habsburg Rule.**—By this most important document the emperor swore to uphold the constitution of Transylvania. which was again considered *de jure* a part of Hungary while remaining *de fncto* a separate unit. He confirmed the privileges and liberties of the three "nations" and four "received religions," and agreed that the diet should meet annually; but he also imposed a tribute on Transylvania. stationed a garrison in it and put it under a *gubernium,* directed after 1694 from the *Siebenbürgische Hofkanzlei* in Vienna. In 1697 Apafi was induced to abdicate. The Porte recognized the situation under the peace of Karlowitz (1699). In Transylvania itself the resistance to the imperial troops and the Jesuits ceased only after the peace of Szatmar (1711).

During the succeeding century the pressure of Catholic and bureaucratic rule gradually broke down the old individuality of Transylvania. which was promoted, in compensation, to the title of a grand principality in 1765. The privileges of the Szeklers had already almost vanished in the 16th century, and many of them had sunk into serfdom. In the 18th the Saxons were in danger of following suit, but were saved by their great minister Samuel Brukenthal.

The Rumanians, however, their numbers rising rapidly both by natural increase and by the influx during the 18th century of refugees from the Phanariot regime of Moldavia and Walachia, were at last able to develop a national consciousness. This was unexpectedly fostered by the creation in 1698 of a Uniate Church in Transylvania. In that year the Orthodox metropolitan and his clergy, harassed by poverty and by Calvinist pressure, yielded to Jesuit offers and signed an act of submission to Rome, while retaining their own rites and customs. By imperial diploma of 1699 the Uniates were to have the same privileges as the members of the Latin rite, though they never in fact enjoyed the full status of the Latin Catholics. None the less the removal of some of their disabilities allowed educational and social advance. to the ultimate benefit of all Rumanians. The Orthodox who refused to join the union were deprived of all contact with their co-religionists over the border and had no proper organization until 1759 when they were placed under the archbishop of Pest.

Some Rumanians emerged from serfdom when Maria Theresa in 1766 extended the system of the Military Frontier (*q.v.*) to three Walach districts in Transylvania. The visits of Joseph II to the country (1773, 1783) gave rise to rumours that the serfs were to be liberated and armed against their masters; he actually abolished the constitution in 1784, dissolving the three "nations."

In 1785 the Rumanian peasants led by Nicolae Horia, Oarga Ion Closca and Gheorghe Crisan rose and massacred many Magyar nobles before their revolt could be suppressed. On Joseph's death in 1790, a strong demand arose among the Magyars for the full union of Transylvania with Hungary. Alarmed by this the Rumanians, led by Uniate and Orthodox ecclesiastics, submitted to Leopold II the *supplex libellus Valachorum* in which they demanded recognition as the fourth nation of the country and that the Uniate and Orthodox churches should figure as the fifth and sixth "received" religions. The petitioners inaugurated the modern "Vlach controversy" by appealing to their "ancient rights" as the autochthonous inhabitants of Transylvania. The document was passed by Leopold to the Transylvanian diet of 1791, which, busily engaged in reaffirming its position, rejected it and restored the old constitution. Under Francis I and Ferdinand II, however, there was in fact little liberty for any party.

On the outbreak of the revolution of 1848 the Magyars petitioned for union with Hungary, promising the Rumanians the abolition of serfdom and other reforms in return for their support. The Rumanians, however, rejected the alliance, and at the "field of liberty" of Blaj declared themselves a free nation, forming an integral part of Transylvania, and swore fealty to the Habsburgs (May 15). A political program, based on "the principles of fraternity and liberty," was drawn up, but rejected by the diet at Cluj. which proclaimed the union with Hungary, the Saxon representatives accepting this decision by a majority. and declared the new Hungarian laws to he sufficient guarantee that all necessary reforms mould be granted.

In the subsequent fighting between the Hungarian and the Austro-Russian troops, much of which took place in Transylvania, both Saxons and Rumanians took up arms against the Magyars, and a very bitter racial war resulted. The Austrian constitution of 1851, which abolished both the Military Frontier and the Saxon privileges, treated all nationalities with equal severity. The diploma of Oct. 20, 1860, restored the old constitution and the *Hofkanzlei,* but these were abolished when Transylvania became an integral portion of Hungary under the Austro-Hungarian compromise of 1867. In the following year it was reorganized in "comitats" with the rest of Hungary.

From 1868 to 1918 Transylvania was dominated by the Magyar racial policy. The basic Nationalities law of 1868 was in theory extremely liberal, but in practice remained almost a dead letter. The Saxons, in view of their numerical inferiority, confined themselves to building up a close organization for the defense of their social and religious individuality. In spite of this they lost ground, especially after their ancient national status was abolished in March 1876.

The Rumanian national movement was more active. The idea of uniting all Rumanians in one body politic had never been wholly dormant since the days of Michael the Brave's brief achievement, but so long as the Danubian provinces remained under Turkish suzerainty, the goal was generally conceived as a Rumanian state under Habsburg rule. Austria, however, lost its last chance of securing Moldavia and Walachia through its unsuccessful diplomacy during the Crimean War, and the compromise nith Hungary of 1867 finally alienated its Rumanian subjects. In past centuries the main trend of the Rumanian movement in Transylvania had been social, but with the abolition of serfdom in 1853–54 the national struggle proper began to occupy the attention of the few intelligentsia and middle classes. Rumanian irridentism, though provided with a focus by the creation of an independent Rumanian kingdom. never assumed the proportions of the Serbian because of the discouragement of King Charles of Rumania, who was allied with Austria-Hungary. It gathered momentum however in the last years before World War I, and the severity of the measures taken during that war in Transylvania by the Hungarian authorities, especially after the advance into the territory of the Rumanian army in 1916, were an indication of the strength of the desire for the dissolution of Austria-Hungary among almost all Rumanians.

Union With Rumania.—In Oct. 1918 the Rumanians of Transylvania announced their decision to direct their own destinies. On Oct. 27 a national council was established at Arad; and on Dec. 1 a convention assembled at Alba Iulia proclaimed the union of Transylvania with the kingdom of Rumania, at the same time promising to respect the rights and liberties of the other nationalities. The Saxons adhered to this resolution on Jan. 21, 1919, the representatives of the Magyars not till 1921, and then under protest. The union was thus carried through without calling on the secret treaty of Aug. 17, 1916, under which the Allies had promised Transylvania to Rumania. The frontier was determined by the treaty of Trianon (June 4, 1920). The effect was to leave a western fringe with a considerable Magyar population; it represented the results of a difficult endeavour to reconcile conflicting ethnical and other claims. The Rumanian minorities treaty guaranteed the rights of the non-Rumanian population; but, for all that, the transference of the administration from Magyar to Rumanian hands was accompanied by considerable friction. This resulted in part from the discontent prevalent in Hungary because of the new frontier, in part from certain undeniable weaknesses in the new regime, aggravated by the confusion of the postwar period.

In July 1940 Hungary took advantage of the international situation to press its claims. which had never been dropped, and forced Germany and Italy to impose on Aug. 30, 1940, the Vienna award, which restored to Hungary about two-fifths (16,830 sq.mi.) of the enlarged Transylvania, with a population of about 2,500,000, composed of Magyars and Rumanians in about equal numbers. The new frontier ran from a point near Salonta (Nagyszalonta) eastward and southeastward, passing just south of Cluj and including the Szekler cities in Hungary but leaving Brasov, Sibiu, Alba Iulia, Arad and Timisoara to Rumania. Both countries were dissatisfied with the partition. and Rumania in particular thereafter based its policy largely on the hope of increasing the award. The Allied-Rumanian armistice of Sept. 12, 1944, promised Rumania the restoration of "all or the greater part" of the territory lost by it. The peace treaty of Feb. 10, 1947, finally re-established the 1920 Rumanian-Hungarian frontier. Under the Communist constitution of 1952 the mainly Szekler districts of Transylvania were constituted as a Magyar autonomous region for local government.

Cabot, *The Racial Conflict in Transylvania* (London, 1926) ; L. Makkai, *Histoire de Transylvanie,* with good bibliography (Paris, 1946).

TRANSYLVANIAN MOUNTAINS. This is an inclusive name for the mountainous region which abuts against the southeastern end of the Carpathian range south of the Jablonica pass. In the east they form a continuation of this range, but across the rest of the tract the mountains are arranged in scattered groups, in broken connection with one another, the land between forming the Transylvanian basin. Formed in Tertiary times, they are part of the eastern arm of the Alpine fold system which passes in a wide arc through the Carpathians, turns abruptly westward at Pietrite Fetei into the Transylvanian Alps, again turns almost as abruptly southward at Retezat through the Szretinye mountains and across the Danube at the Iron Gate to turn eastward into the Balkan mountains.

The eastern mountains, the Moldavian Carpathians, are divided parallel to their trend by the upper valleys of the Mures and the Olt, separating the outer (eastern) ranges which consist of highly folded Flysch (Cretaceous, Eocene and Oligocene) lying upon an (inner) crystalline massif of plutonic rocks, gneisses and schists with Carboniferous, Permian and Triassic rocks. The western of these two ranges. the Harghitei complex of Tertiary volcanic rocks (andesites, andesitic tuffs, etc.), forms the eastern boundary of the Transylvanian basin, and through it break the rivers Olt and Mures. The Transylvanian basin seldom rises above 1,600 ft. in altitude and is covered by Miocene deposits. The southern boundary is formed by the Transylvanian Alps, which consist almost entirely of a crystalline massif of gneiss, schist and granite with a very narrow and broken fringe of Flysch on its southern (outer) edge. This forms the most continuous range in the region and contains the highest peak (Negoi, 8.346 ft.).

The mountains of the southwest and west, which do not form a continuous range but are isolated by wide valleys, have a more complex structure than the Transylvanian Alps, for around crystalline massifs, which beneath the covering rocks are probably continuous with that of the latter chain, are Triassic, Rhaetic, Jurassic and Cretaceous beds and to a less extent Carboniferous and Permian. There are three main masses, the Szretinye mountains, the Transylvanian ore mountains and the Bihor mountains. There, as well as in the Nagybanya district in the north, are Tertiary volcanic rocks of andesitic composition associated with which are important gold and silver lodes. Some of the mines (*e.g.*, Rosia-Montana, or Verespatak) have been worked since Roman times, and the district still contains the most valuable gold deposits in Europe. These volcanic rocks are probably associated with north to south faulting uhich occurs in this region. The northern boundary is less well defined and comprises a low range in the west with the higher range, the Rodna Hegyseg, farther east.

There are evidences of past glaciation among the highest peaks, which nowhere reach 9,000 ft., so that none of them are permanently snow-capped. Precipitation in the Transylvanian basin averages 24 in., and great extremes of temperature are experienced. This basin cannot be called a plateau for it does not possess extensive plains but is cut up by a network of valleys formed by mountain streams that drain into it from the peripheral ranges. The three main streams are the Somes, which, draining the northern half of the basin, flows northwest to join the Tisza; the Mures, which crossing from east to west enters the Hungarian plain along the southern scarp of the Transylvanian ore mountains and also joins the Tisza; and the Olt, which breaks through the Transylvanian Alps by the Turnu Rosu pass to join the Danube. Other passes in this range, all of which are followed by railways, are the Bodza, Tomos, Vulcan and Teregova, while those in the Moldavian Alps are the Prislopul, Rodna, Borgo, Tolgyes, Bekas, Ghimes and Oitoz passes, several of which are used by railways. (See Rumania.)

TRAP, a mechanical device for snaring or catching anything, and especially wild animals. The term trap is also used to designate a wooden instrument, shaped something like a shoe, used in playing trapball; a machine used for throwing clay pigeons or balls into the air; a bent or partitioned chamber, as in a drainpipe (see Plumbing), in which the liquid forms a seal to prevent the passage of sewer gas, etc.; and the term has been used colloquially to designate a light horse carriage.

"Trap" is derived from O.E. *treppe* or traeppe, properly a step, as that on which an animal places its foot and is caught; cf. Ger. *Treppe,* a flight of stairs. Traps for animals are of great antiquity, and no savage people has ever been discovered, whatever its culture, that did not possess some variety of snare.

In the most primitive form of wild animal trap no mechanism need be present; *e.g.*, a cavity into which the animal walks, as the pitfall of the Arabs and Africans or the snow hole of the Eskimos. O. T. Mason divided traps into three classes: enclosing traps, which imprison the victim without injury; arresting traps, which seize the victim without killing it, unless it is caught by the neck or round the lungs; and killing traps, which crush, pierce or cut to death.

Enclosing traps include the pen, cage, pit and door traps. Pen traps are represented by the fences built in Africa into which antelopes and other animals are driven; and by fish seines and pound nets. Among cage traps may be mentioned bird cones filled with corn and smeared with bird lime, which adhere to the bird's head, blinding it and rendering its capture easy; the fish trap and lobster pot; and the coop traps, of which the turkey trap is an example. This consists of a roofed ditch ending in a cul-de-sac into which the bird is led by a row of grains of corn. Over the farther end a kind of coop is built; the bird, instead of endeavouring to retrace its steps, always seeks to escape upward and remains cooped. Pitfalls include not only those dug in the earth, at the bottom of which knives and spears are often fixed, but also several kinds of traps for small animals. One of these consists of a box near the top of which a platform is hung, in such a way that when the animal leaps upon it to secure the bait it is precipitated into the bottom of the box, while the platform automatically swings back into place.

The door traps range in size from the immense cage with sliding door, in which such beasts as tigers are caught, to the common box trap for mice or squirrels, the door of which falls when the spindle upon which the bait is fixed is moved. Four classes of arresting traps are: the mesh, the set hook, the noose and the clutch. The mesh traps include the mesh and thong toils used of old for the capture of lions and other large game, and the gill net in the meshes of which fish are caught by the gills. To the set-hook division are reckoned the set lines of the angler, several kinds of trawls and the toggle or gorge attached to a line, which the animal, bird or fish swallows only to be held prisoner. The noose-trap class is a very extensive one. The simplest examples are the common slip-noose snares of twine, wire or horsehair, set for birds or small mammals either on their feeding grounds or runways, the victim being caught by the neck, body or foot as it tries to push through the noose. When the noose is used with bait it is generally attached to a stout sapling, which is bent over and kept from springing back by some device of the figure-4 kind. This is constructed of three pieces of wood, one the horizontal spindle on which the bait is placed, one the upright driven into the ground and the third the connecting crosspiece. fitted to the others so loosely that only the strain of the elastic sapling keeps the trap together. When the victim tries to secure the bait he dislodges the crosspiece and is caught by the noose. which is spread on the ground under the bait or is so arranged as to encircle the neck.

Besides the figure-4, several other very effective trigger devices are in use. There are two widely different types of clutch traps: bird lime and other tenacious substances, and jaw and claptraps. The simplest form of the first is adhesive flypaper. Some examples of the claptrap are the clapnet, consisting of two nets laid flat on the ground and attached to cords in such a manner that they fly up and close when the draw cord is pulled by a concealed trapper; and the various other springtraps used by birdcatchers. The jaw traps are the most important class of device for the capture of fur-bearing animals. Steel traps consist of two jaws, with or without teeth, which are worked by powerful single or double springs and are sprung when the victim steps upon the pan, which is placed between the jaws and attached to a lever. They are made in many sizes, from the smallest, designed for rats, to the "great bear tamer," weighing over 40 lb., with jaws of 16 in. in which lions, tigers and grizzly bears are trapped. The steel trap is set and concealed in such a rnanner that the animal must step on its pan in passing over it to secure the bait. Many types of traps, designed to reduce suffering and to displace the ordinary steel trap, have been devised, but are not in general use.

With the clutch traps must also be reckoned the oldest form of steel trap, now to be seen only in museums, the mantrap, which was used first about the middle of the 18th century when the systematic preservation of game rendered protection against poachers a necessity. Such a trap, from Gloucestershire, is more than 6 ft. long, has 19 in. serrated jaws and weighs 88 lb. Another form of mantrap, the spring gun, belongs to the next category, the killing traps, which are divided into traps of weight, point and edge. The most important of the weight class is the deadfall, of which the typical form consists of a pen over whose narrow entrance one or more logs are laid across a lighter log. which is balanced upon a spindle necessarily struck by the entering animal, causing the logs to fall upon its back. In some cases the bait is attached to the spindle itself. The deadfall was always the favourite trap of the American Indians and is in use among many aboriginal tribes in Africa and South America. A slab of stone is often used as a weight. The common mousetrap which kills either by a blow or strangulation is a variety of deadfall. Of point traps may be mentioned those of the impaling and the missile classes. An example of the former is the stake or spear placed by Arab and African tribes at the bottom of pitfalls for big game. Another impaling trap common in Africa is the harpoon downfall, generally used for the hippopotamus. It consists of a heavily weighted harpoon suspended in such a way that the animal, passing beneath, breaks a cord and precipitates the harpoon upon itself. Another example of impalement is the hawk trap, consisting of a circle of stout sharp wires, in the centre of which a live fowl is placed. A bird of prey attempting to secure the fowl is impaled upon the wires. Of missile traps the most universal are the ancient spring bow and its modern representative the spring gun. This is fixed upon stakes, or against a tree, with a line attached to the trigger and stretched immediately in front of the muzzle. An animal pressing against the string pulls the trigger and discharges the piece into its own body. An arrangement of sticks holding the bait in front of the muzzle is sometimes substituted for the string. Of edge traps a curious example is the wolf knife of western America, which consists of a very sharp blade embedded in frozen fat. One of the wolves, licking the fat, cuts its tongue and a flow of blood ensues, with the result that not only the wolf itself but its companions become infuriated by the smell and taste, and the wounded beast, and often many of the others, are killed and devoured. The Alaskan knife trap for large game consists of a heavy blade attached to a lever, which, when released by the animal biting at the bait, moves over and strikes the victim.

TRAPANI (anc. DREPANUM), a city and episcopal see of Sicily, capital of the province of the same name, on the west coast, 3 mi. W. of the Monte San Giuliano, which rises above it, 121 mi. S.W. of Palermo by rail and 47 mi. direct. Pop. (1951) 72,289 (commune). The ancient Drepanum (δρέπανον, "sickle," from the shape of the low spit of land on which it stands) was originally the port of Eryx. It is represented by Virgil in the Aeneid as the scene of the death of Anchises. It was an important Carthaginian naval station in the First Punic War (260 B.C.), part of the inhabitants of Eryx being transferred thither. Near Drepanum the Roman fleet was defeated in 250 B.C.. while the struggle to obtain possession of it ended in the decisive Roman victory off the Aegates lslands in 241, which led to the conclusion of peace. (See PUNIC WARS.) Under the Norman kings, at the time of the first crusade, it became a place of importance: it was a residence of the Aragonese kings. In the 16th and 17th centuries it was strongly fortified.

There are some fine Gothic and baroque palaces, and a few churches with interesting details. Trapani has a harbour of some importance. There are also large salt pans near by. Trapani was heavily bombed by the Allies in World War II.

TRAPPISTS, Cistercian monks of the reform instituted by Armand Jean le Bouthillier de Rancé (*q.v.*), abbot of La Trappe, 1664. La Trappe was a Cistercian abbey near Soligny, in the diocese of Sées, in Normandy, founded 1140. It suffered grievously from the English wars and from commendatory abbots. De Rancé became commendatory abbot at the age of ten, in 1636; and on his conversion from a worldly life he began to interest himself in his abbey and in 1662 conceived the project of restoring the monastic life therein. With this object he visited La Trappe, but the monks were recalcitrant and threatened his life; through the intervention of Louis XIV he was able to pension them off; they were replaced by a community of Cistercians of the strict observance, and the monastic buildings, which had fallen into ruin, were repaired at De Rancé's expense. He himself then entered the novitiate in one of the reformed Cistercian abbeys. and came to La Trappe as regular abbot in 1664. He persuaded his community to adopt a manner of life beyond Cistercian practice and far beyond St. Benedict's rule. The Trappist regime is probably the most penitential that has ever had any permanence in the western church. Yet it attracted vocations in such numbers that De Rancé had 300 monks under him. Through age and ill health he resigned his abbacy in 1695 and died five years later.

During the 18th century La Trappe continued faithful to De Rancé's ideas, but the observance spread only into two monasteries in Italy. It was the dispersal of the community at the French Revolution that turned the Trappists into a congregation in the Cistercian order and finally into a separate order. Dom Augustine de Lestrange, the novice-master at the time of the suppression in 1790, kept 20 of the monks together and obtained permission for them to settle at Val-Sainte in Fribourg, Switz. There they made their life still stricter than that of La Trappe, and postulants flocked to them in such numbers that in two years' time colonies went forth to establish Trappist monasteries in England, Belgium. Piedmont, Spain and Canada; and in 1794 Dom Augustine was named by the Holy See father abbot of all these foundations, thus formed into a congregation. In 1817 they returned to La Trappe, many new foundations were made, and by Dom Augustine's death in 1827 there were in all about 700 Trappist monks. In the course of the century three or four congregations arose—a Belgian, an Italian and two French—each with a vicar subject to the general of the Cistercians. In 1892 these congregations were united into a single Order of Reformed Cistercians, or of Strict Observance, with an abbot-general resident in Rome and independent of the general of the Cistercians of the Common Observance. In 1898 the Trappists recovered possession of Citeaux, the mother house of the Cistercians, secularized since the Revolution, and it was declared to be the mother house of the Reformed Cistercians.

The Trappists are a thriving and vigorous order, represented in all the countries of western Europe, and in the United States and Canada. In addition, they have a house in China, one each in Japan, Asia Minor, Palestine, Bosnia and Dalmatia, and four in various parts of Africa. In heathen countries the Trappists now give themselves up to missionary work.

The first Trappist nunnery was the abbey of Les Clairet, near Chartres, which De Rancé persuaded to adopt his reforms. Dom Augustine de Lestrange established another in 1796, and now there are 15 with 350 choir nuns and 500 lay sisters. One is in England at Stapehill, near Wimborne, founded in 1802.

BIBLIOGRAPHY.—See the *Lives* of De Rancé. A minute arcount of the observance is in De Rancé's *Règlemens de la Trappe* (1701). The beginning of the reform is told by Helyot, *Histoire des ordres religieux,* vol. vi, ch. 1 (1718); the developments under Dom Augustine de Lestrange are described in the supplementary matter in Migne's *Dictionnaire des ordres religieux* (1858). The whole subject is well treated by Max Heimbucher, *Orden und Kongregationen,* vol. i, § 48 (1907); in the *Catholic Encyclopaedia;* in Wetzer and Welte, *Kirchenlexicon,* 2nd ed.; and Herzog, *Realenzyklopädie,* 3rd ed. A realistic and sympathetic picture of Trappist life is the redeeming feature of J. Huysmans' *En route* (1895). (E. C. B.)

TRAPSHOOTING AND SKEET SHOOTING both involve firing shotguns at clay birds called pigeons, released from traps. Trapshooting, the forerunner of skeet shooting, started seriously in England about 1830, live birds being used. The first clay pigeon, resembling a saucer in size and shape, was originated in 1860. Previously glass balls combined with feathers served as targets. These were hurled by springs from cups. In 1880 a lighter type of clay pigeon improved the sport. It was followed by a target composed of river silt and pitch, invented by an Englishman, McCaskey, who later perfected an ideal trap.

Trapshooting was introduced to the United States in the late 1870s; enthusiasm soon spread throughout the country, and the Interstate Association of Trapshooters was formed. In 1900 the American Trapshooting association, controlled by gun and ammunition manufacturers, became the national governing body. However in 1924 the sportsmen themselves organized the Amateur Trapshooting association, which later established headquarters at Vandalia, O., site of the famed Grand American shoot. The first of these events was held on Long Island, N.Y., in 1900 with 71 entries. By the mid-1950s the shoot drew more than 2,000 gunners each year from every state and Canada. In 1954 a five-man squad broke the world's amateur record by smashing 995 out of a possible 1,000 clays. The marksmen were Fred Waldock, Jr.. Fred Waldock. Sr., Robert Allen, George Genereux and Marvin Driver. In 1938 Joseph Hiestand set a one-man mark by breaking 900 16-yd. targets in a single week at the Grand.

Skeet shooting's creator mas C. E. Davies of Andover, Mass., who pioneered the sport in 1910. The name was selected in a contest sponsored by the *National Sportsman* and *Hunting and Fishing* magazines. Skeet differed from trap in that the field was laid out in a semicircle, gunners shooting "round the clock."

After the first skeet club was formed at Everett, Mass., in 1925, other clubs sprang up in many states. As a result, the National Skeet association was inaugurated, with headquarters in Boston, Mass.

Headquarters were later established in Dallas. Tex.

Competitive skeet shooting began on a large scale in 1929, with the first Massachusetts state championship being conducted in April. The initial National Skeet championship was held in 1935, L. S. Pratt winning with 244 out of a possible 250 hits.

In the 1954 National Skeet Shoot, Salvador T. Roig of Puerto Rico broke 100 straight targets to win the .28 gauge title. For the first time a woman, Mrs. Leon Mandel, won the .20 gauge title, smashing 100 consecutive clays, followed by 50 more straight in a shootoff.

Richard Shaughnessy of Dedham. Mass., has been considered the most consistent skeet shooter of all time. He won national titles in 1936, 1938, 1939, 1940. 1941 and 1942. In 1950 he won the Amateur Trap championship of America.

Trapshooting and skeet shooting have become popular pastimes in the United States. (T. GH.)

TRASIMENUS, LAKE (Lat. TRASUMENUS LACUS; Ital. LAGO TRASIMENO), a lake of Umbria, Italy. 12 mi. W. of Perugia, 850 ft. above sea level, 50 mi. in circumference and 10 mi. to 13 mi, across.

Having no natural outlet, it was formerly subject to sudden rises, which occasioned inundations, and these in turn malaria. An artificial outlet was completed in 1898 from the southeast corner of the lake to the Caina, a small tributary of the Tiber. The locality was the scene of the second great defeat suffered by the Romans during the Second Punic War.

In the early spring of 217 B.C. Hannibal left the winter quarters (probably near Modena or Bologna) to which he had withdrawn after the victory of the Trebia (*q.v.*) and crossed the Apennines: continuing his march by a shorter route than the usual one, a route which obliged him to march through an inundated and marshy district for four days and three nights. Which pass it was that he took has been much discussed, but it is most likely that he followed the modern route from Bologna to Bagni della Porretta, and thence went by the Collina pass to Pistoia. Frcm there he passed through the (at that time) marshy district between Pistoia and Florence, and after resting his troops advanced toward Cortona and Lake Trasimenus, his object in taking this route being, as Polybius relates, to move onto the rear of the consul Flaminius, who was at Arretium (Arezzo) and, by this strategic surprise, gain an opportunity to fight with the advantage. Fulfilling Hannibal's calculation, Flaminius, on hearing that Hannibal was plundering the countryside, hastily started in pursuit; while the other consul Servilius, who was at Ariminum, marched along the Via Flaminia, their object doubtless being to attack him from two sides before he could reach Foligno. But Flaminius advanced rapidly and without taking the most elementary precautions of scouting. He probably reached the lake in a single day's march from Arezzo, in any case late in the evening, and encamped by it, probably to the east of Monte Gualandro and west of Tuoro, and started early on the following morning along the north side of the lake, which was covered with a thick mist.

Hannibal, as he marched along the shores of the lake, had not failed to notice the exceptionally good opportunities of surprise which the terrain afforded. From the hill of Montigeto, a little to the west of Passignano, to Torricella, where the road to Perugia and Foligno leaves the lake and climbs 300 ft. in half a mile to the pass of Montecolognola over the hills which surround it, is a distance of six or seven miles. For the greater part of this the road runs along a narrow level strip of ground completely commanded by the hills which rise from the lake, while the ascent to the pass is shut in by hills in front and on each side, uith the lake behind; so that it corresponds extremely well with the description of Polybius. Even without the mist, which was of course an added advantage, Hannibal would have been able to conceal the greater part of his troops behind hills or in dead ground at a comparatively short distance away from the road. Flaminius, on the other hand, was in an exceptionally unfavourable situation for resistance; there were three points at least at which his army of about 30,000 men (which, marching in column, would have formed a length of about ten miles) could be easily split up by an attack; the narrow strip of land along the shores of the lake afforded them no room for retreat nor to rally, and there was no point where they could easily break through to the north.

Hannibal therefore encamped on the pass, from which he could command a view of the defile as far back as Passignano, and kept his heavy Spanish and African troops under his own command to hold the pass, while the light troops were placed on the left. behind Montecolognola itself, and the Gauls and cavalry formed the right wing, which extended along the hills above the lake as far as Montigeto, the cavalry being placed at the beginning of the defile, and concealed behind the hill of Montigeto, so as to be able to close the defile as soon as the last units of Flaminius' army had entered it. So the Romans marched on to their doom; and when the head of their column came into contact with the troops in the centre at the pass of Montecolognola, concealment was neither possible, nor indeed necessary, and Hannibal gave the signal for a general attack. The greater part of the army was already in the trap and was attacked on all sides from the higher ground, so that, we are told, the centurions and tribunes could not even understand the situation. still less do anything to help it; the Romans were mostly slain in their marching formation, without having any opportunity of defending themselves or realizing what was to be done. Many of them were driven into the lake and met their death there.

The head of the column however, which was naturally more prepared to offer effective resistance, to a number of about 6,000 men, rallied and advanced against the pass They succeeded in piercing through the light troops on Hannibal's left in a southerly direction, and only when they had done so found that there were no other troops opposed to them. From the high ground they had reached, they were able, now that the mist had cleared, to see the full extent of the disaster, but as they were unable to offer any assistance they marched off to an unnamed Etruscan village. where they surrendered to Maharbal on the following day, in the vain hope of being set free if they laid down their arms; but with the rest of the prisoners (another 10.000 or so) they were all thrown into chains. The number of killed was about 15,000; while the Carthaginian losses were only about 1,500.

It is the only instance in history of a general lying in ambush with the whole of a large army and accounting for practically the whole of the troops opposed to him, and it mas, thanks to the favourable nature of the ground, the carelessness of Flaminius and the fortunate circumstance of the morning mist, a brilliant success.

Immediately after this terrible defeat the Romans suffered a minor discomfiture. Servilius, who was hastening to his colleague's assistance, had sent his cavalry, about 4,000 men, under C. Centenius, ahead of his main body. Hannibal sent Maharbal with the light troops and part of his cavalry against him, and an engagement followed in which, according to Polybius, the Romans lost half their forces, while the rest sought shelter on a hill, but were surrounded and taken prisoners the next day.

(T A.)

TRAT, a remote province in southeast Thailand, is bordered by Cambodia on the east and has a long coast line on the Gulf of Siam, including several large offshore islands. Area 1,127 sq.mi. Pop. (1960) 66.328. Its products include coconuts, fruit and rubber and enough rice to meet local needs. Trat town (pop. [1960] 3,813), the capital, locally known as Ban Bangphra, has some port facilities on the Trat river and is connected by road with Chanthaburi, 43 mi. N.W. (G. W. SK.)

TRAUBE, ISIDOR (1860–1943), German physical chemist who can be designated the founder of capillary chemistry, was born March 31, 1860, at Hildesheim. After receiving his Ph.D. at the University of Berlin in 1882 he rose to the rank of professor at the Technische Hochschule in Berlin in 1900. He made contributions to critical temperature studies, osmosis, colloids and surface tension.

His practical interests included physical chemical studies of gastric juice, urine, blood and milk. For his work he designed a viscometer and capillarimeter. He advocated a physiotherapeutical science to supplement the chemotherapeutical one. Traube's rule, which has been applied to investigation of alcohols, paraffin solution interfaces, corrosion prevention of fatty acids and adsorption of homologous series: states that the surface tension of capillary active organic compounds belonging to one homologous series decreases with each additional CH_2 group in a constant ratio which is approximately 3 to 1. Traube died in Edinburgh, Scot., Oct. 27, 1943. (V. BW.)

TRAUN, OTTO FERDINAND, COUNT VON ABENSPERG UND (1677–1748). field marshal of the Holy Roman empire, was born at Sopron (Ödenburg), Hung., on Aug. 27, 1677, of a Transylvanian noble family. After studying at Halle till 169.3, he went to serve with the Brandenburgers in the War of the Grand Alliance and was present at the Allies' siege of Namur (1695). Entering the imperial army in 1697, he distinguished himself in Italy, on the Rhine and from 1709, in Spain, during the War of the Spanish Succession, being promoted colonel in 1710 and given an infantry regiment in 1712. In the ensuing War of the Quadruple Alliance against Spain he was severely wounded at Francavilla in Sicily (1719). Promoted major general in 1723 and appointed governor of Messina in 1727, he was made lieutenant field marshal in 1733. In the War of the Polish Succession he enhanced his reputation by holding the pass of San Germano for 23 days with 3,000 men. and by his long defense of Capua against the Spaniards (1734). Promoted commander in chief, he was next employed on a mission in Hungary and then appointed interim governor general of Milan (1736).

On the outbreak of the War of the Austrian Succession (*q.v.*) Traun, now a field marshal (1741), at first retained the command in Italy, capturing Modena (1742) and checking the Spaniards at Campo Santo (1743). Sent in 1744 to succeed Count Khevenhiiller as principal military adviser to Prince Charles of Lorraine in the Rhineland, he was called thence to oppose the Prussian invasion of Bohemia, where he completely outmanoeuvred King Frederick II, driving him from the country without having to engage in a pitched battle. The success of his last campaign, against the French on the Main and on the Lahn in 1745, assured the grand duke of Tuscany's being chosen emperor, as Francis I, by the electors at Frankfurt. Appointed to the command of Transylvania in 1747, he died at Hermannstadt (Sibiu) on Feb. 18, 1748.

TRAVANCORE, a former princely state of southern India which on July 1, 1949, joined with Cochin to form the union of Travancore-Cochin (*q.v.*), now Kerala (*q.v.*), a state of India. Travancore extended for 150 mi. along the west coast as far as Cape Comorin, the southernmost point of the peninsula. It formed part of the ancient Tamil kingdom of Kerala (Chera) which is mentioned in Asoka's inscriptions and later in Pliny and in the *Periplus* of *the Erythraean Sea.* Toward the end of the 11th century it was absorbed by the Cholas and. after the decline of Chola power. it was annexed by the powerful rulers of Vijayanagar until their defeat at Talikota in 1565. Afterward it came under Moslem control, and it was not until the first half of the 18th century that Travancore became independent under its own raja, Martanda Varma. His successor, in 1761, constructed the historic Travancore lines as a protection against the incursions of Hyder Ali of blysore. He also allied himself with the rising British power. Tipu Sahib's attack on Travancore in 1789 led to the third Mysore mar, in which he was defeated by Lord Cornwallis in 1792. In 1795, in return for British protection, the raja of Travancore entered into a subsidiary alliance. Resentment of

British influence in the state gave rise to two rebellions in 1804 and 1809 but these were easily suppressed.

The ruling family followed the marumakathayyam law of inheritance through the female line. After the Mutiny of 1857 the raja was granted the right to adopt a successor on the failure of natural heirs. The state was conspicuous for good administration and prosperity. In 1936 the maharaja issued a proclamation throwing open a large number of temples to Hindus of all castes, including the untouchables. Education made great headway in the state, and according to the 1941 census report the percentage of literacy mas 58 for men and 36 for women.

Capital punishment. was abolished in 1944.

(C. C. D.)

TRAVANCORE-COCHIN (KERALA), the southernmost state of India; a union of two former princely states, Travancore (*q.v.*) and Cochin (*see* KERALA). It lies southwest of Madras state along the western coast of India from the Bharata river to the tip of the peninsula at Cape Comorin. Area 15,003 sq.mi.; pop. (1961) 16,875,199. Trivandrum is the capital, pop. (1951 census) 186,931; the other important city is Alleppey. The broad sea belt consists of sandy soil and loam; east of this flat strip undulating plains and irregular hill ranges gradually blend into the Western Ghats. On these slopes are plantations and thick forests. Numerous rivers and waterways intersect the state and provide easy means of communication. Throughout the area the climate is in general temperate although the rainfall is heavy; on the Cardamom hills the annual rainfall is more than 200 in. Rice, tapioca, oilseeds, tea, coffee and rubber are grown, the coastal lowlands having dense coconut plantations. The forests yield much teak, ebony and rosewood. Rubber, cotton, soap and coir provide the main industries.

The beach sands contain large deposits of ilmenite and monazite which are extracted and exported to the United States and other countries. There is a rare-earths factory at Eloor. The natural harbour at Cochin receives ships throughout the year and has extensive sheltered backwaters.

The state is served by two sections of the Southern railway system—one line starting from Ernakulam and running northward into western Madras, the other having a terminus at Trivandrum and going along the coast north to Quilon; there a west-east line crosses to Tinnevelly in southern Madras.

The union of Travancore-Cochin mas inaugurated on July 1, 1949. The maharaja of Travancore is the *rajpramukh* (prince-governor) and governs on the advice of a ministry. There is an elected state assembly of 109 members. The name Travancore-Cochin was changed to Kerala in 1956. (S. GL.)

TRAVELER'S-TREE, a remarkable treelike plant, *Ravenala madagascariensis,* of the banana family (Musaceae), native of Madagascar and Réunion. The straight palmlike stem reaches 30 ft. in height and bears at the top a number of large long-stalked leaves which spread vertically like a fan. Each leaf has a large sheath at the base in which water collects in such quantity as to yield a copious supply—hence the popular name.

TRAVERSARI, AMBROGIO (AMBROSE THE CAMALDULIAN or FRA AMBROGIO) (1386–1439), Italian humanist, ecclesiastic and translator of Greek patristic texts into Latin, was born at Portico, near Florence. on Sept. 16, 1386. He entered the Camaldolese order in 1400, and became its minister general and visitor in 1431. His journey of visitation (1431–34) is described in his *Hodoeporicon* ("Itinerary"). He attended the Council of Basel as papal legate, and was responsible for the decree of union accepted at the Council of Ferrara–Florence He died at Florence on Oct. 21, 1439. Ambrose translated Dionysius the Areopagite, John Moschus and John Climacus, as well as works by Xthanasius. Basil. John Chrysostom. Ephraim the Syrian and Manuel Kalekas. He was a friend of most of the great contemporary humanists, including Cosimo de' Medici, for whom he translated Diogenes Laertius. He was also a discerning bibliophile, and many of his manuscripts, formerly in the celebrated library of Camaldoli. are now in St. Mark's library, Venice.

EDGAR AUBERT DE LA RUE

TRAVELER'S-TREE (RAVENALA MADAGASCARIENSIS). IN SWAMP VEGETATION NEAR TAMATAVE ON THE EAST COAST OF MADAGASCAR

BIBLIOGRAPHY.—Ambrose's letters were published by P. Canneto (1759); ten unpublished letters ed. by G. Mercati in *Studi e testi,* vol. xc (1939); *Hodoeporicon* and three unpublished letters ed. by A. Dini-Traversari, *Ambrogio Traversari e i suoi tempi* (1912). *See* also G. G. Coulton, *Five Centuries of Religion,* vol. iv (1950), and J. Gill, *The Council of Flovence* (1959).

(T. ED.)

TRAVERSER. A long, very shallow structure running on a number of wheels. used to transfer locomotives, carriages and freight cars from one line of rails to another. The vehicle is hauled onto the rails which are fixed to the platform of the traverser. and the latter is then moved on its several sets of rails. by hand. steam or electric power, until the vehicle comes into line with the desired position. There are two types, surface traversers for carriages and freight cars, and pit traversers for locomotives. carriages and freight cars. The surface type has the traverser tracks and the vehicle tracks at the same level, enabling through ways to be provided at any position across the traverser track. The pit design has the traverser rails sunk at a lower level. and is used chiefly in or between shops manufacturing or repairing rolling stock. The vehicle rails are level with those from which the stock is taken and replaced, so that running on and off is simple. The surface machine must have a certain depth of construction. hence the rails upon which it receives the carriage must be at some distance above the ground rails. and to enable the stock to mount the traverser, ramps (inclined rails) have to be provided at the ends.

The Stokes surface traverser is built up of steel plates and girders in such a manner that the distance between the respective heights of the rails can be as little as four inches. This is important because of the large amount of bogie stock used, the six or eight inches difference in ordinary surface traversers being too great to enable these to mount without seriously straining or damaging the bogie and its parts. Another style, the Bowtell, has the traverser vehicle rails ramped for a short distance from the ends. Thus when the back mheels of the bogie begin to mount the ordinary ramps not on the traverser, the front wheels are mounting those on the traverser. By this means a vehicle may mount a traverser which has deep construction. without injury. the angle of tilt being no greater than that which occurs when mounting the Stokes shallow type above mentioned.

TRAY, a flat receptacle with a raised edge used for a variety of purposes. chiefly domestic. The tray takes many forms—oblong, circular, oval, square—and is made in a vast number of materials. from papier-mâché to the precious metals. The tea tray is the most familiar form; next to it comes the small round tray. usually of silver or electroplate, chiefly used for handing letters or a glass of wine. When thus employed it is usually called a "waiter." The English tea trays of the latter part of the 18th century were usually oval in shape and sometimes had handles: mahogany and rosewood were the favourite materials. Sheraton and Shearer. among other cabinetmakers of the great English period, are credited with trays of this type. These were succeeded in the early and mid-Victorian period by trays of japanned iron. which possessed no charm but had the virtue of durability. Sheffield plate snuffer trays of satisfying simplicity were made in large numbers and are now much sought after.

TRAY LANDSCAPE: see MINIATURE LANDSCAPE.

TRAZ, ROBERT DE (1884–1951), French author. was born in Paris on May 14. 1684. He studied law in his native city and afterward lived in England and in Italy, establishing himself finally in Geneva, Switz., where in 1920 he founded *La Revue de Genève.* He first won notice as a novelist by his *Au temps de la jeunesse* (1908) and subsequently published a series of novels and short stories: *Vivre* (1910); *Les Désirs du coeur* (1912); *L'Homme dans le rang: esquisses de la militaire* (1913); *La Puritaine et l'amour* (1917); *Fiançailles* (1922); *Complices* (1924); *L'Ecorché* (1927); *A la poursuite du vent* (1932); and *Les Heures de silence* (1934). His early work dealt mostly with love. His later work showed a delicate understanding of social evils. He travelled widely, and his essays collected in *Dkpaysements* (1923) and *Le Dépaysement orienfal* (1926) were of more than ordinary interest. *L'Ombre et le soleil* (1942) and *La Blessure secrète* (1944) were published during World War II. He died at Nice on Jan. 9, 1951.

TRAZ-0s-MONTES, an ancient frontier province in the extreme northeast of Portugal, bounded on the north and east by Spain, south by the Douro river which separates it from Beira, and west by the Gerez. Cabreira and Marão mountains, which separate it from Entre-Minho-e-Douro. In 1936 the northern part of the old province of Beira was added to Traz-0s-Montes to form the province of Tras-0s-Montes e Alto Douro. Pop. (1950) 639,-846.

TREACLE, the thick viscid syrup obtained in the early processes of refining sugar, the uncrystallizable fluid obtained in the process of procuring refined crystallized sugar being known as golden syrup and the drainings from the crude sugar as molasses *(see* SUGAR). The word was properly and first used for a medical compound of varying ingredients which was supposed to be a sovereign remedy against snake bites or poison generally. A well-known specific was Venice treacle, *Theriaca Andromachi,* a compound of a large number of drugs reduced to an electuary, a medicinal compound prepared with honey, which dissolves in the mouth. The old French *triacle,* of which "treacle," earlier "triacle," is an adaptation, is a corruption of *thériaque,* Latin *theriaca,* Greek *θηριακά (sc. φάρμακα)*, literally drugs used as an antidote against the bite of poisonous or wild animals (*θήριον*, dim. of *θήρ*, "wild beast"). The word "triacle" came to be used of any remedy or antidote. The composition of electuaries with honey or syrup naturally transferred the name to the most familiar syrup, that obtained from the drainings of sugar.

TREADMILL, a penal appliance introduced by Sir William Cubitt in 1818 and intended by him as a means of employing criminals usefully. It was a large hollow cylinder of wood on an iron frame, round the circumference of which were a series of steps about $7\frac{1}{2}$ in. apart. The criminal, steadying himself by handrails on either side, trod on these, his weight causing the mill to revolve and compelling him to take each step in turn.

By the British Prison act, 1865, a male prisoner over 16, sentenced to hard labour, had to spend three months at least of his sentence in labour of the first class. This consisted primarily of the treadmill or, as an alternative, the crank. The latter consisted of a small hand wheel, like the paddle wheel of a steamer, revolving in a box. Both treadmill and crank mere in time made to subserve useful purposes, but both gradually were abolished; in 1895 there were 39 treadmills and 29 cranks in use in English prisons, and these had dwindled down to 13 and 5 respectively in 1901. They are no longer used.

The fundamental idea of Cubitt's invention (*i.e.*, procuring rotary motion for industrial purposes by the weight of men or animals) is very old. "Treadwheels," of this type, usually consist of hollow cylinders, round the inner surface of which a horse, dog or man walks, foothold being kept by slabs of wood nailed across at short intervals.

TREASON, a general term for the crime of attacking the safety of a sovereign state or its head. The law which punishes treason is a necessary consequence of the idea of a state, and is essential to the state's existence. Most, if not all, nations have at an early period of their history made provision by legislation or otherwise for its punishment.

ENGLISH LAW

The law of England as to treason corresponds to a considerable extent with Roman law. In both systems the law was settled by legislation at a comparatively early period, and subsequently developed by judicial construction. In both, too, there were exceptional features distinguishing this crime from other offenses. Treason was the subject of legislation in many of the pre-Conquest codes. The laws of Alfred and Aethelred punished with death anyone plotting against the life of the king. The *Leges Henrici Primi* put anyone slaying the king's messenger in the king's mercy. The crime was shortly defined by Ranulf de Glanvill and at greater length by Britton and by Henry de Bracton, who follows Roman law closely.

The offense of high treason was not precisely defined by the common law (1 Hale, 76), and until the passing of the Treason act, 1351, depended much on the opinions of the king and his judges. That statute appears to be the answer to a petition of the commons in 1348 (1 Hale, 87), praying for a definition of the offense of accroaching royal power, a charge on which several persons—notably Piers Gaveston and the Despensers—had suffered. The offenses made high treason by the statute which still remain are these: (1) to compass or imagine the death of the king, the queen or their eldest son and heir; (2) to violate the king's companion, or his eldest daughter unmarried, or the wife of his eldest son and heir; (3) to levy war against the king in his realm, or be adherent to the king's enemies in his realm, giving them aid and comfort in the realm or elsewhere; (4) to slay the chancellor, treasurer or the king's justices of the one bench or the other, justices in eyre or justices of assize, and all other justices being in their places doing their offices. The statute, so far as it defines the offense of high treason, is still law.

The statute also treated as high treason forgery of the great or privy seal, counterfeiting the king's coin and importing counterfeits thereof; and this was the law until 1832. These offenses are now felonies under the Coinage Offences act, 1861, and the Forgery act, 1913. It also defined petty treason (now merged in wilful murder by s. 8 of the Offences against the Person act, 1861) as the slaying of a master by his servant, a husband by his wife or a prelate by a man secular or religious owing him allegiance. Between 1351 and 1553 many new offenses were made treason, but most of the acts creating these new treasons were repealed at the earliest opportunity by parliament. The reign most prolific in statutory additions to the law of treason was that of Henry VIII. The acts of this period were repealed in 1553 and the act of 1351 was then made the standard of the offense.

Besides the acts of 1351 and 1553 the following statutes are still in force with respect to the substantive law of treason. By a statute of 1495 persons serving the king *de facto* in war are not to be convicted of treason against the king *de jure.* By an act of 1702 it is treason to endeavour to hinder the next successor to the crown from succeeding, and by the Succession to the Crown act, 1707, it is treason maliciously, advisedly and directly by writing or printing to maintain and affirm that any person has a right to the crown otherwise than according to the Acts of Settlement and Union, or that the crown and parliament cannot pass statutes for the limitation of the succession to the crown. By the Treason act, 1796, made perpetual in 1817, the definition of treason is extended so as to include plots within or without the realm to cause the death or destruction or bodily harm of the king, his heir or successors, if such plots are expressed by publishing any writing or by any overt act or deed. Since that date no new forms of treason have been created.

Important Trials.—Trials for treason in Great Britain and Ireland were at one time frequent and occupy a large part of the numerous volumes of the *State Trials.* Some of the more interesting may be mentioned. Before the Statute of Treasons were those of Gaveston and the Despensers in the reign of Edward II on charges of accroaching the royal power. After the statute were those (some before the peers by trial or impeachment, most before the ordinary criminal courts) of Sir Richard Empson and Edmund Dudley, John Fisher, Sir Thomas More, the earl of Surrey, the duke of Somerset, Anne Boleyn, Lady Jane Grey, Sir Thomas Wyat. Thomas Cranmer, Mary, queen of Scots, Sir Walter Raleigh, the earl of Strafford, William Laud, Sir Henry Vane and other regicides, William, Lord Russell, Algernon Sydney, the duke of Monmouth, and those implicated in the Pilgrimage of Grace, the Gunpowder, "popish," Rye House and other plots. In some of these trials the law was considerably strained in order to ensure a conviction. Since the Revolution there have been the cases of those who took part in the risings of 1715 and 1745, Lord George Gordon in 1781, Thomas Hardy and John Horne Tooke in 1794, the Cato street conspirators in 1820, John Frost in 1840, William Smith O'Brien in 1848.

Most of the early treason trials are reported in W. Cobbett's and T. B. Howell's *Complete Collection of State Trials* (33 vol., London, 1809–26) and the *New Series of State Trials,* edited by Sir J. Macdonnell (8 vol., London, 1888–98). There are, however, three later trials which may be referred to. A case arising out of the South African War was the trial at bar of Arthur Lynch for high treason in 1903 *(Rex* v. *Lynch,* 20 Cox C.C. 468). It was there decided that the Naturalization act, 1870, does not permit naturalization in a foreign state at war with Great Britain, and therefore a British subject who renounces his allegiance and attempts to procure himself to be naturalized in an enemy's country in time of war is guilty of high treason. The accused was sentenced to death, but the sentence was afterward commuted and he subsequently received a pardon.

Sir Roger Casement (*q.v.*) was charged with high treason during World War I, and it was there held by the court of criminal appeal, affirming the decision of the king's bench division at the trial at bar, that if a man is adherent to the king's enemies in his (*i.e.,* the king's) realm by giving to them aid and comfort in the realm, or if he is adherent to the king's enemies elsewhere, he commits the offense declared to be high treason by the Treason act, 1351. It was also held by the king's bench division that if a British subject does any act which strengthens or tends to strengthen the enemies of the king in the conduct of a war against the king. or if he does any act which weakens or tends to weaken the power of the king and of the country to resist or attack their enemies, he is guilty of high treason. Sir Roger Casement was convicted, sentenced to death and executed *(Rex* v. *Casement,* 25 Cox C.C. 480 [account of trial], 503 [decision of court of criminal appeal]).

No amount of residence abroad exempts a British subject from the penalty of treason if he bears arms against the king, unless he has become naturalized as the subject of a foreign state before the outbreak of the war in which he bears arms. It is well established that an alien resident within British territory owes local allegiance to the crown and may be indicted for high treason, and there are numerous instances of prosecution of foreigners for treason. The case of William Joyce *(Joyce* v. *Director* of *Public Prosecutions,* reported in 1946 Appeal Cases, p. 347) is in a sense the converse of such cases. The main issue was as stated by Lord Jowitt. the then lord chancellor, at p. 364 of the report: "Whether an alien who has been resident within the realm can be held guilty and convicted in this country in respect of acts committed by him outside the realm." Joyce, who during World War II was the leading figure in the propaganda in English from German broadcasting stations. was a U.S. citizen of Irish extraction who had resided in Ireland from 1909 until 1921 and thereafter until 1939 in England. In 1933 he obtained a British passport, describing himself inaccurately as a British subject by birth. In Sept. 1938, and on Aug. 24, 1939, he obtained renewals of his passport, each for a period of one year; and he was proved to have been employed by the German radio company after the outbreak of war and before the expiration of his passport. The house of lords were of the opinion that an alien abroad holding a British passport enjoys the protection of the crown and if he adhered to the king's enemies he was guilty of treason, so long as he had not renounced that protection.

Court of Trial. — Three modes of trying high treason still remain, viz., impeachment, trial by court-martial and trial by jury on indictment before the high court or a court of assize or a special commission. The offense is not triable at quarter sessions. At common law and under the act of 1553 a peer, and by an act of 1441 a peeress in right of her husband, were triable for treason before the house of lords, or, when parliament was not sitting, in the court of the lord high steward. S. 30 of the Criminal Justice act, 1948, abolished this right.

Procedure. — Until 1945 the position was that in certain cases of treason the procedure on the trial was the same as upon a charge of murder. Those cases, which were statutory exceptions from the statutory procedure prescribed for the trial of high treason and misprision thereof, were: (1) assassination or killing of the king, or any heir or successor of the king, or any direct attempt against his life or any direct attempt against his person whereby his life may be endangered or his person may suffer bodily harm (1800, 1817) ; (2) attempts to injure in any manner the person of the king (1842).

The effect of the Treason act, 1945, was to extend the above provisions to all cases of treason, so that the procedure and rules of evidence are now the same as on charges of murder. Witnesses for the defense have since 1702 been examinable upon oath. The accused may by the Criminal Evidence act, 1898, consent to be called as witness for the defense. The wife or husband of the accused is not a compellable witness for the crown and it is doubtful whether he or she is even competent for this purpose *(see* J. F. Archbold, *Pleading, Evidence and Practice in Criminal Cases,* 33rd ed., 497, London, 1954).

Prosecutions for treason must be begun within three years of the offense, except in cases of attempts to assassinate the king. The rules as to the indictment are stricter than in the case of felony and misdemeanour, much of the modern statutory power of amendment not extending to indictments for the graver offense. No evidence may be given of any overt act not expressly stated in the indictment. The accused is entitled to peremptory challenge of 35 of the jurors summoned for the jury; but they need not now be freeholders. Before 1945 the accused could be convicted only on his own confession in open court, or by the oath of two witnesses either both to the same overt act charged, or one to one overt act and the other to another overt act of the same treason. If two or more treasons of different kinds were charged on the same indictment, one witness to prove one treason and another to prove another were not sufficient for a lawful conviction. Persons charged with treason are not admitted to bail except by order of a secretary of state or by the high court or a judge thereof in vacation. Finally it must be noted that there can be no accessories before or after the fact to treason. Every person who incites, aids or abets treason is a traitor, and must be indicated as a principal.

Punishment. — The punishment of treason at common law was barbarous in the extreme. The sentence in the case of a man was that the offender be drawn on a hurdle to the place of execution, that there he be hanged by the neck but not till he be dead, and that while yet alive he be disembowelled and that then his body be divided into four quarters, the head and quarters to be at the disposal of the crown. Until 1790 at common law a woman was drawn to the place of execution and there burned. In that year hanging was substituted for burning in the case of female traitors. In 1814 the part of the sentence relating to hanging and to disembowelling was altered to hanging until death supervened. Drawing and beheading and quartering after hanging were abolished in 1870. The act of 1814 in the case of men enables the crown by warrant under the sign manual, countersigned by a secretary of state, to change the sentence to beheading. Attainder and forfeiture for treason are abolished by the Forfeitures act, 1870, except where the offender has been outlawed.

Offenses Allied to Treason. — Misprision of treason consists in the concealment or keeping secret of any high treason. This offense was in 1552 declared to be high treason, but the former law was restored in 1553–54. It is an indictable common-law misdemeanour, not triable at quarter sessions, and the procedure for the trial of misprision of treason is the same as in the case of high treason. The punishment is imprisonment for life and forfeiture of the offender's goods and of the profits of his lands during his life. The forfeitures are not abolished by the Forfeitures act, 1870. There is no case of prosecution of this offense recorded during the last century.

The necessity of prosecutions for treason has been greatly lessened by a series of statutes beginning in 1744 which provide for the punishment as felonies of certain acts which might fall within the definition of treason; *e.g.*, piracies (1744), incitement to mutiny (1797), unlawful oaths, including oaths to commit treason (1797, 1812), and aiding the escape of prisoners of war (1812). By the Treason act, 1842, it is a high misdemeanour, punishable by penal servitude for seven years, wilfully to discharge, point, aim or present at the person of the king any gun or other arms, loaded or not, or to strike at or attempt to throw anything upon the king's person, or to produce any firearms or other arms or any explosive or dangerous matter near his person with intent to injure or alarm him or to commit a breach of the peace.

By the Treason Felony act, 1848, s.1, it was made a felony punishable by penal servitude for life within or without the United Kingdom to plot (1) to deprive or depose the king from the style, etc., of the imperial crown of the United Kingdom; (2) to levy war against the king in any part of the United Kingdom in order to change his measures or counsels or to put force or constraint on or to intimidate either or both houses of parliament; (3) to move or stir any foreigner with force to invade the United Kingdom or any of the king's dominions. The plot to be within the act must be expressed by publishing in printing or writing or by an overt act or deed.

The act of 1848 does not abrogate the Treason act of 1351, but merely provides an alternative remedy. The procedure in the case of all the offenses under the act of 1848 is governed by the ordinary rules as to the trial of indictable offenses, and the accused may be convicted even though the evidence proves acts constituting high treason. Principals in the second degree and accessories before the fact are punishable as principals, and accessories after the fact by two years' imprisonment. (W. T. Ws.)

UNITED STATES

The law punishes treason in order to protect the social interest in the safety of the political community. But English political history taught the framers of the United States constitution that men in power might falsely or loosely charge treason against opponents to destroy peaceful political combat and change. Because they saw that the law of treason was two-edged, the framers made this the only crime defined in the constitution. Thus they denied congress the authority to enlarge or reshape the offense; moreover. they spoke in terms which emphasized restrictions upon the definition and prosecution of the offense as much as they underlined the security of the nation: "Treason against the United States shall consist only in levying War against them, or in adhering to their Enemies, giving them Aid and Comfort. No Person shall be convicted of Treason unless on the Testimony of two Witnesses to the same overt Act, or on Confession in open Court. The Congress shall have power to declare the Punishment of Treason, but no Attainder of Treason shall work Corruption of Blood, or Forfeiture except during the Life of the Person attainted" (art. iii, sec. 3). Treason may be committed against a state of the union, and state constitutions or statutes define the crime substantially as does the federal constitution.

The restrictive definition of treason thus became part of what amounts to a constitutional code of political fair play. This code included the bans on bills of attainder or ex post facto laws, the provision of impeachment as the only regular procedure of removing high officials, the veto power given the chief executive to defend the separation of powers, the control of the purse given popular assemblies to curb the executive and the guaranteed tenure given to judges to insulate them from the heat of party.

The United States supreme court did not have occasion to interpret the treason clause decisively until 1945 and 1947, in the Cramer and Haupt cases (325 U.S. 1, 330 U.S. 631), where defendants were charged with aiding German saboteurs during World War II. Partly, the supreme court's scant opportunities to define treason reflected the general security of the United States over its first 150 years. The Burr conspiracy occasioned the only classic 19th-century consideration of the crime; there. John Marshall, as circuit justice, directed a verdict of acquittal (1807), ruling that conspiracy to levy war was not a sufficient overt act within the constitutional definition. Only slender doctrine emerged from the few other lower federal court cases, notably those arising out of the Whisky rebellion, the embargo and the War of 1812 and resistance to the Fugitive Slave law. The Dorr rebellion in Rhode Island and John Brown's Virginia raid brought the only completed prosecutions for treason against a state (1844, 1859). The Civil War presented resistance on a scale too great for ordinary penal process; a presidential proclamation of pardon and amnesty finally cut off treason prosecutions. The constitution was never treated as barring legislation defining other affenses against security; World War I saw three reported treason cases, but most action against persons charged with opposing the war effort was taken under statutes against espionage or trading with the enemy.

Any violent group resistance to an officer or to the making or execution of any particular official policy was treason by levying war under the broader English precedents. There is evidence that the constitution's framers meant to bar such a broad reach of the crime. Apart from wholesale attacks on established legal order (Dorr's rebellion, John Brown's raid), the offense of "levying war" became obsolete through nonuse; consistent United States practice after 1850 was to prosecute as riot conduct which older English law punished as treason.

Treason by adhering to an enemy can be committed only during declared war. The Cramer and Haupt cases made clear that intent to betray and some overt act (showing that intent had moved into action) are distinct elements of the crime, each of which must be proved; the required proof by two witnesses applies, however, only to proving the act. The supreme court had the most difficulty in defining the required act. Probably the act need not be such as in itself to evidence treasonable intent; it may be an act innocent or ambiguous on its face, like giving food or shelter (which, unlike surrendering a fort, would not necessarily appear treasonable without other evidence of intent). But, a majority of the court insisted, the act must confer tangible benefit then and there on the enemy; a mere meeting mas held not a sufficient act, but the giving of shelter was. Dissenting justices challenged both the correctness and the application of this test. But all the justices made plain that, following the lead of the constitution's framers, the court would administer the law of treason both with care to make it a bulwark of security and with caution against its political abuse.

See Willard Hurst, "Treason in the United States," 58 *Harvard Law Review*, 226, 395, 806 (1945), "English Sources of the American Law of Treason," *Wisconsin Law Review*, 315 (1945). (W. Ht.)

TREASURE TROVE, the legal expression for coin, bullion, gold or silver articles, found hidden in the earth, for which no owner can be discovered.

As feudalism spread over Europe and the prince was looked on as the ultimate owner of all lands, his right to the treasure trove became, according to Grotius, *jus commune et quasi gentium*, in England, Germany. France. Spain and Denmark. In England for centuries the right to treasure trove has been in the crown, which may grant it as a franchise. It is the duty of the finder, and indeed of any one who acquires knowledge, to report the matter to the coroner, who must forthwith hold an inquest to find whether the discovery be treasure trove or not. Concealment is an indictable offense. In the statute De *officio coronatoris*, 1276, the coroner is enjoined to inquire as to treasure trove, and the Coroners act of 1887 continued this power as previously. In Scotland the law is similar. Such articles are presumed to have once had an owner, and, in his absence, they belong not to the finder but to the crown. Their concealment is not a criminal offense unless accompanied by intent to appropriate. In India the Treasure Trove act (16 of 1878) defines treasure as "anything of value hidden in the soil." The finder has three-fourths and the owner of the land one-fourth.

In the United States the common law, following English precedent, would seem to give treasure trove to the public treasury, but in practice the finder has been allowed to keep it. In Louisiana one-half goes to the finder and one-half to the owner of the land. Modern French law is the same, as it is also in Germany, Italy and Spain.

(1820); J. Rankine, Landownership, new ed. (1909); J. Murray, Archaeologtcal Survey of the United Kingdom, containing copious references to the literature of the subject (1896); R. Henslowe Wellington, The King's Coroner (1905–06).

TREASURY DEPARTMENT: see GOVERNMENT DEPARTMENTS.

TREATY, an instrument binding two or more states under international la . The word is derived, through the French traitk (Fr. *traiter,* "to negotiate") from the Latin *tractatus,* the term which from the end of the 17th century began to be used in diplomacy instead of the older technical terms conventio *publica* ("public convention") and foedus ("alliance"). According to modern diplomatic usage the term treaty is confined to the more important international agreements and those of lesser or subordinate importance have been called conventions, agreements, arrangements, protocols and acts, but all of these conform to the definition of treaty given above.

Making of Treaties.—Treaties are normally negotiated between plenipotentiaries provided by their respective governments with "full power" to conclude the treaty within the scope of their instructions. Signature, however, is today presumed to be subject to ratification by the government unless explicitly waived. Apart from such express provision the instrument does not become formally binding until ratifications have been exchanged. Multilateral treaties are usually negotiated at a diplomatic conference ending with signature of the instruments agreed upon. In the case of the Japanese peace treaty of 1951, however, the United States presented a text seriatim to the other parties, gaining in most cases their consent. The San Francisco conference of Sept. 1951 was called for formal signature with the understanding that changes in the text would not be permitted. The Soviet Union, its satellites and India refused to sign under these conditions.

Multilateral treaties provide for deposit of ratifications at a particular foreign office or at the secretariat of the United Nations or other international organization. A prescribed number of ratifications must usually be deposited to bring the treaty into force. Provision is often made for the accession of nonsignatory states before a prescribed date.

The problem of reservations after signature presents few difficulties in the case of bilateral treaties. A reservation, whether in the form of an interpretation or amendment, constitutes a new offer which prevents the treaty coming into force unless the other party accepts it, which may happen when ratifications are exchanged. In the case of a multilateral treaty, however, serious complications occur when a reservation is accepted by some signatories and rejected by others. The status of such a treaty has been the subject of conflicting views by the International Court of Justice and the United Nations International Law commission. The tendency has been to forbid reservations to multilateral treaties unless explicitly permitted by the signed text.

Form.—In making a treaty it is not essential to employ any special form. A treaty often takes the form of a contract, but it may take the form of a joint declaration or of an exchange of notes (as in the case of the Rush-Bagot agreement between the United States and Great Britain in r817 for mutual disarmament on the Great Lakes). It is, however, customary to draw up all important treaties on a fixed plan. First comes the preamble, giving the names and styles of the high contracting parties, a statement of the general objects which they have in view, the names and official designations of the plenipotentiaries charged with the negotiation and a statement that their full powers have been verified. Then follow the articles containing the stipulations agreed upon. If the treaty is concluded for a definite period, this is next stated or, if it be in form perpetual, there may be a provision inserted that either party may "denounce" (*i.e.,* give notice to terminate) the treaty. Next follows an article providing for ratification and for the time and place for the exchange of ratifications. At the end is a clause stating that "in witness whereof (en foi de *quoi*) the respective plenipotentiaries have affixed their names and seals." The signatures follow, with the place and date. "Additional articles" are often appended and signed by the plenipotentiaries, with the declaration that they have the same force and value as if they had been included in the body oi the treaty or convention.

General Treaties.—Treaties with a large number of parties, called general, multilateral or multipartite treaties, often have the character of legislation rather than of contract. They have frequently been negotiated at permanent or periodic conferences such as the League of Nations assembly (see LEAGUE OF NATIONS), the Cnited Nations general assembly or the conferences of the specialized agencies under the United Nations (q *v.*), or in special conferences called to deal with a particular subject such as the San Francisco conference on the United Nations organization. Treaties which emerge from such conferences usually refer to the conference in the preamble. though frequently the high contracting parties are individually listed as in bilateral treaties. The democratic tendency of diplomacy during the 19th century can be detected in the increasing utilization of such treaties in preference to bilateral treaties and in the references to popular participation as in the Kellogg-Briand pact in which the high contracting parties "solemnly declare in the names of their respective peoples" and in the United Nations charter the preamble of which begins with the phrase "We the peoples of the United Xations determined . . ." In the interpretation of such treaties there is a tendency to make less use of preparatory discussion which usually discloses the views of only a few of the parties and to rely mainly on the customary or legal meaning of terms and on general rules of construction. Among important treaties of this type mention may be made of the declaration of Paris, 1856; the Geneva Convention on the Red Cross. 1864; the Convention of the Universal Postal Union, 1874; The Hague conventions, 1899 and 1907; the League of Nations covenant, 1919; the Constitution of the International Labour Organization. 1919; the Statute of the Permanent Court of International Justice, 1920; the Geneva Protocol for the Pacific Settlement of International Disputes, 1924; the General Act of Geneva for the Pacific Settlement of International Disputes, 1928; the Treaty for the Renunciation of War (Kellogg-Briand pact), 1928; the Cnited Nations charter, 1945; the Agreement for the Establishment of an International Military Tribunal and the Charter for the International Military Tribunal, 1945; the Convention on the Crime of Genocide, 1948; and the International Covenant on Human Rights, of which a draft was submitted in 1954. These instruments, it may be observed, have a great variety of designations. To these may be added numerous agreements, acts, arrangements, declarations, mandates, protocols, regulations, resolutions, rules and trusteeships proceeding from international conferences or organizations and often having the character of treaties. Manley O. Hudson lists 257 multipartite instruments made from 1864 to 1919 and 700 made from 1919 to 1946. D. P. Myers estimated in 1920 that about 30,000 treaties, both bilateral and general, had been concluded among civilized states of which about one-fifth were then in force. More than 5,000 treaties have been concluded since 1920 and published in the treaty series of the League of Nations or of the United Nations.

Classification of Treaties.—International jurists have classified treaties on a variety of principles. Aside from the distinction between general and bilateral treaties already referred to, the distinction has been drawn between those which represent a definite transaction such as a cession of territory (Rechtsgeschaft) and those which seek to establish a general rule of conduct, such as the "renunciation of war" (*Rechtssatz*). They may be classified in a more practical way according to their object, as follows: (1) political, such as treaties of peace, of alliance, of cession of territory, of pacific settlement and of disarmament; (2) commercial, including tariff, consular, fishery and navigation conventions (see COMMERCIAL TREATIES); (3) constitutional and administrative such as the conventions establishing and regulating international unions, organizations and specialized agencies; (4) relating to criminal justice, as treaties defining international crimes and providing for extradition (*q.v.*); (5) relating to civil justice, as conventions for the protection of human rights, trade-marks and copyright, and the execution of the judgments of foreign courts; (6) codifying international law such as procedures for the peaceful settlement of international disputes. rules for the conduct of war and definitions of the rights and duties of states. In practice it is often difficult to assign a particular treaty to any one of these classes.

Antiwar Treaties. — Treaties for the renunciation of war, for disarmament and for pacific settlement of international disputes might be called "treaties of peace," but that term has been employed to refer to treaties which end a particular war rather than to treaties which are intended to prevent future wars. Antiwar treaties belong in the class of political treaties, but they often contain provisions of administrative or codifying character. Arbitration clauses have often been included in commercial and other treaties and numerous bilateral treaties of arbitration and conciliation have been made providing either for the submission of past controversies to pacific settlement or for the submission of classes of future controversies. The Hague conventions (1899, 1907), the League of Nations covenant (1919), the statutes of the Permanent Court of International Justice (1920) and the International Court of Justice (1945), the General act (1928) and the United Nations charter (1945) provided procedures and institutions for pacific settlement. The optional clause of the court statute, which has been ratified by a large number of states including the United States, the United Kingdom and France, provides for compulsory jurisdiction of the court in legal disputes on application of one party.

Bilateral disarmament treaties have been made, such as the Rush-Bagot agreement of 1817 disarming the Great Lakes. Defeated powers have often been compelled to disarm partially in treaties of peace. General treaties for limited disarmament have been made, as the Washington treaties of 1922 and the London treaty of 1930. Effortsat general disarmament in the League of Nations conference of 1932 failed, as have efforts to eliminate atomic weapons and to reduce conventional armaments in the United Nations. (See DISARMAMENT.)

Treaties for the renunciation of war may apply to particular areas such as neutralized states (see NEUTRALIZATION) or boundanes, or to limited periods of time as the Bryan "cooling-off treaties" negotiated by the United States in 1913–15 with many countries and providing for commissions of conciliation to function for a period of a year during which the parties agreed not to resort to hostilities This idea was included in art. 12 of the League of Nations covenant. By the Kellogg-Briand pact of 1928, 63 states. all in the world except a few Latin-American states, condemned uar, renounced it as an instrument of national policy and agreed never to seek the settlement of any dispute or conflict except by pacific means. This treaty did not prevent hostilities, but it did "outlau war." Third states were no longer obliged to be impartial but mere free to differentiate between the "aggressor" and the "victim." As a consequence, states were not free to recognize that the aggressor's conquest gave legal title; nonbelligerents were free to discriminate against the aggressor; and high officers of governments instituting hostilities in violation of the pact were criminally liable and unable to defend themselves behind the alleged "act of state" of the aggressor state. War in the material sense continued, but the legal sense of war, as understood in the 19th century, a condition which equally permits two or more states to settle their controversies by the use of armed force, had been so altered that it is proper to say war had been "outlawed." (See WAR: International Law and *War*)

Validity. — I. A treaty, like a contract in private law, is only valid when made between competent parties, normally sovereign states. Semisovereign states such as protectorates, vassal states and members of federations may make valid treaties uithin the range of their international capacity. The members of the British Commonwealth are recognized to have sovereign capacity in international relations.

2. In principle a treaty is not valid unless accepted in accord with the treaty-making procedure of each state as determined by its municipal law. A government, however, can understand the provisions of foreign constitutions concerning treaty making only through communications with the foreign office of that state. Consequently, treaties made in accord with the procedure which the foreign office, acting in the name of the representative authority of the state, considers constitutional are deemed internationally valid. The Permanent Court of International Justice said in the East Greenland case that a reply "giyen by a Minister of Foreign Affairs on behalf of his government in response to a request falling within his province is binding upon the country to which the minister belongs." Judge Dionisio Anzilloti in a separate opinion concurred on this point but clarified the phrase "within his province" by saying it was the foreign minister's "duty to refrain from giving his reply until he had obtained any assent that might be requisite" under his country's law (3 World Court Reports 192, zoo). In Great Britain the treaty-making power resides in the executive. In the United States, treaties in the constitutional sense, though negotiated by the president through the state department, can only be concluded "with the Advice and Consent of the Senate." In practice the senate has shown itself very jealous of its right to insist on reservations or amendments before ratification. The two-thirds vote required by the constitution has added to this tendency because it normally makes it necessary to gain the consent of many senators of the minority party. The president has therefore increasingly made use of executive agreements which he can make on his own responsibility if his independent powers are adequate to execute them, or with support of a simple majority of both houses of congress if the normal legislative powers of congress are sufficient to provide for their execution. When the main obligation of the treaty is the payment of money or tariff regulation, the latter method has normally been used. In many countries the treaty-making power is shared between the executive and the legislature only for certain purposes. In France, for instance, treaties of peace, treaties of commerce and those involving financial obligations or relating to the rights of French citizens are not valid until ratified by a majority in both chambers.

3. A treaty, to be valid, must be the expression of an agreement. Unlike a private contract, however, under customary international law a treaty was not voidable on proof that one of the parties to it had been subject to duress, but only if it could be proved that the individual negotiator had been so subject. Thus a treaty imposed by the victor upon the vanquished remained valid, though signed under pressure of force. The Stimson doctrine held that this rule was modified among the parties to the Kellogg-Briand pact for the renunciation of war if the treaty had been made through coercion in violation of that pact, on the principle that rights do not arise from wrongs (jus ex injuria non oritur).

4. In modern practice a treaty, though signed by agents with full powers, is not valid until it has been ratified by both parties and ratifications have been exchanged or, in the case of a general treaty, ratifications have been deposited at a designated place. This condition applies only to instruments subject to ratification. Many agreements, protocols and exchanges of notes become valid uhen signed.

5. Art. 18 of the covenant of the League of Nations provided that every treaty or international agreement entered into after the signature and ratification of the covenant, by any member of the League, should be forthwith registered with the secretariat and should as soon as possible be published by it; and that no such treaty or international agreement should be binding until so registered. A similar provision in art. 102 of the United Nations charter merely declares that a party to an unregistered treaty may not invoke it before any organ of the United Nations.

6. Art. 20 of the covenant provided that treaty obligations among the members were abrogated if inconsistent with the covenant and such obligations with nonmembers should be terminated by members. Art. 105 of the United Nations charter merely provides that the obligation of members under the charter shall in case of conflict supersede their obligations under any other international agreement.

Interpretation and Application. — I. Treaties are to be interpreted in accord with international law. That law gives guidance as to the meaning of technical terms and establishes presumptions useful for construction such as that against sacrifices of sovereignty by the parties. However, evidence in the negotiations or subsequent practice may overrule these presumptive meanings or constructions by indicating that the parties had a different intention in the particular instance. Such historical evidence is, however, more useful in the case of bilateral than of general treaties.

2. The question of the language employed in treaties has often caused trouble. In the 16th century international treaties were drawn up in Latin, more rarely in French. It was not till the 18th century that the latter was generally accepted (except by the pope and the emperor) as the language of diplomacy. The Anglo-French commercial treaty of April 11, 1713, was in Latin. Before World War I general conventions were usually drawn up in French, but the League of Nations and the United Nations adopted both English and French as working languages and treaties related to these organizations were official in both languages. The San Francisco conference recognized, in addition, Spanish, Russian and Chinese as official languages and the United Nations charter appears officially in five languages. Spanish was added to French and English as a working language by the United Nations in 1949. Bilateral treaties are usually in two texts, one in each language, both of which are signed by the plenipotentiaries of the two parties. Such bilingual treaties have sometimes been accompanied by a third version in French, to be decisive in case of a difference of opinion arising as to the precise meaning of the language of the other texts

3. Treaties are in first instance interpreted and applied by the parties. Constitutions of some countries (*e.g.*, the United States) make treaties automatically the supreme law of the land to be applied by courts and administrative officers, while others (*e.g.*, Great Britain) do not consider treaties applicable rules of municipal law until the legislature has acted giving domestic force to the provisions of the treaty. This distinction, however, is in reality one of degree. In all countries some treaties are in some circumstances "self-executing" while others are not. Thus in Great Britain treaties dealing with maritime captures are automatically applied in prize courts and in the United States treaties requiring appropriations or modifications of criminal law are not applicable until congress has acted. Proposals were introduced by Sen. John Bricker of Ohio and others in 1952 to amend the U.S. constitution in order to require congressional action for the internal enforcement of treaties in the United States and to prevent encroachment upon the normal powers of the states. These proposals were opposed by the administration and, after extensive debate, rejected by the senate in 1954.

4. The ultimate interpretation of treaties is an international question. Because of the lack of certainty that a dispute concerning interpretation and application of the treaty will be decided through diplomatic negotiation, treaties frequently include a "compromissary clause" by which the parties agree to submit such questions to arbitration or judicial settlement. The optional clause of the Statute of the International Court of Justice (art. 36, par. 2) provides for the compulsory jurisdiction of the court in "all legal disputes concerning the interpretation of a treaty." This applies only among states which have deposited with the secretary-general of the United Nations a declaration accepting the clause.

5. A treaty sometimes provides for acts intended to secure its due performance; *e.g.*, the occupation of the German Rhine provinces by the Allied powers pending the payment of the reparations imposed by the treaty of Versailles (art. 428–431). The enforcement of treaties is in general secured by the mutual interest of the parties and the right of each to abrogate on nonobservance by the other and by the procedures of customary international law and the Cnited Nations for the maintenance of obligations of states under international law.

Duration of Treaties. — The question of when, and in what circumstances, the obligations incurred under treaties come to an end has been the subject of much debate. A treaty may lapse naturally by the destruction of one of the states party to it, by the object of the agreement ceasing to exist, by the conclusion of a new-agreement among the parties abrogating or superseding it or by denunciation by one of the parties under powers reserved in the treaty itself. Treaties are also in most cases suspended if not terminated by war between the contracting parties, and are therefore usually revived in express terms of the treaty of peace. More debatable is the proposition upheld by certain jurists, *e.g.*, Cornelius van Bynkershoek, that the condition rebus sic stantibus ("things remaining thus") is implicit in every treaty. Bismarck, in his Reminiscences, considered it self-evident that treaties were valid only as long as they are useful to the parties. In practice this was certainly often the case even after the London protocol of 1871, which laid down the principle that "no Power can liberate itself from the engagements of a treaty, nor modify the stipulations thereof, unless with the consent of the contracting Powers, by means of an amicable agreement." Art. 19 of the League of Nations covenant provided that "the Assembly may from time to time advise the reconsideration by members of the League of treaties ahich have become inapplicable." The same purpose is intended by art. 14 of the United Nations charter, though it does not specifically refer to treaties. It authorizes the general assembly "to recommend measures for the peaceful adjustment of any situation, regardless of origin, which it deems likely to impair the general welfare or friendly relations among nations." Jurists, however, recognize these procedures as political measures for modifying undesirable or dangerous treaties and not as applications of the jural principle rebus sic stantibus. The latter holds that treaties may be declared at an end by proper proceedings which find that conditions deemed by the negotiators essential to the agreement have changed.

Treaties of peace usually provide for the continuance or the termination of prewar treaties between the belligerents. The treaties ending World War I listed the treaties of the Central Powers to be continued and explicitly provided that certain treaties were to be abrogated.

The provisions of the treaties of peace after World War II were similar but less complicated. Each Allied power was entitled to notify Italy within six months which bilateral treaties it wished to preserve. Treaties not so notified would be considered abrogated. Express provisions were included in regard to certain general treaties. For example Italy renounced its interest in the mandate system. but the situation of general treaties was not covered comprehensively. The treaties of peace with Bulgaria, Hungary. Rumania, Finland and Japan had similar provisions.

The Inviolability of Treaties. — The principle *pacta* sunt *servanda* ("agreements ought to be observed") is considered basic in international law. Maintenance of this principle, however. requires that nothing should be included in a treaty which the parties to it are not reasonably sure that they and their successors will be able to carry out in any circumstances. This principle led British statesmen during the 19th century from Pitt and Lord Castlereagh onward to avoid commitments "for external exertion" in circumstances which could not be foreseen. For the same reason, in the days of the old diplomacy, there was in the language of the treaties of peace, and of diplomatic intercourse generally, a studied avoidance of anything that might keep open old sores by any unnecessary wounding of the feelings of the vanquished. In this respect the treaty of Versailles of 1919 compared unfavourably with the treaty of Versailles of 1783. In the former the defeated nation was compelled to confess its "war guilt" as the price of its restoration to the community of nations. This condition rankled in the minds of the Germans, and contributed to the rise of Hitler and World War II. Art. i of the treaty of 1783, on the other hand, ended with the words: "There shall be complete oblivion of, and amnesty for, all that may have been done or committed before or during the war which has now come to an end."

This change is a manifestation of the shrinking of the world, the increasing destructiveness of war and the democratization of the conduct of international relations. These conditions have led to the concept of a world community, sustaining principles of peace and justice the violation of which ought to be universally condemned. War crimes trials. applied much more extensively after World War II than after World War I. provided evidence of this change (see WAR CRIMES). The newer view considers treaties by analogy to municipal law, while the old considered them instruments of power politics. Some statesmen, including Theobald von Bethmann-Hollweg, adhering to the new view, held that Germany committed a breach of international law in invading Belgium in defiance of the treaty of 1839 Others, among whom was Sir

Ernest Satow, adhering to the older view, maintained that Germany by violating Belgium in 1914 merely gave any other guaranteeing state the right to attack it. In other words, Germany risked its existence but did not specifically break international law. The first relies upon law to establish the sanctity of treaties, and the latter relies upon the balance of forces. The difficulty of the first view lies in the fact that the community of nations may lack the solidarity necessary to maintain its law. For instance, it was formally declared by the great powers in 1871 that no great power which had joined the other great powers in signing a treaty could violate the provisions of that treaty without the consent of the other signatories; that is, without a European conference. But Russia's violation of the Black sea clauses of the treaty of Paris (1856) was acquiesced in 1871 and in 1908 Austria-Hungary violated art. 25 of the treaty of Berlin (1878) by annexing Bosnia and Herzegovina with apparent impunity.

The peacemakers of 1919, therefore, tried to set up a state of things whereby the sanctity of treaties would be upheld by the general co-operation of all states. Pres. Woodrow Wilson condensed this aspiration into a single sentence: "What we seek is the reign of law, based upon the consent of the governed and sustained by the organized opinion of mankind." The League of Nations covenant attempted to give a general guarantee of territorial integrity and independence to all the members of the League. This general guarantee, embodied in art. 10 of the covenant, was, however, in fact succeeded by a system of special or regional guarantees, including the treaty of Locarno (1925) and the little entente (1920–21) (*qq.v.*). Similarly it was recognized in art. 21 of the covenant that the Monroe Doctrine was "a regional understanding," which meant a practical admission by the principal powers that the United States guaranteed other states on both American continents against the aggression of non-American neighbours. The violation of both general and regional guarantees in the 1930s and the temporary acquiescence in these violations by the powers indicated that the solidarity of the community of nations was still insufficient to enforce treaties.

The United Nations charter agreed to at the end of World War II sought to strengthen the universal guarantees of the League of Nations by making them less rigid and more organized, and sought also to strengthen the outlawry of war formally established by the Kellogg-Briand pact in 1928. The Security council was given the power to decide what measures to take when it found that aggression had occurred or was threatened (art. 41) and all members were obliged to act accordingly (art. 25, 48). Provision was made for a General Staff committee to organize forces provided by advance commitment of the members. The veto given the great powers in the Security council and the consequent inability of that body to function satisfactorily has, as in the interwar period, resulted in a new resort to regional agreements and pacts for "collective self-defense" authorized by the charter (art. 51, 52). The transition from a regime of treaties subject to the exigencies of power politics to a regime of treaties supported by a lax-enforcing community of nations has not yet been effected.

Treaties and the World Order.—Treaties containing what were technically known as transitory provisions with reference to recognition, boundaries or cessions of territory have been considered the title deeds of the nations to which they relate. The treaties of Osnabruck and Munster (Westphalia) in 1648, which were the work of the first modern international congress, were recognized as giving a new juridical basis to the territorial system of Europe. (*See* WESTPHALIA, PEACE OF.) Although, in the 18th century treaties were often violated, it was considered expedient to veil even the most flagrant acts of aggression under legal forms, as in the case of the three partitions of Poland which, as Friedrich von Gentz observed, set an unhappy precedent for the aggressions of Revolutionary France.

The treaties concluded between the powers after the downfall of Napoleon (Paris, 1814; Vienna, 1815; Paris, 1815) represented an attempt to reorganize the European territorial system by endowing the reconstituted states with unimpeachable title deeds and ensuring their stability by establishing a balance of power among them. Other treaties (Chaumont, March 1814, and treaty of alliance, Nov. 20, 1815) provided for the continuance of the quadruple alliance for the purpose of watching over and safeguarding the settlement thus made. Though this "federal system" for Europe broke down for various reasons (*see* EUROPE), the idea of the treaties as the foundation of the European system, and of the Concert of Europe as their guardian, survived long enough to secure an unprecedented period of peace. The principle that the treaties could not be altered without the consent of "Europe" was also more or less effectively asserted: effectively in the case of the treaties of 1831 and 1839 which separated Belgium from the Netherlands, ineffectively in the protests of France and Great Britain against Russia's violation of the terms of the treaty of Vienna by its treatment of the Poles in 1830 and 1863.

The principle of the solidarity of Europe in the matter of territorial changes was even extended to the questions arising out of the disintegration of the Ottoman empire, which had been excluded from the treaties of 1815; and the Concert of Europe survived in the eastern question (*q.v.*) long after the results of the Italian war of 1859 and of the Prussian wars of 1864, 1866, and 1870–71 had blown the Vienna settlement to pieces. Thus the partition of Turkey was regulated by the great powers, or some of them, in the treaties of London, 1832, 1863, 1864, and of Constantinople, 1881, with reference to Greece; and by the treaties of Paris, 1856, London, 1871, Berlin, 1878, and London, 1885, with reference to Montenegro, Rumania, Serbia, Bulgaria and the navigation of the Danube. These settlements underwent extensive and important changes as a result of World Wars I and II, but they still have an effective existence as the ultimate title deeds of the Balkan states. The settlements of World Wars I and II, however, in response to changing military, political and social conditions, gave increasing recognition to the superiority of political rights of "national self-determination" and "collective self-defense" over legal rights to territory established by treaty. As a result, changes have taken place in the political map, especially of Europe and Asia, frequently and often accompanied by violence.

The League of Nations and the United Nations provided more effective machinery than existed in the earlier Concert of Europe both for the maintenance and the peaceful change of treaties and territorial settlements. They were designed less to preserve a *status quo* established by treaties than continuously to adapt national rights and interests to changing conditions, but they remain inadequate to assure such dynamic stability.

P. Myers, *Manual of Collections of Treaties and of Collections Relating to Treaties* (1922). Most governments publish the treaties to which they are parties. Among the general collections mention may be made of G. F. von Martens, *Recueil Général de Traités* (annually, 1791 *et. seq.*); British and foreign state papers (annually, 1815 *et. seq.*); League of Nations, *Treaty Series*, 205 vol. (1920–46); United Nations, *Treaty Series* (1946 *et. seq.*); Manley O. Hudson (ed.), *International Legislation*, containing texts of multipartite international instruments from 1919 to 1946, 9 vol. (1931–50). (Q. W.)

TREATY, COMMERCIAL: *see* COMMERCIAL TREATIES.

TREBIA (mod. TREBBIA), a river of Cisalpine Gaul, a tributary of the Padus (Po), into which it falls about 4 mi. W. of Placentia (Piacenza). Its valley is followed past Bobbio by the modern high road from Piacenza to Genoa (88 mi.). It is remarkable for the victory gained on its banks by Hannibal over the Romans in 218 B.C. Kromayer's investigations made it clear that Polybius' account, according to which the battle took place on the left bank of the river, is to be preferred to that of Livy. T. Frank suggests that the Placentia referred to in both accounts lay west of the river; *i.e.*, about 15 mi. W. of the later Placentia, refounded in 190.

Scipio (the father of Scipio Africanus) had advanced to meet Hannibal two days' march west of Pavia, but was defeated in a cavalry engagement, and in a forced night march recrossed the Ticinus and the Padus (probably at Placentia) and then took up a new position near Clastidium on the south bank of the latter river, about 20 mi. W. of Placentia: while Hannibal, finding himself unable to cross the Ticinus, marched westward up the Padus until he could cross it, and so came up with the Romans and offered battle, which was, however, not accepted; he therefore encamped 5 mi. away from them. Scipio, however, in consequence of the desertion of more than 2,000 of his Gaulish auxiliaries, retreated to the further bank of the Trebia, where he was joined by Sempronius, the other consul, who had brought his army from Ariminum. Hannibal followed them and encamped once more about 4 mi. from them; and as a decisive victory was imperative, in order that he might win over the Gauls to his side, and he had about 40,000 men, or as many as the two armies together, he did nothing to prevent their junction. A successful cavalry skirmish with the Carthaginian foragers encouraged Sempronius to overcome his colleague's objections to a general engagement, and the Romans marched across the Trebia. The battlefield was almost flat, but on the south was rising ground traversed by a number of fairly deep, broad stream beds, in one of which Hannibal concealed a force of 2.000 men under his young brother Mago, which was to have a decisive effect on the fortunes of the day. At the same time he sent his 8,000 light troops out to cover the advance of his main body of infantry, consisting of 20,000 Iberians, Celts and Libyans, while his cavalry (over 10,000, including his Celtic allies) were placed on the wings, with the elephants in advance of them. The Roman cavalry was soon driven back, and the Carthaginian light troops, Numidian cavalry and elephants attacked the Roman infantry on the flanks, so that the wings were put to flight and driven into the river, while Mago's force suddenly fell on the rear of the Roman centre and worked destruction on the rear ranks. The front ranks of the Roman centre, on the other hand, to a number of some 10,000 men broke through the Carthaginian centre with great slaughter, but seeing that the wings had been completely driven back, they took no further part in the battle but marched in good order into Placentia, where they were joined by the cavalry. The greater part of the rest of the army, entirely surrounded by superior numbers, met its death in the river itself. The battle has been rightly described as a Cannae on a small scale, and the similarities are certainly striking, as will be seen by a comparison of the two accounts. (T. A.)

TREBIZOND or TRABZON (Gr. *Trapezus)*, city of Turkey, on the Black sea, near its southeastern angle. From the time of its foundation as a Greek colony to the present day, it has always been a considerable emporium of commerce, and it was for two centuries and a half the capital of an empire. Its importance is due to its command of the point where the chief trade route from Persia and central Asia to Europe, over the tableland of Armenia by Bayezid and Erzerum, descends to the sea. Its safety also was secured by the barrier of rugged mountains (7,000 to 8,000 ft.) which separates its district from the rest of Asia Minor. So complete is the watershed that no streams pass through these ranges, and there is hardly any communication in this direction between the interior of Asia Minor and the coast. For the same reason, together with its northern aspect, the climate is humid and temperate, unlike that of the inland regions, which are exposed to great extremes of heat in summer and cold in winter. The position which was occupied by the Hellenic and mediaeval city is a sloping table of ground (whence the original name of the place, Trapezus, the "Tableland"), which falls in steep rocky precipices on the two sides, where two deep valleys, descending from the interior, run parallel at no great distance from one another down to the sea. The whole is still enclosed by the Byzantine walls, which follow the line of the cliffs and are carried along the sea-face; and the upper part of the level, which is separated from the lower by an inner cross wall, forms the castle; while at the highest point, where a sort of neck is formed between the two valleys, is the keep which crowns the whole. On each side, about halfway between the keep and the sea, these ravines are crossed by massive bridges, and on the farther side of the westernmost of these, away from the city, a large tower and other fortifications remain. The area of the ancient city is now called the Kaleh; eastward of this is an extensive quarter, and beyond this again a low promontory juts northward into the sea, partly covered with the houses of a well-built suburb, which is the principal centre of commerce. The harbour lies on the eastern side of this promontory, but it is an unsafe roadstead, being unprotected towards the northeast and having been much silted up, so that vessels cannot approach within a considerable distance of the shore From here the caravans start for Persia. The population in 1955 was 42,273.

History.—The city of Trapezus was a colony of Sinope, but it first comes into notice at the time of the Retreat of the Ten Thousand. who found repose there. Notwithstanding its commercial importance, the remoteness of its position prevented it from being much known to fame either in the Hellenic or the early mediaeval period. Its greatness dates from the time of the fourth crusade (1204), when the Byzantine empire was dismembered and its capital occupied by the Latins. During the confusion that followed that event, Alexius Comnenus escaped into Asia and, having collected an army of Iberian mercenaries, entered Trebizond, where he was acknowledged as the legitimate sovereign, and assumed the title of Grand Comnenus. Though only 22 yr. of age. Alexius was a man of ability and resolute will, and he succeeded without difficulty in making himself master of the greater part of the southern coast of the Black sea.

The empire thus founded continued to exist until 1461, when the city was taken by Mohammed II. Trebizond was able to defy both the Seljuks and the Ottomans and to maintain its independence against the emperors of Nicaea and Constantinople. But for the same reason its policy was always narrow, so that it never exercised any beneficial influence on the world at large. It was chiefly in the way of matrimonial alliances that it was brought into contact with other states. Members of the imperial family were renowned for their beauty, and the princesses of this race were sought as brides by Byzantine emperors of the dynasty of the Palaeologi, by western nobles and by Mohammedan princes, and the connections thus formed originated a variety of diplomatic relations and friendly or offensive alliances.

The palace of Trebizond was famed for its magnificence, the court for its luxury and elaborate ceremonial, while at the same time it was frequently a hotbed of intrigue and immorality. The Grand Comneni were also patrons of art and learning, and in consequence of this Trebizond was resorted to by many eminent men, by whose agency the library of the palace was provided with valuable manuscripts and the city was adorned with splendid buildings. The writers of the time speak with enthusiasm of its lofty towers, of the churches and monasteries in the suburbs and especially of the gardens, orchards and olive groves. It excited the admiration of Gonzales Clavijo, the Spanish envoy, when he passed through it on his way to visit the court of Timur at Samarkand (Clavijo, *Historia del gran Tamorlan*); and Cardinal Bessarion, who was a native of the place in the latter part of his life when the city had passed into the hands of the Mohammedans and he was himself a dignitary of the Roman Church, was so impressed with Trebizond that he wrote a work entitled *The Praise of Trebizond* (Ἐγκώμιον Τραπεζοῦντος). Little was known of the history of the empire of Trebizond until the subject was taken in hand by Professor Fallmerayer of Munich, who discovered the chronicle of Michael Panaretus among the books of Cardinal Bessarion, and from that work and other sources of information which were chiefly unknown up to that time, compiled his *Geschichte des Kaiserthums von Trapezunt* (Munich, 1827). From time to time the emperors of Trebizond paid tribute to the Seljuk sultans of Iconium, to the grand khans of the Mongols, to Timur the Tatar, to the Turkoman chieftains and to the Ottomans, but by means of skilful negotiations they were enabled practically to secure their independence.

They are found also at war with many of these powers and with the Genoese, who endeavoured to monopolize the commerce of the Black sea. The city was several times besieged, the most formidable attack being that which occurred in the reign of Andronicus I, the second emperor, when the Seljuks, under the command of Melik, the son of the great sultan Ala-ed-din, first assaulted the northern wall in the direction of the sea and afterwards endeavoured to storm the upper citadel by night. They failed, however, in both attempts; and in the latter, owing to the darkness and to the occurrence of a violent storm which suddenly swelled the torrents in the ravines, their force was thrown into inextricable confusion, and they were compelled to abandon their camp and make the best of their escape from the country. So great was the strength of the fortifications that Mohammed II might have experienced much difficulty in reducing it, had it not been for the pusillanimous conduct of David, the last emperor, who surrendered almost unconditionally.

Ancient Memorials. — Several interesting monuments of this period remain at Trebizond in the form of churches in the Byzantine style of architecture. One of these is within the area of the old city, viz., the church of the Panaghia Chrysokephalos, or Virgin of the Golden Head, a large and massive but excessively plain building, which is now the Orta-hissar mosque. On the farther side of the eastern ravine stands a smaller but very well-proportioned structure, the church of St. Eugenius, the patron saint of Trebizond, now the Yeni Djuma djami, or New Friday mosque.

Still more important is the church of Haghia Sophia, which occupies a conspicuous position overlooking the sea, about 2 mi. west of the city. The porches of this are handsomely ornamented, and about 100 ft. from it rises a tall campanile, the inner walls of which have been covered in parts with frescoes of religious subjects, though these are now much defaced. But the most remarkable memorial of the middle ages that exists in all this district is the monastery of Sumelas, which is situated about 25 mi. from Trebizond, at the side of a rocky glen, at a height of 4,000 ft. above the sea. Its position is most extraordinary, for it occupies a cavern in the middle of the face oi a perpendicular cliff 1,000 ft. high, where the white buildings offer a marked contrast to the brown rock which forms their setting. It is approached by a zigzag path at the side of the cliff, from which a flight of stone steps and a wooden staircase give access to the monastery. An antiquity of 1,500 yr. is claimed for the foundation of the monastery, but it is certain that the first person who raised it to importance was the emperor Alexius Comnenus III of Trebizond, who rebuilt it in 1360.

TREBONIUS, GAIUS (*d.* 43 B.C.), Roman general and politician. The son of an aristocrat, he favoured the conservative party during his quaestorship (60 B.C.), the first public office he held; but by the time he became tribune (55 B.C.), he had switched political beliefs and was a strong supporter of Caesar's party. He was responsible for the passage, over the opposition of the conservatives, of the so-called Lex Trebonia, which he sponsored at the instigation of the consuls of the year, Pompey and Crassus. This act provided that the provinces of Spain should be given to Pompey and the province of Syria to Crassus for an additional five years and that the two should have the power to levy troops both in the provinces and in Italy.

During the period of the Gallic Wars, Trebonius served as a general under Caesar, and at the final battle at Alesia he was one of Caesar's most trusted and valuable aides. During the Civil War he commanded three legions at the successful siege of Massilia. He was praetor in 48 B.C. and the following year was governor of farther Spain, a position he was forced to abandon when some of his troops mutinied.

In 45 B.C. Caesar made him consul, promising him also the governorship of Asia, but notwithstanding his friendship and patronage, Trebonius was one of the leaders in the conspiracy which resulted in Caesar's death. His assignment was to engage Mark Antony in conversation outside the senate while the other conspirators assassinated Caesar, and this duty he performed successfully. In 43 B.C. he became proconsul in Asia but had been in office only a short time when Publius Cornelius Dolabella, then governor of Syria, murdered him.

TRÉBUCHET, a mediaeval siege engine, employed either to batter masonry, or to throw projectiles over walls. It was developed from the post-classical Roman *onager* (wild ass), which derived its name from the kicking action of the machine. It consisted of a frame placed on the ground to which a vertical frame of solid timber was rigidly fixed at its front end. Through the vertical frame ran an axle, which had a single stout spoke; on the extremity of the spoke was a cup to receive the projectile. In action the spoke was forced down, against the tension of twisted ropes or other springs, by a windlass, and then suddenly released. The spoke thus kicked the crosspiece of the vertical frame, and the projectile at its extreme end was shot forward. In the trbbuchet the means of propulsion was a counterweight. The axle which was near the top of a high strutted vertical frame served as the bridge of a balance, the shorter arm of which carried the counterweight and the longer arm the carrier for the shot. An alternative name for the trébuchet is the mangonel (*mangonneau*). (*See* also ENGINES OF WAR.)

TREBULA, the name of five ancient towns in Italy. (1) TREBULA in Samnium, a town of the Caraceni, on the left bank of the Sangro, some 20 mi. below Castel di Sangro. It appears to have been a *municipium,* but we know only of its existence in Hadrian's time. (2) TREBULA in Campania, between Saticula and Suessula. The site is probably identical with the hills (about 1,000 ft. above sea level) above the entrance to the valley of Maddaloni. It is possibly the citizens of this Trebula who received Latin rights in 303 B.C. Its territory extended as far as the Via Appia, and its place was taken in imperial times by the Vicus Novanensis, on the road itself, near Suessula. (3) TREBULA BALLIENSIS, also in Campania, 22 mi. north of Capua, in the mountains, about 1,000 ft. above sea level. It revolted to Hannibal and was reduced to obedience by Fabius. Remains of walls, aqueduct and tombs exist. Its territory was mentioned in the projected distributions of land in Cicero's time and its wine was well thought of under Nero. It was a *municipium.* (4) TREBULA MUTUESCA in the Sabine country, 2 mi. east of the point where the Via Caecilia diverges from the Via Salaria. It lies about 1 mi. southwest of the modem Monteleone, and an amphitheatre and other remains are visible. In a dedication made there by the consul Mummius in 146 B.C. it is spoken of as a *vicus,* but when the *praefecturae* were abolished it became a *municipium.* The post station of Vicus Novus on the Via Salaria belonged to its territory. (5) TREBULA SUFFENAS is generally placed 6 mi. south of Reate (mod. Rieti, *q.v.*) on the Via Quinctia, but is with considerable probability identified with Ciciliano, 10 mi. east of Tivoli, 2,030 ft. above sea level, by O. Cuntz. There are remains of an ancient road with substructures in rough polygonal work ascending to it in zigzags.

TRÉCUL, AUGUSTE-ADOLPHE-LUCIEN (1818-1896), French botanist, was born in Mondoubleau, Loir-et-Cher, on Jan. 8, 1818. In 1848 he went to the United States where he remained for two years, studying the flora of the western and southern states, travelling as far west as the Rocky mountains and as far south as Texas and Mexico. He specialized particularly in plant morphology, being among the first to pursue this study systematically. His principal work is *Observations sur le fruit du prismatocarpus* (1842). The genus Treculia of the family Moraceae was named for him. Trécul died in Paris, Oct. 15, 1896.

TREDEGAR, an urban district in the Ebbw Vale parliamentary division of Monmouthshire, Eng., on the Sirhowy, 22 mi. N.N.W. of Newport and 29 mi. W. of Monmouth by road. Pop. (1951) 20,376. Area 12.7 sq.mi. In addition to the town of Tredegar the urban district contains the villages of Bedwellty Pits, Troedrhiwgwair, Trefil and Tafarnaubach. It stands about 1,000 ft. above sea level and owes its existence to the establishment at the beginning of the 19th century of large ironworks. With the use of coal for smelting purposes the region developed industrially. It has a spacious public park.

Coal mining is the chief industry and there are a number of factories.

TREDGOLD, THOMAS (1788–1829), English engineer, who wrote a pioneer work on the strength of materials, *Elementary Principles of Carpentry* (1820). Born near Durham, Aug. 22.

1788, he was apprenticed at the age of 14, after a few years at a village school, to a cabinetmaker in Durham where he worked for six years studying, during his spare time, the subjects of mathematics and architecture. During five years more in Scotland at his trade of joiner and carpenter he devoted all his extra energies to his learning—so much, indeed. as to undermine his health. He then spent six years in London in an architect's office, permitting him to extend his investigations to all subjects connected with architecture and engineering.

Several editions of *Elementary Principles* were published. In 1823, he struck out for himself and in 1824 published two editions of *Principles of Warming and Ventilating Public Buildings* and a third in 1836; A *Practical Treatise on Railroads and Carriages* (1825) ; and a pamphlet on steam navigation, 1825. His last significant work was the *Steam Engine* (1827), which went through three editions and was translated into French.

Tredgold edited other engineering works, contributed several articles to the periodicals of the day and to the 6th edition of Encyclopædia Britannica. He died at London, Jan. 28, 1829, leaving his widow and four children with little property. (W. E. HD.)

TREE, SIR HERBERT BEERBOHM (1853–1917), one of the great figures of the English theatre, who became the most successful actor-manager of his time, was born in London on Dec. 17, 1853, the son of Julius Beerbohm, a London merchant of German parentage; his half brother, Max Beerbohm (*q.v.*), became famous as a writer and caricaturist. Taking the stage name of Herbert Beerbohm Tree, he made his first professional appearance in London in 1876. He was a striking success in 1884 as the curate in *The Private Secretary*. In 1887 he became lessee and manager of the Haymarket theatre, which he ran with great success for ten years.

His range of plays and parts was very wide—dramas such as *Jim the Penman, The Red Lamp* and *A Man's Shadow*, modern dramas like H. A. Jones's *The Dancing Girl*, romantic parts such as Gringoire and literary plays such as W. E. Henley's *Beau Austin* made him outstanding. His Shakespearean productions carried on and even exceeded the beauty created by Henry Irving, and he proved the finest Falstaff and Malvolio the stage had seen, though his Hamlet was not so successful. But his performance as Svengali in *Trilby* put the crown on his career, being perhaps the best individual performance ever seen.

In 1897 Tree moved to the new Her Majesty's theatre, which he had built, and there produced all sorts of plays from poetic drama by Stephen Phillips to children's plays. His Shakespearean productions drew audiences from all over the world. Among the most remarkable were *Richard 11, King John, Henry VIII* and *A Midsummer Night's Dream*. His stage versions of Dickens' works were magnificent and his Fagin was outstanding. He was above all a romantic actor with a strong liking and genius for character parts and comedy, in which he was unequaled.

In 1904 he founded what is now the Royal Academy of Dramatic Art. He was knighted in 1909.

In 1882 Tree married Helen Maud Holt, who frequently acted with him. He died in London on July 2, 1917.

See Max Beerbohm, *Herbert Beerbohm Tree* (1920). (W. J. M.-P.)

TREE, a woody, perennial, seed-bearing plant which at maturity is at least 20 ft. tall and which is characterized by a single trunk that terminates in a well defined crown. Several ferns indigenous to lush, tropical rain-forests attain the stature of trees, but they are not usually regarded as such since reproduction of plants of this category is accomplished by means of spores.

The distinttion between small trees and large shrubs is often effected with difficulty and is occasionally further complicated by the fact that many tree species assume shrub-like habits at or near the extremities of their range or when growing under severe adverse conditions. It is of interest also to record that a few forms, as for an example, the strangler fig, are vine-like (lianas) during the early stages of their development and become tree-like only as they approach maturity.

Plants of arborescent proportions are found in both of the two major divisions of the spermatophyta; *i.e.*, the gymnosperms and the angiosperms (*qq.v.*). The gymnosperms are of very ancient lineage, and by means of fossil remains have been traced backward 300,000,000 yr. through the Carboniferous to the Devonian, where they occurred in great profusion and in vast unbroken forests over the land surfaces from pole to pole. Only a vestige of this once great flora remains; countless forms being long since extinct.

The modern gymnosperms comprise a group of four orders which include the cycads, the gnetums and their allies, the ginkgo and the conifers. Of these only the conifers are of primary economic importance. Several of them, notably the pines, spruces, Douglas-firs, redwood, cypresses, cedars, podocarps, araucarias and cryptomerias are productive of excellent timber. Coniferous wood, because of its long fibres and high cellulose content, is especially suited for pulp and paper manufacture. The wood of the spruces, balsam-firs, hemlocks, Douglas-fir and yellow pines is used in quantity for such conversion. Much of the cellulose employed in the manufacture of cellulose-acetate and cellulose-nitrate plastics is a highly purified form of spruce pulp. Naval stores, oils, resins, waxes, pharmaceutical compounds and gums are other derived products. Because of their pleasing symmetry, showy evergreen foliage and ready response to horticultural treatment, many conifers are prized for decorative purposes.

The angiosperms are the commonest and most widely distributed plants inhabiting the surface of the earth. Fossil evidence indicates that they are of comparatively recent origin, dating back only to the Jurassic (160,000,000 yr.). Since their evolution they have developed very rapidly; and today there are over 150,000 species, many of which are arborescent. This division of the seed-bearing plants is divided into two classes, the *Monocotyledoneae* and *Dicotyledoneae*, respectively. The former comprises but 8 orders; the latter, 32. Palms, yuccas and their allies are arborescent moncots. As a group they are of little value as timber trees, although certain species are sometimes cut and used in the ground for piling. This group of trees is better known for its food products which include the coco-nut, banana, date and sabal starch. The large fern-like leaves of many tropical species are used by aborigines for thatching huts.

Arborescent dicots are legion. Many are productive of excellent cabinet timbers, of tannin, dye principles, oils, waxes, perfumes, powerful alkaloids, pharmaceutical compounds, varnish components, gums and palatable fruits such as the citrus forms, apple and its allies, bread-fruit, mango, persimmon, pomegranate, etc.

Lumbermen, in an attempt to distinguish the broad-leaved species from the conifers, have designated them as the hardwoods and softwoods, respectively. These two terms are used merely to distinguish between classes of material and have no mechanical significance whatever since the range of mechanical properties manifested in each group is very broad.

The various species of trees are treated under their individual titles; *e.g.*, oak, ash, elm, etc.; the articles FIR and PINE treat of two large groups of conifers (*q.v.*); general information is provided by the articles PLANTS AND PLANT SCIENCE and GYMNOSPERMS. Tree cultivation will be found under FORESTS AND FORESTRY and HORTICULTURE, and the various types of trees whose wood enters into commerce under TIMBER. *See* also LANDSCAPE ARCHITECTURE and LUMBERING. (E. S. HR.)

Tree planting involves the removal of a tree from one location and planting in another. In its original position the tree maintains a growth balance between the trunk and branches above ground and the roots below. The roots absorb water and mineral nutrients from the soil, and the growth of the top is limited by the amount of these materials which can be supplied. A portion of the water is transpired by branches (especially when in full leaf), and the remainder, together with the mineral nutrients, is the raw material from which organic food is synthesized. When a tree is lifted from the soil to be transplanted, a large part (25%–75%) of the root system must be cut off. Unfortunately, the terminal parts left behind are the most effective absorbing organs. The balance normally maintained between the top and the roots is, therefore, upset when a tree is lifted. For that reason it is advisable to prune off approximately $ of the branches of a transplant. Roots normally extend far beyond the base of the tree

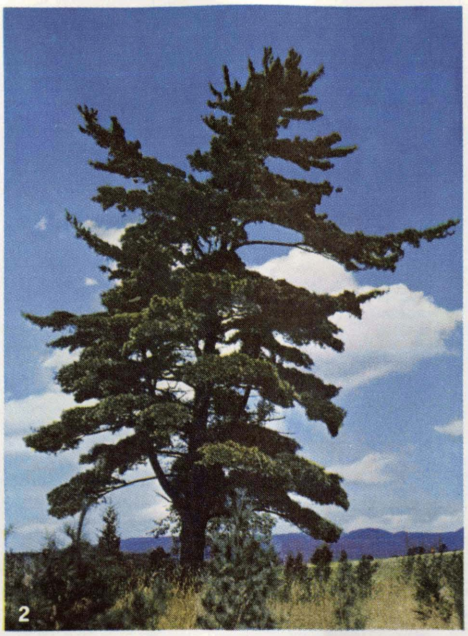
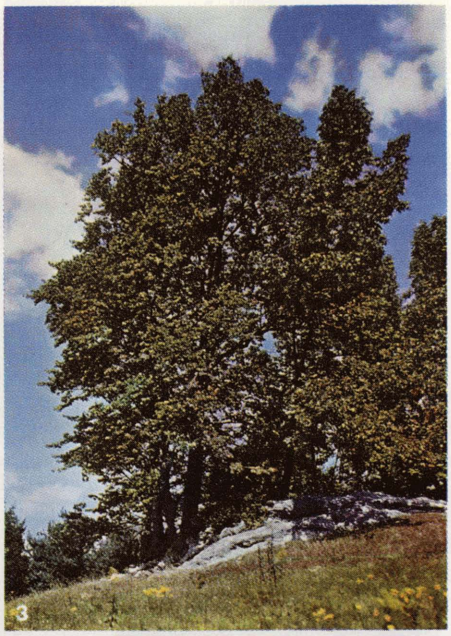
TREES OF NORTH AMERICA

1. Black willow (*Salix nigra*). This tree reaches a height of 120 ft. and a trunk diameter of 3 ft.
2. Common honey locust (*Gleditsia triacanthos*). The maximum height is 75–140 ft.; the trunk usually has a diameter of 2 or 3 ft., sometimes 5 or 6 ft.
3. Quaking or American aspen (*Populus tremuloides*), often called a poplar, to which genus it belongs. It has a maximum height of 100 ft. and a trunk diameter of 3 ft., but is usually smaller
4. Sugar maple (*Acer saccharum*). It sometimes grows to a height of 120 ft., with a trunk 4 ft. in diameter
5. A sugar maple in fall
6. White ash (*Fraxinus americana*). It grows to a height of 120 ft. and often has a trunk diameter of 5 ft.





PHOTOGRAPHS, RUTHERFORD PLATT

TREES OF NORTH AMERICA

1. White oak *(Quercus alba)*. Full height, 80-100 ft.; trunk diameter, 3 4 ft.
2. White pine *(Pinus strobus)*. Some attain a height of more than 200 ft., and a trunk diameter of 4-6 ft. or more
3. Linden (Lime), often called basswood. There are a number of North American species
4. American elm *(Ulmus americana)*. Full height, 100-120 ft.; trunk diameter, 6-11 ft.
5. Paper birch *(Betula papyrifera)*. Full height, 60-70 ft.; trunk diameter, 2-3 ft.

TREES OF NORTH AMERICA

Top left: Sycamore ***(Platanus occidentalis)***, the most massive hardwood trees in the eastern United States. It averages 60–120 ft. in height

Top right: Eastern cottonwood ***(Populus deltoides)***. This tree has a broad, open crown supported by a massive trunk. Average height is 80–100 ft.

Bottom left: Flowering dogwood ***(Cornus florida)***, the most important of some 60 species, many of which are native to North America. Occasionally attains height of 40 ft.

Bottom right: Sassafras ***(Sassafras albidum)***. Little more than a shrub in the north, it attains heights of 40–90 ft. in the south

TREES COMMON IN ENGLAND

Top left: Rows of beech trees (*Fagus sylvatica*) In autumn foliage
Top right: Beech trees (*Fagus sylvatica*) at Burnham Beeches
Centre left: Apple trees (*Malus*) in bloom. The Romans are believed to have introduced the tree to England
Bottom left: Weeping willow (*Salix babylonica*) is an ornamental tree both in England and the US. It is native to China
Bottom right: Qrove of young English oaks (*Quercus robur*) in the autumn

trunk, depending upon the species, the physical condition of the soil and the water supply. For example, a willow tree 4 ft. high growing in sandy soil was found to have a lateral root system 50 ft. in length. A much larger tree in a clayey soil with a high water level had a root system only 10 ft. long. Some species like pine, spruce and holly have what is known as "tap roots"; that is, primary roots uhich tend to taper off from the trunk and grow straight down from the tree. Other species have semi-tap roots with many lateral roots which grow in all directions but not far below the surface of the soil.

The immediate problem in transplanting shrubs or trees is to provide a set of conditions which will keep the plants from drying out until new roots can be regenerated. The top of the plant must remain more or less at a standstill until the new roots are formed and begin to function as absorbing organs. When the natural balance between the roots and the top has been re-established, new branches with green leaves appear and the tree resumes natural growth.

The best time to transplant deciduous trees such as elm, apple, cherry, maple, linden and oak is when they are dormant, without leaves. In the temperate zone of the United States fall and spring planting is practised. In the southern part of the zone, where the ground rarely freezes, planting may be practised during the winter. In tropical or subtropical regions, planting can be done at any season if water and soil requirements are provided.

The size of trees to be planted may vary from one-year-old seedlings a few inches in height to large trees six to ten feet in height. Ten to 20-year-old trees can be moved, but only with special equipment and by expert workmen.

The size of the hole prepared for planting must be determined by the size of the root system of the tree. A root system with a two-foot spread would require a hole 3 to 4 ft. wide and 2 ft. deep. When the transplant is in position, the ground level should be from one to five inches above the original level, which can usually be seen on the trunk. The soil which is removed from the hole can be used to refill around the tree. It is often advisable to discard poor soil and replace with good soil to tamp around the roots. Well-rotted manure and fertilizer are sometimes used when trees are transplanted; however, inexperienced gardeners often injure the trees with this practice. If manure and fertilizer are used, they should be mixed well with soil and placed in the bottom of the hole with an inch or more of soil on top. The fertilizer should not come in direct contact with the roots. If used to the extent of one tablespoonful of commercial fertilizer per gallon of soil, it should not injure the tree. After the tree is established, fertilizer can be broadcast on the ground above the roots and turned under with a spade, care being taken not to dig out the roots.

Evergreen trees such as pine, spruce, fir, hemlock and holly are far more difficult to transplant than the average nursery stock. Nurserymen usually move such plants with a ball of earth around the roots held together with burlap. If plants are properly root-pruned a year or two before digging, they will have a goodly number of fibrous roots near the plant which can be included in the ball. It is usually best to transplant evergreens growing in the temperate regions of the United States in late summer, but they can be successfully planted also in the spring. The requirements as to the size of the hole in which to set the tree, the soil and fertilizer for evergreens are similar to those described for deciduous trees.

The water supply for transplanted trees is important. More failures result from a water shortage than from most other causes. It is advisable to plant the tree as soon as possible after lifting and to water it immediately after planting. It is advisable not to fill the hole entirely with soil so that the water will not run off. After the first soaking the tree should be watered at least once a week or more. Thereafter the hole should be filled and the soil kept cultivated until the tree is established. If there is a shortage of rain, it may be necessary to water transplanted trees throughout the summer months. *See* also ARBORICULTURE.

TREE BEAR, a name given in West Africa to the tree hyrax *(Dendrohyrax). See* HYRACOIDEA.

TREE BURIAL. Among the Andamanese, burial upon a platform placed in a tree is an honourable form of burial and adopted only in the case of a man or woman dying in the prime of life. It is not clear whether this honour is reserved for those who have had children—the point may be significant. A tree sometimes used for this purpose is *Ficus laccifera,* allied to the fig, and the belief of the natives is apparently that the souls of unborn children live in these trees and that if a baby dies before it has been weaned its soul goes back to the tree. *(See* A. R. Brown, *The Andaman Islanders* [1922].)

In Australia tree burial is forbidden to those who violate the law of exogamy—who are thereby excluded from reincarnation. In Indonesia "the position with regard to tree burial may be put in this way, that wherever a myth of origin exists which states that the first men came from trees or bamboos, then it will generally be found that the dead are placed in trees or disposed of in a way derived from tree disposal" (W. J. Perry, *Folklore,* xxvi, pt. 2, p. 147). There are cases of tree burial in central India among the primitive Gonds; the semi-Hinduized Gonds in Bengal tie the corpses of adult males to a *malua* tree previous to burial. The Oraons "revere the tamarind and bury their dead in its shade. One special rite among the Dravidian races is the *imli ghoutna* or 'the gnnding of the tamarind' when the mother of the bridegroom grinds on the family curry stone some pods of the tamarind" (W. Crooke, *Popular Religion of Northern India,* vol. i, p. 109).

TREE CREEPER, one of the smaller British birds, and generally distributed. It is *Certhia familiaris,* and is remarkable for the stiffened shafts of its long and pointed tail feathers, aided by which, and by its large feet, it climbs the trunks or branches of trees, proceeding upward or outward, generally in a spiral direction, as it seeks the small insects that are hidden in the bark and that form its chief food. It never climbs head downward as the nuthatch (*q.v.*) does. Inconspicuous in its upper plumage of brown mottled with white, buff and tawny—for the silvery white of its underparts is not usually visible—the tree creeper is commoner than the incurious suppose; though a shy singer, its song is loud and sweet. The nest is placed behind a half-detached piece of bark, and a mass of material is used to give a sure foundation for the tiny cup, in which are laid from six to nine eggs of a translucent white, spotted or blotched with rust colour.

The tree creeper inhabits almost the whole of Europe as well as Algeria and has been traced across Asia to Japan. It is an inhabitant of the greater part of North America. On the European continent a second species, *C. brachydactyla,* is found. This is similar to C. *familiaris* in appearance but has a quite different song and lives in gardens and parks rather than in woodland.

Allied to the tree creeper, but without its stiff tail feathers, is the genus *Tichodroma,* the single member of which is the beautiful wall creeper *(T. muraria)* of the Alps and some other mountainous parts of Europe and Asia. It is occasionally seen in Switzerland, fluttering up the face of a rock, conspicuous from the scarlet-crimson of its wing coverts and its white spotted primaries. Its bright hue is hardly visible when the bird is at rest, and it then presents a dingy appearance of gray and black. It is a species of wide range, extending from Spain to China.

The passerine family *Certhiidae* contains a number of genera of birds to which the general name "creeper" is applied; they occur in North America, Europe and Asia, the greater part of Africa, and Australia and New Guinea.

TREE CULTS. Primitive man, observing the growth and death of trees, the elasticity of their branches, the sensitiveness and the annual decay and revival of their foliage, anticipated in his own way the tendency of modern science to bridge the gulf between the animal and the vegetable world. Sober Greek philosophers (Aristotle, Plutarch) thought that trees had perceptions, passions and reason. The beliefs of primitive man were part of a small stock of fundamental ideas which persist in one form or another over a large portion of the world and have found a place in the higher religions.

Trees and Human Life.—Numerous popular stories reflect a firmly rooted belief in an intimate connection between a human being and a tree, plant or flower. Sometimes a man's life depends upon the tree and suffers when it withers or is injured. and we encounter the idea of the *external soul*, already found in the Egyptian "Tale of the Two Brothers" of 3,000 years ago. Here one of the brothers leaves his heart on the top of the flower of the acacia and falls dead when it is cut down. Sometimes, however, the tree is an *index,* a mysterious token which shows its sympathy with an absent hero by weakening or dying as the man becomes ill or loses his life. These two features easily combine and represent a mysterious sympathy between tree and human life, which, as a matter of fact, frequently manifests itself in recorded beliefs and customs of historical times. Thus, sometimes a newborn child is associated with a newly planted tree with which its life is supposed to be bound up; or, on ceremonial occasions (betrothal, marriage. ascent to the throne), a personal relationship of this kind is instituted by planting trees, upon the fortunes of which the career of the individual depends. Sometimes, moreover, boughs or plants are selected, and the individual draws omens of life and death from the fate of his or her choice. Again, a man will put himself into relationship with a tree by depositing upon it something which has been in the closest contact with himself (hair, clothing, etc).

The custom of transferring disease or sickness from men to trees is well known. Sometimes the hair, nails, clothing, etc., of a sickly person are fixed to a tree; or they are forcibly inserted in a hole in the trunk, or the tree is split and the patient passes through the aperture. Where the tree has been thus injured, its recovery and that of the patient are often associated. In India when a man is supposed to be tormented by a demon, ceremonies are performed to provide it with a tree where it will dwell peacefully without molesting the patient so long as the tree is left unharmed. Such ideas do not enter, of course, when the rite merely removes the illness, but endangers the health of those who approach the tree. Again, sometimes it is believed that man's personality is mystically united with some healthy and sturdy tree, and in this case we may often presume that such trees already possessed some appropriate reputation. Again hair, nail-clippings, etc., are hung upon a tree for safety's sake lest they fall into the hands of an enemy.

Spirits in Trees.—Among the Arabs the sacred trees are haunted by angels or by *jinn;* sacrifices are made, and the sick who sleep beneath them receive prescriptions. Here, as frequently elsewhere, it is dangerous to pull a bough. This dread of damaging special trees is familiar: Cato instructed the woodman to sacrifice to the male or female deity before thinning a grove *(De re rustica,* 139), while in the Homeric poem to Aphrodite the tree nymph is wounded when the tree is injured and dies when the trunk falls. Early Buddhism decided that trees had neither mind nor feeling and might lawfully be cut; but it recognized that certain spirits might reside in them, and this the modern natives of India firmly believe. Propitiation is made before the sacrilegious axe is laid to the holy trees; loss of life or of wealth and the failure of rain are feared should they be wantonly cut; and there are even trees which it is dangerous to climb. The Talein of Burma prays to the tree before he cuts it down, and the African woodman will place a fresh sprig upon the stump as a new home for the spirit. In the Gold Coast the silk-cotton and odum (poison) trees are especially sacred as the abode of the two deities, who are honoured by sacrifices--even of human victims; these can be felled only after certain purificatory ceremonies. In general, sacred trees must not be injured unless they (*i e.,* their spirits) have been appeased or means taken to provide the occupant with another abode. That the difference between the sacred *object* and the sacred *occupant* was not always clearly drawn is quite intelligible from those beliefs of much less rudimentary religions which confuse the unessential uith the essential.

Forms of Cult.—Often the tree is famous for oracles. One of the best known is the oak of Dodona tended by priests who slept on the ground. The tall oaks of the old Prussians were inhabited by gods who gave responses, and the old Hebrews had their "terebinth of the teacher" (Gen. xii, 6), and "terebinth of the diviners" (Judg. ix, 37). Sacred trees are also the object of pilgrimage, one of the most noteworthy being the branch of the Bo tree at Ceylon brought thither before the Christian era. Again, tree-spirits will hold sway over the surrounding forest or district, and the animals in the locality are sacred and must not be harmed. Thus, the pigeons at the grove of Dodona, and the beasts around the north European tree-sanctuaries, were left untouched; even as the modern Dyak allows no interference with the snake by the side of the bush which enshrines a dead kinsman. Sacred fires burned before the Lithuanian Perkuno and the Roman Jupiter; both deities were closely associated with the oak, and, indeed, according to Frazer, the oak seems to have been very commonly used for the perpetual holy fires of the Aryans.

The powers of the tree-deities, though often specially connected with the elements, are not necessarily so restricted, and the sacred trees can form the centre of religious, and sometimes, also, of national life. Such deities are not abstract beings but are potent and immediate, and the cultus is primarily as utilitarian as the duties of life itself. They may have their proper ministrants: the chief sanctuary of the old Prussians was a holy oak around which lived priests and a high priest known as "God's mouth"; in Africa there are sacred groves into which the priest alone may enter, and among the Kissil-Bashi (or Kizilbashes) of the Upper Tigris and Euphrates, the holy tree of the village stands in an enclosure to which only the father-priest has access. The trees may be the scene of religious festivals and of periodical fairs and markets. Among the Lousiade group in British New Guinea the religious feasts are held under the sacred tree and a portion is laid aside for the spirit-occupants. That the invisible spirit naturally enjoyed only the *spiritual* part of the offerings is a belief which has been shared by others than the African Negro (Tylor ii, 216). Human sacrifice is known on the Slave Coast and in the Punjab; it was practised among the Druids and at Odin's grave at Uppsala. It is also said that the pollution of old Prussian sacred groves and springs by the intrusion of Christians was atoned for by human victims.

Development of Ideas.—As ideas advanced, the spirits associated with trees were represented by posts, idols or masks; altars were added, and the trunk was roughly shaped to represent the superhuman occupant. There is reason to believe that the last-mentioned transformation has frequently happened in the development of iconography. Indeed, the natives of the Antilles suppose that certain trees instructed sorcerers to shape their trunks into idols and to instal them in temple-huts where they could be worshipped and could inspire their priests with oracles. When the tree-spirit was conceived to be of human shape the numerous stories which associate trees with men or deities of flesh and blood would easily arise; and just as Indian natives have gods which are supposed to dwell in trees, so in higher religions we find a Zeus or a Dionysus *Endendros,* gods, "occupants of trees," who have been identified with one or other of the leading members of a recognized pantheon.

Syrian writers speak of a "king of the forest" and of a tall olive tree to the worship of which Satan seduced the people. But these "trees of the demons" were hewn down by zealous Syrian Christians. So also the caliph Omar cut down the tree at Hodaibaya visited by pilgrims lest it should be worshipped, and the Council of Nantes (A.D. 895) expressly enjoined the destruction of trees which were consecrated to demons.

Tradition has preserved some recollections of the overthrow of tree-cult in Europe. Bonifacius destroyed the great oak of Jupiter at Geismar in Hesse and built of the wood a chapel to St. Peter. (A similar continuity was maintained near Hebron when Constantine destroyed the idols and altars beneath the oak or terebinth of Abraham at Mamre and replaced them by a basilica.) On the Heinzenberg near Zell the Chapel of Our Lady stands where the old tree uttered its complaint as the woodman cut it down; and at Kildare (*cilldara,* church of the oak), "Saint" Brigit or Bridget built her church under an oak tree.

On the other hand. at Samosata, the sacred tree worshipped in Christian times was honoured as the wood of Christ's cross.

TREE FARMING: *see* FORESTS AND FORESTRY.

TREE FERN: *see* PTERIDOPHYTA.

TREE FROG in a general sense is a term identifying any tailless Amphibia *(see* FROG) adapted to arboreal life. The term in a special sense, or tree toad, which is equivalent, is often used for the family Hylidae.

The adaptation for an arboreal existence is indicated by adhesive discs on the tops of the fingers and toes. These discs adhere by rapid and intense pressure of the distal phalanx and special muscles upon the lower surface, which is also provided with glands producing a sticky secretion.

The family Hylidae is related to the Bufonidae or toads, being distinguished by the presence of teeth in the upper jaw and by the clawlike shape of the terminal phalanx of the digits. It is a large family, with about 300 species, 250 of which belong to the genus *Hyla,* distributed over Europe, temperate Asia, North Africa, North and South America, New Guinea and Australia.

The best-known European tree frog is the little *Hyla arborea,* which rarely reaches two inches in length. Its upper parts are smooth and shiny, normally of a bright grass green, which may change rapidly to yellow, brown, olive or black; some specimens, however. are sky blue or turquoise blue; the lower parts are white. The commonest North American species are *H. versicolor,* green, gray or brown, with a loud croaking voice, and *H. crucifer,* the spring peeper, having a shrill piping voice.

Other genera of the Hylidae include *Gastrotheca* of South America, which, in the female, develops a broad dorsal pouch in which the eggs undergo their development, and *Phyllomedusa,* also from tropical America, which has the inner finger and toe opposable to the others. Frogs of the latter genus deposit their spawn bet een the leaves of branches overhanging water, into which the tadpoles drop and spend their larval life. (K. P. S.; X.)

TREE KANGAROO, the name of certain arboreal marsupials. forming the genus *Dendrolagus (see* MARSUPIALIA). Four species are inhabitants of New Guinea and two others are found in north Queensland, in dense scrub high up on the mountains. They are nocturnal in habit and feed on bark, leaves and fruit. Reaching a length of four feet (half of which is tail), the tree kangaroo is shorter and broader than the true kangaroo and has relatively shorter hind limbs and longer. more robust fore limbs with strong curved and pointed claws. The flesh of the Queensland species is much prized by the Australian aborigines.

TREE MARRIAGE. In Chota Nagpur, the tribes who speak languages of the Munda group, and in Bengal, low castes such as the Rautias, Bagdis and Murmis, perform the rite of tree marriage as an integral part of the marriage service. The nuptial pair are fastened to trees by thread. The trees selected are either the mahua or the mango, the two most important and conspicuous trees in that area. In the marriage rites for a number of castes in Mysore, whose language is Dravidian, the marriage is celebrated in a booth, one of the posts of which is called the milk post. This, so we are told, is to secure the continuity of the line, and it has to be cut by the maternal uncle—the male representative of an important social grouping. A fig tree is here specified, while in parts of the Punjab, a branch of a jhand tree. *Prosopis spicigera,* is essential to the due performance of the marriage rites. Quite obviously, trees of such economic importance as the mahua, the mango, the jhand and the fig are selected as conspicuously, essentially fertile, but it is not a general fertility, but a specific fertility, that must be looked for as the reason for their selection. They are associated with the beliefs of the people as to the fate of those who are destined or desired to return and be reborn. In general, too, trees, notably the pipal, are in India associated with the spirits, and for this reason barren women walk around them in order that they may be fertilized by a spirit denizen of the tree. In west Africa "nearly all Yoruba believe that souls about to be born live in or among trees, and it is for this reason that women so often pray to the tree spirits to send them children." (P. A. Talbot, *The Peoples of Southern Nigeria,* vol. ii, p. 267.)

There are cases where tree marriage affords a means of attaining the social status of marriage, as where a bachelor who seeks to marry a widow is obliged to marry a tree, which is then cut down. He is then a widower, equal in status with his human bride. It may be a substitute and intended to avoid the curse of widowhood, or to confer the status of married woman on a girl, and thus escape the social and religious penalties attaching to those whose daughters do not marry. Lastly, there is the common practice in India of marrying a newly-constructed tank to a plantain tree for the purpose of blessing the tank.

Tree marriage is part of a series of rites by means of which the continuity of the group life is secured.

TREE SHREW, a small, arboreal, insectivorous mammal of the family Tupaiidae, found in southern Asia and in the islands of the Malay archipelago. It is squirrellike but has a long pointed muzzle; the teeth are like those of the Insectivora *(q.v.)*, and the eye socket is ringed by bone. The common tree shrews *(Tupaia)* are dark olive brown with bushy tails. Pen-tailed tree shrews *(Ptilocercus)* are dark gray-brown with a black facial mask and narrow tail, ending in a featherlike tuft; they are found in Malaya, Sumatra, Borneo and Palawan. Slender-tailed tree shrews *(Dendrogale)* occur in Indochina and Borneo; a similar genus *(Urogale)* is found in Mindanao, the Philippines. Tree shrews, active during the day, feed on insects, some vegetable matter and the young and eggs of birds. Mammals of this type doubtless gave rise to the Primates *(q.v.)*, and some authorities classify these forms with that order. (J. E. HL.)

TREE TOAD: *see* TREE FROG.

TREGELLES, SAMUEL PRIDEAUX (1813–1875), English biblical scholar, editor of a critical text of the New Testament, was born at Wodehouse place, near Falmouth, on Jan. 30, 1813. His parents were Quakers, and he himself for many years was in communion with the Darbyite Plymouth Brethren but afterward became a Presbyterian. For a time he worked at the ironworks, Neath abbey, Glamorgan, and then set up as a private tutor in Falmouth, finally devoting himself to a laborious student life, until he was incapacitated by paralysis in 1870. He died at Plymouth, April 24, 1875.

Most of Tregelles' numerous publications had reference to his critical edition of the New Testament, which he began to plan in 1838. Between 1854, when *An Account of the Printed Text of the Greek New Testament* appeared, and 1870 he published the texts of all the books of the Kew Testament except Revelation. Tregelles wrote also *Heads of Hebrew Grammar* (1852), translated Gesenius' *Hebrew Lexicon* and was the author of a little work on the *Jansenists (1851)* and of various works in exposition of his special eschatological views.

TREILHARD, JEAN BAPTISTE (1742–1810), French revolutionary, was born at Brives (Corrèze). In Paris he gained reputation as an *avocat* at the *parlement,* and was a deputy to the states-general in 1789. In the constituent assembly he showed great capacity in dealing with the reorganization of the church and in the nationalization of ecclesiastical property. Ineligible, like all the members of the constituent assembly, for the legislative assembly, he became president of the criminal tribunal of Paris, but failed through lack of firmness. The *département* of Seine-et-Oise elected him to the Convention, where he attached himself to the group known as The Mountain and voted for the death of Louis XVI. He was a member of the committee of public safety, and became president of the Convention on Dec. 27, 1792.

Under the directory Treilhard entered the Council of the Five Hundred (of which he was president during the month of Nivose, year IV), was a member of the Tribunal of Cassation, plenipotentiary at the congress of Rastatt and became a director in the year VI.

After the *coup d'état* of 18 Brumaire he became president of the tribunal of appeal and councilor of state. He took an important part in drafting the civil code, the criminal code, the code of civil procedure and the commercial code.

Treilhard died on Dec. 1, 1810, a senator and count of the empire.

TREINTA Y TRES, a department in east-central Uruguay, bordering on Lake Merim across from Brazil. Pop. (1954 est.) 80,923; area 3,743 sq.mi. The north and northwest parts of Treinta y Tres reach heights of between 650 ft. to almost 1,000 ft. above sea level, high elevations for low lying Uruguay. The eastern area is level and some corn and wheat are grown there. The principal activity is cattle and sheep ranching on the high rolling lands which make good pastures. The Olimar river drains much of the area. (M. I. V.)

TREINTA Y TRES, capital of the department of Treinta y Tres, Uruguay, is a short distance north of the Olimar river, 200 mi. N.E. of Montevideo. Pop. (1954 est.) 19,400. The city and the department are named for the band of 33 (Spanish, *treinta y tres)* patriots who, commanded by Juan Antonio Lavalleja, in 1825 began the campaign which ultimately produced Uruguay's independence from both Brazil and Argentina. The city, like other Uruguayan departmental capitals, is built around a square with the government house and the parish church as the principal buildings. There is a park on the banks of the Olimar. Treinta y Tres is connected by rail and road with Montevideo and other points, and has an airport. The city's principal function, aside from administration of the department's political, judicial and police affairs, is as a commercial and cattle trading centre. (M. I. V.)

TREITSCHKE, HEINRICH VON (1834–1896), German historian and political writer, the son of a Saxon officer, was born at Dresden on Sept. 15, 1834. Prevented by deafness from entering the public service, he studied at Leipzig and Bonn, where he was a pupil of Dahlmann. He established himself as a *Privatdozent* at Leipzig, lecturing on history and politics, and at once became very popular with the students, but his political opinions made it impossible for the Saxon government to appoint him to a professorship. He was at that time a strong Liberal; he hoped to see Germany united into a single state with a parliamentary government, and all the smaller states swept away. In 1863 he was appointed professor at Freiburg; in 1366, at the outbreak of war, he showed his Prussian sympathies by moving to Berlin, became a Prussian subject, and was appointed editor of the *Preussische Jahrbücher*.

After holding appointments at Kiel and Heidelberg, Treitschke was in 1874 made professor at Berlin; he had already in 1871 become a member of the *Reichstag,* and from that time until his death in 1896 he was one of the most prominent figures in the city. On Sybel's death he succeeded him as editor of the *Historische Zeitschrift.* He had outgrown his early Liberalism and become the chief panegyrist of the house of Hohenzollern.

Treitschke did more than any one else to mold the minds of the rising generation, and he carried them with him even in his violent attacks on all opinions and all parties which appeared in any way to be injurious to the rising power of Germany. He supported the government in its attempts to subdue by legislation the Socialists, Poles and Roman Catholics; and he was one of the few men of eminence who gave the sanction of his name to the attacks on the Jews which began in 1878. As a strong advocate of colonial expansion, he was a bitter enemy of Great Britain; and he was to a large extent responsible for the anti-British feeling of German chauvinism during the last years of the 19th century. In the *Reichstag* he had originally been a member of the National Liberal party, but in 1879 he was the first to accept the new commercial policy of Bismarck, and in his later years he joined the Moderate Conservatives.

Treitschke died at Berlin on April 28, 1896.

As a historian Treitschke confined himself to those periods and characters in which great political problems were being worked out; above all, he was a patriotic historian, and he never wandered far from Prussia.

His great achievement was the *History of Germany in the Nineteenth Century* (Eng. trans. by E. and C. Paul, 7 vol. 1915–19). The first volume was published in 1879, and during the next 16 years 4 more volumes appeared, but at his death he had advanced only to the year 1847. The work shows extreme diligence and scrupulous care in the use of authorities. It is discursive and badly arranged, but it is marked by a power of style, a vigour of narrative and a skill in delineation of character which give life to the somewhat unattractive period of German history with which he was concerned; notwithstanding the extreme spirit of partisanship and some faults of taste, it remains a remarkable monument of literary ability.

The most important of the essays were collected under the title *Historische und politische Aufsatze (4* vol., 1896) ; a selection from his more controversial writings was made under the title, *Zehn Jahre deutscher Kämpfe;* in 1896 a new volume appeared, called *Deutsche Kämpfe, neue Folge.* After his death his lectures on political subjects were published under the title, *Politik* (Eng. trans., 2 vol., 1916). He brought out also in 1856 a short volume of poems called *Vaterlandische Gedichte,* and another volume in the following year. His *Briefe,* edited by M. Cornicelius, 3 vol. (1859–96), were reprinted at Leipzig (1913–20).

TRELAWNY, EDWARD (1699–1754), British governor of Jamaica, was born in Trelawne. Cornwall, in 1699, and attended Christ Church college, Oxford. In 1732 he entered parliament as member for West Looe, Cornwall. In 1736, after several terms in parliament, he was appointed governor of Jamaica. He took office two years later, on April 30, 1738. Trelawny's first task as governor was to suppress the war between the native Negroes, known as Maroons, and the whites on the island. The struggle was a long-standing one but within **a** year Trelawny had concluded a peace which gave the Maroons their freedom and assigned to them 1,500 ac. of land, the chief town of which was for many years known as Trelawnytown. In return, the Negroes were to assist the colony in the event of war with an outside power and deliver fugitive slaves to the government. Scarcely had this difficulty been settled when England became embroiled with Spain in the War of Jenkins' Ear, so-called because of the alleged amputation of the ear of an English seaman. Robert Jenkins, by Spanish sailors. Trelawny not only assisted Adm. Edward Vernon in mapping strategy but took. a personal role in the fighting. Trelawny resigned from office in 1751 and left Jamaica in 1752. He died in London, Jan. 16, 1754.

TRELAWNY, EDWARD JOHN (1792–1881). English sailor and friend of Shelley and Byron, was born in London on Nov. 13, 1792. After a short term in the navy and a naval school, he shipped for India but deserted at Bombay. For several years he led an adventurous life in India, but about 1813 returned to England. Early in 1822 he met Shelley and Byron at Pisa and passed nearly every day with one or both of them until the drowning of Shelley (*q.v.*) and Williams on July 8. He superintended the recovery and cremation of the bodies, snatching Shelley's heart from the flames. He added the lines from the *Tempest* to Leigh Hunt's "Cor Cordium"; and, finally, he supplied the funds for Mrs. Shelley's return to England.

In 1823 he set out with Byron for Greece, to aid in the struggle for independence. Distressed by his companion's dilatoriness, Trelawny left him and joined the insurgent chief, Odysseus, and afterwards married his sister. Tersitza. While in charge of the former's fortress on Parnassus, he was assaulted by two Englishmen and nearly killed. Returning to England, he lived for a time in Cornwall with his mother and afterward in London.

Permission having been refused him to write the life of Shelley, he began an account of his own life in the *Adventures of a Younger Son* (1835; new ed. by E. C. Mayne, 1925), followed much later by a second part: *Recollections of Shelley and Byron* (1858), which was recast as *Records of Shelley, Byron and the Author* in 1878 (new ed. by E. Dowden, 1906). This gives an admirable portrait of Shelley and a less truthful one of Byron.

He died at Sompting. near Worthing, on Aug. 13, 1881.

TRELAWNY, SIR JONATHAN, Bart. (1650–1721), English prelate, was born at Pelynt, Cornwall. on March 24, 1650. Educated at Westminster school and at Christ Church, Oxford, Trelawny took holy orders in 1673. Having rendered good service to James II during Lionmouth's rebellion, Trelawny was consecrated bishop of Bristol on Nov. 8, 1685. He was loyal to King James until the first declaration of indulgence in April 1687, when, as a bishop, he used his influence with his clergy against the king, and, as a Cornish landowner, resisted the attempt to assemble a packed parliament.

In May 1688 Trelawny signed the petition against the second declaration of indulgence and in the following month was imprisoned in the Tower of London with Sancroft and five other bishops, sharing their triumphant acquittal. In spite of Burnet's assertion, it is probable that Trelawny did not sign the invitation to William of Orange. although he certainly welcomed his army into Bristol. Before this James II. anxious to regain the bishop's support, had nominated him to the see of Exeter, but Trelawny lost nothing as this appointment was almost at once confirmed by William III. Unlike five of his colleagues among the "seven bishops," Trelawny took the oaths of allegiance to William and Mary, but he was soon estranged from the new king and sided with the princess Anne.

In 1707 Trelawny was appointed bishop of Winchester and became prelate of the Order of the Garter. but henceforward he took very little part in politics. He died at his residence at Chelsea on July 19, 1721, and was buried at Pelynt.

Trelawny is the hero, or one of the heroes, of the refrain of R. S. Hawker's modern ballad:

"And shall Trelawny die,
Here's twenty thousand Cornishmen
Will know the reason why."

TREMATODES (FLUKES), a class of Platyhelminthes (*q.v.*), in uhich the body is unsegmented and without a cellular epidermis or external cilia, and an alimentary canal is present. All the members of the group are parasitic.

General Morphology. — The body is generally flattened and leaf-like or ribbon-like in shape, but may be relatively stout and oval or circular in transverse section. One or more muscular suckers are usually present on the ventral surface. In general structure the Trematodes closely resemble the free-living Turbellaria (q u.). They differ from them in the development of suckers and other organs for attachment to the host, and in the absence (in the adult) of a ciliated epidermis.

The external covering is a stout cuticle, often armed with spines, below which is a subcuticular layer containing unicellular glands. The number and arrangement of the suckers are very variable. Usually there is an anterior sucker or pair of suckers, and a posterior sucker, or a posterior disk-like organ of attachment provided with subsidiary suckers or with cuticularized hooks of various kinds. The complex development of the posterior organ of attachment is characteristic of the ectoparasitic forms (Monogenea). In endoparasitic forms (Digenea) the posterior sucker is usually a simple muscular disk or cup and may be situated at the posterior end of the body, but is more often displaced anteriorly so as to lie in front of the middle or even close behind the oral sucker.

Pigment is rare in Trematodes, but occurs in the parenchyma of certain species, more especially among the Monogenea. The body of endoparasitic species may, honever, appear more or less brightly coloured on account of the contents of the intestine and uterus, and the vitelline glands. showing by transparency.

The musculature usually consists of an outer circular and an inner longitudinal layer of fibres. Oblique and dorso-ventral fibres are also frequently present.

Except in one family, the mouth is situated at or near the anterior extremity. It may open through an anterior. or oral, sucker or, in certain ectoparasitic forms, may be flanked by a pair of adoral suckers. The alimentary canal may be a simple, blind sac, but usually consists of a relatively short median anterior portion and two posterior branches arising by the bifurcation of the former. These branches may be simple or secondarily branched, and may join again posteriorly, or may remain distinct. In the great majority of forms they are without any posterior opening, but in a few species they have been found to open to the exterior by one or a pair of pores. The median anterior portion of the gut may be differentiated into a muscular sucking bulb, or pharynx, and a simple tubular portion between this and the bifurcation, called the oesophagus.

The whole of the space between the wall of the alimentary canal and the external cuticle is filled up with a spongy connective tissue, or parenchyma, in which the other organs are embedded, as in other classes of Platyhelminthes. The nervous system consists of a pair of central ganglionic masses (the "brain"), situated anteriorly and dorsally, and longitudinal nerve-cords (of which there may be as many as four pairs) running posteriorly throughout the body, and connected at intervals by transverse

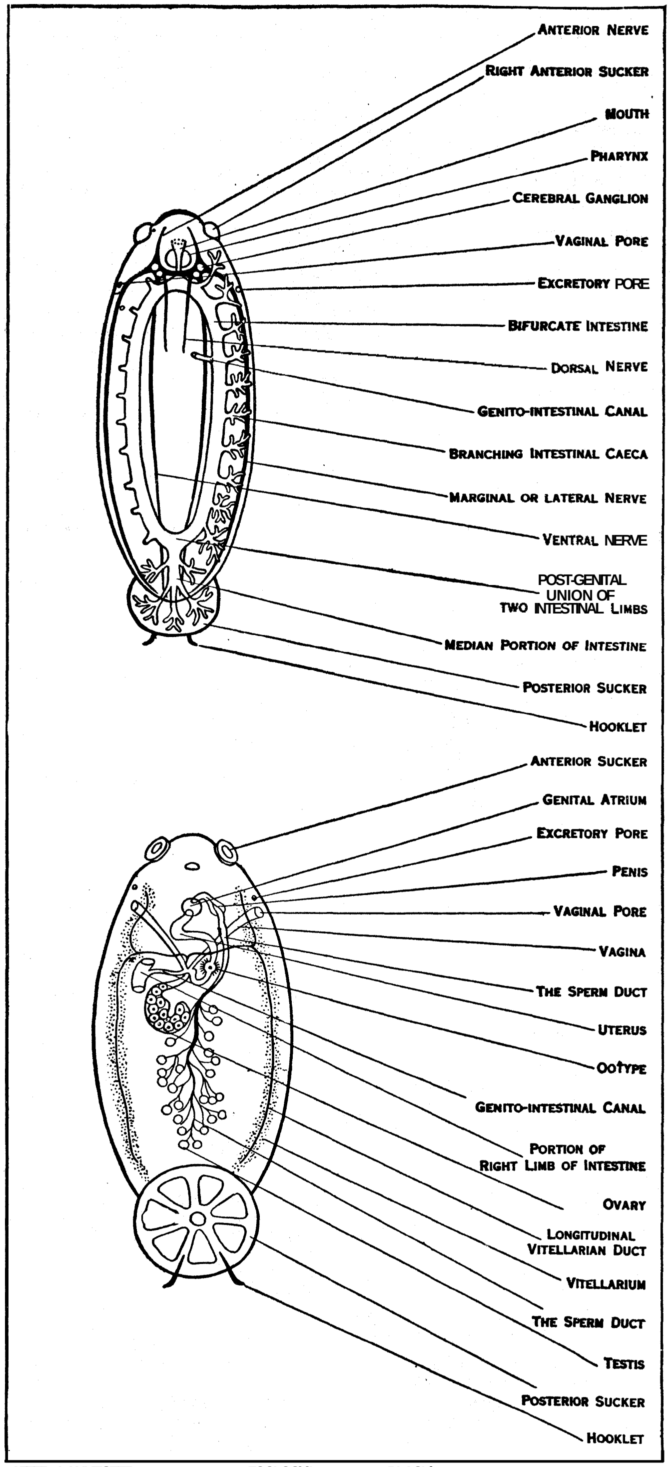
FIG. 1.—LIVER-FLUKE (FASCIOLA HEPATICA), SHOWING FROM ABOVE DOWNWARDS. VENTRAL ASPECT, ANTERIOR PORTION MORE HIGHLY MAGNIFIED, GENITAL SINUS AND OTHER PARTS. FLAME CELL FROM EXCRETORY APPARATUS. EGG

commissures. Eyes are present in some of the ectoparasitic forms, and in the larval stages of some endoparasitic species, but are absent in the adults of the latter. There may also be "tactile cones" on the surface of the cuticle, consisting of small elevations surmounted by groups of stiff cilia.

The excretory system is composed, as in other Platyhelminthes, of branching canals whose smallest branches end in flame-cells.

There are usually two main longitudinal canals, which may open independently, through a pair of excretory sacs, on to the dorsal surface, or may lead into a common posterior "bladder."

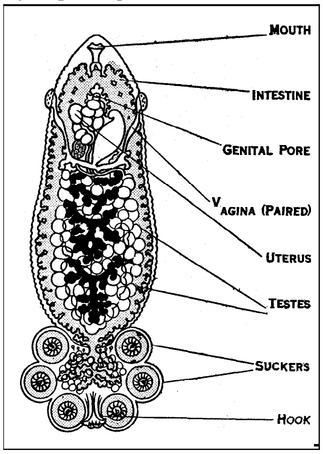
With few exceptions, the Trematodes are hermaphrodite. The complex system of genital organs is arranged on the same general plan as in other groups of Platyhelminthes, but is subject to much variation in details, and is of great importance from the taxonomic standpoint. The testes are almost invariably paired, and are usually compact organs, though they may be deeply lobate or even elaborately branched. The male ducts unite and open through a muscular intromittent organ, or cirrus, which is usually contained in a special pouch (the cirrus-sac). The ovary is single, and, like the testes, may be compact or more or less branched. The vitellaria generally consist of two lateral series of follicles, those of each side being connected by branching ducts with a main yolk-duct, and the two main ducts crossing the body to join in the median region, near the shell-gland.



AFTER LANKESTER. "TREATISE ON ZOOLOGY" (A. & C. BLACK)

FIG. 2.—SCHEMATIC FIGURE OF A MONOGENETIC TREMATODE, ILLUSTRATING STRUCTURE (AFTER BENHAM)

In ectoparasitic forms there is a vagina, opening to the exterior by a pore quite distinct from that of the uterus, or there may be a pair of such structures. In the endoparasitic forms (Digenea) a duct known as Laurer's canal, springing from the oviduct and either opening on the surface of the body or ending blindly below the skin, is usually present. The eggs, after being fertilized and supplied with yolk, are enclosed in a cuticularized shell of variable form, sometimes stalked or with terminal filaments, and very commonly provided with an operculum at one end.

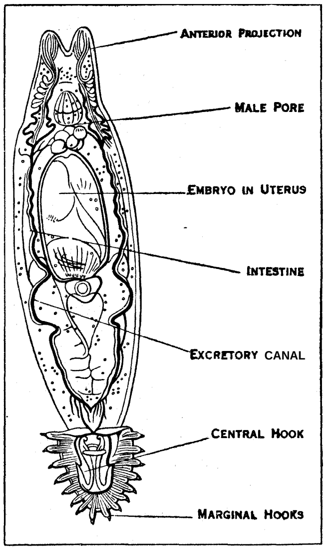


FROM "ZEITSCHRIFT FUR WISSENSCHAFTLICHE ZOOLOGIE" (ENGELMANN)

FIG. 3.—VENTRAL VIEW OF *POLYSTOMUM INTEGERRIMUM* (AFTER ZELLER)

Classification.—The division of the class Trematoda into two main orders, Monogenea and Digenea. proposed by van Beneden in 1858, is still accepted by modern authorities. These orders represent two well marked groups differing fundamentally in structure, habits and life-history.

The order Monogenea comprises forms of almost exclusively ectoparasitic habit. without an alternation of generations in their life-history, and having the following structural peculiarities, among others. The mouth is simple and is not surrounded by an oral sucker, though paired accessory suckers may be present in its neighbourhood. The posterior sucker may be single (but in this case is usually of complex structure and often provided with accessory cuticularized organs of attachment) or there may be a number of paired posterior suckers, which also have cuticularized armatures. There is a vagina, or a pair of vaginae. distinct from the uterus, and there are usually paired excretory pores situated dorsally near the anterior end of the body.



FROM "ARCHIV FÜR ANATOMIE, PHYSIOLOGIE UND WISSENSCHAFTLICHE MEDIZIN" (DE GRUYTER & CO.)

FIG. 4—VENTRAL VIEW OF GYRODACTYLUS ELEGANS (AFTER WAGENER)

These forms live mainly on the external surface or on the gills of fishes and other cold-blooded aquatic animals, and feed on mucus and other matter, or occasionally on the blood of the host. The order includes 13 families, among which are the Tristomatidae, Gyrodactylidae, Polystomatidae and Octocotylidae.

The order Digenea includes all the forms which live as endoparasites within the bodies of other animals. These have a complex life-history involving an alternation between a sexual phase and an asexual or polyembryonic phase of multiplication. They have an oral sucker surrounding the mouth, and usually a posterior sucker which is a simple muscular organ without armature. There is no vagina, as distinct from the uterus, and the excretory pore is usually single and posterior.

The adult forms occur in all classes of vertebrates, the larval forms in both vertebrates and invertebrates.

The old order Aspidocotylea, for many years merged with the

Prosostomata, is again recognized as distinct. It comprises a few genera, as *Aspidogaster* and *Cotylaspis,* parasitic in molluscs, fish and turtles, with simple life cycles and with or without alternation of hosts. They are distinguished by the large ventral sucker sub-

FIG. 5.— FIVE STAGES IN THE LIFE-HISTORY OF THE LIVER-FLUKE
Above, the miracidium; left centre, a sporooyst containing young rediae; right centre, adult redia containing daughter redia and two almost mature cercariae; left bottom, a young redia; right bottom, a free cercaria (all highly magnified)

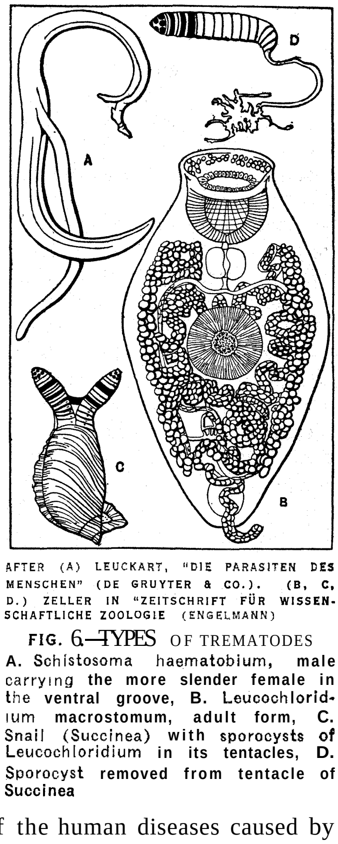
divided into longitudinal rows of compartments.

Development and Life-histories.—The eggs of the Monogenea are either deposited in water or attached to the host by means of stalk-like processes. In some cases (*Gyrodactylus,* a parasite of the gills of minnows and other fishes) but a single egg is produced at a time, and this develops nithin the body of the parent into an embryo, within which another embryo is formed before its birth. There may be a ciliated free-snimming larval stage, as in *Polystomum* (a form inhabiting the bladder of frogs and toads). The larva of this form invades the gill chamber of tadpoles. and migrates by way of the alimentary canal to its definitive habitat. *Diplozoon* (found on the skin of the minnow) also has a free-swimming stage, and is remarkable for the fact that tno larvae (called *Diporpae*) unite, each holding the other by its ventral sucker, and fuse into a single X-shaped organism, the two original sets of genitalia becoming permanently interconnected. In other cases there appears to be no free-swimming stage, and the larvae hatching from the eggs develop directly into the adult form.

In the Digenea the development is indirect, and may involve one or more changes of host, and sometimes a free-swimming stage. The life-history of the liver-fluke of the sheep and other animals may be taken as typical. This form, as an adult fluke, inhabits the bile-ducts of the vertebrate host. The eggs are passed out of the host's body with the faeces, and hatch in a short time in the open if the conditions of moisture and temperature are suitable. The embryo, on escaping from the egg, is a ciliated organism known as a *miracidium*, provided with a pair of eye-spots and an anterior boring organ. It swims about until it meets with a suitable intermediate host (certain snails—in Europe, *Limnaea truncatula*). Boring its way into this through the skin, it sheds its ciliated coat and penetrates into the internal organs. Here it grows into an irregular, sac-like body known as a sporocyst. Within this there are formed by budding numerous bodies called rediae. The redia has an oral sucker and a sac-like intestine. Each redia gives rise, by internal budding. either to a further generation of rediae or to larvae of a different type, called cercariae. The cercaria is somewhat tadpole-like, having a broad body and a narrow tail. It has two suckers and a bifurcate intestine. The cercaria escapes from the snail and swims or ariggles about in water, finally coming to rest on some solid body, such as a blade of grass, where it loses its tail and secretes round itself a "cyst." Should this be swallowed by a suitable vertebrate animal, the cercaria is liberated from the cyst and migrates into the body-cavity and thence into the liver, where it grows into an adult fluke.

An interesting modification of the life-history is found in the genus *Leucochloridium.* The sporocyst of this form sends branches into the head and tentacles of its snail host. The branches are brightly coloured and capable of pulsating movements. making the snail conspicuous and particularly liable to the attacks of birds. The transference of the cercariae contained within the snail to suitable final hosts among the birds is thus ensured.

In most genera the cercariae, instead of remaining passive until swallowed, swim about in water and penetrate actively through the skin either of the final or of a second intermediate host. The fork-tailed cercariae of the blood-flukes (*Schistosoma*) thus attack man and other warm-blooded vertebrates, and the adults inhabit the blood-vessels. The human lung-fluke, *Paragonimus,* leaves its first intermediate host (a mollusc) as a cercaria, and enters certain fresh-water crabs and crayfishes, in which it becomes encysted. Human infection, in the Orient, is acquired by eating these animals. Several small flukes belonging to the genera *Opisthorchis, Clonorchis* and *Metagonimus* make use, in a similar manner, of fresh-water fishes as second intermediate hosts, the first host being always, so far as is known, a snail.



AFTER (A) LEUCKART, "DIE PARASITEN DES MENSCHEN" (DE GRUYTER & CO.). (B, C, D.) ZELLER IN "ZEITSCHRIFT FÜR WISSENSCHAFTLICHE ZOOLOGIE (ENGELMANN)

FIG. 6.—TYPES OF TREMATODES
A. Schistosoma haematobium, male carrying the more slender female in the ventral groove, B. Leucochloridium macrostomum, adult form, C. Snail (Succinea) with sporocysts of Leucochloridium in its tentacles, D. Sporocyst removed from tentacle of Succinea

Economic Importance.—Schistosomiasis (or Bilharziosis) is probably the most important of the human diseases caused by Trematodes. In Egypt and many other parts of Africa two species of *Schistosoma,* S. *haematobium* and S. *mansoni*, are prevalent. The former also occurs in Asia, certain localities in the south of Europe, and Australia, and the latter in the West Indies and South America. In the Far East their place is taken by a third species, S. *japonicum*. These flukes inhabit the mesenteric and portal veins, and their eggs cause obstruction and rupture of the capillaries either in the wall of the bladder or in that of the bowel, with consequent haemorrhage and ulceration.

The cotnmon liver-fluke *(Fasciola hepatica)* is an important parasite of sheep, sometimes causing serious and fatal outbreaks of the disease known as "liver-rot." As a human parasite this worm is rare, but certain smaller liver-flukes (*Opisthorchis* and *Clonorchis*) are not uncommon in eastern countries.

The lung-fluke, *Paragonimus westermani*, is a human parasite of some importance in the Far East, and occurs also in South America and Mexico. The various species of flukes appear to be. on the whole, of little economic significance. (H. A. B ; X)

TREMBLEU, ABRAHAM (1710–1784), one of the outstanding biologists of the 18th century, best known for his *Mémoires* (1744) on the fresh-water polyp, hydra, was born at Geneva on Sept 3, 1710, of a family prominent in the history of that city. He made his chief discoveries between 1739 and 1747, while tutor to two boys at The Hague.

Trembley was the first to prove conclusively that reproduction by budding occurs among animals; the first to show that certain animals can be artificially multiplied by division; the first to make permanent grafts of animal tissues; and the first to witness the multiplication of Protozoa by division and true cell division in algae. He superintended the young duke of Richmond in a grand tour around Europe (1752–56). The duke was so generous in his recognition of Trembley's services that the latter never again had occasion to earn his living. After marriage in 1757 Trembley settled near Geneva and devoted himself to the education of his children and to religious, philosophical and political studies. He died at his home on May 12, 1781.

See J. R. Baker, *Abraham Trembley of Geneva,* etc. *(1952).*

TREMOLITE: *see* AMPHIBOLE.

TRENCH, RICHARD CHENEVIX (1807–1886), Anglican archbishop and poet, was born at Dublin on Sept. 9, 1807. He was educated at Harrow, and Trinity college, Cambridge. While incumbent of Curdridge chapel near Bishops Waltham, Hants, he published (1835) *The Story of Justin Martyr and Other Poems,* which was favourably received, and was followed in 1838 by *Sabbation, Honor Neale, and Other Poems,* and in 1842 by *Poems From Eastern Sources.* He became rector of Itchenstoke (1845), Hulsean Lecturer (1845–46) and professor of divinity at King's college, London. In 1851 he wrote *The Study of Words,* followed by *English Past and Present* (1855) and *A Select Glossary of English Words* (1859). All have gone through numerous editions and have contributed much to promote the historical study of the English tongue. His paper, read before the Philological society "On Some Deficiencies in Our English Dictionaries" (1857), gave the first impulse to the great Oxford *New English Dictionary.* His advocacy of a revised translation of the New Testament (1858) helped to promote another great national undertaking. In 1856 he published a valuable essay on Calderon, with a translation of a portion of *Life Is a Dream* in the original metre. In 1841 he had published his *Notes on the Parables,* and in 1846 his *Notes on the Miracles,* popular works which are treasuries of erudite and acute illustration.

In 1856 Trench was raised to the deanery of Westminster. There he instituted evening nave services. In Jan. 1864 he was advanced to the more dignified but less congenial post of archbishop of Dublin. He died in London on March 28, 1886.

See his *Letters and Memorials,* 2 vol. *(1886).*

TRENCHARD, HUGH MONTAGUE TRENCHARD, 1ST VISCOUNT (1873–1956), British air marshal whose energy and foresight laid the foundations of Royal Air Force (R.A.F.) efficiency, was born on Feb. 3, 1873, at Taunton, Somerset. Entering the army in 1893, he served in the South African War and later in Nigeria. Invalided home in 1912, he learned to fly and in 1913 became assistant commandant of the central flying school. As commander of the royal flying corps during World War I he began the offensive policy which became traditional to the R.A.F., and in Jan 1918 became first chief of air staff. He resigned in April but in 1919 nas recalled when Winston Churchill was appointed air minister, and remained until 1929, becoming the first marshal of the R.A.F. in 1927. His emphasis on staff training led to the foundation of Cranwell cadet college, the Andover staff college and the apprentices' school at Halton, and also to the introduction of auxiliary squadrons and the system of short service commissions. As commissioner of the metropolitan police, 1931–35, he introduced far-reaching reforms, including a short-term service plan and increased application of scientific methods to police nork. His founding of the Hendon Police college to train men from the ranks and from outside as officers caused much controversy. During 1936–53 he was chairman of the United Africa company. He was created a baronet in 1919. baron in 1930 and viscount in 1936; in 1951 he was awarded the Order of Merit. He died in London on Feb. 10, 1956.

TRENCH WARFARE, the term applied to tactics resorted to nhen defensive fire power compels the opposing forces to "dig in" so extensively as to sacrifice mobility to gain protection. The tactical ancestor of modern trench warfare may be found in the system worked out for the attack of fortresses by Sabastien Le Prestre de Vauban (*q.v.*) during the wars of Louis XIV of France. A typical defense complex of World War I had as its basic elements three lines facing the enemy — first, second and reserve lines of trenches comparable to Vauban's three parallels *(see* FORTIFICATIONS). They were linked from front to rear by communication trenches serving the same purpose as Vauban's approaches, which enabled the besiegers to remain under cover while passing from one parallel to another.

The Standard Trench. — The elements of the standard trench have changed but iittle since Vauban's day. Earth from the excavation is used to create parapets both to the front and rear. Within the trench are firing positions, and duck boards provide dry footing The network of trenches defending a sector of any importance becomes in effect a military community — an intricate system of command posts, forward supply dumps, first aid stations, kitchens, latrines, mortar and machine gun emplacements and dugouts deep enough to shelter large numbers of troops during an enemy bombardment.

Trenches follow a zigzag or curving course to localize casualties from a shell explosion and to limit the effectiveness of flanking small arms fire. When fire power becomes so destructive that men can survive only by burrowing into the earth, they accept immobility reluctantly as a lesser tactical evil. Offensive operations of trench warfare are usually confined to raids, patrols and harassing fires, but commanders plan to launch an attack at the first opportunity for the purpose of smashing through the opposing trenches and resuming a warfare of mobility.

The Petersburg lines, as the foremost example of trench warfare in the 19th century, held the Federal and Confederate forces deadlocked during the final months of the American Civil War. Defensive fire power was so deadly that neither army could gain more than a fleeting advantage, and even the explosion of an enormous Federal mine failed to gain a decision.

In World War I, the opposing trenches of the western front, stretching from the North sea to Switzerland, were manned by millions of troops after the mobile warfare of the early months shattered against the destructiveness of the machine gun. By day no sign of life could be seen in a ravaged landscape pocked with shell holes and bristling with barbed wire. The slightest movement in chis "no man's land" was enough to arouse the nervous chatter of a machine gun or the cough of a mortar.

Similar lines of trenches scarred the earth in eastern Europe and the Italian foothills of the Alps. So complex were these systems that the military catacombs had to be identified by names and numbers. The trenches even had their own diseases (trench mouth and trench foot) afflicting men who lived underground.

Observation balloons and reconnaissance aircraft were the "eyes" of the hidden armies. Generalship sank to dismal depths in efforts to blast a path with hundreds of massed guns for infantry frontal attacks. Gains of a few hundred yards, achieved at a frightful cost in casualties, were reported in front-page headlines.

These futile offensives seldom penetrated as far as the enemy's rear areas. After three years of trench warfare the earthbound armies of France, Italy, Austria and Russia were corroded by defeatism.

Eventually the tactical countermeasure to the machine gun was found in the tank (*q.v.*), which restored mobility to the western front in the summer of 1918. But many thousands of men had died during the two years when British and French generals failed to make decisive use of a weapon introduced in 1916.

The Korean War.—Trench warfare mas the exception in World War II, and not until the last two years of the Korean war did it have a revival conditioned by mountain terrain. Red China's tactical system, developed during long years of civil war, was based on semiguerrilla night attacks combined with the defense of earthworks by day. "Better to sweat now than to bleed later," was a motto of Mao Tse-tung's soldiers, who had no superiors in their ability to burrow or to infiltrate enemy positions with noiseless stealth on the darkest night.

By 1952 two opposing belts of trenches crossed the Korean peninsula. Judged by World War I standards, each United Nations division defended a huge sector. Beyond a thinly held main line of resistance were outposts reached by communication trenches. They were manned by picked troops who gave the alarm by radio if an enemy attack threatened. The main body of troops was sheltered by trenches and log-faced bunkers—the equivalent of the World War I dugout. Both sides set out nightly reconnaissance patrols and occasionally launched attacks on a local front.

The Chinese often went to such elaborate lengths as tunneling through a hilltop to the military crest facing the enemy. Mortars or howitzers were fired from these camouflaged outlets and withdrawn to escape enemy counterbattery fire. Such outposts served as a first line of resistance for Chinese who could retreat to trenches on the topographical crest or retire through the tunnel to bunkers on the reverse slope.

Chinese defenses in depth, sometimes including every hill in a belt five to ten miles wide, could be penetrated by United Nations forces only at a prohibitive cost in casualties. Thus the conflict turned into a prolonged stalemate which ended with both sides holding the same ground they had occupied for the past two years.

That trench warfare may have a future in the atomic age is indicated by tests held during the 1950s at the Nevada proving grounds of the U.S. Atomic Energy commission. Troops kneeling in trenches were found to be protected from atomic blast effects at distances much nearer to ground zero than had originally been thought possible.

TRENCK, FRANZ, FREIHERR VON DER (1711–1749), Austrian soldier, was born on Jan. 1, 1711. Educated by the Jesuits at Sopron (Oldenburg), he entered the Imperial army in 1728 but resigned in disgrace three years later. In 1737 he offered to raise an irregular corps of "Pandours" against the Turks, but this offer was refused and he then entered the Russian army. After serving against the Turks for a short time he was accused of bad conduct, brutality and disobedience, and condemned to death, the sentence being commuted to degradation and imprisonment.

Trenck returned to Austria, but came into conflict with every one and actually took sanctuary in a convent in Vienna. Prince Charles of Lorraine obtained for him an amnesty and a commission in a corps of irregulars. At the battle of Soor his irregulars plundered when they should have been fighting and Trenck was accused of having allowed the king of Prussia to escape. He was condemned to death, but the sentence was commuted by the queen into one of cashiering and imprisonment for the rest of his life. He died on Oct. 4, 1749.

His cousin, FRIEDRICH, FREIHERR VON DER TRENCK (1726–1794), the writer of the celebrated autobiography, was born on Feb, 16, 1726, at Konigsberg. He entered the Prussian army in 1742 and became an orderly officer on Frederick's own staff. But within a year he fell into disgrace because of a love affair—whether real or imaginary—with the king's sister Princess Amalie, and in 1743 Frederick had him arrested and confined in the fortress of Glatz, whence in 1746 he escaped. In 1754 he visited Prussia, but was there arrested and confined for ten years. After the close of the Seven Years' War, Maria Theresa requested his release. Returning to his Hungarian estates, he composed his autobiography and undertook various diplomatic or secret service missions. He went to Paris in 1791 to witness the Revolution. He was denounced as an Austrian spy and guillotined on July 24, 1794.

TRENDELENBURG, FRIEDRICH ADOLF (1802–1872), German philosopher and philologist., who reverted to Aristotelian principles in his criticism of the 'prevailing Kantian and Hegelian systems, was born on Nov. 30, 1802, at Eutin near Liibeck. He was educated at the universities of Kiel, Leipzig and Berlin. He became more and more attracted to the study of Plato and Aristotle, and his doctor's dissertation was an attempt to reach through Aristotle's criticisms a more accurate knowledge of the Platonic philosophy (*Platonis de ideis et numeris doctrina ex Aristotele illustrata,* 1826). He spent seven years as tutor in a private family, occupying his leisure in preparing a critical edition of Aristotle's *De anima* (1833). In 1833 K. von Altenstein, Prussian minister of education, appointed him extraordinary professor in Berlin; four years later Trendelenburg was advanced to an ordinary professorship.

In 1865 he engaged in an acrimonious controversy on the interpretation of Kant's doctrine of space with Kuno Fischer, whom he attacked in *Kuno Fischer und sein Kant* (1869), which drew forth the reply *Anti-Trendelenburg* (1870). He died in Berlin on Jan. 24, 1872.

Das Naturrecht auf dem Grunde der Efhik (1860) may be taken as in a manner the completion of Trendelenburg's system, his working-out of the ideal as present in the real. The ethical end is taken to be the idea of humanity, not in the abstract as formulated by Kant, but in the context of the state and of history. Law is treated throughout as the vehicle of ethical requirements. The state he held to be the ethical organism in which the individual (or "potential" man) first emerges into actuaiity.

Trendelenburg was also the author of the following works: *Elementa logices Aristotelicae* (1636; Eng. trans. 1881), a selection of passages from the *Organon* with Latin translation and notes, containing the substance of Aristotle's logical doctrine, supplemented by *Erlauterungen zu den Elementen der Aristotelischen Logik* (1842); *Logische Untersuchungen* (1640) and *Die logische Frage in Hegels System* (1843), important factors in the reaction against Hegel; *Historische Beiträge zur Philosophie, 3* vol. (1846–67), vol. i containing a history of the doctrine of the categories; and *Lücken im Volkcrrecht* (1870), a treatise on the defects of international law, occasioned by the Franco-German war.

A number of papers on nonphilosophical subjects (mainly politics and education) were collected as *Kleine Schriften,* 2 vol. (1871).

TRENT, JESSE BOOT, 1ST BARON OF NOTTINGHAM (1850–1931), British pioneer of the chain store and of workers' welfare, was born at Hockley, Nottingham, on June 2, 1850. Upon the death of his father in 1860, he began to help in the family herbalist shop. Through bulk buying, convenient packaging and very long hours of work, he was able to bring such products as epsom salts, camphor and bicarbonate of soda within the reach of a large public. By 1885, with the then revolutionary practice of low profit margins applied to drugs and proprietary medicines, Boot had laid the foundations of Britain's first chain of shops with branches at Nottingham and Sheffield. Diversifying his merchandise as a result of his wife's influence, he started manufacturing his own drugs in 1888, and by 1908 had several factories and 300 shops. Although ill, he continued to direct a business which, by the beginning of the 1960s, had grown to over 1,300 branches and 40,000 employees. Boot was quick to offer financial incentives to employees taking the examinations of the Pharmaceutical society and was among the first British employers to introduce pension schemes, industrial health units and facilities for recreation. He devoted his last years to public benefactions amounting to some

£2,000,000, including a gift of the land and a grant toward the building of what is now Nottingham university. Having been knighted in 1909 and created a baronet in 1917, he was elevated to the peerage in 1929. Lord Trent died at Millbrook, Jersey, on June 13, 1931. (Jo. P. S.)

TRENT, the chief river of the English midlands and the third longest in the country. It rises on Biddulph moor in north Staffordshire and after following a southward curving course for about 170 mi. enters the Humber estuary 40 mi, from the open sea. Its basin covers an area of a little more than 4.000 sq.mi. Its course is first southerly. skirting the Potteries. and then southeasterly from Stone to Rugeley where it turns eastward. So far it has flowed in a normal upland valley but it then begins to meander over a wide flat floor. At Burton the hilly country which has bordered the valley finally recedes and the river crosses a wide flood plain thence over southern Derbys., Notts.. the Notts.-Lincs. border and a corner of Lincs. to its outfall. Especially below Newark the fall becomes slight and the lowest section of its course resembles the Fen country. The Trent is believed to have originated on an eastward sloping surface of Mesozoic rocks reaching far to the west into north Wales. The Dee, before it makes its northward bend. is thought to follow the line of the upper Trent of that time: It continued eastward near its present middle course beyond Nottingham, and thence through the Ancaster gap to the North sea near the present mouth of the Witham. After the Cretaceous cover was removed the ancestor of the present lower Trent developed its valley southward along the soft Keuper Marls and so captured the older river. Its southern tributaries — the Penk, Tame and Soar— drained northward from a divide running east and west from Market Harborough through Birmingham to mid-Wales. The upper Trent. Churnet, Dove. Derwent and Erewash flowed south from a northern watershed. All these streams have maintained their general courses throughout the long intervening period.

The Trent is tidal from its outfall for about jo mi. to Cromwell lock 3 mi. north of Newark. At spring tide a bore is developed with a wave front about 4 ft. in height. Barge traffic is possible on the river as far as the Erewash junction. Vessels drawing up to 9 ft. can reach Gainsborough and that section is under the control of the Humber Conservancy board. By the construction of weirs and locks above Newark the river was opened as far as Nottingham for craft drawing as much as 6 ft. Canals along the Erewash valley to Langley Mill and by the Soar valley to Leicester join the Trent near Long Eaton. The Fossdyke navigation links it with the Witham at Lincoln and the South Yorkshire navigation with Sheffield. Plans for the improvement of the latter were being carried out in the later 1950s. The Trent and Mersey canal is now only of importance from the Potteries to the Mersey, The river is mentioned as Trisantona by Tacitus. (T. HER.)

TRENT (ITALY): see TRENTO.

TRENT, COUNCIL OF. The Council of Trent (1545–1563) has a long antecedent history of great significance for the fortunes of the Catholic Church. During the 15th and the earlier half of the 16th century, the conception of an "ecumenical council" remained an ideal of which the realization was expected to provide a solution for the serious ecclesiastical difficulties which were then prevalent. The emperor Charles V. urged on the papacy the necessity of convening a general assembly of the church. The passive resistance of the Curia was so stubborn that the decisive step was postponed time and again. But the goal was finally attained, and this result was the work of Charles, aided by three powerful cardinals.

The bull *Laetare Hierusalem* (November 19, 1544) fixed the meeting of the council for March 1j, 1545, in Trent, and assigned it three tasks: (1) the pacification of the religious dispute by doctrinal decisions, (2) the reform of ecclesiastical abuses, (3) the discussion of a crusade against the infidels.

The opening of the council was deferred once again. Towards the end of May 1545, twenty bishops were collected at Trent; but there was no sign of action, and the papal legates— Del Monte, Corvinus and Reginald Pole — delayed the inauguration, the emperor and the pope being at cross purposes as to procedure. In the eyes of Paul III. the council was simply the means by which he expected to secure a condemnation of the Protestant heresy, in hopes that he would then be in a position to impose the sentence of the Church upon them by force. For him the question of ecclesiastical reform possessed no interest whatever. In contrast to this, Charles demanded that these very reforms should be given precedence, and the decisions on points of dogma postponed till he should have compelled the Protestants to send representatives to the council. The pope, however, alarmed by the threat of a colloquy in Germany, at last ordered the synod to be opened (December 13, 1545).

The procedure adopted secured the predominance of the Roman chair from the first. As the voting was not to be by nations, as at Constance, but by individuals, the last word remained with the Italians, who were in the majority.

The council began its work in the region of dogma by defining the doctrines of the Church with reference to the most important controversial points — a procedure which frustrated the emperor's hopes for a reconciliation with the Protestants. The doctrines dealt with, up to March 1547, were the Holy Scriptures and tradition (sessio iv.), original sin (sessio v.), justification (sessio vi.), and the sacraments in general, and baptism and confirmation in particular (sessio vii.). In March the council was moved to Bologna on the pretext that an epidemic was raging in Trent (sessio viii.), though, at the imperial command, part of the bishops remained behind. But on the 2nd of June the council of Bolcgna resolved (sessio x.) to adjourn its labours. At the Diet of Augsburg the emperor secured a *modus* vivendi, leavened by the Catholic spirit, between the adherents of either religion; and this provisory settlement — the so-called Interim of Augsburg—was promulgated as a law of the empire (June 3, 1548), and declared binding till the council should reassemble. But the confusion of ecclesiastical affairs had grown worse confounded through the refusal of the pope to continue the council, when his death (November 10, 1549) changed the situation.

Pope Julius III., the former legate Del Monte, caused the council to resume its labours on May 1, 1551 (sessio xi.), under the presidency of Cardinal Crescentio. The personnel was, for the most part, different; and the new members included the Jesuits, Laynez and Salmeron. The French clergy had not a single delegate, while the Spanish bishops maintained an independent attitude under the aegis of the emperor, and Protestant deputies were on this occasion required to appear at Trent. Their participation, however, was useless, for the discussion of doctrine on the basis of Holy Writ was from the Catholic standpoint impossible; and the revolt of the elector Maurice of Saxony (March 20, 1552) compelled the emperor to leave Innsbruck, and dissolved the conclave. Its dogmatic labours were confined to doctrinal decrees on the Lord's Supper (sessio xiii.), and on the sacraments of penance and extreme unction (sessio xiv.). On April 28, 1552, the sittings were suspended.

Ten years elapsed before the council reassembled for the third time in Trent. During the intervening period, the religious problem in Germany had received such a solution as the times admitted by the peace of Augsburg (155j); and the equality there guaranteed between the Protestant estates and the Catholic estates had left the former nothing to hope from a council. The incitement to continue the council came from another quarter. It was no longer anxiety with regard to Protestantism that exercised the pressure, but a growing conviction of the imperative need of more stringent reforms within the Catholic Church itself. In France and Spain — the very countries where the Protestant heresy had been most vigorously combated — a great mass of discontent had accumulated; and France already showed a strong inclination to attempt an independent settlement of her ecclesiastical difficulties in a national council. Pius IV. therefore announced (Nov. 29, 1560) the convocation of the council; and on Jan. 18, 1562, it was actually reopened (sessio xvii.).

The Protestants indeed were also invited but the Evangelical princes, assembled in Naumburg, withheld their assent. To secure freedom of action, France and the emperor Ferdinand required that it should rank as a new council; Pius IV., however, designated it a continuation of the earlier meetings. Ferdinand, in addition to regulations for the amendment of the clergy and the monastic system, demanded above all the legalization of the marriage of the priesthood, while France and Spain laid stress on the recognition of the divine right of the episcopate, and its independence with regard to the pope. In consequence of these reformatory aspirations, the position of the pope and the council was for a while full of peril. But the papal diplomacy, by concessions, threats, and by exploiting political and ecclesiastical dissensions, broke the force of the attack. In the third period of the council, which, as a result of these feuds, witnessed no session from September 1562 to July 1563, doctrinal resolutions were also passed concerning the Lord's Supper *sub utraque specie* (*sessio* xxi.), the sacrifice of the Mass (*sessio* xxii.), the sacrament of ordination (*sessio* xxiii.), the sacrament of marriage (*sessio* xxiv.), and Purgatory, the worship of saints, relics and images. On Dec. 4, 1563, the synod closed.

The dogmatic decisions of the Council of Trent make no attempt at embracing the whole doctrinal system of the Roman Catholic Church, but present a selection of the most vital doctrines, partly chosen as a counterblast to Protestantism, and formulated throughout with a view to that creed and its objections.

The reformatory enactments touch on numerous phases of ecclesiastical life — administration, discipline, appointment to spiritual offices, the marriage law (*decretum de reformatione matrimonii "Tametsi," sessio* xxiv.), the duties of the clergy, and so forth. The resolutions include many that marked an advance; but the opportunity for a comprehensive and thorough reformation of the life of the Church — the necessity of which was recognized in the Catholic Church itself—was not embraced. No alteration of the abuses which obtained in the Curia was effected, and no annulment of the customs, so lucrative to that body and deleterious to others, was attempted.

The Council of Trent in fact enjoyed only a certain appearance of independence. For the freedom of speech which had been accorded was exercised under the supervision of papal legates, who maintained a decisive influence over the proceedings and could count on a certain majority in consequence of the overwhelming number of Italians. That the synod figured as the responsible author of its own decrees (*sancta oecumenzca et generalis tridentina synodus in spiritu sancto legitime congregata*) proves very little, since the following clause reads *praesidentibus apostolicae sedis legatis;* while the legates and the pope expressly refused to sanction an application of the words of the Council of Constance—*universalem ecclesiam repraesentans.*

The whole course of the council was determined by the presupposition that it had no autonomous standing, and that its labours were simply transacted under the commission and guidance of the pope. This was not merely a claim put forward by the Roman see at the time; it was acknowledged by the attitude of the synod throughout. The legates confined the right of discussion to the subjects propounded by the pope, and their position was that he was in no way bound by the vote of the majority. In difficult cases the synod itself left the decision to him, as in the question of Clandestine Marriages and the Administration of the Lord's Supper *sub utraque specie.* Further, at the close of the sessions a resolution was adopted, by the terms of which all the enactments of the council *de morum reformatione atque ecclesiastica disciplina* were subject to the limitation that the papal authority should not be prejudiced thereby (*sessio* xxv. *cap.* 21). Every doubt as to the papal supremacy is removed when we consider that the Tridentine Fathers sought for all their enactments and decisions the ratification (*confirmatio*) of the pope, which was conferred by Pius IV in the bull *Benedictus Deus* (January 26, 1564); and in its last meeting (*sessio* xxv.) the synod transferred to the pope a number of tasks for which their own time had proved inadequate. These comprised the compilation of a catalogue of forbidden books, a catechism, a short conspectus of the articles of faith and an edition of the missal and the breviary. Thus the council presented the Holy See with a further opportunity of extending its influence and diffusing its views. The ten rules *de libris prohibitis* were published in March 1564; the *Professio fidei tridentinae* in November 1564; and the *Catechismus a decreto concilii tridentini ad parochos,* early in 1568.

The oecumenical character of the council was never seriously questioned. On the motion of the legates, the resolutions were submitted to the ambassadors of the secular powers for signature, the French and Spanish envoys alone withholding their assent. The recognition of the council's enactments was, none the less, beset with difficulties. So far as the doctrinal decisions were concerned no obstacles existed; but the reformatory edicts—adhesion to which was equally required by the synod — stood on a different footing. In their character of resolutions claiming to rank as ecclesiastical law they came into conflict with outside interests, and their acceptance by no means implied that the rights of the sovereign, or the needs and circumstances of the respective countries were treated with sufficient consideration. The consequence was that there arose an active and, in some cases, a tenacious opposition to an indiscriminate acquiescence in all the Tridentine decrees, especially in France, where only those regulations were recognized which came into collision neither with the rights of the king nor with the liberties of the Gallican Church. In Spain, Philip II. allowed, indeed, the publication of the *Tridentinurn,* but always with the reservation that the privileges of the king, his vassals and his subjects, should not thereby be infringed.

In his official confirmation Pius IV. had already strictly prohibited any commentary on the enactments of the council unless undertaken with his approval, and had claimed for himself the sole right of interpretation. In order to supervise the practical working of these enactments, Pius created (1564) a special department of the Curia, the *Congregatio cardinalium concilii tridentini interpretum;* and to this body Sixtus V. entrusted the further task of determining the sense of the conciliar decisions in all dubious cases. The *resolutiones* of the congregation — on disputed points—and their *declarationes*—on legal questions — exercised a powerful influence on later development of ecclesiastical law.

The Council of Trent attained a quite extraordinary significance for the Roman Catholic Church; and its pre-eminence was unassailed till the *Vaticanum* subordinated all the labours of the Church in the past — whether in the region of doctrine or in that of law—to an infallible pope. On the theological side it fixed the results of mediaeval scholasticism and drew from it all that could be of service to the Church. Further, by pronouncing on a series of doctrinal points till then undecided it elaborated the Catholic creed; and, finally, the bold front which it offered to Protestantism in its presentation of the orthodox faith gave to its members the practical lead they so much needed in their resistance to the Evangelical assault. It showed that Church as a living institution, capable of work and achievement; it strengthened the confidence both of her members and herself, and it was a powerful factor in heightening her efficiency as a competitor with Protestantism and in restoring and reinforcing her imperilled unity. Indeed, its sphere of influence was still more extensive, for its labours in the field of dogma and ecclesiastical iaw conditioned the future evolution of the Roman Catholic church.

BIBLIOGRAPHY.—Supreme among the sources for the history of the council stands the splendidly planned work *Concilium tridentinum; diariorum, actorum, epistularum, tractatuum nova collectio*, ed. Societas Goerresiana (in successive volumes, 1901 ff.). The following deserve special mention. P. Sarpi, *Istoria del concilio tridentino* (London, 1619); Cardinal Sforza Pallavicini, *Istoria del concilio di Trento* (Rome, 1656–57, a counterblast to the preceding); Brischar, *Zur Beurteilung der Kontroversen zwischen Sarpi und Pallavicini* (1844); J. J. v. Dollinger, *Sammlung von Urkunden zur Geschichte des Konzils von Trient*, i. 1, 2 (1876); *Beiträge zur politischen kirchlichen, und Kulturgeschichte* (3 vols., 1862–82); G. Paleottus, *Acta concilii tridentini a 1562 et 1563 usque in finem concilii*, ed. F. Mendham (1842); A. v. Druffel, *Monumenta tridentina* (3 parts, 1884–87, parts 4 and 5, continued by K. Brandi, 1897–99); *Zur Geschichte des Konzils von Trient. Aktenstücke aus den österreichischen Archiven*, ed. T. v. Sickel (3 parts, 1870–72); F. Lainez, *Disputationes tridentinae*, ed. TRENTE ET QUARANTE (Rouge et Noire), a French gambling game of cards played at Monte Carlo and other continental casinos. It is not popular in North America. The name *trente et quarante* ("thirty and forty") is derived from the fact that the winning point always lies between these two numbers. Its other title, *rouge et noire* ("red and black"), comes from the colours marked on the layout, or tapis, such as the one illustrated. The table usually carries two identical layouts. All betting is done against the house or bank. Before the deal begins, a player may place his bet on *rouge, noire, couleur* or *inverse.* Six 52-card packs are shuffled together by the dealer and cut by any player against the house. The dealer then deals out the first row, called *noir;* he first deals one card whose suit is specially noted, face upward. He then continues to deal to either side, alternately, of the card already placed, announcing the cumulative total of the spots with each card dealt. Dealing stops with the card which causes the total to reach or exceed 31. Since aces count 1 each, face (court) cards and tens count 10 each and every other card counts its numerical or pip value, the total cannot exceed 40. The second row, *rouge,* is dealt below the first and in the same manner.

DIAGRAM SHOWING HALF OF TRENTE ET QUARANTE TABLE

The row with the total nearer to 31 is the winning row. For example, a bet on *noir* wins if the count of the first or *noir* row is 34 while the *rouge* row totals 36. A bet on *couleur* wins if the very first card dealt is the same colour as that designating the winning row. If this card is of the opposite colour, a bet on *inverse* wins. The croupier traditionally announces the result for red and colour only, calling "*rouge gagne* (wins)" or "*rouge perd* (loses)," "*couleur gagne*" or "*couleur perd.*"

If both rows count the same (tie), it is called a *refait* and all bets are called off. If there is a *refait* at *31—refait de trente et un*—the bank takes half of all bets. In such cases, however, the player has the option of leaving his bet in "prison," where it remains for the next game or coup. If he wins on this coup, he withdraws his bet; but if he loses, he loses the whole.

As bets are settled, the cards dealt for that coup are brushed into the bowl. When there are insufficient cards for the next coup all the cards are reshuffled. A *refait* at 31 occurs more frequently than at any other number. Estimates of its frequency vary from once in 45 coups (giving the bank about 1.1% of all money bet against it) down to once in 31 coups (1.6% advantage to the bank). All bets are at even money. (P. Fr.)

TRENTINO, a mountainous area of north Italy, extending east and west of the middle course of the Adige river. Before World War I it was part of the Austrian province of Tirol. The Trentino frontier, which had been delimited after the war of 1866, was strategically most unfavourable to Italy, as it left the mountain ranges in Austrian hands and formed a wedge where a dozen military roads branched outward threatening the richest and most fertile parts of Italy. It also left 400,000 Italians under Austrian rule.

During World War I the region was the scene of heavy fighting between the Italians and Austrians. Some of this (around Stelvio pass, the Adamello mountain group, Ampezzo and San Martino di Castrozza) was at very high altitude, with the Austrians usually holding the more favourable positions. The Austrian object was to cut the communications of the Isonzo army, but although after the battle of Caporetto (*q.v.*) the Italians had to evacuate the Ampezzo and Cadore areas, their positions on the outer edge of the Asiago plateau held firm. For the history of the area *see* Tirol: Venetia.

TRENTO (Lat. Tridentum; Ger. Trent or Trient), the capital of a province of the same name in the region of Trentino-Alto Adige, Italy. Pop. (1951) 39,287. It stands on the left bank of the Adige where this river is joined by the Fersina and is a station on the Brenner railway, 35 mi. S. of Bolzano and $56\frac{1}{2}$ mi. N. of Verona, while a railway runs along the Fersina valley and the Val Sugana to Bassano (60 mi.). There is also an electric railway to Mali: (45 mi. N.). It has a very picturesque appearance, especially when approached from the north, with its embattled walls and towers filling the whole breadth of the valley. A conspicuous feature in the view is the isolated rock Doss Trento (the site of the Roman Verruca), that rises on the right bank of the Adige to a height of 308 ft. above the city. The cathedral (dedicated to San Vigilio, the first bishop) was altered at various times between the 11th and 15th centuries and was restored in 1882–89.

Outside is the fine fountain of Neptune (1767–69). The Renaissance church of Santa Maria Maggiore, built in 1520–39, was the scene of the sessions of the famous ecumenical council which lasted, with several breaks, from 1545 to 1563, during the episcopate of Cristoforo Madruzzo. To the east of the city rises the Castello del Buon Consiglio, for centuries the residence of the prince-bishops, which is decorated with interesting frescoes and contains the museum of antiquities and fine arts for the district. Opposite the railway station a statue of Dante by Zocchi was erected in 1896.

Tridentum, the capital of the Tridentini, was a station on the great road from Verona to Veldidena (Innsbruck) over the Brenner. It was later ruled by the Ostrogoths (5th century) and the Lombards (6th century) after the conquest of whom by the Franks (774) Trento became part of the medieval kingdom of Italy. But in 1027 the emperor Conrad II bestowed all temporal rights in the region on the bishop (the see dates from the 4th century) and transferred it to Germany. Venetian attacks were finally repulsed in 1487, and the bishop retained his powers until 1803, when they passed to Austria until 1809.

From 1810 to 1814 Trento was part of the Napoleonic kingdom of Italy and capital of the Alto Adige province. In 1814 the Trentino was annexed to the Austrian province of Tirol and in 1918 was ceded to Italy.

TRENTON, the capital of New Jersey, U.S., and seat of Mercer county, is located at the head of navigation on the Delaware river, 30 mi. N.E. of Philadelphia and 55 mi. S.W. of New York city. The population of the city in 1960 was 114,167, a decrease of 10.8% in the decade; that of the standard metropolitan statistical area (Mercer county) was 266,392, an increase of 15.9%. For comparative population figures *see* table in New jersey: *Population.*

History.—The Dutch established a trading post and fort at the site of the present city of Trenton during the 1630s. Mahlon Stacy, a Quaker from Lancashire, Eng., established a gristmill there in 1679. William Trent purchased these holdings from his son, Mahlon Stacy, Jr., and proceeded to lay out the town which in 1721 was named Trenton in his honour. His home, erected in 1719, still stands. King George II of England granted the municipality a charter as a town and a borough in 1745. Barracks were erected in 1758 to house British troops engaged in the French and Indian War. During the American Revolution these quarters were occupied at various times by British, Hessian and American soldiers. Constructed of stone and of early Georgian architecture, a section, now termed the Old Barracks, is open to the public as a museum.

In the midst of a heavy snowstorm on Christmas night, 1776, George Washington and his army crossed the ice-choked Delaware river at McKonkey's ferry, now Washington crossing, marched downstream and the next morning launched an attack on the Hessian troops quartered at Trenton under the command of Col. Johannes Rall. The Hessians, completely confused by the unexpected onslaught, quickly surrendered. On Jan. 2, 1777, Lord Cornwallis arrived to face the Americans at Trenton. Because his troops were fatigued from their long march, he postponed his attack until morning. During the night Washington withdrew and marched to Princeton where he defeated a detachment under Col. Charles Mawhood. This series of actions caused the British to evacuate all of New Jersey and turned the tide of the war. *(See* also TRENTON *AND* PRINCETON, BATTLES OF.)

Trenton served as the temporary capital of the United States in 1784 and again in 1799. Several proposals to establish the national capital there permanently were rejected. It became the capital of the state of New Jersey in 1790 and the state house was erected two years later. Since that time numerous additions have been made and it has become a massive stone structure, of Renaissance style. To the north of it stands the State Capitol annex, completed in 1931, and containing numerous offices, courtrooms, the state museum and the state library.

Industry.— The iron industry was established in Trenton as early as 1734. In 1845 Peter Cooper opened a rolling mill and in 1868 his associate. Abram Hewitt, introduced into America the open-hearth system of making steel. At Cooper's suggestion John A. Roebiing moved his wire mill from Pennsylvania to Trenton in 1848 and produced cable for suspension bridges. Although he died during its construction, the success he achieved with the Brooklyn bridge brought acclaim to him and to his firm, which continues to supply cable for that type of span all over the world.

Potteries have operated in Trenton since 1723 and by the middle of the 13th century some of the finest china was being produced there. In 1889 Walter Scott Lenox founded the firm which bears his name and is world famous for the quality of its products.

The industrial structure of the city and its metropolitan area has become highly diversified. The establishment of the integrated steel mills across the Delaware at Morrisville, Pa., in 1952, exerted a tremendous impact on the entire area by bringing to it more industrial plants and many housing developments. Despire the industrial expansion, Mercer county continues to be important in the value of agricultural products, with dairying and truck-farming predominating.

Education.— Educational institutions in the metropolitan area include Princeton university; Trenton State college, established in 1885; the Trenton Junior College and School of Industrial Arts, established in 1890; and Rider college, a private institution established in 1865. Private preparatory schools in Mercer county are the Pennington school, Pennington; Peddie school, Hightstown; and Lawrenceville school, Lawrenceville, whose 19th-century atmosphere was depicted in the novels of Owen Johnson.

(E. R. D.)

TRENTON AND PRINCETON, BATTLES OF (1776–1777). These battles in the American Revolution *(q.v.)* are noted as the first successes won by George Washington in the open field. Following close upon a series of defeats, their effect upon his troops and the population at large was marked. They put new life into the American cause and renewed confidence in Washington.

After the capture of Ft. Washington on Manhattan Island, on Nov. 16, 1776, the British general, Sir William Howe, forced the Americans to retreat through New Jersey and across the Delaware river into Pennsylvania. Howe then went into winter quarters, leaving the Hessian, Col. Johannes Ral!, at Trenton on the river with about 1,400 men. Although Washington's army was discouraged by the year's disasrers, it could still be trusted for a promising exploit and by reinforcements had been brought up to about 6,000 effectives. Ascertaining that the Hessians at Trenton were practically unsupported, Washington determined to attempt their capture.

He planned to recross the Delaware with three columns, but only his own got across. The passage was made on the night of Dec. 25, 1776, through floating ice, to a point 9 mi. above the enemy, whom he expected to reach at dawn of the following day, Dec. 26. Dividing his force of 2,500 men into two divisions under Gen. John Sullivan and Gen. Nathanael Greene, he approached the town by two roads, surprised the Hessian outposts and then rushed upon the main body before it could form effectively. The charge of the American troops and the fire of their artillery and musketry completely disconcerted the enemy. A few hundred escaped but the majority (over 900) were surrounded and forced to surrender. Colonel Rall was mortally wounded.

Washington carried his army and prisoners back across the river. Eager to harass the enemy's posts at other points, he again crossed the Delaware on Dec. 30 and occupied Trenton. Hearing of this move, Lord Cornwallis marched with about 7,000 troops upon the Americans on Jan. 2, 1777, and drove them across the Assunpink, a stream running east of the town. The Americans, who encamped on its banks that night, were placed in a precarious position. As they had no boats at their disposal at that point they were unable to recross the Delaware into Pennsylvania, and all the roads led toward the British lines to the northeast. Washington accordingly undertook a bold maneuver. Fearing an attack by Cornwallis on the next morning, he held a council of war, which confirmed his plan of quietly breaking camp that night and taking a byroad to Princeton. He would cut through any resistance that might be offered there and push on to the hills of northern New Jersey, thus placing his army on the flank of the British posts. His tactics succeeded.

At Princeton he came upon three British regiments, which for a time held him at bay. The 17th foot especially, under Col. Charles Mawhood, twice routed the American advanced troops, inflicting severe losses, but were eventually driven back toward Trenton. The other regiments retreated northeast toward New Brunswick, and Washington continued his march to Morristown, N.J., where he was on the flank of the British communications with New York. Cornwallis retired to New Brunswick. Washington, besides his success in breaking through Howe's lines, had placed himself in an advantageous position for recruiting his army and maintaining a strong defensive in the next campaign.

TREPOV, DIMITRI FEODOROVICH (1855–1906), Russian general, chief of the imperial police, born at St. Petersburg, was city prefect of Moscow. In the disturbances of 1905 he was placed in command of St. Petersburg, when he immediately took steps to expel all those who had taken part in the procession led by Father Gapon to the Winter palace. The result was an epidemic of strikes throughout the empire. In the railway strike (Oct. 20) Trepov gave the famous order to the troops "not to spare their cartridges." He was made commandant of the imperial police and used his great power to undermine the authority of Count Witte with the tsar. He then became assistant minister of the interior. An unsuccessful attempt to assassinate him was made on March 30, 1905.

Trepov died on Sept. 15, 1906.

TRESCOT, WILLIAM HENRY (1822–1898), U.S. diplomatist and historian, was born in Charleston, S.C., on Nov. 10, 1822. He graduated from Charleston college in 1841, read law and was admitted to the bar in 1843. He studied diplomatic history and published *The Diplomacy of the Revolution* (1852), *An American View of the Eastern Question* (1854) and *The Diplomatic History of the Administrations of Washington and Adams* (1857).

Trescot was appointed assistant secretary of state in 1860 and served as acting secretary during the secession crisis. While serving as a channel of communication between President Buchanan and the governor of South Carolina, he encouraged both to maintain the *status quo* in the Charleston forts pending negotiations for their evacuation. He resigned his position when South Carolina seceded and thereafter served in the Confederate forces.

After the Civil War his services were primarily diplomatic. He was one of the U.S. representatives before the Halifax Fishery commission in 1877; was sent on special missions to China in 1880, to Chile in 1881, and to Mexico in 1882; and was a delegate to the Pan-American conference in 1889. He died at Pendleton, S.C., on May 4, 1898. (H. S. S.)

TRESPASS, in law, any transgression of the law less than treason, felony or misprision of either. The term includes a great variety of wrongs committed to land, goods or person. Up to 1694 the trespasser was regarded, nominally at any rate, as a criminal, and was liable to a fine for the breach of the peace, commuted for a small sum of money, for which 5 Will. and Mar. c. 12 (1693) substituted a fee of 6s. 8*d*. recoverable as costs against the defendant. Trespass is not now criminal except by special statutory enactment, *e.g.*, the old statutes against forcible entry, the game acts and the private acts of many railway companies. When, however, trespass is carried sufficiently far it may become criminal, and be prosecuted as assault if to the person, as nuisance if to the land. At one time an important distinction was drawn between trespass general and trespass special or trespass on the case, for which *see* TORT.

In its more restricted sense trespass is generally used for entry on land without lawful authority by either a man, his servants or his cattle. To maintain an action for such trespass the plaintiff must have possession of the premises. The most minute invasion of private right is trespass. In addition to damages for trespass, an injunction may be granted by the court.

Trespass may be justified by exercise of a legal right, as to serve the process of the law, or by invitation or licence of the owner, or may be excused by accident or inevitable necessity, as deviation from a highway out of repair.

In Scots law trespass is used only for torts to land. By the Trespass (Scotland) act 1865 trespassers are liable on summary conviction to fine and imprisonment for encamping, lighting fires, etc., on land without the consent and permission of the owner.

In the U.S., common law doctrines as to trespass hold in most states. It means, more particularly, an injury to the person, property or rights of another, as the immediate result of a wrongful act committed with actual or implied force. The statutes have provided for criminal trespass in many states, but not to the extent as existed prior to 1694 in England. Trespass on the realty of another often is a criminal offence, through statutory enactment in the states.

TRESVIRI (TRIUMVIRI), in Rome, a board of three, either ordinary officials or extraordinary commissioners.

1. *Tresviri capitales,* who assisted the higher magistrates in their judicial functions, especially criminal. were first appointed about 289 B.C. They possessed no criminal jurisdiction or right of arrest themselves. They kept watch over prisoners; carried out the death sentence; took accused or suspected persons into custody; exercised general control over the city police; went the rounds by night to maintain order; and were present at fires. They assisted the aediles in burning forbidden books. They collected the deposit forfeited by the losing party in a suit and examined the plea of exemption put forward by those who refused to act as jurymen. In imperial times most of their functions passed to the *praefectus vigilum*.

2. *Tresviri epulones,* a priestly body, assisted at public banquets. They were first created in 196 B.C. to superintend the *epulum Iovis* (banquet of Jupiter) on the Capitol, but they also served on the occasion of triumphs, imperial birthdays, the dedication of temples, games given by private individuals, and so forth, when public entertainments were provided.

3. *Tresviri monetales* were superintendents of the mint; after the Social War, permanent officials. As they acted for the senate they only coined copper money under the empire, gold and silver coinage being exclusively controlled by the emperor.

4. *Tresviri reipublicae constituendae* was the title bestowed upon Octavianus, Lepidus and Antony for five years by the Lex Titia. 43 B.C. The coalition of Julius Caesar, Pompey and Crassus has also been called a "triumvirate," but they never had the title *tresviri*, and were not a formally appointed commission.

See W. E. Heitland, *The Roman Republic* (1923).

TREVELYAN, GEORGE MACAULAY (1876–), English historian, whose belief that the same book should appeal to the general reader and to the history student gives his work vividness and warmth, was the third son of Sir George Otto Trevelyan (*q.v.*). Born at Stratford-on-Avon, Feb. 16, 1876, he was educated at Harrow and Trinity college, Cambridge. became regius professor of modern history at Cambridge in 1927 and master of Trinity college in 1940. He received the Order of Merit in 1930. He retired in 1951.

Essentially liberal by training and temperament, Trevelyan shows as a historian a love of England also indicated by his association with the National trust and youth hostels; a respect for the Whig tradition in English thought, exemplified in his *Lord Grey of the Reform Bill* (1920) and *Grey of Fallodon* (1937); and a keen interest in the Anglo-Saxon element in the English constitution. The romantic aspect of his liberalism led to three books on Garibaldi: *Garzbaldi's Defence of the Roman Republic* (1907); *Garibaldi and the Thousand* (1909); and *Garibaldi and the Making of Italy* (1911). Other works are *England in the Age of Wycliffe*, new ed. (1904); *England Under the Stuarts* (1905); *Lifr of Jolzn Bright* (1913); *British History in the Nineteenth Century* (1922; rev. ed., 1938); *History of England* (1926; new enlarged ed., 1937); *England Under Queen Anne, 3* vol. (1930–34); *The English Revolution, 1688–1689* (1939); *English Social History* (1942); and *The Seven Years of William IV* (1952). His *An Autobiography and Other Essays* appeared in 1949.

TREVELYAN, SIR GEORGE OTTO (1838–1928), English historian and statesman, is chiefly remembered for his *Life and Letters* of his uncle, Lord Macaulay (1876) and for his part in the complex political events following Gladstone's introduction of Irish Home Rule in 1886.

The son of Sir C. E. Trevelyan and Hannah More Macaulay, he was educated at Harrow and Trinity college, Cambridge, and in 1862 went to India as his father's private secretary. While there he wrote *The Competition Wallah* (1864) and *Cawnpore* (186;). He returned to England in 1864 and in the parliament of 1865–68 (in which he sat for Tynemouth as a Palmerstonian) he became friendly with John Bright. In 1868 he was returned for the radical seat of Hawick Burgh's, and was made civil lord of the admiralty in Gladstone's first ministry. He resigned in 1870, as a protest against W. E. Forster's Education act, and although during the Liberal opposition years, 1874–80, he advocated a measure for extension of the working class franchise subsequently adopted by Gladstone, he was passed over in the ministry of 1880. In 1881, however, he became secretary to the admiralty and in 1882 chief secretary for Ireland.

In 1884 Trevelyan was made chancellor of the duchy of Lancaster with a seat in the cabinet, and in 1885 secretary for Scotland, but when Gladstone introduced Home Rule in 1886 he resigned, with Joseph Chamberlain; standing as a Liberal Unionist at the general election, he was defeated. Preferring Gladstone and Home Rule to alliance with the Conservatives, however, he stood as a Gladstonian for a Glasgow division in 1887 and held his seat until his retirement in 1897.

Apart from his life of Macaulay, his chief historical works were the *Early History of Charles James Fox* (1880), valuable for its evocation of an age; and *The American Revolution,* part i, *1766*–1776 (1899), part ii (1903–05), part iii (1907), concluded in *George III and Charles Fox* (1912–14). The last was especially important in the United States, where its sympathetic attitude to the U.S. position helped to dispel anti-British prejudice. Trevelyan died at Wallington, Northumberland, on Aug. 17, 1928.

TREVET (or **TRIVET**), **NICHOLAS** (*c.* 1258–*c.* 1328), English chronicler, was the son of Sir Thomas Trevet (d. 1283), a judge, and became a Dominican friar. After studying at Oxford and in Paris, he spent most of his subsequent years in writing and teaching, and died about 1328. His chief work is his *Annales sex regum Angliae,* a chronicle of English history covering the period between 1135 and 1307; this is valuable for the later part of the reign of Henry III and especially for that of Edward I.

The *Annales* were published in Paris in 1668, in Oxford in 1719, and were edited by Thomas Hog for the English Historical society in 1845. Manuscripts are at Oxford and in the British museum.

TREVISO (anc. TARVISIUM), a town and episcopal see of Veneto, Italy, capital of the province of Treviso, 49 ft. above sea level. Pop. (1951) 53,165. It is on the plain between the

Gulf of Venice and the Alps, 18 mi. by rail north of Venice, at the confluence of the Sile with the Botteniga. The cathedral of San Pietro, dating from 1141 and restored and enlarged in the 15th century by Pietro Lombardo, with a classical façade of 1836, has seven domes. It contains a fine "Annunciation" by Titian (1519), an important "Adoration of the Shepherds" by Paris Bordone (born at Treviso in 1500), and frescoes by Pordenone. There are also sculptures by Lorenzo and Battista Bregno and others. The baptistery is Romanesque. The Gothic church of San Nicolb (1310–52) contains important works of art, including a large altarpiece by Fra Marco Pensabene and others; in the church and adjoining chapter-house are frescoes by Tommaso da Modena (1352), some frescoes by whom (life of S. Crsula) are also in the Museo Civico. The churches of S. Leonardo, S. Andrea, S. Maria Maggiore, and S. Maria Maddalena also contain art treasures. The Piazza dei Signori contains picturesque brick battlemented palaces —the Palazzo dei Trecento (*c.* 1207) and the Palazzo Pretorio (1218–68).

The ancient Tarvisium lay off the main roads, and is hardly mentioned by ancient writers. In the 6th century it appears as an important place and was the seat of a Lombard duke. Charlemagne made it the capital of a marquisate. It joined the Lombard league, and was independent after the peace of Constance (1183) until, in 1339, it came under the Venetian sway. From 1318 it was for a short time the seat of a university. Its walls and ramparts were renewed under the direction of Fra Giocondo (1509), two of the gates, the Porta Mazzini and Porta Cavour, dating from 1517–18. Treviso was taken in 1797 by the French under Mortier (duke of Treviso). In March 1848 the Austrian garrison was driven from the town by the revolutionary party, but in the following June the town was bombarded and compelled to capitulate.

TREVITHICK, RICHARD (1771–1833), English engineer, pioneer builder of high-pressure steam engines and "father of the locomotive," was a prolific inventive genius of great energy and physique. He was born on April 13, 1771, near Illogan, Cornwall, the son of a manager of mines. At 19 he was already engineer at various Cornish mines. In 1797–98 he constructed his improved plunger-pole pump and water-pressure engine for mining. He made high-pressure noncondensing steam engines, which were smaller and cheaper than low-pressure condensing beam engines. He built his first high-pressure steam road carriage at Camborne in 1801. On Christmas Eve he drove it, carrying passengers, part way up Beacon hill but it ran out of steam; three days later it was destroyed by fire. In 1802 Trevithick and his cousin Andrew Vivian obtained their epoch-making patent covering the high-pressure engine for stationary and locomotive use. Trevithick drove his second steam carriage in London from Holborn to Paddington and back in 1803, but public opinion and road surfaces were not ready. He returned to building stationary engines at Samuel Homfray's Penydarren ironworks, Merthyr Tydfil, Wales! and at his suggestion constructec! his first steam locomotive there. On Feb. 21, 1804, it successfully hauled five wagons, ten tons of iron and 70 men at nearly 5 m.p.h. on the 10-mi. tramway to Abercynon. Heavier loads broke the cast-iron tram plates, bur the trials proved that useful loads could be hauled solely by adhesion of locomotive wheels on the track, ten years before William Hedley's and George Stephenson's earliest locomotives. In 1808 Trevithick drove his locomotive "Catch-me-who-can" on a circular railway near Euston road, London, at 12 m.p.h. He constructed steam dredgers on the Thames, but his work on the Thames driftway was stopped after tunneling 1,000 ft. He patented the use of iron for ship construction.

Returning to Cornwall, in 1812 he introduced his Cornish boiler with long shell and single flue, and built at Wheal Prosper the first Cornish pumping engine, a condensing engine of Watt type working with high-pressure steam expansively. Cornish engines later created records for economy. Trevithick applied steam power to agriculture and made his small, high-pressure, single-acting expansive engine (preserved in the Science museum, London) for Sir Christopher Hawkins of Trewithen for threshing corn. In 1813 Francisco Uvillé came from Peru and ordered high-pressure engines for the Cerro de Pasco silver mines. In 1816 Trevithick sailed to Peru, installed his engines and worked at the mines there and in Chile. After crossing Nicaragua he reached Cartagena, Colombia, and eventually landed penniless in England in 1827. Trevithick petitioned parliament unsuccessfully for a reward for his inventions. He finally worked for John Hall at Dartford, Kent, where he died on April 22, 1833. A window in Westminster abbey and a statue at Camborne perpetuate his achievements.

TRIAL: *see* PRACTICE AND PROCEDURE.

TRIAL OF ANIMALS, an ancient legal custom which persisted in Europe until relatively recent times. There is evidence that it grew out of the popular belief that animals are intelligent and consequently morally responsible for their acts. However, the old doctrine of deodand (*q.v.*), which penalized inanimate objects that had taken human life. may be germane to the concept of the responsibility of animals, in which case both must be traced to the idea underlying animism: that not only human beings, but all other entities, are endowed with volition and consciousness. An early example of legal procedure against animals is furnished by Exodus xxi, 28: "And if an ox gore a man or a woman to death, the ox shall be surely stoned." Piato, in *The Laws*, prescribed that "If a beast of burden or any other animal shall kill anyone, except while the animal is competing in the public games, the relatives of the deceased shall prosecute it for murder."

In western Europe procedure against animals was settled, both in the ecclesiastical and civil courts; in all cases they were provided with counsel, were duly summoned to appear, exceptions taken in their favour were considered, and their sentences sometimes commuted on the grounds of relative youth, exiguity of body, or a reputation for respectability: a she-ass condemned to death in France in 1750 was pardoned because of good character.

TRIANGLE. A triangle, or more precisely a plane triangle, is the geometrical figure composed of three points called the *vertices* (not lying in one straight line), and the three straight lines joining these, called the sides. Since no part of a plane can be inclosed by fewer than three straight lines, the triangle ranks as the simplest figure of its class, and plays a correspondingly important part in both practical and theoretical geometry.

Congruence Theorems.—It is important to recognize the conditions under which two triangles may be known to be *congruent;* that is, alike in all respects except position in space, so that the one triangle is merely the other moved into a new position without change of form. The most important theorems of this character have been known from very ancient times, and were handed down in the first book of Euclid's *Elements*.

Two triangles are congruent if two sides of the one are respectively equal in length to two sides of the other, and if these two sides are in each case inclined at the same angle.

Thus in figure 1, to be sure that the triangles ABC and *abc* are exactly alike, it is enough to know that $AB=ab$, $AC=ac$, and the angle at $A=$ the angle at *a*. It would *not* be enough to know that these same two pairs of sides were equal together with the angles at B and *b,* since in this case the triangle ABC might equally well have had the form of ABC' in the figure, and therefore not have agreed with *abc* in form.

Two triangles are congruent if the three sides of the one are equal respectively to the three sides of the other.

Two triangles are congruent if a side of one is equal to a side of the other, and if the angles at the ends of these equal sides are the same in both triangles.

Thus the triangles ABC and *abc* will be identical in form if $BC=bc$, the angle at $B=$ the angle at b, and the angle at $C=$ the angle at *c*.

This theorem supplies the basis for the method of triangulation. If B and C are given stations whose positions are known, the measurement of the angles ABC and ACB will determine, together with a knowledge of *BC*, the form of the triangle *ABC*, and so the position of A.

Two triangles are congruent if two angles of the one are equal

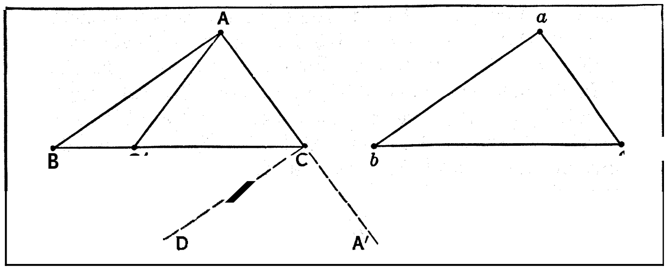

FIG. 1

to two angles of the other respectively, and if the sides opposite one of the equal pairs of angles are equal.

This theorem is readily reduced to the one before by means of the property stated at the beginning of the next section. The same consideration prepares us to accept the statement that two triangles may have the angles of one equal to the angles of the other without being congruent. In such a case the triangles are similar in shape, but may be of different sizes.

Relations Between the Parts of a Triangle.—The foregoing remarks emphasize the fact that the three sides and the three angles are not six independent magnitudes to which any values whatsoever may be given. For instance it is impossible to draw a triangle in which all the sides are equal and the angles unequal.

The simplest relation connecting the parts of a triangle in general is that *the sum of the three angles is two right angles.* This follows from the fact that, when one side is continued outside the triangle, the angle so formed on the outside is equal to the sum of the angles inside the triangle at the other two vertices. The latter relation is exhibited in figure 1 for the triangle ABC, the line CD, drawn parallel to BA, dividing the exterior angle into two parts, of which DCA' is equal to A, and DCC' to B. The relation between the three angles enables one to find the value of the third when two of the angles are known. Thus, if two of the angles are 60° and 70°, the third is 180°–60°–70° = 50°.

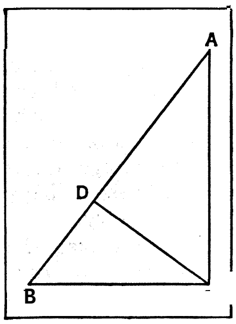

FIG. 2

It is convenient to consider here certain special forms of triangle. A triangle with two equal sides is called *isosceles.* Such a triangle has the angles opposite to these sides also equal. This is easily proved by joining the middle point of the unequal side to the opposite vertex and deducing the congruence of the two triangles so formed. The proof given by Euclid was much more elaborate, because Euclid did not permit the use of the middle point at a stage when the problem of finding it had not been taken up; and the theorem was nicknamed the *pons asinorum,* and regarded at one time as a notable obstacle to the beginner in geometry.

A right triangle is one which has one of its angles a right angle. In figure 2 the triangle ABC has a right angle at C. Evidently $CB = AB \times s$, and $AC = AB \times k$, where s and k are proper fractions depending on the angle A, and not on the size of the triangle The ratios s and k are called the sine and cosine respectively of the angle A, and their theory constitutes the science of trigonometry (*q.v.*). If CD is perpendicular to AB, by the similarity of the three triangles, $BD = CB \times s = AB \times s^2$, *and* $AD = AC \times k = AB \times k^2$. Since $AD + BD = AB$, it follows that $s^2 + k^2 = 1$. On multiplying this equation by AB^2, it is seen that $BC^2 + AC^2 = AB^2$. Here the meaning of BC^2 may be understood to be the arithmetical square of the number of units in BC. The side AB opposite the right angle is called the *hypotenuse* of the right triangle, and the result just obtained is that *the square of the hypotenuse is equal to the sum of the squares of the other two sides,* a theorem ascribed to Pythagoras (*q.v.*), and of the utmost importance in geometry.

Allusion may be made to two triangle inequalities. (1) *The sum of any two sides is greater than the third side;* (2) *the greater of two unequal sides has the greater angle opposite to it.*

As supplementing the preceding statement (2) we have the *sine formula.* In fig. 3, if CR is perpendicular to AB, the sines of A and B are respectively $\frac{RC}{AC}$ and $\frac{RC}{BC}$. These are proportional to BC and AC, so that *the sines of angles are proportional to the lengths of the opposite sides* Also $BC^2 = RB^2 + RC^2 = (AB - AR)^2 + (AC^2 - AR^2) = AB^2 + AC^2 - 2AB \cdot AR = AB^2 + AC^2 - 2AB \cdot AC \cdot k$, where k is the cosine of A. These two relations are of great importance in triangle computations.

Associated Lines and Circles.—It is only possible to quote summarily a few of the more interesting configurations that arise in connection with the triangle. The construction for the circumscribed circle (which passes through the vertices) reveals that the three straight lines drawn perpendicular to the sides through their middle points meet at a common point, the centre of the circle in question.

The centre of the inscribed circle (which touches the sides and lies between them) is the intersection of another set of concurrent

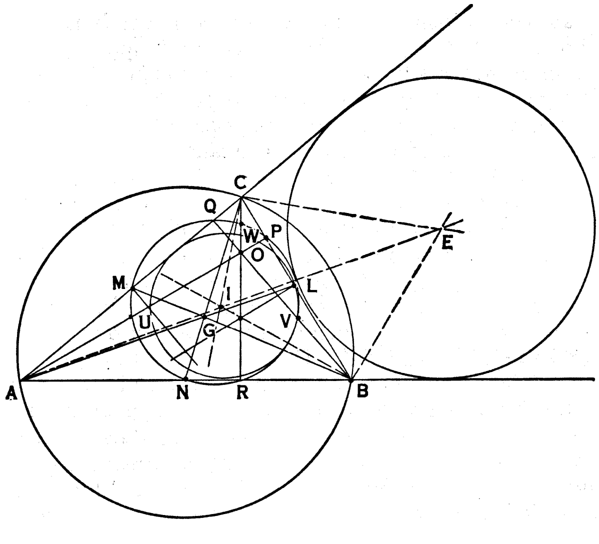

FIG. 3

lines, the three internal bisectors of the angles of the triangle.

The bisectors of two exterior angles, as BE and CE in fig. 3, meet at a point on the bisector of the interior angle at the other vertex, this point being the centre of another circle touching the three sides. Four circles in all are found to touch the sides.

The lines joining the vertices to the middle points $L,M,N,$ of the opposite sides meet in a point G called the *centroid.* The perpendiculars AP, BQ and CR meet in a point O, called the *orthocentre.*

There is the remarkable theorem that the points $L,M,N,P,$ Q,R and the middle points U,V,W of AO, BO, CO lie on a circle (the *nine-point circle*), and the still more striking result (Feuerbach's Theorem) that this circle touches the four circles touching the sides of the triangle.

TRIANGLE, in music, an instrument of percussion of indefinite musical pitch, consisting of a rod of steel bent into the form of a triangle. Suspended by a loop, it is played by means of a short steel rod. The tone of the triangle is clear and ringing, but it should have no definite pitch.

TRIANON, TREATY OF. The treaty of peace between the Allied and Associated Powers and Hungary, after World War I, was signed at the Trianon on June 4, 1920. The Supreme council of the Conference of Paris had decided and published the frontiers with Czechoslovakia and Rumania as early as June 13. 1919; but the presentation of the treaty was delayed by the existence in Hungary of the Bolshevik regime of Béla Kun. with whom the Allies were unnilling to treat and afterward by the inability of the counterrevolutionary regime which succeeded Kun to form a stable government. (See HUNGARY: History; PARIS, CONFERENCE OF.) After the terms had been presented (on Jan. 15, 1920) to the Hungarian delegates, further delays occurred. Certain circles in France were for a time prepared to consider revising those terms against which the Hungarian delegates had protested most strongly, in return for various concessions, national and international. Counterpressure brought by rival circles in France ended these negotiations, and Hungary had to sign the original draft terms almost unaltered, although a covering letter to the treaty, signed by Alexandre Millerand, the French premier and foreign minister, held out the prospect of subsequent revision if later consideration showed this to be desirable. No noteworthy revision was in fact accorded to Hungary on the basis of this letter: although its own resistance, aided by diplomatic support from Italy, brought the concession that the Allies allowed a plebiscite in the city of Sopron (Oedenburg), originally allotted unconditionally to Austria. This vote, taken in 1921, resulted in Hungary's retaining that city.

Terms of the Treaty.— The treaty was presented to the government of Hungary, whose complete international independence was thus recognized. The treaty made no reference to Hungary's form of government: the legislation enacting the dethronement of the Habsburg (*q.v.*) dynasty was passed, under pressure from the Allies, at a later date. The territorial provisions of the treaty liquidated the ancient historic state of Hungary, which had been a multinational one. According to official Hungarian calculations: the area of the state was reduced from 282,870 sq.km. (or 325,411 if Croatia-Slavonia were included), to 92.963 sq.km., while 4,020 sq.km. were eventually assigned to Austria (*i.e.*, after the Sopron plebiscite), j89 to Poland. 61,633 to Czechoslovakia, 103,093 to Rumania. 21 to Italy and 20,551 (plus Croatia-Slavonia 42,541 sq.km.) to Yugoslavia. The census of 1910 had given the population of Hungary at that date as 18,264,533, plus 2,621,954 in Croatia-Slavonia. Calculated from these figures, Hungary retained only 7,615,117 under the treaty while 291,618 went to Austria. 23,662 to Poland. 3,517,568 to Czechoslovakia, 5,257,467 to Rumania, 49.806 to Italy and 1.509,295 plus 2,621,954 to Yugoslavia. Hungary's armed forces were limited to a lightly armed long-service force of 35,000 men, to be used exclusively for maintenance of internal order and the defense of the frontiers. Hungary was required to accept in advance the obligation to pay reparations to an unspecified total, these being made a first charge on all assets and resources. The remaining clauses of the treaty, which in general resembled that of St. Germain, concluded with Austria, call for no special description. (See ST. GERMAIN, TREATY OF.)

Reception of the Treaty.— These terms mere bitterly resented in Hungary (and also by some circles outside the country) as intolerably harsh and unjust. It was pointed out that the dismemberment of the old historic unit caused great economic hardship and dislocation and that even the ethnic principle invoked to justify this dismemberment (which the Hungarians claimed did not even correspond with the wishes of many of the non-Magyars themselves) was not honoured in its application: more than 3,000,000 persons shown by the 1910 census as Magyar by mother tongue had been allotted to successor states: Czechoslovakia having received more than 1,000,000 such persons and Rumania nearly 1,750,000. While some of these groups constituted ethnic islands in Slav or Rumania areas, in many cases large blocs of solid Magyar population, contiguous to the main central bloc left in Hungary, had been assigned to successor states for the economic or strategic benefit of the latter, or in order to facilitate their internal or mutual communications. The struggle to secure revision of the treaty dominated Hungarian policy from the day of signature until the end of World War II.

TRIASSIC SYSTEM, a geological term designating the lowest system of the Mesozoic era (*q.v.*) as indicated on the accompanying geologic time chart. The dinosaurs had their origin in the Early Triassic, and became abundant before the end of the period. Most of the Triassic dinosaurs were small, ranging in length from 1 to 8 ft., but some fossils of the Upper Triassic are 30 ft. long. This article deals with the identification and correlation of the stages of the Triassic, the paleogeography of the period and the fossils of ammonites and other invertebrate marine animals that form the basis for the standard sequence of Triassic rocks. Separate subsections deal with the distribution of Triassic rocks in various parts of the world. For information on the evolution of life during the period see PALAEOBOTANY; PALAEONTOLOGY. See also AMPHIBIA; DINOSAURIA; FISHES; REPTILES.

Geologic Time Chart

System and Period	Series and Epoch	Distinctive Records of Life	1,000 Years
		CENOZOIC ERA	
Quaternary	Recent	Modern man	11
	Pleistocene	Early man	1,000
Tertiary	Pliocene	Large carnivores	
	Miocene	Whales, apes, grazing forms	
	Oligocene	Large browsing mammals	
	Eocene	Rise of flowering plants	
	Paleocene	First placental mammals	70,000
		MESOZOIC ERA	
Cretaceous		Extinction of dinosaurs	130,000
Jurassic		Dinosaurs' zenith, primitive birds, first small mammals	160,000
Triassic		Appearance of dinosaurs	200,000
		PALEOZOIC ERA	
Permian		Reptiles developed, conifers abundant	235,000
Carboniferous			
Upper (Pennsylvanian)		First reptiles, coal forests	260,000
Lower (Mississippian)		Sharks abundant	285,000
Devonian		Amphibians appeared, fishes abundant	320,000
Silurian		Earliest land plants and animals	350,000
Ordovician		First primitive fishes	400,000
Cambrian		Marine invertebrates	500,000
		PRE-CAMBRIAN TIME	
		Few fossils	3,500,000–4,000,000

The term Trias, later modified to Triassic, was proposed by Friedrich von Alberti (1834) for a sequence of strata in central Germany lying above marine Permian (Zechstein) and below marine Jurassic (Liassic) because of the threefold division of the strata into a lower nonmarine red-bed facies (Bunter), a middle marine limestone, sandstone and shale facies (Muschelkalk), and an upper nonmarine continental facies like the lower division (Keuper). This sequence and character of facies typifies Triassic strata of northern Europe, France. Spain and north Africa; it is commonly known as the Germanic facies. In contrast to the predominantly continental Germanic facies, there are developed in the Alps, covering all of Triassic time. a complete marine fossiliferous sequence, that is commonly called the Alpine facies and that, uith the addition from southern Asia of some minor units in the lower beds, forms the primary standard sequence of stages. The standard divisions and correlation of the Germanic and Alpine units (descending from the most recent) plus the main zones, identified by ammonite fossils, are shown in Table I.

It should be noted from this chart that the French geologists define the term Keuper in more restricted fashion than do the German geologists and apply Keuper to the middle part of the German sequence (Gypskeuper), and refer the Rhaetian (Rhät) to the Jurassic and the Lettenkohle to the Middle Triassic (Muschelkalk). In the French literature the German terms have been translated in ascending order, as Grès bigarré (Bunter). Calcaire conchylien (Muschelkalk) and Marnes irisées (Keuper. restricted). An additional but minor variation is the use of Virglorian for Anisian and Werfenian for Scythian.

TRIASSIC PALEOGEOGRAPHY

The widespread orogenies uhich began during the Carboniferous period and continued intermittently until the end of the Paleozoic era brought to an end the pattern of widespread geosynclines that had characterized the Paleozoic. Thus during the later phases of the Paleozoic much of Europe north of the Alps, the Cral mountains region, eastern North America and much of Asia north of the Himalayas, which had been active geosynclinal regions were transformed into rigid continental blocks and became part of the stable portion of the respective continents. With the close of the Permian. epicontinental and geosynclinal seas retreated from most of the continents and the geography of the lands and seas must have been very similar to what it is today.

It is upon this pattern that Triassic history began. Early Triassic seas are marginal to the continents except for the Tethyan geosyncline extending from the Alps through the middle east, the Himalayas and to Indonesia. Thus one finds marine Triassic rocks in all the countries on the margins of the Pacific and marginal to the Arctic ocean. In nearly all of these cases the marine strata grade landward into continental facies. South America except for its western margin now occupied by the Andes was land area with local basins of continental deposition. Africa was also emergent except for a narrow intermittent zone in extreme north Africa. Madagascar has mainly continental sediments like those of south Africa except for a few thin marine tongues in the north. Australia was also a continental area much as today. The main central area of Eurasia was a land area with localized sedimentary basins.

It was not until the Jurassic that shallow shelf seas began to spread beyond these main geosynclinal belts and inundated parts of Eurasia, North America, etc.

TRIASSIC INVERTEBRATE MARINE LIFE

The great restrictions of epicontinental and geosynclinal seas in Late Paleozoic time led to the extinction of a large part of the marine faunas that are characteristic of the Paleozoic era. Major taxa of the corals. echinoderms. arthropods, rnollusca, bryozoa and brachiopods became extinct. This great crisis in the evolutionary history of marine animals is reflected in the composition of Triassic marine faunas. For instance, in the Lower Triassic no corals, foraminifera or bryozoa have been discovered. Brachiopods. crinoids. sponges, asteroids, ophiuroids, echinoids and ostracods are represented by few genera. The dominant marine animals in the Early Triassic seas are rnollusca, especially the ammonites. Pelecypods (Lamellibranchia). nautiloids and gastropods are fairly common but not nearly to the extent of the ammonoids. The most characteristic feature of Early Triassic faunas is their great homogeneity wherever they occur.

Table I.—Triassic System Correlation Table

Germanic facies			Series	Stage	Alpine facies Zones*
Keuper	Rät	Rhaetian	Upper Triassic	Rhaetian	*Choristoceras marshi*
	Gypskeuper	Keuper of French geologists (Marnes irisées)		Norian	*Sirenites argonautae* *Pinacoceras metternichi* *Cyrtopleurites bicrenatus* *Cladiscites ruber* *Sagenites giebeli* *Discophyllites patens*
				Karnian	*Tropites subbullatus* *Carnites floridus* *Trachyceras aonoides* *Trachyceras aon*
	Lettenkohle			Ladinian	*Protrachyceras archelaus* *Protrachyceras reitzi*
Muschelkalk (Calcaire conchylien)			Middle Triassic	Anisian (Virglorian)	*Paraceratites trinodosus* *Paraceratites binodosus* *Nicomedites osmani* *Neopopanoceras haugi*
Bunter or Bundsandstein (Grès bigarré)			Lower Triassic	Scythian (Werfenian)	*Prohungarites similis* *Columbites parisianus* *Tirolites cassianus* *Anasibirites multiformis* *Meekoceras gracilitatus* *Flenimgites flemigianus* *Koninckites volutus* *Xenodiscoides fallax* *Prionolobus rosenkrantzi* *Vishnuites decipiens* *Ophiceras commune* *Otoceras woodwardi*

*Indexed by the ammonite (*q.v.*) fossils

Chronology and correlation of Triassic marine rocks is based mainly on the sequence and distribution of ammonites. *(See also* FOSSIL: *Index Fossils.)* There are roughly 400 genera. of Triassic ammonoids, many of world-wide distribution; in the Lower Triassic alone there are 130 genera. This reflects a phenomenal evolutionary radiation of the group from a single surviving Paleozoic stock. The ammonoids underwent another period of crisis at the end of the Triassic and only a single stock survived into the Jurassic. This reflects another phase of extensive regression of the seas during the Rhaetian stage.

The great crisis of mass extinctions that affected marine invertebrate life at the end of the Paleozoic and led to such a different character of Triassic faunas did not affect the land-living animals. There are no sharp breaks or interruptions in the evolutionary history of the amphibians or reptiles. The same applies to the evolutionary development of plants.

DISTRIBUTION OF TRIASSIC ROCKS

Germanic **Facies.**—The Triassic strata of Germany are mainly clastic, that is, made up of fragments of other rocks, except for limestones and dolomites with marine fossils in the Muschelkalk. The Bunter is composed mainly of sandstones with some shale and conglomerate; divisions that are recognized are chiefly lithological. In places the upper Bunter has marine faunas and indicates the initial phases of the incursion of the Muschelkalk sea. The fauna of the Muschelkalk is characterized by peculiar endemic types that are not particularly diverse in kind but abundant in individuals. The commonest fossils are ammonites of the genus *Cerutites.* The Keuper is composed mainly of mottled red clays, containing masses of gypsum and salt and also bright coloured sandstones and thin impure limestones and dolomites. The lower division of the Keuper, the Lettenkohle, represents a regressive facies of the retreating Muschelkalk sea leaving lagoons and swamps. The sequence contains a mixture of marine, brackish water and continental facies. The overlying Gypskeuper is mainly of continental origin.

In Great Britain the Germanic facies is also present but represented by only the Bunter and Keuper, the Muschelkalk seas never reaching there. The Triassic occurs chiefly in a Y-shaped outcrop belt across central England, with outlying patches. The Bunter is represented mainly by sandstones with conglomerate bands. The Keuper is made up of marls and sandstones with thick beds of gypsum and salt.

The Triassic strata of France, Spain, Sardinia, Corsica and hlorocco are of Germanic facies. The Muschelkalk of Spain and Sardinia, however, contain some marine faunas of Alpine affinities indicating at least partial connection to the east.

Alps.—The classic area of the Triassic of the Alpine facies is in the eastern Alps where carbonate facies prevail. Because of complex facies changes and the recumbent fold (nappe) structure of the Alps (*q.v.*) only the barest. outline of Triassic history or formations can be given here.

In the northern calcareous Alps, the Lower Triassic consists of sandstones, conglomerates and shales. The Anisian'stage is represented by sandy marls and limestones with brachiopods and ammonites. The Ladinian comprises two facies, a lower shale formation with ammonites and brachiopods overlain by thick reef carbonate facies. The Karnian is a marginal shallow-water sandstone facies, but the Norian and Rhaetian are represented by thick, massive dolomite formations. In many places the Rhaetian consists of platty marls and limestones.

To the south in the Dolomite Alps the Scythian stage consists of shales, sandstones and marls with a small pelecypod fauna and rare ammonites. The Anisian is represented by a sandy cephalopod limestone, overlain by dolomites. The Ladinian is a complex of volcanic deposits, reef limestones and dolomites and cephalopod marls. Most of these facies are richly fossiliferous. The Karnian is represented also by a similar complex of facies and the Norian by massive dolomites.

Thus in the eastern Alps there is to the north a mainly shallow-water facies with ammonites common only in the Anisian limestones. In the Dolomite Alps, reefy dolomites and limestones predominate. In both regions the Lower Triassic is a shallow-water, and even lagoonal, clastic facies. Between the northern and southern areas of the eastern Alps mentioned, through the Middle and Upper Triassic are other carbonate facies, with abundant cephalopod faunas, that are thought to represent deeper water deposits. Table II summarizes the stratigraphy of the Triassic in the eastern Alps.

TABLE 11.—*Stratigraphy of Triassic in the Eastern Alps*

Stage	North	Central	South
	Bavarian nappe	Hallstatt nappe	Dolomite Alps
Rhaetian	Marls and limestones	Marls	Absent
Norian	Dolomite	Hallstatt limestone	Dolomite
Karnian	Beds with *Cardita*		Raibl beds
Ladinian	Wetterstein limestone Partnach shales	Dolomites or limestones with cephalopods	Marly facies (with tuffs), St. Cassian } Coral facies Wengen, Buchenstein } Schlern Dolomite
Anisian	Virgloria limestone Sandy marls		Dolomites Sandy limestone with cephalopods
Scythian	Sandstone, conglomerate	Werfen sandstone and shale	Sandstone and shales

Asia.—The classic area of Triassic rocks in the eastern Tethys is in the Himalaya mountains at Spiti. Garhwal, Kumaon and Kashmir. The exposures at Spiti are well developed and fossiliferous. The Lower Triassic (Scythian) consists of 50 ft. of dark coloured shales and limestones conformable to the underlying Productus shales of Permian Age. The rich ammonite fauna represents several of the Scythian ammonoid zones. The Anisian stage is represented by limestones containing an extremely diverse ammonoid fauna. The Ladinian consists of thin black limestones and shales containing Daonella, a bivalve rnollusca, and ammonoids. The whole Middle Triassic is around 400 ft. thick. The Upper Triassic is 2,800 ft. thick at Spiti, consisting of shale and limestone in the lower part and dolomite and limestone in the upper part. The lower part includes the Karnian and Norian stages and is richly fossiliferous. the upper part is generally unfossiliferous and of Rhaetian age. The Triassic of Kashmir consists mainly of limestone and dolomite facies that are generally not as fossiliferous as those of Spiti. In the region of Mount Sirban, south of Abbottabad, the Lower and Middle Triassic is represented by volcanic deposits overlain by Upper Triassic limestones.

The Salt range of Pakistan is one of the more important localities for study of the Scythian stage. The Lower Triassic strata, called the Ceratite beds, are less than zoo ft. thick and consist of limestone. sandstone and marls with an abundant and diverse fauna of ammonoids. Incomplete and poorly known Middle and Upper Triassic formations also occur in the Salt range. All the Triassic facies in the Salt range are shallow-water shelf deposits.

The Triassic rocks discussed so far for India and Pakistan are all of marine origin and part of the Tethyan geosyncline. Throughout geologic history after the Pre-Cambrian. peninsular India has been a prominent stable shield area in contrast to the highly unstable geosynclinal area of north India. Kashmir and Pakistan. The most significant depositional phase on the peninsula was from Late Carboniferous to Lower Cretaceous time when a vast thickness of continental sediments accumulated in linear, local depressions, or grabenlike basins.

This sedimentary complex makes up the Gondwana series (see INDIA: Geology: *Peninsular* India). The beds of the Triassic Age are mainly sandstones and shales.

Indonesia.— Throughout this area there is a varied complex of Triassic strata representing a highly involved depositional history. The most classic region is the island of Timor where extremely abundant and diverse Triassic faunas and facies are present. From the island of Timor about 900 species of invertebrates have been described. The Scythian stage is represented by a cephalopod limestone facies. The Anisian is a limestone facies rather similar to the Hallstatt facies of the Alps. This facies contains mainly cephalopods and some pelecypods and gastropods, there is also an Anisian brachiopod marl facies. In the Ladinian three distinct facies are recognized (1) a cephalopod limestone facies of dark, brownish-red crinoidal limestone with cephalopods and pelecypods, interbedded with a dark red limestone uithout cephalopods but filled nith *Daonella* indica; (2) the Halobia facies of brown, red claystone, clay shale, marl, radiolarian chert, siliceous limestone, siliceous shale and limestone with Halobia and Daonella; and (3) an Alpinelike flysch (*q.v.*) facies of poorly fossiliferous sandstone, calcareous sandstone and graywacke. rich in plant remains, echinoderm breccias and conglomerate.

The Karnian stage shows four distinct facies: (1) a cephalopod limestone facies in which the lowest Karnian zone is a three-foot tuffaceous limy marl. This is overlain by a seven-foot pale, reddish, manganese coated limestone which contains an extraordinarily rich fauna of 462 species of ammonites. jo species of nautiloids. 12 species of orthocerids. 20 species of belemnoids, 32 species of pelecypods. 26 species of gastropods, 2 species of brachiopods, hydrozoa, crinoid stems and segmented worms (serpulids). The ammonites are a mixture of middle and upper Yarnian and Norian elements; the clamlike mollusca Halobia facies; the flysch facies with *Halobia*,.calcareous shale and thin chert beds; and finally a reef limestone facies.

The Norian rocks reach the highest facies development. There is a cephalopod limestone facies, a Halobia facies, a flysch facies and a reef facies. The latter. called the Fatukalksteinfacies. is a massive limestone composed of coralline material, oolitic material or fine echinoderm fragments. Parts of this facies of stratified limestone contain pelecypods, brachiopods and a few ammonites. The Rhaetian is a bituminous series. In places bedded marly limestone and shale contain liquid petroleum and pelecypods and ammonites.

Australia and New Zealand.— The essential features of the tectonic framework, or crustal structure! of this continent were formed by the end of the Paleozoic era. The Tasman geosyncline which had occupied much of eastern Australia since the Cambrian had been completely consolidated. What little Triassic there is in Australia was deposited in remnants of Late Paleozoic Age coal basins or in faulted basins. Deposits of this age are known only in extreme southeastern Queensland, eastern New South Wales and eastern Tasmania. The Triassic rocks are mainly continental sandstones and shales that in places have important coal seams. Plants and vertebrates are the commonest fossils but in New South Wales some beds contain marine ostracods and foraminifera.

If rocks of the Recent and Pleistocene epochs are excepted, the New Zealand rock sequences can be divided into three parts. each forming a well-defined natural unit without major unconformities. The lower division includes the Lower Paleozoic, the middle division the Upper Paleozoic and Lower Mesozoic and the upper division the Upper Cretaceous and Cenozoic. Two distinct facies complexes are recognized in the middle division formations, the Alpine and Hokonui. Both facies are very thick graywacke, arkose, mudstone and conglomerate complexes with some volcanic rocks. Details of the stratigraphy have been poorly known because of extremely complex structure, homogeneity of facies and sparsity of fossils. The little paleontological data available shows that most stages of the Triassic are represented.

Japan.——Triassic formations are present in many widely scattered but small, restricted areas. Where present they rest unconformably on Paleozoic strata and are also unconformable to the overlying Jurassic formations. A significant unconformity within the Triassic sequence, the Akiyoshi orogenic (mountain-building) movement of Ladinian age, makes a convenient lower and upper division which show great contrast in facies and thickness. The lower (preorogenic) part generally consists of thick marine fine-grained clastic sediments. The upper part consists, on the one hand, of thin sediments formed on a neritic shelf, that is, not more than 600 ft. deep (see MARINE BIOLOGY), to the east of the orogenic zone and, on the other, of conglomerates, sandstones and shales of mixed marine, lacustrine and continental origin. This latter facies is thought to have been laid down within the orogenic zone. All of the above facies are predominantly clastic; limestones are rare and volcanic rocks unknown. In addition to these facies there are in extreme southeastern Japan thick fine-grained sediments which contain much chert, but little limestone and almost no conglomerate. This series is thought to represent a continuous depositional series from Permian through Jurassic. The unconformities noted above did not affect this area.

The Triassic occurrences may be classified into those of the Kitakami mountain land, of the inner side of southwestern Japan and of the outer side of the southwestern Japan.

Kitakami Mountain Land. — Resting unconformably on Permian Toyoma series are 9,800 ft. of sandy shale, sandstone, a little limestone and conglomerates of the Inai group. The lower part of this group has yielded Scythian fossils and the upper part Anisian fossils. An unconformity exists in the middle of the Inai group.

Unconformably overlying the Inai group are 650 ft. of sandstone, shale and conglomerate of the 'Saragai group which contain pelecypods of Norian age (Entomonotis ochotica, etc.).

Inner Side of Southwestern Japan. — This region is characterized by scattered occurrences of clastic sediments deposited within the orogenic area. Marine. continental and brackish water facies are represented. Most of these formations are of Upper Triassic age. Both marine invertebrates and land plant fossils are present.

Outer Side of Southwestern Japan. — This is an area of extremely complicated structure. Various beds of Early to Late Triassic Age are identified from their fossils but their stratigraphical relations are much in doubt. On the island of Shikoku are many areas of clastic rocks that have yielded Middle and Upper Triassic pelecypods and a few ammonites.

Africa. — The Triassic in south Africa comprises the major part of the Karroo system, a thick sedimentary complex of continental origin spanning Upper Carboniferous to Lower Jurassic time (see also AFRICA: Geology). The Triassic rocks are divided into a Beaufort series overlain by the Stormberg series. The sequence is as follows:

Stormberg series	Drakensberg volcanics	Lower Jurassic
	Cave Sandstone	Triassic
	Red beds	
	Molteno beds	
Beaufort series	Upper	
	Middle	
	Lower	
		Upper Permian

The Beaufort series consists of highly coloured shales, mudstones and intercalated sandstone beds. The series is especially known for the rich and varied fauna of fossil reptiles it has yielded. Aside from the reptiles, plant fossils of the *Glossopteris* flora are also fairly common. The Molteno beds are dull coloured sandstones and shales with some workable coal seams; the Red beds are highly coloured sandstones and shales conformable to the underlying Molteno beds; the Cave Sandstone is a light coloured, fine grained massive rock primarily of aeolian origin; the Drakensberg volcanics are a thick succession of lavas, in places 4,000 ft. thick, which are thought by some authorities to be of Late Triassic (Rhaetian) Age. All of the formations are thickest in the Cape regions of the Union of South Africa and thin northward toward Rhodesia.

The lithologic character of the sedimentary succession of the Karroo formations and their fauna and flora have many similarities to rock successions of the same age in South America (Argentina and Brazil) and peninsular India. This similarity has led to the thesis that all of these continental areas were once connected, forming the vast continent of Gondwanaland (*q.v.*). This is a very controversial hypothesis. Few people in the northern hemisphere accept the ideas of continental connections of these southern lands during the geologic past. Most geologists in the southern hemisphere are strong supporters of the idea.

South America. — By the end of the Paleozoic, geosynclinal conditions persisted only in the region of the present Andes cordillera. The remainder of the continent was emergent and the site of continental deposition in scattered regions. Marine and continental Triassic formations crop out in the Andean mountain chain in isolated areas from Colombia southward to the southern part of Chile. These formations are everywhere unconformable upon older rocks ranging in age from Pre-Cambrian to Permian. The Triassic rocks in Colombia consist of a thick series of marine and continental formations. The marine part of this sequence (Payande formation) contains pelecypods and ammonoids of Norian age. This formation is transitional upward with a volcanic series of flows, tuffs and breccias of uppermost Triassic Age.

Limestones with Norian fossils crop out in northern and central Peru where they are respectively named the Utcubamba and Pucara formations. The key guide fossil in these areas as well as in Colombia is Entomonotis ochotica, a Norian pelecypod of circum-Pacific distribution.

Various isolated localities of marine and continental Triassic strata are known from Chile. Fossils are generally very scarce but in the marine strata a few supposed Karnian pelecypods and ammonites have been found. The continental strata have yielded Rhaetian plants.

An area of more than 800,000 sq.km. in southern Brazil, northern Argentina, Uruguay and Paraguay was the site of tremendous deposition, mainly continental, in Late Paleozoic and Early Mesozoic times. The Triassic is represented by the Santa Maria formation of red sandstone and shale containing an Upper Triassic or latest Middle Triassic vertebrate fauna; this is overlain disconformably by a thick aeolian sandstone, the Botucatu sandstone.

North America.—Geosynclinal and shelf seas were confined to the western part of the continent covering western Mexico, the Rocky mountain and Pacific coast states, western Canada and Alaska. The Arctic islands of Canada and northern and eastern Greenland were also periodically inundated by Triassic seas. Continental deposits of this age are known in the eastern United States from Florida (subsurface data) to Nova Scotia and in the western United States in Wyoming, Utah, Colorado, New Mexico and Texas.

In the geosynclinal area of western North America a highly complex and varied sequence of Triassic facies, many richly fossiliferous, are present. The western portion of this vast geosynclinal tract is characterized by presence of thick volcanic accumulations along with a varied suite of sedimentary rocks. The eastern half of this geosynclinal region has no volcanic materials and the sedimentary facies consist of shallow water limestones, sandstones and shales that grade eastward into nonmarine red bed formations. This general pattern of facies had persisted since the Early Paleozoic. At the end of the Lower Triassic the seas retreated from the eastern geosynclinal region in the United States, and through Middle and Upper Triassic time the seas were confined to a region west of a north-south line through central Nevada. The area east of this line, which formerly had been covered by geosynclinal seas, became the site of active continental deposition during the Upper Triassic and following Jurassic. To illustrate the lithologic character of the strata in the western. volcanic part of the geosyncline the region of southwestern Nevada is classic. The Lower Triassic (Candelaria formation) is represented by 3,000 ft. of marine shales and limestones with tuffaceous sandstones unconformably overlying Permian and older rocks. The Middle Triassic is represented by first a marine limestone and shale formation (Grantsville) and a volcanic sequence with some lenses of shale and limestone (Excelsior formation). This volcanic formation may be in part equivalent to the Grantsville formation. Unconformably above, the Upper Triassic consists of a varied sequence of marine shales and limestones nearly two miles thick which grade without change into the overlying Lower Jurassic.

From California north through southern Alaska no Lower or Middle Triassic is present, only Upper Triassic strata consisting of sedimentary and volcanic rocks. From northern Alaska eastward through the Arctic islands of Canada to Pearyland are many areas of Triassic rocks; poorly known except that in one place or another a nearly complete sequence of marine faunas occur.

East Greenland has various areas with marine Lower Triassic rocks of a near shore facies that have yielded an abundant ammonite fauna nearly identical with those from the classic Himalayan sections.

Continental Triassic deposits are exposed along the Atlantic coast and in the Rocky mountain — Colorado plateau region. The exposures in eastern North America are confined to a series of isolated troughs from Nova Scotia south to North Carolina. This is the area of the former Appalachian geosyncline which underwent its final orogenesis in the Late Paleozoic. After the orogenic phase a series of downwarped and faulted troughs developed within this new mountain system. Sediments from the adjoining highlands poured into the troughs, forming thick deposits of sandstones, shales and conglomerates representing fan, stream and lake deposits. Associated with the sedimentary deposits are igneous rocks in the form of flows, sills and dikes. These Triassic deposits are known as the Newark group and are all Upper Triassic in age. No marine fossils are known from the Newark group but land plants, fresh-water fish and dinosaur tracks are fairly abundant.

A sequence of terrestrial or marginal clastic rocks tentatively classified as Triassic was penetrated in 12 scattered oil-test wells in southeast Alabama, southwest Georgia and north-central Florida. Lithologically, the subsurface sedimentary rocks are closely similar to rocks of the Triassic Newark group, that crop out at various localities along the Atlantic seaboard from Massachusetts to North Carolina; also. like the Newark group, intrusions and flows of diabase and basalt cut the Triassic (?) strata in several wells.

In the Colorado plateau area Lower Triassic deposits are termed the Moenkopi formation; to the west and north these grade into marine formations. The Moenkopi consists of dark-red sandstone, siltstone, interbedded gypsum and some marine limestones in its more western exposures. The vertebrate fauna contained in these beds resembles that of the Early Triassic of Spitzbergen and the Bunter of Germany. Unconformably overlying the hloenkopi and overlapping it extensively to the east is the Chinle formation, with a basal sandstone or conglomerate often separately recognized as the Shinarump. In eastern New Mexico and western Texas equivalents of the Chinle are termed the Dockum group. From the Wind River mountains of Wyoming east into South Dakota extensive Triassic red beds are designated as the Chugwater and Spearfish formations. All of these formations are Upper Triassic in age and contain only fair fossil faunas of reptiles, amphibians and fish. Konmarine formations of Rhaetian age (Wingate sandstone. Moenave formation; and possibly the Kayenta formation) are widespread in southwestern United States.

Arctic Region. — The continental areas marginal to the Arctic ocean have extensive development of Triassic formations. Besides those on the northern margin of North America that have already been mentioned, marine formations of the Triassic Age are known from Spitzbergen, Bear Island. New Siberian islands, and the coast of Siberia off the Laptev and East Siberian seas.

The best known of these regions is Spitzbergen where a thick fossiliferous sequence is fairly well known. The lowest Triassic formations consist of sandstones. calcareous sandstones and marly limestones. poor in fossils: resting unconformably on 'the underlying Permian. The higher strata of the Lower Triassic and the Middle Triassic are represented by black and gray sandy marls and shales rich in the fossil remains of reptiles, fish, ammonites and pelecypods. Toward the close of the Middle Triassic there was a general regression of the seas and a mixed succession of marine and nonmarine formations was formed. The nonmarine formations frequently contain coal beds. With the advent of the Cpper Triassic another general inundation took place and an alternating sequence of fossiliferous marine calcareous and arenaceous beds accumulated. During the Rhaetian the seas again retreated from Spitzbergen.

(B. KL.)

TRIBALLI, in ancient geography, a Thracian people whose earliest home was near the junction of the Angrus and Brongus (the east and west Morava), and included toward the south "the Triballian plain" (Herodotus iv, 49), which corresponds to the plain of Kossovo in Turkey.,

In 424 B.C. they were attacked by Sitalces, king of the Odrysae, who was defeated and lost his life in the engagement. On the other hand they were overcome by the Autariatae. an Illyrian tribe; the date of this event is uncertain (Strabo vii, 317). In 376 B.C. a large band of Triballi crossed Mt. Haemus, and were preparing to besiege Xbdera when Chabrias appeared off the coast with the Athenian fleet and compelled them to retire. In 339 B.C. when Philip II of Macedon was returning from his expedition against the Scythians, the Triballi refused to allow him to pass the Haemus unless they received a share of the booty. Hostilities took place, in which Philip was defeated (Justin ix, 3), but the Triballi appear to have been subsequently subdued by him. After the death of Philip, Alexander the Great in 334 crossed the Haemus and drove the Triballi to the junction of the Lyginus with the Danube. Their king Syrmus took refuge in Peuce, an island in the Danube, whither Alexander was unable to follow him. The punishment, however. inflicted by him upon the Getae (*q.v.*) induced the Triballi to sue for peace. In spite, however, of misfortunes at the hands of the Gauls, they continued (135–84 B.C.) to cause trouble to the Roman governors of Macedonia. Under Tiberius mention is made of Triballia in Moesia, and the Emperor Maximin (A.D. 235–237) had been commander of a squadron of Triballi.

TRIBE. W. H. R. Rivers defined a tribe as "a social group of a simple kind, the members of which speak a common dialect, have a single government, and act together for such common purposes as warfare." Other typical characteristics include a common name, a contiguous territory, a relatively uniform culture or way of life and a tradition of common descent. Tribes are usually composed of a number of local communities, *e.g.*, bands, villages or neighbourhoods, and are often aggregated in clusters of a higher order called nations. The term is seldom applied to societies that have achieved a strictly territorial organization in large states but is usually confined to groups whose unity is based primarily upon a sense of extended kinship ties. It is no longer used for kin groups in the strict sense, such as clans.

All the elements in the above definition are subject to exceptions. Thus the Amba of Uganda are considered one tribe though they speak two mutually unintelligible languages; the Zuiii "tribe" comprises only a single community; the Kiowa Apache constitute one band of the larger Kiowa tribe; the Dorobo tribe of Kenya live scattered among the Kandi and blasai for whom they hunt and perform ritual services. The criterion of political integration. in particular, is inapplicable to many primitive peoples. *e.g.*, of Australia. Melanesia, Amazonia and western North America, among whom each community may be politically autonomous. Anthropologists, nevertheless, are accustomed to divide such peoples into "tribes" on the basis of linguistic and cultural resemblances. Sometimes a cluster of independent local groups forms an intermarrying unit or maintains peaceful trade relations or is unified by a common cult or age-grade organization, despite the lack of political integration, but oftentimes all that distinguishes it from other clusters is a common dialect and culture. For this reason there has been a discernible recent trend toward employing the term tribe for any group that can be isolated as the carrier of a distinctive culture, at least in the absence of territorial states.

Where the latter have developed, the term nation is preferred to designate the comparable but larger culture-bearing groups. *See* also Index references under "Tribe" in the Index volume

TRIBONIAN (TRIBONIANUS) (d. *c.* A.D. 545), Justinian's legal adviser and minister, chiefly responsible for the codification of the law, was probably born in Pamphylia in the late 5th century. He practised as an advocate at Constantinople, where he attracted the attention of Justinian and thereafter enjoyed imperial favour. He was appointed *magister officiorum* (A.D. 528) and *quaestor sacri palatii* (A.D. 530), a minister not unlike the late medieval English chancellor. From this office Justinian removed him in A.D. 532, yielding to the mob in the Kika riot, but Tribonian was restored in A.D. 534 and apparently remained *quaestor* until his death, about A.D. 545. Tribonian's personal character was attacked by the contemporary author Procopius, who accused him of venality and religious unorthodoxy, but the charges are not necessarily reliable and may be, in part, misconceived. Tribonian was a versatile man and his interest in philosophy, astronomy and the calendar may be the source of the charge of atheism.

His great interest, however, was the law, and it is as the principal agent of the codification which distinguished Justinian's reign that Tribonian is renowned. It may be, indeed, that he was in large measure its instigator. He appears first as a member of the commission which produced the first *Codex* of imperial legislation in A.D. 529. In A.D. 530 he was president of the commission compiling the *Digest,* excerpting extracts from the works of the great jurists of earlier times, and Justinian himself acknowledged the benefit derived by the commission from Tribonian's own private library of older legal works. It was again to Tribonian (with two others) that the emperor entrusted the preparation of an elementary handbook, the *Institutes,* published before the *Digest* at the end of A.D. 533. Finally, Tribonian was president of the commission which, in A.D. 534, produced a completely revised *Codex.* In the codification, the various commissions were empowered to amend and alter the texts they used where they felt such course necessary. It is a measure of Tribonian's pre-eminence that scholars designate such alterations *emblemata Triboniani.* After the second *Codex,* Tribonian remained Justinian's legal adviser and was doubtless responsible for the earlier *Novellae,* enactments subsequent to the codification. It is noticeable that Justinian legislated less after Tribonian's death. *See* also JUSTINIAN I.

TRIBUNE (Lat. *tribunus,* connected with *tribus,* "tribe"). a name assigned to officers of different descriptions in ancient Rome.

Military Tribunes. — The original tribunes were the commanders of the contingents of cavalry and infantry supplied to the Roman army by the early tribes: the Tities, the Ramnes, and the Luceres. The *tribuni celerum,* or commanders of the horsemen, no longer existed in the later times of the republic. So long as the monarchy lasted these tribunes were nominated by the king as commander in chief; and the nomination passed over to his successors, the consuls. From 362 B.C. six tribunes were annually nominated by popular vote, in 311 B.C. the number was raised to 16, and in 207 B.C. to 24, at which figure it remained. The rights of the assembly passed to the emperors, and "the military tribunes of Augustus" were still contrasted with those nominated in the camp by the actual commanders. (For *Tribuni aerarii, see* AERARIUM.)

Tribunes of the Plebs. — The most important tribunes were the tribunes of the *plebs (tribuni plebis).* These were the outcome of the struggle between the patrician and the plebeian orders. When in 494 B.C. the plebeian legionaries met on the Sacred Mount, it was determined that the plebeians should by themselves annually appoint executive officers, two tribunes to confront the two consuls and two helpers, called *aediles,* to balance the *quaestors,* and that the persons of the tribunes and aediles should be regarded as inviolable. The ancient traditions concerning the revolution are extremely confused and contradictory. It must have ended in something which was deemed by both the contending bodies to be a binding compact, although the lapse of time has blotted out its terms. This is necessary to explain the "sacrosanct" character always attached to the tribunate. There must have been a formal acceptance by the patricians of the plebeian conditions; probably the oath which was first sworn by the insurgents was afterward taken by the whole community, and the "sacrosanctity" of the plebeian officials became a part of the constitution. There must also have been some constitutional definition of the powers of the tribunes. These rested at first on an extension of the power of veto which the republic had introduced. Just as one consul could invalidate an order of his colleague, so a tribune could invalidate an order of a consul, or of any officer inferior to him. There was, no doubt, a vague understanding that only orders which sinned against the just and established practice of the constitution should be annulled, and then only in cases affecting definite individuals.

Development of the Tribunate.—Although the revolution of 494 B.C. gave the tribunes a foothold in the constitution, it left them with no very definite resources against breaches of compact by the patricians. The traditional history of the tribunate from 494 to 451 B.C. is obscure; we hear of attacks by patricians on the newly won privileges, even of the assassination of a tribune, and of attempts on the part of the plebeians to bring patrician offenders to justice. The plebeians attempted to set up a criminal jurisdiction for their own assembly parallel to that practised by the older centuriate assembly. Furthermore, the *plebs* attempted something like legislation; it passed resolutions which it hoped to force the patrician body to accept as valid. As to details, only a few are worth notice. In the first place, the number of tribunes was raised to ten; how we do not know, but apparently some constitutional recognition of the increase was obtained. Then an alteration is made in the mode of election. As to the original mode, the authorities are hopelessly at variance. It was in accordance with the Roman spirit of order that the tribunes, in summoning their assemblies, should ask the plebeians to organize their supporters in bands. The *curia* was certainly a territorial district, and the tribunes may have originally used it as the basis of their organization. If tribunes were elected by plebeians massed *curiatim,* such a meeting would easily be mistaken in later times for the *comitia curiata.* A change was introduced in 471 B.C. by the Publilian Law of Volero, which directed that the tribunes should be chosen in an assembly organized on the basis of the Servian tribe, instead of the *curia.* This assembly was the germ of the *comitia tribute.* The question by what authority the Law of Volero was sanctioned is difficult to answer. Possibly the law was a mere resolution of the plebeians with which the patricians did not interfere, because they did not consider that the mode of election was any concern of theirs. Whatever view may be taken of the movement which led to the decemvirate, an important element in it was the agitation carried on by the tribunes for the reduction of the law of Rome to a written code. Until they obtained this, it was impossible for them to protect those who appealed against harsh treatment by the consuls in their capacity of judges.

During the decemvirate the tribunate was in abeyance. It was called into life again by the revolution of 449 B.C., which gave the tribunes a considerably stronger position. Their personal privileges and those of the aediles were renewed. The road was opened up to legislation by the tribunes through an assembly summoned by them on the tribe-basis *(concilium plebis),* but subject to the control of the senate. The growth of the influence of this assembly over legislation belongs rather to the history of the *comitia* (*q.v.*) than to that of the tribunate. After the Hortensian Law of 287 B.C., down to the end of the republic, the legislation of Rome was mainly in the hands of the tribunes. The details of the history of the tribunate in its second period, from 449 to 367 B.C., are hardly less obscure than those which belong to the earlier time. There was, however, on the whole, undoubtedly an advance in dignity and importance. Gradually a right was acquired of watching and interfering with the proceedings of the senate, and even with legislation. Whether the absolute right of veto had been achieved before 367 B.C. may well be doubted. But the original auxilium, or right of protecting individuals, was, during this period, undergoing a very remarkable expansion. From forbidding a single act of a magistrate in relation to a single person, the tribunes advanced to forbidding by anticipation all acts of a certain class, whoever the persons affected by these restrictions might prove to be. It therefore became useless for the senate or the comitia to pass ordinances if a tribune was ready to forbid the magistrates to carry them out. Ultimately, the mere announcement of such intention by a tribune was sufficient to cause the obnoxious project to drop; that is, the tribunes acquired a right to stop all business alike in the deliberative assembly, the senate, and in the legislative assemblies, or comitia. The technical name for this right of veto is intercessio. The two main objects of the tribunes were the opening of the consulate to plebeians, and the regulation of the state domain in the interests of the whole community. Both were attained by the Licinio-Sextian laws of 367 B.C.

Then a considerable change came over the tribunate. From being an opposition weapon it became an important wheel in the regular machine of state. As the senate became more and more plebeian, the old friction between senate and tribunes disappeared. It was found that the tribunate served to fill some gaps in the constitution, and its power was placed by common consent on a solid constitutional basis. From 367 to 134 B.C. (when Tiberius Gracchus became tribune) the tribunate was for the most part a mere organ of senatorial government.

Qualifications and Powers.—Even after the difference between patrician and plebeian birth had ceased to be of much consequence, the plebeian character was a necessity for the tribune. When the patricians P. Sulpicius Rufus and, later, P. Clodius (the antagonist of Cicero) desired to enter on a demagogic course, they were compelled to divest themselves of their patrician quality by a peculiar legal process. The other necessary qualifications were such as attached to the other Roman magistracies: complete citizenship, absence of certain conditions regarded as disgraceful, and fulfilment of military duties. The election took place in a purely plebeian assembly, ranged by tribes, under the presidency of a tribune selected by lot. The tribune was bound by law to see a complete set of ten tribunes appointed. Technically, the tribunes were reckoned, not as magistrates of the Roman people, but as magistrates of the Roman plebs; they therefore had no special robe of office, no lictors, but only messengers (viatores), no official chair, like the curule seat, but only benches (subsellia). Their right to summon the plebs together, whether for the purpose of listening to a speech or for passing ordinances, was rendered absolute by the "laws under sacred sanction" (leges sacratae), which had been incorporated with the constitution on the abolition of the decemvirate. The right to summon the senate and to lay business before it was acquired soon after 367 B.C., but was seldom exercised, as the tribunes had abundant means of securing what they wanted by pressure applied to the ordinary presidents, the consuls or the praetor. When an interregnum came about and there were no "magistrates of the Roman people," the plebeian tribunes became the presidents of the senate and conductors of state business. At the end of the republic there were interregna of several months' duration, when the tribunes held a position of more than usual importance.

The Right of Veto.—The real kernel of the tribune's power consisted in his intercessio, or right of invalidating ordinances, whether framed by the senate or proposed by a magistrate to the comitia, or issued by a magistrate in pursuance of his office. From 367 B.C. down to the time of the Gracchi the power of veto in public matters was, on the whole, used in the interests of the governing families to check opposition arising in their own ranks. A recalcitrant consul was most readily brought to obedience by an exercise of tribunician power. The tribunes found a field for constant activity in watching the administration of justice, and in rendering assistance to those who had received harsh treatment from the magistrates. The tribunes were, in fact, primarily legal functionaries, and constituted in a way a court of appeal. It was to this end that they were forbidden to pass a whole night away from the city, except during the Latin festival on the Alban Mount, and that they were expected to keep their doors open to suppliants by night as well as by day. They held court by day in the Forum and frequently made elaborate legal inquiries into cases where their help was sought. We hear of this not infrequently in Cicero's speeches, and in other writings which deal with legal matters. According to the general principle of the constitution, magistrates could forbid the acts of magistrates equal to or inferior to themselves. For this purpose, the tribunes were deemed superior to all other officers. If a tribune exercised his veto no other tribune could annul it, for the veto could not be itself vetoed, but it was possible for another tribune to protect a definite individual from the consequences of disobedience. The number of the tribunes made it always possible that one might baulk the action of another, except at times when popular feeling was strongly roused. The veto was not, however, absolute in all directions. In some it was limited by statute; thus, the law passed by Gaius Gracchus about the consular provinces did not permit a tribune to veto the annual decree of the senate concerning them. When there was a dictator at the head of the state, the veto was of no avail against him. One of the important political functions of the tribunes was to conduct prosecutions of state offenders, particularly ex-magistrates. These prosecutions began with a sentence pronounced by the tribune upon the culprit; whereupon, exercising the right given him by the XII. Tables, the culprit appealed. If the tribune sought to inflict punishment on the culprit's person, the appeal was to the assembly of the centuries; if he wished for a fine, the appeal was to the assembly of the tribes.

The Late Republic and Empire.—It is commonly stated that a great change passed over the tribunate at the time of the Gracchi, and that from their day to the end of the republic it was used as an instrument for setting on foot political agitation and for inducing revolutionary changes. This view is an inversion of the facts. The tribunate did not create the agitation and the revolutions, but these found vent through the tribunate, which gave to the democratic leaders the hope that acknowledged evils might be cured by constitutional means, and in the desperate struggle to realize it the best democratic tribunes strained the powers of their office to their ruin. For the bad tribunes did not hesitate to use for bad ends the powers which had been strained in the attempt to secure what was good. But the tribunate only fared like all other parts of the republican constitution in its last period. The consuls and the senate were at least as guilty as the tribunes. After a severe restriction of its powers by Sulla and a restoration by Pompeius, which gave a twenty years' respite, the essential force of the tribunate was merged in the imperial constitution, of which indeed it became the principal constituent on the civil side. The ten tribunes remained, with very restricted functions. The emperors did not become tribunes, but took up into their privileges the essence of the office, the "tribunician authority" (*tribunicia potestas*). This distinction between the principle of the office and the actual tenure of the office was a creation of the late republic. Pompeius, for example, when he went to the east, was not made proconsul of all the eastern provinces, but he exercised in them a "proconsular authority," which was the germ of the imperial authority on its military side. Similarly the emperor, as civil governor, without being tribune, exercised powers of like quality with the powers of the tribune, though of superior force. By virtue of his tribunitian authority he acquired a veto on legislation, became the supreme court of appeal for the empire, and to his person was attached the ancient sacrosanctity. Augustus showed the highest statesmanship in founding his power upon a metamorphosed tribunate rather than upon a metamorphosed dictatorship, upon democratic rather than aristocratic traditions.

Rienzi.—The name "tribune" was once again illuminated by a passing glory when assumed by Cola di Rienzi (*q.v.*). The movement which he headed was in many respects extremely like the early movements of the plebeians against the patricians, and his scheme for uniting Italy in one free republic was strangely parallel with the greatest dream of the Gracchi.

TRICAMERON, BATTLE OF (A.D. 533). This battle, the second major engagement in the campaign led by Belisarius to restore Vandal Africa to the power of Justinian (see JUSTINIAN I), completed the defeat of the Vandal king Gelimer (Geilimir), Tzazo his brother and the whole Vandal army. The Roman provincials had no love for their Vandal masters and favoured the Byzantine army, advancing professedly as liberators. Gelimer could prevent neither the Byzantine victory at Ad Decimum on Sept. 13, 533 nor the capture of Carthage, his capital, but his remaining army was still much more numerous than that of Belisarius. The final clash came at Tricameron, about 20 mi. W.S.W. of Carthage, in the middle of December. It was a notable battle, because the Byzantines, with cavalry only, attacked and routed a much larger force of horsemen and infantry. According to the account of Procopius the Vandals were drawn up on the bank of a shallow river, with tribunes commanding the wings and Tzazo the centre. Gelimer rode hither and thither haranguing his troops and commanding that the Vandals (as distinguished from the federate horsemen on their wings) should use no throwing weapon but only their swords—a defensive measure. Belisarius, arriving hastily with the cavalry and in advance of his infantry, would not wait to give battle but drew up his line with his federates on the wings and the Byzantine general John with the praetorian standard in the centre. At his order John and his small cavalry force crossed the river and attacked. The Vandals repulsed them, but could not cross the river themselves, not being on horseback. Twice more John crossed the river and attacked, the third time advancing with the whole army and the praetorian standard, whereupon the Vandal centre broke, Tzazo was killed, and Gelimer fled. (M. DY.)

TRICERATOPS, the best-known member of the horned dinosaur group (Ceratopsia) of the Upper Cretaceous. This was a four-footed dinosaur about 20 ft. long. Its head bore a pair of long brow horns and a smaller horn over the nose; a large bony frill protected the neck. (See DINOSAURIA.) (A. S. RR.)

TRICHINOPOLY (TIRUCHIRAPALLI), a city and district of Madras state, Republic of India. The city is on the right bank of the Cauvery river, 180 mi. by rail S.W. of Madras. Pop. (1951) 218.921. The fort which forms the nucleus of the city measures about 1 mi. by ½ mi.; its defenses have been removed. Within it rises, 273 ft. above the city, the isolated Trichinopoly rock, upon which is a temple reached by a covered stone staircase, entered by a carved gateway and profusely ornamented. Trichinopoly is an important trading centre and railway junction. Its industries are goldsmiths' work and modelling in pith, silk weaving, cigar and soap making. Trichinopoly and its neighbourhood was the scene of much hard fighting between the English and the French during the Carnatic wars between 1749 and 1761.

The DISTRICT OF TRICHINOPOLY has an area of 5,514 sq.mi. Pop. (1951) 2,943,882. It is a flat plain bisected by the Cauvery river, but there are a few rocky heights in the south and southwest. The chief crop is paddy, a little sugar cane is also grown. There are large deposits of gypsum, phosphate rock and limestone. In March 1948 the princely state of Pudukkottai was merged into the district. (S. GL.)

TRICHINOSIS (TRICHINIASIS), a disease in man and other animals caused by infection with the parasite Trichinella *spiralis*. The parasite was named by Sir Richard Owen on the basis of encysted trichinae discovered in human muscle by Sir James Paget in 1835. The larvae were first found in the muscle tissue of swine by Joseph Leidy in 1846. The complete life cycle was elucidated in 1859 by Rudolf Leuckart and Rudolf Virchow, who, working independently, found the adult worms in the intestinal tract. The clinical character of the acute disease caused by the invasion of the parasite was demonstrated by Friedrich von Zenker in 1860. Following Zenker's discovery, severe outbreaks of the disease were recognized in Prussia and other parts of Germany. (W. H. WT.)

Trichinosis is acquired by eating uncooked or inadequately cooked flesh containing infective encysted larvae, which, after release from their cysts, migrate from the stomach to the small intestine, in the wall of which they embed themselves. There the male and female worms rapidly develop to maturity, reaching lengths of approximately $\frac{1}{16}$ and $\frac{1}{6}$ in., respectively. After mating, birth of minute living young may take place for six weeks or longer. These larvae enter the lymph spaces in the intestinal wall and are carried to the heart, from which they reach the general circulation. They penetrate into many tissues. but further growth occurs only in voluntary muscle fibres. Within approximately 30 days the larvae reach a length of $\frac{1}{25}$ in., and are spirally coiled. They are gradually enclosed in cysts, and may remain alive for many years, or may die and be absorbed, or become calcified. Trichinae become infective after approximately 14 days' development in muscle; when they are ingested alive by another animal, the cycle described above is repeated.

Symptoms. — The clinical manifestations of trichinosis are in general related to the number of worms developing in a particular infection, the most severe illness usually being associated with large numbers of organisms. Persons contracting light infections may show no evidence of ill-health. Diagnosis of sporadic cases is difficult because the symptoms simulate closely those of many other conditions. Nausea, vomiting, diarrhea and abdominal pain may appear within 24 to 48 hours, related to development of worms in the intestine. Such symptoms may be absent, but those arising from the migration of larvae through the body may be detected between one and three weeks after infection. They include weakness, fatigue, headache and fever accompanied by chills and sweats; some patients have sore throat or laryngitis with cough. Swelling around the eyes and face is a common symptom. A rash may be present on the trunk and upper extremities.

When the larvae begin to reach the muscles, pronounced muscle pain and stiffness of the joints are experienced. Symptoms of heart disease may be present, and pneumonia is not an unusual complication. The larvae may invade the spinal cord and brain and give rise to symptoms simulating meningitis. encephalitis or poliomyelitis. The acute phase of the disease lasts from two to three days in mild cases and up to three to four weeks in more severely infected persons. If complications ensue, the course may be prolonged.

After recovery, the muscle pain gradually disappears, and in most cases there are no residual symptoms. The mortality rate of clinically recognized cases is fairly low; in the United States between 1930 and 1938, for example, it was approximately 6%.

Diagnosis and Treatment. — Diagnosis may be aided by laboratory findings. Blood examinations generally reveal an increased white cell count, and increase in eosinophiles is usually but not invariably present. A biopsy of muscle tissue may disclose the larvae. Skin and blood tests are of value but, like the biopsy, are generally not positive until after the larvae have reached the muscles.

Unfortunately, there is no drug of specific value, and treatment is mainly symptomatic. Adrenocorticotropic hormone (ACTH) and cortisone are of considerable benefit in alleviating symptoms during the acute stage.

Incidence and Prevention. — Despite the fact that Trichinella is widespread in many hosts, such as rats, dogs and cats, man, because of his food habits, acquires trichinosis primarily from the consumption of pork. Occasional epidemics have occurred from the ingestion of bear, smoked dog and walrus meat.

It is estimated that approximately 28,000,000 persons throughout the world are infected with Trichinella, and that 21,000,000 of them live in the United States. Probably 350,000 new infections develop in the U.S. each year. The majority of these persons have only light infections and seemingly never suffer ill-health as a result. Only an average of about 300 cases exhibiting clinical symptoms are actually recognized and reported each year. Outbreaks have occurred in most European countries, but incidence of the parasite in England, elsewhere in Europe, Canada and Australia at mid-20th century was only a small fraction of that in the U.S.

Prevention lies in reducing or eliminating the infection in hogs and in the thorough cooking of pork. As a general rule, all pork should be cooked until the pink colour has completely disappeared

(137° F. throughout). In the United States, where feeding of raw garbage to swine is a common practice, approximately 6% of the animals maintained on such food are infected. Undoubtedly, infection is carried through pork scraps in the garbage. The incidence in grain-fed hogs is less than 1%. In European countries for which data are available, only a fraction of 1% of swine carry the parasites; many of these countries require the microscopic examination of pork. Infection in hogs is equally low in England, which requires the cooking of garbage fed to swine. In the United States. federal meat-inspection regulations require processing for the destruction of trichinae of all pork products customarily eaten without cooking (frankfurters, salami, mettwurst, cervelat, etc.); these products are potent sources of infection unless processed to kill the parasite. Protection extends only to such products; there is no federal inspection or treatment of fresh pork or other types of pork products for trichinosis. See also PARASITIC DISEASES. (P. P. W.)

TRICHOPTERA, an order of usually somberly coloured insects commonly known as caddis flies, though they are not true flies (Diptera). See CADDIS FLY.

TRICHUR, a town and district of Kerala, India. The town, formerly in Cochin state and now headquarters of the district, lies 12 mi. inland at the head of an extensive system of backwaters or lagoons within the Malabar coast (*q.v.*), 37 mi. N. of Ernakulam. Pop. (1951) 69,515. It is considered to be the oldest town on the west coast, its origin being ascribed to the legendary Parashurama; its name signifies "a small sacred place." The town is built around a hillock surmounted by the temple of Vatakkuntha ("the god of the north"). Its site off the western spurs of the Anaimalai hills is important, as the north-south traffic in Kerala must pass there.

The Southern railway to the interior and Madras through the gap at Palghat, and the good road connections, much assisted Trichur's development; Trichur is both a commercial and a cultural centre. There is some cotton spinning and weaving and the town contains a museum, a zoological garden and five colleges affiliated to Kerala university.

TRICHUR DISTRICT was constituted from the components of the former princely state of Cochin (*q.v.*). Area 1,149 sq.mi. Pop, (1961) 1,634,251. It is essentially a lowland coastal area broken along the-coast by numerous lagoons, and ridged on the .east by laterite hills and knolls. The chief crops are rice and coconuts, The district is much industrialized, with factories making glass, aluminum, fertilizers and caustic soda at Alwaye. Cranganore, the ancient capital of the Chera kings, lies in the southwest. (V. V. B.; P. B. D.; M. S. H.)

TRICLINIUS, DEMETRIUS (14th century A.D.), the foremost Byzantine scholar of the Palaeologan era, devoted his energies to editing the Greek poets, mainly the tragedians, with metrical and exegetical scholia. These incorporated, beside his own, notes by Thomas Magister and Manuel Moschopoulos, as well as scholia taken from older traditions. Triclinius was the first Byzantine scholar to examine closely the metrical structure of the lyrics of Attic plays; but striving to apply the rules of Hephaestion and misled by his own unsatisfactory views of Greek prosody he often tampered with the text. Most of Triclinius' textual changes have now been discarded, but this does not detract from the importance of his scholarly achievement in its own time.

His text of Aeschylus (Codex *Farnesianus* I.E. 5) survives, probably in his own handwriting, as does his transcript of Hesiod (*Codex Marcianus* Graecus 464); his text of Sophocles (represented in the so-called libri *Tricliniani*) printed by A. Turnebus (1553) became the vulgate of this author until it was superseded by R. F. P. Brunck's edition (1786). Triclinius also wrote scholia to Euripides, Pindar, Aristophanes and Theocritus.

See K. Krumbacher, *Geschichte der Byzantinischen Litteratur*, 2nd ed. (1897) ; A. Turyn, *Studies in the Manuscript Tradition of the Tragedies of Sophocles* (1952). (S. J. PA.)

TRICONODONTA, a group of small, extinct, carnivorous mammals of the Jurassic Age, characterized by the condition of their molar teeth, which typically bore three cusps arranged in a line, the long axis fore-and-aft. They left no descendants. *See* MAMMALIA; MULTITUBERCULATE; PALAEONTOLOGY.

TRICOUPIS (TRICOUPI, TRIKOUPIS), **CHARILAOS** (1832–1896), Greek prime minister, was born at Nauplia in 1832 and studied law and literature in Athens and Paris. After serving in the Greek diplomatic service, he entered the chamber of deputies in 1865 and in the following year was made foreign minister. In 1875 he became prime minister for a few months, but he had no opportunity to begin carrying out his policy—to develop the resources of the country and create an army and navy. In 1882 he became prime minister for the third time (his second period of office, two years earlier, had lasted only a few months) and at once set about the task of putting Greek finance upon a firmer basis and of increasing the prosperity of the country by making roads, railways and harbours. He was defeated in the general election of 1885, but in the following year resumed office.

His difficulties were now increased by the large expenditures which had been incurred for military preparations while he had been out of office (see GREECE: Modern History). Tricoupis, nevertheless, believed that he could raise the value of Greek paper currency to par in a few years, and based his calculations upon that assumption. His dexterity in finance was generally admired, and his schemes for the construction of roads and railways met with a certain amount of success. But Greece could not meet its obligations, and Tricoupis failed in his attempts to make terms with the creditors of the country.

In Jan. 1895 he resigned. At the general election four months later, he and his party were defeated. He retired from public life and died at Cannes, France, on April 11. 1896.

Although Tricoupis has been criticized for being excessively ambitious and far too optimistic, he was regarded, even during his lifetime, as the foremost Greek statesman of his time. By nature he was reserved—his nickname was "the Englishman"—and he had no sympathy with the arts of the demagogue. Both in the ranks of his party and by the country at large, however, his abilities and character were unquestioned. Unfortunately the circumstances of the time did not allow his wide schemes for the benefit of the country to be carried into effect.

TRIDYMITE, a rare mineral consisting of silicon oxide or silica, SiO_2, but differing from quartz in crystalline form. The crystals are small, thin hexagonal plates or scales, which are usually twinned together in groups of three; hence the name, from Greek. meaning "triplet." The apparent hexagonal plates are themselves pseudosymmetric twins of optically biaxial material, but at a temperature of 117° C. these optical anomalies disappear and the plates are then truly hexagonal (β-tridymite). The specific gravity is 2.28 (that of quartz being 2.65). Unlike quartz, tridymite is soluble in a boiling solution of sodium carbonate; it occurs in the cavities of acid volcanic rocks (rhyolite, trachyte and andesite), but in most instances the crystals are replaced by a fine granular aggregate of quartz. Tridymite also is found in meteorites. At 870° C. quartz passes over into β-tridymite with a considerable increase in volume; and this change has an important bearing on siliceous refractory materials used for furnace linings and silica bricks. At a still higher temperature (1,470° C.) tridymite itself passes over into another modification of silica known as cristobalite.

See SILICA; METEORITES.

TRIER (French TRÈVES; sometimes in English TREVES; Lat. AUGUSTA TREVERORUM), the oldest town in Germany, founded by the Romans about 15 B.C. and later nicknamed "Roma secunda" or "Roma transalpina." It was formerly the capital of an archbishopric and electorate of the empire, and is now the seat of a Roman Catholic bishop and chief town of a governmental department in Rhineland-Palatinate. Pop. (1959 est.) 85,431. It is on the Moselle, about 6 mi. from the Luxembourg frontier and 69 mi. S.W. of Coblenz by rail on the Coblenz-Metz and Cologne-Saarbrücken lines. Trier is the centre of the Moselle wine trade, and manufactures textiles, machinery, leather and tobacco products. The well-preserved amphitheatre just outside the modern town to the southeast was probably built in the reign of Trajan or Hadrian. It accommodated about 30,000 spectators. The most remarkable Roman building is the Porta Nigra, the fortified north gate of the city, 118 ft. long, 98 ft. high and 75 ft. deep, built of sandstone blocks. This building may date from the 3rd to 4th century A.D. It is also called the Simeonstor, after a Greek hermit who inhabited it. In 1035 Archbishop Poppo converted the gate into two churches, one above the other, but all the additions except the apse have been removed. In the southeast of the city are ruins of 4th-century Roman baths (Imperial thermae) and near the old Roman bridge substructures of the 2nd-century Roman baths (Barbara thermae), 660 ft. long. On the Constantinsplatz stands the brick basilica, probably of the age of Constantine. Converted into a palace for the Frankish kings and their deputies, it passed in 1197 to the archbishops, and was restored (1846–56) and turned into a Protestant church. Near the basilica are the electoral palace (1757–61) and the palace garden. Another Roman basilica forms the nucleus of the cathedral. Built under the emperors Valentinian I and Gratian as a quadrilateral hall, it was converted into a church about the close of the 4th century, and restored by Bishop Nicetius about 550. Archbishop Poppo and his successors in the 11th and 12th centuries extended the cathedral and added an apse at each end. The vaulting of the nave and aisles and the cloisters were added in the 13th century. The most famous relic preserved is the "Holy Coat of Trier," believed by the devout to be the seamless robe of the Saviour, and said to have been discovered and presented to the city by the empress Helena. The cloisters connect the cathedral with the Church of Our Lady, a building in the form of a circle intersected by a cross, with a vault, built 1235–70 and said to be the oldest Gothic church in Germany. St. Matthias in the south, now represented by a 12th-century building, has a Christian cemetery of the Roman age. A market cross dates from 958, and a beautiful Renaissance fountain, the Petersbrunnen, was erected in 1595. Close by are the Steipe or Rotes Haus, formerly the town hall, of the mid-16th century, and the Frankenturm or *propugnaculum*, of the 11th century. Built on a Roman burial ground north of the Porta Nigra is the church of St. Paulinus (1732–57), by Balthasar Neumann, a masterpiece of the baroque period. The Landesmuseum (1885–89) contains many Roman and mediaeval antiquities. Among the Stadtbibliothek's most treasured manuscripts are the codex aureus, a copy of the gospels presented to the abbey of St. Maximin by Ada, a reputed sister of Charlemagne, and the codex Egberti of the 10th century. At Igel is a remarkable Roman column, 72 ft. high. It dates from the 2nd century, and was the family monument of the Secundini.

History. — The Treveri were among the most powerful tribes of the Belgae, and according to Julius Caesar, who conquered them in 56 B.C., possessed the best cavalry in Gaul. The Roman city, Augusta Treverorum, was probably fortified by Augustus about 15 B.C., and organized as a colony about A.D. 50, in the reign of Claudius, but is not mentioned before the war of Civilis in 69 (Tacitus, *Hist.*, iv). At first the Treveri resisted the appeal of Claudius Civilis and his Batavi to join the revolt, and built a defensive wall from Trier to Andernach, but soon afterward the two Treverans, Julius Tutor and Julius Classicus, led their fellow tribesmen, aided by the Lingones (Langres), in the attempt to set up a "Gallic empire." After a brief struggle the rebels were overthrown at Trier by Petillius Cerealis (70). Mainly on account of its strategic position, Diocletian, on his reorganization of the empire, made Trier the capital not only of Belgica Prima, but of the whole "diocese" of Gaul. Constantine the Great, who generally resided there from 306 to 331, and his successors, beautified the city.

The Franks, who had three times previously sacked the city, gained permanent possession of it about 455. The city was included in Lothair's kingdom (Lotharingia) in 843, and in the East Frankish kingdom in 870. Archbishop Hetti, who occupied the see from 814 to 847, is said to have been the first archbishop of Trier, and Archbishop Radbod acquired the temporal rights of the counts of Trier in 898. In the 10th century Archbishop Dietrich I obtained the primacy over Gaul and Germany.

The temporal power of the archbishops was not gained without opposition. The German kings Otto IV and Conrad IV granted charters to the city, which, however, admitted the jurisdiction of its archbishop, Baldwin of Luxembourg, in 1308. This prince, a brother of the emperor Henry VII, ruled from 1307 to 1354 and was the real founder of the power of Trier. He raised it to great prosperity by his foresight, and enlarged his dominions almost to their ultimate extent. He assumed the title of arch-chancellor of Gaul and Arles (or Burgundy), and thenceforward the elector of Trier held the third place in the electoral college. After Baldwin's death the prosperity of Trier was checked by wars and disputes between rival claimants to the see, and in 1456 the estates united for the purpose of restoring order and secured the right of electing their archbishops.

Throughout the middle ages the sancta civitas Trevirorum was a great seat of monastic learning. The university, founded in 1473, existed until 1797.

The last elector and archbishop, Clement Wenceslaus (1768–1812), granted toleration to the Protestants in 1782, established his residence at Coblenz in 1786, and fled from the French in 1794. In 1815 nearly the whole of the former electoral dominions were given to Prussia. A bishopric was again founded in 1821, but it was placed under Cologne.

After World War I Trier was occupied by the 3rd U.S. army from Nov. 1918 to the spring of 1923. In World War II the town suffered damage by bombing. It was taken by Gen. G. S. Patton's 3rd U.S. army on March 13, 1945. Later in the year it became part of the French zone of occupation.

TRIESTE (Slovene and Serbo-Croatian TRST), a port of Italy situated at the northeastern angle of the Adriatic sea, 70 mi. E.N.E. of Venice. Under Roman control about 177 B.C., made into a *colonia* by Julius Caesar and mentioned in his De *bello gallico* as Tergeste, the city attracted the attention of Octavian (Augustus) in 33 B.C. He ordered a harbour to be built there and the city to be surrounded by walls. After the breakup of the Roman empire Trieste shared the general fortunes of Istria. In 948 it received from Lothair II, king of Italy, independence under its count-bishops. It was captured by the Venetians in 1202 but constantly agitated for autonomy. In 1382 it placed itself under the protection of Leopold III of Habsburg whose overlordship gradually developed into actual Austrian possession. As part of the Austrian dominions Triest, as the Germans called it, was a small city built on and around Monte Giusto. The castle (1470–1680), which now houses a medieval museum, is believed to occupy the site of the Roman capitol. The Romanesque cathedral of S. Giusto was formed in the 14th century by the union of an early Christian baptistery with two adjacent 6th-century churches; the campanile of the cathedral (1337) incorporates part of a Roman temple. When the emperor Charles VI proclaimed it an imperial free port in 1719 Trieste had 5,700 inhabitants. In 1891, when it was deprived of this privilege, it had 156,000 inhabitants. A new town was built on the flat land adjoining the crescent-shaped bay, partly on ground that had been reclaimed from the sea. This modern town, with its broad streets and handsome squares, has typical 18th-century baroque and 19th-century neoclassical architecture, the church of S. Antonio, the Verdi theatre and the Exchange being the best examples of the latter. About 4 mi. N.W. of the city centre Archduke Maximilian, the ill-fated emperor of Mexico, built for himself in 1854–56, on the very edge of the sea, the neo-Gothic castle of Miramare.

On the eve of World War I Trieste was a prosperous city. It was the main port of the Austro-Hungarian empire, and its seaborne trade in 1913 amounted to 6,200,000 metric tons of merchandise loaded and unloaded. It was the headquarters of the Austrian Lloyd Steam Navigation company and of a few other companies formed mainly by local shipowners who were of Croatian origin but Italians by assimilation. The total tonnage of shipping registered in Trieste in 1914 was 720,000 tons.

The Austrian census of 1910 showed that the city of Trieste had a population of 229,510, including 118,959 Italians, 59,319

Slovenes and Croats, 12,635 other Austrian subjects (including 9.600 Germans) and 38.597 foreigners (including 29,439 Italian subjects). Among the Italians who were Austrian subjects there were some Italianized Croats and Italian-speaking Jews. Other Jews gave German as their mother tongue. Nevertheless. the Italians (Austrian and Italian subjects together) composed nearly tuo-thirds of the population of the city. That was the ground on nhich. in the secret treaty of London signed on April 26. 1915, the U.K., France and Russia agreed to give the city to Italy at the peace settlement. Trieste was occupied by Italian troops on Nov. 4, 1918.

As part of Italy and cut off by a political frontier from its natural hinterland, the port of Trieste lost most of its maritime trade. The volume of merchandise loaded and unloaded fell in 1930–34 to 2.200.000 metric tons; but Italy also inherited the flourishing shipbuilding industries, steel mills, oil refineries and an important insurance business. A11 this was maintained and, with government subsidies, even developed, industrialization being the only way to keep the population of the city employed. A university was founded in 1938. But the population stopped increasing: in 1913 it was estimated at 247.000; in 1936 it amounted to 237.717.

In Sept. 1943 the Germans occupied Trieste. not hiding their intention of keeping it as one of the southern outlets to the sea of the Grossdeutsches Reich. On April 30. 1945, Marshal Tito's Yugoslav troops, having liberated Dalmatia and Istria, entered Trieste and claimed its incorporation into Yugoslavia. The peace treaty with Italy signed in Paris on Feb. 10, 1947, created instead the Free Territory of Trieste which was to be a small independent state, demilitarized and neutral, whose integrity and independence were to be guaranteed by the Security council of the UN. Temporarily it was divided into two zones, zone A, with the city of Trieste, under British-U.S. military administration and zone B under Yugoslav administration.

The statute of the Free Territory of Trieste was as unworkable as that of the Free City of Danzig. The deadlock in Trieste came about immediately after the ratification of the Italian peace treaty. On March 20, 1948, the U.S., G.K. and French governments proposed the inclusion of the free territory in Italy. a solution refused by both the U.S.S.R. and Yugoslavia. On Oct. 8, 1953. the U.S. and U.K. suggested the partition of the free territory and the handing over of zone A to Italy and zone B to Yugoslavia. This nas opposed by Yugoslavia. mainly on the ground that it had not been consulted beforehand. In Feb. 1954 the U.S. and U.K. started in London negotiations for a solution with the two powers directly interested. This move was successful and an agreement was concluded on Oct. 5, 1954. It provided for the partition of the free territory between Italy and Yugoslavia with a small addition of about 5 sq.mi. in the latter's favour. Italy agreed to maintain Trieste as a free port and received 91 sq.mi. with a population of about 310.000, including 63.000 Slovenes, while the Yugoslav part covered an area of 202 sq.mi. with a population of about 73,000, including 30,000 Italians. The Italian and Yugoslav governments agreed to a special statute regulating the rights of national minorities left on both sides of the demarcation line of the former free territory. On Oct. 26, 1954. Italian troops re-entered the city after an absence of over 11 years. On the same day the last units of the U.S.and British occupation troops left zone A.

By 1961 the population of the territory attributed to Italy was 299,187. including about 283.000 for the city of Trieste.

The port's sea-borne trade steadily improved after 1954 and in the early 1960s exceeded 5,000.000 metric tons of goods annually. about one-fifth of the total being in coastal traffic.

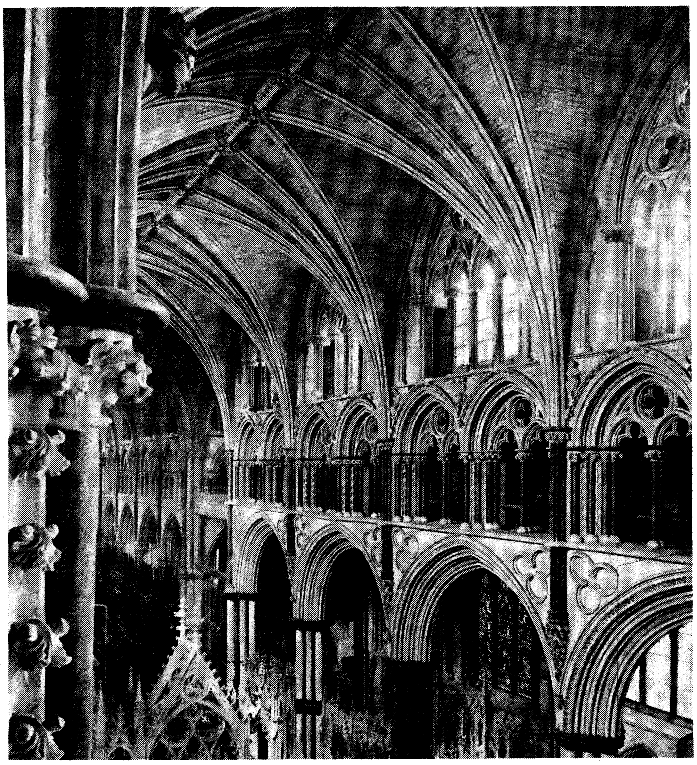
TRIFOLIUM, the generic name of the plants commonly called clover (*q.v.*), from the Latin *tres*, "three," and *folium*, "a leaf."

TRIFORIUM, in architecture, is the space in a church above the nave arcade, below the clerestory and extending over the vaults or ceilings of the side aisles. The usage of the term is loose; by some it is limited to an arcaded gallery in that level. In other cases it is applied to any second-floor gallery opening onto a higher nave by means of arcades or colonnades, Like the galleries in some pagan Roman basilicas or in Byzantine churches. The triforium became an integral part of interior design during the Romanesque period, sometimes as a series of openings to



A F KERSTING

ANGEL CHOIR, LATE 13TH-CENTURY TRIFORIUM, LINCOLN CATHEDRAL, ENGLAND

light and ventilate the roof space and sometimes as an open gallery. Often it was covered with a quarter-circle vault and served to partially transmit the thrust of the nave vaults, although originating below their springing, to the outer walls (St. Sernin, Toulouse, begun 1096). With the development of the Gothic vaulting system in France, the triforium diminished in size and importance. Reims (begun 1220) and Amiens (1220–47) both have triforia of little relative height but with rich arcading. By the end of the 13th century the triforium was usually replaced by greatly heightened clerestory windows.

The more horizontal English Gothic architecture shows an important development of the triforium gallery as a decorative element. It is relatively much higher than in similar work in France, often almost equaling the pier arcades. The richest, most characteristic example is in the Angel choir, Lincoln cathedral (completed 1282). In the 15th century the tendency toward height of pier arcade and clerestory window led to the reduction in importance and final disappearance of the triforium. *See* GOTHIC ARCHITECTURE. (*E.* B. MACD.)

TRIGONOMETRY. The desire to compute numerically angles and distances for which geometry would require diagrams plotted to scale led to the development of the science of trigonometry. This science is concerned with the definitions, properties and relations of certain functions of angles. Application of the science to problems requiring the determination of unknown angles and distances from known or measured angles and distances, occurring in a figure lying wholly in one plane, is the subject matter of plane trigonometry. Applications to similar problems whose diagrams lie in more than one plane of three-dimensional space are comprised in spherical trigonometry. Their relation to the sphere is shown below.

TRIGONOMETRIC FUNCTIONS

For the purpose of trigonometry, a somewhat more general concept of angle is required than that used in geometry. An angle A with vertex at V, whose initial side is VP and whose terminal side is VQ, is indicated in fig. 1 by the solid circular arc. This angle is said to be generated by the continuous counterclockwise rotation of a line segment about the point V from the position VP to the position VQ. A second angle A' with the same initial and terminal sides, indicated in fig. 1 by the dotted circular arc, is generated by the clockwise rotation of the line segment about the point V from the position VP to the position VQ. Angles are considered positive when generated by counterclockwise rotations, negative when generated by clockwise rotations. The positive angle A and the negative angle A' in fig. 1 are generated by less than one complete rotation of the line segment about the point V. All other positive and negative angles with the same initial and terminal sides are obtained by rotating the line segment counterclockwise or clockwise about the point V one or more complete turns before coming to rest at VQ.

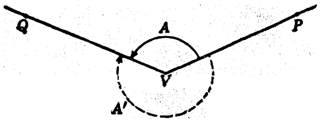


FIG 1.—GENERAL ANGLE (see TEXT FOR FURTHER EXPLANATION)

Numerical values can be assigned to angles by selecting a unit of measure for angles. Besides the complete revolution and the right angle, the units commonly used are the degree (minutes. seconds) and the radian. The degree is $\frac{1}{90}$ of a right angle. There are 60' in a degree and 60″ in a minute. In theoretical work, the radian is the most convenient unit. It is the angle at the centre of a circle which intercepts an arc equal in length to the radius. From these definitions, it follows that

$$1 \text{ revolution} = 4 \text{ right angles} = 360° = 2\pi \text{ radians}$$

Equal angles are angles nith the same measure; *i.e.*, they have the same sign and the same number of degrees. The angle $-A$ has the same number of degrees as A but is of opposite sign. Hence its measure is the negative of the measure of A. If the angles A and B have the initial sides VP, VQ and the terminal sides VQ, VR, respectively, then the angle $A + B$ has the initial

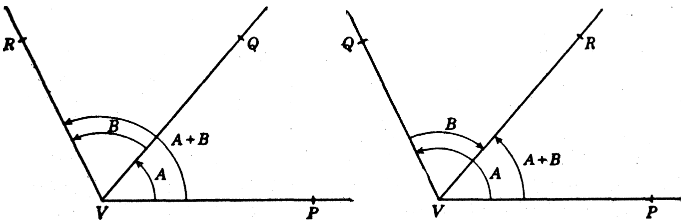

FIG. 2.— ADDITION OF ANGLES (see TEXT.)

and terminal sides VP, VR, respectively. The angle $A + B$ is called the sum of the angles A and B and its relation to A and B when A is positive and B is positive or negative is illustrated in fig. 2. The sum $A + B$ is the angle whose measure is the algebraic sum of the measures of A and B. The difference $A - B$ is the sum of A and $-B$. Thus all angles coterminal with angle A (*i.e.*, nith the same initial and terminal sides as angle A) are given by $A \pm 360\,n$, where $360\,n$ is an angle of n complete revolutions. The angles $180 - A$ and $90 - A$ are the supplement and complement of angle A respectively.

Trigonometric Functions of an Angle.—There are six functions of an angle commonly used in trigonometry. Their names and abbreviations are sine (sin), cosine (cos), tangent (tan), cotangent (ctn), secant (sec), cosecant (csc). To define these functions for any angle A, the angle is placed in standard position on a rectangular co-ordinate system (see ANALYTIC GEOMETRY); *i.e.*, with the vertex of A at the origin and the initial side of A along the positive x-axis. Let r (positive) be the distance from V to any point Q on the terminal side of A dnd let (x,y) be the rectangular

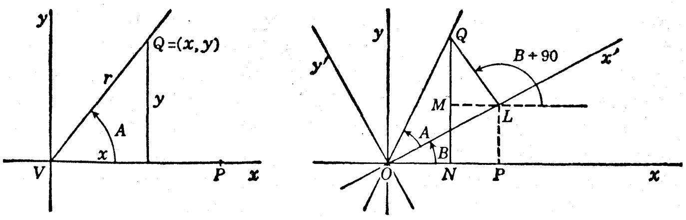

FIG. 3.— (LEFT) ANGLE IN STANDARD POSITION. (RIGHT) ROTATION OF AXES

co-ordinates of Q. The six functions of A are then defined by six ratios as follows:

$$\begin{array}{ll} \sin A = y/r, & \operatorname{ctn} A = x/y \\ \cos A = x/r, & \sec A = r/x \\ \tan A = y/x, & \csc A = r/y \end{array} \qquad (1)$$

Since division by zero is not allowed, the tangent and secant are not defined for angles whose terminal side falls on the y-axis, and the cotangent and cosecant are undefined for angles whose terminal side falls on the x-axis.

From these definitions, follow the three reciprocal relations:

$$\operatorname{ctn} A = 1/\tan A \quad \sec A = 1/\cos A \quad \csc A = 1/\sin A \qquad (2)$$

and also the quotient identities:

$$\tan A = \sin A/\cos A \qquad \operatorname{ctn} A = \cos A/\sin A \qquad (3)$$

When the Pythagorean equality $x^2 + y^2 = r^2$ is divided in turn by r^2, x^2, y^2, the three square relations

$$\cos^2 A + \sin^2 A = 1 \quad 1 + \tan^2 A = \sec^2 A \quad \operatorname{ctn}^2 A + 1 = \csc^2 A \qquad (4)$$

are obtained.

If the point Q on the terminal side of angle A in standard position has co-ordinates (x,y), this point will have co-ordinates $(x,-y)$ nhen on the terminal side of $-A$ in standard position. From this fact and the definitions are obtained the identities:

$$\begin{array}{ll} \sin(-A) = -\sin A & \operatorname{ctn}(-A) = -\operatorname{ctn} A \\ \cos(-rl) = \cos A & \sec(-A) = \sec A \\ \tan(-A) = -\tan A & \csc(-A) = -\csc A \end{array} \qquad (5)$$

These relations may also be stated briefly by saying that cosine and secant are even functions whereas the other four are odd functions.

It is immediately evident that a trigonometric function has the same value for all coterminal angles. Hence. when n is an integer,

$$\sin(A \pm 360\,n) = \sin A \qquad (6)$$

with similar relations for the other five functions. These results may be expressed by saying that the trigonometric functions are periodic and have a period of 360°.

When Q on the terminal side of A has co-ordinates (x,y), it has co-ordinates $(-x,-y)$ on the terminal side of $A \pm 180$ and consequently

$$\begin{array}{ll} \sin(A \pm 180) = -\sin A & \operatorname{ctn}(A \pm 180) = \operatorname{ctn} A \\ \cos(A \pm 180) = -\cos A & \sec(A \pm 180) = -\sec A \\ \tan(A \pm 180) = \tan A & \csc(A \mp 180) = -\csc A \end{array} \qquad (7)$$

These relations show that tangent and cotangent have the smaller period of 180°. In fact, this is the smallest period for these two functions. the other four having 360° for their minimum period. The relations (7) also show that an angle and its supplement have the same sine and the same cosecant whereas for each of the other four functions the value for the supplement is the negative of the value for the angle.

When Q on the terminal side of A in standard position has co-ordinates (x,y), it has co-ordinates $(-y,x)$ and $(y,-x)$ on the terminal side of $A + 90$ and $A - 90$ in standard position respectively and consequently

$$\begin{array}{ll} \sin(A \pm 90) = \pm \cos A & \operatorname{ctn}(A \pm 90) = - \tan A \\ \cos(A \pm 90) = \mp \sin A & \sec(A \pm 90) = \mp \csc A \\ \tan(A \pm 90) = - \operatorname{ctn} A & \csc(A \pm 90) = \pm \sec A \end{array} \qquad (8)$$

Thus a function of the complement of A is equal to the corresponding cofunction of A.

Of fundamental importance for the science of trigonometry are the addition formulas:

$$\cos (A \pm B) = \cos A \cos B \mp \sin A \sin B \qquad (9)$$
$$\sin (A \pm B) = \sin A \cos B \pm \cos A \sin B$$

These relations may be derived from the formulas

$$x = x' \cos B - y' \sin B \qquad (10)$$
$$y = x' \sin B + y' \cos B$$

for the rotation of the co-ordinate axes through the angle B about the origin, and these formulas are evident from fig. 3 (right) since

$$x = ON = OP + LM = OL \cos B + LQ \cos (B + 90)$$
$$= x' \cos B - y' \sin B$$

and

$$y = NQ = PL + MQ = OL \sin B + LQ \sin (B + 90)$$
$$= x' \sin B + y' \cos B$$

To obtain the addition formulas (9), it is only necessary to divide each equation in (10) by $r = OQ$ and use the definitions of sine and cosine.

From the addition formulas are derived the double-angle and half-angle formulas:

$$\sin (2A) = 2 \sin A \cos A$$
$$\cos (2A) = \cos^2 A - \sin^2 A = 2 \cos^2 A - 1 = 1 - 2 \sin^2 A \qquad (11)$$
$$\sin^2 (A/2) = (1 - \cos A)/2$$
$$\cos^2 (A/2) = (1 + \cos A)/2$$

Numerous examples of the various identities of lesser importance that can be derived from the above basic identities may be found in any standard textbook on trigonometry.

Historically the trigonometric functions were lines associated with arcs. For example, half of a chord of a circle was called the sine of half of the arc subtended by the chord. The presentation of the science was greatly simplified by the substitution of angle for half arc and ratio for half chord. However, for convenience in spherical trigonometry, sine of the arc is still written for the sine of the central angle intercepting the arc.

Tables of Natural Functions.— To be of practical use, the values of the functions must be readily available for any given angle. The identities (6), (7) and (8) show that the values of the functions for all angles can readily be found from their values for angles from 0° to 45°. For this reason, it suffices to list in a table the values of sine, cosine, tangent, cotangent of all angles from 0° to 45° that are integral multiples of some convenient unit (commonly 1'). Such tables are called tables of natural trigonometric functions. For angles that are not integral multiples of the unit. the values of the functions are found by the usual methods of interpolation (*q.v.*). Since the values of the functions are in general irrational numbers, they are entered in the table as decimals, rounded off at some convenient place. For almost all purposes. four or five decimal places are sufficient and tables of this accuracy appear in most texts. Most scientific libraries have available tables of greater accuracy (see A. Fletcher et al., Index of Mathematical Tables, 1946). A method of computing the entries in the tables is explained below. However, simple geometrical facts alone suffice to determine the values of the trigonometric functions for the angles 0°, 30°, 45°, 60° and 90°. These values are listed in the table, which also illustrates the arrangement used in larger tables.

Functions of 0°, 30°, 45°, 60° and 90°

	sin	cos	tan	ctn	
0	0	1	0	—	90
30	$\frac{1}{2}$	$\frac{1}{2}\sqrt{3}$	$\frac{1}{3}\sqrt{3}$	$\sqrt{3}$	60
45	$\frac{1}{2}\sqrt{2}$	$\frac{1}{2}\sqrt{2}$	1	1	45
	cos	sin	ctn	tan	

The names at the head of the table are used for angles less than 45°, listed in the left-hand column, whereas the names at the foot of the table are used for the complementary angles larger than 45°, listed in the right-hand column. For example, from the table $\cos 30 = \frac{1}{2}\sqrt{3}$ and $\text{ctn } 60 = \frac{1}{3}\sqrt{3}$.

PLANE TRIGONOMETRY

To conduct a survey of a plane region, the surveyor inspects the terrain and then sets up stakes at points which the inspection indicates will be convenient for his purpose. The surveyor then measures uith a transit enough of the angles between the lines joining pairs of stakes so that, when two points are arbitrarily selected on a plat to represent two of the stakes, all points that represent the other stakes can be located as the intersections of lines drawn on the plat in the directions determined by the measured angles; *i.e.*, the angles measured suffice to completely determine the plat except for scale. The scale of the plat is found by measuring the distance with a steel tape between one pair of stakes and comparing this distance with the distance between the corresponding points on the plat. With the scale determined, the distance between any two stakes can be found approximately by measuring the distance between the corresponding points of the plat and multiplying by the scale factor. When greater accuracy is required, the unknown distances are computed by means of the trigonometric functions. Enough of the points of the plat are first joined by lines to divide the region of the plat into triangles and each triangle is solved; *i.e.*, the lengths of its sides. the size of its angles and its area are computed. Triangles can be solved by the law of sines and the law of cosines. To secure symmetry in the writing of these laws, the angles of the triangle are lettered A, B and C and the lengths of the opposite sides are lettered a, b and c respectively as shown in fig. 4.

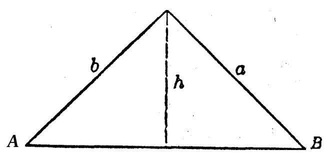

FIG. 4.—STANDARD LETTERING OF A TRIANGLE (see TEXT)

The law of sines or sine theorem is

$$\frac{a}{\sin A} = \frac{b}{\sin B} = \frac{c}{\sin C} \qquad (12)$$

and the law of cosines or cosine theorem is

$$\cos A = \frac{b^2 + c^2 - a^2}{2bc} \qquad (13)$$

with similar expressions for cos B and cos C, obtained by cyclic permutation of the three letters. In fig. 4, $b \sin A = h = a \sin B$, from which the first equality in (12) follows. The second is shown by drawing a perpendicular from A to the opposite side of the triangle. Also $c = b \cos A + a \cos B$ and likewise $b = a \cos C + c \cos A$, $a = c \cos B + b \cos C$. When these three equations are multiplied by c, b, $-a$, respectively, and added, the result is $c^2 + b^2 - a^2 = 2bc \cos A$, which when divided by $2bc$ becomes (13). To solve a triangle, we substitute in formulas (12) and (13) all the known values and solve the equations for the unknown values. The law of sines is effective when two angles and a side are known or when two sides and an angle opposite one are known. The law of cosines is effective when two sides and an included angle are known or three sides are known. The area of the triangle may be found from

$$\text{area} = \tfrac{1}{2}bc \sin A \qquad (14)$$

This formula is derived from the relations area $= \frac{1}{2}ch$ and $h = b \sin A$ in fig. 4.

Texts on trigonometry derive other formulas for solving triangles and for checking the solution. especially those suited to logarithmic calculation (see LOGARITHMS). The most important among these are the law of tangents or tangent theorem and the half-angle formulas. However, with the advent of mechanical calculators, computation by logarithms has lost some of its advantage, and it is no longer so necessary to adapt formulas to logarithmic computation when machines are available.

SPHERICAL TRIGONOMETRY

The fundamental configuration of space to which the formulas of spherical trigonometry apply is the trihedral angle formed by three rays—half lines—radiating from a point. The point is the vertex, the rays are the three edges, the planes and angles determined by the rays taken in pairs are the three faces and the three face angles α, β, γ of the trihedral angle. The faces in pairs form three dihedral angles A, B, C opposite respectively to the face angles α, β, γ. The formulas of spherical trigonometry relate the trigonometric functions of these six angles.

For a trihedral angle, there is the law of sines

$$\frac{\sin \alpha}{\sin A} = \frac{\sin \beta}{\sin B} = \frac{\sin \gamma}{\sin C} \tag{15}$$

which may be derived from fig. 5 (left) in which the planes PQS and PRS are perpendicular to the edges VQ and VR, respectively. The first equality in (15) is a result of the relations

$$\begin{aligned} \overline{PS} &= \overline{QP} \sin B = \overline{VP} \sin \alpha \sin B \\ &= \overline{RP} \sin A = \overline{VP} \sin \beta \sin A \end{aligned}$$

The second equality may be proved in like manner.

A first law of cosines for the trihedral is

$$\cos \alpha = \cos \beta \cos \gamma + \sin \beta \sin \gamma \cos A \tag{16}$$

with similar expressions for $\cos \beta$ and $\cos \gamma$ obtained by cyclic permutation of the letters. In fig. 5 (right), the plane PQR is perpendicular to the edge VP. The law of cosines applied to the plane triangles PQR and VQR gives

$$\begin{aligned} \overline{QR}^2 &= \overline{PQ}^2 + \overline{PR}^2 - 2\,\overline{PQ}\,\overline{PR} \cos A \\ &= \overline{VQ}^2 + \overline{VR}^2 - 2\,\overline{VQ}\,\overline{VR} \cos \alpha \end{aligned}$$

Hence, after transposing and using the Pythagorean theorem,

$$2\,\overline{VQ}\,\overline{VR} \cos \alpha = 2\,\overline{VP}^2 + 2\,\overline{PQ}\,\overline{PR} \cos A$$

This relation when divided by $2\,\overline{VQ}\,\overline{VR}$ becomes (16) after using the definitions of the trigonometric functions.

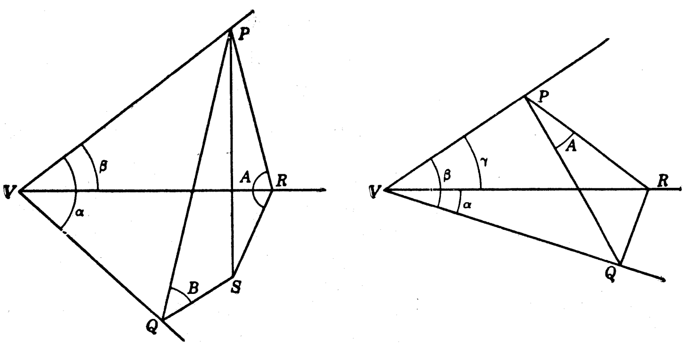

FIG. 5.—TRIHEDRAL ANGLES FOR DERIVATION OF THE LAWS OF (LEFT) SINES AND (RIGHT) COSINES

If at the vertex of a trihedral three rays are drawn perpendicular to the three inner faces of the trihedral, a second trihedral is obtained called the polar trihedral of the first. The first is also the polar of the second. The face angles α', β', γ' of the polar trihedral are the supplements of the dihedral angles A, B, C of the given trihedral and hence the face angles α, β, γ of the given trihedral are the supplements of the dihedral angles A', B', C' of the polar trihedral.

The first law of cosines when applied to the polar trihedral and simplified by the relations $\cos \alpha' = \cos (180 - A) = -\cos A$, etc., yields the formula

$$\cos A = -\cos B \cos C + \sin B \sin C \cos \alpha \tag{17}$$

and two additional relations for $\cos B$ and $\cos C$, obtained by cyclic permutation of the letters, which are called the second law of cosines for the given trihedral.

Spherical Triangles.—When the vertices of a spherical triangle are joined to the centre of the sphere, there is formed a trihedral angle with vertex at the centre (fig. 6).

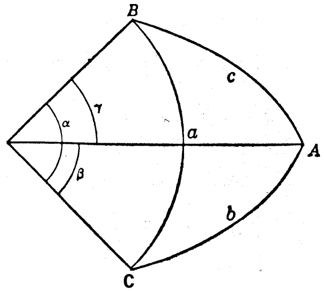

FIG. 6.— SPHERICAL TRIANGLE AND TRIHEDRAL

The sides a, b, c of the spherical triangle are the great circle arcs intercepted by the face angles α, β, γ, and the angles of the spherical triangle are the dihedral angles A, B, C of the trihedral. The faces of the polar trihedral intersect the sphere in the polar triangle of the given spherical triangle. Since a trigonometric function of a central angle and of the intercepted arc have the same value, the law of sines (15) yields a law of sines for spherical triangles:

$$\frac{\sin a}{\sin A} = \frac{\sin b}{\sin B} = \frac{\sin c}{\sin C} \tag{18}$$

Similarly, the first law of cosines (16) gives a law of cosines for the sides of the spherical triangle:

$$\begin{aligned} \cos a &= \cos b \cos c + \sin b \sin c \cos A \\ \cos b &= \cos c \cos a + \sin c \sin a \cos B \\ \cos c &= \cos a \cos b + \sin a \sin b \cos C \end{aligned} \tag{19}$$

and the second law of cosines (17) furnishes a law of cosines for the angles of a spherical triangle:

$$\begin{aligned} \cos A &= -\cos B \cos C + \sin B \sin C \cos a \\ \cos B &= -\cos C \cos A + \sin C \sin A \cos b \\ \cos C &= -\cos A \cos B + \sin A \sin B \cos c \end{aligned} \tag{20}$$

To solve a spherical triangle, the known values are substituted in formulas (18), (19) and (20) and the resulting equations solved for the unknowns. When three sides or two sides and the included angle are given, (19) is effective, and (20) may be used when three angles or two angles and an included side are given. If two sides and an angle opposite one side or two angles and a side opposite one angle are given. (18) is applied first and the solution is finished by the use of a pair of equations one each from (19) and (20). The area of the spherical triangle is given by

$$\text{area} = E\, r^2 \tag{21}$$

where r is the radius of the sphere and E is the excess of $A + B + C$ over two right angles measured in radians. Observe that a solution of a spherical triangle yields a solution of the polar triangle.

Other relations between the sides and angles of a spherical triangle are derived in texts on spherical trigonometry. In particular, John Napier's analogies are formulas relating the half angles and half sides. Each formula contains five of the six parts and is well suited to logarithmic solutions of a spherical triangle. Other formulas of a similar character are the half-angle formulas, the half-side formulas and the analogies of Gauss-Delambre.

When angle C is 90°, the triangle is a right spherical triangle. Since $\sin C = 1$ and $\cos C = 0$, the relations in (18), (19), (20) yield the following formulas for the right spherical triangle:

$$\begin{aligned} \sin a &= \sin c \sin A = \tan b \operatorname{ctn} B \\ \sin b &= \sin c \sin B = \tan a \operatorname{ctn} A \\ \cos c &= \cos a \cos b = \operatorname{ctn} A \operatorname{ctn} B \\ \cos A &= \cos a \sin B = \tan b \operatorname{ctn} c \\ \cos B &= \cos b \sin A = \tan a \operatorname{ctn} c \end{aligned} \tag{22}$$

Napier's rules of circular parts given in texts is a mnemonic for these ten relations.

ANALYTIC TRIGONOMETRY

Trigonometric functions of a real variable x are defined by means of the trigonometric functions of an angle. For example, $\sin x$ where x is real is defined to have the value of the sine of the angle containing x radians. Similar definitions are made for the other five trigonometric functions of the real variable x. These functions satisfy the relations (2)–(9) and (11) with A, B, 90, 180. 360 replaced by x, y, $\pi/2$, π, 2π, respectively. Thus the minimum period of $\tan x$ and $\operatorname{ctn} x$ is π, and of the other four functions is 2π.

In the calculus it is shown that sin x and cos x are sums of power series:

$$\sin x = x - \frac{x^3}{3!} + \frac{x^5}{5!} - \frac{x^7}{7!} + \dots \tag{23}$$

$$\cos x = 1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \frac{x^6}{6!} + \dots$$

These series may be used to compute the sine and cosine of any angle. For example, to compute the sine of 10°, it is necessary to find the value of $\sin \pi/18$ since 10° is the angle containing $\pi/18$ radians. When $\pi/18$ is substituted in the series for sin x, it is found that the first two terms give ,17365, which is correct to five decimals for the sine of 10°. By taking enough terms of the series, any number of decimal places can be correctly obtained.

Tables of the functions may be used to sketch the graphs of the functions, shown in fig. 7.

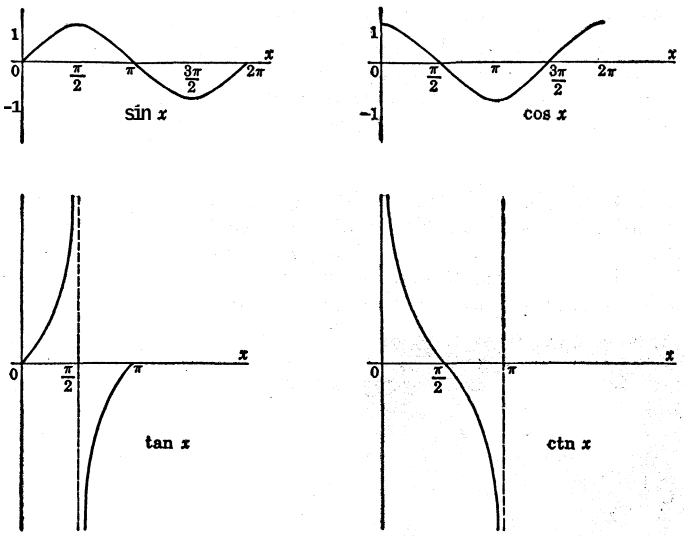

FIG. 7.— GRAPHS OF TRIGONOMETRIC FUNCTIONS

The diagrams give the graph of each function for one period. To obtain the complete graph in each figure it is only necessary to extend the curve indefinitely in both directions by repetitions of the piece of graph shown in the figure.

Trigonometric Functions of a Complex Variable.—Since the series in (23) converge for all complex numbers, they can be used to define trigonometric functions sin z and cos z of the complex variable z. The functions tan z and ctn z are then defined by the quotient identities (3), and sec z and csc z by the reciprocal relations (2). Since all trigonometric identities are derivable from the series (23), these functions of the complex variable z satisfy the same identities as the corresponding functions of the real variable x.

In the realm of complex numbers, the trigonometric functions are closely related to the exponential function. From the series expression for these functions, the relations

$$\begin{aligned} e^{iz} &= \cos z + i \sin z \\ e^{-iz} &= \cos z - i \sin z \end{aligned} \tag{24}$$

are readily derived. Hence

$$\begin{aligned} \sin z &= (e^{iz} - e^{-iz})/2i \\ \cos z &= (e^{iz} + e^{-iz})/2 \end{aligned} \tag{25}$$

Some interesting relations follow easily from these formulas among which is DeMoivre's theorem,

$$(\cos z + i \sin z)^n = \cos n z + i \sin n z \tag{26}$$

This is shown by raising both members of (24) to the power n and then using (24) with z replaced by $n z$.

Each of the six trigonometric functions has an inverse. For example, the inverse of sin z is written arcsin z and is the function (multiple-valued) for which sin (arcsin z) = z is an identity in z. Thus w = arcsin z is the solution of sin w = z for w as a function of z.

Trigonometric Polynomials and Series.—The graph of the function

$$M \sin (wx + \alpha) = A \cos wx + B \sin wx$$

where $A = M \sin \alpha$, $B = M \cos \alpha$ and M and w are positive is called a sine wave. It may be obtained from the graph of sin x in fig. 7 by a change of the scales on the two co-ordinate axes and a horizontal shift of the origin. The length of the wave is the period $2\pi/w$ of this function, its amplitude is the maximum value M of the function and α is its phase. Sine waves occur in the study of wave motion, simple harmonic motion, alternating electric currents, light, sound and other periodic phenomena where the tone is pure.

The absence of purity of tone may be due to the presence of overtones. Such phenomena may be successfully studied by trigonometric polynomials.

$$\tfrac{1}{2}A_0 + A \cos wx + B \sin wx + \dots + A_n \cos nwx + B_n \sin nwx$$

where the constant term is added to allow for a vertical shift of origin. There is, in fact, a theorem that every continuous periodic function can be approximated as nearly as desired by a trigonometric polynomial. showing that all phenomena representable by a continuous periodic function differ arbitrarily little from a suitably chosen fundamental with its overtones, combined with properly selected amplitudes and phases.

It is natural to pass from trigonometric polynomials to infinite trigonometric series

$$\tfrac{1}{2}A_0 + A_1 \cos x + B_1 \sin x + A_2 \cos 2x + B_2 \sin 2x + \dots$$

where it is usual to select the scale on the x-axis so that $w = 1$. These series (see FOURIER SERIES) have occupied the attention of mathematicians for more than a century and have played a central role in the development of modern analysis. The most important trigonometric series are the Fourier series in which the coefficients have the special form

$$A_n = \frac{1}{\pi}\int_{-\pi}^{\pi} f(t) \cos (nt)\, dt,\ B_n = \frac{1}{\pi}\int_{-\pi}^{\pi} f(t) \sin (nt)\, dt$$

where f(x) is a given function integrable on the interval $(-\pi, a)$. These series were first introduced by Joseph Fourier (1768–1830) in studies on the flow of heat when boundary temperatures are maintained. For a very large class of continuous periodic functions f(x), the corresponding Fourier series converges to f(x).

HISTORY

Trigonometry among the early mathematicians was essentially a computational science based on geometrical theorems. The simplicity of the modern science was brought about by the perfection of the number system, originating with the Hindus about the 5th or 6th century A.D., and of highly developed algebraic symbolism with its complete system of rules of operation, largely developed by Europeans of the Renaissance and later.

What is now embodied in a formula earlier had to be described by words as a succession of computational steps each justified by the citation of an appropriate geometrical theorem. The absence of negative numbers (first systematically used in the early 17th century) made necessary the discussion of many more cases in the solution of triangles. One or more steps in a solution was the passage from the length of an arc to the length of its chord (Greek) or the length of half the chord of the double arc (Hindu) or vice versa, a feat accomplished by means of a table. In the 12th century the Arabic word for the half chord of the double arc was confused with another word and translated sinus (sine). The difficulty of making tables with irrational entries without decimals (first systematically introduced into arithmetic late in the 16th century) was met by selecting a circle so large that when the chords used were computed to the nearest integer the desired accuracy was attained. This unfortunately introduced into the arguments supporting the solutions the added complexity of proportionality between similar figures.

Trigonometry, uniting as it did aspects of the three sciences of arithmetic, algebra and geometry, progressed more slowly than did geometry. However, astronomy, the first love of the early Hindus and Arabs, required as a tool the solution of spherical triangles, a fact which drove them to master this art. It is accordingly not surprising that the development of spherical trigonometry preceded that of plane trigonometry. Not until about the 13th century did trigonometry divorce itself from astronomy and become an independent science.

In the extant mathematical literature of the civilizations preceding the Greeks occur a few calculations suggestive of trigonometric calculations but no further evidence of the science. The early Greek writers appear to have advanced a step further by making calculations based on the proportionality of similar triangles. In the determination of a height by comparison of its shadow with the shadow of a known height can be seen the germ of the tangent function. Greek writers of the 4th century make Hipparchus the originator of the science of trigonometry. He was reputed to have calculated a table of chords in 12 books about the middle of the 2nd century B.C. To what extent he may have developed the uses of the table is unknown since the complete work is lost. Menelaus was also reputed to have produced about the end of the 1st century a treatment of the trigonometry of chords in six books, but this is also lost. An extant work contains the important lemma of Menelaus and the corresponding theorem for the sphere *regula* sex *quantitatum* upon which later writers based their work on trigonometry.

The first extant work on trigonometry is contained in the *Almagesf*, a work on astronomy in 13 books, produced by Ptolemy of Alexandria around the middle of the 2nd century. In one section is a table of chords at intervals of 30' accurate to at least five places, and the method of computing the tables is explained. Another section is devoted to the solution of triangles, particularly spherical. Theorems concerning chords are proved which involve implicitly the equivalence of the addition formulas, the half-angle formulas and the lam of sines.

There is no work of the Hindus extant, but it is known they made tables of sines, the half chord of the double arc, at intervals of 3° 45' using the equivalent of $\sin^2 a + \cos^2 a = 1$, $\cos a = \sin (90 - a)$ and $1 - \cos 2a = 2 \sin^2 a$ only. These tables were used to solve right triangles: plane and spherical. This work was translated into Arabic about the last quarter of the 8th century.

In the late 9th century the Arab al-Battani added the law of cosines for oblique spherical triangles and introduced the sine for the chord into the work of Ptolemy and also into his tables. He brought into use the tangent and cotangent functions and constructed a table for them at intervals of 1°.

Abul Wefa in the last half of the 10th century gave a more accurate method for computing sines and established the complete generality of the sine law for spherical triangles. He introduced the secant and cosecant and studied the interrelations of the six trigonometric lines associated with an arc. Credit for establishing the general sine law for plane triangles is given to the Persian al-Biruni (973–1048).

Jabir of Seville, in the second half of the 11th century, added to the four formulas of Ptolemy the equivalent of the fifth formula for right spherical triangles. The systematization of plane and spherical trigonometry as a science independent of astronomy was finally achieved by the great Persian mathematician Nasir ad-din at-Tusi in the second half of the 13th century. Essentially, the same work was done for the western world independently by Regiomontanus (1436–76), the science of the Arabic world having filtered into Europe over several centuries, that of the east coming much later than that from Spain. The development of arithmetic and algebra allowed the successors of Regiomontanus in Europe to unify and simplify the trigonometry of the triangle by substituting the angle for arc and ratios for the trigonometric lines, and by abstracting from the cumbersome treatment of Regiomontanus the essential formulas convenient for calculations. The cosine law for plane triangles appears for the first time in the work of François Vieta (1540–1603).

The invention of logarithms by Napier (1550–1617) stimulated the development of formulas suitable to their use. The law of tangents appears in the writings of Vieta and the half-angle formulas in the works of Rhaeticus (1568) and William Oughtred (1657). Napier's analogies appeared in 1619, while the Gauss-Delambre and Mollweide relations came later (1807–09). Abraham de Moivre (1667–1754) artd Leonhard Euler (1707–83) were among the first to open the field of analytic trigonometry. The work of Fourier on trigonometric series appeared in 1807.

TRIKKALA (anc. Tricca), a town of Thessaly (Thessalia), Greece, capital of department of Trikkala, 35 mi. W. of Larissa. In winter, when great numbers of Vlach herdsmen settle in the town, its population exceeds that of Larissa. It has the appearance of a Moslem town because of the mosques built there and is a centre of trade in wheat, maize: tobacco and cocoons. In ancient times it was a seat of the worship of Aesculapius. Pop. (1951) 24,131, department (1961) 142,450.

Occupied by Axis troops in April 1941, it was bombed during World War II.

TRILLIUM (alluding to the three leaves), a genus of beautiful plants of the lily family (Liliaceae, *q.v.*), comprising about 30 species, natives of North America and eastern Asia. The plant is a smooth low perennial, having a rhizome from which proceeds a simple stem bearing at the top a whorl of three leaves and a single, erect or nodding, conspicuous flower consisting of three green sepals, three showy petals: six stamens and a three-celled ovary; the fruit is a many-seeded berry. About 18 species occur in the United States and Canada; these include many handsome spring wild flowers, known as wake-robin and birthroot. Well-known eastern species are the great white trillium (*T. grandiflorum*), the purple trillium (*T. erectum*), the painted wake-robin (*T. undulatum*) and, in the southeastern states, the mountain wake-robin (*T. stylosum* or *nervosum*, as it is also called). The only yellow trillium is *T.* sessile *luteum* from the southern Appalachians west to Arkansas and hlissouri. Of all these the finest and most easily grown in the wild garden, needing shade and woodsy soil, is *T. grandiflorum*, its large white flower being very showy in late spring. (N. TR.)

ROCHE
(TRILLIUM GRANDIFLORUM) GREAT WHITE TRILLIUM

TRILOBITA, a group of extinct. Arthropoda of which the fossil remains are found in the rocks of the Palaeozoic era. Many species are found in the Lower Cambrian, among the earliest known fossils. They are abundant in the Ordovician and Silurian when they begin to decline and only three genera survive in the Permian.

A typical trilobite has a segmented body roughly resembling that of a wood louse, with the dorsal surface marked by two longitudinal furrows which divide it into the three lobes alluded to in the name of the group. In the head-region the middle lobe is the glabella and usually shows transverse grooves marking the five segments of which the head is composed. On either side of the head are plates, the "free cheeks," divided from the central part of the head by the "facial sutures" and bearing the compound eyes. In some trilobites, however, the eyes are reduced or absent. Behind the head a number of the body-segments, from two to 44, are freely movable, and they are followed by a tail-shield or "pygidium" which often shows, by transverse furrows, that it is composed of a number, sometimes a large number, of segments. Most trilobites, after the Cambrian, could roll up into a ball like many wood-lice and are often found in this condition.

For long no definite traces of the limbs of trilobites could be discovered and their nature was the subject of much speculation. They have now been described in several genera by C. D. Walcott, C. E. Beecher and P. E. Raymond. The structure is most fully known in *Triarthrus,* investigated by Beecher and by Raymond. The appendages of the first pair, placed at the sides of the fore-lip (hypostoma) which underhangs the mouth, are long, slender, many-jointed antennae. The remaining appendages are all similar in structure and are attached, four pairs to the head and one pair each to the somites of the body whether free or coalesced into the pygidium. They are two-branched, the inner branch (endopodite) being a jointed leg, while the outer (exopodite) bears a fringe of what seem to be stiff flattened bristles. The two branches spring from a single basal segment drawn out on the inner side as a jaw-lobe (gnathobase) which served, no doubt, to seize food and pass it forward to the mouth. Towards the hinder end of the body the appendages become smaller and the inner edge of the endopodite is lobed in a way recalling the appendages of the Branchiopod Crustacea. In *Neolenus* another point of resemblance to certain Branchiopoda is provided by a pair of long thread-like tail-filaments. Walcott believed the structure of the limbs to be more complex, certain genera possessing, in addition to the parts mentioned, two or three "epipodites," but the presence of these awaits confirmation. Still less probable is Walcott's conclusion that *Calymmene* and *Ceraurus* possessed corkscrew-like gills.

The development of various species has been traced. Starting with a minute larva with only indications of head and pygidium, segments appear between these regions in order from behind forwards, the new segments being set free in succession from the front edge of the pygidium. The relationships of trilobites to the various groups of Arthropoda now living have been the subject of much discussion but the elucidation of their appendages leaves no doubt that their main affinities are with the Crustacea (*q.v.*). The five pairs of appendages on the head-region are directly comparable with those of Crustacea, since the second pair or antennae of Crustacea are still postoral and biramous and carry a masticatory process or gnathobase in the nauplius larva as in the trilobites. The biramous form of all the postoral limbs is also a weighty argument in favour of crustacean affinity. On the other hand, there is no trace of the characteristic crustacean shell-fold or carapace. In the uniformity of the postoral appendages, however, the trilobites are more primitive than any living crustacean. The view that trilobites are phylogenetically connected with Arachnida (*q.v.*) has less to support it, but it is possible that connecting links may yet be proved to exist in the imperfectly known Cambrian *Limulava* of Walcott.

The trilobites were all marine and lived, some on sandy or muddy bottoms, some on coral reefs, and some, perhaps, in the deep sea. They were distributed all over the world and in some localities were in such abundance that rock strata are crowded with their remains. A very large number of genera and species are known. Their range of size is from a quarter of an inch to 27 in. in length, but most species are between one and three inches long. (W. T. C.)

TRIM, a market town and the county town of Co. Meath, Ire., on the upper waters of the Boyne, 28 mi. N.W. of Dublin by road. Pop. (1956) 1,342. Monthly fairs are held, and there is considerable trade in corn and flour, The town was the seat of a very early bishopric. A Norman tower, called the Yellow Steeple, is supposed to mark the site of St. Patrick's Abbey of St. Mary. Two gates remain from the old town walls. King John's castle mas originally founded by Hugh de Lacy in 1173, but a later date is assignable to the greater part of the building. Other castles are Talbot's and Scurlogstown castles; the former erected by Sir John Talbot, lord lieutenant of Ireland in 1415, the latter dating from 1180. At Newtown Trim, about a mile east of the town, the ruins of the abbey of St. Peter and St. Paul. founded in 1206 by Simon Rochfort, occupy both banks of the river. These include the Transitional-Norman cathedral on the north bank, and a castle guarding the crossing of the river on the south, together with a chapel and other remains. North of the town, ruins may be seen of a 13th-century Dominican friary. The tower of the old parish church dates from 1449. Several Irish parliaments met at the castle until the middle of the 15th century, and a mint was established in 1469. The town was incorporated by Edward III.

TRIMONTIUM, according to Ptolemy (ii. 3, 6) a "city" in the territory of the Selgovae, was probably the name of the Roman fort at Newstead, near Melrose, Scotland, close under the three Eildon Hills (whence the name *trium montium*). It was an advanced post of the Romans towards Scotland from about A.D. 80 onwards, and again (after an interval of evacuation) from about A.D. 140–180. Excavations carried out between 1907 and 1911 yielded finds of almost unique importance, These included the foundations of several successive forts, one above the other, which throw much light on the character of the Roman military post, an unparalleled collection of Roman armour, notably ornate helmets, and a good series of coins and datable pottery. The whole illustrate the history of the Roman army and that of Roman Scotland very remarkably and to an extent equalled by no other Scottish site as yet explored.

See James Curle, *A Roman Frontier Post and its People* (Glasgow, 1911).

TRINCOMALEE, a town and former naval station on the northeast coast of Ceylon, 100 m. N.E. by N. of Kandy. Pop. (1953) 28,236. It is built on the north side of the bay of Trincomalee, on the neck of a bold peninsula separating the inner from the outer harbour. The annual average rainfall is 64.8 inches and the average temperature 81.2° F.

The town was one of the first Tamil settlements in Ceylon. Their temple, dedicated to Konatha, or Konasir, on a height at the extremity of the peninsula, was known as the "temple of a thousand columns." The building was destroyed in 1622 by the Portuguese. The town was successively held by the Dutch (1639), the French (1673), the Dutch (1674), the French (1782), and the Dutch (1783). It surrendered to the British fleet in 1795, and with other Dutch possessions in Ceylon was ceded to Great Britain by the Treaty of Amiens in 1802.

With its magnificent harbour--one of the five or six greatest natural harbours in the world—it used to be the headquarters of the admiral commanding on the East Indian station and had a military garrison. Pearl oysters are found in the lagoon of Tambalagam to the west of the bay. Some tobacco, rice, and coco-nuts are grown in the district.

Rice and general merchandise are imported while paddy, timber, dried fish, tobacco, deer horns and skins are exported. The merchant anchorage in the harbour is in 4 to 8 fathoms about 4 cable lengths from the wharf. The harbour can accommodate the largest vessels.

TRING, a market town and urban district in the Hemel Hempstead parliamentary division of Hertfordshire, Eng., 32 mi. N.W. of London by road. Pop. (1951) 5,017. Area 6.9 sq mi. It lies on the western slope of the Chiltern hills. The Rothschild museum contains an extensive natural history collection. The museum stands near an entrance to Tring park with its magnificent beech woods. Tring reservoirs, which supply the Grand Union canal. were leased as a nature reserve in 1955 to protect the wintering duck and migratory birds.

TRINIDAD, a town near the southern coast of Cuba, in Las Villas province, about 45 mi. southeast of Cienfuegos, and 3 mi. from its seaport, Casilda. which lies due south. Pop. (1953) 21,605. There is a local railway. connected with the central trunk line of the island. The city lies on the slope of La Vigia hill (goo ft.) amid higher mountains, and on the banks of the Jayoba (San Juan) river. Casilda has a land-locked, shallow harbour; but Masio bay, a trifle farther distant, accommodates larger craft; and there are excellent deep-water anchorages among the quays off the coast. The Manatí river is navigable for about 7 mi. inland and is used as an outlet for sugar and molasses crops. These and honey are the chief exports; tobacco and various vegetables and fruits are of minor importance. Trinidad is one of the seven original cities of Cuba established by Diego Velásquez. It was founded in 1514 on the coast, but after being attacked by pirates was removed inland. It was thrice sacked by English buccaneers—in 1642, 1654 and 1702. The late 18th century witnessed the development of sugar in this area on a scale that led Trinidad to become by the middle of the 19th century Cuba's fifth city. with more than 14,000 inhabitants. But it did not recover from the civil war and the shift of the sugar industry to other areas. Its traditional architecture makes it one of the most interesting tourist centres in Cuba.

TRINIDAD, the most southerly and, next to Jamaica, was the largest territory of the former West Indies federation. Politically. Trinidad and Tobago (*q.v.*), which was amalgamated with it in 1888, constitute a single colony. Trinidad is 16 mi. east of the coast of Venezuela, between 10° 3' and 10° 50' N. and 60° 55' and 61° 56' W. Average length, 50 mi.; breadth, 37 mi.; area, 1,864 sq.mi. Geographically it is a part of South America, from which it is separated by the Gulf of Paria. Off the northwest coast of Trinidad lie several islands, of which Chacachacare, Huevos, Monos and Gaspar Grande are the most important; Patos. westernmost of the islands, was ceded to Venezuela in 1942. Cnder its "destroyer bases" agreement with Great Britain in 1940, the United States acquired 99-yr. lease rights for naval and air bases in Trinidad. Several areas were taken over and occupied beginning in 1941, but by 1950 all of these had been relinquished except the naval base at Chaquaramas, although the United States retained full rights to re-establish bases in the event of war or grave emergency. An agreement signed April 14, 1953, demarcated the submarine boundaries in the Gulf of Paria between Trinidad and Venezuela.

Both in the north and south of Trinidad there are ranges of hills running east and west, prolongations of the Venezuelan coast ranges. Of these, the northern is the more elevated, its highest point being Mt. Aripo (3,085 ft.). A small ridge runs through the centre of the island, from Manzanilla point to San Fernando, with the isolated Mt. Tamana (1,009 ft.). All hills are densely wooded. There are four mineral springs and several mud volcanoes, but the two most striking natural features are the Maracas falls and Pitch lake. The Maracas falls, 312 ft. high, are situated at the head of a valley of the same name, to the northeast of Port-of-Spain. Pitch lake lies about 38 mi. S.E. of the capital, by water, in the ward of La Brea. It is circular in form. about 2 mi. in circumference, and 148 ac. in extent. The asphalt wells up in low bulging masses, separated from one another by narrow channels. in which the rain forms pools. Near the centre of the lake the pitch is always liquid and can be observed bubbling up. When the sun is hot the lightest footfall leaves an impression, and the pitch emits a strong odour. The soil of the surrounding district is charged with asphalt, but is very fertile, while the road to the neighbouring port of La Brea, running over a bed of asphalt, moves slowly toward the sea like a glacier. The lake is worked by a company which exports the asphalt to the United States, paying royalty to the local government. Asphalt production in 1954 was 142,101 tons, of which 81,529 tons were exported.

The mountain range which runs along the north coast is formed of clay slates, micaceous and talcose schists and crystalline and compact limestones, constituting the group of unknown age called the Caribbean series. The rest of the island is composed of Cretaceous, Tertiary and Quaternary strata. The Cretaceous beds rise to the surface in the centre and are flanked to north and south by later deposits. The relations of the various divisions of the Tertiary formation ate still somewhat obscure. but they are grouped by J. B. Harrison into (1) Nariva and San Fernando beds = Eocene and Oligocene; (2) Naparima marls = Miocene; and (3) Moruga series = Pliocene and Pleistocene. The Naparima marls consist of a lower division containing Globigerina and an upper division with Radiolaria and diatoms and are clearly of deep-sea origin. The bitumen of the Pliocene and Pleistocene deposits appears to have been formed by the decomposition of vegetable matter. Salses or mud volcanoes occur upon the island.

Trinidad's seasons are regular, wet from May to January except for a short break in October, and dry from late January to mid-May. The temperature varies only slightly—daylight average 84° F.. night average 64° F. Annual rainfall averages 64 in. at Port-of-Spain and from 50 in. to 120 in. elsewhere.

Trinidad was discovered by Columbus in 1498. A Spanish governor was appointed in 1532, and before the end of the 16th century San José de Oruna (site of the modern town of St. Joseph), 7 mi. inland from Port-of-Spain, became the capital. San Jose de Oruna was burned by Sir Walter Raleigh in 1595, and the island was raided by the Dutch in 1640 and by the French in 1677 and 1690. Foreigners of all nations were encouraged to settle in Trinidad by advantages offered in 1783, and a large influx of people included many French families driven from Haiti and elsewhere by events of the French Revolution. In 1797, during mar between Great Britain and Spain. a British expedition under Sir Ralph Abercromby sailed from Martinique to reduce the island. Trinidad capitulated without a fight on Feb. 18, 1797, and it was formally ceded to Great Britain by the treaty of Amiens in 1802.

The 1960 census showed the entire population to be 827.957, a 26.9% increase in 15 yr. In 1960 the population of Trinidad was 786.434. General health conditions are excellent. A mass B.C.G. inoculation campaign against tuberculosis was carried out in 1952–53. One-third of the inhabitants are of East Indian extraction. constituting the largest unit of that racial element in the western hemisphere. The population in 1946 was made up as follows: Negro 46.8%; East Indian 35.1%; mixed 14.1%; white 2.8%; Chinese 1.0%; Syrian 0.2%. English is spoken generally; some French patois, Hindi and Spanish are still in use. Port-of-Spain (1960 pop., 91,596), the capital, is on the west coast. It is the leading port of The West Indies and handles virtually all the island's external trade. King's wharf and King's wharf extension provide six berths for discharging and loading of bulk and general cargoes to and from six transit sheds and eight annexes. There is also a seventh berth used mainly by vessels engaged in the mineral trade and two small berths capable of accommodating lighters and small vessels trading within the Caribbean. The eastern portion of King's wharf extension also provides berthing facilities for passenger vessels and royal navy ships. The wharf is well equipped mechanically and there is a 24-hr. service which enables vessels to enter and leave at any time. Pilotage is compulsory for vessels moving between the outer anchorage and the quay side. The government operates two passenger and freight-carrying steamers connecting Port-of-Spain with Scarborough, Tobago, where the wharf was reconstructed in 1953 to enable berthing of the steamers alongside. A new 1,800-ton slipway was opened in 1946. In addition to the city of Port-of-Spain there are two other municipalities, both of them rated as boroughs: San Fernando (pop. 38,587), on the Gulf of Paria about 30 mi. from Port-of-Spain. and Arima (pop. 10,941), 16 mi. inland and east of Port-of-Spain.

Elementary education is free, but is compulsory only in Port-of-Spain, San Fernando and San Juan. In 1955 there were 559 primary and 8 intermediate schools, total enrolment 154,127. Most of these schools are denominational, including Moslem and Hindu, receiving government subsidies. Of the primary schools 65 were government, 311 government-assisted and 153 private. There were 2 government intermediate schools and 2 assisted. Fees are charged at the intermediate and secondary schools. Colleges for training teachers for elementary schools comprised government and Roman Catholic institutions at Port-of-Spain and the Naparima training college at San Fernando. Several high schools in Trinidad. and one in Tobago, were affiliated with the Queen's Royal college at Port-of-Spain.

The government awarded annually three four-year scholarships to universities overseas. A government technical training institute was opened at San Fernando in 1953; also an eastern Caribbean farm training institute in Feb. 1954. In 1921 the Imperial College of Tropical Agriculture was established at St. Augustine, about 8 mi. E. of Port-of-Spain; it was incorporated by royal charter in 1926. Its purposes are to provide training in the science and practice of tropical agriculture for students intending to become planters, agricultural administrators or specialists in agricultural science and technology. It also conducts research relating to a wide range of tropical crops. and advises other British possessions in the Caribbean area with respect to agricultural problems. The college was enlarged in 1951 by two new research laboratories.

Under the constitution of 1956 a governor was appointed by the crown. There was a legislative body consisting of an executive council of 11 (8 chosen by members of the legislative council from among their own number) and a legislative council of 5 appointed by the governor, 2 ex-officio and 24 members elected by universal suffrage. A chief minister was elected by the legislature. There are three municipalities and seven county councils: the latter were given executive powers by statute effective Feb. 2, 1953.

In 1958 the colony of Trinidad and Tobago became a member of The West Indies federation. A constitution scheduled to go into effect in 1962 provided for a bicameral legislature of nominated senators and elective representatives, and terminated the governor's reserved executive powers.

Trinidad has a rich soil well adapted to the cultivation of tropical products For many years cacao was the most important crop. but sugar eventually supplanted it. By the 1960s sugar production had risen to about 200,000 tons annually. About 23,000 tons annually is consumed locally, the rest is exported. Sugar and its by-products have an annual value of more than W.I. $20,-000.000. Coconuts are third in agricultural importance. Coffee, tonka beans, citrus fruits and bananas are raised. The manufacture of Angostura bitters is important.

Petroleum accounts for about 75% of all export values, with sugar and sugar products second. By the 1960s imports and exports had reached a value of more than W.I. $400,000,000 each, not including re-exports. An important ship supply trade usually accounts for more than 15% of export values. The heaviest trade is normally with the following countries. *Exports:* United Kingdom, Brazil, Canada and Newfoundland, The West Indies federation. *Imports:* United Kingdom, Venezuela, United States, Canada and Newfoundland.

Trinidad is the third largest producer of petroleum in the British commonwealth. The first well was drilled at Aripero in 1867, but no shipments were made until 1911. Much of this oil is refined by the island's two refineries, which are also refining an increasing volume of crude oil from Colombia and Venezuela. The average depth of oil wells exceeds 4,500 ft.

A government railway system of 108 mi, links Port-of-Spain with other parts of the island. There are 1,091 mi. of main roads and 1,318 mi. of secondary roads. The island is served by British, Canadian, United States, Venezuelan, Dutch, Brazilian, Argentine, Colombian and Spanish air lines. In an average year, between 4,000 and 5,000 ships touch at Trinidad ports.

The official monetary unit is the West Indian (W.I.) dollar, valued at W.I. $4.80 to the pound sterling. Prior to 1960 this monetary unit was called the British West Indian (B.W.I.) dollar.

The colony's revenues usually exceed expenditures. They were estimated at W.I. $169,968,000 and W.I. $167,640,000, respectively, in 1959.

In 1955 a five-year economic program, which called for W.I. $38,885,275 expenditure on public works, was completed. The largest single outlay was $14.000.000 toward completion of an island-wide water scheme, eventually to cost an estimated $23,-724,000. Other projects included highways, slum clearance an3 erection of schools.

(L. W. BE.; H. E. CN.)

TRINITARIANS, a religious order founded in 1198 by St. John of Matha and St. Felix of Valois, for the liberation of Christian prisoners and slaves from captivity under the Moors and Saracens. The two founders went to Rome and there obtained the approbation of Innocent III, 1198. The rule was the Augustinian, supplemented by regulations of an austere character. The habit was white, with a red and blue cross on the breast. The Trinitarians are canons regular, but in England they were often spoken of as friars. The first to go on the special mission of the order were two Englishmen, who in 1200 went to Morocco and returned thence to France with 186 liberated Christian captives. Vast sums of money were collected by the Trinitarians; but they were called upon, if other means failed, to offer themselves in exchange for Christian captives. Many thousands were liberated by their efforts. In the 17th century a reform called the Barefooted Trinitarians was initiated, which became a distinct order and is the only one that survives. There are now less than 500 members. Their headquarters are at San Crisogono in Rome. They devote themselves to the ransoming of negro slaves, especially children, and a great district in Somaliland has been since 1904 entrusted to them as a field for missionary work.

BIBLIOGRAPHY.—The chief modern book on the Trinitarians is Deslandres, *L'Ordre français des Trinitaires* (2 vols., 1903). Sufficient information will be found in Max Heimbucher, *Orden u. Kongregationen* (1907), ii. §57; and in the *Catholic Encyclopaedia,* article "Trinitarians."

TRINITY. The Christian doctrine of the Trinity can be best expressed in the words '(The Father is God, the Son is God, and the Holy Ghost is God, and yet they are not three Gods but one God . . . for like as we are compelled by the Christian verity to acknowledge every Person by himself (*singillatim*) to be God and Lord, so we are forbidden by the Catholic religion to say that there be three Gods or three Lords" *(Quicunque vult)*. Though this doctrine was one of the first to be dealt with by modern methods of "comparative religion" (as long ago as when Gibbon wrote, "300 B.C., The Logos taught in Alexandria, A.D. 97. Revealed by St. John") — and though it is natural to ask its relation to certain triple arrangements of Pagan deities, to Jewish doctrines of "Wisdom" and the "Word," to the Hegelian triad "The Idea: Nature: Spirit" — it is probably less well adapted to this treatment than other Christian doctrines. At any rate the first step is to discover what, in using this *prima facie* paradoxical language, the Christian Church believed itself to be asserting.

Here a common misunderstanding must be cleared away. "The Creed"—it has been suggested (see *Hibbert Journal,* xxiv. No. *1*) —"means that there is only one being that can, with strict theological correctness, be called 'God,' viz., the Trinity as a whole; but each of the three persons can be called 'God' in a looser sense." This suggestion is offered as a short method of "rendering consistent" the statements of the Creed. But the paradox is not thus lightly to be got rid of. Plainly the Church did not regard itself as lowering the conception of the Father, so that He should become merely one Component of a Divine Whole. "The Father," says St. Thomas Aquinas, "is as great as the whole Trinity," and explains that in such matters "greatness signifies perfection of nature and pertains to essence" *(Summa Theol.* i., xxx. *1*, xlii. *4)*.

Fundamental Conceptions. — This conception of the Trinity is systematically developed by theologians, Greek, Latin and Protestant. "The whole perfection of the. Divine nature is in each of the persons. The essence and dignity of the Father and the Son is the same, but is in the Father according to the relation of Giver, in the Son according to the relation of Receiver" *(S.T.* i., xlii. *4)*. Writers in the 4th and 5th centuries had compared the relation of the Father to the Son with the relation of the "flame to its light," of the "spring to the stream," of the "seal" to its "impress." "Think," says St. Augustine *(Sermo ad Catechumenos,* sec. *8)* "of fire as a father, light as a son. See: we have found coevals: and it is easy to see which begets which." The meaning of these comparisons is plain. They teach that the whole Divine nature or essence is in each of the Three Persons. The impress, for example, is a *full* reproduction of the character of the seal. They teach also that the Divine persons are inseparable. We are dealing both with a "generical" and a "numerical" unity (cf. Aug., F. *and S.,* sec. 4; *Modern Churchman,* vol. xv. 12, 675–7; Webb; *God and Personality,* 69n).

Thus, side by side with language declaring that Father and Son are each in the full sense God, there is other language — not intended. to be inconsistent with the former — which implies that the Son is "necessary to the completeness of the Godhead." The Son, we are told, is not "external" to the Father (Athan., *Discourse I.,* ch. v.), does not "accrue" to the Father from without, but is "of the Substance of the Father." If the Son, it is argued, were not eternal, the Father would not always be Father, and this absence of fatherhood, it is implied, would be a defect (*cf.* the words *consortium, solitarius,* S.T. i., xxxi., 2 and 3). What is the value of these speculations? They cannot be understood apart from a knowledge of the context in which they grew up. This context may be summed up in a sentence. Christians, who were willing to die for Monotheism, deliberately held Jesus to be worthy of full Divine worship; and offered the phrase *Consubstantialem patri* as the intellectual justification of this attitude. In contact with the "Spirit" (who was held to speak in the heart of the individual Christian) they believed themselves to be in contact with God. In contact with Jesus as Master, they likewise found themselves in contact with God; but with no divided allegiance, since they conceived the Universe—in spite of its manifest evils—as the work of the Father of Jesus Christ, and so the embodiment of the same Holy Will which expressed itself most clearly in Jesus and in the Holy Spirit.

The doctrine, then, is primarily religious; and if we define God—as in practice religion does—as "That which has an absolute claim upon our obedience" or as "the Supreme Object of our reverence," the paradoxical element in the doctrine is at least diminished. The ultimate Object of the Christian's reverence is—as reflection will show—the Christian ideal of holiness. A being who fell short of this standard, however omnipotent or self-existent he might be, would not receive the Christian's worship. Conversely, this standard would have an equal claim upon our reverence—since its claim to our obedience is conceived as being absolute—whether or not it were embodied in a person. Jesus is worshipped because the Christian "identifies" Him with His Call—His Law. Reverence and subjection to Him are reverence and subjection to it (John xiv. 21, etc.). Is there, then, any insuperable difficulty in the notion of a threefold personal embodiment of the one Divine Will and Character, an embodiment so complete in each case that contact with the Divine Person is contact with God?

Claims of Unity.—The answer to the foregoing question turns upon the claims of unity. The unity of the world is sometimes represented as based upon its presence to, and its existence in, a single Divine Mind. Religion, however, is interested primarily in the unity of the moral ideal, of the ideal of perfection generally. "The Monotheism of Israel," it has been well said, "was primarily moral seriousness." Religion is concerned also with a faith—which is the basis of its trust and hope—in the necessity of the complete realization of the good in the universe as seen in God; with a faith in that "perfection of the Universe" which St. Thomas regarded as God's chief purpose in creation (i. 50, 3). A Universe which has unity as the complete realization of this single ideal, has the unity which chiefly concerns religion. This ultimate unity of subordination to a single principle is not necessarily identical with the unity which comes from being included within the mind of a single Divine Being. Nor is it obviously identical with the theologian's "numerical unity of substance" (see *e.g.*, Tanqueray, Syn. *Theol.* Dog., ii. 575–576). The Unity, then, of the Object of our supreme reverence and trust is not plainly inconsistent with the existence of personal distinctions (in the modern sense of the word) within the Godhead. It was probably an afterthought to regard the doctrine of the Trinity as providing a more satisfactory conception of "personality in God" than could grow up under a "unipersonal" theology. Yet Trinitarianism has some points of superiority over a theory which may compel us to conceive God as waking up at the Creation from "an eternity of idleness" (Shelley, Queen Mab, vii. *cf.* Journal of Theol. Studies, iv. 376). Love—it may be argued—can only be at its highest perfection in the "love of God for God"—in a love in which He that loves and He that is loved are wholly adequate to one another. A faith in God's perfection would thus tend to a belief in the "plurality of persons in the Godhead."

Amplifying Conceptions.—It has been similarly argued that in conceiving the "not-self with which God contrasts Himself" as "wholly internal to His essence" while the unity (the Holy Spirit) "within which the relation of the. two falls is not, as in us, a dark mystery at the back of our life but something which 'proceeds from both' " we have "the best notion that we can frame of Being at its highest" (Webb, *J.T.S.,* Oct. 1900). Such an argument leads not merely to a plurality but to a trinity of Divine persons, and supports the Western doctrine of the procession of the Spirit from the Father and the Son, tanquam ab *uno principio* et *unica spiratione* (Council of 1274). It agrees also with the conception of the mutual indwelling of the Three Persons (Tanqueray, S.T.D., ii., 664–665). Again, the argument—if joined with the belief that "whatever we conceive the Divine life to be, our life cannot be outside it"—is in accordance with the Scriptural conception that mankind is within the Eternal Son, that the Church is His "body" or His "fulness." Such a conception would lead us beyond any mere "trinity of manifestation"; since it implies that, though in knowing each Person of the Trinity we are knowing God, yet to know God as Trinity is a real addition to our knowledge, and further, that the personal relations within the Trinity are necessary to His full glory, since they make possible to God something better than mere self-contemplation.

The doctrine, then, we may conclude, arose primarily from the conviction that worship of Jesus is consistent with Monotheism. But if, secondarily, the doctrine when formed is defended as offering the best attainable conception of the Divine perfection, it follows that our sense of what is good and fitting, our aesthetic and religious instinct for perfection, and likewise those qualities in the doctrine which moved Dante (*Parad.,* x. 1–6) to give it poetic expression, are all relevant to its discussion. (See PANTHEISM, ATHEISM.) (C. J. SH.)

TRINITY HOUSE, CORPORATION OF. A fraternity of seamen connected from early times with the river Thames and described in the charter of incorporation granted in the name of the Holy Trinity by King Henry VIII on May 20, 1514, as the Shipmen of Mariners of England. Its present charter, granted by King James II on July 8, 1685, describes it as the "Guild, Fraternity, or Brotherhood of the Most Glorious and Undivided Trinity and of St. Clement in the Parish of Deptford Stronde in the County of Kent." The first master appointed was the founder of the corporation, Sir Thomas Spert, Controller of the Navy to King Henry VIII. Deptford having been made a royal dockyard by Henry VIII, and being the station where outgoing ships were supplied with pilots, the corporation rapidly developed. By an Act of Parliament, 8. Queen Elizabeth, the corporation was granted power to erect seamarks at its own costs, and in 1594 it received the very valuable grants of ballastage in the river Thames, and the rights to erect and place beacons and buoys up to that time held by the Great Admiral of England. The charter was regranted by successive sovereigns; King James I made considerable changes and added a number of "Elder Brethren" as distinct from the remaining brethren who were designated "Younger Brethren", whose sole rights consisted of having a vote in the election of the master and wardens.

During the Commonwealth the constitution of the corporation was suspended and the work was conducted by nominees of Parliament, but on the restoration the charter was given back but subsequently surrendered to King Charles II towards the end of his reign, and a new charter was granted by King James II under which the corporation now functions.

The original home of the corporation was at Deptford, but in the seventeenth century it was moved to Water Lane, London, where it remained until 1795 when it was transferred to its House on Tower Hill where it still remains. The corporation by virtue of letters patent granted by the Crown from time to time had erected lighthouses and established light vessels and buoys, for the maintenance of which it was empowered to collect tolls, and in 1836 Parliament passed an Act giving the corporation power to purchase from the Crown, as well as from sundry private proprietors, all their interests in certain principal coast lights. From the earliest days the maintenance of the lights, buoys, etc., was met out of the tolls levied on shipping, any surplus being devoted to the relief of old and indigent mariners and their families, but in 1853 the control of the light dues or tolls was transferred to the Board of Trade, and the corporation was left with only its private and charitable income.

The corporation is now the general lighthouse authority for England and Wales, the Channel Islands and Gibraltar; it is also the principal pilotage authority for England and Wales, and its functions in both these respects are controlled by statute. The Elder Brethren act as nautical assessors in the House of Lords, the Admiralty Division of the High Court of Justice, and the Court of Session in Scotland. Other Trinity Houses established under ancient charters exist at Hull, Newcastle and Leith.

See W. H. Mayo, *Trinity House, London, Past and Present* (1905); C. R. B. Barrett, *The Trinity House of Deptford Strond* (1893).

TRINITY SUNDAY, the Sunday next after U'hitsunday. A festival in honour of the Trinity had been celebrated locally at various dates for many centuries before Pope John XXII (1316–1334) ordered its general observance on the octave of Whitsunday. From Trinity Sunday onward all Sundays until the close of the ecclesiastical year are reckoned in the Church of England as "after Trinity," in the Roman Church as "after Pentecost."

TRINOVANTES, commonly Trinobantes, a powerful British tribe about 50 B.C.–A.D. 50 dwelling north and northeast of London, rivals and neighbours of the Catuvellauni. When Gaius Julius Caesar invaded Britain 54 B.C. they joined him against their domestic rivals. They were conquered by Rome in A.D. 43 and joined in Boadicea's revolt in 61. In the tribal division of Roman Britain given by Ptolemy their land included Camulodunum (Colchester), but nothing more is known of them. Their name plays a part in mediaeval legends and romances. There it was interpreted as Troy Novant, the "new Troy," and connected with the names of the Trojans Brutus and Corineus who were reputed to have given their names to Britain and Cornwall.

(F. J. H.)

TRIOLET, one of the fixed forms of verse invented in medieval France, and preserved in the practice of many modern literatures. It consists of eight short lines on two rhymes, arranged a b a *a a* b a b, and in French usually begins on the masculine rhyme. The first line reappears as the fourth line, and the seventh and eighth lines repeat the opening couplet; the first line, therefore. is repeated three times. and hence the name. No more typical specimen of the triolet could be found than the following, by Jacques Ranchin (c. 1690):

Le premier jour du mois de mai
Fut le plus heureux de ma vie:
Le beau dessein que je formais,
Le premier jour du mois de mail
Je vous vis et je vous aimais
Si ce dessein vous plut, Sylvie,
Le premier jour du mois de mai
Fut le plus heureux de ma vie.

This poem was styled by Gilles Ménage "the king of triolets." The great art of the triolet consists in using the refrain line with such naturalness and ease that it should seem inevitable, and yet in each repetition slightly altering its meaning, or at least its relation to the rest of the poem. The triolet seems to have been invented in the 13th century. The earliest example known occurs in the *Cléomadés* of Adenès-le-Roi (1258–97). The medieval triolet was usually written in lines of ten syllables, and the lightness of touch in the modern specimens was unknown to these perfectly serious examples. One of the best-known is that of Jean Froissart, "Mon coeur s'ebât en odorant la rose." The rules are laid down in the Art *et* Science de Rhethorique (1493) of Henry de Croi, who quotes a triolet written in words of one syllable. According to Jean Sarasin, who introduces the triolet as a mourner m his *Pompe funèbre* de Voiture, it was Froissart who brought back into fashion the ancient precise forms of verse by his ballades, his triolets and his rondeaus, which after his death (1645) returned to their former disrepute. N. Boileau-Despreaux threw scorn upon the delicate art of these pieces, but they continued to be written in France, though not by poets of much pretension, until the middle of the 19th century, when there was a great revival of their use. There are delightful examples by Theodore de Banville.

The earliest triolets in English are those of a devotional nature composed in 1651 by Patrick Carey, a Benedictine monk at Douai, where he probably had become acquainted with what Voiture had made a fashionable French pastime. The triolet was reintroduced into English by Robert Bridges, in 1873, with his

When first we met, we did not guess
That Love would prove so hard a master;
Of more than common friendliness
When first we met we did not guess.
Who could foretell this sore distress,
This irretrievable disaster,
When first we met?—we did not guess
That Love would prove so hard a master.

Since then the triolet has been cultivated very widely in English, most successfully by Austin Dobson, whose "Rose kissed me today," "I intended an Ode" and "In the School of Coquettes" are masterpieces of ingenuity and easy grace.

In French literature, triolets are innumerable; perhaps the most graceful cycle of them is "Les Prunes," attached by Alphonse Daudet to his Les Amoureuses in 1858. In Germany the triolet has attracted much attention. Those which had been written before his day were collected by Friedrich Rassmann in 1815 and 1817. But as early as 1795 an anthology of triolets had been published at Halberstadt and another at Brunswick in 1796. Rassmann distinguished three species of triolet: the legitimate form (which has been described above), the loose triolet, which only approximately abides by the rules as to number of rhymes and lines and single-strophe poems which more or less accidentally approach the true triolet in character. The true triolet was employed by W. Schlegel, F. Hagedorn, F. Riickert, A. Platen and other romantic poets of the early 19th century. In many languages the triolet has come into frequent use to give point and brightness to a brief stroke of satire; the French newspapers are full of examples of this. The triolet has laboured under a suspicion of frivolity, but in the hands of a genuine poet the form possesses a delicate charm. (E. G.; G. W. A.)

TRIPOD, in classical antiquities, any "three-footed" utensil or article of furniture. The name is specially applied to: (1) a seat or table with three legs; (2) a stand for a cauldron in cooking. or for a camera, compass. theodolite, etc.; (3) a sacrificial tripod or altar, the most famous of which was the Delphic tripod, on which the Pythian priestess took her seat to deliver the oracles of the god. the seat being formed by a circular slab on the top, on which a branch of laurel was deposited when it was unoccupied by the priestess. Another well-known tripod was the "Plataean," made from a tenth part of the spoils taken from the Persian army after the battle of Plataea. This consisted of a golden basin, supported by a bronze serpent with three heads (or three serpents intertwined), with a list of the states that had taken part in the war inscribed on the coils of the serpent. The golden bowl was carried off by the Phocians during the Sacred War; the stand was removed by the emperor Constantine to Constantinople. Tripods have been given since Homer's time as prizes in athletic games and as gifts.

TRIPOLI, a city in Lebanon and the seat of administration of the sanjak of Yorth Lebanon in French mandated territory until 1941, mod. Tarabulus. It is situated about 2 mi. inland from its port. El-Mina, to which it is joined by a streetcar line. Pop. (1956 est.) 80,000. The city is the 'terminal of railroads connecting with Turkey and Egypt, has a modern port for seaplanes and is the terminal of one of the two pipelines of Mosul oil. The chief industries are soap manufacture. sponge fishing, tobacco cultivation and fruitgrowing. It has an export trade in fruit (especially oranges). eggs and cotton.

History. — Tripoli is known only by its Greek name. Founded after 700 B.C., it became in the Persian period the capital for the Phoenician triple federation — Sidon, Tyre and Aradus. Each of the three had its own district in the "triple town," which at that time stood on the El-hlina peninsula. The Seleucids and Romans extended and embellished the city. The Moslems took possession in A.D. 638. In 1109 it surrendered to Raymond of St. Gilles, after a five-year siege. A great library founded by Ammar, the ruling family, and consisting, it is said, of 100,000 volumes, was consigned to the flames. When Sultan Kala'un of Egypt took the town in 1289 it was destroyed: and a new city arose on the present site. Tripoli was often a disputed possession of the rival princes of Aleppo and Acre. In 1834, during the Egyptian conquest of Syria, it was made a centre of administration. The British occupied it Oct. 13, 1918. It was incorporated in the state of Grand Liban on Aug. 31, 1920. In 1941 it was occupied by the British and Fighting French and became part of the independent republic of Lebanon on Nov. 26 of that year. (E. Ro.; X.)

TRIPOLI, one of the two capitals (the other being Benghazi) of the united kingdom of Libya, and its chief port, is situated on the north African coast on a promontory stretching out into the Mediterranean. Pop. (1954) 130,238, including the European and American populations. Mass emigration to Israel has reduced the Jewish element.

The oasis of Tripoli is very fertile and beautiful. The desert almost touches the western side of the city, while to the east is the oasis of Mechia, where the tombs of the Karamanlian sultanas are to be seen. Tripoli has a brief winter (lasting from November to January) which is also the rainy season. Night temperatures may drop as low as 32° F. The summer is hot and at times uncomfortably humid. The winter is inclined to be windy, but the spring is frequently accompanied by the ghibli, a hot, rapidly moving sandstorm which may take a day or two to pass.

Tripoli, seen from the sea: is a picturesque city dominated by the ancient Spanish castle dating from the first half of the 16th century. Stretching along the whole length of the bay are the sea wall and a wide boulevard shaded by palm trees. Many of the brightly coloured houses have beautiful gardens.

The city was originally surrounded by walls, now no longer in existence. They dated from Roman times, but the earliest parts actually preserved belong to the Byzantine period, and the greater part to the 16th century. The old city is quite distinct from the new and is characterized by its bazaars, Arab coffee shops and narrow streets, some of which are completely roofed over. Certain streets are associated with special trades, the street of brass-workers being particularly well known where brass and copper trays, bowls, lamps and ornaments are fashioned. Silver articles are also made. In the street of dyers, cobblers and tailors there are many mosques. Of these the largest is the Gurgi mosque and the most famous the Karamanli mosque with its octagonal minaret. Near the harbour is the Marcus Aurelius arch, a Roman triumphal arch, made entirely of white marble and richly embellished with sculpture. It was erected in A.D. 163. In the Turkish quarter the minarets and cupolas of numerous mosques are clearly silhouetted above the flat-roofed and whitewashed houses.

The modern part of the city to the southwest of the old town is more spaciously planned and includes a garden-city residential area. At the centre of the city is the Roman Catholic cathedral. The English church is on the outskirts. Most of the city's streets have been renamed and given Libyan names with one main exception; the boulevard along the sea front (formerly the Lungomare Conte Volpi) has been named Adrian Pelt avenue in honour of the Dutch representative, of the United Nations in Tripoli when Libya acquired its independence. Many of the city's official buildings, theatres and hotels are on this boulevard. The King's palace, white and domed and with a Moorish façade, stands in beautiful grounds; a royal guard of Libyan troops is mounted at the gates.

Communications and Industry. — The coastal road linking Tunis with Benghazi passes through Tripoli; westward toward the Tunisian frontier the road passes the ancient city of Sabratha and, toward the Egyptian border, east of Homs, passes Leptis Magna. Other roads lead south from Tripoli to el Azizia, Gharyan and Jefren. The local rail service runs to a few of the smaller towns, to Zuara, 68 mi. to the west, and Homs, 70 mi. to the east, both of which are on the coastal road. There is an airport at Idris el Awal, 21 mi. S. of the city, which serves several main airlines. At Wheelus Field there is a U.S. military air base.

Agriculture, animal husbandry and fishing form the basis of the local economy. Tunny fishing is particularly important but can only take place for a very short period, when the fish approach the coast. With the aid of Italian experts the fish are prepared and tinned for export. There is a little sponge fishing. Along the shore large salt pans have been dug in which sea water is evaporated; a certain amount of the salt is exported, but most of that produced is used in the drying and preserving of hides and skins. Small local industries include the culture of tobacco and manufacture of cigarettes, and the weaving of carpets and rugs.

The principal exports are esparto grass, tunny fish, peanuts and olive oil, sheep and cattle, hides and skins, and fresh, mainly citrus, fruits. Goods imported include sugar, clothes and general foodstuffs, cars and agricultural machinery, and crude and refined oil. In 1958 a number of European and American companies were prospecting for oil in Libya; a supply of natural gas was discovered a few years previously 40 mi. W. of Tripoli.

The Port. — In addition to a busy transshipment trade, Tripoli handles most of the imports and exports of the kingdom of Libya. The main quays accommodate vessels with a draft of 24 ft. and the Karamanli oil quay can with pontoons accommodate oil tankers of 24–27 ft. draft. The harbour is enclosed by two breakwaters, the Spanish mole and Rasel Zur. The entrance is 310 ft. wide; the buoyed channel, which is 250 ft. wide, has a depth of 29 ft. and there is deeper water in the harbour. The docks are well equipped with mobile cranes, lighters and tugs, and there is a good supply of fresh water.

History. — Tripoli, the ancient Oea, is the only city which has survived of the three — Oea, Leptis Magna (*q.v.*) and Sabratha (*q.v.*)—that formed Tripolitania between 700 B.C. and 146 B.C. It was probably founded by Phoenicians from Sicily, but was under Roman occupation from 146 B.C. until A.D. 450. Invasion by the Vandals followed and conquest by the Byzantines (A.D. 533–643). During the Arab invasions in the 11th century Sabratha and Leptis were destroyed and as a result Tripoli grew in importance. In 1146 it was overrun by the Normans from Sicily and in 1510 it was taken by the Spaniards. It fell to the Turks in 1551 and was in their hands until 1911. They made it the capital of the vilayet of Tripoli. During the first century of the Turkish period Tripoli was a pirates! stronghold. The Italians occupied it from 1911 until Jan. 23, 1943, when British forces entered the city. From 1911 it served as the capital of the Italian colony, and from 1939 it was the capital of the Italian province of Tripolitania. Prior to the establishment of an independent kingdom on Dec. 24, 1951, Tripoli was under British administration. (A. J. Bn.)

TRIPOLI is a porous, friable, microcrystalline silica rock of sedimentary origin comprised chiefly of chalcedony and microcrystalline quartz. It does not include diatomite, although the name was chosen because of its superficial resemblance to tripolite, a diatomite from Tripolitania in north Africa. Some tripoli is a coherent residuum from leached limestone, dolomite or chert; other is probably leached, flocculated colloidal silica which has partly recrystallized. The friable variety is more typical. The chemical composition is usually more than 95% silica, SiO_2, but the impurities may impart beneficial, desirable physical properties. Tripoli is used mainly as a polishing or buffing abrasive, wherein it excels because of its physical properties (particle shape and porosity), and also as a foundry facing. Commercial tripoli powder is finely pulverized, much of it being reduced below ten microns in diameter.

Production in the U.S. is chiefly from Missouri and Illinois, less from Arkansas, Georgia and the Tennessee valley. Besides domestic consumption, large exports go to England chiefly and to other European, Asian and South American countries. (W. D. Kr.)

TRIPOLITANIA, the western part of the kingdom of Libya, has an area of about 348,000 sq.mi. (only 96,471 if the desert hinterland of the Fezzan be excluded) and is bounded on the east by Cyrenaica, on the north by the Mediterranean sea, on the west by Tunisia and, beyond the Fezzan, by Algeria and on the south, likewise beyond the Fezzan, by French West Africa and by French Equatorial Africa. The population in 1951 was estimated as follows: Moslems 753,240; Italians 46,838; Jews 8,000; others, mainly Maltese and Greeks, 3,800; total 811,878. The chief towns, both coastal, are Tripoli (*q.v.;* pop., 1951 est., 119,000) and Misurata (pop., 1951 est., 48,000).

Physical **Features.**—Tripolitania is essentially an undulating plateau, forming a northern part of the central Sahara desert. The surface rises generally southward, where, at the extreme southern frontier, it merges into the Ahaggar, Timmu and Tibesti uplands of the central Sahara. In the northeast, between Misurata and the Gulf of Sirte, the land rises gradually from sea level without much discontinuity; but westward there is first a coastal plain, known as the Jefara, that is backed to the south by a line of northward-facing scarps, successively from east to west the Jabal Misurata, Jabal Tahuna, Jabal Garian and Jabal Nefusa. This latter feature, formed by subsidence along fracture lines trending from east to west with downthrow to the north, is often referred to simply as the Jabal. It does not run parallel to the coast but strikes inland from the coast due westward between Misurata and Homs (Khums), giving the Jefara a triangular shape, with its broadest, part in the west.

The Jabal reaches a general elevation of 2,000 ft. and is marked in places by outpourings of lava (*e.g.,* at Takut, due south of Tripoli). Beyond the crest of the Jabal lies the Hammada al-Hamra (Red desert), a stony plateau about 1,700 ft. above sea level, that covers 40,000 sq.mi. The Hammada is uninhabited, but the presence of numerous well-developed and now dry river valleys indicates that climatic conditions were once very different. There are a few ridges running east-west, the most imposing being the Jabal as-Suda (Black mountain), about 1,000 ft. higher than the plateau. About 400 mi. S. of the Mediterranean coast, the Hammada gives place abruptly to a series of depressions aligned east-west, which form the basin of the Fezzan. There water can be tapped at three distinct levels below ground—at 20 ft., 70 ft. and 200 ft.—and settlements occur in three main districts, Murzuk (the capital), Gatrun (south) and Sebha-Ubari (north). Away from these oases, there is the same alternation of seas of soft sand, gravel desert and volcanic masses. Two isolated oases lie in the extreme west of Tripolitania: Ghadames, an ancient centre 350 mi. S.W. of Tripoli; and Ghat, a much newer settlement 250 mi. S.W. of Murzuk. Both centres command trade routes skirting the main Hammada on the west and continuing southward between the Ahaggar and Timmu ranges toward the Niger and Lake Chad. For several decades previous to 1920 the only caravan routes from the Niger to Tripoli used the track via Ghat, disturbances in Bornu and the Tuareg country farther east having closed all others. The importance of both places has greatly declined.

Because of its open topography, with few screening hills, Tripolitania is affected by unmodified influences alternately from the Mediterranean and from the Sahara. Hence the climate is somewhat unstable, with rapid changes in temperature and unreliable. sporadic rainfall. Temperatures are generally high, with modification caused by the sea near the coast and by altitude in the Jabal. Day maxima in summer frequently exceed 100° F. or even 110° inland. Typical mean conditions for the different regions are: coldest month 54" F. (coast), 52° (Jefara), 47° (Jabal) and 51° (Hammada); warmest month 80° F. (coast), 86" (Jefara), 81° (Jabal) and 84" (Hammada). In summer, the whole of Tripolitania falls under the influence of the Azores anticyclone, and there is no appreciable rainfall. In winter, the northern half of the country is affected from time to time by small depressions that move eastward over the Mediterranean sea; but the northward-jutting promontory of Tunisia shelters Tripolitania from the main rain-bearing northwesterly winds, so that most of the country has only eight inches or less of annual rainfall. The Tripoli area and the Jabal lying to the south and east may receive 10 in. to 15 in. Figures of average rainfall can, however, be misleading, as rain may be entirely restricted to a few weeks, or even days, in each year. Severe droughts occur roughly at ten-year intervals, with, at times, successive seasons of drought. A special feature is the *ghibli,* a violent dusty wind from the south that can suddenly raise temperatures to more than 105° F. and cause enormous damage to growing crops.

The flora of Tripolitania is mainly Saharan, with the date palm and tamarisk highly characteristic. Acacia, asphodel, sapanwood and mastic are found in the wadies, and wormwood forms clusters in the Hammada. Near the coast laurel, myrtle, oak and other evergreens are common, with rarer patches of cypress, pine and carob. Among the commoner animals are the hare, rabbit, hyena, fox, jackal and marmot, while reptiles include the horned viper and gecko. Birds include the vulture, hoopoe, wood pigeon and dove. (W. B. FR.)

History.—Tripolitania, also commonly called Tripoli simply, was originally a Phoenician colony. The wars between the Libyans and the ancient Egyptians do not come properly into its history. (See EGYPT.) Before the colonization of the neighbouring territory to the east by the Greeks (see CYRENAICA) the Phoenicians appear to have founded the cities of Sabratha, Oea and Leptis. Oea, which stood between the other cities, became the capital of the country and was named Tripolis (the "Three Cities"). These towns commanded the trade of the central Sudan, and caravans regularly crossed the Sahara, there at its narrowest. The early history of Tripolitania was similar to that of Cyrenaica: Cyrenaica passed from the Greeks to the Ptolemies and from them to the Romans; Tripolitania, adjoining Carthaginian territory on its west, fell under the sway of Carthage and, following its fortunes, became eventually a Roman province.

In the 5th century A.D. both Tripolitania and Cyrenaica were conquered by the Vandals, whose power was destroyed in the 6th century by the Byzantine general Belisarius. In the middle of the 7th century North Africa was overrun by the Arabs, and Christianity gave place to Islam. From this period dates the decay of a civilization which had lasted about 1,000 years. Tripolitania became subject to the successive rulers of Tunisia. It was pillaged in 1146 by the Normans of Sicily. In 1321 the Beni Ammar established an independent dynasty, which lasted, with an interval during which two sovereigns of the Beni Mekki reigned (1354–69), until 1401, when Tripolitania was reconquered by the Tunisians. In 1510 Ferdinand the Catholic of Spain took the city of Tripoli, and in 1530 it was given to the Knights of St. John, who were expelled in 1551 by the Turkish corsairs Dragut and Sinan. Thus the country fell to the Turks, though after the death of Dragut the connection with Constantinople seems to have weakened. The Tripolitan pirates soon became the scourge of the Mediterranean; half the states of Europe seem at one time or other to have sent fleets to bombard the capital of the country, nor was piracy stopped until after the French occupation of Algiers in 1830. In 1714 Ahmed Pasha Karamanli achieved practical independence. He and his descendants governed the country as a regency, the claims of the Porte being recognized by the payment of tribute, or "presents."

In the early part of the 19th century the regency was twice involved in war with the United States. In May 1801 the pasha demanded from the U.S. an increase in the tribute ($83,000) which the government had paid' since 1796 for the protection of its commerce from piracy. The demand was refused and a naval force was sent from the U.S. to blockade Tripoli. The war dragged on for four years, and the Americans in 1803 lost the frigate "Philadelphia," Capt. William Bainbridge and the whole crew being made prisoners. The expedition undertaken by William Eaton (*q.v.*) had the object of enthroning an exiled pasha, elder brother of the reigning sovereign, who had promised to accede to all the wishes of the United States. Eaton, at the head of a motley assembly of 500 men, marched across the desert from Alexandria and with the aid of U.S. ships took Derna. Soon afterward (June 3, 1805) peace was concluded, the reigning pasha relinquishing his demands but receiving $60,000 (about £12,000) as ransom for the "Philadelphia" prisoners. In 1815, in consequence of further outrages, Captains Bainbridge and Stephen Decatur again visited Tripoli with a squadron and forced the pasha to comply with the U.S. demands.

In 1835 the Turks took advantage of a civil war to reassert their direct authority. They administered the country as an ordinary vilayet (province) under a pasha. Turkish rule was marked by occasional, spasmodic and mainly ineffective efforts to develop the country. When in 1881 the French seized Tunisia the Turks were alarmed and greatly strengthened their garrison in Tripolitania. Disputes followed as to the extent of the Tripolitanian hinterland, which the French endeavoured to circumscribe. It was not only the French that the Turks had to fear: Italy had looked upon Tunisia as its heritage and, baulked in that direction, now fixed its eyes upon Tripolitania and Cyrenaica; and understandings were reached with other European powers interested. For another generation, however, the Turks remained undisturbed and under the impetus of the pan-Islamic movement penetrated farther south, a Turkish garrison even occupying the oasis of Bilma in 1910. Meanwhile Germany was making endeavours to secure economic and, as a result, political predominance in both Tripolitania and Cyrenaica. This led to action by Italy; war was declared upon Turkey in Nov. 1911 and both Tripolitania and Cyrenaica were declared to be under the full sovereignty of Italy. (For the war see ITALO-TURKISH WAR.) However, when the first treaty of Lausanne was signed in Oct. 1912 the Italians held only the coastal region and they met with considerable opposition from the natives (Berbers and Arabs) in their occupation of the interior. But by Aug. 1914 every place of importance in the vilayet, including Fezzan, was in Italian hands. Meanwhile in the coastal districts the Italians had with great energy begun a big program of public works, while toward the Arabs and Berbers they adopted a policy of confidence and trust.

In Cyrenaica the war continued, the Turks having incited the Senussites to continue the struggle. (See SENUSSI.) In Sept. 1914 the *Fezzani*, many of whom adhered to the Senussite sect, rose in revolt. Turkish, German and Senussi propaganda was very active throughout Tripolitania, and the declaration of war by Italy upon Austria (May 28, 1915) was the signal for a general rising. After some hesitation the Italians, in view of the situation in Europe, abandoned the whole country, with the exception of the seaports of Tripoli and Homs. Another seaport, Zuwara, was reoccupied in Aug. 1916. Meanwhile a brother of the Senussi chief ruled in Fezzan; Sulaiman al-Baruni, a Berber chieftain who had given much trouble in 1912–13, reappeared (Sept. 1916) with a firman from the sultan of Turkey appointing him governor general of the vilayets of Tripoli, Tunis and Algiers; and Ramadan ash-Shitaiwi, another powerful chieftain, established a so-called republic of Tripoli and ruled at Misurata, which place became a German submarine base. There was, however, little cohesion and much jealousy among the opponents of Italy.

A campaign under the direction of the governor, Count Giuseppe Volpi, during 1922–23 restored Italian authority as far east as Misurata. It was extended southward to the Hammada al-Hamra in 1924, eastward over the Sirte desert in 1928 and southward again over the Fezzan in 1929–30. In Jan. 1935 the French government under Pierre Laval ceded to Italy a strip of territory 700 mi. long and 40–90 mi. broad along the northern margin of the Tibesti massif. On Jan. 1, 1934, Tripolitania and Cyrenaica had been united to form the colony of Libya, and this was incorporated into the metropolitan kingdom of Italy on Jan. 9, 1939.

The Italian population of Tripolitania rose from 18,000 in 1921 to 90,000 in 1940, nearly half of these living in the capital while large agricultural colonies were settled in the comparatively fertile coastal area.

With the expulsion of the axis forces from North Africa in the spring of 1943, Tripolitania came under British military administration with local Arab and Italian councils, while the southern Fezzan oases had been occupied by the Free French and remained under French administration. The political situation was more complex than in Cyrenaica because of the large Italian minority and also because the Moslem population was less united in its views, since only a minority of Tripolitanian Moslems belonged to the Senussite sect. However, on Nov. 21, 1949, the United Nations general assembly decided that Tripolitania should form part of an independent and sovereign state of Libya. Accordingly, the British and French, who had progressively transferred authority to the embryo state, completed the transfer on Dec. 24, 1951, when the emir Mohammed Idris el-Mahdi es-Senussi became King Idris I of Libya. (See LIBYA.)

Economic Conditions. — Agriculture occupies at least 80% of the population, but, because of severe environmental limitations, production is low. It is estimated that only 11% of the land is potentially productive. Four-fifths of this productive land is fit only for grazing, and of the remaining fifth only 960,000 ac. are used for static agriculture, 3,950,000 ac. being partly unused, partly occupied by shifting agriculture. Barley is the chief crop, being best suited to the severe conditions (average annual production under British administration, 66,000 metric tons), and there is some wheat (7,000 tons annually) and millet. There are 3,500,000 olive trees (yielding 9,000 tons of oil in 1951), of which 2,500,000 were planted by the Italians. Dates are important, forming a staple food in the southern oases, but quality is much inferior to that of Tunisian dates. There would seem to be about 1,500,000 palms in the north and as many as 10,000,000 in the Fezzan, giving an annual production of at least 30,000 metric tons. The Italians planted 300,000 citrus trees, and 50% more were planted after 1945; quality is high, and the export of oranges and tangerines had met with some success by the end of 1951. Other crops are almonds (1,800,000 trees and 2,000 tons in 1951), figs, peaches, apricots, peanuts, castor beans, henna, tobacco, vegetables and vines. There were 20,000,000 vines (mostly Italian-owned) in 1951, yielding more than 660,000 gal. of wine annually. Animal husbandry is of great importance, and in 1950 livestock numbers were: sheep 305,000, goats 314,000, camels 63,000, donkeys 33,000, cattle 31,000, horses 5,400. Industrial activities are small, many being carried on as local crafts. . The main activity consists in the processing of agricultural and fishing products; olive- and castor-oil pressing, the canning of tunny and sardines, brewing and macaroni making. Textiles are mainly produced at home, but there are a few carpet and weaving factories in Tripoli and Misurata. Other activities are the collection of esparto grass, which grows wild in the Jabal and Jefara (18,000 tons in 1950; value £220,000), and fishing for tunny, sardines and sponges (2,500 tons of fish and 25 tons of sponges in 1950). Total exports in 1950 amounted to £2,300,000; imports to £4,600,000. An annual budgetary deficit was met by grants-in-aid from the British government during the period of British administration.

Development under the Italians.—The Fascist government (see *History,* above) spent about £20,000,000 in developing Tripolitanian agriculture. Two main types of farming grew up: concessions, which were moderately large farms financed by private firms; and demographic settlements organized on a communal basis. The concessions were a kind of small plantation, employing much Arab labour; the communal settlements were planned and subsidized by the state, and occupants (Italian immigrants) worked first as semilabourers and then as part owners and were finally to become full owners (after about 20 years) on liquidation of debt charges. No Arabs were employed. In 1949 there were still 7,400 Italians living in private concessions (covering an area of 314,000 ac.) and 11,000 in public settlements (240,000 ac.). Thus 60% of the land under static farming was in Italian hands when Tripolitania was incorporated into the predominantly Arab-Berber kingdom of Libya. The concessions were approximately self-supporting, but the settlements had depended on state subsidies.

Railways comprise 122 mi. of narrow-gauge line centred on Tripoli.

TRIPOLITSA, officially TRIPOLIS, a town of Greece, capital of the nomarchy of Arcadia, 22 mi. S.W. of Argos. The name refers to the three ancient cities of Mantineia, Pallantium and Tegea, of which Tripolitsa is the modern representative. It does not stand on any ancient site. Before the War of Independence it was the capita1 of the Morea and the seat of a pasha, with about 20,000 inhabitants; but in 1821 it was sacked by the insurgents, and in 1825 its ruin was completed by Ibrahim Pasha. The town was later rebuilt; German troops captured it in April 1941. Pop. (1951 census) 17,585.

TRIPOLYE (KOMSOMOLYE), a town of the Ukrainian Soviet Socialist Republic, U.S.S.R., on the Dnieper river, 35 mi. south of Kiev, with which it has steamer communication. It is famous for its painted pottery of late Neolithic date; its site and others near by were explored by Chwojka and the name

Tripolye was given to the culture there represented. This highly developed civilization probably dates from about 2750 B.C. Two types of pottery have been discovered, Tripolye A, the grooved type, being the more common. Tripolye B, or painted pottery, is thought to be an imported product and both are considered to be contemporary. Tripolye is mentioned in 1093 and later was inhabited by refugees from Kiev, after the capture of that city by the Mongols. In the 17th century Tripolye was a fortress, and the remains of its walls still stand, as do two old churches built in the Ukrainian style. During the 1917–20 civil war it was the headquarters of the bandit chief Zeleny, who drowned 100 victims in the Dnieper. A battle ensued between the Communist Youth party (Komsomol) and the bandits and the town was renamed Komsomolye in memory of the Communist victims.

TRIPTOLEMUS, an agricultural hero of Eleusis, first priest of Demeter, and founder of the Eleusinian mysteries. His name is of doubtful meaning ("he who ploughs or toils thrice"; *i.e.,* diligently?); in some legends he is the inventor of the plough. In the best known legend (Apollodorus, i) Triptolemus was the son of Celeus, king of Eleusis, and Metaneira. Demeter, during her search for her daughter Persephone, arrived at Eleusis in the form of an old woman. There she was hospitably received by Celeus, and out of gratitude would have made his son Demophon immortal by anointing him with ambrosia and destroying his mortal parts by fire; but Metaneira, happening to see what was going on, screamed out and disturbed the goddess. Demophon was burnt to death, and Demeter, to console his parents, took upon herself the care of Triptolemus, instructed him in everything connected with agriculture, and presented him with a wonderful chariot, drawn by dragons, in which he travelled all over the world, spreading the knowledge of her gifts. In another account (Hyginus, *Fab.* 147) Triptolemus is the son of Eleusinus, and takes the place of Demophon in the above narrative, but does not die. In the Homeric hymn to Demeter, Triptolemus is simply one of the nobles of Eleusis, who was instructed by the goddess in her rites and ceremonies. The Attic legend represented him as one of the judges of the underworld. He is often represented in art, and formed the subject of a play (now lost) of Sophocles. His altar and threshing floor were shown on the Rarian plain near Eleusis; hence he is sometimes called the son of Rarus.

See Preller-Robert, p. 767, vol. i, and the classical dictionaries.

TRIPTYCH: *see* ALTARPIECE.

TRIPURA, a constituent state of the republic of India, adjoining the East Pakistan district of Tippera. Area, 4,036 sq.mi.; pop. (1961) 1,141,492. Tripura comprises six parallel ranges of hills running from north to south, at an average distance of 12 mi. apart. The hills, of which the highest is 3,200 ft above sea level, are covered for the most part with forest and bamboo jungle, while the low ground abounds with trees of various kinds, canebrakes and swamps. The forests shelter wild elephants, bison, tigers, leopards and deer. The principal crop and food staple is rice. Half the population consists of Tiparas, a tribe of Mongolian origin. The capital is Agartala (pop., 1951, 42,595), where there is a college affiliated to Calcutta university.

Tripura represents the remnant of an ancient kingdom which at various times extended in the north to Kamrup and in the east to Arakan. Ralph Fitch, who travelled through the country in 1585, noted that "the king of Tippara had almost continual wars with the Arakanese." The country now included in the Tippera district of East Pakistan was conquered by the Moguls and annexed in 1733, but Tripura still remained under its own line of rulers. When the East India company obtained the ***diwani*** or financial administration of Bengal in 1765 they placed a rajah on the throne and, after 1808, each successive ruler received investiture from the British government. After the state's accession to India a chief commissioner's administration was established on Oct. 15, 1949. This led to serious disturbance for, although the maharaja's rule had been autocratic, the new administration was regarded as an attempt of non-Tripuris to dominate.

TRISECTRIX: *see* CURVES, SPECIAL.

TRISTAN or TRISTRAM, one of the most famous heroes of mediaeval romance. In one of the earlier versions of his story he is the son of Rivalîn, a prince of northwest Britain, and Blancheflor, sister of King Mark of Cornwall. Rivalîn is killed in battle and Blancheflor dies after giving birth to a son. The boy is brought up as his own by Roald or Rual, seneschal of the kingdom, who has him carefully trained in all chivalric and courtly arts. With the possible exception of Horn, Tristan is by far the most accomplished hero in the whole range of knightly romance; a finished musician, linguist and chess player, no one can rival him in more knightly arts, in horsemanship or fencing. He has, besides, the whole science of *vénerie* at his fingertips. Being kidnapped by pirates, Tristan is carried to Cornwall where he finds his way to the court of his uncle, King Mark, who is at first unaware of his identity but, on learning it, joyfully accepts him as nephew and heir. The Tristan romance proper begins at this point, and the following incidents are common to most of the early versions: Tristan defeats the Irish giant, Morholt, who comes to claim the tribute payable every third year by Cornwall, but is desperately wounded in the encounter. Set adrift in a boat, Tristan is carried by the waves to Ireland, where he is healed by the queen, sister to Morholt. Later on he returns to ask the hand of the princess Iseult for his uncle, King Mark, and, having slain a dragon which is devastating the country, succeeds in his quest. On the homeward journey Tristan and Iseult, by misadventure, drink of the love potion prepared by the queen for her daughter and King Mark. Henceforward the two are bound to each other by an imperishable love which dares all dangers and makes light of hardships, but does not destroy their sense of loyalty to the king. The greater part of the romance is occupied by plot and counterplot; Mark and the courtiers seeking to entrap the lovers, who escape the snares laid for them until finally the two are discovered under circumstances which admit of no evasion, and Tristan is obliged to flee to Brittany. There he weds Iseult of the White Hand, daughter of the duke, "for her name and her beauty," but makes her his wife only in name. Wounded by a poisoned weapon he sends to Iseult of Ireland to come and heal him. If she accedes to his request the ship on which she embarks is to have a white sail, if she refuses, a black. Actuated by jealousy, his wife, who has discovered his secret, seeing the ship approach on which Iseult is hastening to her lover's aid, tells him that it carries a black sail. Tristan, turning his face to the wall, dies, and Iseult, arriving too late to save her lover, yields up her life in a final embrace. A miracle follows their deaths: two trees grow out of their graves and intertwine their branches so that they can in no wise be sundered.

The legend of Tristan and Iseult was one of the most popular themes of mediaeval romance; it was translated into many tongues, and the episodes are preserved in miniatures, carvings and embroideries. The earliest form of the story is still a matter of debate. The name of Iseult's father, Gormond, is certainly Scandinavian, and she herself is noted for her golden hair; she may be a northern, not a Celtic, princess. The name of Tristan, on the other hand, has been referred to the Pictish Drustan, and some elements in the story are now generally admitted to be of insular origin. Since the publication of Joseph Bédier's epoch-making study it is more generally believed that there was but one poem at the root of all the varying versions of the Tristan story, and that that work, composed in the 12th century by an unknown French poet, was of such force that it determined for all time the form of the tradition. One of the adaptations of that archetype is a poem composed late in the 12th century by an Anglo-Norman named Thomas, which was translated into German, English and Old Norse. Only fragments now remain, but they are sufficient to show that the original was a work of outstanding merit. The German translation, by Gottfried von Strassburg, which seems to have followed the original closely, is one of the classics of the middle ages. But the most authentic adaptations of the archetype are those produced late in the 12th century by the Norman poet, Béroul, and the German poet. Eilhart von Oberge. Of the former only about one-third or less is extant. There also exists in two manuscripts a short poem, *La Folie Tristan,* relating how Tristan, disguised as a fool, visits the court of King Mark. This poem is valuable, as, relying upon the sufficiency of his disguise, Tristan audaciously gives a résumé of his feats and of his relations with Iseult, in this agreeing with the earliest versions. The "Gerbert" continuation of the *Perceval* contains the working over of a short *Tristan* poem, called by him the *Luite Tristan;* the latter part, probably a distinct poem, shows Tristan, in the disguise of a minstrel, visiting the court of Mark.

Finally, in consequence of the popularity of the cyclic version of the Arthurian romances, the original *Tristan* story was worked over in prose on the model of the prose *Lancelot,* and so served to swell the already unwieldy bulk of the romantic corpus. The original tragic beauty of the primitive story is here obscured by an interminable series of banal adventures. It was in this form that Thomas Malory knew it. Richard Wagner, inspired by the text of Gottfried von Strassburg, restored the story to one of its earlier forms and enshrined it in imperishable music.

TRISTAN DA CUNHA, the group name for three small volcanic islands belonging to Great Britain, situated in the South Atlantic, approximately midway between South Africa and South America in latitude 37° 5' S., longitude 12" 16' W. The population of Tristan was evacuated in 1961 after a volcanic eruption; the other two islands, Inaccessible and Nightingale, are uninhabited as is Gough Island *(see* below) which is associated with the group.

Physical Geography.—Inaccessible, the westernmost island, is about 20 mi. from Tristan. It is quadrilateral, the sides being about 2 mi. long, with cliffs about 1,000 ft. high. Its highest point (2,260 ft.) is on the west. At the base of the cliffs in some places are narrow fringes of beach, but landing is possible only in small boats in favourable weather. The small flightless land rail *Atlantisia rogersi* is a bird peculiar to this island.

Nightingale, the smallest and southernmost island, is 10 mi. from Inaccessible and 25 mi. from Tristan. Its area is not more than 1 sq.mi. and its highest point 1,200 ft. Its coasts are marked by low cliffs and rocks and landing is made, under favourable conditions, by leaping onto a rocky platform as the swell raises the boat to its level. Millions of greater shearwaters, petrels and other sea birds nest on the island. Two small islets, Stoltenhoff (325 ft.) and Middle (150 ft.), and several rocks are adjacent to the coast.

The island of Tristan da Cunha, the largest and northernmost, has an area of 40 sq.mi. It is roughly circular, having a coast line of 21 mi. and a volcanic cone 16.760 ft.) which is frequently covered by clouds. Winds are generally strong and variable. The prevailing winds are westerly; cloud forms with northerly winds and clear skies accompany southerly winds. The climate is mild. temperatures averaging 68° F. in summer and 55° F. in winter. There is no frost and only rarely does hail or snow fall on lower ground. Rain, however, is frequent and humidity is high.

From a distance the island presents a bleak and barren appearance, but closer approach reveals that, though the sand and rocks on the beach are black, the 2,000-ft. cliffs, which on all sides except the northwest rise sheer out of the sea, are green with many kinds of fern. grasses and the island tree *Phylica arborea.* Where the cliffsare bare, the colour of the different rocks—basalt, porphyritic basalt, augite-andesite. palagonite, volcanic tuff and ashes—enriches the austere grandeur. The island is surrounded by a broad belt of kelp beyond which visiting ships can anchor when there is sufficient lee. There is no harbour. Tides rise and fall 4 ft. and there is a westerly ocean drift. On the northwest an irregular plateau, rising from 100 to 200 ft. high and roughly half a mile wide and five miles long, is crossed by a stream and provides the only habitable site. A new volcanic cone formed at its eastern end in Oct. 1961.

History.—The islands were discovered in 1506 by the Portuguese admiral Tristão da Cunha. Attempts to form settlements were made by the Dutch in 1656 and by the East India company about 30 years later. Jonathan Lambert from Salem. Mass., settled there with two companions in 1810 but was drowned in a boat accident. In 1816 a British garrison was stationed on Tristan to prevent any attempt to rescue Napoleon from St. Helena. and the island group was formally annexed to Britain. Corporal William Glass, a Scotsman, was permitted to remain with his family when the garrison was withdrawn in 1817. They were joined by shipwrecked sailors, settlers of European extraction and women from St. Helena. By 1886 there were 97 inhabitants. During World War II a naval meteorological and radio station was established on Tristan which was commissioned as H.M.S. "Atlantic Isle"; after the war the station was taken over by the South African government. Following severe earth tremors, an eruption and lava flow on Oct. 9, 1961, threatened the settlement of Edinburgh. The inhabitants were evacuated on the following day in fishing craft to Nightingale, whence they were picked up by a liner and carried to England. The majority were resettled in the former Royal Air Force married quarters at Calshot. Hampshire. The total population at the date of evacuation was 295, of whom 264 were islanders; the latter spoke English with a Victorian cockney intonation, pronouncing w for *v*. The only settlement was the village of 60 houses on the north coast, called Edinburgh.

In 1938. Tristan, Inaccessible. Nightingale and Gough islands were made dependencies of St. Helena. In 1950 the colonial office appointed an administrator for Tristan, which had hitherto managed its own affairs with the occasional aid of a resident Anglican chaplain. A representative island council, with the headman and headwoman ex-officio members, advised the administrator, who was empowered to make bylaws.

The homes of the islanders faced the sea and resembled Scottish crofts. They were built of volcanic tuff and thatched with New Zealand flax. Wood or imported coal was used for fuel. Potatoes were grown on the plateau and some vegetables in the gardens. Apples grow wild on the east of the island.

Sea birds and their eggs and guano were collected from the other islands, and wool was carded. spun and knitted into the long white stockings worn by all of the former inhabitants. In 1949 a South African fishing company was permitted to establish an industry for catching. freezing and canning crawfish (rock lobsters) for export. In return the company was required to provide a doctor, nurse, agriculturalist, teacher and store; later these obligations were substituted by a levy on net profits. Public expenditure was further assisted by the revenue from post-office receipts and by grants from colonial development and welfare funds. Developments achieved or in progress before the evacuation included improvement of the limited pasturage, a piped water supply and a sewerage system. (X.)

Gough Island.—Gough Island or Gonçalo Alvarez lies in 40° 20' S., 9° 55' W. about 255 mi. S.S.E. of Tristan da Cunha. It is about 8 mi. long by 4 mi. broad and is of volcanic origin. The summit, Edinburgh peak (2,956 ft.), rises from a central plateau which is bordered by a series of deep valleys and craggy ridges. The island is bounded by coastal cliffs 200–1.500 ft. high, over which many streams cascade. Grassland and bog cover the uplands; the valleys are filled with dense scrub and the cliffs support tussock grasses. Several species of flowering plants and two land birds are found only on Gough; vast numbers of rock hopper penguins. petrels, and shearwaters breed there, as do three species of albatross. Fur seals are common and sea elephants occur.

Gonçalo Alvarez was found by Portuguese navigators about 1505 and rediscovered by a Captain Gough in 1731. With the Tristan group, it became a dependency of St. Helena in 1938. Sealers, castaways and scientific expeditions have visited it occasionally, and since 1949 the Tristan da Cunha Development company's ships have exploited the crawfish around Gough Island. In 1955–56 the island was studied by a scientific expedition whose base was thereafter used for a South African weather station.

TRITON, the Greek merman, demigod of the sea; he was the son of Poseidon and Amphitrite. According to Hesiod in his Theogony, Triton dwelt with his parents in a golden palace in the depths of the sea.

The story of the Argonauts places his home on the coast of Libya. When the "Argo" was driven ashore on the Lesser Syrtes the crew carried the vessel to Lake Tritonis, whence Triton, the local deity, guided them across to the Mediterranean. He was represented as human down to the waist, with the tail of a fish, but ancient artists portray other and more fantastic sea creatures as well.

ALINARI

ANTIQUE SCULPTURE OF TRITON ABDUCTING A NYMPH. IN THE VATICAN MUSEUM. ROME, ITALY

Triton's special attribute was a twisted seashell, on which he blew to calm or raise the waves. Various stories represent him as jealous or violent.

TRITUBERCULATA (PANTOTHERIA), a group of very small insect-eating mammals from the Jurassic rocks, characterized by the sharp-cusped lower molar teeth with a posterointernal heel (tuberculo-sectorial type).

Some of them, such as Amphitherium, are, perhaps. the ancestors of all modern mammals except the platypus and echidna (Monotremata; *q.v.*). See MAMMALIA; MULTITUBERCULATE; PALEONTOLOGY.

TRIUMPH, the highest honour bestowed in Rome upon a victorious general (Lat. triumphus). It was only granted on certain conditions, relaxed in special cases. Only those who held the office of dictator, consul, or praetor were entitled to the distinction; the war must have been brought to a definite conclusion, resulting in an extension of the boundaries of the state; the victory must have been gained over a foreign enemy. The power of granting a triumph rested with the senate. Special legislation was necessary to keep the general in possession of the *imperium* on his entry into the city. Without this, his command would expire and he would have no right to a triumph. He remained outside the city limits until the ordinance was passed; Lucullus on his return from Asia waited outside Rome three years.

The triumph, a solemn procession, starting from the Campus Martius, passed through the city to the Capitol. The streets were adorned with garlands, and the procession was greeted with shouts of *Io* triumphe. At its head were the magistrates and the senate, followed by trumpeters and then by the spoils (arms, standards, statues, etc., representations of battles, and of the towns, etc., of the conquered country). Next came the victims destined for sacrifice, especially white oxen with gilded horns. They were followed by the prisoners kept to grace the triumph.

The chariot of the victorious general (*triumphator*) was crowned with laurel and drawn by four horses. The general was attired like the Capitoline Jupiter in robes of purple and gold; in his right hand he held a laurel branch, in his left an ivory sceptre surmounted by an eagle. Above his head the golden crown of Jupiter was held by a slave, who reminded him in the midst of his glory that he was a mortal man. Last came the soldiers shouting *Io* triumphe.

On reaching the temple of Jupiter on the Capitol, the general placed the laurel branch on the lap of the image of the god, and offered the thank offerings. A feast of the magistrates and senate concluded the ceremony. Under the empire-only the emperors celebrated a triumph, because the generals commanded under the auspices of the emperors as lieutenants (*legati*); the only honour they received was the right of wearing the triumphal insignia (the robes of purple and gold and the wreath of bay leaves) on holidays.' The last triumph recorded is that of Diocletian (A.D. 302).

A naval triumph was sometimes allowed for victories at sea, the earliest being that celebrated by C. Duilius for his victory over the Carthaginians in 260 B.C.

See Marquardt, *Romische Staatsverwaltung* (1884) ; Mommsen, *Ronzisches Staatsrecht* (1887) ; J. E. Sandys, *Companion to Latin Studies* (1921).

TRIUMPHAL ARCH is an arch that was built to commemorate the victory of a Roman general; in a broader sense, any monumental arch built for purely commemorative or even decorative purposes. The term is also used for the great arch between the nave and the apse of an early Christian basilica (*q.v.*) although this arch is an integral part of the interior structure of the church and has no resemblance with the Roman triumphal arch.

The origin and significance of this typically Roman form of monument is much debated. It was a separate structure, with no connection with city gates or city walls, and should not be confused with the Porta Triumphalis through which the victorious Roman army had to pass before entering the sacred city territory (*pomerium*) of Rome. Its basic form consisted of two piers connected by an arch and crowned by a superstructure, *attica,* that served as a base for statues. The arch was usually placed over a street; in Rome, preferably over a street used by the triumphal processions. The attica carried a commemorative inscription. The statuary at first usually represented the victor in his triumphal chariot; later, only the emperor was depicted. The function of the arch therefore seems to have been that of an honorary monument of unusual importance; it was so interpreted by the only ancient author who discussed it, Pliny the Elder (c. A.D. 70).

By the age of Augustus, it sometimes took the form of a triple arch with the central passage somewhat higher than the flanking ones. Few triumphal arches of the time of the republic are known. In Rome three were erected: the first, in 196 B.C. by L. Stertinius; the second by Scipio Africanus on the Capitoline hill in 190 B.C.; and the third, the first in the Forum area. by Q. Fabius Allobrogicus in 121 B.C. All carried statuary, but little is known of their architectural form.

In Augustan times and during the imperial period the triumphal arch was very popular. Early in the 4th century A.D. there were

TYPES OF THE TRIUMPHAL ARCH

(Left) Arch of Trajan, Benevento, 2nd century; (centre) Arc de Triomphe, Paris, early 19th century; (right) Arch of Constantine, Rome, 4th century

36 such monuments in Rome. The triumphal arch of imperial times was a very articulate monument. The façade was of marble, columns and ornamental cornices were added to the piers and *attica,* and the archway and sides were adorned with sculpture in relief referring to victories and other achievements of the emperor. In Rome three triumphal arches have survived: the Arch of Titus (completed after the emperor's death in A.D 81) with representations of his triumph over Jerusalem; the Arch of Septimius Severus (203–205) commemorating his victory over the Parthians; and the Arch of Constantine (312). The latter is a composite product, decorated with reused material from the times of Domitian, Trajan and Hadrian. Outstanding examples of arches outside Rome are. those of Augustus in Susa. Aosta, Rimini and Pola; those of Trajan in Ancona and Benevento; that of Marcus Aurelius in Tripoli, and that of Septimius Severus in Leptis Magna in north Africa. *(See* also ROMAN ARCHITECTURE.)

In Castelnuovo in Naples is a marble gateway called the triumphal arch of Alfonso I (1453–70); in its decoration it was inspired by its ancient forerunners. The 17th-century Porte St. Denis and Porte St. Martin and, above all, the Arc de Triomphe by Chalgrin (1836), all in Paris, are noteworthy. The Marble arch in London, designed by John Nash in 1828 for an entrance gate to Buckingham palace and later moved to its present position, was inspired by the Arch of Constantine; the Hyde Park Corner arch from the same year was of more independent design.

The Washington arch in New York city, built to commemorate the 100th anniversary of Washington's presidential inauguration (completed 1895), is exceptional for its balanced blend of modern and ancient stylistic features. *See* also MONUMENTS AND MEMORIALS. (EK. S.)

TRIVANDRUM, city and district of Kerala state, India. The city, 2 mi. from the sea, is the state capital; pop. (1951) 186,931. It is famous for an old temple, around which the city grew. It is the seat of Travancore university.

The DISTRICT OF TRIVANDRUM is the southernmost district of India. Area 847 sq mi.; pop. (1951) 1,327,812. The climate is damp, except in the south.

The produce is mainly paddy and coconut, with some tea, rubber and coffee. Deposits of monazite and ilmenite have been found in the sands. (S. GL.)

TRIVIUM, in medieval educational systems, the curriculum which included grammar, rhetoric and logic (Lat. for "crossroad." *i.e.,* where three roads meet, from *tres,* three, and *via,* road). The trivium and the quadrivium (arithmetic. music, geometry and astronomy) together made up the seven liberal arts.

TRNAVA, a town in Bratislava. Czech., on the Trnava river, was transferred from Hungary to Czechoslovakia by the treaty of Trianon, 1920. It is a market town for a rich agricultural region. Manufactures include sugar refining, starch, beer, shoes and, oldest of all, cloth; fertilizers are also prepared.

The population in 1950 was 26.078.

TRNOVO (TIRNOVO), a city and capital of a department in Bulgaria; 124 mi. E.N.E. of Sofia, on the Yantra river, on the Trans-Balkan railway, nhich joins the Sofia-Varna line at Gorna-Orehovitsa. 8 mi N. of Trnovo. Pop. (1956) 24,751.

The city is remarkably situated. The Yantra runs in a deep gorge, doubling first left. then right, round two promontories which stand like high fortresses. surrounded by water on three sides. The first of these, the Tsarevitsa, is connected with the rest of the town by a high causeway, in part a bridge; the other, the Trapesitsa, is entirely isolated. The inhabited town covers the two sides of the rooflike ridge which terminates in the Tsarevitsa.

On the latter are a ruined tower, known as Baldwin's tower, where the Frank emperor is supposed to have been imprisoned, and, behind it, the somewhat unimposing remains of the palace of the Asens (*q.v.*). Few of these ruins have been excavated. The Trapesitsa contains the fragments of several medieval churches in the Byzantine style.

Trnovo is believed to have been a Roman fortress; it was the birthplace of Tsar Sisman, and the home of the second Bulgar empire, proclaimed there in 1185 by the brothers Peter and Ivan Asen, who were boyars of the Tsarevitsa and Trapesitsa. It was capital of Bulgaria 1186–1394, when it was adorned with great splendour; most of the relics were destroyed in the earthquake of 1911. It was the seat of the Bulgarian patriarchate from 1232 to its abolition in 1767.

Trnovo was taken by the Turks on July 17, 1394. It remained, however, a commercial centre. It nas captured by Russia in 1877. Prince Alexander of Battenberg was there proclaimed Bulgarian prince (1879). There the Bulgarian constituent assembly sat and the independent kingdom of Bulgaria was proclaimed in the Church of the Forty Martyrs (Oct. 5, 1908) *(see* BULGARIA: *Hzstory).* (C. A. M.)

TROAD: *see* TROY AND TROAD.

TROCHEE (CHOREE), literally the "running" or "dancing" foot (– ⏑) (Gr. *Trechein,* "to run," and *Choros,* "a band of dancers"). Classical trochaic metre is of several kinds, usually described by the number of *metra,* or groups of two trochees, which they contain. In example, the dimeter:

Rōmă Rōmă, | cērnĕ quāntă
Cōmrădes, leave mĕ | hēre ă lĭttlĕ

consists of two *metra* or four trochees. The commonest form, especially in ancient drama, is the *tetrameter catalectic* or *septenarius* (four *metra* or eight trochees, lacking the final syllable), as

~om: ~om:,- | cērne quāntă | sīt dĕūm bĕn|īgnĭtās
Cōmrădes, leave mĕ | hēre ă lĭttlĕ, | while as yet 'tĭs | ēarly mŏrn.

Trochaic metre in English accentual verse, a stressed syllable followed by an unstressed, has an especially lilting. buoyant effect, but it is less flexible than the iambic. Completely regular trochaic verse is usually monotonous. as Longfellow's blank trochees in *Hiawatha* prove, or Tennyson's in "Locksley Hall."

It was not used extensively until the 19th century, but then with frequent iambic substitutions and omissions of the unstressed syllable at the end of the line, thus permitting masculine rhyme (*q.v.*).

See METRE; VERSE. (G. W. A.)

TROCHOPHORE (TROCHOSPHERE), the names applied to the free-swimming larval form of the segmented worms or Annelida (*q.v.*) and to the very similar (first) larval stage of the Lamellibranchia (bivalves) and Gastropoda (univalves) (*q.v.*) among the Mollusca (*q.v.*).

TROCHU, LOUIS JULES (1815–1896), French general, was born at Palais, Belle-Ile-en-Mer, on March 12, 181j. He served as a captain in Algeria and as a colonel throughout the Crimean campaign. He commanded a division in the Italian campaign of 1859.

In 1866 he was employed at the ministry of war in the preparation of army reorganization schemes, and he published anonymously in the following year *L'Armée française en 1867,* a work inspired with Orléanist sentiment! which brought him into bad odour at court. He left the war office on half pay, and was refused a command in the field at the outbreak of the Franco-German War.

After the earlier disasters in 1870, he was appointed by the emperor first commandant of the troops of Châlons camp, and soon afterward (Aug. 17) governor of Paris and commander in chief of all the forces destined for the defense of the capital, including about 120,000 regular troops, 80,000 mobiles and 330,000 national guards. He put Paris in a state of defense, and showed himself a master of the passive defensive. At the revolution of Sept. 4 he became president of the government of national defense. His "plan" for defending the city failed; the successive sorties were unsuccessful, and when capitulation became inevitable he resigned the governorship of Paris on Jan. 22, 1871, to General Vinoy, retaining the presidency of the government until after the armistice in February.

He was elected to the national assembly by eight departments, and sat for Morbihan. In July 1872 he retired from political life, and in 1873 from the army. He published in 1873 *Pour la vérité et pour la justice,* in justification of the government of national defense, and in 1879 *L'Armée française en 1879, par un officier en retraite.*

He died at Tours on Oct. 7, 1896.

TROELSTRA, PIETER JELLES (1860–1930), Dutch Socialist leader, was born at Leeuwarden and educated for the legal profession at the University of Groningen, but early abandoned it for politics and journalism. He adopted Socialist opinions and, becoming dissatisfied with the leadership of Domela Nieurenhuis, under whom Dutch Socialism had assumed an extremist complexion bordering on anarchism, he founded the Social Democratic Workers' party in 1894 for the constitutional achievement of Socialism.

In 1913, the Liberal party offered the Socialists three seats in a government which would include in its program universal suffrage and old-age pensions. This Troelstra refused, on the assumption that the entrance of the Socialists into the government would strengthen the opposition to universal suffrage. His point of view was approved by the conference of the party. At the elections of 1918, as a result of the introduction of universal suffrage. the Socialists scored important gains, and under the influence of the German revolution. Troelstra, in a remarkable speech in the chamber, called upon the government to resign with a view to the formation of a socialist state. The leading members of his party repudiated his tactics but pressure was brought to bear upon the government, which resulted in the eight-hour day and other reforms.

Thenceforward Troelstra's influence with the proletariat increased steadily, until in 1925, because of failing health. he retired from politics.

TROELTSCH, ERNST (1865–1923), German liberal Protestant theologian and historian, was born in Haunstetten near Augsburg on Feb. 17, 1365. From 1894 to 1914 he was professor of theology and from 1910 to 1914 also professor of philosophy at Heidelberg; from 1915 to 1923 he was professor of philosophy at Berlin. Troeltsch also served as undersecretary for Protestant affairs in the Prussian ministry of public worship and education (1919–21). He died at Berlin on Feb. 1, 1923.

The bulk of Troeltsch's writings were historical studies dealing with philosophy of religion, philosophy of history, Christian theology and social ethics, and with the broad periods and movements of western history. Two underlying philosophical concerns determined these and his other studies: the significance of the modern historical consciousness for understanding and evaluating western religion and culture, and the problem of relating the living power of historical Christianity to the needs growing out of the cultural situation and the religious unrest of his time. As a Neo-Kantian, and in opposition to the Marxists, he insisted, in the name of "the religious a priori," upon the independence of religion in its relation to and influence upon society; at the same time, as a sociologist of religion, he investigated the ways in which social factors have influenced the development of religion and its institutions. Under the influence of A. Ritschl he emphasized the decisive concern of Christianity with the enhancement of the human personality, the personality of Jesus being assumed as the unifying element in all forms of Christian faith. In contrast to Ritschl, however, he stressed the autonomous role of reason and intuition in religion and the sole right of historical method in theology; he demanded also a comparative study of the world's religions.

In his view of history Troeltsch, like W. Windelband and H. Rickert, stressed the differences between nature and history, viewing the latter in terms of individuality, unique development and (provisional) creative synthesis. Each religion, in his view, is closely bound up with its local culture. With a strong inclination to nominalism and relativism, he rejected the claim of any religion to absoluteness.

In his interpretation of the history of Christian social ethics Troeltsch gave prominent place to the various formulations of (ethical and legal) natural law theory. He severely criticized Luther and Lutheranism for the social conservatism issuing from a dualism between the church and the world and between Gospel and Law. Like Max Weber, he examined the relations between Calvinism and capitalism. He went beyond Weber in discriminating three types of Christian group in history—the church type, the sect type and the mystical type.

The Neo-Reformation theologians (*e.g.,* Karl Barth and Emil Brunner) have viewed Troeltsch as a major misinterpreter of Christian faith and of the Reformation. Among the philosophical theologians of existentialism, Paul Tillich and H. Richard Niebuhr in qualified ways have acknowledged special indebtedness to him, as did also the Roman Catholic theologian Friedrich von Hügel.

Many of Troeltsch's writings have been assembled in *Gesammelte Schriften,* 4 vol. (1912–25). The most influential of his books are *Die Absolutheit des Christentums und die Religionsgeschichte* (1902 and later ed.); *Die Bedeutung des Protestantismus für die Entstehung der modernen Welt* (1906 and later ed.; Eng. trans., *Protestantism and Progress,* 1912); *Die Soziallehren der christlichen Kirchen und Gruppen* (1912; Eng. trans., *The Social Teaching of the Christian Churches,* 1931); *Der Historismus und seine Probleme* (1922); and *Der Historismus und seine Überwindung* (1924; Eng. ed., *Christian Thought, Its History and Application,* 1923).

TROGIR (TRAU), a seaport of Croatia, Yugos. Pop. (1953) 4,348. The town is built upon an island. The Venetian loggia is a fine specimen of a 16th-century court of justice; and the Hungarian Gothic cathedral, founded in 1200, was completed in 1450. Trau has some trade in fruit and wine, the fertile soil producing vines, figs, pomegranates and olives.

The chief industries are the weaving of *rascia,* a coarse blue serge, and metalwork.

Tragurium, by which name it was known to the Romans, was probably colonized about 380 B.C. by Syracusan Greeks from

Lissa, and its name is sometimes derived from τρώγιλος, a place near Syracuse. In 998 it submitted to Venice; but in 1105 it acknowledged the supremacy of Hungary, while retaining its municipal freedom, and receiving, in 1108, a charter which is quoted by Lucio. After being plundered by the Saracens in 1123, it was ruled for brief periods by Byzantium, Hungary and Venice. In 1242 the Tatars pursued Bela IV of Hungary to Trau, but were unable to storm the island city, which remained in the possession of Hungary till 1413. The Italians attempted to take possession of the town at the close of World War I, but were driven out by the inhabitants, 99% Slavs. After Germany's Balkan successes in World War II, Italy occupied the port (1941).

See T. G. Jackson, *Dalmatia, the Quarnero, and Istria* (Oxford. 1887); E. A. Freeman, *Sketches from the Subject and Neighbour Lands of Venice* (London, 1881); and G. Lucio, *Memorie istoriche in Tragurio, ora detto Trau* (Venice, 1673).

TROGLODYTES, "cave-dwellers," a name applied by ancient writers to different tribes in various parts of the world. Strabo speaks of them in Moesia, south of the Danube (vii. 318), in the Caucasus (xi. 506), but especially in various parts of Africa from Libya (xvii. 828) to the Red Sea. The troglodyte Ethiopians of Herodotus (iv. 183) in inner Africa, very swift of foot, living on lizards and creeping things, and with a speech like the screech of an owl, have been identified with the Tebus of Fezzan. According to Aristotle (*Hist. An* viii. 12) a dwarfish race of Troglodytes dwelt on the upper course of the Nile, who possessed horses and were in his opinion the Pygmies of fable. But the best known of these African cave-dwellers were the inhabitants of the "Troglodyte country" (Τρωγλοδυτική) on the coast of the Red Sea, as far north as the Greek port of Berenice, as recorded by Diodorus (iii. 31) and Photius (p. 454 Bekker) from Agatharchides of Cnidus, and by Artemidorus in Strabo (xvi. 776).

They were a pastoral people, living entirely on the flesh of their herds, or, in the season of fresh pasture, on mingled milk and blood. But they killed only old or sick cattle (as indeed they killed old men who could no longer follow the flock), and the butchers were called "unclean." They gave the name of parent to no man, but only to the cattle which provided their subsistence. They went almost naked; the women wore necklaces of shells as amulets. They practised circumcision or an operation of a more serious kind. The dead body, its neck and legs bound together with withies of the shrub called *paliurus,* was set up on a mound, and pelted with stones amidst the jeers of the onlookers, until its face was completely covered with them. A goat's horn was then placed above it, and the crowd dispersed with manifestations of joy.

TROGON, the name of birds forming the family Trogonidae. The trogons are birds of moderate size, the smallest hardly bigger than a thrush, the largest less bulky than a crow. The bill is wide at the gape, which is beset by recurved bristles. They seize most of their food on the wing. Their flight is short, rapid and spasmodic. Their feet are weak and of a unique structure, the second toe, which in most birds is the inner anterior one, being reverted; in all other birds that have two toes before and two behind, the outer toe is turned backward. The plumage is beautiful and characteristic, and the glory of the group culminates in the quezal (*q.v.*). The plumage is further remarkable for the absence of down and for the large size of its contour-feathers, which are extremely soft and so loosely seated as to come off in scores at a touch. The tail is a characteristic feature, the rectrices being often curiously squared at the tip. The nidification of these birds is in holes of trees, wherein are laid without any bedding two roundish eggs, generally white, but certainly in one species (quezal) tinted with bluish green.

The trogons form a very well-marked family of Coraciiform birds placed near the colies (*see* COLY) and swifts (*q.v.*). The remains of one have been found in the Miocene of France. This discovery seems to account for the remarkable distribution of the trogons at the present day. While they chiefly abound in the tropics of the New World, they occur too in the tropical parts of the Old. About sixty species are recognized, which J. Gould in the second edition of his *Monograph* of the family (1875) divides into seven genera.

TROGUS, GNAEUS POMBEIUS, Roman historian from the country of Vocontii in Gallia Narbonensis, nearly contemporary with Livy, flourished during the age of Augustus. The name Pompeius was adopted by his grandfather, who received the citizenship from Pompey. Trogus' books on natural history are frequently quoted by Pliny; his principal work, however, was *Historiae Philippicae* in 44 books, so called because the Macedonian empire founded by Philip is the central theme of the narrative. This was a general history of the world, or rather of those portions of it which came under the sway of Alexander and his successors. Of this great work, we possess only the epitome by Justin, the *prologi* or summaries of the 44 books, and fragments. But even in its present mutilated state it is often an important authority for the ancient history of the East. Ethnographical and geographical excursuses are a special feature of the work.

Fragments edit. by A. Bielowski (1853); *see* also, A. H. L. Heeren, *De Trogi P. fontibus et auctoritate* (prefixed to C. H. Frotscher's edition of Justin); A. Enmann on the authorities used by Trogus for Greek and Sicilian history (1880); A. von Gutschmid, *Dber die Fragmente des Pompeius Trogus* (1857); M. Schanz, *Geschichte der römischen Litteratur* (2nd ed., 1899), ii., where all that is known of Timagenes is given; and article JUSTIN.

TROILUS, in Greek legend, son of Priam (or Apollo) and Hecuba. In the *Iliad* (xxiv., 257) he is already slain before the action of the poem commences. According to a non-Homeric tradition (*e.g.,* Virgil *Aen.* i. 4743, when a mere boy he fell by the hand of Achilles. In another account he was dragged to death by his own horses. His death formed the subject. of a lost tragedy hy Sophocles.

The story of Troilus and Cressida (Caxton, Chaucer, Shakespeare, etc.) is entirely medieval.

TROIS-RIVIÈRES (THREE RIVERS), a city and port at the confluence of the St. Maurice and St. Lawrence rivers in Quebec, Can., 100 mi. from Montreal and 78 mi. from Quebec city. Founded in 1634 by order of Samuel de Champlain and named after the St. Maurice, which flows into the St. Lawrence by three channels or three rivers, it is one of the oldest settlements of Canada. In 1857 it was incorporated as a city. Ironwares were manufactured as early as the 17th century at the St. Maurice forges located several miles from the city. At the turn of the 20th century the development of cheap hydroelectric power on the St. Maurice and the availability of vast forest reserves of pulpwood in the immediate area occasioned a great industrial and commercial development. Trois-Rivikres is one of the largest newsprint-manufacturing centres in the world. Ironworks, textiles, clothing and electrical equipment are also manufactured. Trade is carried on in lumber, grain, asbestos and chemical products; its port handles an annual traffic of over 3,000,000 tons of commodities. Trois-Rivières is the commercial centre of an urban area comprising more than 135.000 inhabitants within a 25-mi. radius and including such cities as Shawinigan (*q.v.*), Grand'Mère and Cap de la hfadeleine. The city is the seat of a Roman Catholic bishopric and the county seat of St. Maurice. Ferryboats cross the St. Lawrence the year around, giving access to the south shore area. Pop. (1961) 53,477. More than 95% of the population is French Canadian.

(P. CA.)

TROITSKOSAVSK, a town of the Buryat Autonomous Soviet Socialist Republic, Russian Soviet Federated Socialist Republic. U.S.R.R., in 51° 28' N., 106" E., on the Kyakhta river near its junction with the navigable Selenga, which forms a waterway from Asiatic Russia to the Mongolian People's Republic. Two miles south of it is Kyakhta, on the frontier, which adjoins Maim''-Chen, a walled town with a large market place. and 10 mi. N., at the confluence of the Kyakhta and Selenga, is Ust-Kyakhta. It was formerly the great route by which Chinese tea entered Russia; and its December fair, when Russian leather, furs and wool were exchanged for tea. was very important.

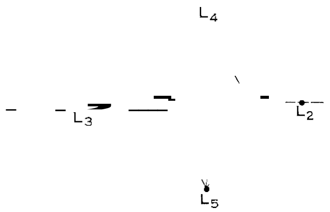
From 1689 to 1727 the trade was a government monopoly, but from then till 1860 trade was thrown open to private merchants, and as all trade across the Chinese border was by law compelled to pass through it, the town increased greatly in importance.

In 1860. however, the whole frontier was declared open, and Kyakhta declined; the Transbaikal railway further diminished its importance.

Gold and osmiridium are found in the district. The town was a storm centre in the post-1917 period, and nas the scene of the massacre of 800 Bolshevik prisoners in 1920 by order of the Cossack ataman Semyonov.

TROJAN PLANETS, a group of asteroids or minor planets, named for characters in Homer's *Iliad,* revolving around the sun in the same period as Jupiter. Achilles, the first member of the group, was discovered by Max Wolf in 1906, and subsequently the number of known members was increased to 13.

The orbit of Achilles was calculated by Adolf Berberich, who found that its period was almost exactly that of Jupiter Thereupon C. V. L. Charlier, noting that Achilles was about 55° in front of Jupiter, as seen from the sun, suggested that it was an example of one of the particular cases of planetary motion deduced by Joseph Louis Lagrange in 1772. Until 1906 these results had been of mathematical interest only.



SCHEMATIC REPRESENTATION OF GENERAL PROBLEM OF THREE CELESTIAL BODIES (*see* TEXT)

Lagrange's work dealt nith the general problem of three bodies, a simplified case being that in which the sun and Jupiter are the only bodies with sensible masses, the orbit of Jupiter being considered circular. The figure represents schematically a co-ordinate system rotating with Jupiter's period in which the sun, S, and Jupiter, J, will occupy fixed positions. A minor planet located in any of the three points L_1, L_2 or L_3 on the line joining S and J, or at either of the points L_4 or L_5, which form equilateral triangles with S and J, if started with an appropriate velocity. would then continue to occupy the same position relative to the sun and Jupiter. The straight line solutions are of little practical importance, honever, since slight disturbances would cause the minor planet to move away from the Lagrangian points. The greater practical significance of the equilateral solutions is due to the fact that these solutions are stable in the sense that small oscillations about these positions exist. The oscillations about the triangular points fall into two classes: (1) an oscillation, called the libration, nith a period of about 148 years for small amplitudes, increasing with the amplitude; (2) oscillations aith approximately the same period as that of Jupiter's revolution. about 11.86 years. Oscillations of this second type correspond to the eccentricity and inclination of the asteroid. In the case of Achilles these are approximately 0.15° and 11°, respectively.

Of the 13 known members, 8 asteroids—588 Achilles, 624 Hector. 659 Nestor, 911 Agamemnon, 1143 Odysseus, 1404 Ajax, 1437 Diomedes and 1583 Antilochus—are in the neighbourhood of the triangular point L_4, which is 60° ahead of Jupiter (greater longitude).

Five asteroids—617 Patroclus. 884 Priamus, 1172 Aeneas. 1173 Anchises and 1208 Troilus—are about 60° behind Jupiter.

As a group they belong among the fainter known asteroids. However, their faintness is due to the fact that they are much more distant than the typical asteroid located betneen Mars and Jupiter. The known Trojans undoubtedly rank among the larger asteroids. There are probably many smaller and even fainter members as yet undiscovered. The mathematical theory of the motions of the Trojans has attracted the interest of a number of astronomers and mathematicians, and sequences of possible orbits have been obtained under certain simplifying hypotheses. However, the limiting cases (*see* fig.) present great difficulties in analytical treatment.

No certain information exists concerning the possibility that the action of other planets may cause a Trojan to change into a non-Trojan or, conversely, change an orbit circling around the sun or Jupiter, or both, into a Trojan type.

(D. BR.; D. L. H.)

TROJAN WAR: *see* TROY AND TROAD.

TROLLE, HERLUF (1516–1565), Danish naval hero, was born on Jan. 14, 1516, at Lillö. At the age of nineteen Trolle went to *Vor Frue Skole* at Copenhagen, subsequently completing his studies at Wittenberg, where he adopted the views of Melanchthon, with whom he was in intimate correspondence for some years. His marriage with Brigitte, the daughter of Lord Treasurer Mogens Gjoe, brought him a rich inheritance, and in 1557 he took his seat in the senate. Both Christian III. and Frederick II. had a very high opinion of Trolle's trustworthiness and ability and employed him in various diplomatic missions. Trolle was, indeed, richly endowed by nature, and his handsome face and lively nature made him popular everywhere. His one enemy was his wife's nephew, Peder Oxe, the subsequently distinguished finance minister, whose narrow, grasping ways, especially as the two men were near neighbours, did not contribute towards family harmony. In 1559 Trolle was appointed admiral and inspector of the fleet, and in 1563 he superseded the aged Peder Skram as admiral in chief. On May 10 he put to sea with twenty-one ships of the line and five smaller vessels and, after uniting with a Liibeck squadron of six liners, encountered, off the isle of Öland, a superior Swedish fleet of thirty-eight ships under Jacob Bagge. Supported by two other Danish ships Trolle attacked the Swedish flagship "Makalös" (Matchless), then the largest flagship in northern waters, but was beaten off at nightfall. The fight was renewed at six o'clock the following morning, when the "Makalös" was again attacked and forced to surrender, but blew up immediately afterwards, no fewer than 300 Liibeck and Danish sailors perishing with her. The Swedish admiral was captured, and the remnant of the Swedish fleet took refuge at Stockholm. Despite the damage done to his own fleet and flagship "Fortuna" by this victory, Trolle, on Aug. 14, fought another but indecisive action with a second Swedish fleet under Klas Horn, and kept the sea till Oct. 13. Trolle spent the winter partly at his castle of Herlufsholm completing his long cherished plan of establishing a school for all classes, and partly at Copenhagen equipping a new fleet for the ensuing campaign. On June 1, 1565, he set sail with twenty-eight liners, which were reinforced off Femern by five Lubeck vessels. Klas Horn had put to sea still earlier with a superior fleet and the two admirals encountered off Fehmarn on June 4. The fight was severe but indecisive, and both commanders finally separated to repair their ships. Trolle was severely wounded in the thigh and shoulder, but he insisted on being the last to receive the surgeon's attention. He died of his wounds at Copenhagen on June 25.

TROLLHATTAN, a town of Sweden in the district (*län*) of Älvsborg, 45 mi. by rail N. by E. of Gothenburg. Pop. (1950) 24,157. It lies on the left (east) bank of the Gota at the point where that river descends 108 ft. in the course of nearly a mile by the famous falls of Trollhättan (six in number) and several rapids. The scenic setting of the falls is not striking, but the great volume of water, nearly 18,000 cu.ft. per second, makes the falls imposing. The narrowed river here surrounds several islands, on either side of one of which (Toppö) are the first falls of the series, Toppo and Tjuf. These are 42 ft. in height. The water-po er is used in rolling-mills, a cellulose factory and other works. The electric works supply power to Gothenburg and other Swedish towns. (*See* GÖTA.)

TROLLOPE, ANTHONY (1815–1882), English novelist, was born in London, April 24, 1815. He came of a family which engaged in literary pursuits. His father, THOMAS ANTHONY TROLLOPE (1774–183j) was a learned but unbusinesslike barrister, who spent much time on an *Encyclopedia Ecclesiastica* and gave up law for farming, with ruin as the result. His mother, FRANCES MILTON TROLLOPE (1780–1863) went with her husband to Cincinnati to retrieve their fortunes by running a fancy-goods shop, and coming back disappointed achieved notoriety and roused violent resentment by her caustic book, *Domestic Manners of the Americans* (1832). She aftenvards wrote some fifty novels and books of travel, and maintained the family by her literary earnings, her best novel being *The Vicar of Wrexhill* (1837) and *The Widow Barnaby* (1839), a fair second. (See *Frances Trollope, her Life and Literary Work,* 1895, by her daughter-in-law.) Her eldest son, THOMAS ADOLPHUS TROLLOPE (1810–92), was a popular writer of novels and miscellaneous works, largely on Italian subjects, his adopted home being in Florence. His second wife, FRANCES ELEANOR TROLLOPE, also a novelist, collaborated with him in *Homes and Haunts of Italian Poets* (1881).

Anthony, who was the third son, gave an unvarnished account of his unhappy youth in his *Autobiography* (which was edited by his son Henry M. Trollope in 1883), an extraordinarily candid book that had a disillusioning effect on too fervid admirers by giving away the secrets of his workshop. It probably caused the long eclipse of his fame, which has recently been followed by a striking renewal. During the family impecuniosity, he was a day-boy at Winchester and Harrow, and suffered pangs through his shabby and dirty appearance, and the unpopularity and general discouragement which were the result. He reached the verge of manhood almost as ignorant as if he had had no schooling at all, yet he tried to start in life by taking the post of classical usher in a private school in Brussels. But he received the offer of a clerkship in the General Post Office, London, and after a farcical pretence at an examination was appointed (1834). For the seven years of his service here, his salary was small, he was in debt, troubled with awkward love-affairs, and often in hot water with his superiors. Then he was transferred to Ireland (1841) as a surveyor's clerk, with a moderate salary but liberal allowances and the duties of a sort of travelling inspector. The change brought out a business capacity hitherto unsuspected. He enjoyed a comfortable income, he had time in spite of a busy life to indulge freely in hunting, he consorted with people of all classes and began to stock his memory for the long-cherished purpose of trying his hand at fiction, and in 1844 he married an English lady, Rose Heseltine, whom he had met in Ireland, and established himself in a house at Clonmel.

Trollope's first two novels, *The Macdermots of Ballycloran* (1847) and *The Kellys and the O'Kellys* (1848), failures though they proved, are examples of his thoroughness in making himself acquainted with a given sphere of life, as he was afterwards to do with clerical society, political life, and legal affairs, and also of his aptitude for developing a good story casually heard. The first is dark and pathetic, the second has many sparkling scenes; neither is the work of a Carleton or Banim, but both steer clear of the mere stage Irishman of Lever and Lover. Trollope persevered, but a historical novel, *La Vendée* (1850) deservedly fell flat.

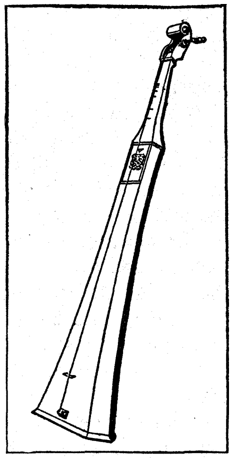
A chance visit to Salisbury Close gave him his idea for *The Warden* (1855), the simple, touching, but humorous story of a precentor in a cathedral town, who out of sensitiveness to public criticism resigns the well-paid office of warden to an ancient charity. Mr. Harding and his blustering son-in-law Archdeacon Grantly reappear, with other clerical dignitaries, their wives, families and friends, including the famous "Bishopess," Mrs. Proudie, the unctuous and pushful Mr. Slope, and the epicurean Dr. Stanhope and his disreputable children, in *Barchester Towers* (1857). The "Barsetshire Chronicles" were thus launched, bringing their author praise and, in due time, substantial profit. Trollope was now inspector of rural deliveries for the south-west of Ireland, with a roving commission that suited his tastes, scope for improvements on which he prided himself, and plenty of time for hunting. He is said to have been the inventor of the pillar-box. His ability and his experience of Post Office business led to his being sent on a mission to the West Indies (1858), which gave him material for a travel-book, *The West Indies and the Spanish Main* (1859). Other official journeys took him to Egypt (1858), the United States (1862), Australia and New Zealand (1871–72), and South Africa (1878), and resulted in further gossipy narratives and several tales. He got himself transferred to England (1859), taking charge of the eastern postal district and settling in a house at Waltham Cross. He retired from the Post Office (1867), out of annoyance at being passed over for promotion. Trollope was instrumental in starting the *Fortnightly Review* (1865), edited the *St. Paul's Magazine* (1868), rather disastrously, and was a contributor to *Cornhill, Blackwood* and other periodicals. He stood for Beverley (1868), but only acquired useful experience for future novels of political life.

All this time he was steadily writing fiction. The first of his books to bring him remuneration was *The Three Clerks* (1858), a poor novel of the Civil Service which sold for £250. But before long, he tells us in the *Autobiography*, he was earning on the average £4,500 a year, and in one instance he received £3,525 for a single book. An enormous output—for, besides more than fifty novels he wrote much else, and believed that no writer had made a larger contribution to letters in an equal space of time—was rendered possible by a methodical apportionment of the 24 hours. He rose regularly at 5.30 A.M., wrote steadily for two hours and a half, at the rate of 250 words every quarter of an hour, and thus calculated each book as so many days' work, which was carefully checked off as it proceeded. Yet he found leisure to hunt three times a week during the season, played whist daily, and had plenty of time for social enjoyments. He lived in London for about eight years (1872–80), and then removed to the village of Harting, under the Sussex Downs. He was staying in town when he died of paralysis, Dec. 6, 1882.

Trollope was a big, bluff, vociferous person, whose blustering and overbearing ways offended some, but whose John Bull philistinism did not conceal an essential honesty and good nature and a tender heart. He thought *Pride and Prejudice* the greatest novel in the language, and he idolized Thackeray; but he was as far from the exquisite art of the one writer as from the perfect mastery and irony of the other. With perhaps too much fidelity to the usual and commonplace, he depicted the great middle class as it was in mid-Victorian times. He was a "character-monger" of first-rate quality, who showed his personages moving in their own little spheres, and as he widened his circle of characters took in a larger sweep until he embraced almost as large and diversified a world as that surveyed by Thackeray. Among the characters that stand out, along with the two or three already mentioned, Mr. Crawley, the grimly pathetic hero of *The Last Chronicle of Barset,* the wicked but delightful Signora Neroni, Lucy Robarts, the best of many admirable heroines (unless Lady Glencora be preferred to that place), her husband, Mr. Plantagenet Palliser, afterwards Duke of Omnium, Lady Lufton, and that shrewd and downright person Miss Dunstable, with such different examples of the unattractive in life turned to artistic account as Mr. Sowerby and Mr. Chaffanbrass—these make a notable gallery and are only a selection from the catalogue. Other characters show uncertainty of touch and a failure of motivation. Trollope was best at a sort of coarse or at any rate very broad comedy, but he also had a command of real pathos. Tragedy was outside his scope. He revelled in mankind's idiosyncrasies, but shirked the closer scrutiny into the byways of conscience, just as he was shy of the spiritual questions which must, surely, have played some part in the lives of his clerical personages. George Eliot, his contemporary, would have dealt with Mr. Harding and Mr. Crawley in a totally different way.

Besides *The Warden* and *Barchester Towers,* the Barchester series comprises:—*Dr. Thorne* (1858), *Framley Parsonage* (1864), *The Small House at Allington* (1864), and *The Last Chronicle of Barset* (1867). The best of Trollope outside that series, besides such as are named above, are probably *Orley Farm* (1862), *Can You Forgive Her* (1864), *Phineas Finn* (1869) and its sequel *Phineas Redux* (1874), *The Claverings* (1867), *The Belton Estate* (1866), *He Knew He was Right* (1869), *The Vicar of Bullhampton* (1870), *The Eustace Diamonds* (1873), *The Way We Live Now* (1875), *The American Senator* (1877), *The Duke's Children* (1880), *Ayala's Angel* (1881) and *Mr. Scarborough's Family* (1883). Trollope's *Autobiography* was edited by his son (1883). The best biography is T. H. S. Escott's *Anthony Trollope, His Work, Associates and Literary Originals* (1913) which may be supplemented by Michael Sadleir's *Trollope, a Commentary* (1927), H. Walpole's *Trollope* ("English Men of Letters," 1928), Leslie Stephen's *Studies of a Biographer, IV.* (1902), Henry James's *Partial Portraits* (1888), and Professor Saintsbury's "Trollope Revisited" (*Essays and Studies by members of the English Association,* VI., 1920). (E. A. BA.)

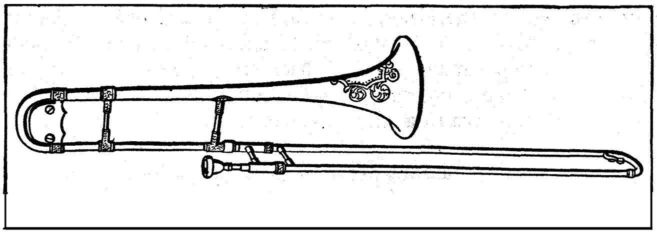
TROMBA MARINA or **MARINE TRUMPET,** an obsolete bowed instrument about 6ft. in length, with an outline somewhat recalling that of an elongated cricket bat. It consisted of a body and neck in the shape of a truncated cone resting on a triangular base. In the days of Michael Praetorius (1618), its length was 7ft. 3in. and the three sides at the base measured 7in., tapering to 2in. at the neck. These measurements varied considerably, as did also the shape of the body and the number of strings. The bridge had the curious feature that a portion of its foot was left loose so that it vibrated against the belly with every movement of the bow, producing a trumpet-like timbre. It is to this feature, in conjunction with its general resemblance in contour to the marine speaking-trumpet of the middle ages, that the name of the instrument is doubtless due, though other derivations have been suggested. In Germany, at the time when the trumpet was extensively used in the churches, nuns often substituted the tromba marina, whence the name *Nonnengeige.* The instrument, whose tone was not beautiful. fell into disuse during the first half of the 18th century.



FROM GALPIN, "OLD MUSICAL INSTRUMENTS"
THE TROMBA MARINA, AN OBSOLETE STRING INSTRUMENT

TROMBONE, an important member of the brass wind family of musical instruments formerly known as sackbut (*q.v.*). The trombone is characterized by the slide, consisting of two parallel cylindrical tubes, over which two other cylindrical tubes, communicating at their lower extremities by means of a short semicircular pipe, slips without loss of air. The outer tube, therefore, slides upon the inner, thereby altering the total length of tube and so modifying the pitch. When the slide is closed the instrument is at its highest pitch. To the upper end of one of the inner tubes is fastened the cup-shaped mouthpiece and to the end of the other tube is fixed the bell-joint, on the proper proportions of which depend the acoustic properties of the instrument.

Sound is produced on the trombone, as on the horn, by means of the lips stretched like a vibrating reed across the cup mouthpiece from rim to rim; the acoustic principles involved are the same for both instruments. By overblowing, *i.e.,* by the varying tension of the lips and pressure of breath, the harmonic series is obtained, which is effective between the second and the tenth harmonics, the fundamental being but rarely of practical use. There are seven positions of the slide on the trombone, each giving a theoretical fundamental tone and its upper partials a semitone lower than the last, and corresponding to the seven shifts on the violin and to the seven positions on valve instruments. These seven positions, which give a complete chromatic compass of two octaves and a sixth, are found by drawing out the slide a little more for each one.



BY COURTESY OF BOOSEY & CO., LONDON
THE TROMBONE, FORMERLY KNOWN AS THE SACKBUT, CHARACTERIZED BY ITS SLIDING TUBES

The quality of tone varies greatly in the different instruments and registers. The alto trombone has neither power nor richness of tone, but sounds hard and has a timbre between that of a trumpet and a French horn. The tenor and bass have a full rich quality suitable for heroic, majestic music. The contra-bass trombone, formerly little in request in the concert hall, is required for some modern orchestral music.

Besides the slide trombone, which is most largely used, there are the valve trombones, and the double-slide trombones. The former in which the slide is replaced by three pistons permit more brilliant execution than the slide instruments, but their tone is inferior. In the double-slide trombone the sliding branches are doubled and their length accordingly halved, thereby making the instrument more compact and lessening the length of the shifts, though demanding greater nicety in the adjustment of the slide.

The evolution of the trombone from the buccina is referred to in the article on the sackbut (*q.v.*), the name by which the earliest draw or slide trumpets, and subsequently the trombones, were known in England.

Of all wind instruments the trombone has perhaps been least modified in form; changes have occasionally been attempted, but for the most part with only trifling success. The application of ventils or pistons was made for the first time in 1818, in Germany, but instruments of this kind, though extensively used, have never superseded the original sliding type.

TROMP, the name of two famous Dutch admirals.

1. MARTIN HARPERTZOON TROMP (1597–1653) was born at Brielle, South Holland. At the age of eight he made a voyage to the East Indies in a merchantman. but was made prisoner and spent several years on board an English cruiser. On making his escape to Holland he entered the navy in 1624, and in 1637 was made lieutenant-admiral. In February 1639 he surprised, off the Flemish coast near Gravelines, a large Spanish fleet, which he completely destroyed, and in the following September he defeated the combined fleets of Spain and Portugal off the English coast—achievements which placed him in the first rank of Dutch naval commanders. On the outbreak of war with England Tromp appeared in the Downs in command of a large fleet and anchored off Dover. On the approach of Blake he weighed anchor and stood over towards France, but suddenly altered his course and bore down on the English fleet, which was much inferior to his in numbers. In the engagement which followed (May 19, 1652) he had rather the worst of it and drew off with the loss of two ships. In November he again appeared in command of eighty ships of war, and a convoy of 300 merchantmen, which he had undertaken to guard past the English coast. Blake resolved to attack him, and, the two fleets coming to close quarters near Dungeness on Nov. 30, the English, after severe losses, drew off in the darkness and anchored off Dover, retiring next day to the Downs, while Tromp anchored off Boulogne till the Dutch merchantmen had all passed beyond danger. The statement that he sailed up the Channel with a broom at his masthead in token of his ability to sweep the seas is probably mythical. In the following February (1653), while in charge of a large convoy of merchantmen, he maintained a running fight with the combined English fleets under Blake, Penn and Monk off Portland to the sands of Calais, and, though baffling to some extent the purposes of the English, had the worst of the encounter, losing nine ships of war and 30 or 40 merchantmen. On June 3, he fought an indecisive battle with the English fleet under Richard Dean in the Channel, but the arrival of reinforcements under Blake on the following day enabled the English to turn the scale against him and he retired to the Texel with the loss of seventeen ships. Greatly discouraged by the results of the battle, the Dutch sent commissioners to Cromwell to treat for peace, but the proposal was so coldly received that war was immediately renewed, Tromp again appearing in the Channel towards the end of July 1653. In the hotly contested conflict which followed with the English under Monk on the 29th Tromp was shot by a musket bullet through the heart. He was buried with great pomp at Delft, where there is a monument to his memory.

2. CORNELIUS VAN TROMP (1629–1691), the second son of the preceding, was born at Rotterdam on Sept. 9, 1629. At the age of 19 he commanded a small squadron charged to pursue the Barbary pirates. In 1652 and 1653 he served in Van Galen's fleet in the Mediterranean, and after the action with the English fleet off Leghorn on March 13, 1653, in which Van Galen was killed, Tromp was promoted to be rear-admiral. On July 13, 1665 his squadron was, by a hard stroke of ill-fortune, defeated by the English under the duke of York. In the following year Tromp served under De Ruyter, and on account of De Ruyter's complaints of his negligence in the action of Aug. 5, he was deprived of his command. He was, however, reinstated in 1673 by the stadtholder William, afterward king of England. and in the actions of June 7 and 14, against the allied fleets of England and France, manifested a skill

and bravery which completely justified his reappointment. In 1675 he visited England, where he was received with honour by King Charles II. In the following year he was named lieutenant-admiral of the United Provinces. He died at Amsterdam on May 29, 1691, shortly after he had been appointed to the command of a fleet against France. Like his father he was buried at Delft.

TRONDHEIM (TRONDHJEM), a city and seaport of Norway; chief town of the diocese of Trondheim and the county of Sør-Trøndelag, 384 mi. by rail N. of Oslo. Pop. (1950) 55,522. It lies on the Trondheim fiord on a peninsula between the fiord and the Nid river. The cathedral is the finest church in Norway, and the scene of coronation of the Norwegian kings Building was begun in the 11th century and continued through the 12th and 13th centuries. Repeatedly the church was burned, but as often restored. In the 20th century it was expanded and enriched with Vigeland sculptures. The port trades chiefly in timber. wood pulp, oil, fish and copper. In the town are shipbuilding, fish-curing, sawmills and machine works. Olaf Tryggvesson founded the town of Nidaros there in 996, building a church and a royal residence. (For a brief time from 1930 the town was renamed Nidaros.) It became an archbishopric (1182) and was the capital to 1380. It was an important pilgrimage centre, but suffered many sieges. Declining after the Reformation period, its commerce and population grew rapidly again in the 20th century, aided by new port facilities and the railway from Oslo (1921). The Norwegian Institute of Technology is there.

TROON, a small burgh of Ayrshire, Scot., on a spit of land on the coast of the Firth of Clyde, 30 mi. S.W. of Glasgow by road. Pop. (1951) 10,063. It is a popular holiday resort, with sandy beaches and extensive golf courses. Troon is also a coal port, and industries include shipbuilding, engineering and railway equipment repair work. Lady Isle, a bird sanctuary, lies about 4 mi. out at sea.

TROPAEOLACEAE, the nasturtium or tropaeolum family of plants, consisting of one genus, *Tropaeolum,* with about 65 species of mostly climbing or sprawling herbs. The often peltate leaves are simple but sometimes deeply lobed. The showy, spurred flowers have five sepals; five entire or lobed, often fringed, petals; eight stamens; and a three-celled ovary. The fruit separates into three one-seeded sections. Species of *Tropaeolum* are native from Mexico to southern Chile and Argentina, mostly in mountainous regions. Perhaps 20 species are knonn in cultivation, the most familiar being T *majus,* the garden nasturtium, and T. *peregrinum,* the canary-bird vine. The añu, T. *tuberosum,* is cultivated in Andean highlands for its edible tubers. See also NASTURTIUM.

(J. W. TT.)

TROPHY. In ancient Greece, a memorial of victory set up on the field of battle at the spot where the enemy had been routed. It consisted of captured arms and standards hung upon a tree (preferably an olive or an oak) and booty heaped up at its foot, dedicated to the god to whom the victory was attributed. In the case of a naval victory the trophy, composed of the beaks of ships, was set up on the nearest beach and consecrated to Poseidon The Romans showed a preference for setting up the memorials of victory in Rome rather than on the field of battle. In imperial times their place was taken by columns or triumphal arches. See ROMAN ARCHITECTURE; TRIUMPHAL ARCH.

TROPICAL AGRICULTURE. About one-quarter of the land surface of the earth lies between the Tropic of Cancer and the Tropic of Capricorn, and almost one-third of the world's population lives within this intertropical zone. In all intertropical countries most of the people are cultivators. Tropical agriculture may be taken to mean all the varieties of agriculture practised within the tropics, including animal husbandry. In many instances, seas and deserts so isolate the areas of cultivation in the intertropical zone from those in higher latitudes that there is little difficulty in distinguishing tropical agriculture from other kinds. In countries like Brazil, China and India, however, such sharp physical boundaries are absent, and it is less easy in these cases to say where tropical agriculture ceases and another sort begins. Many of the crops, as well as forms of organization and techniques, characteristic of tropical agriculture also occur widely in extra-tropical areas.

Tropical Environments.—The intertropical milieu offers, on the whole, uniquely favourable conditions for plant and animal life. The variety and luxuriance of plant growth in the tropics are paralleled nowhere else, and tropical animal life is similarly rich and populous. Climatic and soil conditions, however, limit the kinds of crops that can be grown in any area, and ecological factors seriously interfere with agriculture.

Agriculture in the intertropical zone is little hindered by temperature conditions because a suitable temperature can be found at some altitude for almost any crop known. In many tropical countries different altitudinal levels are recognized (tierra *fría, tierra templade* and tierra celiente in Latin America), to each of which corresponds a distinctive group of crops; temperatures in the higher (tierra *fría*) elevations often are suitable for standard northern European crops. Relatively little land in the tropics is high enough to be too cold for crops, although here and there are found glaciated mountains (e g., in New Guinea, east Africa and the Andes) and barren cold plateaus (upland Peru and Bolivia). Throughout most of the intertropical zone frosts are unknown.

Tropical temperature conditions are but slightly variable from one month to another; the range may be only a few degrees Fahrenheit during the year. Often the range of temperatures during a single day is greater than the difference between any two monthly means. This equable climate means a year-round growing season if sufficient water is present. For some crops, however, the absence of strong seasonal rhythms prolongs vegetative growth and defers, or even prevents, flowering, fruiting and other desired phases of the plant life cycle. The nearly uniform intensity of sunlight and the even length of the daylight period throughout the year affect plants similarly.

Rainfall in tropical areas is either continuous throughout the year or sharply interrupted for a period of some months. The total precipitation during the year usually is high, so that soils are heavily leached of minerals, leaving behind a dense clay of low nutrient value. Abundant rainfall and high temperatures favour bacterial decay, so that in lands of moderate elevation organic wastes are quickly decomposed and little humus accumulates in the soil.

Despite poor surface soils, where there is rain throughout the year a luxuriant vegetation may develop, composed of as many as five or six different stories of trees, the tallest of which may be over 300 ft. This rich tropical rain forest depends on deep roots to furnish it with minerals from the unleached lower layers of the soil. Where the moisture supply is interrupted for three or more months, the vegetation ranges from less dense forest of deciduous trees where the dry season is relatively short, through open woodland and spiny shrub, to impoverished short-grass steppe and ultimately to deserts where rainfall is rare or even altogether lacking in most years (as in coastal Peru, Somaliland and northwestern Mexico). The savannah soils of drier regions have impermeable hardpans that cause ponding of water on the surface in the wet season and deep fissuring and desiccation of the soil in the dry period.

The soils of mountainous areas in the tropics are also impoverished as a rule and are rapidly washed and eroded on the steeper slopes. As temperature decreases with elevation, total yearly precipitation and relative humidity of the atmosphere usually increase for some distance upslope. The higher lands are, therefore, usually characterized by cooler, wetter conditions than the lowlands. The vegetation of highlands with year-round rain grades off from the tropical rain forest, growing progressively lower and finally stunted at higher elevations, but remaining lush and dense. A fantastic dwarf forest with curious forms and aerial growths occurs at certain elevations where the slopes are constantly bathed by clouds. Where a marked dry season occurs, the forests tend to become richer with altitude, but are usually deciduous.

Land Use.—The luxuriance of the tropical rain forest is no assurance that agriculture can flourish where it grows. In all the great rain forest regions (the Amazon and Congo basins, the Guinea coast, Mozambique, Madagascar, the Caribbean, southeast Asia, Indonesia, New Guinea) agriculture has indeed invaded the primeval forest, but it has suffered considerable handicaps. Crop plants, except for a few tree crops like rubber, kapok, oil palm and cacao, are not equipped to reach down into the deeper layers of the soil for nutrients, and most crops do poorly after the first year on heavily leached rain forest soils; this is not a favourable environment for small annual plants. Furthermore, the forest is a great reservoir of animal and plant pests. Certain mild plant species especially adapted to colonize clearings become weeds in cultivated land. Harmful microorganisms flourishing under high temperatures and abundant moisture readily attack the struggling crop or unadapted domestic animal. Weeds, plant diseases and raiding animals are a constant menace to crops, and predators threaten domestic stock. Under these conditions, agriculture can succeed only when it is possible to invest heavily in control measures (as on plantations) or to move from deteriorated lands to new sites (shifting cultivation).

In the seasonally dry areas most of these same handicaps apply, but without the advantage of a year-round groning season. The moisture regime restricts agriculture mostly to the rainy months. Here, too, the soil is usually poor, and the hosts of pests are still present. It is often simply not found worthwhile to confront these difficulties for the meagre return that can be expected, and vast expanses of the drier areas are left uncultivated. For this reason much tropical land is used for cattle raising. Livestock, however. suffer greatly from pests and are sometimes unable to withstand them (*e.g.,* in the tsetse-fly areas of Africa). On the whole, livestock raising is economically inefficient on most tropical lands, except where high investment makes possible the use of improved breeding stock, artificial pastures, good fences and pest and disease control measures; even then there often is no suitable market for the product.

In higher altitudes. rainfall patterns and temperature usually are conducive to successful agriculture, but soil erosion is the frequent consequence of most farming practices. The areas suitable for agriculture in the highlands are very limited in total extent, and population often is crowded, resulting in overintensive use and ultimate ruin of the land.

Wherever conditions of soil. temperature and moisture are suitable for use under existing local practices, tropical lands are intensively exploited. Land well suited to cultivation is scarce, however, and much of the cultivated land is found in scattered mountain valleys (*e.g.,* in Mexico, the northern Andes, the south Asiatic mainland from Assam to Laos, interior New Guinea and Ethiopia). Elsewhere coastal lands are well tilled, against a solid backdrop of primitive forest (as in Caribbean Central America, the Malabar Coast, Mozambique and Borneo). Much of the agricultural population of the tropics, especially in Asia, inhabits alluvial lowlands and deltas (those of the Ganges-Brahmaputra in India and Pakistan, and the Irrawaddy, Chao Phraya [Nenam], Mekong and Red [Song-Coil rivers in southeast Asia).

Parts of the Amazon basin, central Africa and many of the islands of Indonesia and beyond are still occupied by wandering hunters and gatherers or isolated subsistence farmers. Most of the people of the tropics, however, are peasants, low in income, producing some or most of the goods they use, but also raising crops for market or working for wages. In most of tropical America, tropical Africa. upland southeast Asia and the more easterly islands of Indonesia and Oceania, the cultivators live in small villages or on isolated homesteads: in coastal south Asia and western Indonesia the population is densely concentrated in gardenlike lowlands where tillage and settlement are continuous.

Techniques. — Everywhere in the tropics permanent plantings of varied crops, often surrounded by fruit or shade trees. are maintained the year round. The garden usually is planted mostly from cuttings rather than seeds, and the plants are tended individually with hand tools. There is no single harvest, but food is available throughout the year. Such plants as bananas, ginger and other spices. gourds and yams are found as garden crops throughout the tropics.

In hilly tropical lands upland rice. corn (Indian corn or maize), millets, various kinds of beans and some root crops like taro, yam and sweet potato are groan in clearings made by cutting off all or most woody growth and burning the plot clean. Crops are planted and cared for with a simple digging stick or hoe and few other tools are used. This so-called shifting agriculture, using the slash-and-burn technique, seldom succeeds for more than a few years in one spot because of erosion, declining soil fertility and rapid increase of weeds and pests. This technique is widespread throughout the tropics. where it is known under several names (roy, *rastrojo, kaingining, ladang, tavy,* etc.); in the past it was also common in higher latitudes. (See AGRICULTURE, PRIMITIVE.)

Asian and Indonesian lowland peasants, as well as some Africans, employ the plow with domestic animal traction and raise seed crops on permanent farm plots. Heavy use of organic fertilizers and the skilled management of water supply, as well as intensive hand labour, characterize the very productive rice agriculture of the Asiatic tropics and the nearby far east. In Africa and the Americas. plow agriculture is commonly associated with market crops, and often with irrigation, but corn, millets, manioc, peanuts, beans, cotton and other field crops of these areas also are grown without the plow.

Tropical Crops. — In the tropical regions, supremely rich in species and long inhabited by man, many domestic plants have originated. Throughout the tropical American. African and Asiatic-Oceanian realms, two classes of crops occur, one reproduced from seed, the other vegetatively. Of the seed-grown tropical cereals, corn originated in the Americas, rice in Asia and various millets in Africa. Lesser cereal crops (amaranths. quinoa, Job's-tears and others), as well as distinctive kinds of beans and seed-propagated vegetables came out of each region (*e.g.,* from America, tomato, squash. pumpkin and chili pepper; from Africa, okra; and from Asia, cucumber). Examples of vegetatively propagated root or tuber crops are the arrowroot, yautia (Xanthosoma), sweet potato and manioc (cassava) from the lowlands of America and the potato, oca (*Oxalis*) and potatolike ulluco and arracacha from the American highlands; various yams from Africa; and taro, ginger and other yams from Asia and Oceania. In each region numerous fruit trees were developed — the guava, papaya and hog plum in South America, the mango. citrus fruit and breadfruit in Asia-Oceania, the karite (the shea-butter tree) and some annonas in Africa. There are domestic plants serving many other uses in each area (*e.g.,* cotton for textiles in Asia and America; drug plants like the South American coca, Asiatic betel and African kola; sources of beverages like Asiatic tea, African coffee, American cacao).

Plants like the banana, sugar cane and coconut, of Asiatic-Oceanian origin, spread to Africa and perhaps even to America before the period of European expansion. Others like the sweet potato and cotton may represent some sort of pre-Columbian borrowing betneen America and the old world. After 1500 there took place a wholesale exchange of domestic plants among tropical countries, and the lowland crop plants, of America and Asia especially, were spread everywhere through the tropics and well intermixed. Some tropical highland crops like the potato have become established in middle latitudes as well. In turn, some crop plants of higher latitudes invaded the tropics, but are confined chiefly to highland areas (*e.g.,* wheat).

The plantation system is old in the tropics. Spice plantations have long been characteristic of the Malabar Coast and Indonesia, and the early European colonies in the Caribbean and elsewhere developed great sugar plantations. Coffee, tea, rubber, cacao, oil palm, coconut, abaci, banana, vanilla, pineapple, sugar cane, pepper, cloves, cinnamon, ginger and many other spices, medicinals and insecticides, and textile, lumber, food and oil plants are grown on tropical plantations for the world market. Incorporating high investment capital and skilled management with choice but difficult environments and low-cost labour, the plantations occupy a relatively small total area in the tropics, but produce a large proportion of all tropical goods entering world commerce. (See also FRUIT FARMING; OIL PLANTS.)

Animal Husbandry. — Most species of domestic animals and practically all forms of animal husbandry occur somewhere in the tropics. The pig infests native settlements from Polynesia to the southern Sudan and Guinea — except where proscribed for religious reasons—and in the new world. In Melanesia, pigs are important in ritual. Everywhere the pig acts as a village scavenger, and its flesh is eaten. The animals are allowed to shift for themselves, but are sometimes fed on coconuts. garden crops and wild fruits. The sale of live pigs is an important source of cash income in many tropical countries. Pork products, however, are difficult to process and preserve in tropical climates.

Domestic fowl are common in settlements throughout the tropics, and in the new world turkeys are often kept. Fowl are allowed to forage for themselves, and sometimes are fed on fruit or grain. Live fowl and eggs constitute another chief source of cash for people and furnish a major part of the scant protein consumed by many in the tropics.

Goats are raised in many drier tropical areas for their meat, milk, hair and hides. Sheep are found at the higher elevations and in the arid lands of Arabia and Africa where nomads wander.

The horse is not common as a riding animal in the tropics, except in the Americas and in Moslem countries. Horses are rarely used for ploning in tropical lands. The ass is a common beast of burden in dry areas of Africa and the Americas.

Horned cattle and the closely related buffalo or carabao are the draft animals of tropical Asia, the Arab lands and America; draft animals are seldom used in Negro Africa. Cattle are kept for prestige by many peoples in Africa and Madagascar; some of these folk also subsist almost entirely on their products. Vast numbers of cattle are found in India. where they are venerated and their slaughter is forbidden by the dominant religion. Open-range cattle are vastly more numerous in the American and African tropics than those raised on improved pasture or fodder crops. In Asia, the buffalo is a village animal fed on garden products and plant refuse. Improved races of meat or dairy cattle are rare in tropical countries, and commercial meat production is sufficient only for local needs. Numerous diseases and parasites and periodic drought afflict the herds. Facilities for shipping animals and milk products are poorly developed, and packing and processing plants are few. Native animal husbandry is traditionally oriented and grossly undercapitalized for commercial production. *See* also BANANA, COFFEE, PINEAPPLE, etc.

TROPICAL FISH, a term popularly applied to numerous small, brightly coloured fish kept in home aquariums. *See* AQUARIUM: *Aquariums in the Home*.

TROPICAL MEDICINE. The peoples of the tropics, numbering almost half the population of the world, made little cultural or material progress during centuries of colonial rule and extractive economy. After World War II, with the emergence of a score of self-governing nations, they entered upon a period of vigorous self-development, In this enterprise, tropical medicine assumed enormous importance, since the prevalence of disease was a barrier to development and, in the age of air transportation, a threat to the world.

Diseases of tropical climates reach their highest incidence and present the greatest problems where high temperatures and heavy rainfall prevail at all seasons. Such conditions favour the multiplication and longevity of man's enemies and competitors—rodents, insect species that transmit disease, parasitic worms with free-living stages in the soil, and infective organisms that pass part of their lives outside the body of the host. The tropics also are characterized by the prevalence of diseases spread by filth and overcrowding, insanitary habits and lack of sanitation—marks of a low socioeconomic status. In this they reveal the characteristics of the so-called underdeveloped regions: low standard of living, illiteracy, high incidence of disease and short life expectancy, an unending cycle of poverty, ignorance and disease. In fact, the economist's "underdeveloped areas" virtually coincide geographically with the tropics, suggesting a causal relationship between tropical environment and slow economic progress.

Certainly a combination of climatic and social factors has fastened upon the tropics such chronic and debilitating diseases as malaria, hookworm and yaws. which throughout history have undermined the physical, economic and social vitality of whole peoples. Life expectancy is an index of the economic burden of disease, and in many countries less than half the children reach the productive age of 15; these premature deaths have undoubtedly been one of the chief limiting factors on productivity.

History.—It was not until Louis Pasteur's revelation in the 1870s of the world of microorganisms that it was possible to identify the causal agents and understand the modes of transmission of infectious diseases. This was accomplished for most of the important tropical diseases in the following half century. Malaria presented the most serious problem and Alphonse Laveran's observation of the parasites of malaria in the blood of man (1880) was a signal event. Seventeen years later the mystery of its transmission was solved by Ronald Ross in India. Spurred by Sir Patrick Manson, whose observations in China had led him to suspect the transmission of tropical elephantiasis by mosquitoes, Ross in 1897 observed the human malaria parasite in *Anopheles* mosquitoes and in 1898 infected birds with malaria by the bites of *Culex* mosquitoes, a discovery completed by G. B. Grassi in Italy in transmission experiments on human beings. Walter Reed in Havana in 1900 demonstrated the mosquito transmission of yellow fever (*q.v.*), which led to its control by W. C. Gorgas in Panama beginning in 1904 and made possible the construction of the Panama canal. Within a few years the roles of the tsetse fly as vector of African sleeping sickness, the sand fly of kala azar, the tick of relapsing fever, the rat flea of plague, the body louse of typhus fever and the snail of schistosomiasis were all clarified. These and other discoveries opened the way to rational and scientific treatment, prevention and control of tropical disease. Tropical medicine had evolved from a clinical specialty in exotic diseases into a public health movement to protect and improve the health of native populations. The establishment of schools and research institutions accompanied this evolution. The London and Liverpool schools of tropical medicine were opened in 1899. followed by others in the colonial nations of Europe and in a score of tropical countries around the globe. The U.S. government supports tropical research laboratories in the National Institutes of Health and in Panamá. International collaboration in disease control, in the strengthening of health services and training of personnel has been invaluable, beginning with the International Health division of the Rockefeller foundation in 1914 and later offered by the World Health organization (WHO) and by the International Cooperation administration (ICA) of the U.S. government.

Biological and pharmaceutical laboratories contributed signally to the success of the efforts to bring tropical diseases under control, producing powerful new drugs without which it is conceivable that many projects would have failed or might not even have been attempted. The proposed eradication of malaria and smallpox and the co-ordinated attacks on yaws, syphilis and tuberculosis would not have been deemed possible without the antibiotics, synthetic drugs, vaccines and insecticides made available during and after World War II in a burst of technological achievement. Meanwhile, a handful of stubborn diseases remain uncontrolled, a stimulus to research: amoebic dysentery, the schistosomal, filarial and leptospiral worm infections, leprosy and the sleeping sickness of Africa.

Tropical Diseases.—The term tropical disease is accepted to mean any disease that is prevalent chiefly in the tropics, though not necessarily limited to those areas. Very few diseases are thus restricted, the only important ones being African sleeping sickness, filariasis of several types, yaws and yellow fever. The first two have not been effectively controlled with either drugs or insecticides. Yaws is spread by contact among crowded and dirty people, but it is rapidly cured by penicillin and its eradication by mass treatment is a major objective of countries where it occurs, aided by WHO and the United Nations Children's fund (UNICEF).

Yellow fever is limited to the tropics because its vector mosquitoes do not survive northern winters. In summer, ship-borne from the tropics, they once caused devastating epidemics in North America and Europe, but the species has been eradicated in all tropical ports and is on the road to extinction throughout the western hemisphere. The virus persists as jungle yellow fever in the monkeys of the American and African tropics, transmitted by forest mosquitoes. An effective vaccine exists to protect person's who may be exposed; the major hazard is that an infectious case may by plane reach the orient. where yellow fever is unknown but where the vector mosquito abounds.

Most of the diseases that flourish in the tropics were once widespread as well in the temperate zones, where they have been controlled or eradicated. For example, such pestilences as cholera, plague and smallpox no longer sweep the earth; they can persist only where water supplies are constahtly polluted, environmental sanitation is neglected and populations go unvaccinated. Such conditions now exist mainly in the tropics.

More important in their long-term effects on health and prosperity are six chronic diseases strongly entrenched in the tropics. Malaria, first in importance, a scourge of rural populations and a killer of children, can be eliminated from any stable community by insecticides and drugs. but over vast areas it is still the major health problem. Tuberculosis. when introduced in areas of tropical climate, runs through populations like an acute infection, but it too is susceptible of control with modern drugs and mass vaccination. Schistosomiasis, caused by a parasitic worm, afflicts millions of farmers. Larval forms of the worm, which infest irrigation water. require the snail as intermediate host. The disease is an unsolved problem since neither an effective drug nor a method of snail eradication is known. Hookworm disease, caused by an intestinal bloodsucking parasite, occurs everywhere in the wet tropics. It causes profound anemia and stunts the growth of children. It could be eradicated by preventing pollution of the soil with human feces, but this requires an educational effort continued over generations. Leprosy; almost eliminated in economically advanced countries, is prevalent in every part of the tropics where segregation of infected persons is impracticable. Continued treatment with the sulfone drugs arrests or retards most cases, but search for an even more effective drug continues. Finally, nutritional deficiencies are almost universal among tropical agricultural peoples. The cause is low food production resulting from climate. poor soils and farming methods. hookworm and malaria. conservatism or custom. Beriberi, pellagra and scurvy are only extreme forms of a general malnutrition (*q.v.*), but more important is kwashiorkor; highly fatal, after weaning, to children whose diet is grossly deficient in protein and protective substances. Several international agencies have attacked the problem in collaboration : WHO deals with the nature, prevalence and prevention of malnutrition; the Food and Agriculture organization (FAO) and UNICEF with the production, improvement and distribution of food; the Institute of Nutrition of Central America and Panama (INCAP) with research and education.

Control of disease, resulting in a greatly lowered death rate without a corresponding decrease in birth rate, raises a spectre of future calamity that has alarmed many persons. In spite of international aid and better distribution of food, living standards have actually fallen in many areas as a result of uninhibited population growth. In Ceylon, for example, control of malaria reduced the death rate by half and doubled the life expectancy, resulting in a rate of increase of the population that threatens to nullify the benefits obtained unless positive steps are taken to restrict fertility. A few believe. on the other hand, that scientific agriculture can produce the required food until urbanization, industrialization and "modernization" automatically, though gradually, bring birth rates and death rates into balance.

The **White Man** in the Tropics.—The health of the white dweller in the tropics, unlike that of persons native to those regions, depends on how fully his physiology can adapt to the unaccustomed heat, humidity and solar radiation and on his ecologic adjustment—his relations with the physical and biological world around him, including his fellow man. The newcomer relies on acclimatization, which is little understood, and on modification of his indoor environment by air conditioning, which he finds necessary partly because of his unwillingness to discard the usages and paraphernalia of his own culture—housing, clothes, food, ways of life—and adopt those appropriate to the climate.

His ecologic adjustment begins with an exchange of diseases; he falls victim to malaria, viral infections and dysentery, and gives to the native peoples tuberculosis, "children's diseases" and venereal infections. Whether the white man can carve a permanent niche for himself and retain his faculties and stamina over generations is still a moot question even after centuries of colonization. The answer awaits further experience under modern conditions and physiological research carried out in the tropical setting.

TROPICAL STORM. Severe cyclonic disturbances of the atmosphere in low latitudes are called tropical storms. In the western Atlantic they are known regionally as hurricanes and in the western Pacific as typhoons. It is the fury of the weather associated with tropical storms that distinguishes them from the many minor weather disturbances that more commonly produce periods of greater than normal rainfall in the tropics. They are, roughly. 50 to 500 mi. in diameter.

Description.—Tropical storms frequent the tropical oceans between latitudes of approximately 5° and 30° of both hemispheres. Their characteristics are not entirely uniform, but depend somewhat on age, size and latitude of the storms. They are cyclonic whirls. *(See* CYCLONE.) The winds near the centre form an almost circular vortex, with a slight inward motion toward the centre near the ocean surface.

As a result of the effect of the earth's rotation, the rotation of the vortex is clockwise in the southern hemisphere and counterclockwise in the northern.

A cyclonic whirl is called a hurricane or typhoon if the surface winds exceed 75 m.p.h. (Beaufort force 12). The area covered by such high winds may have a diameter of only 10 mi. when the storm is in its early stage. In fully grown storms the diameter is rarely less than 50 mi. and may attain 150 mi. The diameter of the entire area affected in some measure by a large storm may exceed 500 mi. Even the largest tropical storms, however. have an area which is less than the area covered by strong cyclones of middle and high latitudes.

An outline of the wind and weather distribution connected with a mature storm is given in fig. 1.

Winds.—While the areal extent of tropical cyclones is small compared with storms outside the tropics, the violence of the weather within the disturbed zone is usually far greater. This is the most spectacular feature of tropical storms. Sustained winds in excess of 100 m.p.h. are common near the centre, and winds as high as 200 m.p.h. have occurred. Since mature storms usually lie within the broad easterly trade winds, the distribution of the hurricane winds around the centre tends to be asymmetrical.

On the poleward side of the cyclones the trade winds reinforce the wind field produced by the disturbances themselves; on the equatorward side they counter this wind field. Thus. the high winds around centres located in the trades extend a far greater distance poleward than equatorward. In a mature storm of the northern hemisphere, for instance, hurricane winds may extend for only 30 to 40 mi. south of the centre but they will occur for twice that distance to the north.

Eye of the Storm.—Within the region of hurricane winds, the wind speed rises toward the innermost portion of the storm. Very close to the centre of mature cyclones, however, the winds drop abruptly from their extreme maximum to light breezes or even to complete calm. Clear skies or only thin clouds prevail. The central circular calm area bears the name "eye of the storm." The diameter of the eye is variable, but it is about 15 mi., on the average. Within the eye. the roar of the surrounding storm is often audible in the distance. Everyone who has passed from the outer ring of hurricane winds into the eye has commented on the sudden drop of the violence of the elements as a most remarkable experience. The eye figures prominently in many works of fiction. Outstanding among them is Joseph Conrad's Typhoon.

Pressure.—Coincident with the rise of wind speed from the, edge of the storm inward, the atmospheric pressure as measured by the barometer drops. Tropical storms are low-pressure centres, and the lowest sea-level pressures observed on earth occur in or near the eye of hurricanes. Up to 1957, the lowest official pressure on record was registered at Key West. Fla.. on Sept. 2. 1935, with a reading of 26.35 in. of mercury. This low pressure existed in a storm of small diameter, indicating that the intensity of a tropical storm does not depend on its areal extent. There are many other instances to substantiate this conclusion. The drop of the barometer can be exceedingly rapid as the winds increase to hurricane strength. and its rise after passage tends to be equally rapid.

Clouds and Ruinfall.—The interior of a tropical storm contains a great mass of cumulo-nimbus clouds (see CLOUD) from which heavy rain is falling. Only in the eye is there a lightening of the clouds; here many times the sky is even entirely clear. The distribution of the rainfall around the central core often is not symmetrical. As revealed by radar observations, the large clouds gather in a series of narrow bands, often only a few miles wide, that spiral cyclonically from the outside toward the centre. The length of a band may be 100 mi. and more; as many as ten bands may be encountered in a large storm. In a fully developed cyclone located in the trade-wind stream, the heaviest rain is concentrated on the poleward side, while on the equatorward margin the bad weather ceases just as quickly as the winds.

The amount of rainfall received on tropical islands and coastal areas of continents during the passage of a storm is dependent on the speed. size and intensity of the rain-producing centre and on the topography of the land. Several small storms in the stage of development have given less than five inches of rain over Puerto Rico in the West Indies. A great storm passing over the same island in 1928 produced 10 to 15 in. of rain near the coast and up to double that amount in the mountainous interior. Precipitation in excess of 20 in. in one day has occurred on several occasions along the southern coast of the United States and in various parts of the tropics. At Baguio in the Philippines 42 in. fell within 24 hours in 1911. For a general estimate, a rainfall of 10 to 1j in. should be expected during the passage of a fully developed cyclone over coastal regions.

Dangers to Flying.—The dangers caused by turbulence as well as other dangers to flying in and near tropical storms are not quite so prohibitive in most instances as was supposed prior to 1940. After 1944, military aircraft carried out regular reconnaissance flights in tropical cyclones at heights from 500 to 20,000 ft. Most missions succeeded in flying through and around the centres, spending at times several hours in the zone of very rough weather. Others have flown over hurricanes at great heights. It appears that most dangerous clouds can be topped at 40,000 ft.

Sequence of Events at Fixed Location.—Young, developing disturbances will give little or no advance indication of their arrival, except to the meteorologist who has wind measurements from the upper parts of the atmosphere at his disposal.

A mature cyclone is preceded by a distinct ocean swell with a frequency two to four times less than that of normal waves. In the Gulf of Mexico, for example, waves normally reach the shore about every four to five seconds. The presence of a hurricane may be suspected if they arrive only every 12 to 1j sec. and if the swell is correspondingly higher. At sea, moreover, the direction of the swell indicates the direction in which the storm is located, since the swell travels outward from the central area. It can precede the centre by 500 mi. and more. a great distance compared with the diameter of the hurricane winds.

The drop of the barometer often does not begin until 12 hr. before the arrival of the storm centre. Appearance of a sheet of cirrus clouds (see CLOUD). gradually thickening, frequently supplies an earlier warning. In addition. the inhabitants of the tropics often rely on other abnormalities of the local weather, such as brilliant red sunsets and winds from unusual directions, as precursory signs of a cyclone. Kone of these indications is entirely reliable, however, and may fail badly. On Sept. 13, 1945, a hurricane of great intensity was approaching the southeastern Bahamas. Nevertheless, the fishermen of South Caicos Island went out in their boats. They did not believe that there was a hurricane because the usual warning signs were missing. More than 50 of them drowned.

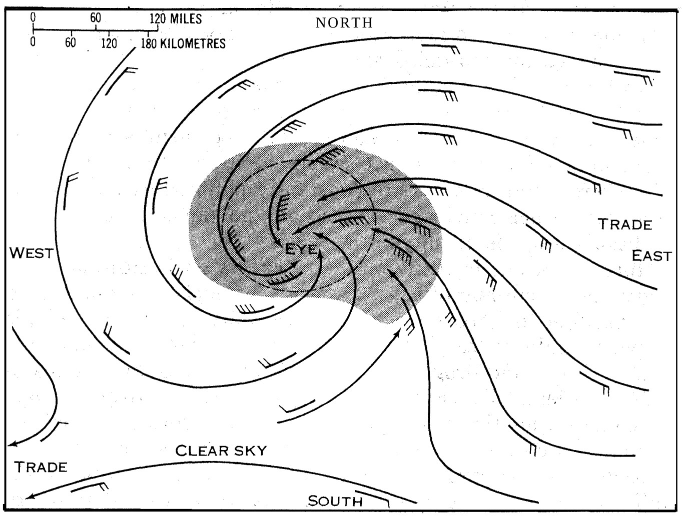

FIG. I.—DISTRIBUTION OF WIND AND WEATHER AROUND MATURE TROPICAL STORMS OF THE NORTHERN HEMISPHERE. MOVING WEST-NORTHWESTWARD IN THE TRADE WIND ZONE. STREAMLINES GIVE SURFACE WIND DIRECTION. WIND ARROWS FLY WITH THE WIND. EACH BARB REPRESENTS TWO BEAUFORT FORCES. DASHED LINE SURROUNDS AREA WITH WINDS HIGHER THAN BEAUFORT FORCE 12. SHADED AREA OUTLINES REGION OF HEAVY RAINFALL

The arrival of the storm area itself begins with a gradual picking up of the wind and increasing gustiness, followed by a thickening of low clouds in the sky and intermittent squally showers. Sometimes the main wall of cumulo-nimbus clouds can be seen approaching in the distance. It is called the bar of the storm.

When a storm is observed from a point that is not on the path of the centre itself, it will be noted that the hurricane winds gradually change direction. They will not let up materially, however, until the cyclone passes. Should the eye travel over the observation point, however, it will be noted that the winds drop from hurricane strength to light breezes within a few minutes. At the same time the rain ceases and the clouds lighten. After passage of the eye the winds and the precipitation resume with full force, but the winds come from the opposite direction.

The duration of the hurricane winds depends on the size of the storm and its rate of movement. If the high winds extend over 100 mi. and the storm moves 10 m.p.h., then the gales will last for ten hours If the cyclone advances at 15 m.p.h., the winds will last for less than seven hours. The same consideration applies to the eye. The central calm may remain for only a few minutes or stay for one to two hours.

Origin.—The development and maintenance of any vortex of the dimension of a tropical storm depend on the effect of the earth's rotation (see METEOROLOGY). As the component of this rotation is zero on the equator, tropical cyclones cannot develop in its immediate vicinity. Areas of strong squalliness and heavy rainfall appear near the equator, but few tropical storms have been observed between latitudes 5° N. and S. On the poleward margin of the tropics, conditions favourable for the development of tropical cyclones occasionally exist even beyond latitude 30°. Formation between latitudes 20° and 30° is fairly common. especially in the western Atlantic ocean and in the Gulf of Mexico.

All tropical storms develop over water. Long before the turn of the 20th century some authors drew attention to the fact that most of them develop along a narrow zone of air convergence, where the trades of both hemispheres meet This zone. which girdles the globe. has been variously called doldrums, intertropical front and equatorial low-pressure trough. It is not of uniform strength around the globe, and it changes its position and intensity with the seasons of the year, following the sun with a lag of two to three months. The equatorial trough penetrates to about latitude 15° N. between July and October and to latitude 10° to 15° S. from January to March or April. These months, then, represent the principal cyclone seasons of the respective hemispheres. In the northern hemisphere, the peak month of activity usually is September.

The distance by nhich the equatorial trough moves away from the equator in the course of a year is not uniform around the globe but is greatest in the regions indicated in fig. 2. The formation of tropical storms is most frequent in those places where the zone deviates far from the equator. Where there is little or no seasonal variation of its position cyclonic developments are rare or nonexistent. The zone appears in the transition periods between summer and minter in the Arabian sea and the western part of the Caribbean sea. Over those parts of the tropical oceans, therefore, the cyclone frequency is greatest about June and October, with a lull in midsummer. There is also a tendency toward two peaks of cyclone activity in the Bay of Bengal.

Tropical storms can develop also in the absence of the equatorial trough, although they do so less frequently. The storms of the western North Atlantic and the Gulf of Mexico are the outstanding examples of formation without equatorial trough. However, cyclonic development will net take place near the equatorial trough or near other disturbances of the tropics unless a broad-scale atmospheric circulation pattern is present in the low and high atmosphere that is favourable for formation. The high-atmospheric observations taken over the oceans during World War II have shown that tropical aeather is greatly dependent on the atmospheric flow in middle latitudes. In order to predict the formation of a tropical storm in the West Indies region, for instance, a weather forecaster must have knowledge of weather conditions over all of the North Atlantic ocean and the United States, besides the information as to conditions over the tropics themselves.

Those regions of the earth where tropical storms form principally are shaded in fig. 2. The greatest frequency should be found over those parts of the tropical oceans where the equatorial trough is strong and has large seasonal departures from its average position and where, moreover, sea surface temperatures are high and the average atmospheric flow in middle and high latitudes is favourable. In the western North Pacific ocean these conditions are fulfilled to a higher degree than anywhere else. On the average, about 20 tropical storms form in that area each year. Although statistics are lacking, the cyclone frequency of the South Indian ocean is thought to be almost as high. Compared with these large figures, other hurricane areas of the world have few storms. In the western North Atlantic, the Caribbean and the Gulf of Mexico the mean annual frequency is about six. The deviations from this average, however, are very large. In 1933, 21 tropical cyclones appeared in the area just mentioned; in 1929 and 1930 there were only 2 each. The South Atlantic is the only ocean where tropical storms are unknown. The equatorial trough does not penetrate far enough southward.

Movement. — Within the tropics, storms that have attained maturity usually drift westward with the prevailing trade wind. While the speed of the winds within the disturbances frequently exceeds 100 m.p h., the rate of movement of the disturbances themselves is about 15 m.p.h. on the average. It may deviate, however, by 5 m.p.h. or more from this mean figure in individual cases. Besides the westward movement there is also a tendency for most storms to approach the poleward limit of the tropics gradually. When they reach this limit near latitude 30°, they leave the tropical easterlies and come under the influence of the prevailing westerlies of higher latitudes. Their direction of motion then reverses and they are said to recurve. After the recurvature they drift eastward while continuing to approach the high-latitude regions. During the recurvature the speed of the cyclones is lowest, and they frequently become almost stationary for 12 to 24 hours. After recurving, their speed increases rapidly and they may be moving at 50 to 60 m.p.h. when they reach the polar zone.

The general path of tropical storms just outlined has a large number of exceptions because of constant changes of the broad-scale atmospheric currents and their effect on the tropics. Weather observation networks extending over large portions of the globe and experienced forecasters are necessary to predict the path of individual storms. These predictions become especially difficult when a storm lies between the broad-scale easterlies and westerlies (see WINDS, GENERAL CIRCULATION OF) so that it is temporarily controlled by neither of these currents.

End of Storms. — Dissipation of tropical storms over the tropical oceans is rare. Most disturbances eventually enter the middle and high latitudes where they are absorbed into the prevailing westerly circulation of those regions. Tropical storms normally lose intensity when striking land, irrespective of latitude. Even passage over smaller islands of the tropics can result in great reductions of their strength. Within 24 hr. after striking land, the winds of a severe hurricane may have been reduced to 20 to 30 m.p.h. Over flat ground, such as Florida, the dissipation is far slower than over rugged country. It should be noted, however, that tropical storms passing into the temperate zone occasionally encounter conditions favourable for regeneration as strong extra-tropical cyclones. In these cases, which are fairly rare, the winds at first lose intensity when the hurricane reaches land, and the eye disappears. Later the circulation again increases, even over a continent, but the strongest winds then are found at a distance of about 200 mi. from the centre.

Damages. — The loss of life and property on tropical islands and coastal areas of continents is caused by the direct and indirect effects of the high winds and the excessive rains.

Winds. — The pressure exerted by the air on solid objects, for instance houses, is proportional to the square of the wind speed. Thus an increase of the wind from 40 to 50 m.p.h. produces far

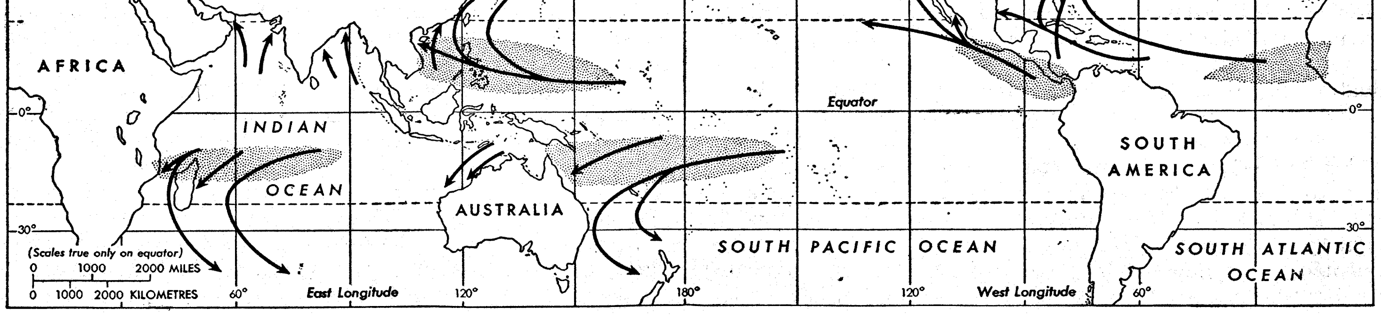

FIG. 2. — TYPICALTRACKS OF TROPICAL STORMS THROUGHOUT THE WORlD AND REGIONS OF GREATEST DEPARTURE OF THE EQUATORIAL FRONT FROM ITS MEAN POSITION

less added danger to buildings than a rise from 90 to 100 m.p.h. Moreover, the resistance capacity of many structures appears to become exhausted rapidly when the winds exceed 75 to 80 m.p.h. In industrial and city areas, danger to industrial and electrical installations is great. Short circuits in the midst of a raging storm and the explosion of gasoline tanks have led to uncontrollable fires. Much damage also results from the impact of flying debris.

Storm Waves.—Some of the most disastrous losses of life and property have been caused by a sudden rising of the ocean and widespread inundations of low-lying, poorly protected coastal areas. The abrupt increase of the water level, referred to as the storm wave, is caused by the action of the wind on the water The storm wave appears so quickly and is carried with tremendous force so far inland that often there is no time for the coastal inhabitants to rescue themselves or their belongings.

Rainfall.—The heavy rainfall often accompanying tropical storms frequently causes landslides in mountainous and hilly areas. Because of the great and sustained intensity of the precipitation, the runoff of the water is extreme and produces rapid and excessive rises of the water level of the rivers along which the human settlements and valuable agricultural activities are concentrated.

The damaging power of tropical storms is not confined to the tropics. Occasionally, storms moving up against Japan, China and the northeastern coast of the United States have struck with a violence equal to that of storms within the lower latitudes.

Storm **Warning** Services.—Forecasting of the appearance of tropical storms was attempted long before the start of the 20th century. These activities were begun largely by the Society of Jesus whose members developed a high forecasting standard notably in the West Indies and the Philippines. With the gradual expansion of governmental weather services after 1900, the forecasting work passed more and more into official hands, aided also by the military weather services during World War II. From 1935, for instance, the United States weather bureau has maintained special hurricane forecast centres which advise the public concerning the position, the intensity and the probable movement of hurricanes and indicate what type of precautions are necessary.

TROPIC BIRD, a genus (Phaethon) of sea birds of the order Steganopodes with webbed feet and long forked tails. The flight is by rapid strokes of the wing. The yellow-billed tropic bird (P. *flavirastris*) has the widest range, inhabiting the Atlantic, Indian and Pacific oceans, and breeding on trees in various islands, including the Bermudas. It lays a single pinkish-white egg, mottled with brownish-purple. The plumage is white, with black patches. P. aethereus is larger and lacks the yellow bill. It does not occur in the western part of the Indian ocean. P. *rubricauda* is still larger and has a red tail and a roseate tinge to the rest of the plumage. It is confined to the Pacific and Indian oceans. The tropic birds form the family Phaethonidae.

TROPINE (TROPANOL), the amino-alcohol portion formed, together with tropic acid, when the ester linkage in atropine or hyoscyamine is hydrolyzed with acids or alkalies. It forms white, hygroscopic crystals melting at 63° C. and does not rotate the plane of polarized light (see STEREOCHEMISTRY). Its synthesis (Richard Willstatter, 1901) furnished proof of the structure of the parent alkaloids. Tropine has no medical uses but is employed in the manufacture of homatropine and similar agents used in dilating the pupil of the eye. Tropine is closely related to ecgonine, the basic portion of cocaine. See also ATROPINE; COCAINE; HYOSCYAMINE (L. F. SL.; V. E.)

TROPISM, a term introduced by plant physiologists by 1835, grew to designate the bending of a plant in relation to some definite stimulus like that furnished by gravity (geotropism) or light (phototropism). The turning continues until the plant is so oriented that symmetrically placed parts are equally stimulated. As outlined in ANIMAL BEHAVIOUR (*q.v.*), tropism has retained essentially this same meaning except that it also includes the orientation of sessile animals. Jacques Loeb initiated and developed the transfer of concepts centring about tropisms from plant physiology to animal behaviour. He believed that, despite the more complicated reaction system of animals, plants and animals behave fundamentally alike. The tropism theory of orientation as applied to higher animals postulates that these bilaterally symmetrical organisms give a quantitatively different reaction of the locomotor appendages or tissues on opposing sides in direct proportion to the strength of stimuli received by the corresponding receptors. After being oriented, a motile organism is held on its path by balanced thrusts of its locomotor apparatus, much as a rudderless boat is guided and propelled by laterally operated oars or by a tail-like sculling oar at the stern. This tropism theory of oriented response—also called the muscle-tonus theory—is an incomplete explanation of oriented behaviour. The term tropism has been expanded to include all aspects of unlearned, reflex actions of whole organisms that appear to result from the direct interaction of physical forces in the environment with physiological processes within the organism. Taxes (taxis, singular), as well as tropisms in the restricted sense, were called tropisms with the implication that the reacting organism is mechanically forced to behave as it does. Loeb skilfully developed this mechanistic conception of behaviour; after 30 yr. of study he wrote (1918): "Motions caused by light or other agencies appear to the layman as expressions of will and purpose on the part of the animal, whereas in reality, the animal is forced to go where carried by its legs. For the conduct of animals consists of forced movements." (Jacques Loeb, Forced Movements, Tropisms, and Animal Conduct, J. B. Lippincott Co., 1918.) According to this theory, behaviour is not primarily adaptive; the male moth is not trying to find a mate, and fishes do not will to swim upstream; they are mechanically forced to do so. Loeb applied this interpretation very widely and (1918) suggested that, with the enlargement resulting from memory, the tropism theory might include human conduct. Largely because of its close association with unproved theories, some students avoid the word tropism entirely; others use it descriptively, without theoretical implications, for orientation reflexes of sessile organisms.

TROPOSPHERE, the lowest region of the earth's atmosphere. It is characterized by turbulent mixing, cloud formation and, generally, a decrease in temperature with altitude. The upper boundary, called the tropopause, has an altitude of 25,000 to 55,000 ft. See ATMOSPHERE.

TROPPAU: see OPAVA.

TROPPAU, CONGRESS OF, a conference of the allied sovereigns or their representatives to discuss a concerted policy with regard to the questions raised by the revolution in Naples of July 1820. At this congress, which met on Oct. 20, 1820, the emperors Alexander I of Russia and Francis I of Austria were present in person; King Frederick William III of Prussia was represented by the crown prince (afterward Frederick William IV). The three eastern powers were further represented by the ministers responsible for their foreign policy: Austria by Prince Metternich, Russia by Count Capo d'Istria, Prussia by Prince Hardenberg. Great Britain, on the other hand, which objected on principle to the suggested concerted action against the Neapolitan Liberals, sent no plenipotentiary, but was represented by Lord Stewart, ambassador in Vienna. France, too, had given no plenary powers to her representatives.

In a series of conferences—to which the representatives of Great Britain and France were not admitted, on the excuse that they were only empowered to "report," not to "decide"—was drawn up the famous preliminary protocol signed by Austria, Russia, and Prussia on Nov. 19. The main pronouncement of the "Troppau protocol" is as follows: "States which have undergone a change of government due to revolutian, the results of which threaten other States, ipso facto cease to be members of the European Alliance, and remain excluded from it until their situation gives guarantees for legal order and stability. If, owing to such alterations, immediate danger threatens other States the powers bind themselves, by peaceful means, or if need be, by arms, to bring back the guilty State into the Great Alliance"

No effort was made by the powers to give immediate effect to the principles enunciated in the protocol; and after its promulgation the conferences were adjourned, it being decided to resume them at Laibach in the following January (*see* LAIBACH, CONGRESS OF).

TROSSACHS, THE (Gaelic, "the bristled country," an allusion to its rich, wild vegetation), a defile in the southvest of Perthshire. Scot. It is a narrow, beautifully wooded glen. of no great depth, extending from Loch Achray to Loch Katrine. and continued thence by a strip on the northeastern shore to a point above the now submerged Silver Strand opposite to Ellen's Isle—a total distance of $2\frac{1}{2}$ mi. It is situated about 7 mi. N.N.W of Aberfoyle, between the steep green slopes of Ben Venue (2,393 ft.) on the southwest and the precipitous crags of Ben A'an (1,750 ft.) on the northeast. The Trossachs region has been famous for its beautiful scenery since the appearance of Sir Walter Scott's *The Lady of the Lake* and *Rob Roy*, with their vivid descriptive passages.

TROTSKY, LEV DAVIDOVICH (1879–1940), Russian politician, whose real name was Bronstein, was born near Elizavetgrad, the son of middle-class Jews. He was educated at the Peter and Paul *Real Schule* in Odessa and at the university of that town. He was arrested as a revolutionary in 1898. and soon after exiled to eastern Siberia. In 1902 he escaped to England by means of a forged passport in the name of Trotsky (which name he used thenceforward). In London, despite his youth, he soon became an important member of the small body of social democrats which included Plekhanov and Lenin. He collaborated with the latter and others in the publication of *Iskra* (Spark), the most famous of the Russian revolutionary newspapers. In 1905 he returned to Russia, was elected a member of the St. Petersburg Soviet of Workers' Deputies and was chairman of the meeting at which the whole soviet was arrested. He was exiled to Tobolsk but escaped immediately on his arrival in Siberia and went to Vienna, where he worked for the *Arbeiter Zeitung* and the *Pravda*. He also worked in a chemical factory. In 1910 he attended the Social Democratic congress at Copenhagen, defending a position of his own, midway between that of the bolshevists and that of the menshevists. In 1913 he was in Constantinople as a war correspondent. The following year found him in Zurich and Paris, taking part in the publication of a revolutionary paper. He wrote a book on the origins of World War I, published in German, and was sentenced to eight months' imprisonment. But he opposed the War not only in Germany but in the Allied countries, and in 1916 was expelled from France. He was arrested by the Spanish authorities on crossing their frontier but was allowed to leave for America, where he edited the Russian revolutionary ***Novy Mir*** (The New World).

When the revolution broke out in March 1917 Trotsky's friends and subscribers to the paper collected the money for his journey to Russia. He was, however, arrested by the British authorities and taken ashore at Halifax, where he was interned until the Russian Provisional government asked for his release. He arrived in Petrograd soon after Lenin. He was the leader of a small party of social democrats and soon joined the Bolsheviks but did not actually become a member of the Bolshevik party until July 1917, when he was arrested for being concerned in the rising which took place in that month. He played a part hardly less important than that of Lenin in organizing the Bolshevik revolution in 1917 and became People's Commissar for foreign affairs in the new Soviet Government.

Trotsky was the most important figure in the Russian delegation during the negotiation of the Brest-Litovsk peace treaty. Believing that the moral effect of the revolution had already been such that the Germans would be unable to force their troops to move against Russia, he met the oppressive German demands with the statement that Russia would not sign a treaty on such terms but that she considered the War to be at an end and would demobilize her troops. The Germans thereupon continued their advance. Lenin had disagreed with Trotsky, considering that the risk was too great since at that time the Germans could easily have taken Petrograd. After a series of debates, Trotsky announced that he now sided with Lenin and by a majority of one it was decided to sign an even more unfavourable treaty than that previously refused. Trotsky was replaced by Chicherin as Commissar for foreign affairs and took over the Commissariat of war. In spite of opposition he made great use of officers of the old régime in organizing a new Red army. The results obtained were used to justify the employment of "bourgeois" technical experts in the factories. When he had made a new army that showed itself superior to those of the Whites his energies were used in preventing the complete collapse of the railways. In 1920 he organized as "labour armies" the troops that were not needed for war.

Until the introduction of the new economic policy Trotsky urged industrial conscription, but wholeheartedly accepted the new policy which made such measures impossible. During the Polish war of 1920, he opposed the disastrous advance on Warsaw but was overruled by Lenin. In the autumn of 1923 he adopted a position that made it possible for the "old guard" of the Communist leaders to accuse him of canvassing for the support of the younger men. He was violently attacked by Stalin, Zinoviev and others. Many of his friends were shifted from their posts and he himself was on the way to the Caucasus to take a cure, when Lenin died. Throughout the revolution the names of Lenin and Trotsky had been coupled and the death of the one seemed to leave the other alone in the field. This was not really so. Seniority counts for much in the Communist party and the older leaders never forgot that Trotsky had only joined the party in 1917. The campaign to discredit him was continued. He lost his post as Commissar of war. When he returned from the Caucasus he was given work of small political significance, being made head of the committee for the development of electric power in Russia. In 1925 he resigned from this post and was made head of the Central Committee for Concessions. In Nov 1927 he was expelled from the Communist party for his anti-party activities, and in Jan. 1928 he was exiled to Viernie in Turkestan. He was subsequently banished and went to Constantinople (1929).

In 1936 he made his home in Norway; in Jan. 1937 he went to live in Mexico. He was (1936) accused of joining Zinoviev and Kamenev in a plot to murder Stalin but emphatically repudiated the charge. On Aug. 20, 1940 he was attacked in his suburban home at Mexico city by a "friend" whom the exile's intimates described as a Stalinist agent. He died the next day.

TROTZENDORFF (or TROCEDORFIUS), **VALENTIN FRIEDLAND** (1490–1556), German educationist, called Trotzendorff from his birthplace, near Gorlitz, in Prussian Silesia, was born on Feb. 14, 1490, of parents so poor that they could not keep him at school. Nevertheless he was sent to study at Görlitz, and became a schoolmaster there. He resigned presently to study under Luther and Melanchthon, supporting himself meanwhile by private teaching. He then became master in the school at Goldberg in Silesia, and in 1524 rector. There he remained three years, when he was sent to Liegnitz. He returned to Goldberg in 1531 and began that career which has made him the typical German schoolmaster of the Reformation period. He made his best elder scholars the teachers of the younger classes, and insisted that the way to learn was to teach. He organized the school in such a way that the whole ordinary discipline was in the hands of the boys themselves. Every month a "consul," twelve "senators" and two "censors" were chosen from the pupils, and over all Trotzendorff ruled as "dictator perpetuus." One hour a day was spent in going over the lessons of the previous day. The lessons were repeatedly recalled by examinations, which were conducted on the plan of academical disputations. Every week each pupil had to write two "exercitia styli," one in prose and the other in verse, and Trotzendorff took pains to see that the subject of each exercise was something interesting. The fame of the Goldberg School extended over all Protestant Germany, and a large number of the more famous men of the following generation were taught by Trotzendorff. He died on April 20, 1556.

TROUBADOURS, poets of southern France, northern Spain and northern Italy who wrote in the *langue d'oc* (*see* PROVENÇAL LANGUAGE) from the end of the 11th century to the last decade of the 13th. The word *troubadour* is a French form of the Occitanian *trobador*, accusative singular of *trobaire*, "poet," from *trobar*, "to find," "to invent"; *cf.* Fr. *trouvère, trouver*. A troubadour, then, was one who invented new poems, finding new verse forms for his elaborate lyrics; he might be a great prince, such as Richard Coeur de Lion, or a wandering adventurer who made song his profession.

The social influence exercised by the troubadours was unprecedented in the history of medieval poetry. They had great freedom of speech. they entered into questions of politics and above all they created around the ladies of the court an atmosphere of cultivation and amenity which nothing had hitherto approached. The troubadour was occasionally accompanied by an apprentice or servant, called a *joglar*, who provided a musical setting for his words and sometimes sang his songs. About 400 troubadours were recognized in the 200 years in which they flourished.

The efficient cause of the decadence and ruin of the troubadours was the struggle between Rome and the Albigensian heretics (*see* CATHARI). This broke out into actual war in 1209, when the barons of northern France, responding with alacrity to Pope Innocent III's invitation to a crusade, fell upon the rich dominions of the count of Toulouse. Most of the protectors of the troubadours had been. if not heretics, at least liberally disposed toward the heretical party, in whose downfall they consequently found themselves involved. As the desolation of Languedoc became more and more entire, the darkness gathered round patrons and poets alike. Thus it was that Guiraut Riquier at the end of the 13th century was already speaking to the wind. He was in a decayed world. the mourner of one of the most brilliant poetical schools that ever flourished; an eminently creative school from which proceeded all the new European lyrism.

Literary Forms.—A considerable number of specimens, if not the greater part, of the work of the troubadours is extant, having been preserved in the manuscripts known as *chansonniers* ("song books"); and the rules of their art are formulated in the *Leys d'amors* (1340). The verse form most frequently employed by the troubadours was the *canzo*, consisting of five or six *coblas* ("stanzas") with a *tornada* ("envoy"). When the *canzo* was of a political or satirical nature, it was called a *sirventés*. The troubadours also used the *hnlada* or *dansa*, which was a dance song with a refrain; the *pastorela*, illustrating the love request of a knight to a shepherdess; the *alba* or morning song, one of the most exquisite of their forms, in which lovers are warned by the *gaita*, ("watchman") that day is close at hand and that *el gilos*, the jealous husband, may surprise them (there were also, however, *albas* of a religious sort). Corresponding to the *alba*, was the *serena* or evening song, a later invention. Particularly interesting were the *tenson* and the *partimen* or *joc partit*, which were lyrical conversations between two or more persons discussing, as a rule. some point of amorous casuistry or matters of a religious, metaphysical or satirical character. Though some of them wrote other kinds of poems. the troubadours were essentially lyrical.

For an account of the troubadours' importance in the literature of the Midi *see* PROVENÇAL LITERATURE.

Lives of the Troubadours.— Information on the careers of 111 of the 400 troubadours can be gathered from the several manuscript collections of biographies of these poets. The principal collection, made by various hands toward the middle of the 13th century, includes contributions by Uc de Saint Circ (*c.* 1200–40), himself a troubadour. The *Vies des plus célèbres et anciens poètes provensaux*, published by Jehan de Nostredame (or Nostradamus) in 157j. is another source, but unreliable.

Even the numerous genuine biographies. however, are often embroidered with statements that make a severe demand on a modern reader's credulity; and a major task of research in the 19th and 20th centuries has been to disentangle the true from the fanciful in these writings.

Something must be said of a few of the most notable troubadours.

GUILHEM VII, count of Poitiers (William IX, duke of Aquitaine), who was born in 1071 and reigned as count-duke from 1086 to his death in 1127, was the first troubadour to come to renown. He is still regarded both as the patron and earliest poet of the school. Some of his songs are rather licentious; in another he makes a pathetic farewell to the world.

Second on the ordinary list of great troubadours is JAUFRÉ RUDEL of Blaye (fl. 1130–50), whose heart burned like the disc of a sunflower toward his "far-away love." Little else than the famous adventure of the Lady of Tripoli (dramatized by Edmond Rostand in *La Princesse lointaine*) is told about this troubadour, whose stanzas, inspired either by the Church of Christ or by the Lady of Tripoli herself, have a simple and pathetic accent.

Another of the early troubadours, the Gascon MARCABRUN (fl. *c.* 1130–48), from whose pen 45 poems survive, was an innovator and a reformer. To him the severity of the classical troubadour's style is mainly due, and he was one of the first to make use of the complex form known as the *trobar clus*. He posed as a violent misogynist: "I never loved any lady, and no lady ever loved me." Several of his songs are of a rough beauty.

More famous is the name of BERTRAN DE BORN (*c.* 1140–1215), the warrior poet, viscount of Hautefort in Périgord. Dante met Bertran de Born in hell, carrying his severed head before him like a lantern and comparing himself with Xchitophel, who incited Absalom to rebellion against David (*Inferno*, xxviii, 112 ff.). This was because of Bertran's part in promoting the rebellion of "the young king," Prince Henry of England, against his father, Henry II. The death of Prince Henry (1183) moved Bertran to two beautiful *planhs* ("laments"). The poet was immediately afterward besieged in his castle of Hautefort by Richard Coeur de Lion, to whom he became reconciled and accompanied to Palestine. He grew devout in his old age. About 2j *sirventés* by him are extant, including some of the most colourful and vivid poems that war ever inspired.

Eleanor of Aquitaine, queen first of France and then of England, was a great patroness of the troubadours; and it was at her court that BERNART DE VENTADOUR (*c.* 1150–95) rose tb eminence. Bernart, whose name is perhaps the highest in Occitanian poetry, was the son of a kitchen scullion in the castle of Eble, viscount of Ventadour. Eble, himself a poet, early noticed the talents of his serving boy and trained him to be a poet. The beautiful wife of Eble encouraged the boy's attentions; indeed. they had secretly loved one another since childhood. The poems which this passion inspired are among the best to come down to us from the middle ages. When Eble at last discovered the intrigue and exiled him from Ventadour, Bernart took shelter at Eleanor's court. After her marriage to Henry Plantagenet (1152) he left her service and attached himself to the court of Toulouse.

The most famous adept of the *trobar clus* mas a knight of Ribérac in Périgord, ARNAUT DANIEL (fl. c. 1180–1210), who attached himself as a troubadour to the court of Richard Coeur de Lion. Arnaut owes to the repeated praise given to him by Dante in the *Purgatorio* (xxvi. 115 ff.) and elsewhere a dazzling glory that to modern readers seems somewhat excessive. To Dante he is *il miglior fabbro* ("the better craftsman") and it is evident that it was the brilliant art of the Perigourdin's elaborate verse which delighted the Florentine. Arnaut's invention of forms of verse particularly impressed Dante (*see* SESTINA).

Dante was curiously anxious to exalt Arnaut Daniel as a better artist than his immediate rival. also one of Richard Coeur de Lion's protégés, GIRACT DE BORSELH (*c.* 1165–1220), who came from the vicinity of Excideuil, between Périgueux and Limoges. Modern taste. however, is inclined to reverse Dante's verdict. Giraut indeed, besides some pieces no less laboured than Arnaut Daniel's, left an *alba* of incomparable freshness, the *Reis glorios* imitated by Ezra Pound in his *Lustra* ("Languedoc," i).

The same freshness, with a still more touching sincerity, characterizes the work of Giraut's contemporary ARNAUT DE MAREUIL, another Perigourdin, who is credited with having introduced the amatory epistle (*salut*) and the short didactic poem (*ensenhumen*) into Occitanian poetry. Attached to the court of Béziers, he was driven from it by Alphonso II of Aragon, who wanted his mistress.

GAUCELM FAIDIT (*c.* 1185–1215) came from Uzerche in the Limousin. He seems to have been a wandering minstrel of gay and reckless habits and to have been accompanied by a loose woman, Guilhelma Monja, who was the object of much satire and ridicule. Homesick, he found deep and moving notes to speak of his native Limousin.

RIGAUT DE BARBEZIEUX (*c.* 1170–1200), a poet of Saintonge, equally famous for his love affairs, was another example of the naïveté and tenderness so frequent among the troubadours.

In Provence proper flourished BEATRIX, countess of Die, whose career was inextricably interwoven with that of another noble troubadour, RAIMBAUT III (fl. *c.* 1150–73), count of Orange, who held his court at Courthézon, a few miles south of Orange. Raimbaut said that since Adam ate the apple no poet had been born who could compete in skill with himself, but his surviving lyrics have neither the tenderness nor the ingenuity of those of Beatrix, who appears to have been much in love with him.

The greatest troubadour of Provence, however, is undoubtedly RAIMBAUT DE VAQUEYRAS (fl. *c.* 1155–1207), who passed the greater part of his life at the court of Montferrat. There he devoted himself to the lady Beatrix, sister of the marquis Boniface. One of the most moving poems of the age commemorates her death. He had earlier made himself famous by a *descort* in five languages and by his lively "War of the Ladies."

PEIRE VIDAL (*c.* 1175–1206) of Toulouse, was the prototype of the reckless and scatterbrained troubadour. His biographer says that he was "the maddest man in all the world." His early life was a series of bewildering excursions through France and Spain. He is said to have stolen a kiss from Alazaïs (the wife of his patron and friend Barral viscount of Marseilles) thereby incurring her dangerous resentment. He committed a thousand follies; for instance. being in love with Loba de Penautier, he dressed himself as a wolf (*lop;* "she-wolf," *loba*) and was hunted by a pack of hounds in front of her castle in the hills of Cabaret.

FOLQUET DE MARSEILLA (*c.* 1161–1231) was the son of a Genoese merchant In the latter part of his life he became bishop of Toulouse (*c.* 1202), in which capacity he engaged in the persecution of the Albigenses Dante met him in paradise (*Paradiso*, ix, 82 ff.) and gives an interesting notice of him. It is in the *sirventés* of Folquet that critics have seen the earliest signs of that decadence which was so rapidly to destroy Provencal poetry.

Auvergne had already produced one of the first troubadours, the not very remarkable poet of Clermont known as PEIRE D'ALVERNHA. The same country was represented later by two typical troubadours: the MONK OF MONTAUDON (fl. *c.* 1180–1213), famous for his truculent *tensons* with God on the duties of monks and on ladies' rouge (*c.* 1200); and PEIRE CARDENAL (d. *c.* 1272) of Le Puy. Cardenal, a poet of the first rank, was a protégé of James I of Aragon, having apparently fled from Narbonne and then from Toulouse to escape the armies of Simon de Montfort. He was the inventor of the moral or ethical *sirventés* and the author of singularly outspoken satires against the clergy. In a score of *sirventés* he proves himself the most unorthodox spirit and the most transcendental satirist of the Midi in the middle ages.

The chief of Italian troubadours was SORDELLO (d. *c.* 1270), born at Mantua early in the 13th century, who by his barbaric *planh* for the lord Blacatz (whose heart he desired the princes of western Europe to eat, so as to ingest his qualities) achieved a fame to which Dante (*Purgatorio*, vi–ix) and Robert Browning added by the use they made of his name.

It is to the class of unfortunate lovers rather than to that of great troubadours that legend assigns GUILHEM DE CABESTANH. Guilhem is said to have made love to Seremonda, wife of Raymund of Castel-Roussillon, and to have been killed by the jealous husband. who then cut out his heart and had it delicately cooked and served to his wife at dinner. When Seremonda had eaten it, Raymund told her what she had done, whereupon she threw herself out of the window, to her death. Historical research has raised serious doubts about this story since Guilhem seems to have been alive in 1212, and Ramon de Castell-Rossello predeceased his wife Saurimonde de Perclada (between 1212 and 1221).

Another troubadour of this time was GUILHEM FIGUEIRA (*c.* 1215–50), the son of a tailor of Toulouse, an open heretic who attacked the papacy with extraordinary vigour, supported and protected by the emperor Frederick II. But the end was already in sight. After him the ruin of the southern courts, to which their fortune was attached, precipitated the decline of the troubadours.

GUIRAUT RIQUIER (1230–94), the last of the troubadours, was born in Narbonne and found protection at the court of Alphonso the wise of Castile. Guiraut, in a *sirventés* of c. 1285, gives expression of his sense of the gathering darkness, which makes it useless and almost unbecoming for a troubadour to practise his art, while of himself he mournfully confesses, "Song should express joy, but sorrow oppresses me, and I have come into the world too late." He left no successor, unless one should call troubadours the academical poets of the Gay Saber who in Toulouse remained faithful for a time to the decaying rule of the *Leys d'amors*.

BIBLIOGRAPHY.—For comprehensive works, *see* the bibliography of the article PROVENÇAL LITERATURE. For individual troubadours, including many not cited in the text above, there are editions as follows: *William IX of Aquitaine:* A. Jeanroy, *Guilhem VII of Poitiers* (1905; rev. ed. 1927), *Cercamon* (1922), *Jaufré Rudel*, new ed. (1924); J. M. L. Dejeanne, *Cercamon* (1905), *Marcabrun* (1909); A. Stimming, *Jaufré Rudel* (1873); C. Appel, *Bernart de Ventadour* (1915); J. Anglade and C. Chabaneau, *Rigaut de Barbezieux* (1919).

Raimbaut III of Orange: C Appel, eight poems (1928), *Cadenet* (1920); W. L. Pattison (ed.), *Raimbaut III, Comte d'Orange* (1952); R. Zenker, *Peire d'Alvernha* (1900); A. Stimming, *Bertran de Born* (1879); A. Thomas, *Bertran de Born* (1888); U. A. Canello, *Arnaut Daniel* (1883), rev. by R. Lavaud (1910); R. C. Johnston, *Arnaut de Mareuil* (1935); A. Langfors, *Guilhem de Cabestanh* (1924); J. Anglade, *Peire Vidal* (1924); A. Kolsen, *Giraut de Bornelh* (1910); S. Stronski, *Folquet de Marseilla* (1910), *Elias de Barjols* (1905); E. Philippson, *The Monk of Montaudon* (1873); G. Klein, *The Monk of Montaudon* (1885); A. Jeanroy, *Gavaudan* (1905); H. J. Chaytor, *Perdigon* (1926); E. Levy, *Guilhem Figueira* (1880), *Bartolome Zorzi* (1883); J. Boutière, *Peire Bremon* (1930); A. Jeanroy and J. J. Salverda de Grave, *Uc de Saint-Circ* (1913); C. de Lollis, *Sordello* (1896); M. de Riquer, *Cerverì de Girona* (1947); J. Coulet, *Guilhem Montanhagol* (1898); W. Bernhardt, *At de Mons* (1887); A. H. Schutz, *Daude de Pradas* (1933); J. Sjellman, *Raimon Jordan* (1920); M. Dumitrescu, *Aimeric de Belenoi* (1935); A. Parducci, *Granet* (1929); E Niestroy, *Pistoleta* (1914); E Hoepffner, *Bernart Marti* (1929); W. P. Sheppard, *Jausbert de Puycibot* (1924); J. J. Salverda de Grave, *Bertran de Lamanon* (1912); H. Pfaff, *Guiraut Riquier* (1853), on which J. Anglade's work, *Guiraut Riquier: étude sur la dtcadence de l'ancienne poésie provençale* (1905) serves as a commentary.

(A. A. F. B.)

TROUBETZKOY, AMÉLIE, PRINCESS (1863–1945), U.S. author whose first novel, *The Quick or the Dead?* (1888), dealing with a widow's attachment to a new lover, created a sensation and established her as a popular novelist. Born on Aug. 23, 1863, in Richmond, Va., the granddaughter of William Cabell Rives (*q.v.*), U.S. senator and minister to France. she inherited his estate.

She wrote essays, poems and plays as well as novels. Her works include the novels *Virginia of Virginia* (1889), *The Golden Rose* (1908), *Pan's Mountain* (1910), *Hidden House* (1911), *The World's-End* (1914), *The Queerness of Celia* (1926) and *Fire-damp* (1930); *Augustine the Man* (1906) is a blank verse tragedy. Prince Pierre Troubetzkoy was her second husband. She died in Charlottesville, Va., on June 15, 1945.

TROUPIAL, a collective name suggested by Ridgway for the American family Icteridae, which includes the North American orioles, meadow larks, cowbirds, grackles and blackbirds and the Central American caciques.

TROUT. The general common name applied to certain species of the family of fishes called Salmonidae. *See* SALMON AND SALMONIDAE.

TROUT LILY, a nearly stemless plant of the lily family with yellow blossoms, native to the United States and southern Canada. It is one of the dog's-tooth violets (*q.v.*).

TROUVÈRE, the name given to the medieval poets of northern and central France, who wrote in the *langue d'oil* or *langue d'oui*. The trouvères flourished abundantly in the 12th and

13th centuries. They were court poets who devoted themselves almost exclusively to the composition and recitation of aparticular kind of poetry, the subject of which was some refinement of love.

The first appearance of trouvkres seems to date from 1137, when Eleanor of Aquitaine, herself the granddaughter of an illustrious troubadour, arrived in the court of France as the queen of Louis VII, speaking the Poitiers dialect of the *langue d'oc.* She was queen for 15 years (1137–52), the period during which the southern influence was strongest in the literature of northern France, and the successive crusades tended to produce relations between the two sections of poetical literature. The northern poets rarely approach the grace and delicacy of the troubadours, while their verse shows less ingenuity and less variety. The earliest trouvhres, like Conon de Béthune and Hugues de Berze, in writing their amatory lyrics, were, however, certainly influenced by what troubadours had written.

The poetical forms adopted by the trouvbres bore curious and obscure names, the signification of which is still in some cases dubious. The *rotruenge* was a song with a refrain; the *serventois* was, in spite of its name, quite unlike the sirventes of the troubadours and had a more ribald character; the estrabot was allied to the *strambotto* of the Italians, and was a strophic form "composed of a front part which was symmetrical, and of a tail which could be varied at will" (Gaston Paris).

The court poetry of the trouvhres particularly flourished under the protection of three royal ladies. Marie, the regent of Champagne, was the practical ruler of that country from 1181 to 1197, and she encouraged the minstrels in the highest degree and discussed the art of verse with Chrktien of Troyes. Her sister, Aélis or Alice, welcomed the trouvkres to Blois; she was the protector of Gautier d'Arras and of Le Châtelain de Coucy. Another Aélis, who became the second queen of Louis VII in 1160, received Conon de Béthune in Paris, and reproved him for the Picard accent with which he recited his poetry. At the end of the 12th century the refinement and elegance of the court poets was recognized in the north of France by those who were responsible for the education of princes. A trouvkre, Gui de Ponthieu, was appointed tutor to William III of Macon, and another, Philippe of Flanders, to Philippe Auguste. The vogue of the trouvkres began during the third crusade; it rose to its greatest height during the fourth crusade and the attack upon the Albigenses. The first 40 years of the 13th century was the period during which the courtly lyrical poetry was cultivated with most assiduity. At first it was a purely aristocratic pastime, and among the principal trouvères were princes such as Thibaut IV of Navarre, Louis of Blois and John, king of Jerusalem. About 1230 the taste for court poetry spread to the wealthy bourgeoisie, especially in Picardy, Artois and Flanders. Before its final decline, and after the courts of Paris and Blois had ceased to be its patrons, the poetry of the trouvkres found its centre at Arras, where some of the most skilful of all the trouvères, such as Jacques Bretel and Adam de la Halle, exercised their art. About 1280 the poetical system suddenly disappeared.

The poet was invariably a lover, devoted to a married lady who was not his wife, and to whose caprices he was bound to submit blindly and patiently. The progress of this conventional courtship was laid down according to certain strict rules of ceremonial; love became a science and a religion, practised by the laws of precise etiquette. The *rondel* of Adam de la Halle (published in E. de Coussemaker's edition, 1872) beginning

"A Dieu comant amouretes,
Car je m'en vois
Souspirant en tere estrange!"

marks perhaps the highest point to which the delicate, frosty art of the trouvkres attained. Music took a prominent place in all their performances, but little is known of the melodies which they used. But enough has been discovered to justify the general statement of Tiersot that "we may conclude that the musical movement of the age of the trouvères was derived directly from the most ancient form of popular French melody." A precious ms. in the Faculty of Medicine of Montpellier contains the music of no fewer than 345 part-songs attributed to trouvhres.

BIBLIOGRAPHY.—E. de Coussemaker, *Art harmonique aux XII^me^ et XIII^me^ siècles* (186;) ; A Jeanroy, *Les Origines de la poe'sie lyrique en France au moyen âge* (1889); J. Tiersot, *Histoire de la chanson populaire en France* (1889); H. Binet, *Le Style de la lyrique courtoise en France aux XII^me^ et XIII^me^ siicles* (1891); G. Paris, *Les Origines de la poe'sie lyrique en France au moyen âge* (1892) The works of the principal trouvères have been edited; those of Le Châtelain de Coucy by F. Michel (1830) and by Fritz Fath (1883); of Thibaut IV, king of Navarre, by P Tarbé (1851) and by A Wallensköld (1925); of Adam de la Halle by E de Coussemaker (1872); of Conon de Béthune by Wallensköld (Helsingfors, 1891).

TROUVILLE, a seaside town of northwestern France, in the *département* of Calvados, on the English channel, 34 mi. N.E. of Caen by rail. Pop. (1954) 6,213. Trouville stands at the mouth of the Touques on its right bank opposite Deauville. Its fine stretches of sand and excellent bathing make it the most frequented French resort on the channel. Deauville is well known for its racecourse and villas. The port, shared with Deauville and formed by the Touques, is entered by a channel between jetties with a depth at high tide of $17\frac{1}{2}$ ft.; it is supplied with a half-tide dock, filled to scour the channel. and a floating dock, with average depth of 18 ft. Timber, coals and cement are imported.

TROWBRIDGE, a market and manufacturing town and urban district in the Westbury parliamentary division of Wiltshire, Eng.. 33 mi. S.W. of Swindon by road. Pop. (1951) 13,859. Area 3.5 sq.mi. The first description of the town is that of John Leland, in about 1530, who reported that its castle was in ruins. Trowbridge is the administrative centre for the county and is well known for its manufacture of fine woollen fabrics. Its prosperity is also due to brewing, light engineering, manufacture of gloves and bedding, bacon curing, creameries, printing and seed preparation. St. James's church. where the poet George Crabbe was once rector, has a 14th-century, 160-ft. spire. Sir Isaac Pitman, originator of a method of shorthand, was born in the town.

TROY, a city of eastern New York, U.S., the seat of Rensselaer county, lies on the east bank of the Hudson river at the mouth of the Mohawk a few miles from Albany. The area is designated by the census bureau as the Albany-Schenectady-Troy standard metropolitan statistical area; *see* ALBANY. Troy was originally part of the Van Rensselaer manor, one of the patroonships granted in 1629 by the Dutch West India company to encourage Dutch colonization in the Hudson valley. After the American Revolution, a town was laid out on the farm of the Van der Heyden family, who had acquired the property in 1707. In 1789 the name of Troy was adopted and in 1793 the county seat was established there. Troy was incorporated as a village by an act of the New York state legislature in March 1794 and was chartered as a city in 1816.

During the War of 1812 Troy filled large contracts for army beef, the brothers Ebenezer and Samuel Wilson being major suppliers. The latter was known locally as "Uncle Sam" and, as government purchasers stamped "U.S." on the barrels of meat being shipped, local workmen referred to it as "Uncle Sam's beef." As tradition has it, the name was picked up by soldiers and soon came into familiar usage as a nickname for the United States.

Troy has long been an important industrial and commercial city. At one time it was the steel centre of the United States but was doomed in 1873 when Andrew Carnegie set up his mills near Pittsburgh, Pa. It is a principal centre in the United States for the manufacture of men's shirts and other garments. The clothing industry dates from 1819 when Hannah Montague of Troy had the ingenious idea of making separate collars for her husband's shirts. The idea spread, and in 1829 Ebenezer Brown. a local merchant, had collars made to sell in his store. After the introduction of the sewing machine in 1852 the industry grew rapidly, reaching its peak about the time of World War I.

Among the educational institutions in the city are the Rensselaer Polytechnic institute, founded in 1824 by Stephen van Rensselaer of Albany, one of the oldest institutions in any English-speaking city continuously offering instruction and research in science and engineering; and Russell Sage college, a private liberal arts college for women, established in 1916 Emma Willard, famous feminist and leader in educational opportunities for women, founded Troy Female seminary in 1821, later known as the Emma Willard school, which still provides college preparatory training for girls.

The population in 1960 was 67,492. For comparative population figures *see* table in NEW YORK: *Population.* (P. F. W.)

TROY, a city of western Ohio, U.S., about 20 mi. N. of Dayton on the Great Miami river; the seat of Miami county. Settled about 1807. Troy was incorporated in 1818 and chartered as a city in 1890. From its earliest days Troy was a river port for the loading of farm products on flatboats for delivery to Cincinnati and beyond. With the completion of the Miami and Erie canal (1845; destroyed by flood in 1913) the town began to develop industrially. Manufactures include welding and food preparation machinery, electric motors and generators, aircraft parts and paper products. For comparative population figures *see* table in OHIO: *Population.*

TROY and **TROAD.** The Troad (*ἡ τρῳάς*), or land of Troy, is the north-west promontory of Asia Minor, between the valleys of the Caicus on the south and the Aesepus flowing into Propontis on the east. The eastern limit was variously defined by ancient writers. Geographically, it is undoubtedly (as Strabo says) the range of Ida, which, from the north shore of the Adramyttian gulf, sends its north-western spurs nearly to the coast of the Propontis. The greatest length of the Troad from north-west at Cape Sigeum (Yeni Shehr), to the south-west at Cape Lectum (Babā Kale), is about 40 m.; the breadth, not much greater. The central area is drained by the Menderes (anc. *Scamander*), which rises in Ida and reaches the Hellespont east of Cape Sigeum.

Timber is supplied by pine forests on Mt. Ida. But the plains and hills are fairly wooded. Besides valonia oak, there are elm, willow, cypress and tamarisk, with lotus, galingale and reeds, as in Homeric days, about the streams. The vine is cultivated; watermelons are abundant; cotton, wheat and maize are grown. Even under Turkish rule, the natural advantages of the land mitigated the poverty of its inhabitants; in antiquity it was fertile and populous.

Early History.—In Greek legend, Priam of Troy ruled all that is bounded by "Lesbos, Phrygia and the Hellespont" (*Il.* xxiv. 544). The Achaeans under Agamemnon destroyed Troy, and overthrew Priam's dynasty. But there is Homeric prophecy that Aeneas and his descendants shall still rule over the Troes, in a passage probably later than the bulk of the book, and it is certain that in the 7th or 6th century B.C. reputed descendants reigned somewhere in the Troad. Thracian tribes, including Bithynians and Treres, swept into Asia Minor from Europe in the 7th century *B.C.*, and the Ionian poet, Callinus, recorded the terror which they caused.

Greek Settlements.—The earliest and most important of the Greek settlements were Aeolic, mainly from Lesbos and Cyme in Aeolis; some may have been as early as the 13th century B.C. About 620 B.C. Athenians occupied Sigeum, and were resisted by Aeolic colonists from Mytilene, already established in that neighbourhood.

Chief Greek towns in the Troad were Ilium in the north, Assus (*q.v.*) in the south, and Alexandria Troas (*q.v.*) in the west. The site of the Greek Ilium is marked by the low mound of Hissarlik (Turk. "place of fortresses") in the Trojan plain, about 3 m. from the Hellespont, the traditional site of Homer's "Troy." When Xerxes visited the Trojan plain, he "went up to the Pergamon of Priam," and sacrificed to the Ilian Athena. Ilium yielded to Dercyllidas in 399 B.C., and was captured by Charidemus in 359 B.C., but was evidently still of small importance when, in 334 B.C., Alexander visited it on landing in the Troad. In their temple of Athena the Ilians showed him arms which had served in the Trojan war, including the shield of Achilles. Either then or after the battle of Granicus, Alexander enlarged the town to be a "city," with political independence and exemption from tribute. Lysimachus executed the intentions of Alexander when north-west Asia Minor fell to him in 301 B.C., building a wall 5 m. in circumference, incorporating decayed towns of the neighbourhood, and building a temple of Athena. In the 3rd century B.C. Ilium was the head of a federal league of free Greek towns, from Lampsacus on the Hellespont to Gargara on the Adramyttian gulf. In 278 B.C. the Gauls, under Lutarius, occupied Ilium, but abandoned it. Forty years later (218 B.C.) other Gauls brought by Attalus I. for his war against Achaeus, deserted his standard. pillaged the towns on the Hellespont, and besieged Ilium, from which, however, they were driven off by the troops of Alexandria Troas. In the 2nd century B.C. Ilium was in decay; as Demetrius of Scepsis says, the houses "had not even roofs of tiles." The temple of Ilian Athena, however, retained its prestige; in 192 B.C. Antiochus the Great visited it before sailing to the aid of the Aetolians. In 190 B.C., before the battle of Magnesia, Romans and Ilians were alike eager to recall the legend of Roman descent from Aeneas; Lucius Scipio offered sacrifice to the Ilian Athena; and after the defeat of Antiochus the Romans annexed Rhoeteum and Gergis to Ilium, "not so much in reward of recent services, as in memory of the source from which their nation sprang." The later history of Ilium is a catalogue of Roman benefactions, though, in 85 B.C., when Fimbria took it, he left it in ruins; Sulla, however, was careful to rebuild it; Augustus confirmed its ancient privileges and gave it new territory; Caracalla (A.D. 211–217), like Alexander, paid honours to the tomb of Achilles. In the 4th century, the Ilians were attracting tourists by their pseudo-Trojan memorials. After the 4th century the place is lost to view.

Of the other ancient cities, *Neandria* seems to be rightly fixed at Mt. Chigri, not far from Alexandria Troas, remarkable for its fine view of the whole Troad. *Cebrene* has been located in the eastern part of the plain of Bairamich; *Palaeoscepsis,* farther east, on Ida, while the new *Scepsis* was near Bairamich. At Kulakli, south of the mouth of the Tuzla, Corinthian columns mark the temple of Apollo Smintheus (excavated in 1866 by Pullan) and (approximately) the Homeric *Chryse. Colonae* was on the coast opposite Tenedos. *Scamandria* was at Eneh, in the plain of Bairamich, and *Cenchreae* probably some way north of it. The shrine of Palamedes, *Polymedium,* has been discovered by J. T. Clarke between Assus and Cape Lectum; the sacred enclosure and the statue of Palamedes were on the acropolis. Clarke also found very ancient walls on Gargarus, the highest peak of Ida.

The Site of Troy.—The traditional site, at the Hellenistic Ilium, is the mound of Hissarlik, on a spur between the main Scamander valley and its last tributary from the east (anc. *Simois),* about $3\frac{1}{2}$ m. from the Hellespont and from the Aegean shore, north of Besika bay. The famous academic dispute concerning the site, which began about A.D. 160 with Demetrius of Scepsis, may be regarded as settled by the discovery, made in 1893, of a fortress on the mound of Hissarlik, contemporary with the great period of Mycenae, and overlying the smaller and the earlier acropolis first identified by Schliemann in 1872. The rival ruins of a small hill fort on the Bali Dagh which, with another on an opposite crag, commanded the gorge where the Scamander descends into the plain neither accord with Homeric description nor challenge the remains at Hissarlik in importance.

No site in the Troad accords completely with all the topographical clues ingeniously derived from the text of Homer. The hot and cold springs that lay just without the gate of "Troy" are no more to be identified with Bunarbashi, which wells out more than a mile from the Bali Dagh ruins, than with the choked conduits south of Hissarlik, opened by Schliemann in 1882. But the broader topography is recognizable in the modern plain of the Menderes. The old bed of that river is the Scamander, and its little tributary, the Dumbrek Su, is the Simois. In their fork lies Hissarlik or Troy. In sight of it are, on the one side, the peak of Samothrace (Il. xiii. 11–14); on the other Mt. Ida (Kaz Dagh; viii. 52). Hissarlik lies in the plain (xx. 216), easily reached by foes from the shore, or left and regained in a night by a Trojan visiting the Achaean camp (vii. 381–421).

Archaeological Investigation of Troy.—Schliemann's excavations at Hissarlik in 1872–74, supplemented and confirmed by W. Dörpfeld in 1891–94, established the existence of nine superposed settlements, as follows:—

1. On the virgin soil of the natural hillock a small village of the late Aegean Neolithic period, at the dawn of the Bronze age, contemporary with the upper part of the Cnossian Neolithic bed, includes what were supposed by Schliemann to be two primitive settlements. Thin walls of rough stones, bonded with

mud, reveal no house-plans, nor traces of fortress wall. Implements in obsidian and various kinds of stone, clay whorls, a little worked ivory, accompany dark monochrome pottery, hand-polished, with simple geometric decoration, incised and often filled with white.

2. Superposed and comprehending a larger area, lies the "second city," better constructed and preserved, and twice rebuilt. Its massive fortress wall of rudely squared "Cyclopean" masonry suffered several restorations and eventual destruction, except on the south. Double gates at south-east and south-west are well-preserved. The most complete and most important structures within are a *megaron* and vestibule of the type familiar in "Mycenaean" palaces, with one or more smaller replicas alongside it, like the "women's quarters" at Tiryns (q v.) and Phylakopi. *(See* AEGEAN CIVILIZATION.) This is the fortress proclaimed by Schliemann in 1873 to be the "Pergamos" of Troy, mainly because it perished by fire. But this second stratum belongs to a primitive stage of local civilization preceding the "Mycenaean," which is the earliest recalled by the Homeric poems. The pottery now shows the first rare use of paint, and of technique and fantastic forms parallel to those of the pre-Mycenaean Cyclades. Trough-spouted vases are characteristic, and rude reproductions of human features are common in this ware, which seems all native. Bronze had come into use for implements, weapons and vessels; a hoarded treasure found in the ruins of the fortification wall includes much gold and silver. But the forms are primitive and the workmanship very rude. Personal ornaments are cut out of thin plate gold or built of coiled wire. But some of the discs, bracelets and pendants, with advanced spiral ornament, found in 1878 and ascribed to this stratum, belong undoubtedly to the sixth or "Mycenaean." Rough fiddle-shaped idols, whorls, a little worked ivory and some lead make up a find, of whose early period (probably about 2000 B.C.) comparison of objects found elsewhere leaves no doubt. This treasure is now deposited in Berlin with the bulk of Schliemann's collection.

3, 4, 5. After the burning of the "second city," Hissarlik ceased for a time to have any considerable population. Three small village settlements have left their traces superposed and show only slight advances of material culture.

6. The mound, however, occupied too important a site, in relation to the plain and the sea, to remain desolate, and it was occupied in the 14th or 13th century by a great fortress, while a city not yet explored, spread below. This "sixth city" was first distinguished clearly by Dorpfeld in 1882, but Schliemann's drastic methods confused its commoner pottery and metal objects with those of lower strata; and some grey ware, to which Schliemann gave the name "Lydian" was alone referred to this sixth or "Lydian" city, in his *Troja* (1884). This ware has been compared with the "Minyan" fabric at Orchomenus, but also resembles the "Lausitz" pottery, which originated on the middle Danube, and was intruded into Macedonia at the close of the 12th century. For years this "sixth city" was neglected.

In 1893, however, excavations in hitherto undisturbed ground outside the earlier fortress, exposed a wall of massive ashlar masonry resembling the fortifications of Mycenae itself, and "Mycenaean" walls at Phylakopi in Melos. With this wall occurred not only the grey ware, but painted potsherds unmistakably "Mycenaean"; and further search showed that such sherds were characteristic of "sixth city" deposits. The inevitable inference is that this city imported contemporary "Mycenaean" ware to supplement its own ruder products. The area of its citadel is larger than the "second city," its buildings, which include a large *megaron*, are of finer construction. This was the most important city yet built on the mound. It belonged to the "Mycenaean" age, which precedes the composition of the Homeric poems, and is reflected by them. Therefore this is Homer's Troy.

Its remains, however, having been obliterated on the crown of Hissarlik, almost escaped recognition, for when, long afterwards, the Hellenistic Ilium was built, the top of the mound was cut away and the uppermost strata vanished, Thus we find them now on the southern slope of the mound only, but have no difficulty in estimating their original extent. Tombs and the outer quarters of this city will doubtless be found eventually.

7. The "sixth," or "Mycenaean" Troy, perished by violence like the "second city," but its inhabitants reoccupied its ruins, until, in early Hellenic times, the small unfortified settlement was established which maintained itself till the Homeric enthusiasm of Alexander the Great called a city again into being on Hissarlik.

8. The Hellenistic Ilium, however, has left comparatively little trace; fortifications erected by Lysimachus are visible on the acropolis and in the plain. A small Doric temple belongs to this city, and a larger one, probably dedicated to Athena, seems to be of Pergamene age. Fragments remain of its metopes, representing Helios and a Gigantomachia. Coins of this city show Athena on both faces, and inscriptions prove that Hellenistic Ilium was of some importance.

9. Lastly, about the Christian era, the Graeco-Roman city built a theatre and an ornate gateway on the south-east slope, a large building on the south-west and others to north-east. This city seems to have decayed in the 5th century A.D.

The Legend of Troy.—In Greek legend, the oldest town in the Troad was that founded by Teucer, who was a son of the Scamander (a Cretan stream, according to Tzetzes) and the nymph Idaea. In his reign, Dardanus, son of Zeus and the nymph Electra, daughter of Atlas, in consequence of a deluge, drifted from Samothrace to the Troad, where he received land from Teucer, married his daughter Batea, and founded Dardania, at the foot of Mt. Ida. On the death of Teucer, Dardanus succeeded him, and called the whole land Dardania. He begat Erichthonius, who begat Tros by Astyoche, daughter of Simois. Tros called the country Troy and the people Troes (Trojans). By Callirrhoe, daughter of Scamander, Tros had three sons—Ilus, Assaracus and Ganymede. From Ilus and Assaracus sprang two separate lines; Ilus, Laomedon, Priam, Hector; and Assaracus, Capys, Anchises, Aeneas. Ilus went to Phrygia, where he received, as a wrestling prize from the king of Phrygia, a spotted cow, with an injunction to found a city where she lay down. The cow lay down on the hill of the Phrygian Atē; here Ilus founded Ilion; and Dardania, Troy and Ilion became one city. Desiring a sign from Zeus, Ilus prayed and found lying before his tent the Palladium, a wooden statue of Pallas, for which he built a temple. By Eurydice, daughter of Adrastus, he had a son, Laomedon, who married Strymo, daughter of Scamander (or Placia, daughter of Atreus or of Leucippus). In his reign, Poseidon and Apollo (or Poseidon alone), built the walls of Troy, but Laomedon withheld their reward. In his reign also, Heracles besieged and took the city, slaying Laomedon and his children, except one daughter, Hesione, and one son, Podarces. The life of Podarces was granted at the request of Hesione, on condition that Podarces first be a slave and then be redeemed by Hesione; she gave her veil for him; hence his name of Priam (Gr. πριάσθαι, to buy). Priam married first Arisbe and afterwards Hecuba, and had 50 sons and 12 daughters. Among the sons were Hector and Paris, and among the daughters Polyxena and Cassandra. Paris, betrothed to Oenone, awarded the golden "apple of strife" to Aphrodite (who promised him the love of the fairest of women) and brought upon Troy the resentment of Hera and Athena. Thereafter, Paris, visiting Sparta, found favour with Helen, heiress of

Tyndareus and wife of Menelaus, son of Atreus, and carried her to Troy. To recover Helen, the Achaeans under Agamemnon, brother of Menelaus, besieged Troy for ten years. In the tenth pear Hector was killed by Achilles, and he by Paris. At last a wooden horse was contrived in whose hollow many Achaean heroes hid themselves. Their army and fleet then withdrew to Tenedos, feigning to have raised the siege. The Trojans conveyed the wooden horse into Troy; in the night the Greeks stole out, opened the gates to their friends, and Troy was taken. See also HOMERIC POEMS.

See Homer, *Il.* vii. 452 seq, xx. 215 *seq.,* xxi. *446 seq.;* Apollodorus ii. 6, 4, iii. 12; Diodorus iv. 75, v. 48; Tzetzes, *Schol. on Lycophron, 29,* 72, 1302; Conon, Narrat. 21; Dionysius Halicarn., *Antiq. Rom.* i. *68 seq.* The *Iliad* deals with a period of 51 days in the tenth year of the war: the *Odyssey* with the wanderings and homecoming of an Achaean leader, Odysseus. For the wooden horse *see* Homer, *Od.* iv. 271 *seq.;* Virgil, *Aen.* ii. **13** *seq.*

The Historical Background of the Trojan War.—The "Tale of Troy," with legends of heroes who "fought in the war," was popular when the Odyssey (see HOMER) was composed; wherein minstrels sing lays about it, and the Sirens boast that they "know it all." From the 7th century B.c., at least. it supplied subjects to vase painters and other craftsmen, and in the 5th, to the sculptors of the Aegina pediments (see GREEK ART), and to Athenian dramatists. (See DRAMA: Greek) Herodotus and Thucydides, like ancient writers generally, accepted the Trojan war as historical, though they criticized epic statements in detail, and Herodotus noted discrepancy between the *Cypria* and the *Iliad.* Ephorus, and afterwards Strabo, marshalled geographical learning as commentary on the Achaean and Trojan "catalogues" in *Il.* ii.; the scholars of Alexandria elucidated Homeric antiquities. those of Pergamum their topographical and historical background; Demetrius of Scepsis in the Troad, misdouhted. on geological grounds, the reputed site of Troy. Traditional genealogies, collated by Hecataeus (see HECATAEUS OF MILETUS) and others, enabled Eratosthenes (*q.v.*) to date the "Fall of Troy" to 1194 B.C., in the third generation before the "coming of the Dorians" and in the second after Laomedon's foundation. Homeric references to Egypt (where Thebes, not Memphis, is the capital) and to Phoenicia (where Sidon is known, but not Tyre) supply a historical background for the war. not later than the 12th century; but the names of Egyptian kings (*Thôs, Thuôris*) in epic and classical tradition, are not identified: Pliny (36.64) alludes to a Rameses "in whose time Troy fell." Egyptian references, however, to repeated sea-raids into the Levant. between 1230 and 1190 B.C., depict a situation closely resembling Homeric descriptions; and the *Aquaiusha* (*Akhaywasha*), *Danauna, Tikkara* (*Tzakarai*) and probably other participants in these raids may be safely recognized as Achaeans, Danaans, and Teucrians in Greek tradition. Hittite documents confirm the existence of an oversea régime called Akkhayawa, aggressive against south-west Asia Minor, one of whose leaders, Attarissyas, active in Caria and north Syria about 1230, was a contemporary, if not namesake. of Atreus, father of Agamemnon. Consequently, 19th century doubts as to the historical content of epic tradition, and attempts to discover "solar" and other mythological allegories in the personages and events of the war, are being superseded by recognition of a social and political régime historically assignable to the 13–12th centuries, of which the following are turning-points: (1) The establishment of the Trojans, with other Thraco-Phrygian peoples, in north-west Asia Minor before 1260 B C. fully justifying the defensive alliance between the Hittite king and Rameses II. in 1271 B.C. (2) The consolidation of a dominion, of which the "sixth city" at Hissarlik was an important centre; the geographical range of Priam's vassals, from the Axius river to the Xanthus, and the memory of a great fight "on the Sangarius river" far inland, are instructive. (3) The overthrow of Hittite dominion by this new régime, about 1200 B C., followed by the land-and-sea-raids of 1197–94 as far as south Palestine, where they were stopped by Rameses III. (4) The counterparts, west of the Aegean, of the dynasty Laomedon-Priam-Hector, are the "divine born" kingships (Pelops-Atreus-Agamemnon, Aeacus-Peleus-Achilles. and the like) established by adventurers of unknown antecedents, and foreign names, from Ithaca and Aetolia to Crete and Rhodes, and as far north as Thessaly; their distribution closely covering that of the "Late Mycenaean" settlements, which are surely dated archaeologically to these generations, in Egypt, Cyprus and Palestine. (5) Whether the destruction of the "sixth city" resulted from an attack of this "Achaean" confederacy of the south-west Aegean on the Hellespontine citadel of its Thraco-Phrygian cousins, or directly from those Danubian representatives of the "Lausitz" culture which characterizes the "seventh city," and is recognizable as a disturbing factor in Macedonia also, later in the 12th century, cannot at present be determined, nor the value of the synchronism between the attack on Troy and the great sea-and-land-raids towards Egypt, of which the tale of Tithonus and Memnon may preserve echoes. (6) Traditions of the establishment of settlements, eventually Greek, round the margins of the Late Mycenaean world, are so numerous, and coherent both with Homeric and with archaeological evidence, that they may be accepted as an essentially historical counterpart of the situation described in the Odyssey; which, however, was transformed as profoundly by the "coming of the Dorians" as the Mycenaean world had been by the irruption of the "divine born" adventurers five generations before. Between those two crises lies the "Heroic Age" of the Aegean; of its central episodes one is the struggle between Argos and Thebes, ended by the tragic fall of the Cadmeian dynasty; the other is the Trojan war, as disastrous to the victors as to the conquered. (J. L. MY.)

The Mediaeval Legend of Troy.—The mediaeval *Roman* de Troie, exercised greater influence in its day and for centuries after its appearance than any other work of the same class. Just as the chansons de geste of the 10th century were the direct ancestors of the prose romances which afterwards spread throughout Europe, so, even before Heliodorus and Achilles Tatius, there were quasi-histories, which reproduced in prose, with more or less exactness, the narratives of epic poetry. The Ἡρωικός of Flavius Philostratus (*fl.* 3rd century A.D.) is a discourse on 26 heroes of the war. A fictitious journal (Ephemeris), professing to give the chief incidents of the siege, and said to have been written by Dictys of Crete, a follower of Idomeneus, is mentioned by Suidas, and was largely used by John Malalas and other Byzantine chroniclers. This was abridged in Latin prose, probably in the 4th century, under the title of *Dictys Cretensis de bello Trojano libri* VI. It is prefaced by an introductory letter from a certain L. Septimius to Q. Aradius Rufinus, in which it is stated that the diary of Dictys had been found in his tomb at Knossos in Crete, written in the Greek language, but in Phoenician characters. The narrative begins with the rape of Helen, and includes the adventures of the Greek princes on the return voyage. With Dictys is always associated Dares, a pseudo-historian of more recent date. Old Greek writers mention an account of the destruction of the city earlier than the Homeric poems, and in the time of Aelian (and century A.D.) this *Iliad* of Dares, priest of Hephaestus at Troy, was believed to be still in existence. Nothing has since been heard of it; but an unknown Latin writer, living between 400 and 600, took advantage of the tradition to compile *Daretis* Phrygii de *excidio* Trojae historia, which begins with the voyage of the Argo. It is in prose and professes to be translated from an old Greek manuscript. Of the two works that of Dares is the later, and is inferior to Dictys. The matter-of-fact form of narration recalls the poem of Quintus Smyrnaeus. In both compilations the gods and everything supernatural are suppressed; even the heroes are degraded. The permanent success, however, of the two works distinguishes them among apocryphal writings, and through them the Troy legend was diffused throughout western Europe. The Byzantine writers, from the 7th to the 12th century, exalted Dictps as a first-class authority, with whom Homer was only to be contrasted as an inventor of fables. Western people preferred Dares, because his history was shorter, and because, favouring the Trojans, he flattered the vanity of those who believed that people to have been their ancestors. Many mss. of both writers were contained in old libraries; and they were translated into nearly every language and turned into verse.

In the case of both works, scholars were long undecided whether a Greek original ever existed but fragments of the Greek text of Dictys have been recovered. (*See* DICTYS CRETENSIS.) The Byzantine grammarian, Joannes Tzetzes (*fl.* 12th century), wrote a Greek hexameter poem *Iliaca* on the subject. In 1272, a monk of Corbie translated "sans rime *L'Estoire de Troiens et de Troie* (de Dares) du Latin en Roumans mot à mot" because the *Roman de Troie* was too long. Geoffrey of Waterford put Dares into French prose; and the British Museum has three Welsh mss. translations of the same author, of a much later period.

For a thousand years the myth of descent from the dispersed heroes of the conquered Trojan race was a sacred literary tradition throughout western Europe. The first Franco-Latin chroniclers traced their history to the same origin as that of Rome, as told by the Latin poets of the Augustan era; and in the middle of the 7th century Fredegarius Scholasticus (*Rcr. gall. script.* ii. 461) relates how one party of the Trojans settled between the Rhine, the Danube and the sea. In a charter of Dagobert occurs the statement, "ex nobilissimo et antiquo Trojanorum reliquiarum sanguine nati." This statement is repeated by chroniclers and panegyrical writers, who also considered the *History of Troy* by Dares to be the first of national books. Succeeding kings imitated their predecessors in giving official sanction to their legendary origin; Charles the Bald, in a charter, uses almost the same words as Dagobert, "ex praeclaro et antiquo trojanorum sanguine nati." In England a similar tradition had been early formulated, as appears from Nennius's *Historia Britonum* and Geoffrey of Monmouth. The epic founder of Britain was Brutus, son, or in another tradition, great-grandson, of Aeneas, in any case of the royal house of Troy. The tradition, repeated in Wace's version of Geoffrey, by Matthew Paris and others, persisted to the time of Shakespeare. Brutus found Albion uninhabited except by a few giants. He founded his capital on the banks of the Thames, and called it New Troy. Otto Frisingensis (12th century) and other German chroniclers repent similar myths. About 1050 a monk named Bernard wrote De *excidio Trojae,* and in the middle of the 12th century Simon Chèvre d'Or, canon of the abbey of Saint-Victor, Paris, followed with another poem in leonine elegiacs on the fall of the city and the adventures of Aeneas, in which the Homeric and Virgilian records were blended.

About the year 1184 Benoît de Sainte-More (*q.v.*) composed a poem of 30.000 lines entitled *Roman de Troie* He derived his information chiefly from the pseudo-annals of Dictys and Dares, but we may justly consider the *Roman de Troie* as an original work. From this source subsequent writers drew their notions of Troy, mostly without naming their authority and generally without even knowing his name. This is the masterpiece of the pseudo-classical cycle of romances: and in the Latin version of Guido delle Colonne it passed through every country of Europe.

The *De bello trojano* of Joseph of Exeter, in six books, a genuine poem of no little merit. was written soon after Benoît's work or about the years 1187–88. At first ascribed to Dares Phrygius and Cornelius Nepos, it was not published as Joseph's until 1620, at Frankfurt. It was directly drawn from the pseudo-annalists, but the influence of Benoît was considerable Of the same kind was the *Troilus* of Albert of Stade (1249), a version of Dares, in verse, characterized by the old severity and affected realism. But these Latin works can only be associated indirectly with Benoît, who had closer imitators in Germany at an early period. Herbort of Fritzlar reproduced the French text in his Lied *von Troye* (early 13th century), as did also Konrad von Würzburg (d. 1287) in his *Buch von Troye* of 40,000 verses, which he himself compared to the "boundless ocean." It was completed by an anonymous poet. To the like source may be traced a poem of 30,000 verses on the same subject by Wolfram von Eschenbach; and Jacques van Maerlant reproduced Benoît's narrative in Flemish. The Norse or Icelandic *Trojumanna saga* repeats the tale with some variations

In Italy, Guido delle Colonne, a Sicilian, began in 1270 and finished in 1287 a prose *Historza trojana,* in which he reproduced the *Roman de Troie* of Benoît, and so closely as to copy the errors of the latter. The vivacity and poetry of the Anglo-Norman trouvère disappear in a dry version. The immense popularity of Guido's work is shown by the large number of existing manuscripts. In the 14th and the commencement of the 15th century four versions appeared in England and Scotland. The best known is the *Troy Book*, written between 1414 and 1420, of John Lydgate, who had both French and Latin texts before him. An earlier and anonymous rendering exists at Oxford (Bodleian ms. Laud Misc. 595). There is the *Gest Hystoriale of the Destruction of Troy* (Early Eng. Text Soc., 1869–1874), written in a northern dialect about 1390; a Scottish version (1jth century) by a certain Barbour, not the poet, John Barbour; and *The Seege of Troy,* a version of Dares (Harl. ms. 525 Brit. Mus.). The invention of printing gave fresh impetus to the spread of Guido's work. The first book printed in English was *The Recuyell of the Hystoryes of Troye,* a translation by Caxton from the French of Raoul Lefèvre.

BIBLIOGRAPHY.—The Troy legend is dealt with in the elaborate work of A. Joly, *Benoît de Sainte-More et le Roman de Troie* (1870–71); G. Korting, *Der altfranz. Roman de Troie* (1883); F. Settegast, *Benoît de Ste-More* (Breslau, 1876); G. C. Frommann, *Herbort v Fritzlar u. Benoît de Ste-More* (Stuttgart, 1837); R. Jäckel, *Dares Phrygius u. Benoît de Ste-More* (Breslau, 1875); Le *Roman de Troie,* ed. L. Constans (Soc. d. anc. textes fr. Paris, 1904).

TROYES, a town of France, capital of the department of Aube, 104 mi. E.S.E. of Paris on the Eastern railway to Belfort. Pop. (1946) 58,805. The town stands in the wide alluvial plain watered by the Seine, the main stream of which skirts it on the east. It is traversed by several small arms of the river, and the Canal de la Haute-Seine divides it into an upper town, on the left bank, and a lower town, on the right bank. The churches of the town are numerous, and especially rich in stained glass of the Renaissance period. St. Pierre, the cathedral, 13th to 16th centuries, consists of an apse with seven apse chapels, a choir with double aisles, on the right of which are the treasury and sacristy, a transept without aisles, a nave with double aisles and side chapels and a vestibule. There are stained glass windows of the 15th and 16th centuries. The treasury contains some fine enamel work and lace. The church of St. Urban has windows dating for the most part from the years 1265–80. Most of the old houses of Troyes are of wood, but some are of stone of the 16th century, notably the hôtels de Vauluisant. de Mauroy and de Marisy. The prefecture occupies the buildings of the old abbey of Notre-Dame-aux-Nonnains; the *hôtel de ville* dates from the 17th century.

Troyes is the seat of a bishop and a court of assize. Its public institutions include a tribunal of first instance. a tribunal of commerce, a board of trade arbitrators and a chamber of commerce. It has a school of hosiery. The dominant industries in Troyes are the manufacture of cotton, woollen and silk hosiery, printing and dyeing of fabrics.

History.—At the beginning of the Roman period Troyes was the principal settlement of the Trecassi, from whom it derives its name. In the first half of the 4th century its bishopric was created as a suffragan of Sens St Loup, the most illustrious bishop of Troyes, occupied the episcopal seat from 426 to 479. In the early middle ages the bishops were supreme in Troyes, but in the 10th century this supremacy was transferred to the counts of Troyes (*see* below), who from the 11th century were known as the counts of Champagne. Under their rule the city attained great prosperity. Its fairs, which had already made it a prominent commercial centre, flourished under their patronage, while the canals constructed at their expense aided its industrial development. The union of Champagne with the domains of the king of France in 1304 was disastrous to the city, since one of the first measures of Louis le Hutin was to forbid the Flemish merchants to attend its fairs. For a short time (1419–25), during the Hundred Years' War, the town was the seat of the royal Government, and in 1420 the signing of the Treaty of Troyes was followed by the marriage of Henry V. of England with Catherine, daughter of Charles VI. in the church of St. Jean. In 1429 the town capitulated to Joan of Arc. The next 100 years was a period of prosperity, marred by the destruction of half the town by the fire of 1524. In the 16th century Protestantism made some progress in Troyes, but in 1562, after a short occupation, the Calvinist troops were forced to retire, and in 1572 fifty Protestants were put to death. The revocation of the Edict of Nantes in 1685 was a severe blow to the commerce of Troyes, which was not revived by the re-establishment of the former fairs in 1697. The population fell from 40,000 to 24,000 between the beginning of the 16th century and that of the 19th century.

See T. Boutiot, *Histoire de Troyes et de la Champagne méridionale* (4 vols. Troyes, 1870–80); R. Koechlin and J. J. Marquet de Vasselot, *La Sculpture à Troyes et dans la Champagne méridionale au seizième sitcle* (1900).

TROYON, CONSTANT (1810–1865), French painter of the Barbizon school, an animal painter of the first rank, was born on Aug. 28, 1810, at Sèvres, near Paris, where his father was connected with the porcelain factory. Until he was 20 he laboured at porcelain ornamentation, but by the time he reached 21 he was traveling the country as an artist, painting landscapes. Troyon was a pupil of Camille Roqueplan, who introduced him to Théodore Rousseau, Jules Dupré and the other Barbizon painters. In 1847 Troyon went to The Hague, where he saw Paul Potter's famous "Young Bull." From the studies he made of this picture, of Albert Cuyp's sunny landscapes and of Rembrandt's masterpieces he evolved a new method of painting, and it is only in works produced after this time that Troyon's true individuality is revealed. He died at Paris on Feb. 21, 1865.

All Troyon's famous pictures are dated between 1850 and 1864. In the Wallace gallery in London are "Watering Cattle" and "Cattle in Stormy Weather"; the Louvre contains his famous "Oxen Going to Their Work" and "Returning to the Farm"; "Cattle" may be seen in the Isabella Stewart Gardner museum, Boston, Mass., "Drinking Place" in the Corcoran Gallery of Art. Washington. D.C., and "Return From Market" in the Art Institute of Chicago, Ill. Other examples are found in many public collections in the United States and Europe.

TRUCE OF GOD, an attempt of the Church in the middle ages to alleviate the evils of private warfare. The two measures which were adopted by the Church to remedy this evil—the *pax ecclesiae* or *Dei* and the *treuga* or *treva* Dei—are usually both referred to as the Truce of God, but they are distinct in character. The latter was a development of the former.

The *pax ecclesiae* is first heard of in the year ggo at three synods held in different parts of southern and central France—at Charroux, Narbonne and Puy. It enlisted the immediate support of the regular clergy, particularly the vigorous congregation of Cluny, and of William V. of Aquitaine, the most powerful lord of southem France, who urged its adoption at the councils of Limoges (994) and Poitiers (999). The peace decrees of these various synods differed considerably in detail, but in general they forbade, under pain of excommunication, every act of private warfare or violence against ecclesiastical buildings and their environs, and against certain persons, such as clerics, pilgrims, merchants, women and peasants, and against cattle and agricultural implements. With the opening of the 11th century, the *pax ecclesiae* spread over northern France and Burgundy, and diocesan leagues began to be organized for its maintenance. The bishop, or count, on whose lands the peace was violated was vested with judicial power, and was directed, in case he was himself unable to execute sentence, to summon to his assistance the laymen and even the clerics of the diocese, all of whom were required to take a solemn oath to observe and enforce the peace. At the council of Bourges (1038), the archbishop decreed that every Christian 15 years and over should take such an oath and enter the diocesan militia. The idea that peace is a divine institution seems to have given rise to a new name for the peace, the *pax Dei,* or peace of God.

The *treuga* or *treva Dei,* the prohibition of every act of private warfare during certain days, goes back at least to the Synod of Elne (1027) which suspended all warfare from Saturday night till prime on Monday. Like the *pax ecclesiae* it found ardent champions in the regular clergy, especially in Odilo (962–1049), the fifth abbot of Cluny, and soon spread over all France. It penetrated Piedmont and Lombardy in 1041 and Normandy in 1042. By this time the truce extended from the Wednesday evening to the Monday morning in every week and also, in most places, lasted during the seasons of Lent and Advent, the three great vigils and feasts of the Blessed Virgin, and those of the 12 apostles and a few other saints. The *treuga Dei* was decreed for Flanders at the Synod of Thérouanne (1063) and was instituted in southern Italy in 1089, probably through Norman influence. The bishop of Liége introduced it in Germany in 1082, and three years later a synod held at Mainz in the presence of the emperor Henry IV. extended it to the whole empire. It did not extend to England, where the strength of the monarchy made it unnecessary. The popes took its direction into their own hands towards the end of the 11th century; and the first decree of the Council of Clermont (1095), at which Urban II. preached the first crusade, proclaimed a weekly truce for all Christendom, adding a guarantee of safety to all who might take refuge at a wayside cross or at the plough. The Truce of God was reaffirmed by many councils, such as that held at Reims by Calixtus II. in 1119, and the Lateran councils of 1123, 1139 and 1179. When the *treuga Dei* reached its most extended form, scarcely one-fourth of the year remained for fighting, and even then the older canons relating to the *pax ecclesiae* remained in force. The means employed for its enforcement remained practically the same: spiritual penalties, such as excommunication, special ecclesiastical tribunals, sworn leagues of peace, and assistance from the temporal power. The Council of Clermont prescribed that the oath of adherence to the truce be taken every three years by all men above the age of 12, whether noble, burgess, villein or serf. The results of these peace efforts were perhaps surprisingly mediocre, but it must be borne in mind that not only was the military organization of the dioceses always very imperfect, but Continental feudalism, so long as it retained political power, was inherently hostile to the principle and practice of private peace. The Truce of God was most powerful in the 12th century, but with the 13th its influence waned as the kings gradually gained control over the nobles and substituted the king's peace for that of the Church.

TRUCK SYSTEM. The payment of the wages of workmen in *kind,* or in any other way than the unconditional payment of money, a practice known as the "truck system." Sometimes the workman was paid with "portion of that which he has helped to produce," but the more usual form was to give the workman the whole or part of his wages in the shape of commodities suited to his needs. There was also a practice of paying in money, but with an express or tacit understanding that the workman should resort for such goods as he required to shops or stores kept by his employer. The truck system led in many cases to grave abuses and was made illegal in Great Britain by the Truck Acts, under which wages must be paid in current coin of the realm, without any stipulations as to the manner in which the same shall be expended. (See LABOUR LAW.)

TRUFFLE, an edible, subterranean type of fungus of the class Ascomycetes. *(See* FUNGI.) Truffles have been prized as a delicacy from classical times. Pliny thought that they were among the most wonderful of all things springing up as they do and living without a root. Caelius Apicius gave six recipes for cooking them.

The subterranean Ascomycetes are usually placed in two main groups, the Tuberales and the Plectascales, depending upon the possession of fruit bodies with or without an opening to the exterior during development. The suggestion is that these have arisen along parallel lines.

The best-known genus of the Tuberales is *Tuber,* which is mainly native to temperate regions. The different species range in size from a pea to an orange. A section of a young specimen shows a whitish homogeneous flesh that, as maturity is approached, becomes a rich dark colour showing a lighter "marbling." The spores of *Tuber* are large and from one to four may be seen in an ascus. These were the first ascospores to be observed; J. P. de Tournefort described them in 1710–11. Truffles flourish in open woodland on calcareous soil. They are saprophytes, usually associated with the roots of trees and are possibly mycorhizal fungi, *i.e.*, living symbiotically with roots of higher plants (*see* MYCORHIZA).

The most valued truffle in French cookery is the Périgord (T. *melanosporum*), which is said to have first gained favour toward the end of the 15th century. It is brown or black, rounded and covered with polygonal warts having a depression at their summit; the flesh (gleba) is first white, then brown or gray, and when mature becomes black with white veins having a brown margin. The odour is well marked and not unpleasant. The main French *truffières* (truffle grounds) are in Périgord and the *département* of Vaucluse, though truffles are gathered throughout a large part of France. The truffle industry is an important one and about one-third of the gatherings are exported. The French government undertook the reforesting of many large and barren areas, for many of the best truffle regions become productive by the planting of trees, particularly oaks. As the truffles often occur at the depth of a foot it is difficult to detect them unaided. Truffles, when occurring near the surface of the ground, crack it as they reach full size and experienced gatherers are thereby enabled to locate them. Further, many species of fly live on truffles and in the morning and evening columns of small yellow flies (*Helomiza lineata*, etc.) may be seen hovering over a colony. Occasionally man is sufficiently susceptible to the scent of truffles to locate them but truffle hunting is usually carried on with the aid of pigs and dogs.

Direct cultivation is difficult. Calcareous ground is dug over and acorns or seedlings planted. Soil from truffle areas is usually spread about and the ground is kept in condition by light plowing and harrowing. After three years clearings are made and the trees are pruned. If they are to appear, the plants do so only after five years or so; gathering begins then but it hardly pays until eight or ten years have passed. The yield is at its maximum from 5 to 25 years later. Tuber *melanosporum* has not been recorded for England.

The English truffle is T. *aestivum*, which is found principally in beech woods. It is bluish black, rounded and covered with coarse polygonal warts; the gleba is white when immature, then ochreous and finally brown with white, branched, labyrinthine markings. Truffles are so rare in North America that few people have collected them in any quantity. They are found most often in Oregon and California. (J. RM.; AR. H. S.)

TRUJILLO, a province in southern Dominican Republic (pop. [1960] 249,776; area 1,445 sq.mi.), is mostly mountainous, occupying a section of the Cordillera Central (to 3,265 ft.) in the northern part, and an outlying range in the southwestern part. It is a significant producer of rice, sugar, cacao and coffee. The province was established in 1934 when the coastal plain around Ciudad Trujillo (Santo Domingo) was set aside as the federal district of Santo Domingo. The capital, San Cristóbal (1960) 15,525, was founded in 1575. The name of the province was changed to San Cristóbal in 1961. (D. R. D.)

TRUJILLO, a city in the coastal desert of northern Peru and capital of the department of Libertad, is approximately 300 mi. N.N.W. of Lima, at an elevation of about 200 ft. above sea level. It is 8 mi. from its port, Salaverry, with which it is connected by rail. Pop. (1958 est.) 59,265. The climate is cool and dry with temperatures averaging between 63° F. in June and 74.3° F. in March. The coolness of the air, in spite of its tropical location, is due to the cold Peruvian current. The figure generally quoted for the average annual rainfall (1.2 in.) is misleading, for in most years there is no rain. Trujillo is the commercial and industrial centre of the department, and is one of the important cities of Peru. The irrigated lands around the city produce sugar cane and rice, sugar being exported in large quantity. Trujillo serves two important mining communities in the northern Andes: Quiruvilca (copper) and Milluachaqui (gold and silver). Transport facilities include railroads, the Inter-American highway, an all-weather highway to the highland mines, an airport and a seaport. It has a considerable industrial development and its products include foods (rice, noodles, chocolate, confectionery), beer, leather, cocaine, soap, wax, candles, textiles and machinery.

The city was founded in 1534 by Diego de Almagro, and is Peru's second oldest Spanish city (the oldest is Piura). During the colonial period it enjoyed little prosperity for most of the wealth was concentrated in Lima. In 1617 a wall was built around the city as a defense against the attacks of English pirates, and traces of this wall could still be seen in the second half of the 20th century. The city was partially destroyed by earthquakes in the 17th century and again in the 18th century. Its modern growth followed British investments in sugar-cane plantations during the latter part of the 19th century. Trujillo remains essentially a city of old churches and has a cathedral and also several colonial mansions. The University of La Libertad is there. Four miles west are the pre-Inca ruins of Chan Chan (*q.v.*). (P. E. J.)

TRUJILLO VALDEZ, a province in southern Dominican Republic. Pop. (1960) 106,736; area, 626 sq.mi. It is largely mountainous, being bounded on the north by the Cordillera Central and crossed in the central part by the Sierra de Ocoa (to 5,678 ft.). The southern coastal plain is semiarid. The province is a leading coffee producer and a significant producer of rice and peanuts. Trujillo Valdez was created in 1944 from parts of Trujillo and Azua provinces; it was renamed Peravia in 1961. The provincial capital is Bani (pop. [1960] 14,472). (D. R. D.)

TRUMAN, HARRY S. (1884–), 33rd president of the United States, was born May 8, 1884, in Lamar, Mo., the son of Martha Ellen and John Anderson Truman. Soon after his son's birth, John Truman moved to Independence, Mo., where he purchased a small farm. John Truman made a comfortable living for his family, and from his childhood Harry Truman was called on to perform his daily chores and to help on the farm. He was regarded as a bright student by his teachers and he was graduated from high school at the age of 17. Financial considerations kept him from college and nearsightedness from appointment to the U.S. military and naval academies. After finishing high school, he left the farm to go to Kansas City, Mo. Depressed after five years with the prospects of carving out a career for himself in the city, he returned to his father's farm.

The entrance of the United States into World War I in 1917, however, uprooted him from his tranquil life on the farm. Truman, who had joined the national guard while in Kansas City, was called up for service and he sailed for France with a commission as a first lieutenant with an artillery unit. Modest and shy, he made little impression on the members of his unit in the pre-combat phase of their training. But in action, he proved to be a cool and resourceful leader. He participated in the St. Mihiel and Meuse-Argonne operations in 1918 and showed great consideration for the members of his battery, an attribute which won him their affection and admiration. Truman's commanding officers also recognized his ability, and toward the end of the war he was promoted to the rank of captain.

After the Armistice and upon his return to the United States, Truman married, June 28, 1919, Bess Wallace, a childhood sweetheart. They had one daughter, Mary Margaret Truman. Unwilling to return to farming, Truman and an army comrade set up a haberdashery in Kansas City. This venture failed after the depression of 1921 and left Truman saddled with debts totalling about $20,000. He refused to file bankruptcy proceedings and insisted upon repaying his creditors penny for penny. It took him more than ten years to do this.

This was a dismal epoch in Truman's life. Searching about for a job, he looked up another comrade in arms, who introduced him to Thomas J. ("Tom") Pendergast, then entering his heyday as boss of the Democratic machine that ruled Kansas City, and later Missouri, politics with an iron hand. Pendergast, a shrewd assayer of the vote-getting potentialities of aspirants for public office, regarded Truman's Baptist, Masonic and American Legion connections and his war record as political assets. He appointed Truman to the post of overseer of highways for Jackson county. After serving one year in the highway department, Truman was picked by Pendergast to run for the post of county judge for Jackson county. He was elected and served in this post from 1922 to 1924. He was defeated when he ran for a second term in 1924, but came back in 1926 and was elected presiding judge, a post he held until he became senator. Truman was determined to measure up to his new title and although the state laws of Missouri did not require that a county judge should be a qualified lawyer, he studied law in a Kansas City night school from 1923 to 1925.

Despite his association with the Pendergast political machine, whose dishonesty and corrruption were recognized and part of the public record, Truman established a reputation for personal honesty that was never questioned.

Election as Senator. — In 1934 Truman ran for senator. Accounts differ as to how he was selected for this post. One version said he had asked Pendergast for a particular post that paid about $25,000 annually in fees. According to this story, the Missouri state boss demurred, protesting that Truman did not as yet have the qualifications for that lucrative position and offered him, instead, the candidacy for U.S. senator, an office which paid $10,000 annually. More credible is the story that Truman was urged by friends to file for the senatorship and that Pendergast, needing a respectable name on his own slate to defeat Sen. Bennett Champ Clark's candidate, agreed to support Truman.

Truman won in the primary by a plurality of about 40,000 votes. He later won the election. The machine support was extremely effective in both the primary and the final election.

In 1940, when Truman came up for re-election, his defeat was predicted by many. The Pendergast machine had collapsed. Two years before, in 1938, a grand jury convicted more than 250 persons, most of them "machine" stalwarts, who had been indicted on charges of vote fraud. Pendergast himself had been convicted of income tax evasion and was sentenced to serve a prison term. His machine was thoroughly discredited and it was believed that Truman's association with Pendergast would prove a handicap. However, Truman not only won the primary but also emerged victor in the regular election.

While his foes always made capital out of his affiliations with the Missouri machine, Truman had never tried to conceal the fact that it was with Pendergast's help that he got his political start. His views on the ethics of machine politics were frank and perhaps practical in a broad sense of the term. In an interview regarding this matter, he declared: "There was nothing wrong with my relations with the Pendergast machine. . . . Every Democratic politician including myself went to Tom Pendergast for support. . . ." After he was nominated for the vice-presidency, he steadfastly refused to heed the pleas of fellow Democrats who urged him to disown his political mentor, and he even attended Pendergast's funeral in Jan. 1945. His defenders stressed that his attitude on the necessity of machine support was perhaps no different from that of scores of other politicians. Republicans or Democrats, holding high and responsible public offices. An offshoot of Truman's view on the political machine was his belief in political patronage.

Truman's first term in the senate (1935–41) was not highlighted by any marked accomplishments. He served on Sen. Burton K. Wheeler's committee investigating railroads and made modest fame as an able investigator and cross-examiner.

Although Truman probably did not realize it at the time, his path to the White House was fixed at the start of his second senate term. As a result of letters from friends and his own investigations revealing waste and graft in many national defense projects, he introduced a resolution for creation of a senate committee to act as "watchdog" of the rearmament program. As is customary, he was named chairman because of having proposed the action.

The Truman committee did an excellent and impartial job. It exposed grafting contractors, revealed collusion between corporation agents and certain army officials, and urged more comprehensive planning for conduct of the war and for postwar reconstruction. It is estimated that the committee saved the government hundreds of millons of dollars. This investigation first made the hitherto obscure Missourian a national figure.

Vice-President and President. — As the Democratic convention assembled in 1944, the big city bosses — Edward J Flynn of New York city, Frank Hague of New Jersey, Edward J. Kelly of Chicago, Robert E. Hannegan of St. Louis — convinced Franklin D. Roosevelt that Henry A. Wallace's radical, pro-Russian sympathies would endanger the ticket in the south and in metropolitan areas. Roosevelt then wrote a letter to the convention, suggesting Truman or Justice William O. Douglas as possible vice-presidential nominees. The bosses preferred Truman, who was nominated on the second ballot.

When President Roosevelt died April 12, 1945, Truman was sworn in as chief executive, asking newspaper friends to "pray for me." He knew his limitations, especially since Roosevelt had not consulted him on major domestic or foreign problems since the election five months before. It is doubtful that any president entered the White House more unprepared than Truman. At the outset, however, he had only to preside over the final conquest of Germany and Japan, for the plan of victory had been fixed and put into effect before he took office. On April 25 axis defeat was so assured that he addressed the United Nations Conference on International Organization at San Francisco, Calif. He urged creation of a "strong and lasting" organization that would make "future peace not only possible but certain." On May 8 he announced the surrender of Germany. In July he authorized and later announced the virtual destruction of Hiroshima by the first atomic bomb. On Aug. 14 he announced Japan's capitulation.

Truman's own legislative program, which he called the Fair Deal and uhich proposed even more far-reaching domestic reforms than Roosevelt had sponsored, was first presented to congress on Sept. 6. 1945 It began the breakup of the artificial coalition which had backed Roosevelt through depression and war years and which had offered its support to Truman on the assumption that he would lean toward the conservative side. Conservative elements of both Republican and Democratic parties, the latter principally from the south, blocked enactment of Truman's domestic program, until he was eventually forced to abandon most of it. The pressure of foreign problems after 1947 (as during Roosevelt's third term) gave Truman good cause for subordinating controversial domestic issues.

Serious strikes in several heavy industries, hampering production of consumer goods, embarrassed the admittedly prolabour administration A politico-economic crisis occurred in Aug 1946, when a railroad brotherhood strike threatened to tie up national transportation. Truman asked congress for a law to draft into the armed services anyone refusing to work in industries taken over by the government. His request embittered certain labour leaders, even though congress refused to grant it.

Another significant labour event of 1946 was the government's injunction to prevent a coal strike. When John L. Lewis, head of the United Mine Workers of America, ignored the order, he and his union were assessed fines totalling more than $3,000,000 by a federal court.

The "Cold War"; Korea. — These domestic problems, however, dwindled into insignificance as Truman tried to tackle the Russian problem. In July 1945 he had met with British Prime Minister Winston Churchill and Premier Joseph Stalin of the U.S S R. at Potsdam, Ger., for a discussion of postwar problems. Prospects for mutual understanding seemed favourable at the time, but the amity did not last. As the U.S S.R. became increasingly recalcitrant and then openly hostile, Truman was forced to ask for the resignation of Henry A. Wallace as secretary of commerce On Sept. 12, 1946, Wallace had delivered a speech in New York city undermining Secretary of State James F. Byrnes's position vis-a-vis Russia at the Paris peace conference. Truman nominated W. Averell Harriman, former ambassador to Moscow, to replace Wallace. When Harold L. Ickes resigned as secretary of the interior in a dispute with the White House over oil tidelands, Truman replaced him with J. A. Krug. On the resignation of Byrnes, Truman named Gen. George C. Marshall secretary of state.

But the development which affected the Truman administration most markedly and premonitorily shifting emphasis from domestic to foreign problems, was the British government's official notice in Feb 1947 that it could no longer afford to supply military and economic aid to Greece and Turkey, key Mediterranean countries which the U.S.S.R. sought to bring into its orbit. In what became known as the Truman doctrine, the president announced that the U.S. would undertake this responsibility. This was the inauguration of an ever-widening program under which the U.S. took over the global burdens England had borne since the middle of the 18th century.

The foreign-aid program was soon expanded following an address delivered by Secretary of State Marshall at Harvard university in June 1947 in which he proposed vast U.S. financial aid to restore Europe's shattered economy. Although he included the U.S.S.R. and its satellites among the prospective beneficiaries of the Marshall plan (European Recovery program). Moscow chose to regard the offer as an "imperialistic" manoeuvre, and refused to join. Under the Marshall plan, the U.S. spent $12,000,000,000 for European recovery during 1948–51 alone.

Meanwhile a new problem had arisen in the far east, where Chinese nationalists under Chiang Kai-shek and Communists under Mao Tse-tung were warring for control. In 1946 Truman had sent General Marshall to China in an effort to negotiate an agreement between the t o factions. After more than a year of futile talks, Marshall reported no progress and recommended withdrawal of U.S. economic and military aid from the nationalists. This action, together with evidence that certain state department officials sympathized with the Communists in the belief that they were mere "agrarian reformers," led to Republican charges that the administration was responsible for the loss of China to the Reds.

Associated with this issue were charges by the house committee on un-American activities and by Sen. Joseph R. McCarthy of Wisconsin that the administration was "coddling Communists" within the government, especially in the state department. Truman angrily denounced these allegations as "a red herring." But when a federal court convicted Alger Hiss, a former state department official and Yalta conference adviser, of perjury for denying before a federal grand jury that he had relayed official documents to a Soviet agent. Truman set up a federal loyalty board to weed out subversives among government employees.

Relations with the U.S.S.R. continued to deteriorate until the two countries became engaged in what was described as the "cold war." It developed into a shooting affair on June 25, 1950, when North Korean Communists attacked South Korea. Truman acted promptly. Committing U.S. forces without prior authorization by congress, he obtained United Nations sanction for the action. Characterizing the invasion as a "direct challenge to the United Nations," he announced that the U.S. had no aggressive or imperialistic aims in China, and he requested Chiang Kai-shek, the Chinese nationalists' leader on Formosa, not to attack the mainland. Gen. Douglas MacArthur was named commander of the United Nations forces in Korea.

After initial reverses which forced the U.N. forces to withdraw into a small area around Pusan in southeast Korea, General MacArthur launched an amphibious attack at Inchon, far behind the North Korean lines. By Nov. 1950 most of Korea was under U.N. control. The whole complexion of the military scene changed later that month, however, when Chinese Communists reinforced the North Koreans and dealt a severe setback to the U.N. forces (of which about 90% were U.S.). President Truman then placed the U S on a semiwar basis, calling for a greatly expanded defense establishment, partial mobilization of industry, huge appropriations and controls of wages, prices and materials. Congress gave him almost all the authority and funds he asked in response to his warning that "our homes, our nation, and all the things we believe in, are in great danger—danger created by the rulers of the Soviet Union."

On Dec. 16, 1950, Truman proclaimed a national emergency and organized a virtual wartime cabinet. with Charles E. Wilson as director of defense mobilization. Besides imposing controls on wages, prices and material allocations, Wilson began a slow but ordered shift from civilian to military production to make the **U.S.** and its allies capable of resisting Russian attack.

As a further bulwark against the U.S.S.R. the United States inspired formation of the North Atlantic Treaty organization (NATO), consisting of the U.S., Canada, Iceland and nine western European states. On Dec. 19, 1950, the NATO council approved the appointment of Gen. Dwight D. Eisenhower, then president of Columbia university, as organizer of a western European army under NATO auspices.

On April 11, 1951, President Truman removed General MacArthur from his posts as commander of U.S. and U.N. forces in the far east. Truman justified his action on the ground that MacArthur's proposed tactical plan, which included bombing of Communist bases in North Korea and China, would have transformed a local conflict into a possible global war. Returning to the U.S., MacArthur delivered a series of speeches attacking the administration's policies in the far east.

Domestic Problems; Decision Not to Run Again.—In view of unsettled conditions at home and abroad, Truman's election in 1948 had been a minor miracle of U.S. politics. Powerful influences within the party, including political professionals and liberals, wanted to sidetrack him in favour of General Eisenhower. The election of Gov. Thomas E. Dewey of New York, the Republican nominee, was forecast by almost every public-opinion poll and political prophet. But Truman made what he called a "whistle stop" campaign, appearing before thousands of voters in every section except the south and assailing the Republicans as reactionaries and isolationists

Truman received 303 electoral votes and Dewey 189, with 39 going to the States' Rights Democrats ("Dixiecrat") ticket, which was entered in the race as a southern protest against the strong civil rights plank in the Democratic platform. The "Dixiecrat" ticket was headed by J Strom Thurmond of South Carolina with Fielding L. Wright of Mississippi the vice-presidential candidate.

Congressional revelations of corruption and maladministration in several executive agencies, notably the bureau of internal revenue, the Reconstruction Finance corporation and the department of justice. embarrassed the administration in 1950–51. After defending his appointees for almost a year, the president discharged many high government and political officials and ordered Attorney General J Howard McGrath to "clean up" venal conditions among federal officeholders.

On Nov. 1, 1950, President Truman was the object of an attempted assassination. He escaped unharmed. One assassin was killed and the other wounded; one secret service guard was killed and two others wounded. The would-be assassins, Griselio Torresola (killed) and Oscar Collazo, were Puerto Rican nationalists.

Truman's seizure of the steel industry April 8, 1952, to avoid a strike precipitated a grave constitutional issue which was settled only when the supreme court, by a vote of six to three, ruled that the seizure was unconstitutional. Truman announced March 29, 1952, that he would not run for the presidency again, although he made another "whistle stop" tour in support of the unsuccessful Democratic nominee. Adlai E. Stevenson. At the 1956 Democratic National convention. Truman supported Xverell Harriman, but Stevenson was again nominated and again defeated at the polls. The same year Truman made a tour of Europe, and he received an honorary degree from Oxford university. In 1957 the Harry S. Truman library, part of the national archives, was dedicated in Independence, Mo. His *Memoirs* were published in two volumes, 1955–56. (R. Tu.; X.)

TRUMAN DOCTRINE. As the union of the World War II Allies dissolved in the emerging "cold war," conflict in Greece (1944–49) between the communist-oriented National Liberation Front (EAM) and the British-supported government forces created what Pres. Harry S. Truman called a "grave situation."

Considering Greece as outside the Soviet sphere of influence since the Oct. 1944 Churchill agreement with Stalin, but unable in its economic condition to maintain its strategic commitments, the British government asked the United States for aid to save Greece and Turkey for the free world.

President Truman, in a historic about-face in U.S. foreign policy, on March 12, 1947, asked a joint session of congress to provide $400,000,000 in military and economic aid to Greece and Turkey to stop the spread of communism in the Balkans. Such aid, according to the president, did not necessarily constitute an endorsement of the governments of these countries.

The subsequent United Nations investigatory commission report of May 23, 1947, which charged that Greek guerrillas were receiving aid from across the Yugoslav, Bulgarian and Albanian frontiers, had not as yet been issued, but President Truman was sure that the spread of communism to Greece and Turkey would have a decidedly bad effect upon the middle east, Italy and western Europe. The appeal of the Greek and Turkish governments for aid on March 3, 1947, was promptly met. The president's request was passed by congress and signed on May 22, 1947. The "Truman Doctrine," thus formed, was considered by the president as "the turning point in America's foreign policy, which now declared that whenever aggression, direct or indirect, threatened the peace [and] security of the United States . . . ," action would be taken to stop that aggression. *See* also GREECE: *Modern History;* TURKEY: *The Republic.*

TRUMBIĆ, ANTON (1863–1938), Yugoslav statesman, was born at Split. He became successively mayor of Split, and deputy for the city in the Dalmatian diet, and after 1907 deputy in the Austrian parliament. In 1905 he and his fellow Dalmatians, Pero Čingrija, Smodlaka and Supilo, as delegates of the Croat National party, worked for the renewed co-operation between Serb and Croat, which culminated in the resolutions of Fiume and Zara in 1905, and in the parallel negotiations with the Magyar coalition parties. In 1917 Trumbić and others negotiated, with the exiled Serbian government in Corfu and representatives of all the Serbian parties, the so-called "Declaration of Corfu," which provided the basis for a united Yugoslav state. Trumbić met representative Italians in Dec. 1917 and March 1918, and shared in the arrangements for the congress of oppressed nationalities held in Rome in April. In Oct. 1918 Trumbić was appointed foreign minister in the Yugoslav provisional government and peace delegate in conjunction with Pašic and Vesnić. The Yugoslavs were obliged to come to a direct agreement with Italy, and the Treaty of Rapallo was signed in Nov. 1920.

Trumbić's long absence in Paris, coupled with the policy of abstention pursued by the Croat Peasant party under Radić, placed him at a fatal disadvantage when the question of the new constitution came up in 1921. The sudden *volte face* of Radić after the elections of 1925 left Trumbić somewhat isolated, as the leader of the newly constituted "Croat Federalist Peasant party."

TRUMBULL, JOHN (1750–1831), U.S. poet known for his political satires, was born in what is now Watertown, Conn., on April 24, 1750. At the age of seven he passed the entrance examinations at Yale, but did not enter until 1763, when he was 13; he graduated in 1767, remained at the college studying, and in 1771–73 was a tutor. He spent a year in Boston in the office of John Adams, and after 1774 practised law in Connecticut. He was state's attorney in 1789, a member of the Connecticut assembly in 1792 and 1800, a judge of the superior court in 1801 and a judge in the supreme court of errors in 1808; the last two positions being held until 1819. The last six years of his life were spent in Detroit, Mich., where he died on May 11, 1831.

While studying at Yale he had contributed in 1769–70 ten essays, called "The Meddler," imitating *The Spectator,* to the *Boston Chronicle,* and in 1770 similar essays, signed "The Correspondent" to the *Connecticut Journal* and *New Haven Post Boy.* While a tutor he wrote his first satire in verse, *The Progress of Dulness* (1772–73), an attack in three parts on educational methods of his time. His great poem, which ranks him with Philip Freneau and Francis Hopkinson as an American political satirist of the period of the Revolutionary War, was *M'Fingal,* of which the first canto, "The Town Meeting," appeared in 1776 (dated 1775). This canto, about 1,500 lines, portrays a Scotch Loyalist, M'Fingal, and his Whig opponent, Honorius, apparently a portrait of John Adams. This first canto was divided into two, and with a third and a fourth canto was published in 1782 bringing the poem's total length to 3,000 lines. After the war Trumbull was a rigid Federalist, and with the "Hartford Wits," David Humphreys, Joel Barlow and Lemuel Hopkins, wrote *The Anarchiad,* a poem directed against the enemies of a firm central government.

TRUMBULL, JOHN (1756–1843), U.S. patriot-artist, visual recorder of the American Revolution, author and amateur architect, was born on June 6, 1756, at Lebanon, Conn., the brilliant and erratic son of Gov. Jonathan Trumbull. A boyhood injury to his left eye made him virtually monocular, with the consequence that his small-scale work is finer than the large. He was educated locally and attended Harvard college for a year and a half, graduating in 1773, the youngest member of his class. Returning to Lebanon he taught school and prepared maps of Connecticut's western claims for his father. During the American Revolution he served with the 1st Connecticut regiment under Gen. Joseph Spencer, as an aide to General Washington (who utilized his ability as a cartographer at Boston) and with Gen. Horatio Gates at Ticonderoga, achieving a colonelcy before reaching the age of 21. Thus he unconsciously provided himself with the subject matter that was to be his lifework.

He resigned his improperly dated commission and in 1780 left for London to study under Benjamin West. There, as a reprisal for the hanging of the British agent Maj. John André (*q.v.*), he was imprisoned, improving his time the while by studying architecture at the insistence of Edmund Burke. Released, he returned home but was back in London by 1784, again working under West. Shortly thereafter he abandoned his early Copley manner of painting, when Sir Joshua Reynolds pronounced Trumbull's portrait of Jeremiah Wadsworth and his son Daniel "bent tin"; he adopted, instead, the current English mode. He was also influenced by the work of his French friends, Jacques Louis David and especially Mme. Vigée-LeBrun.

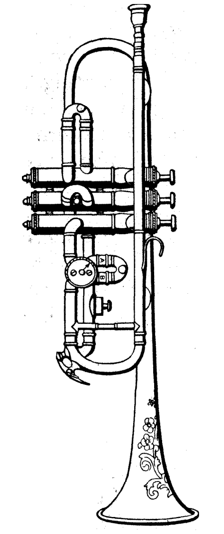
At the suggestion of West and with the encouragement of Thomas Jefferson he began his celebrated historical series. In 1789 he was back in the U.S. collecting data and soliciting subscriptions for the projected engravings to be made after the small original paintings (now at Yale university). He returned to London in 1794 as secretary to John Jay, remaining for ten years as a commissioner for the implementing of the Jay treaty—to the great detriment of his art. In 1800 he married an Englishwoman, the beautiful Sarah Hope Harvey. Once again in the U.S. (1804–08), he designed the Congregational meetinghouse at Lebanon, his only architectural work to survive, and painted panoramas of Niagara falls. In 1808 he attempted portrait painting in London with little success. From 1815 to 1837 he maintained a studio in New York city, where he executed four of the eight large pictures in the rotunda of the Capitol at Washington ("Washington Resigning His Commission," "The Surrender of Cornwallis," "The Surrender of Burgoyne" and, best known of all Trumbull's paintings, "The Declaration of Independence"). He was the dictatorial president (1817–36) of the American Academy of Fine Arts, the younger members of which seceded under S. F. B. Morse to found the National Academy of Design in 1826. In 1831 the artist gave his best work to Yale university in exchange for an annuity. The Trumbull gallery at Yale, designed by him, was founded by the scientist Benjamin Silliman, his nephew-in-law, at whose New Haven home he wrote his *Autobiography* (1841; edited and supplemented by T. Sizer, 1953). He died on Nov. 10, 1843, and according to his wish lies buried, with his wife, under the Yale Art gallery.

See Theodore Sizer, *The Works of Col. John Trumbull, Artist of the American Revolution* (1950); Mary Bartlett Cowdrey, *American Academy of Fine Arts and American Art-Union, 1816–1852,* vol. i, pp. 3–94 (1954). (T. SR.)

TRUMBULL, JONATHAN (1710–1785), American political leader, was born at Lebanon, Conn., on Oct. 12, 1710. He graduated from Harvard in 1727 and began the study of theology, but in 1731 engaged in business with his father. He next studied law, was elected to the assembly in 1773 and held public office almost continuously afterward. He served for 7 years in the assembly, being speaker for 3 years; for 17 years as county judge of Windham County; for 23 years (after 1740) as governor's assistant; for 2 years as deputy governor (1767–69); and for 3 years (1766–69) as chief justice of the colony. In 1769 he was elected governor and continued in office until his voluntary retirement in 1784. During the War of Independence he was a valued counsellor of Washington. The story that the term "Brother Jonathan," a sobriquet for the United States, originated in Washington's familiar form of addressing him seems to be without any founrlation. After the war Trumbull was a strong Federalist. He died in Lebanon on Aug. 17, 1785.

Bibliography.—His public papers have been printed in the Massachusetts Historical Society's *Collections*, 5th series, vol. ix, x (1885–88), and 7th series, vol. ii, iii (1902). See I. W. Stuart, *Life of Jonathan Trumbull*, sen. (1859).

TRUMPET, in music, a brass wind instrument with cup-shaped mouthpiece and a characteristic tone. It consists of a brass or silver tube with a narrow cylindrical bore except for the bell joint, forming from one-third to one-fourth the length, which is conical and terminates in a bell of moderate diameter. The tube of the trumpet is doubled round upon itself to form a long irregular rectangle with rounded corners. A tuning slide consisting of two U-shaped cylindrical tubes fitting into each other is interpolated between the bell joint and the long cylindrical joint to which the mouthpiece is attached.



BY COURTESY OF BOOSEY & CO., LONDON

THE TRUMPET, SHOWING THE MODERN FORM EQUIPPED WITH VALVES

The mouthpiece consists of a hemispherical cup with a rim across which the lips stretch. The shape of the cup, and more especially of the bottom. in which is pierced a hole communicating with the main bore, is of the greatest importance on account of its influence on the tone quality and on the production of the higher harmonics. It is recognized that the shallower and smaller the cup the more easily are the higher harmonics produced; the sharper the angle at the bottom of the cup the more brilliant and incisive is the timbre, given, of course, the correct style of blowing. The diameter of the cup varies according to the pitch and to the lip power of the player who chooses a cup to suit him.

There are three principal kinds of trumpets: (1) the natural trumpet. mainly used in cavalry regiments, in which the length of the tube and pitch are varied by means of crooks; (2) the slide and double-slide trumpets. in which a chromatic compass is obtained, as in the trombone, by double tubes sliding upon one another without loss of air; (3) the valve trumpet. similar in its working to all other valve instruments. The first and second of these alone give the true trumpet timbre. The tone of the valve trumpet approximates that of the cornet; nevertheless, it is now almost universally used.

In the trumpet the notes of the harmonic series from the 3rd to the 10th or 16th upper partials are produced by the varied tension of the lips and pressure of breath called overblowing. The fundamental is not often used but the second harmonic is the regular pitch note of the modern trumpet; the next octave from the fourth to the eighth harmonics contains only the third, fifth and minor seventh, and is therefore mainly suitable for fanfare figures based on the common chord. The diatonic octave is the highest and its upper notes are only reached by very good players on trumpets of medium pitch.

The lituus or cavalry trumpet of the Romans seems to have vanished with the fall of the Roman empire. Its successor, the cavalry trumpet of the 15th and succeeding centuries. was evolved from the straight busine, an instrument traced, by means of its name no less than by the delicate proportions of its tube and the shape of the bell, to the Roman buccina (*q.v.*). The bending of the tube of the trumpet in three parallel branches, thus creating its modern form, has usually been claimed for a Frenchman named Maurin (1498–1515). But the transformation was really made much earlier, probably in the Low Countries or north Italy; in any case it had already been accomplished in the bas-reliefs of Luca della Robbia intended to ornament the organ chamber of the cathedral of Florence where a trumpet having the tube bent back as just described is very distinctly figured. And this shape the instrument retained for more than 300 years. Later crooks and slides were introduced, then keys, and finally in 1815 Heinrich Stölzel made the first completely satisfactory chromatic trumpet by the invention of the ventil or piston. (See Wind Instruments.)

TRUMPET CREEPER, common name for *Campsis*, a genus of ornamental deciduous perennial vines. One species, *Campsis vudicans*, also called trumpet vine and cow itch, occurs naturally in the United States from Pennsylvania and Illinois to Florida and Texas. Although often an aggressive weed in parts of the south, it is frequently grown as a climbing ornamental and as a cover for banks. It clings firmly to its support by the aerial rootlets developed at the nodes. Numerous handsome, tubular orange and scarlet flowers are borne in terminal racemes. The Chinese trumpet creeper. C. *grandiflora* (*C. chinensis*). produces few to no aerial rootlets and thus is not a good climber, but produces larger and more brilliant flowers. It is not hardy in the U.S. as far north as the native species. A hybrid between the two species, sometimes referred to as *C. tagliabuana* or *C. kybrida*, is rather intermediate but tends to be more bushy. It blooms while quite small and is suited for pot growing. Trumpet creepers are propagated by seeds. by cuttings of both green and mature wood, by root cuttings and by layering. (J. M. Bl.)

TRUMPET CREEPER (CAMPSIS RADICANS) FLOWERS

TRUMPETER or Trumpet Bird, a South American bird of the Psophiidae family, so called from the sound it utters. The family contains the single genus *Psophia* with half a dozen species, differing in little but colour and size. The range of several species seems to be separated by rivers (Wallace, *Geogr. Distr. Animals*) and in this connection it may be observed that the birds seldom fly, though they run very fast. The best-known species, *P. crepitans*, inhabits Guiana and is about the size of a large barn-door fowl, but with longer legs and neck. The plumage is black with green and violet reflections on the tips of the neck feathers and a brown and gray patch on the back. The legs are bright green and the hird lays white eggs, about the size of a bantam's egg.

Although the trumpeters must undoubtedly be accorded the rank of a distinct family, Psophiidae, like so many other South American birds they seem to be the less specialized descendants of an ancient generalized group — perhaps the common ancestors of the Rallidae and Gruidae. The structure of the trachea, though different from that described in any crane (*q.v.*), suggests an early form of the structure which in some of the Gruidae is so marvellously developed, for in *Psophia* the windpipe runs down the breast and belly immediately under the skin to within about an inch of the anus, whence it returns in a similar way to the front of the sternum, and then enters the thorax. Analogous instances of this formation occur in several other groups of birds not at all allied to the Psophiidae.

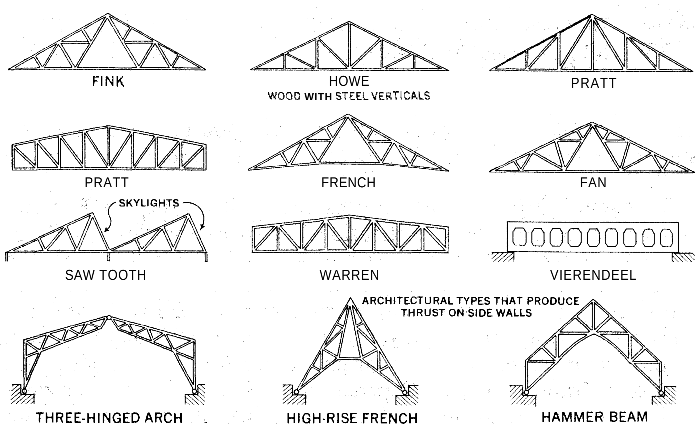
TRUMPLER, ROBERT JULIUS (1886–1956), Swiss-U.S. astronomer known for his extensive studies of galactic star clusters. for observational tests of relativity theory and for his study of Mars Born at Zurich. Switz., on Oct. 2, 1886. he was educated there and in Germany After a postdoctoral year at Gottingen (1911) and a period with the Swiss geodetic survey, Trumpler became a staff member of the Allegheny observatory, Pittsburgh, Pa., in 1915. He joined the staff of the University of California's Lick observatory in 1919 and transferred to the Berkeley campus in 1938. He retired, as professor emeritus, in 1951.

Trumpler who was a skilled observer, discovered the differences in galactic clusters used to determine their ages and proved that there exists in the Milky Way a tenuous interstellar haze that dims the light of stars seen through it. Recognition of the existence of interstellar material and its effects brought about a profound change in modern understanding of the character and extent of the stellar system in which the sun and planets are located He was elected to the National Academy of Sciences in 1932. Among his publications are: *Observations of the Deflection of Light Passing Through the Sun's Gravitational Fzeld,* with W. Campbell (1923); *Spectral Types in Open Clusters* (1925); *Observations of Mars at the Opposition of 1924* (1927); *Preliminary Results on the Distances, Dimensions, and Space Distribution of Open Star Clusters* (1930); *Observational Evidence* of *a Relativity Red Shift in Class O Stars* (1935). (H. F. Wr.)

TRURO, a cathedral city and municipal borough in the Truro parliamentary division of Cornwall, Eng., 25 mi. S.W. of Bodmin. Pop. (1951) 12,860; area 4.1 sq.mi. It lies in a shallow valley at the confluence of the Kenwyn and Allen, uhich together form the Truro, and its rise was greatly due to this position at the head of a tidal estuary. It is the administrative and ecclesiastical centre of Cornnall. The cathedral church of St. Mary, begun in 1880 by J. L Pearson, is in Early English style with Normandy Gothic spires. The episcopal see covers the whole of Cornwall, the Scilly Isles and three parishes in Devon. In the town are technical and art schools. a library and a museum. Truro's municipal charter dates from between 1130–40; a new charter was given in 1589; in 1877 the borough became a city. From 1295 to 1885 Truro returned two members to parliament. Industries include a pottery. sawmills, a biscuit factory and knitting mills. Small vessels can lie at the quays, though the harbour is dry at low water. China clay is the chief export

TRUSCOTT, LUCIAN KING (1895–), U.S. army officer, was born at Chatfield. Tex., Jan. 9, 1895. Commissioned as a 2nd lieutenant of cavalry in 1917, he had an uneventful career in World War I followed by long training as a student and instructor in army schools during the 1920s and 1930s and two tours as commander of a troop. During World War II. after unique and valuable experience in the Dieppe raid (Aug 1942), Truscott, as a major general. successively commanded a brigade-size task force in the north African invasion. (Nov. 1942), served as the "eyes and ears" of Gen. Dnight D. Eisenhower during the reverses in southern Tunisia and trained and led the U.S. 3rd infantry division in the Mediterranean through the operation in Sicily and the early phases of the Italian campaign As deputy commander of the 6th corps in Italy, he took energetic measures to strengthen its defense and frustrated the Germans' strongest efforts to eliminate the beachhead at Anzio Taking command of the 6th corps in March 1944. he planned and directed the breakout of the beachhead, and later led the amphibious assault on southern France and the drive up the Rhône valley. Returning to Italy in Dec. 1944, he led the 5th army in its final victorious drive to the Alps. Truscott's *Command Missions* (1954) stands out as an honest and knowledgeable contribution to the study of war.

TRUSS, as used in engineering and architecture, is a structural member usually fabricated from straight pieces of metal or timber to form a series of triangles lying in a single plane. This member gives a stable form capable of supporting considerable external load over a large span with the component parts stressed



FROM LINTON E. GRINTER'S "THEORY OF MODERN STEEL STRUCTURES'; REPRODUCED BY PERMISSION OF THE MACMILLAN CO., 1949

ROOF TRUSSES

primarily in axial tension or compression. The individual pieces intersect at truss joints, usually called panel points, where they may be connected by bolts, rivets or welds. The connected pieces forming the top and bottom of the truss are referred to respectively as the top and bottom chords. The sloping and vertical pieces connecting the chords are collectively referred to as the web of the truss. Trusses are formed in many shapes, varying from circular to those in which the top and bottom chords are horizontal. the latter being called parallel chord trusses. The two most commonly used methods of web configuration are the Pratt and the Warren systems. In the Pratt truss the sloping web members are parallel to each other on either side of the centre of the truss. In the Warren truss the sloping web members alternate in direction of slope along the length of the truss.

Trusses are used in buildings to support roof and floor loads, and in pairs to form bridges to carry various types of loads. The trusses are usually connected by a floor system that supports the external load. Other bracing is generally used between the trusses to give lateral stability and to carry horizontal forces such as wind. Sizable trusses are found in many large office and industrial buildings. Trusses are used for industrial purposes, as in the construction of cranes. Truss principles are incorporated into the design of airplane and automobile frames. The world's longest truss span, 1,800 ft.. is in the cantilever bridge across the St. Lawrence river at Quebec, Can.

Trusses were probably first used by primitive man in lake dwellings during the early Bronze Age, about 2500 B.C. The first trusses were built of timber. Cast iron was first used in the 18th century, wrought iron during the first part of the 19th century and steel later in the 19th century. Aluminum alloys are used for trusses in airplane wings and fuselages. The early trusses were proportioned by art and intuition. Andrea Palladio, a famous Roman architect, published a four-volume work *A Treatise* on *Architecture* in the 16th century; it contained his plans for wooden trusses and had great influence on the development of trusses. The later growth of railways gave impetus to the further improvement of truss design and construction. Squire Whipple, a U.S. engineer, published the first scientific and rational analysis of trusses in 1847. Herman Haupt. another U.S. engineer, published his *General Theory of Bridge Construction* in 1851; this contained much material on the design and construction of trusses. August Ritter, a German engineer, published a complete and general method for the analysis of simple trusses in 1863. James Clerk Maxwell (*q.v.*), English physicist, and Otto Mohr, a German engineer, simultaneously developed and published procedures for analyzing highly indeterminate trusses in the late 19th century. Karl Culmann (*q.v.*), another German engineer. developed graphical procedures for truss analysis during the same period.

In the early part of the 20th century the Vierendeel truss was invented. a type of truss composed of individual pieces formed into rectangles but without sloping web pieces. Such a truss is highly indeterminate, and the individual pieces are stressed directly in bending as well as axially. *See* Architecture: *Tech-*

niques; BRIDGES; ROOF: *Forms* of Roofs. (J. M. H.)

TRUST, as used in this article, means the legal relationship in which one person has title to property, subject to a duty as fiduciary to apply the property to the benefit of another. Business monopolies, sometimes called trusts, have no relation to the subject here treated (see MONOPOLY). For corporations engaged in the business of executing trusts, see TRUST COMPANY.

History.—Origins.—As early as the 11th century in England lawyers invented a legal institution known as the "use." Property was conveyed to a grantee "to the use" of another, with the purpose of making it the duty of the transferee to give that other the benefits of the property or permit him to take such benefits. This transaction was employed not only as a legitimate method of providing for property management and for conveyancing, but also to defraud creditors, deprive feudal landlords of their dues and permit religious institutions to derive the benefit of land they could not own directly. The use was framed on the model of the German Treuhand and not the Roman *fidei-commissum.* In this latter relationship, one who received property on the death of its owner was requested to hold it for the benefit of another and was under a duty to do so, For about 300 years the carrying out of the use depended on the conscience of the transferee to uses, since the common-law courts did not enforce it for lack of a writ to fit the case. But early in the 15th century the chancellor who administered equity began to issue decrees for its enforcement, and so the use changed from a merely honorary to an enforceable obligation.

Development of the *Use Into* the *Trust.*—By 1535 the use had become so objectionable because of its frequent employment for improper and illegal objects that parliament enacted the Statute of Cses (27 Henry VIII, ch. 10), which was intended to abolish the use. However, the courts construed the statute as destroying only uses of real property where there were no positive duties on the part of the grantee, as not abolishing uses where the donee to uses had active duties, and as not affecting uses of personal property. The uses that thus survived the Statute of Uses were called trusts, and they constitute the foundation on which the modern law of trusts exists. The trust is peculiar to the English system of law, in force in Great Britain and in the commonwealth and the United States. There was no trust in the Roman law, and there is none in countries whose jurisprudence is founded on that law, except to a limited extent as a result of recent statutes (*e.g.,* Louisiana, Puerto Rico, Mexico and Cuba).

Development of Trusts After the *Statute* of Uses.—For about 300 years following the enactment of the Statute of Uses the rules of trust law were developed by decisions of the courts of equity, with little influence from statute law. In the 19th and 20th centuries, however, there was a strong tendency to codify that law in statutory form. as shown in England and the commonwealth by the Charitable Trusts act of 1853, the Trustee act of 1925 and statutes regarding judicial and the public trustees; and in the United States by many statutes covering part of the topic, including the Uniform Fiduciaries, Principal and Income, Trusts, Common Trust Fund and Trustees' Accounting acts, drafted by the Commission on Uniform State Laws under the auspices of the American Bar association. Furthermore the American Law institute published a complete statement of trust law, with comments and illustrations, in a document called Restatement of Trusts (1935; 2nd ed., 1957), which is not a statute and has no binding effect on the courts but is highly influential.

Classification of Trusts.—With respect to their method of creation trusts are classified as (1) express, arising because of clearly stated intent that they shall exist; (2) resulting, coming into being because of an inferred or implied intent; and (3) constructive. created by the courts to remedy a wrong. From the point of view of their purposes trusts are classified as (1) private, for the financial benefit of described persons; or (2) charitable, for the welfare of society.

Elements Involved in a Trust.—Certain features are always found in a trust.

Settlor.—The settlor is so called because early trusts in England were created in marriage and other settlements. He is the person who owns property and goes through the acts necessary to create a trust of it. With negligible exceptions, any person who owns or has a power over property may create a trust of it.

Trust Property.—There can be no trust without identified property to which the trust is to attach, which is called the trust property or subject matter. It may consist, for example, of stocks, bonds, mortgages, insurance policies or a bank account. Certain other legal relationships do not impose obligations with regard to any particular property, but merely personally. This is true with regard to contract or debt.

Trustee.—Although a trustee is not necessary in order that a trust be created (since the court will supply one if none is named by the settlor), the trust cannot be carried out without some person in whom title to the trust property can be vested and who can perform the acts of trust administration. There may be two or more trustees. They are usually persons in whom the settlor has confidence (relatives, friends or business associates) or corporations to whom the power to carry out trusts has been given by statute (banks and trust companies [*q.v.*]). Because of the great difficulties of modern trust administration, a very large percentage of trusts is handled by corporate trustees. A person who is named as trustee may decline or accept, as he chooses. After acceptance he may resign (usually by court permission); he may be removed by the court if he has committed serious breaches of trust or if his continuance greatly endangers the welfare of the beneficiaries. In most cases before a trustee can act he must go through certain formalities called qualifications; *e.g.,* filing a surety bond for the faithful performance of his duties. Corporate trustees are generally excused by statute from giving a bond but are required to deposit a security fund with a public official to guarantee their responsibility.

Beneficiary.—No private trust can exist without beneficiaries who are identifiable legal entities (natural persons or corporations) or a class of persons (*e.g.,* children of the settlor). While the beneficiaries must be described with certainty at the beginning of the trust, provision may be made for the addition of new beneficiaries as persons are born and other events happen, and so the group may shift in membership from time to time, as long as all are clearly identifiable at any particular time.

In the United States the interest of the beneficiary may be made nontransferrable and not subject to the claims of creditors by the insertion of a clause in the trust instrument to that effect, the phrase "spendthrift trust" or "spendthrift clause" being used to describe the result. Where this is done, the beneficiary is unable to sell or give away his right to future payments from the trustee, and his creditors cannot take for the collection of their claims this right to payments later to be made; but after trust income or capital has been turned over by the trustee to the beneficiary, such payments may be freely spent by the beneficiary or taken to satisfy his creditors. In England spendthrift trusts are not allowed, but another trust (the protective trust), having somewhat similar effects, is sanctioned. In the protective trust the beneficiary's interest ends when he attempts to transfer it or when his creditors attempt to take it, and immediately a new trust begins for the benefit of the family of the original beneficiary, so that the transferees and creditors of the original beneficiary will have no rights, and yet the benefits of the new trust will in all probability come to the original beneficiary in part through the medium of his family.

In the case of charitable trusts the beneficiaries are not identifiable persons, since society is the beneficiary of such a trust, and any human beings who are involved are merely conduits through whom the advantages flow to the state. Thus, in the case of a trust to aid the poor, the individuals chosen yearly by the trustees to receive trust income are not the beneficiaries: rather society, which is benefited by the relief of poverty, is the beneficiary. Since charitable trusts are allowed to continue indefinitely and are granted many other privileges (*e.g.,* freedom from taxation), it often becomes important to decide whether a trust purpose involves substantial social advantages and is therefore technically charitable or is a private trust. Certain purposes are admittedly charitable, as, for example, the advancement of education and scientific research, the prevention or cure of disease, the relief of poverty and the support of religion. According to Lord Macnaughten (1891 A.C. 531) there is another class of charitable gifts, that is, those "for other purposes beneficial to the community." In this class may be cited gifts to furnish governmental services and to beautify towns and cities. Among borderline cases may be placed gifts for cemeteries and monuments, generally not charitable at common law but made so by many statutes: the furnishing of recreation and amusement, not charitable in England until very recently but approved in the United States; and the protection and care of animals, charitable if for domestic animals in general but not if for particular animals or for wild animals that are hostile to man. Trusts to care for poor relatives of the settlor or to aid a political party are not charitable.

The social benefit involved in a charity must be substantial. Hence the aid of a business enterprise that has small incidental public advantages is not charitable. The views of the courts as to what is charity are controlling and not the opinion of the settlor. At one time in England religious trusts were not charitable unless for the benefit of the established church, but toleration acts have changed the law. In the United States the support of any religion would probably be sustained as charitable; trusts for masses are now regarded as valid religious charitable trusts. In England and in a minority of U.S. states donors of property to trustees for charity have been restricted by the so-called mortmain acts, which either require such a gift to be made a considerable period before the death of the donor (*e.g.,* one year), or limit the proportion of the estate that can be given to charity if the donor left certain described close relatives.

Private trusts may be created to accomplish any legal purpose. They are used to achieve a variety of objects. If the end sought is illegal, *e.g.,* to defraud creditors, they are not enforced.

Trust Instrument.—The trust instrument is the document in which the settlor expresses his intent to have a trust and describes its provisions. It usually consists of a deed or a will.

Methods of Trust Creation.—There are several ways in which a trust may be created.

A property owner may declare himself trustee of that property; he may convey it during his life to another to hold in trust; or he may give it by will to a trustee who is to take the property at the death of the maker of the will. The trusts created by the first and second of these methods are called living trusts; those created by will are called testamentary trusts.

Trusts also may be created by decree of a court. Resulting trusts arise because the court finds that a property owner intended to have a trust, although he did not expressly say so, as where one pays for land and has the deed made out to another without any agreement as to the intended effect (so-called purchase-money resulting trust), and where the courts find that the payer of the price did not intend to give away his money but rather expected the grantee to hold the land for him. Constructive trusts are created by court decree, where the court finds a person holding property which in all fairness should belong to another, and the court adjudges the titleholder to be a constructive trustee for the wronged person, with a duty to convey to him (*e.g.,* where a son who is the sole heir of his father murders the father in order to inherit the father's property, and a trust is constructed for those who would have been the father's heirs if the son had predeceased the father).

No consideration is necessary to the creation of a trust. It is not necessary that the settlor be given anything of value in return for the act of trust creation. Herein lies a great difference between trust creation and the formation of a contract. Most trusts are by way of gift and yet are just as enforceable as if the settlor had been paid for their creation. In England from 1676 until the 20th century a trust of real estate created during the life of the settlor was unenforceable against the objection of the trustee unless it was proved by a signed writing, but this did not apply to resulting or constructive trusts; and in most states of the U.S., a writing is required for express trusts of land. If an attempt is made to create a trust to begin at the death of the settlor, he must make a will which complies with the statutes as to the execution of wills, which usually require a signed writing with witnesses.

Duties of the Trustee.—Some of the more important duties of the trustee are the following: (1) To use the care and skill a reasonably prudent and capable man would employ in managing property for objectives like those of the trust, and if he has or professes to have, greater abilities, to use them in his trust work. (2) To be loyal to the beneficiaries in all trust administration and thus to exclude consideration of his own selfish interest or the welfare of third persons; the courts set aside at the option of the beneficiary all disloyal transactions and take from the trustee the fruits thereof. (3) To display the utmost fairness in any direct business dealing with the beneficiaries, as, for example, the purchase of the beneficiary's interest under the trust. (4) To take possession of the trust property by procuring it from the settlor or his executor or a predecessor trustee. (5) To defend the trust against attack and not to attack it himself. (6) In the case of cotrustees, to be active and not to leave to fellow trustees the entire control of the trust. (7) To protect the trust property in whatever way is reasonable, as, for example, to place trust securities in a safety deposit box, deposit cash in a bank, repair buildings and take out insurance where prudent business practice would require it. (8) To make an inventory of the trust assets, keep adequate records of all transactions and obtain vouchers for payments made. (9) To keep, sell or buy trust investments as required by the terms of the trust or by the investment laws of the jurisdiction. (10) To pay the expenses of operating the trust and the carrying charges on trust property; *e.g.,* taxes, mortgage interest and principal. (11) To pay out trust income and capital to the beneficiaries as directed by the trust instrument or by statute. (12) To make a report or accounting to the beneficiaries in court when required to do so by the terms of the trust or by statute or court decree. (13) To familiarize himself with the terms of the trust and the law of trusts, in order that he may perform the duties laid upon him.

Powers of a Trustee.—A trustee has such powers as are expressly granted to him by the trust instrument or are implied because their use is necessary or highly convenient to the accomplishment of the settlor's purposes. Some of the commoner powers are to sell, make investments, collect and distribute income, make leases, carry on the business of the settlor or do any other act of trust administration that it is his duty to do. The powers of cotrustees of private trusts are jointly held, unless otherwise prescribed in the instrument, hence all must unite in performing the important acts of trust administration; a majority, however, may act in the case of a charitable trust. A trustee cannot lawfully delegate to a cotrustee or an employee the power to perform discretionary acts (*e.g.,* fixing the price of property to be sold), but he may leave to another work that a prudent businessman would delegate to a subordinate (*e.g.,* advertising the property for sale). The trustee's powers may be mandatory, where the settlor has ordered the performance of an act, or discretionary, where the trustee has the option to use the power or not, provided he does not abuse his discretion in making a decision.

Liabilities of a Trustee.—If a trustee violates his trust (*e.g.,* by making an unlawful investment), the beneficiary may hold him liable for any loss caused thereby. If the breach of trust was the wrongful transfer of the trust property to a third person, the beneficiary may reclaim the property or its proceeds as long as he can identify them, unless they have come into the hands of a purchaser who did not have notice of the breach of trust. A trustee may also be personally liable to others than the beneficiaries, as where he makes a lawful contract in connection with the trust business (unless he expressly excludes such personal liability in the contract), or commits a tort (*e.g.,* negligence) in managing the trust property. But if the contract was properly made, or the tort involved no personal fault on the part of the trustee, the courts will direct the use of trust property to reimburse or indemnify the trustee with respect to liability. There is a strong modern tendency to permit a contract or tort creditor to collect directly out of trust property by an action against the trustee in his representative capacity, both in the case of private and charitable trusts.

Accounting by Trustees. — The beneficiary has the right to have the trustee present in court at reasonable intervals a written statement of receipts and expenditures, how the trust has been operated and what its present situation is. In some states, statutes require periodic court accountings, but in other jurisdictions there are no such statutes and court accountings occur only when a beneficiary brings a suit to require an account or when the trustee voluntarily presents one in court. Corporate trustees frequently voluntarily send reports to their beneficiaries or voluntarily file accounts in court in order that the court may pass upon the validity of the trustee's acts and may award him compensation for his work since the last accounting. The beneficiaries are entitled to notice of the filing of an account in court, and may object to any item in the account and have the court pass upon the objection.

Compensation of Trustees. — In England, trustees originally were not entitled to any compensation, and this continues to be the rule there except where the trust instrument provides for pay, or the trustee will not act without compensation and the court therefore allows it, or the court authorizes the compensation of a corporate trustee that it appoints. In the United States, trustees are universally allowed fees, as well as payment of their reasonably incurred expenses, the amount of the compensation being set by different standards in the various states. Sometimes a fixed percentage of the trust income is granted to the trustee, while in other states the amount is left to the discretion of the court. Some settlors prescribe the amount of commissions in the trust instrument. Corporate trustees often have fee schedules and insist on an agreement that they be paid accordingly. The court has power to deprive a trustee of his compensation or reduce it, where his administration has been markedly defective; and in rare cases the court may award extraordinary compensation, where unusual difficulties have been encountered by the trustee.

Trust Investments. — One of the most difficult duties of the trustee is to secure for his trust the maximum practicable safety and at the same time secure a steady flow of reasonable income. He should shun speculation and investments for the purpose solely of capital gains. He should consider the tax situations of his beneficiaries, the need for readily saleable investments, hedges against inflation and a reasonable degree of diversification.

The rules as to trust investments have passed through three stages: (1) the fixing by the courts of a very small number of permitted investments (government bonds and first mortgages on real estate); (2) the adoption by the legislatures of lists of classes of investments, but not particular investments, in which a trustee was permitted or required to invest; and (3) the establishment by the courts, or more frequently by statute, of the so-called "prudent man rule," under which a trustee is protected in holding, selling or buying investments if he uses the skill and care of a reasonably prudent man in managing investments for purposes similar to those of the trust in question. This latter rule has the virtue of great flexibility and of taking account of changes in investment practices. The second rule named above is applied in England; it once was followed in most American states and is still in force in a few, but a large majority of the states have shifted from the statutory lists to the prudent man rule. While corporate shares were rarely approved as trust investments under the older case and statutory law because of their supposedly speculative nature, the courts acting under the prudent man rule allow a reasonable proportion of common or preferred stocks on the basis of the satisfactory performance of stocks in recent years and the practice of prudent investors.

A trust investment device popular in the U.S. is the common trust fund, which consists of a group of investments purchased with funds of many trusts; each contributing trust has a share in the capital and income of the common trust fund corresponding to the amount of its participation. Such a fund provides diversification and permits ready investment of small balances. These funds are recognized by federal and state law for operation by corporate trustees, and their use is spreading.

Many modern trust instruments grant to the trustee discretion as to the making of investments, which is believed equivalent to making the trust governed by the prudent investor rule. If the instrument prescribes certain investments, the trustee will be protected in following these directions, if he used reasonable care in doing so.

Principal **and** Income Problems. — Since nearly all trustees act for income beneficiaries with temporary interests and also for remaindermen beneficiaries who are to take the capital of the trust at a future date, they have the problem of determining what receipts are to be applied to the income account and what to the capital fund, and also from which of these two sources expenditures shall be made. The court decisions and statutes attempt to give the income account that portion of the receipts which represents earnings or gains from the use of the trust property (*e.g.*, interest, rents, cash dividends) and to treat as trust capital the results of a mere change in the form of the trust property, as where land is sold and cash received in return. With respect to expenditures, the burden of merely maintaining and preserving the original trust property should be placed on the income account (*e.g.*, taxes, repairs and insurance), while the cost of adding to the value of the trust property should be taken from trust capital (*e.g.*, improving real property by constructing buildings). There are many complicated problems in this field that cannot be treated here. The modern tendency is to treat stock dividends as trust capital.

Enforcement of Charitable Trusts. — Enforcement is usually by the attorney general and not by persons who would obtain benefits from the charity, since the government on behalf of its subjects or citizens is the real beneficiary of a charitable trust and the attorney general is in charge of enforcing the government's rights; but private persons may begin proceedings in the name of the attorney general, if he refuses to act. It has been recognized that many charitable trusts are neglected and not enforced, due to lack of knowledge by the attorney general of their existence. This situation brought about legislation in England requiring registration of charitable trusts in a public office and regular reports as to their situations, and giving public authorities powers of investigation, the charities commissioners being employed for these purposes. Similar statutes applying to the attorney general have been adopted in several states of the C.S.

Revocation, Termination or Alteration of a Trust. — Unless a settlor reserved to himself, or granted to another, in the trust instrument a power to revoke the trust so as to procure a return of the property to the settlor, no such power will be recognized by the courts. There is no implied power to revoke, even though the creation of the trust was by way of gift and there has been a change in the circumstances of the parties. The same rule applies to the amendment or alteration of the trust. There is a small amount of statutory law in the United States permitting the settlor to revoke, either alone or in conjunction with the beneficiaries. The insertion of a power of revocation may cause the trust property to be regarded as property of the settlor for income and death tax purposes. Frequently the settlor alone, or the settlor and the beneficiaries or merely the beneficiaries, attempt to procure from a court a decree terminating the trust, and either the return of the property to the settlor or the distribution of it immediately to the beneficiaries. If the settlor is the sole beneficiary or if he secures the joinder of all the beneficiaries in his request for termination, the courts are inclined to grant the application, since a property owner should be allowed to enjoy his property as he likes, and the donees of a gift should be able to return it to the donor if they are competent and so desire. But if the settlor is not joined in his application for court termination by all the beneficiaries — either because some refuse or because there are possible contingent beneficiaries for whom no one can act or because certain of the beneficiaries are incompetent mentally or by reason of minority and the court does not permit a representative to act for them — then, if the trust purpose as expressed originally by the settlor has not yet been accomplished, the court will not decree a destruction of the trust A similar rule applies if the applicants are merely beneficiaries, the settlor having died or having refused to join in the application. If the trust purpose has been accomplished or has become impossible of accomplishment, the court mill end the trust. In some cases where there is bona fide litigation regarding the validity of the trust, the court will sanction a termination of the trust and a compromise distribution plan, where it believes that the interests of all parties would be foruarded thereby.

When a single provision in a trust instrument proves to be an obstacle in the way of carrying out the purposes of the settlor, the courts have power to direct the trustee to ignore the undesirable clause and to deviate from the methods of administration prescribed by the settlor. The machinery he devised for running the trust is of slight importance as compared with the benefits he wished his beneficiaries to obtain. For example, if the purpose of a trust is to furnish a comfortable living for the settlor's children, and he directs that the trust fund shall be invested in government bond: exclusively, and these bear interest at such a low rate that the beneficiaries are in want, the court might direct the trustee to ignore the settlor's investment clause and to invest in stocks and bonds that would bring in tnice as much income. This power may also be used to advance the date of payment of trust income or capital. It may not be used in the United States to vary the amounts of the gifts to the beneficiaries, but in Great Britain the power to vary the trust under the Trustee act includes this latter change

Cy Pres Power.—The courts of equity have the power to vary the administration of a charitable trust, when circumstances have changed since the creation of the charity so that it is now impossible or highly inexpedient to use the fund for the charity named by the settlor The court or in England the charity commissioners, may substitute another charitable purpose as nearly like the original as possible and direct the trustee to apply the fund for this substituted purpose. For example, if the original trust purpose was the prevention and cure of a named disease, and modern discoveries had so reduced the danger of contracting the disease and the cost of treatment of it that the sum given to the trust is greatly in excess of the amount that can reasonably be used for the original purpose, the court might "frame a scheme" for revised administration and apply part of the property to prevent and cure other diseases

In the early terminology of the English law this was called the *cy près* poner. a phrase abbreviated from the Norman French *cy pres comme possible,* meaning that the new plan was as nearly like the old as possible and that it carried out nhat the settlor would have nanted.

TRUST, INVESTMENT: *see* INVESTMENTS: INDIVIDUAL.

TRUST COMPANY is a corporation engaged in ninding up estates. administering trusts and performing agencies for individuals, partnerships, corporations, associations and institutions both public and private, under authority of law. The trust company may be engaged exclusively in trust business or it may perform commercial banking functions as well as those of a savings bank.

In all of its purely trust functions, the trust company acts as a fiduciary for its customers in that it acts for the benefit of someone other than itself. It cannot delegate the performance of its duties.

In the United States, trust powers are granted to corporations by governmental authority; they are not implied rights. National banking Institutions receive their trust powers from the federal government. Other corporations receive their trust powers from state governments. Power to engage in trust business in one state does not carry with it power to engage in trust business in other states of the United States. Each corporation must meet the requirements of the governmental authority under which it wants to do business. Each state has the authority to determine the conditions under which a corporation may conduct a trust business within its borders.

In addition to its trust charter, each trust company must obtain a licence to operate. National banks receive their licences to operate from the board of governors of the federal reserve system. State banks apply to the state banking authority for their licences.

Other requirements are imposed on corporations before they can engage in trust business. The laws of the various states are not uniform. Some require a minimum capital and surplus which is fixed according to the population of the city in which the corporation is located, while others base the requirement on the volume of the trust business of the corporation. Some states further require that a deposit be made with the proper state authority to protect the trust property. In some states a deposit of securities of a fixed amount permits the handling of an unlimited volume of trust business.

The trust company renders three kinds of service for three distinct groups of persons. The three services are: distribution of property; administration of property; and custody and agency functions with respect to property. These three services may be rendered for individuals, for business firms, or for public institutions. For convenience, most trust companies classify their services as personal trusts and corporate trusts.

Personal Trusts.—The trust company serves individuals in many ways but its chief function is that of executor or administrator of estates. When a person dies, leaving property and a will that is admitted to probate, he often nominates a trust company to wind up his estate. The court of competent jurisdiction usually appoints the trust company so named and it is knonn as the executor of the estate If an executor is not named in the will, or if the person so named is not appointed by the court, the court appoints someone to act. Such a person is knoun as an *administrator with a will.* Should the person nho dies leaving property not make a valid will, the court appoints an *administrator.* The trust institution so appointed is known as the *administrator of the estate.*

The principal duties of the executor or administrator are to obtain *letters testamentary* or *letters of administration* from the court giving the trust company authority to settle the estate, assemble the assets of the estate, take such steps as are necessary to protect the assets, pay all just claims, and distribute the remainder to the heirs.

Personal Trusteeships.—The administration of personal trusteeships constitutes the second main function of personal trusts A trutt exists when one person has legal title to property and another person hai the beneficial ownership Personal trusts are of two hinds testamentary trusts and living trusts

A testamentary trust is created by a person who leave5 a will which transfers his title to property to one person to hold for the benefit of a third person or persons A living trust is created when a person during his lifetime conxeys title to property to another person to he held for the benefit of himself or a third person. I hese living trusts may be revocable or irrevocable The living trusts are of several kinds

Guardianships.—Under court appointment trust companies serve individuals as guardians ot property In some states a trust company may also act as guardian of a person Guardianships of property arise nhen the court appoints someone to manage the property tor an incompetent person Such appointee is known as a guardian trustee or conservator The incompetent person may be mentally incapable ot managing his own property or he may be a minor

A guardianship differs from a trusteeship in that under the former the title to the property remains in the minor or the incompetent whereas under the latter the title resides in the trustee The administrator of estates under guardianship is controlled by the statutes and court decisions of the state. Under trusteeships the trustee derives his powers and duties from the trust instrument creating the trust.

Agencies. — The third principal function performed by trust companies for individuals is that of agent. Agencies are created when one person authorizes another to act for him. The principal retains title to his property and may terminate the agency at any time. It is automatically terminated on the death of either the principal or the agent. Agencies are of many kinds but may be grouped under five headings: safekeeping, custodianships, management agencies, attorneyships-in-fact and escrow agencies.

Safekeeping is the simplest kind of agency and involves the receipt of property or claims to property, care in its protection and delivery upon order of the owner. No responsibility other than due care and diligence in the physical protection and delivery of the identical property is imposed.

Custodianships constitute the next step beyond safekeeping. The custodian, in addition to receiving, caring for and delivering property performs many other duties set forth in the agreement. The custodian is expected to relieve the principal of the details connected nith ownership.

Management agencies represent the third step in activity and responsibility under agencies in that the exercise of judgment is involved. In addition to the duties of safekeeping and custodianship, the management agent may be expected to render a multitude of services in which it must exercise the same kind of care and judgment that it would for property held in a trust account.

Attorneyshzps-in-fact arise from a written authorization by the principal conveying to the agent authority to perform certain acts. Attorneyships-in-fact accepted by trust institutions do not involve the practice of law.

These agencies may cover any business transaction which the principal has a legal right to perform.

Escrow agencies constitute the fifth agency function of trust companies. In performing this service the escrow agent acts as a stakeholder for two or more persons engaged in a business transaction. The agent exercises no discretion and assumes no responsibility other than following the instructions agreed upon.

Corporate Trusts. — Corporate trusteeships are one of the principal services rendered by trust companies. As corporate trustee, a trust company serves as trustee under bond issues. It takes title to property under deed of trust from corporations which wish to sell notes or bonds. The trustee holds title for the benefit of the noteholders or bondholders. The trustee certifies that each bond or note is one of a series issued under trust deed.

It protects against an overissue but does not guarantee the value of the security. As agent, the trust company acts as transfer agent or registrar. As transfer agent, it acts for corporation stock and registered bonds. It also acts as transfer agent for many forms of business paper such as warrants for stock rights, voting trust certificates and receivership certificates. As registrar, trust companies guard against an overissue by checking the certificates against the number of shares authorized. When certificates are issued the registrar checks the old and new certificates. Another function of the trust company is that of depositaryship. These services are governed by the depositary agreement. The trust company accepts the securities, accounts for their safety and delivers them on demand. Because of the vast detail involved in connection with the payment of dividends on stocks, interest on bonds and the payment of matured issues, corporations appoint trust companies as paying agents.

Trust companies also serve corporations as custodians, management agents, escrow agents and attorneys-in-fact.

In addition to their services for corporations and individuals, trust companies act as fiscal agents for governmental bodies and for social institutions such as clubs, schools, churches and fraternal institutions. (H. F. W.)

Historical Development. — The first trust companies in the United States were not chartered as trust companies originally but as insurance companies; trust activities remained secondary until, with the growth of wealth, the fiduciary services became of greatest importance. whereas insurance and annuity business was secondary. By 1822 several companies were placing chief emphasis upon the fiduciary business. Their development before the Civil War was slow, and by 1850 there were about 50 trust companies scattered throughout the commercial states.

Besides performing trust functions, some of these early trust companies operated as savings banks and provided safe deposit facilities. The charters of trust companies around the middle of the 19th century included these functions specifically.

With the development of a national banking system and a national currency after 1863, trust companies grew in importance and number and developed into powerful financial institutions. In the 25 years following the Civil War great changes took place in the activities of trust companies. Whereas state banks were decreased in number and in extent of their operations as a result of the National Banking act of 1863, trust companies began to grow in number and resources. The regulatory measures provided in their charters were regulatory in name only.

Deposit banking and discounting activities became the chief functions of trust companies. The old alliance with insurance and annuity business was completely dropped and fiduciary business began to occupy a rank of secondary importance.

After 1880, trust companies became commercial banks in reality even though not always in name. As a result of the growth of trust companies, banks complained that they were being discriminated against and clamoured for state supervision of trust companies. The three chief complaints of the banks were that trust companies were not subject to taxation as were banks; that trust companies kept no reserves, but depended on the banks for cash and clearing service; and that trust companies were not subject to state supervision and regulation in their operations, which constituted a danger to sound banking. After many heated controversies measures of relief were started. New Tork enacted a trust company reserve law in 1906, but the law was changed in 1908 and trust companies were brought under the same law as banks.

Other states followed suit. When the Federal Reserve act was passed in 1913 the same powers to act in a fiduciary capacity as were enjoyed by trust companies were extended to commercial banks. The act also provided that trust companies could become members of the reserve system.

After that time, trust companies became almost indistinguishable from commercial banks, though they generally place a heavier emphasis on fiduciary business than do most commercial banks. By 1939 about one-third of the country's banking resources were in the hands of trust companies. (B. F. H.)

TRUSTEESHIP SYSTEM, the method provided in art. 75 of the Gnited Nations charter for the administration and supervision of such nonself-governing territories as may be placed thereunder by individual agreements. The system superseded the mandate system which had similar functions under the covenant of the League of Nations *(see* MANDATE). As the trusteeship system was established following World War II, there were, however, certain distinct differences from the mandate system, both with respect to (1) the form of international supervision; and (2) the geographical scope to which this system may apply.

Concerning supervision, the United Nations charter provides for periodic UN visits of inspection to the various trust territories and it also provides that the UN general assembly or Trusteeship council may hear petitioners from such territories in person. Although these two provisions were not specifically excluded from the mandate system, they were not explicitly made a part of that system. Both practices are widely regarded as rendering United Nations supervision more effective and realistic.

The UN charter also provided that the system may apply to (1) the former mandated territories; (2) territories detached from enemy states as a result of World War II; and (3) other nonself-governing territories which might voluntarily be placed under the trusteeship system by the states responsible for their administration. In each case, however, it was provided that a subsequent agreement between the state administering the territory and the United Nations would be necessary to bring any such territory under the trusteeship system.

Except for one territory — Somalia, which was taken from Italy, following World War 11 — there was in fact no extension of the system beyond the former mandated territories. The territories under UN trusteeship in the late 1950s are shown in the table.

Trust territory	Population	Area (in sq.mi.)	Administering authority
Togoland (French)*	1,052,318†	22,008	France
Cameroons (British)	1,439,870‡	34,081	United Kingdom

††Placed under Italian trusteeship, 1950.
Note: Following World War II, the Union of South Africa refused to place South-West Africa (*q.v.*), a League-mandated area, under UN trusteeship.

In practice; the trusteeship system may be described as a system of national administration under international supervision. Although the United Nations is itself empowered (art. 81) to administer a territory, it has. in fact, not done so. The states which administer trust territories are referred to as "administering authorities." and the precise terms under which they administer the respective territories are indicated in detail in the separate trusteeship agreements made between them and the United Nations general assembly.

Objectives and Purposes.—The basic objectives of the trusteeship system are defined in the charter (art. 76) as "(a) to further international peace and security: (b) to promote the political. economic, social. and educational advancement of the inhabitants of the trust territories. and their progressive development towards self-government or independence as may be appropriate to the particular circumstances of each territory and its peoples and the freely expressed wishes of the peoples concerned . . . ; (c) to encourage respect for human rights and for fundamental freedoms for all without distinction as to race. sex. language, or religion, and to encourage recognition of the interdependence of the peoples of the world; and (d) to ensure equal treatment in social, economic and commercial matters for all Members of the United Nations and their nationals. and also equal treatment for the latter in the administration of justice, without prejudice to the attainment of the foregoing objectives. . . ."

Strategic Areas.—The UN charter provides (art. 82) that there may be designated in any trusteeship agreement a strategic area or areas which may include part or all of the territory to which the agreement applies. Under this provision, the United States agreed in 1947 to place the Trust Territory of the Pacific Islands (the Marshalls, Marianas and Carolines) within the trusteeship system under a strategic trusteeship agreement. Art. 13 of this agreement provided that while the territory might be broadly administered as an ordinary trusteeship with the relevant articles of the charter applying to it, the administering authority may determine the extent to which art. 87 and 88 of the charter may be applied to any areas in the territory "which may from time to time be specified by it as closed for security reasons." The charter provides (art. 83) that the functions of the United Nations relating to strategic areas shall be exercised by the Security council and that the annual reports on the territory shall be made to it, but the article also provides that the Security council shall avail itself of the assistance of the Trusteeship council in political. economic, social and educational matters. In practice, as regards the Trust Territory of the Pacific Islands, the Trusteeship council examined its annual reports in the same manner as the reports made on all the other trust territories. but its report was made directly to the Security council and was not discussed, as were the other reports, in the general assembly. (See also PACIFIC ISLANDS.)

The Trusteeship Council.—The United Nations Trusteeship council examines the annual reports of the various administering authorities, hears petitioners and sends visiting missions every three years to each of the territories. Under the charter (art. 86), the council was comprised of all the member states of the United Nations that administered trust territories, and an equal number of other members elected for three-year terms by the general assembly. The Soviet Union and China were, however, ex officio members by virtue of their permanent membership in the Security council. The president of the council was elected annually and in practice was chosen alternately from among the two classes of members.

The Trusteeship council roughly combined the functions of the former League of Nations permanent mandates commission, a technical body, and the former League council, a political body. to which the permanent mandates commission had reported. The Trusteeship council was composed (art. 86) of one "specially qualified" person appointed by each of the member states. Thus, it was intended that the council should, as one body, take into account both the technical and political aspects of the operation of the trusteeship system. How far this blending of competencies succeeded was disputed,

Origins of Trusteeship.—The concept of trusteeship, which has analogies to the relationship of the guardian to his ward. is traced by some authorities to Edmund Burke. who, in a speech on Fox's India bill in 1783 in the house of commons, said that "all political power which is set over men . . . ought to be some way or other exercised ultimately for their benefit"; and that "every species of political dominion and every description of commercial privilege . . . are' all in the strictest sense a trust; and it is of the essence of every trust to be rendered accountable." The term "trusteeship" was widely used during the 19th and 20th centuries, especially in England and the British colonies during the struggles for the abolition of the slave trade and slavery. When, therefore, a new expression was sought during and after World War II to replace the mandate system, it was quite readily agreed at the UN organizing conference in San Francisco in 1945 that the new system should be known as the "trusteeship system." The term "sacred trust" was used in the covenant of the League of Nations in connection with the mandate system and, in fact, the underlying concept of both systems was in essence the same. Both were based on the idea of some degree of collective responsibility among the family of nations for the welfare of still dependent peoples. and both systems assumed that the harsher forms of alien rule over such peoples should give may to collective action and responsibility under which the interests of the inhabitants were to be considered paramount. The basis of both the mandate and trusteeship systems derived from Pres. Woodrow Wilson's fourteen points (q v), in which he proposed (point 5):

> A tree, open-minded, and absolutely impartial adjustment of all colonial claims, based upon a strict observance of the principle that in determining all such questions of sovereignty the interests of the populations concerned must have equal weight with the equitable claims of the government whose title is to be determined

Visiting Missions.—The visiting mission feature of the trusteeship system was regarded as the most important added element in the supervisory function of the United Nations. As of the late 1950s the Trusteeship council organized a mission each year to spend six or eight weeks in eastern Africa. western Africa or the Pacific area, each area being visited every third year.

In order that the principle of balance uhich was basic in the Trusteeship council's composition might be maintained in its visiting missions, the council annually invited two administering members and two nonadministering members each to nominate an individual to participate in the visiting mission. The council, upon receiving the nominations, retained the right to approve or disapprove such nominations on the ground that the individual members of the visiting missions in a sense represented the entire council, were paid their expenses by the United Nations and reported directly to the United Nations. Participants did not go under instructions from their governments but acted in an individual and expert capacity. The council customarily elected the chairman of the mission. alternating each year between members from the administering and nonadministering groups. Five or six members of the trusteeship department of the UN secretariat customarily accompanied the mission and assisted it in drawing up its report.

When a visiting mission visited an area it reported separately upon each individual territory. Reports were submitted for comment to the administering authority concerned. The report of the visiting mission and the observations were laid before the Trusteeship council and with the annual report of the administering authority and written and oral petitions with respect to that territory, furnished the basis for the eventual evaluation made by the council in its annual report to the general assembly.

Targets and Final Goals. — The rate of progress made toward self-government or independence by UN trust territories aroused frequent comment by visiting missions. UN member states which were critical of the colonial relationship, even in its trusteeship form, tended to urge early independence, and in some cases recommended a fixed time limit for its attainment. Such a time limit, for instance, was fixed in the trusteeship for Somalia in the assembly's 1950 agreement with Italy, pursuant to the peace treaty with Italy. In every other instance, however, the administering authorities took the position that until a territory was clearly near its goal, such time limits were unrealistic and impracticable. The council did not adopt recommendations calling for such fixed time limits, but it did recommend that administering authorities consider specific intermediate plans for political, economic and social development involving targets of three or five years.

Administrative Unions. — Another subject of protracted consideration was the practice of governing a trust territory as an integral part of a neighbouring colony. Although the trusteeship agreements provided for governing certain trust territories under so-called "administrative unions," it was nevertheless required that the trust territory be maintained as a separate entity for the purpose of reporting statistical and other information. It was also considered necessary that the development of a trust territory toward independence should not be jeopardized, regardless of the political development of a neighbouring territory with which it might be administratively associated.

Administration But Not Sovereignty. — In each trusteeship agreement it was provided that the administering authority should have full powers of legislation, administration and jurisdiction in the territory, subject to other provisions of the agreement and of the UN charter. This enabled the administering authority to extend such of its legislation and administrative machinery to the trust territory as it might deem necessary. Nevertheless, it was clearly understood that such powers should in no sense be construed as meaning that the administering authority might annex the territory or that it had sovereignty over the territory. It might exercise many of the prerogatives of a sovereign, but it was recognized that a trust territory, unlike a colony, was not under the sovereignty of the country which governed it.

Termination of Trusteeship. — Since the objective of trusteeship was defined (art. 76) as self-government or independence, the attainment of either goal was regarded as a valid basis for termination. Thus, the trusteeship for British Togoland was terminated in 1957, after a UN-supervised plebiscite showed that a large majority of the population favoured union with Ghana. The 11th general assembly completed the formalities and hailed the successful outcome of the first territory to "graduate" from the system.

Three UN trust territories gained their independence during 1960: French Cameroun became a republic on Jan. 1, French Togoland became the Republic of Togo on April 27 and Somalia (formerly Italian Somaliland) became independent on July 1 and was united with former British Somaliland.

Conclusions.—Colonialism in all its manifestations had come in the second half of the 20th century to be looked upon as a temporary expedient which should give way as rapidly as feasible to self-government or independence. The colonial relationship, even in its trusteeship form. was widely regarded as objectionable, since no people desired to be governed by alien authorities.

Most of the states which emerged after World War II from colonialism, on the other hand, did so without going through the trusteeship phase, and it seemed unlikely that many of the colonial peoples would consider that trusteeship was an advantage to them in attaining self-government or independence.

It might be concluded, therefore, that since both colonies and trust territories were rapidly moving toward these goals, the trusteeship system, with all its possible benefits, had only a limited future. In the meantime, the eyes of the world closely scrutinized these territories, and high administrative standards would be necessary in order to satisfy the opinion of mankind.

TRUTH. There has always been, since the first beginnings of philosophy, some topic of current philosophical discussion to which could be assigned the title "the problem of truth." It would be easily admitted, however, that it is not one single question which has been debated under this heading — indeed, that some of the questions so discussed have been only remotely connected with each other.

That all might be expressed in the formula "What is truth?" is a matter of superficial verbal resemblance. In the course of time, however, there has occurred some profitable narrowing of the points at issue, so that in examining here the most important group of modern theories on this subject, we have the advantage of being able to concentrate, not indeed on one single question, but at least on questions that are reasonably akin.

The Correspondence Theory. — The theory with which it is natural to begin, on the ground that it seems to accord most closely with common sense, is the so-called correspondence theory. This theory's pedigree is extensive and respectable: it could be traced back, through the medieval definition of truth as "*adaequatio intellectus* et *rei*," to Aristotle. But a conveniently precise and not overelaborate statement of it may be taken from G. E. Moore's *Some Main* Problems *of* Philosophy, lectures originally delivered in 1910–11 but not published until 1953.

Moore takes beliefs to be that to which the predicates "true" and "false" are applicable. He then proposes to show what the difference between true and false beliefs is, or what property there is uhich is common to all true beliefs but possessed by no false one. His argument proceeds as follows. Consider for example the (true) belief that Leeds is in Yorkshire. Now there is, Moore holds, between this belief and the fact that Leeds is in Yorkshire a certain relation, which that particular belief cannot be said to have to any other fact; there is, in general, such a relation between any true belief that p and the fact that p. Moore names this relation "correspondence" and proceeds at once to answer his questions. The difference between true and false beliefs is that every true belief, but no false belief, corresponds to a fact; the property common to all true beliefs is the property of corresponding to a fact, and no false belief possesses this property. Moore's conclusion is characteristically guarded. He does not insist that, when we say that a belief is true, we must mean that it has the property of corresponding to a fact. Nor does he deny that there may be other senses of the word "true" to which his observations would not apply. He definitely asserts only that very often, when we say truly that a belief is true, it in fact has the property of corresponding to a fact; though he is also inclined to believe that this is actually what is meant by saying that it is true.

One minor adjustment should be made to this account: there are objections to Moore's restriction of the discussion to beliefs. For, with this restriction, nothing could properly be said to be true or false unless someone believed it; whereas we may, for instance, quite properly ask whether it is true or false that fish can hear (presupposing that it is one or the other) without being obliged first to establish that anyone believes that fish can hear. This objection can be met (not without some harmless artificiality) by substituting "statement" for "belief." For though no doubt any statement is normally believed to be true at least by those who make it, it may be true even though no one believes that it is; nor perhaps is it excessively unnatural to say that there are true (and false) statements which no one has ever either made or believed. With this amendment. Moore's view may be briefly stated as follows: a statement is true if it corresponds to a fact and false if it does not correspond to a fact. This simple observation forms the foundation of any correspondence theory of truth.

The Coherence Theory. — This theory's traditional rival, the coherence theory, must next be briefly described, though. since there are at least two widely different versions of it and each raises very extensive problems, the description given here must be somewhat bald.

According to some idealist critics. of whom F. H. Bradley may be taken as representative. the correspondence theory errs fundamentally in taking any single statement whatever to be wholly true. To say that a statement is true if it corresponds to a fact is to assume. it was argued, that the statement. the fact and the relation between them can be properly assessed in absolute isolation; whereas in reality (or, in Reality) nothing whatever is thus separate from anything else. To suppose that there are facts each singly capable of being uniquely correlated with its own statement was held to be to impose upon reality a "mutilation"; indeed, according to Bradley, there are, strictly, no facts—if we try to find them, we get merely an "artificial extract," a "fragment" resulting from mutilation *(The Principles of Logic,* 2nd ed., p. 584, 1922).

There is thus, in reality, nothing for our ordinary statements, or "judgments," to correspond to. Though each purports to correspond to its distinct "fragment" of reality. reality in fact contains no fragments. Presumably there is. ideally, one exhaustive and all-embracing truth; but since no judgment that we can actually make can be thus exhaustive. our judgments may at best be partially true — fragments of an unattainable whole which alone would be adequate to reality. On this view. then, the correspondence theory is really a theorists' myth; its apparatus of distinct judgments and distinct facts is a tissue of "abstraction," a grave intellectualist misrepresentation of the actual character of reality.

A much later view, which has also been called a coherence theory, is that formulated by Rudolf Carnap in *The Logical Syntax of Language* (1937). But the motives underlying this theory differ from Bradley's. Two considerations can perhaps be picked out as its starting points. First, it was realized that there are occasions, particularly in scientific contexts, on which it is to some extent a matter of choice how observed phenomena are to be described, and the choice made is likely to be determined by the aim of maintaining the consistency, or "coherence," of some theory or symbolic system already adopted. Second, it mas felt (perhaps less explicitly) that, whereas the relations of sentences to each other seemed perfectly clear and intelligible, the relation between statements and facts alleged in the correspondence theory seemed only the more obscure and artificial the more closely one sought to examine it (this latter problem did not arise in Moore's treatment, since Moore made no attempt at all to analyze the relation which he called "correspondence"). It had been supposed that statements corresponded to facts in somewhat the same way as a picture corresponds to what it portrays, that facts and sentences had some identity of "elements" and of "structure"; but this view, taken seriously, was soon felt to be a hopeful myth rather than a statement of the actual case, nor was it thought that amendments of it offered much promise.

Accordingly, truth became identified with the consistency of propositions: a proposition is false if inconsistent with some chosen corpus of propositions, true if it can be consistently included in that corpus. Efforts were made, though they did not meet with much success, to explain how this corpus itself comes to be chosen.

Pragmatism. — Though regarded by idealists with scorn and detestation. pragmatism in fact displays, at least in its account of truth, important points of resemblance to Bradley's doctrine. For it expresses, as that doctrine did, dissatisfaction with the notions of "facts" and of "correspondence" to facts, as these notions were employed for instance by Moore.

William James in his *Pragmatism* (1907) did not deny that truth could be defined as correspondence to fact or to reality; but he regarded this as a mere item of lexicography, of no interest unless the further question were raised, in what correspondence to reality consists.

His own answer to this question is somewhat obscured by his preoccupation with colourful metaphor, but at least his general position is clear and indeed familiar: those beliefs are true which it is expedient for us to act upon and believe, and to say that they correspond to reality is only another way of saying the same thing. (*See* PRAGMATISM.)

Tarski's Semantic Conception. — This survey of theories of truth may be concluded with a brief account of A. Tarski's influential article "The Semantic Conception of Truth" *(Philosophy* and *Phenomenological Research,* vol. iv, 1944; also in *Readings in Philosophical Analysis,* edited by H. Feigl and W. S. Sellars, 1949). In the attempt, apparently, to avoid philosophical complications, Tarski construes the predicate "true" as being applicable to sentences; it forms part of a so-called "metalanguage" in which statements are made about the sentences of an "object-language."

Hence. he maintains, the notion of truth must always be related to a specified language, "for it is obvious that the same expression which is a true sentence in one language can be false or meaningless in another." He then introduces the technical notions of a "sentential function" and "satisfaction" of a sentential function by objects; defines a sentence as "a sentential function which contains no free variables"; and concludes that "a sentence is true if it is satisfied by all objects, and false otherwise." This definition he declares to be "formally correct" and "materially adequate"—the test of material adequacy being that it should imply all equivalences of the form "The sentence 'snow is white' is true if, and only if, snow is white."

It should be particularly observed that this definition of truth is offered as applying only to languages having a "specified structure." in the author's sense of that expression; and that "at the present time the only languages with a specified structure are the formalized languages of various systems of deductive logic." In spite of this evidently severe restriction. however. Tarski does "happen to believe that the semantic conception does conform to a very considerable extent with the common-sense usage," though he also considers this usage to be very gravely blurred by vagueness and possibly disrupted by ambiguity. He adds, moreover that. if the "philosophical problem of truth" is not to be formulated in some such question as he has undertaken to answer, nor solved by some such answer as he has supplied, then he does not know what this problem is — indeed he does not believe that there is such a problem.

He insists that all that his own definition requires is that. whenever for instance we assert or deny that snow is white. we must also be ready to assert or deny that the sentence "snow is white" is true. To this at least, he contends. there seems small possibility of objection.

General Considerations. — It is now possible to attempt some general assessment of the problem, in the light of the above-mentioned disparate and conflicting contributions to it. Let us first reconsider the question to what it is that we ordinarily apply the predicate "true."

Consideration of this question at once reveals the limited relevance of Tnrski's remarks. For it is clear that only in rare and peculiar cases can we say, as he would have us say, that a sentence is true (or false). For example, the words "The cat is on the mat" certainly constitute an English sentence; but clearly it is out of place to raise the question whether this sentence is true or false. For these words might be used on many occasions to say something true and on many other occasions to say something false; whether what is said is true or false will depend on the context (in a broad sense) in which the sentence is uttered, and unless some context is specified no question of truth or falsehood can arise. (This becomes obvious if one considers, for instance, the sentence "It rained yesterday.") There appear to be two cases in which we might say that a sentence is true or false: first. where a context of utterance is understood; and second, where the context of utterance does not matter. We might say. for example, "The very first sentence he uttered was untrue," where the sentence is understood to have been used on a particular occasion to make a particular assertion. An example of the second case might be, for instance, a sentence in a system of geometry, the truth of which is a matter solely of the rules of the system and not dependent on any other contextual factors. Here lve might well say that the sentence is "true in" that system, though of course it might not be true in another. It seems clear, partly from Tarski's observation that strictly we ought always to say "true in" a particular language and partly from his account of "formalized" languages of "specified structure." that his definition of truth was framed with an eye to cases of this latter kind; *i.e.*, cases where the context of utterance of a sentence may be neglected.

However. in ordinary spoken or written languages, cases of this kind are exceedingly rare and quite exceptional; nor, incidentally. is it in place to entertain the hope that a natural language. if suitably modified. might be somehow endowed with the necessary independence of context. It thus appears that Tarski's definition of truth is very far removed from "the common-sense usage." since the predicate "true" so defined could have hardly any (if any) application to languages ordinarily employed. It is not necessary to assert that there are no cases in which it is employed in the sense that Tarski defines. but at least it must be said that in enormously many familiar cases it cannot be supposed to be thus employed. An important indication of this is the fact that his expression "true in English" is not English.

Let us then return to Moore's observation that a belief or statement (not a sentence) is true if and only if it corresponds to a fact. What exactly, if any, are the proper objections to this? The idealist criticism has sometimes been said to rest on a simple confusion. on passing from the fact that no statement which we can make could he supposed to state the whole of the truth to the conclusion that no such statement can be wholly true. More fundamentally, however. it rests upon a metaphysical view of "reality" as an unanalyzable, indissoluble n-hole. which. however persuasively and powerfully presented, there is, we must state dogmatically, no need to share.

The later coherence theorists may be thought justified both in their contention that attempts to analyze the relation of "correspondence" were apt to prove unsatisfactory and also in their view that sometimes the aim of maintaining consistency with other propositions determines our choice of words to describe so-called facts: but they cannot but be thought mistaken in their evident implication that nonlinguistic phenomena can play no part at all in determining truth.

The pragmatist account in terms of the satisfaction of our interests could be held, it may be suggested. to explain our adoption of certain theories. or more generally our employment of certain conceptual systems, but it seems to he grossly out of place as an account of the truth of such simple, conceptually unperplexing statements as "The cat is on the mat."

However. it may well be felt that William James was justified in objecting to the correspondence theory as unilluminating, as hardly more than an item of lexicography. The crux of this objection would be that the notions of "truth" and of "fact" are not independent.

Facts cannot be conceived as nonlinguistic objects *about* which we make statements; on the contrary, they are *what* we may be said to state when we make true statements and may themselves be said to be *about* that of which we are speaking. If so, the project of defining truth in terms of facts, although it can hardly be mistaken. can make almost no progress; for the notion of "fact" already includes exactly those features of the notion of "truth" which require elucidation. What is presumably required is an account of the relations between the words which we use in making statements and the things (persons, events. etc.) *about* which we speak and *of* which what we say is true or false. But if we confine our attention to statements and iacts. these relations are not brought into view at all.

More importantly. it is misleading to suggest that when a true statement is made. there is between the words and the world just one relevant relation, called "correspondence." For: as J. L. Austin points out (in the Aristotelian society's *Supplementary Volume* xxiv. p. 116), it is important to distinguish. even in the simplest subject-predicate statement, at least two radically different types of correlation between words and world: (1) that of "demonstrative" conventions, which dztermine what our words are taken to be referring to; and (2) that of "descriptive" conventions, which determine what we are understood to be saying *about* that to which we refer. He further points out that the name "correspondence" is liable to suggest the relation which a portrait bears to,its subject, or a map to the ground. whereas both these relations are fundamentally unlike the conventional relations between things and words. It is not in virtue of any natural, pictorial. or structural similarity between words and things that words spoken or written may be "true of" things; that they may be so is a matter of the existence of rules or conventions for the employment of words. The philosopher's task is to elucidate the nature and working of these conventions. for instance by comparison and contrast with the conventions of map making or signaling, and with the use of other linguistic predicates such as "accurate," "vague" or "exaggerated." This P. F. Strawson (*Supplementary Volume* xxiv, p. 142) has called the problem of "elucidating the fact-stating type of discourse." It is to this problem that the traditional correspondence theory must be supposed to have made its misleading, indeed almost nugatory, contribution.

It is now, perhaps, natural to suppose that. if a satisfactory account were given of the ways in which the words of a true statement are related to that about which it is made, we could conclude that. in saying that the statement is true. one is asserting that those relations obtain; *i.e.*, to suppose, in other words. that an elucidation of the fact-stating type of discourse comes essentially to the same thing as a definition of the predicate "true." Strawson, however, argues forcibly that'this is not so. Although, he contends, the words used in making a true statement of course are related in diverse ways to that about which the statement is made, to say that the statement is true is not to state that they are so related; it is rather to agree with what the maker of the statement has said.

To say "That is true" is neither to make the same statement as that the making of which is the occasion for one's so saying; nor is it to make a different statement, namely about the relations between the words used and the world. It is rather to endorse (or confirm, or admit, or concede, according to context) what has been said. The words "That is true" might often be replaced satisfactorily by "Yes" or "I agree." The problem of elucidating the nature of the empirically informative type of communication must be distinguished, Strawson maintains, from that of determining the functioning of the word "true" within the framework of that type. On this view, the "problem of truth" as traditionally conceived should be further divided into at least two problems: first, that of examining "the fact-stating type of discourse"; and second, that of describing our actual employment of "true." *See* also Index references under "Truth" in vol. 24. (G. J. WK.)

TRUXTUN, THOMAS (1755–1822), U.S. naval officer, was born at Jamaica, Long Island, N.Y.. Feb. 17, 1755, and, at the age of 12 went to sea in the London trade. During the Falkland Island war scare (1770–71) he was impressed for a short space in the British navy. At the outbreak of the American Revolution he was engaged in importing powder, but turned early to privateering.

From 1777 to the close of the war, he commanded letters of marque bringing supplies from France and the West Indies. and won a number of hard-fought engagements with enemy vessels. He engaged in the China trade during the peace years, and was appointed a captain in the new U.S. navy by President Washington in 1794. He superintended the building of the frigate "Constellation" at Baltimore, and commanded her during most of the quasi-war with France.

Truxtun won naval renown on Feb. 19. 1799, when he took the French frigate "Insurgente" in a spectacular fight off Antigua, and added to his reputation a year later when he defeated the

French frigate "Vengeance," and drove her into Curacao. His resignation from the command of a fleet planned to combat the Barbary pirates in 1802 was interpreted by the secretary of the navy as a resignation from the navy itself. Highly incensed and cherishing the supposed slight, Truxtun refused overtures from the navy department during the War of 1812. He engaged successfully in Pennsylvania politics until his death in Philadelphia on May 5, 1822.

See *Quasi-War With France* and *Barbary Wars* (1935–1942); John Frost, *The Pictorial History of the American Navy* (1854).
(W. B. Ck.)

TRYON, DWIGHT WILLIAM (1849–1925), U.S. painter of delicate New England landscapes, was born at Hartford, Conn., Aug. 13, 1849. In 1876 he went to Paris for study; rejecting Impressionism, he chose for his principal teacher Jacquesson de la Chevreuse, the favourite disciple of J. A. D. Ingres. After his return to the United States (1881), he taught first in Hartford and from 1885 at Smith college, Northampton, Mass., where the art gallery bears his name. He became a member of the National Academy of Design in 1891. Extravagantly praised while alive, his work later seemed to appear unduly repetitious in colour and design. He died at South Dartmouth, Mass., 'July 1, 1925.
(Vl. B.; X.)

TRYPANOSOME, the common name for single-celled parasitic flagellated animals of the genus *Trypanosoma*. As adults they are mostly blood parasites of vertebrates, especially fish, birds and mammals. Most species require an intermediate host (often an insect or a leech) for completion of the life cycle. African sleeping sickness of man is due to *Trypanosoma gambiense* or *T. rhodesiense,* both transmitted by tsetse flies. In South and Central America *T. cruzi* (agent of Chagas' disease) and the innocuous *T. rangeli* are both transmitted by bloodsucking bugs. Other species induce economically important diseases of livestock: nagana, surra, mal de caderas and dourine. *See* also Parasitic Diseases; Protozoa; Sleeping Sickness; Trypanosomiasis. (T. C. v. B.)

TRYPANOSOMIASIS (American or Brazilian Trypanosomiasis, or Chagas' Disease) is a disease condition produced by a flagellate protozoan, *Trypanosoma* (or *Schizotrypanum) cruzi,* transmitted to man by a bloodsucking bug. The causative agent was discovered by Carlos Chagas in Brazil in 1909 in the intestine of the bug *Panstrongylus megistus*. Chagas named it in honour of Oswaldo Cruz, a prominent Brazilian microbiologist. Later he found the parasite in the blood of patients who were thought to be suffering from atypical forms of malaria and described the main clinical and pathological aspects of the disease.

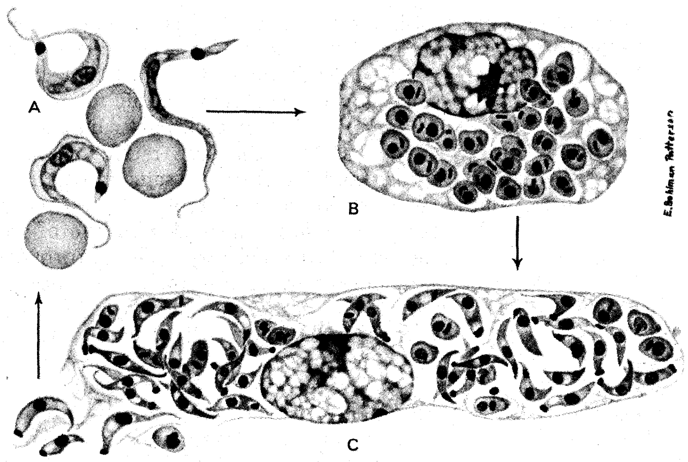
Natural **History.**—Trypanosomiasis is endemic in most rural areas of Central and South America, especially in Brazil, Argentina and Chile, where infection rates of over 10% are reported. Only sporadic cases have been reported from Mexico and one indigenous case from the United States. Many mammals, especially dogs, cats and rodents, may be infected and act as reservoirs of the infection.

The insect vector belongs to the Reduviidae, a family of the order Hemiptera, which includes the true bugs. The commonest species involved in the transmission of Chagas' disease are *Triatoma infestans, Panstrongylus megistus* and *Rhodnius prolixus*. The bugs infest huts and rural dwellings made of mud or adobe, hiding in cracks of the walls during the day and feeding nocturnally on sleeping persons by biting exposed areas of the skin, especially sites where the skin is thin. One of the preferred places is the eyelids. Such species as *Triatoma protracta*, which exist in the southwestern United States, particularly in Texas and California, seem to be less adapted to live in human houses, and this fact probably explains the low incidence of Chagzs' disease in North America.

The insect vector becomes infected by sucking the blood of an infected mammal. Trypanosomes, upon entering the bug's intestine with a blood meal, transform into developmental stages and reproduce intensively. Later, infective trypanosomes appear in the posterior gut of the insect and are eliminated with feces. As the insects regularly defecate while sucking blood, the wound made by the bite is easily contaminated. Also trypanosomes may penetrate undamaged mucous membranes.

The complicated life cycle of this trypanosome in the vertebrate host includes nonreproducing trypanosome stages that are found in the blood (*see* fig. [A]), and reproductive stages that are found in the cells of different tissues. The reproductive stages are small rounded bodies, without flagella (fig. [B]), resembling the protozoa of the genus *Leishmania,* which cause leishmaniasis. T. *cruzi* can infect any cell, but prefers connective-tissue cells and muscle fibres, especially those of the heart.

Disease in Man.—An incubation period of about one week follows the first inoculation of *T. cruzi,* after which local signs appear at the site. Frequently the disease begins with an edematous swelling of the eyelids on one side of the face, where the bug has contaminated the conjunctiva or the eyelids. The lymph nodes near the ear and in the neck and the tear gland are usually enlarged. The patient may have fever and prostration for several weeks. Children sometimes develop severe reactions with generalized edema. high fever and heart and nervous symptoms. Following



(B) AND (C) REDRAWN FROM W H TALIAFERRO AND T PIZZI, CONNECTIVE TISSUE REACTIONS IN NORMAL AND IMMUNIZED MICE TO A RETICULOTROPIC STRAIN OF TRYPANOSOMA CRUZI" IN 'JOURNAL OF INFECTIOUS DISEASES", BY COURTESY OF THE UNIVERSITY OF CHICAGO PRESS

DIFFERENT STATES OF TRYPANOSOMA CRUZI IN THE MAMMALIAN HOST (MAGNIFIED 1,500 TIMES; SPECIMEN STAINED WITH HEMATOXYLIN-EOSIN-AZURE II)

(A) Nonreproducing trypanosome forms in the blood; (B) reproducing leishmanialike forms in a macrophage of the spleen; (C) transformation of leishmanialike forms into trypanosome forms In a fibroblast of the skin just before reentering the blood

this acute stage, the disease may enter a chronic stage, characterized chiefly by heart symptoms, mainly disturbances of the rhythm. Sometimes heart failure occurs due to the development of the parasite in the muscle fibres of the heart and to the accompanying inflammatory reaction. The infection may end in death, or the course of the disease may be mild with recovery. In Chile and other countries of the Pacific coast and in Central and North America. the disease is generally mild.

Diagnosis is usually made by finding the parasite in the blood, either directly in acute cases or indirectly by inoculating blood into animals. Uninfected reduviid bugs may be applied to the patient, and the insect feces may later be examined. Serological reactions. such as the precipitin test, are useful during the acute stage, and complement fixation is of value during the chronic stage.

No known drug will cure infections with T. *cruzi*. Some quinoline derivatives, mainly primaquine (*see* Malaria), have a transient suppressive action. Prevention and control are centred in providing "insectproof" houses and in eliminating the insect host by insecticides. *See* also Parasitic Diseases; Sleeping Sickness.

(T. P. P.)

TSAIDAM (ZAIDAM), a mountain basin south of the Nan Shan in Tsinghai province, China, covering about 50,000 sq.mi., with its floor at an elevation of nearly 9,000 ft. It is covered with thinly grown marsh, brackish lakes and, in the east, some salt lakes.

In the east salt is produced by evaporation, and the upper slopes of the basin provide grazing for goats, sheep and horses. The basin is sparsely populated.

The Peking government built a new motor road east-west along the northern margin of the marshland and another north-south through the marsh. In the late 1950s successful exploratory drilling for petroleum was carried out along the northern marsh margins. (J. E. SR.)

TSANKOV, ALEKSANDR (1879–1959), Bulgarian statesman, was born in 1879 in the town of Oriakhovo and studied law at Sofia university, where he became professor of economics. In 1922 he became leader of a small group called the National Concord (Naroden Zgovor), drawn from the intelligentsia of the various political parties and the mass of former officers, which aimed at combining the dispersed national forces for a struggle against the semidictatorship of Aleksandr Stamboliski. To him fell the premiership of the coalition government, representing all the political parties except the Communists, that took power on June 9, 1923, after a military coup *d'état,* in the preparation of which Tsankov's National Concord had its share. Tsankov remained prime minister until 1926, when he was replaced by Andrei Liapchev (*q.v.*). His tenure of office coincided with one of the most tragic periods in modern Bulgaria's history. The disturbance that broke out after Stamboliski's overthrow took thousands of lives. On Sept. 9, 1944, after Soviet troops had occupied Bulgaria, Tsankov formed a National Bulgarian government in Austria under German auspices and tried to recruit a volunteer corps. The advance of the Russians put an end to these efforts; Tsankov surrendered to the U.S. forces and, for several months, was interned at Kitzbuhel in Austria. Later, he was released and emigrated to South America. From 1948 he lived in a suburb of Buenos Aires, Arg., where he died on July 17, 1959.

TSCHAIKOVSKY, PETR ILICH: see TCHAIKOVSKY, PETR ILICH.

TSCHUDI, GILES or AEGIDIUS (1505–1572), Swiss historian, a zealous Catholic, who became the chief magistrate or *landammann* of Glarus in 1558, and in 1559 was ennobled by the emperor Ferdinand, to whom he had been sent as ambassador. He is best known as the historian of the Swiss Confederation. His great work is the Chronicon *helveticum,* or Eidgenossche Kronik, dealing with the period from 1000 to 1470. In spite of its many inaccuracies, falsifications and acceptance of baseless legends (comp., *e.g.*, the article, TELL, WILLIAM) this work is one of great interest and merit, and was long considered the leading authority on its subject. It enshrines the text of many ancient documents that would otherwise have been lost.

Tschudi's chief works were not published until long after his death. The Beschreibung Galliae Comatae appeared under Gallati's editorship in 1758, and is mainly devoted to a topographical, historical and antiquarian description of ancient Helvetia and Rhaetia, the latter part being an early work on Rhaetia revised and greatly enlarged. This book was designed practically as an introduction to his magnum opus, the Chronicon helveticum above mentioned, which was published by J. R. Iselin in two stately folios (1734–1736).

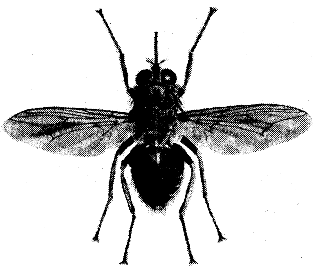
See Lives by I. Fuchs (1805) and C. Vogel (1856).

TSENG KUO-FAN (1811–1872), Chinese scholar, military leader and statesman, was born Nov. 26, 1811, at Hsiang-hsiang, Hunan province, of a peasant family. Tseng studied for the Imperial examinations and passed the first in 1833, one year after his father passed the same examination. In 1838 Tseng passed the highest examination at the capital and became a Han Lin academy member. After holding high office in several central government ministries he returned home in 1852 to observe mourning for his mother. During this period the T'ai P'ing rebellion (1851–64) had spread through central China and the rebels established tneir capital in Nanking in 1853. Since the corrupt imperial troops were too weak to resist the rebels, the government encouraged members of the scholar-gentry to organize local self-defense corps in their home areas. Tseng became the most outstanding of these new military leaders. He not only established a local corps but combined the units formed by several scholars in his home district into a regional army. This army, paid and equipped by voluntary contributions and local funds, was loyal to Tseng and his officers. Tseng's example was followed by other regional leaders such as Tso Tsung-t'ang and Li Hung-chang who first served on Tseng's staff and then organized their own regional armies under Tseng's general direction. Beginning in 1860, the imperial government found it necessary to appoint the new military men as governors general and governors of the provinces that their troops occupied. The armies of Tseng wrested from the rebels their supply areas along the upper Yangtze and finally besieged and captured their capital, Nanking, in 1864.

After the defeat of the T'ai P'ing, Tseng devised the strategy, carried out by Li Hung-chang, for defeating the Nien rebellion in northern China. Tseng and other regional leaders were loyal to the imperial government, but the autonomy of regional political and military organizations established by them remained after the rebellions were suppressed and led eventually to the downfall of the dynasty. Tseng died on March 12, 1872. Tseng was a voluminous writer and his collected works were edited and published after his death by Li Hung-chang. (F. H. MI.)

TSETSE FLY, any of 21 species of African bloodsucking flies of the genus *Glossina,* family Muscidae (see FLY), certain of which are of great medical and economic importance as carriers of human sleeping sickness and of a similar disease in domestic animals.

In Africa these insects are usually known simply as fly, or tsetse, a name from Bechuanaland, meaning a fly that destroys cattle. As the flies readily attack man, his herds and his beasts of burden, it seems probable that the relatively slow development of agriculture, communications and other practices of modern civilization in tropical Africa has been in large measure due to the widespread presence of the tsetse in that region.



BY PERMISSION OF THE BRITISH MUSEUM (NATURAL HISTORY)

TSETSE FLY (GLOSSINA PALPALIS), FOUND IN WEST AND CENTRAL AFRICA. ENLARGED ABOUT 2 TIMES

All species of tsetse are similar in appearance, being robust, sparsely bristly flies, usually somewhat larger than the related housefly, although ranging in length from 6 to 16 mm. Their colour varies from yellowish brown to dark brown; the thorax often is grayish above with darker markings, and the abdomen sometimes is banded. The stiff, piercing mouthparts, directed downward as the fly bites, are at other times held horizontally, ensheathed by the elongate maxillary palps and giving the appearance of an unusually conspicuous proboscis. In repose, the wings are held flat over the back. A bristlelike appendage (arista) on the antenna bears a single row of long, branched hairs. These characteristics apply equally to both sexes of Glossina and differentiate them from all other flies.

Tsetse flies ordinarily live one to three months, occasionally longer, the life span depending on many environmental factors. All species bear their young alive. A larva, hatched from an egg within the female fly, feeds on a nutrient fluid secreted by paired "milk glands" on the uterine wall. Embryonic development and three stages of larval growth require about nine days. Without a sufficient blood meal, the female fly will produce a small, underdeveloped and nonviable larva; when adequately fed, however, she will produce a fully matured larva about once every ten days throughout her life.

Larvae are usually deposited near food sources, as along shaded game trails or near resting places of reptiles or mammals. The larva takes no further food but burrows into the ground and pupates within an hour. Several weeks are required for the development of the adult within the pupal case.

Species of tsetse vary in their environmental requirements. In general they occur in woodlands, although they may fly out a short distance into open grasslands when attracted by the sight of a host animal.

The flies have a discontinuous distribution corresponding to the irregular occurrence, in areas known as fly belts, of characteristic associations of trees and shrubs comprising their particular appropriate environment. *Glossina palpalis,* a species of medical importance, occurs primarily in dense stream-side vegetation, while G. *morsitans,* in contrast, feeds in more open woodlands.

Both sexes suck blood, feeding almost daily, especially in the brightest, warmest part of the day. Although some tsetse bite at night, most of them cease activity soon after sunset, or at temperatures below 60° F. Of the flies attacking man usually 80% or more are males; the females seem more attracted to larger animals.

The genus *Glossina* occurs from Gambia eastward through Nigeria to western Abyssinia, southeastward through Kenya and Uganda to Mozambique, and southward through the Belgian Congo to northern Angola. One species has been found in the southwestern Arabian peninsula. Within this vast area the distribution of tsetse is largely governed by vegetation and climate. Although the genus is now virtually restricted to Africa, four fossil species in Miocene deposits (about 21,000,000 years oid) of North America indicate a once widespread distribution.

Only two species of tsetse commonly transmit the flagellate protozoan parasites (trypanosomes) causing human sleeping sickness (*q.v.*). Taken up in a blood meal by the fly, these microscopic blood parasites may be transferred unchanged from one host to another within a couple of hours, but otherwise they undergo a transformation within the fly's body, passing from the alimentary tract to the salivary glands. The fly once more becomes infective after 11 to 18 days. When the tsetse bites, it injects saliva into its host to prevent blood coagulation, and during this process trypanosomes are transferred. In this way, *Glossina palpalis* of western and central Africa infects man with *Trypanosoma gambiense,* one of the trypanosomes causing sleeping sickness.

When this disease was first introduced into eastern Africa, however, its virulence was much greater; between 1901 and 1906, there were in Uganda an estimated 200,000 deaths from sleeping sickness, a frightful toll representing probably two-thirds of the human population of the affected region. Sleeping sickness in east-central Africa is usually caused by *Trypanosoma rhodesiense,* carried by *Glossina morsitans*. Although relatively rare and of local occurrence, this form of sleeping sickness is more severe and is often fatal within a few weeks or months. *Trypanosoma brucei* and two other trypanosomes cause nagana, a wasting disease in cattle but usually fatal to horses. Certain wild game, particularly ungulates such as antelope, are regarded as the natural reservoirs of trypanosome infection, although they themselves seem unaffected by the parasites.

The most effective control of the flies has been environmental — destruction of wild game, clearing of woodlands, and periodic burning to prevent growth of brush. Fly trapping, control by natural parasites, and application of insecticides to livestock have not been successful. Aerial sprays of residual insecticides have given inconclusive results.

Bibliography.—P. A. Buxton, *The Natural History of Tsetse Flies,* an Account of the Biology of the Genus *Glossina* (Diptera) (1955) ; R. Newstead, A. M. Evans and W. H. Potts, *Guide to the Study of Tsetse-Flies (1924).* (G. W. Bs.)

TSIMSHIAN, an American Indian linguistic stock on Nass and Skeena rivers and Milbank sound, British Columbia. They are typical north Pacific coast tribes, forming, with the Tlingit, the Haida and certain Athabascans of the adjacent interior, a matrilineal sub-culture group.

The four Tsimshian phratries, Raven, Wolf, Eagle and Grizzly Bear, are distributed through the three tribes composing the stock, namely Tsimshian proper, Niska and Gitksan. Population, originally estimated, 7,000; 1906, 3,700.

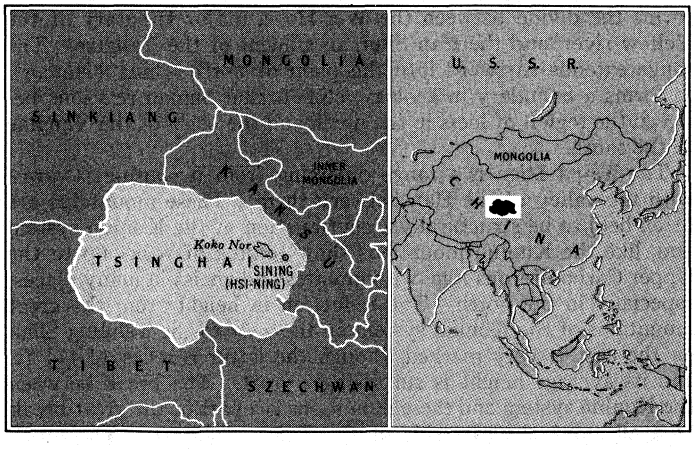
TSINAN (Chi-nan), the capital of Shantung province in north China. Pop. (1957 est.) 862,000. Tsinan is situated at the northwestern corner of the Shantung highlands (near T'ai Shan, China's most sacred mountain), at the edge of the hill country, along a line of springs which fostered very early settlement. Its history is bound up with that of the ancient states of Chi and Lu in the classical (Chou) period, and almost continuously it has been a regional centre and political capital of importance. With the creation of the modern Shantung province during the Ming dynasty (1368–1644) — closely corresponding to the territory of the two feudal states — Tsinan became the political capital. The return of the Hwang Ho (Yellow river) to a course north of Shantung in 1852 brought the river within five miles of the city and augmented its strategic location for modern affairs.

Tsinan was brought into contact with foreign trade through the building of the railway (1899–1904), by German interests, from Tsingtao to a point very close to the city. The city was voluntarily opened to foreign commerce in 1904, and a suburban settlement was created outside the old city. Though not a treaty port, the foreign population grew to sizable proportions, and the participation of foreign concerns in local trade helped to make Tsinan one of the most westernized of the large cities of China. With the completion of the Tientsin-Pukow (P'u-K'ou) railway in 1912 Tsinan became a rail junction, and the city became an important regional trading centre for one of the most productive portions of the north China plain. Though the Yellow river and other local waterways are not fully navigable, small-boat traffic has focused on Tsinan. Because there was ample coal not far away, silk and cotton textile manufacturing, flour milling, vegetable oil extraction and a variety of light manufacturing developed. A government arsenal set up near Tsinan caused the city to be the military objective of contending factions between 1915 and 1937, when it was occupied by Japanese forces and held until 1945; it was seized by the Chinese Communists in 1948. The Communists have not earmarked Tsinan for spectacular expansion. but iron and steel manufactures and heavy machinery and chemical (soda ash) industries have grown steadily. (J. E. Sr.)

TSINGHAI (Ch'ing-hai Sheng), province of northwestern China, in the Tibetan highlands. Area 278.378 sq.mi., pop. (1957) 2,050,000. About 90% of the territory consists of mountains and high plateaus, whose sparse grasslands are used for livestock raising. Animal products (sheeps' and yaks' wool and hides) make up a large part of the provincial economic production. The stock herders (about 440,000 in 1953, or 27% of the total population) are made up of non-Chinese minorities, Tibetans, Mongols and Kazakhs, who inhabit their own autonomous areas. Crop raising is largely limited to the northeastern corner east of Koko Nor (*q.v.*) and around Sining, where the province's Chinese population (approximately 1,000,000) is concentrated. Farming in this area is also the main occupation of some ethnic minority groups, Chinese Muslims, Tu and Salar, based within their own areas of national autonomy.

Food crops include spring wheat, millet and barley. Tsinghai

TSINGHAI PROVINCE. IN THE TIBETAN HIGHLANDS OF CHINA



is traversed from east to southwest by a truck highway linking Lanchow, in Kansu province, with Lhasa, in Tibet. Construction of a railroad from Lan-chou to Hsi-ning began in the late 1950s. Under the Communist regime, an intensive petroleum-exploration program was organized in the Tsaidam (*q.v.*) basin of northwestern Tsinghai. The Five-Year plan of 1958–62 called for a production of 3,000,000 tons of crude oil by 1962. Other mineral resources include coal, mined at Ta-t'ung north of Hsi-ning, borax and salt from the numerous salt lakes. Hsi-ning (1953 pop. 93,700), the provincial capital, was the only large city of the province. Tsinghai became a province in 1928 when the Hsi-ning area was detached from Kansu. (T. SD.)

TSINGTAO (CH'ING-TAO), city and port on the south coast of Shantung province, China, situated on Kiaochow bay (Chiaochou Wan), an iniet of the Yellow sea. It is connected by a railroad with Tsinan, an inland city, 190 mi. W.N.W. Kiaochow bay was occupied by Germany after the murder of two missionaries in Shantung in 1897, and negotiations followed, resulting in a lease of land to Germany for 99 years. The area leased was about 117 sq.mi. and all points within 32 mi. of any point on the bay were held not to be affected by Chinese ordinances without German consent.

A free port was created at Tsingtao in 1899, and a branch of the Imperial Maritime customs was established there for collection of duties on shipments to and from the interior. The German government built up the city of Tsingtao, and created educational and agricultural institutions in the leased territory. After Japan had declared war on Germany in World War I, the first Japanese objective was the reduction of Tsingtao, which served as an operational base for German sea marauders menacing Allied trade routes in eastern Asia. In August, 1914, the Japanese navy began a blockade of Tsingtao, and the following month, Japanese troops landed at Lung-k'ou (Lungkow), on the north coast of Shantung, and advanced on the German stronghold. The Japanese were fortified by a British force and on Nov. 7, 1914. Tsingtao capitulated after a week-long attack on its land positions and bombardment by the Japanese blockading fleet. Japan held Tsingtao until 1922, when the port was handed over to China under the Washington agreement.

During the Chinese-Japanese war, Japan again seized control of the port in 1938 and held it until 1945. During the Nationalist-Communist hostilities following World War II, Tsingtao was briefly headquarters of United States naval forces in the Pacific until the Communist conquest of the mainland.

Under the Communist regime, after 1949, Tsingtao's industries provided a major base for the industrial construction effort in the interior. The city has a large cotton-milling industry, paper mills, oilseed and flour mills, as well as locomotive and rolling stock shops, shipyards and a rubber tire factory. Many industrial plants are situated in the suburbs of Ssu-fang (Szefang) and Ts'ang-k'ou (Tsangkow), north of the city proper. Tsingtao is a major fishing port, with extensive saline deposits nearby. It is the seat of Shantung university, and has an Institute of Technology. Pop. (1953), 916,800; (1957 est.) 1,121,000. (T. SD.)

TSINLING SHAN (CH'IN LING), a range of mountains which forms the divide between the Wei Ho, a major tributary of the Yellow river, and the Han Shui, an affluent of the Yangtze. The range extends eastward into the plain of north China (Honan). It forms a boundary in geology, climate and human relations between the region of loess in the north and the basin of the Yangtze to the south.

The Ta-pa Shan is a range diverging from it south-eastwards, with the valley of the Han between them. These mountains are often held to be structurally a continuation of the Kunlun system and, like the Kunlun mountains show folding of rocks up to the Upper Carboniferous Age, with granites and gneiss in many places, especially in the north. The reduction in height from the great mountains of the Kunlun system on the west to the Tsinling Shan on the east is very marked, though the latter reaches 13,474 ft. and its average height is surprisingly great. The break between the Kunlun system and these mountains is a part of the great break seen all along the east side of the Tibetan plateau. The north face is very steep and loess reaches up to about 3,300 ft. above sea level at places along it. The top of the range is broad, with sharp heights. The south face has rounded heights and wild, deep-cut valleys.

Despite its size and height the range is essentially one mass, not a complex of chains such as found in the Alps. (T. SD.)

TSO TSUNG T'ANG, one of the high scholar-officials in China who made their careers as military leaders in the suppression of the great rebellions that threatened the imperial government during the second half of the 19th century. Born in Hunan province in 1812 of a scholarly family of moderate means, Tso passed, at an early age, the examination which admitted him to the privileged scholar-gentry group.

When the T'ai P'ing rebellion broke out in 1850 Tso helped organize local defense forces against this uprising. He joined the staff of Tseng Kuo-fan (*q.v.*), and as commander of a major branch of Tseng's Hunan army, drove out the Taiping rebels from Chekiang and Fukien and was appointed governor-general of the two provinces in 1863.

In 1866 he was sent to Shansi and Kansu as governor-general to fight the Moslem rebels there. After recovering the provinces by 1869 Tso argued in favour of the reconquest of Sinkiang from the rebel Yakub Beg since, without the control of the Sinkiang frontier passes, China's whole inner Asian position would collapse. In a brilliant campaign started in 1875 he succeeded not only in destroying Yakub Beg but in re-establishing Chinese power so convincingly that China regained, in the Treaty of St. Petersburg in 1881, the important border passes which Russia had occupied during the Moslem rebellion.

In 1882 Tso was appointed governor-general of Liang Kiang and in 1884 he was placed in charge of China's defense in the war with France. He died at Fuchow on Sept. 5, 1885. *See* also CHINA: *History: 19th Century and Revolution.* (F. H. Mr.)

TSU, industrial city and capital of Mie prefecture, Japan, originated in an ancient castle town on Ise bay. Between 1940 and 1960 its area expanded from 9 sq.mi. to 31 sq.mi. and the population from 68,600 to 110,900. Textiles woven frorn cotton and artificial fibres are the chief industrial products.

There are two large temples Kannonji and Shitennōji. The latter rebuilt in 1615, marks the site of one of the earliest Buddhist temples of Japan. (C. A. MR.)

TSUSHIMA, a group of five rocky islands in Nagasaki prefecture, Japan, located in the strait separating Japan and Korea. The islands divide the strait into the Eastern channel or Tsushima strait, 56 mi. wide, and the Western channel or Korean strait (formerly called the Chosen strait), 56 mi. wide. The warm Tsushima current, a branch of the Japan or Kuroshio current, flows through the straits into the Sea of Japan. The five islands, the largest of which are Kamiagata and Shimoagata, have a total land area of about 274 sq.mi. Between 1940 and 1960 the population increased from 56,600 to 69,556. The principal towns are Izuhara, the administrative centre, and Keichi. Most of the people are fishermen.

Japanese mythology credits the creator gods with producing Tsushima as one of the original islands of Japan. The islands played a critical part in history as a steppingstone between Korea and Japan. Archaeological evidence shows this was a route followed by ancient men in their migration to Japan. Throughout its early history Tsushima was raided by Korean and Japanese pirates. From the 12th century to the Restoration of 1868 the islands were the fief of the Sō family who were *daimyo* (feudal lords) and frequently acted for Japan in diplomatic relations with Korea. During the Mongol attempt to invade Japan in 1274 and 1281 the population was massacred. In 1861 Russia made an unsuccessful attempt to secure concessions. A Japanese fleet under Adm. Heihachiro Togo completely defeated a Russian fleet under Adm. Z. P. Rozhdestvenski in the battle of Tsushima (May 27–28, 1905), north of the islands. (C. A. MR.)

TSWANA, or BECHUANA, are the westerly division of the Sotho- (Bantu-) speaking people of South Africa. They are thought to have emigrated from northeastern Africa and to have arrived in the area of eastern Bechuanaland and southern Transvaal by A.D. 1600. A process of dispersal and fission was accelerated during the 19th century by a series of invasions by Sotho, Nguni and Europeans, as a result of which the various Tswana people lost much of their territory. In the second half of the 20th century they comprise several groupings, the most important of which are the Hurutshe, Kgatla, Kwena, Rolong, Tlhaping and Tlokwa.

Tswana are to be found in western and central Transvaal, British Bechuanaland and at Thaba Nchu, all within the Union of South Africa, and in the Bechuanaland Protectorate, especially its eastern and northern peripheries. Within this area, the Okovango depression is the home of the Tawana (Kwena) tribe; the Motloutse basin is occupied by the Ngwato (Kwena) with their alien dependents; the Limpopo-Molopo watershed and its eastward extension into the Crocodile river basin supports concentrations of Kgatla, Ngwaketse (Kwena), Tlokwa and Malete living on tribally owned land or on European farms: and the Kuruman-Molopo river area is occupied by Tlharo (Hurutshe), Rolong and Tlhaping. The Tswana number about 750.000, of whom 580.000 live in South Africa. Bechuanaland has about 167,000 Tswana, but it is usual to add about 100,000 who, though subject to Tswana tribes, are ethnically, culturally and linguistically heterogeneous.

Tswana live in a grassland environment in which they practise animal husbandry (their main interest) and a precarious subsistence agriculture. Livestock kept include sheep, horses, donkeys and cattle, the index of wealth and status. Basic crops are maize and sorghum. The plough is in general use and both men and women are employed in agriculture. Game is sufficiently plentiful in the Bechuanaland Protectorate to permit casual and professional hunting as a profitable supplementary activity. This simple peasant economy is complicated by the seasonal and periodical migration of large numbers of men to work at the mining and industrial centres of South Africa. All three aspects of modern Tswana economy disturb the routine of settled home life: herd boys are obliged to spend long periods at grazing camps distant from their homes; fields are usually far away from villages so that, during the cultivating season, family units live in temporary huts on their own arable land; and the demands of wage earning take the younger adult men out of the country for periods of nine months or more at a time.

Tswana material culture reflects the widespread intrusion of European goods and standards. House forms range from the traditional circular single-roomed dwelling with a conical thatched roof to the multi-roomed, rectangular house roofed with corrugated iron. Transport similarly varies from ox-drawn sledges to motor vehicles. European dress prevails generally.

The Tswana language is the common tongue, but many other African languages are in everyday use by the numerous alien communities. English and Afrikaans are in frequent use. Tswana literature, including regular newspapers, was becoming increasingly available in the second half of the 20th century to meet the needs of a growing literate population. Christianity is the official religion of most tribes and, of the traditional cults, ancestor veneration alone survives. Greater resistance to change is displayed by beliefs in traditional medicinal practices and the magic of hate and spitefulness: the curing of sickness, the protection of person and property and the safeguarding of crops and livestock all have their general practitioners, diagnosticians and specialists, who continue to play an important part in everyday life, but malevolent and deliberate use of harmful medicines is distinguished from a fictional belief in the activities of witches.

Historical and cultural differences within the whole Tswana population are expressed through a system of descent groups. Every Tswana is affiliated to the descent group of his father, each group being associated with a distinctive symbol which serves as a polite mode of address and sometimes as a surname. These groups, which are neither corporate nor localized, are not to be confused with marriage regulating groups. They are carriers of historical and cultural tradition, each being differentiable from others in terms of myths of origin, variations of ritual and customary practices and of slight dialectical differences.

Social Organization. — This varies with circumstances and the following details refer particularly to those Tswana living in self-administering political units, and especially in the Bechuanaland Protectorate. The essential social unit is the ward, a readily identifiable, self-contained, social and administrative entity, comprising a number of lineally related family groups together with their dependents and servants. Its leader is usually the head of the senior family. It is always territorially distinct, forming a residential group of the small village pattern when in a rural setting and of the precinct pattern within larger villages and tribal capitals. Within the ward, the smallest kinship group is that of the simple family; more important and more self-sufficient is a group consisting of a simple family together with a number of dependent close relatives and occupying a homestead enclosed within a single wall or fence. In the case of polygynous marriage, each wife usually has her own homestead. Several homesteads, the heads of which are lineally related, frequently congregate and form homestead clusters of varying size. Such groups of homesteads are usually laid out in a circular plan, enclosing an open space which serves as meeting place, court and administrative centre.

Kindred groupings, embracing all people who are related by ties of descent and marriage, are wider in territorial range and less concentrated than kin and residential groups. Their greater dispersal is partly a product of marriage rules and practices. Among the Tswana, there exists no formal objection to first-cousin marriage: marriage with cross cousins is more highly favoured than that with ortho-cousins and, among the latter, marriages with a mother's sister's daughter are rare. In practice, however, most people marry nonrelatives and so help to unite members of many different wards into loose, unformalized but practical associations. Age distinctions serve to build up associations cutting across ward loyalties. Adult status depends upon admittance to a formal age set or regiment, a parallel organization permitting the differentiation of males and females. New regiments are formed periodically on a tribal basis, each commanded by a member of the tribal chief's family, although traditional initiation ceremonies and training courses are being abandoned. Their continued importance lies in their function as organized labour units for public works and in the fact that, being self-administering, they provide an instrument of social control on a tribal-wide basis. But the most extensive and intensive form of inter-ward integration is that achieved by the political administrative system. The Tswana favour the clustering of many wards to form large villages within which each ward maintains its own clearly defined precinct. The isolated hamlets and small villages are usually the homes of alien adherents and dependent people. Most Tswana tribes have one large capital village or town (*e.g.,* Serowe) at which the majority of Tswana members reside. The entire Tlokwa tribes of Bechuanaland Protectorate, live in one large settlement. The government of these large settlements of the Tswana and the Tlokwa and of the surrounding arable land, grazing areas and hunting grounds is vested in a hereditary chieftainship; *e.g.,* Tswana tribe is a political association united by loyalty to a single political head, who is responsible for tribal government and administration, subject only to the overriding authority of a European government. Tribal membership is heterogeneous and Tswana members are often in the minority, so that a Tswana tribe accordingly lacks cultural and even linguistic uniformity. The chief rules with the assistance of advisers and officials, but at the same time all matters of public policy usually require the approval of a general council open to all adult male tribal members. Within this framework, local administration is vested in heads of lineally defined groups which form the structural core of the various settlement units. The emphasis placed upon the political mode of tribal aggregation and government serves to demarcate hereditary strata within Tswana society. The alien tribal members are clearly differentiated from those members of Tswana descent, who are in turn divided into "nobles" (*i.e.,* agnatic descendants of ruling lineages) and commoners; within these strata finer distinctions depend on family position and political role. Hereditary status is modifiable by the acquired status conferred by wealth, personal prowess, education and occupation. Aliens who are voluntary immigrants into Tswana society may become assimilated with the commoners, but the others, such as Bushman and Kgalagadi people, are relegated to a more or less permanent socially, though no longer legally, servile position. The essentials of Tswana social organization thus consist of the initial formation of small, localized, lineally integrated groups and their ultimate combination in terms of kindred ties, age organizations and a political system.

See J. T. Brawn, *Among the Bantu Nomads* (1926); I. Schapera, *Ethnic Composition of Tswana Tribes* (1952), *Tswana* (1953), *A Handbook of Tswana Law and Custom* (1955). (V. G. J. S.)

TUAM, the ecclesiastical capital of Connaught and the chief market town of the northern part of east Galway, Ire., lies 21 mi. N.E. of Galway and 120 mi. W.N.W. of Dublin by road. Pop. (1961) 3,500. Tuam is the seat of a Roman Catholic archbishop, the see having been founded by St. Jarlath (c. 550), and of a Protestant bishop. The Protestant cathedral was probably founded by Toirdelbhach Ua Conchubhair (Turlough O'Connor), king of Connaught, in *c.* 1130. The chancel, of red sandstone, is all that remains of the ancient structure, the rest having been rebuilt in its original style in the 19th century. The Catholic cathedral, in late Gothic style, is outside the town. In the market square stands the cross of Tuam which bears inscriptions in memory of Turlough O'Connor and Abbot O'Hoisin, archbishop in 1152.

TUAN CHI-JUI (1864–1936), Chinese politician, was born in Anhwei. He succeeded Yuan Shih-kai as viceroy of the Hukuang province, and was one of the signatories to the memorial of Jan. 1911, urging the emperor to abdicate. He was acting premier from May to July 1913, minister of war in 1914, and premier in April 1916. In Oct. 1918 Tuan Chi-Jui resigned, and, after an ill-advised coup on behalf of the Anfui club, played no great part in affairs till Nov. 24, 1924, when he succeeded Tsao Kun as president.

TUAPSE, a town on the Black sea in the Krasnodar *krai* of the Russian Soviet Federated Socialist Republic, U.S.S.R., in 44° 10' N., 38° 59' E., linked by a branch line with Armavir on the Rostov-Baku railway. It is the terminus of pipelines from the Grozny and Maikop oil fields and has refineries. Pop. (1956 est.) 34,100.

TUAREG, also TAWAREK (sing. *Tarqi)*, the name given by Arabs to the western and central Saharan Berber peoples in the desert from Tuat to Timbuktu and from Fezzan to Zinder, an area of about 1,500,000 sq.mi. The Tuareg resort to the centres from which the trade routes radiate, Timbuktu, Ghat, Ghadames, Murzuk and Tuat. Their general colour is reddish yellow. Their hair is long, black and silky, beards black and thin, eyes generally black; noses small, hands delicate, and bodies muscular. They are tall and graceful. The aristocratic section is called *Tmajagh;* Arabs call them *muleth themin* (veiled people). The men wear the veil day and night, the women never. The Tuareg, at any rate the noble class, are among the purest of the Berber stocks but have become largely Arabized. The script, known as T'ifinagh, consists of 40 to 50 symbols. They dress generally in a black tunic (some wear white), trousers of white cotton, and wear a cloth called *litham* or *tagilmus,* the end of which is drawn over the face, leaving visible only the eyes and the tip of the nose. These cloths are dark blue or white. To this difference of colour is due the terms "black" and "white" Tuaregs.

TUAREGS OF THE REPUBLIC OF NIGER

PAUL ALMASY

Socially the Tuareg are divided into six classes: *Imajeghan* or nobles; *Marabout* or priests; *Imghad* or serfs; *Irejanaten* or mixed people, issue of noble and Imghad; *Ikelan* negro slaves and *Buzu* outdoor slaves. The nobles are all pure blooded and provide the tribal chiefs. They do no manual work. Among the Imghad serfdom is hereditary, and they are bound collectively to a noble tribe or group of tribes.

TUATARA (TUATERA), the last surviving species *(Sphenodon punctatus)* of the reptilian order Rhynchocephalia ("beak-heads"). This lizardlike reptile of New Zealand has two pairs of well-developed limbs, a strong tail and a scaly crest down the centre of its neck and back. The scales that cover the entire animal vary in size. Adults are between 24 and 30 in. long. The tuatara is easily distinguished from the lizards by the presence of a third eyelid, the nictitating membrane, which mcves horizontally across the eye. Also the tuatara has a bony arch low on the skull behind the eye, which is not found in lizards. It was the presence of this bone that first suggested that the tuatara was a survivor of the otherwise extinct order Rhynchocephalia and not a lizard. The pineal eye, a median uncovered spot on the head, is prominent in young tuataras for about six months after birth. It is not known what function this structure serves: there is no evidence that it acts as an endocrine gland, and experiments to test it as a light or heat receptor give inconclusive results.

JOHN MARKHAM

TUATARA (SPHENODON PUNCTATUS)

Originally living on the two main islands of New Zealand, the tuatara exists only on certain of the smaller islets, where it is protected from introduced, domesticated animals that probably exterminated it from the main islands. The tuatara burrows in the top soil and emerges to bask in the sun for short intervals during the day. It is active at night and feeds mostly on insects.

The eggs are laid in spring in shallow excavations, usually at some distance from the home burrow. Development of the embryo is slow, and hatching does not take place until the following spring. *See* REPTILES.

TUBA, in music, the tubas — bombardon, helicon, euphonium —are a family of valved instruments of powerful tone forming the tenor and bass of the brass wind. In the orchestra these instruments are called tubas; in military bands euphonium (tenor), bombardon and helicon (bass).

The modern tubas owe their existence to the invention of valves or pistons by two Prussians, Stolzel and Bliimel, in 1815. The tubas are often confounded with the baritone and bass of the saxhorns, being, as they are, the outcome of the application of valves to the bugle family. There is, however, a radical difference in construction between the two types. Given the same length of tubing, the fundamental octave of the tubas is an octave lower than that of the saxhorns, the quality of tone being immeasurably superior. This difference is due to the proportions of the truncated cone of the bore and of the column of air within. By increasing the calibre of the bore in proportion to the length of the tube it was found that the fundamental note of the harmonic series was obtained in a full rich quality, and by means of the valves, with this one note as a basis, a valuable pedal octave, absent in the saxhorns, is obtained.

The modern tuba finds its prototype in the Roman tuba. Comparedwith the other military service instruments of the Romans, the buccina and cornu, the tuba was straight and was used to sound the charge and retreat, and lead the soldiers in action.

TUBE, a term that has various meanings as applied to industry, electronics, transportation and medicine. *See* AQUEDUCT; BOILER; ELECTRON TUBE; GLASS; IRON AND STEEL; LIGHTING; PNEUMATIC CONVEYING; RADIOLOGY; STEAM; SUBWAY (UNDERGROUND RAILWAY).

TUBER, in botany, a short fleshy, usually underground stem bearing small scale leaves with buds or "eyes" in their axils, as the potato (*q.v.*). The name is also applied to a genus of fungi, in the Tuberaceae family of the Ascomycetes, characterized by subterranean tuberlike fruiting bodies, as the European truffle. *See* STEM; TRUFFLE. (J. M. BL.)

TUBE RAILWAY: see SUBWAY (UNDERGROUND RAILWAY).

TUBERCULIN. In 1890 Robert Koch found a specific substance produced in artificial culture media during the growth of tubercle bacilli (*Mycobacterium* tuberculosis) which caused an inflammatory reaction when injected into animals or human beings previously infected with the tubercle bacillus but not in uninfected persons. Koch called it old tuberculin (OT). It was made by sterilizing the culture, filtering off the bacilli and concentrating the whole germ-free culture liquid to one-tenth the original volume. This tuberculin and many succeeding modifications of it have Seen used for the diagnosis of tuberculosis.

One of the purest products isolated was the purified protein derivative (PPD), and this has been used extensively for the diagnosis of tuberculosis in all parts of the world since 1934. One large lot, prepared in 1940 and designated PPD-S, was adopted by the U.S. government and by the World Health organization as the standard for comparison of human-type tuberculins. All PPD preparations, in general, consist of tuberculoprotein, the specifically active fraction isolated by chemical means from germ-free filtrates of heated human tubercle bacillus cultures grown on synthetic nonprotein media. The protein fraction contains several proteins of the tubercle bacillus, and these proteins have been separated chemically. They differ in their relative skin-reacting power and are being compared for their specificity in detecting active disease.

Tuberculin Test. — The most quantitative method of administering tuberculin is known as the Mantoux test, after Charles Mantoux, who devised the method. A small amount of tuberculin (0.1 ml.) is injected intradermally, usually on the flexor surface of the arm. When the test is positive, a swelling, usually accompanied by redness, occurs within 48 hours at the site of injection. Other less accurate methods of testing are by scratch, patch, ophthalmic and subcutaneous techniques. PPD is so potent that only 0.00002 mg. is required to give a positive Mantoux skin reaction in 94% to 96% of all persons with active tuberculous infection. A dose of 0.0001 mg. will detect practically any case of clinically significant tuberculosis. A larger dose (0.005 mg.) is frequently given if the patient gives no reaction in 48 hours with either of the smaller doses, but the significance of positive reaction to this dose is still under investigation. Still larger doses are not used because there are indications that they give nonspecific reactions. A patient giving a negative reaction to the 0.005-mg. dose is considered to be uninfected. However, a rare person may fail to react in spite of known infection.

The specificity of the reaction is very great when used in the prescribed doses. Practically 100% of guinea pigs artificially infected with tubercle bacilli or persons vaccinated with attenuated tubercle bacilli (BCG) react to tuberculin after having been negative previously. Furthermore, in an isolated population in Dutch Guiana (Surinam), where there was no infection with tubercle bacilli, no reactions occurred even with the 0.005-mg. dose. However, in certain parts of the world, such as India and southeastern U.S., the correlation between the number of reactors to the 0.005-mg. dose and the extent of known tuberculous infection does not correspond with that found in other parts of the world. The explanation for this discrepancy is being sought.

The extent of tuberculous infection in any locality can be determined approximately by finding the percentage of reactors to low doses of tuberculin. These percentages correspond to the intensity of exposure, which usually reflects the prevailing economic and sanitary conditions. A positive reaction, however, merely indicates infection with the tubercle bacillus and not necessarily active disease. The test is a help to the physician in determining the source and time of an infection, and in distinguishing between tuberculosis and other pulmonary conditions, such as histoplasmosis and other fungus diseases, in which the pulmonary lesions resemble those of tuberculosis on X-rays.

Tuberculin Therapy. — Tuberculin was used therapeutically by Koch. It is seldom used today except in the treatment of tuberculosis of the eye and some other forms of nonpulmonary tuberculosis. Patients are desensitized by a series of injections of increasing dosage, beginning with a 1:100,000 dilution of old tuberculin.

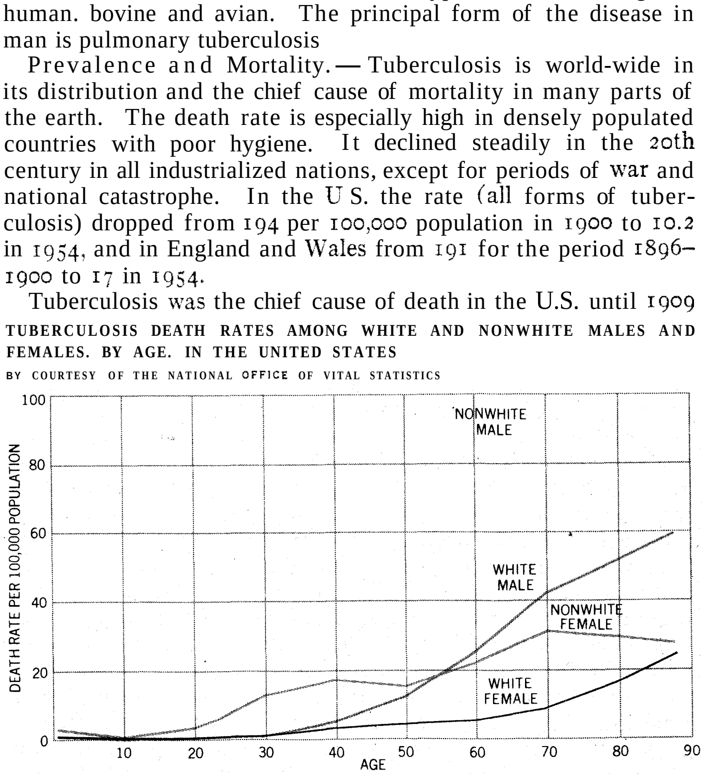
TUBERCULOSIS. Tuberculosis is an infectious disease of man and animals caused by the tubercle bacillus (*Mycobacterium tuberculosis*), which belongs to the acid-fast group of bacteria (*Mycobacteria*), and of which several types exist, including the human. bovine and avian. The principal form of the disease in man is pulmonary tuberculosis

Prevalence and Mortality. — Tuberculosis is world-wide in its distribution and the chief cause of mortality in many parts of the earth. The death rate is especially high in densely populated countries with poor hygiene. It declined steadily in the 20th century in all industrialized nations, except for periods of war and national catastrophe. In the U S. the rate (all forms of tuberculosis) dropped from 194 per 100,000 population in 1900 to 10.2 in 1954, and in England and Wales from 191 for the period 1896–1900 to 17 in 1954.

Tuberculosis was the chief cause of death in the U.S. until 1909

TUBERCULOSIS DEATH RATES AMONG WHITE AND NONWHITE MALES AND FEMALES. BY AGE. IN THE UNITED STATES

BY COURTESY OF THE NATIONAL OFFICE OF VITAL STATISTICS



and 11th in 1954, being exceeded by heart diseases. cancer, vascular lesions of the nervous system, accidents, certain diseases of infancy. pneumonia, arteriosclerosis, diabetes, congenital malformations and chronic nephritis.

In 1954 in the United States 16,000 deaths from tuberculosis were recorded.

It is calculated that in general the prevalence is approximately 20 times the mortality, but both prevalence and mortality vary considerably in different circumstances. Usually tuberculosis rates are higher in urban than in rural communities, because of crowding. greater opportunity for infection and the frequent hygienically less favourable position of large parts of some cities. However, with economic improvement, better sanitation, more widespread education and particularly with the establishment of public health practice, including specific measures for tuberculosis control, many cities have lower tuberculosis rates than adjacent rural areas. In the U.S. one of the chief factors influencing the mortality rate is the relative proportion of Negro inhabitants. The over-all mortality rate from tuberculosis is three times as high in nonwhites as in whites. In New York city, with an estimated population of 8,042,000, the tuberculosis mortality rate was 14 in 1955, but in central Harlem, with a predominantly Negro population, the rate was 53, while in adjoining Westchester county, a district with relatively few Negro inhabitants, the rate was only 6.

Economic conditions have a notable effect on the rate. The well-to-do and professional classes exhibit a low rate, while unskilled labourers have a high rate. A study by J. S. Whitney based on death rates in the U.S. in 1930 revealed a rate for unskilled labourers seven times as high as that among professional men. Sex and age are equally important.

Aetiology.—The view that tuberculosis might be a contagious disease is centuries old, but it was not until 1865, when Jean Antoine Villemin in Paris showed that it could be transmitted from tuberculous to healthy animals by inoculation, that it was proved to be due to an infecting agent. The actual cause, the tubercle bacillus, was discovered by Robert Koch in Germany in 1882.

The bacillus is the best-known member of the family of acid-fast bacteria, distinguished by their capacity to resist destaining by such reagents as acids, alkalies and alcohol when once stained with aniline dyes like fuchsin. As compared with other bacteria it grows slowly in artificial culture media. Once isolated it may be grown readily in large quantities on simple media of well-defined chemical structure. It is relatively resistant to the usual disinfecting agents, and withstands drying for long periods. It is killed quickly by sunlight and ultra-violet light from artificial sources.

The bacillus is a rod from one-half micron to four microns in length which reproduces apparently both by direct fission and by a complex division into minute particles from which new bacilli arise. Colony growth on solid culture mediums is of two types, "rough" and "smooth," which exhibit differences in virulence. Virulent bacilli tend to grow in serpentine cords, and can be distinguished from nonvirulent bacilli in some cases by a cytochemical reaction with neutral red and other dyes.

Advantage has been taken of its capacity to grow on media of known composition, to make exact studies of its chemical composition. In the bodies of bacilli grown on such media, lipides, carbohydrates and proteins occur in approximately equal proportion, The lipides of the bacillus were shown by R. J. Anderson, E. Lederer, J. Asselineau and others, to be distinctive for acid-fast bacteria, and one of them, a phosphatide containing a specific fatty acid, phthioic acid, was shown by Florence Sabin and followers to stimulate in animal tissue the histologic changes characteristic of tuberculosis. Certain waxy constituents of the bacillus were shown by Anderson and his co-workers to play a role in the phenomenon of acid-fastness. The proteins are extremely important, for they include the specific substance tuberculin, which is a valuable diagnostic agent and which is believed to be responsible for many of the toxic manifestations of tuberculosis in the body. The physicochemical studies of Florence Seibert showed that proteins of different tuberculin potency occur in the filtrate from cultures of tubercle bacilli, and that extremely minute amounts of certain of the proteins will elicit a tuberculin reaction. (See TUBERCULIN.) The carbohydrates are important in serological tests for the disease, including the haemagglutination reaction of G. Middlebrook and R. J. Dubos. They are closely linked to the lipides of the bacillus, and have a characteristic chemical composition, as shown by M. Heidelberger, M. Stacey and others.

Mode of Transmission. — Tuberculosis is transmitted to healthy bodies by way of the respiratory and alimentary tracts, and rarely by direct inoculation through the skin. Most tuberculosis is acquired by inhalation of bacilli from the sputum of persons with ulcerative pulmonary tuberculosis. Investigation has shown that the minute droplets may be discharged by cough or sneeze, and droplets of such size, sometimes containing hundreds of tubercle bacilli, may float in the air for hours.

The principal source of primary infection by way of the alimentary tract is contaminated milk. Secondary, endogenous infection of the alimentary tract, from swallowing sputum discharged from tuberculous ulcerations in the lungs or bronchi, is frequent in advanced pulmonary tuberculosis. In milk from cattle with infected udders, bacilli may be numerous, and the practice of pooling milk from several dairies may distribute tubercle bacilli widely in a city's milk supply if pasteurization is not practised. The bacillus concerned is the bovine type.

Pathology. — The anatomic unit of tuberculosis is a highly characteristic pathological formation known as the tubercle. When tubercle bacilli lodge in tissues the first reaction is an outpouring of polymorphonuclear leucocytes which surround and engulf the bacilli. This phase of reaction is over within a few hours, and is succeeded by a stage of infiltration of large mononuclear phagocytic cells which enlarge, with production of abundant cytoplasm, and engulf the polymorphonuclear leucocytes and their content of tubercle bacilli. The enlarged mononuclear cells, because of an early fancied resemblance to epithelial cells, have long been known as "epithelioid" cells. The latter tend to assume a radial arrangement around the site of infection, and among them appear large cells, designated by the name of an early describer as "Langhans' giant cells." These differ from the usual giant cells of foreign-body reaction in tissue in a distinctive arrangement of their nuclei. The giant cells arise from epithelioid cells as a result of fusion or incomplete division of the latter. In the normal course of development of the mass of epithelioid cells a specific type of necrosis of the central portion occurs, which is designated as "caseation" necrosis because of its cheese-like appearance when seen in large tuberculous masses. In time fibroblasts appear at the periphery of such an epithelioid mass. The complete structure, with a caseous centre, a zone of radially arranged epithelioid cells and a periphery of young mononuclear cells and fibroblasts, still microscopic in size, is known as an epithelioid tubercle. Most of the visible manifestations of tuberculosis, from barely visible nodules to large tuberculous masses, are fundamentally conglomerations of such tubercles, in which caseation necrosis progresses. Under certain circumstances large caseous masses tend to soften, and if such softened areas discharge their content into a segment of the bronchial tree, a cavity results. In typical pulmonary tuberculosis, varying in degree according to individual circumstances, exudation occurs into the pulmonary alveoli, and frequently into the pleural space.

In time reparative processes occur, with evolution of a chronic lesion characterized by localized destruction and scarring, with surrounding exudation.

The principal site of tuberculosis is the lung. Ordinarily pulmonary tuberculosis is a chronic disease, although many of the manifestations that enter into its complex character are acute. and rapidly progressive pneumonic forms, almost entirely exudative in character, occur. The typical lung of chronic advanced tuberculosis is characterized by cavity formation and scarring in the upper part, tuberculous consolidation with smaller cavities in the zone immediately below, and scattered shotlike tubercles in the lower regions. Ulceration, the result of the softening process described above, is the immediate cause of the chain of events leading to progressive tuberculosis. When this occurs, semiliquid material containing tubercle bacilli is poured into the bronchial tree and aspirated into adjacent bronchi, with the production of new tuberculosis, called "bronchogenic" from its mode of origin. As the disease progresses, new cavities develop and the process is repeated. At the same time reparative processes are under way, and scarring may be extensive.

Pulmonary Tuberculosis; Clinical Features. — Approximately 90% of all clinically recognized tuberculosis is pulmonary. The disease is insidious in onset and early course, and may reach a moderately advanced stage before identifying symptoms are manifest. The chances for cure are much better when the disease is discovered in an early rather than advanced stage.

Several classifications of pulmonary tuberculosis were in use in the mid-1950s. That recommended by the National Tuberculosis association in the U.S. is widely employed. It distinguishes primary and reinfection types of the disease, and minimal, moderately advanced and far advanced stages.

Primary tuberculosis (first infection) was formerly most frequent in children. In contrast to the reinfection type of tuberculosis in adults, first infection tuberculosis in children occurs in any part of the lung, and the draining lymph nodes soon become involved. The course in children is usually benign, and healing occurs in both the primary lung focus and regional lymph nodes, with scarring and calcification, leaving two or more nodules which are often readily visualized in chest X-ray films, and are easily found on post-mortem examination. Severe forms of primary tuberculosis sometimes occur in children, with rapid pneumonic progression, or with invasion of the blood stream and ensuant miliary tuberculosis or meningitis.

With improved measures for tuberculosis control primary infection is less frequent in children. First infection with tubercle bacilli often takes place in later life, when in its localization and character, it commonly resembles reinfection-type tuberculosis in adults more closely than it does primary tuberculosis in children.

Reinfection-type tuberculosis represents disease from repeated infection with tubercle bacilli. The bacilli concerned may come from fresh infection from a new source (exogenous infection) or from an already existing focus in the body (endogenous infection). Reinfection-type tuberculosis, in generally accepted classifications, is subdivided on the basis of its anatomical extent and the presence or absence of gross cavity formation, into minimal, moderately advanced and far advanced stages. Its onset is often difficult to detect. Fatigue, weight loss and cough are the usual symptoms. With advance of the disease these symptoms become more severe, and others may occur, the most striking of which is haemorrhage from the lungs (haemoptysis). Pleurisy with effusion of fluid into the pleural space is common.

Diagnosis is made by a combination of methods. Discovery of the tubercle bacillus in the sputum establishes it beyond question. In early stages this may not be possible, for tubercle bacilli do not appear in the sputum until ulceration of the lesion has occurred. Prior to the development of X-ray techniques chief reliance was placed on physical examination, with emphasis on differences in density of the lung, evident on percussion, and the detection of characteristic *râles* on auscultation with the stethoscope. X-ray evidence of infiltration of the lung is highly important in establishing the diagnosis. Early tuberculosis of minimal extent is usually found in the upper part of one lung, either above or below the clavicle.

Sputum is examined by a special staining technique used to detect acid-fast bacteria, either by direct smear of a selected portion of the expectorated material, or by concentration methods in which a large amount of sputum is reduced to a small volume by chemical treatment and centrifugalization. In cases where the presence of tubercle bacilli is suspected, but the amount of sputum is too small for examination, the contents of the stomach, containing small accumulations of swallowed sputum, may be aspirated and examined. When the number of bacilli is too small for detection by staining methods, they may be found by culture methods or inoculation of guinea pigs.

Treatment. — Tuberculosis is treated by rest, improved nutrition and hygiene, drugs and surgery. Until 1945 the chief treatment of the pulmonary disease was collapse therapy, in which an affected lung was collapsed and put at rest by artificial pneumothorax, effected by introducing air between the lung and chest wall, or thoracoplasty, in which a permanent collapse was induced by surgical removal of ribs. In 1943–44 S. A. Waksman and his associates discovered the potent antimicrobial agent streptomycin in the growth medium of the soil microorganism *Streptomyces griseus*, and in 1944–45 W. H. Feldman and H. C. Hinshaw demonstrated its specific effect in inhibiting tuberculosis. Wide clinical use promptly followed. Two defects were soon discovered, namely. some toxicity for the nervous system and a frequent development of tolerance to the drug by the offending bacillus. Lower dosage and combination with another drug, para-aminosalicylic acid (PAS), introduced in the treatment of tuberculosis by J. Lehmann of Sweden in 1946, largely obviated the difficulty. In 1952 a great advance was made with the introduction of another drug, isonicotinic acid hydrazide (isoniazid. INH), which came about with simultaneous discovery of its efficacy in the United States and Germany; a large number of investigators took part in demonstrating its therapeutic value, including W. McDermott, C. Muschenheim. E. H. Robitzek, I. J. Selikoff and G. Domagk. Isoniazid is usually administered with another drug, commonly PAS, to avoid development of isoniazid-resistant bacilli.

Trials in many countries rapidly proved the value of these drugs. Results rarely seen with the older methods of treatment became the rule. At the same time, and partly because of the protection afforded by the drugs, excisional surgery, with actual removal of affected parts of lungs, became a standard procedure, so that by the mid-1950s in medically progressive countries most known cases of active tuberculosis were under treatment by the drugs, excisional surgery or both. A significant part in the current great decrease in the mortality of tuberculosis was attributed to this therapy.

Nonpulmonary Tuberculosis. — Approximately one-tenth of clinically recognizable tuberculosis is nonpulmonary. The organs chiefly affected are the lymph nodes, bones and joints, serous surfaces, genital organs, kidneys, adrenal glands and skin. Lesions in these organs are usually caseous and there is a tendency for tuberculous abscesses and sinuses to develop. Tuberculosis of the intestines is common, but is usually a complication of pulmonary tuberculosis. Generalized tuberculosis of the lymph nodes (scrofula) was at one time one of the most frequent manifestations of tuberculosis, but with improved hygiene has become rare. Tuberculosis of the bones and joints is a grave disease requiring immobilization for arrest and usually leaving permanent damage to function when healing occurs. Tuberculosis may destroy the adrenal glands, in which case Addison's disease (*q.v.*) results. In countries where bovine tuberculosis is not well coiitrolled, nonpulmonary tuberculosis caused by infection with bovine-type tubercle bacilli is frequent. In the treatment of nonpulmonary tuberculosis, in addition to chemotherapy (*see* above), rest of the affected part is secured, in so far as possible. When practical, as in the case of tuberculosis of a single kidney, surgical measures are employed.

Generalization of tuberculous infection, with dissemination through the blood stream, is a not-rare complication of nonpulmonary tuberculosis. Miliary tuberculosis is a grave form, in which small nodules, likened by early investigators to millet seeds (and hence the term "miliary"), are scattered throughout the body. They represent individual implantations of tubercle bacilli discharged into the blood stream from a tuberculous focus which invades a vein wall, and are conspicuous in the lungs, in which they give rise to a characteristic X-ray picture. Tuberculous meningitis, the most severe of all forms of tuberculosis, is a frequent complication of miliary tuberculosis; at times it occurs without grossly evident miliary tuberculosis. Chemotherapy. especially with isoniazid, greatly improved prognosis in the severe forms of tuberculosis.

Resistance and Immunity. — Resistance and immunity in tuberculosis may be natural or acquired. Certain animals, like the monkey and guinea pig, are highly susceptible to the disease; others, like the cat, dog and horse, are relatively resistant. Some animals are susceptible to invasion by one type of tubercle bacillus and not by others. The rabbit succumbs to infection by bovine and avian strains of bacilli, but is resistant to the human type. Man is virtually immune to the avian type, but suffers from progressive disease caused by human- and bovine-type bacilli.

Heredity and constitution play an important part in determining the outcome of tuberculous infection. Before the discovery of the tubercle bacillus heredity was believed the chief determinant in man. That heredity is a vital factor in resistance has been proved experimentally by several investigators. In a long series of investigations from 1932 to 1956, M. B. Lurie showed that inbred strains of rabbits of different genetic constitution varied considerably in their resistance to tuberculosis and in the character assumed by the disease. Constitutional resistance is in part a function of the body's internal secretions. Cortisone depresses resistance and thyroid hormones appear to enhance it.

Racial variation in resistance to tuberculosis has also long been recognized. In 1908 S. Lyle Cummins called attention to the high rate of tuberculosis in Sudanese troops in Egypt; his subsequent studies indicated great susceptibility in "primitive" peoples in general. Negroes are more severely affected by the disease than whites, and different white stocks appear to vary in resistance. The significance of the higher death rate for Negroes in the U.S. is complicated by the generally unequal environmental conditions of the two races. Pathological studies disclose differences in the character of the disease in the two races, however; more extensive caseation necrosis and more frequent nonpulmonary tuberculosis are evident in the Negro.

Studies of populations in periods of deprivation show a correlation between nutritional deficiencies, particularly in proteins and vitamins, and increase in tuberculosis. Certain diseases, notably silicosis, depress resistance to tuberculosis.

Enhancement of resistance by infection itself is easily demonstrated experimentally. Animals inoculated with tubercle bacilli of low virulence reveal much greater resistance to subsequent infection with virulent tubercle bacilli than do normal animals. Advantage is taken of this fact in vaccination against tuberculosis. Animals, including man, when infected with tubercle bacilli, in addition to manifesting increased resistance to further infection from without, develop a remarkable hypersensitivity to a protein substance derived from tubercle bacilli (see TUBERCULIN). The virtually invariable development of hypersensitivity to tuberculin following infection of man and cattle with tubercle bacilli, regardless of the severity of infection, makes tuberculin valuable in detecting tuberculous infection and determining its prevalence in human groups and herds of cattle.

Prevention and Control. — Specific measures for the control of tuberculosis were inaugurated by Sir Robert W. Philip in Edinburgh, Scot., in 1887, by establishment of a tuberculosis dispensary in which patients convalescing from tuberculosis could be watched carefully and persons from households with a tuberculosis patient could be observed to detect evidence of developing disease. At the same time, through regular home visiting by dispensary personnel, efforts were made to improve the standard of living of the families under supervision, while the dispensary itself acted as a centre for the dissemination of knowledge concerning tuberculosis.

In 1889 in New York, H. M. Biggs, with his colleagues T. M. Prudden and H. P. Loomis, developed a similar plan based on the contagiousness of tuberculosis and need for protection of the public. Reporting of the disease to the department of health, was made compulsory by the New York city department of health, and public health measures for the prevention of tuberculosis became recognized as a governmental obligation. In the development of a sense of public responsibility in the control of tuberculosis, voluntary agencies played a great part. In the U.S. the National Tuberculosis association, founded in 1904, in Great Britain the National Association for the Prevention of Tuberculosis, in Canada the Canadian Tuberculosis association and similar associations in other countries, created a public understanding of tuberculosis that was reflected in steadily increasing official tuberculosis control. The National Tuberculosis association is financed by the sale of Christmas seals, a device originated in Denmark in 1904 by Einar Holbøll. By mid-20th century the association, made up of about 3,000 co-ordinated state, county and city units, was raising more than $25,000,000 annually by this means.

Local official tuberculosis control at the state level was practised in the U.S. long before a federal division for tuberculosis was organized. Many states developed strong programs with clinics, case-finding programs and state hospitals. In 1944 a tuberculosis control division was established in the bureau of state services of the U.S. public health service to aid state health departments in developing adequate programs, and to bring about other "measures for the prevention, treatment and control of tuberculosis." The direct operation of tuberculosis control programs remained a state, county and municipal responsibility.

In Great Britain the prevention and treatment of tuberculosis was a statutory responsibility of local government authorities until 1948. In that year new administrative machinery was set up under the National Health Service act of 1946 placing tuberculosis control in the hands of the minister of health, who was responsible only to parliament. Under the new plan all tuberculosis hospitals, sanatoriums and chest clinics, with few exceptions, were transferred to his jurisdiction. Regional hospital boards were set up with provision for specialist and consultant services in the treatment of chest diseases and for programs of case finding by mass X-ray surveys. Hospital accommodations were allocated by the regional boards and their specialist staffs. In 1954 about 30,000 beds were occupied by tuberculosis patients.

Financial help was given to patients on a standard scale by the ministry of national insurance supplemented in some cases by the National Assistance board.

Sanatoriums, in the notable decline of tuberculosis, played a highly effective role, not only in providing medical care, but in isolating tuberculous patients who would otherwise be sources of infection. In the early years of the 20th century most of the sanatoria in the U.S. were private; by mid-century the great majority of such institutions were under state, county or municipal control, and of hospital rather than sanatorium character. In 1900 there were only 4,500 beds for tuberculous patients in the U.S.; by 1956 there were approximately 100,000, exclusive of beds in mental and penal institutions.

With improved understanding of the means for combating tuberculosis, progressive health departments, ably assisted by voluntary agencies, incorporated extensive case-finding programs in their general procedure for tuberculosis control. Two methods came into use. In the older, an effort is made to ensure examination of all persons in the same household or in close association with a person known to have tuberculosis. This is based on the fact that tuberculosis is contagious, and the persons most likely to become tuberculous are those in intimate contact with the disease. In the later method large groups or whole communities are X-rayed by one of several inexpensive and rapid methods.

In World War II, mass X-ray examination was used to detect cases of tuberculosis in prospective recruits and draftees. After the war millions of examinations were made annually in co-operative enterprises by official and voluntary public health agencies.

In determining the prevalence of tuberculosis in a population, tuberculin is an important agent. A person infected with tuberculosis develops a specific inflammatory reaction when tuberculin is injected into the skin or placed in prolonged contact with the skin in an ointment. Only a fraction of those infected develop the disease, but possible future cases are thus recognized; when large groups are examined the results furnish a measure of the extent of infection in a community.

In guarding the health of previously uninfected persons exposed to the disease, such as members of the household of a tuberculous patient or nurses caring for patients, the tuberculin test furnishes the earliest evidence of infection.

An essential part of an adequate program of tuberculosis control is the prevention of human infection by bovine-type bacilli in milk. In countries with continuing measures for the eradication of tuberculosis in cattle and universal pasteurization of milk, human tuberculosis of bovine origin became rare, but in countries without such measures, bovine-type bacillus infection of children was still frequent.

Preventive inoculation against tuberculosis, in which live but attenuated tubercle bacilli are used as a vaccine. was introduced in France in 1921 by Albert Calmette and Camille Guerin. The strain designated BCG (Bacillus Calmette-Guérin) was one of bovine origin, which became attenuated while growing on culture media containing bile. After its introduction by Calmette, large numbers of children were vaccinated in France. elsewhere in Europe and South America; after 1930 the vaccine was used on an extensive scale.

The procedure met with little favour in the U.S. until after 1940, when studies by J. D. Aronson and S. R. Rosenthal were accepted as indicating definite value. A well controlled investigation by a tuberculosis vaccines clinical trials committee of the Medical Research Council in Great Britain, reported in 1956, also indicated substantial protective action against tuberculosis. The World Health organization (WHO) carried out an extensive program, emphasizing adequate organization, records and procedures for administration of the vaccine.

Rehabilitation of Tuberculous **Patients.**—When patients return to normal life after arrest of their disease. relapse may occur. A sheltered post-treatment environment. where work can be carried out under medical supervision and gradually increased until normal activity can be resumed safely. is important for many patients.

Likewise, for those who cannot arrest their disease and who may be a menace to society because of the persistence of tubercle bacilli in their sputum, but who retain the capacity for some degree of productive work. it is desirable to have an environment as nearly satisfactory as possible. with the medical supervision necessary to guard against undue strain and maintain proper facilities for medical treatment. The need in each respect was met by an increasing number of organizations for vocational training, part-time employment and custodial care with graded activity.

The Altro workshops in New York city, manufacturing washable garments, and the Associated Craftsmen in Bergen county, N.J., working on subcontracts from industry. became examples of sheltered workshops in which convalescing tuberculous patients could work within the limits of their strength and gradually increase their capacity for employment.

The Papworth Village settlement near Cambridge. Eng., achieved world-\vide fame for its provision of suitable living and working conditions for patients with chronic disease. The Disabled Persons Employment act (1944), the National Health act (1946) and coincident introduction of effective drugs for tuberculosis, enabled concentration on the return of patients to normal industry. through rehabilitation in former work or vocational training for more suitable occupation.

Tuberculosis in Animals and Birds.—Tuberculosis is occasionally encountered in wild animals and birds in their native state; it is much more frequent when they are in captivity. Presumably the greater exposure and opportunity for infection in captivity account for the difference. One form. the vole bacillus, affects certain rodents. Among domestic animals and birds, tuberculosis is an important disease in cattle, swine and fowl.

Cattle are infected by the bovine type of bacillus and relatively infrequently by the avian, swine frequently by both and occasionally by the human type, and domestic fowl only by avian bacilli.

In cattle the mesenteric and other lymph nodes and the liver, spleen, serous cavities and other organs are involved; tuberculosis of the udder is frequent and is serious because it leads to heavy contamination of milk with tubercle bacilli.

In the U.S. bovine tuberculosis by mid-20th century was a vanishing disease. Less than 0.5% of the nation's herds included reactors to tuberculin. The slaughter of infected cattle, detected by the tuberculin reaction, had become a universally accepted procedure. and the avoidance of tuberculous infection from dairy products was made doubly sure by the general pasteurization of milk. In much of the rest of the world, however. bovine tuberculosis was still a common disease responsible for widespread infection of children. Adequate programs of control, including slaughter of infected cattle and pasteurization of milk, were expensive and still to be developed, but the principle was recognized and progress was being made.

The control of tuberculosis in swine had not been so successfui as in cattle. Cattle infect each other, as do humans, and in both species removal of sources of infection halts the spread of disease. Swine, however, are susceptible to avian-type tubercle-bacillus infection, as well as bovine. It is difficult to keep swine and poultry entirely separate, and birds other than domestic poultry are likely to establish sources of infection.

Tuberculosis in domestic poultry is also difficult to control. Intestinal ulceration is the rule, and droppings may be heavily contaminated. The most practical procedure is to market birds at an early age and thereby limit opportunities for infection. Avian tuberculosis is a source of serious economic loss, but is not, like bovine tuberculosis, a significant source of human disease. (See also INFLAMMATION.)

TUBEROSE. The cultivated tuberose (Polianfhes tuberosa) of the amaryllis family (Amaryllidaceae; *q.v.*) is a plant distantly allied to the American agaves. but has not been found wild. The tuberose rootstock sends up a stem three feet in height, with numerous lanceolate leaves and terminal racemes of waxy white, funnel-shaped, very fragrant flowers. Each flower is about 1½ in. long. with a long tube and a six-parted limb.

The ovary is three-celled, and the ovoid fruit is crowned by the persistent flower. The plant is largely grown in the United States and at the Cape of Good Hope for export to England, as it is found that imported tubers succeed better than those grown in the United Kingdom. The double-flowered form is that principally grown.

TUBEUF, KARL (FREIHERR) VON (1862–1941), German plant pathologist, was born at Amorbach on Jan. 20, 1862. and was educated at the University of Munich, from which he obtained the degree of Ph.D. in 1886. He became *privatdozent* of botany at the University of Munich in 1888. and professor of plant anatomy, physiology and pathology in 1892, holding that position until his retirement in 1933.

Tubeuf was appointed a member of the Imperial board of health in 1898, becoming director of its biological section in 1901. He was also coeditor (1916–21) and editor (1925–36) of the *Zeitschrift für Pflanzenkrankheiten.*

Tubeuf was an outstanding plant pathologist, contributing many important works on the subject, as well as many on dendrology, forestry and mycology. His monograph on mistletoe, *Monographie* der *Mistel* (1923), ranks as one of the best works in the long list of literature on that parasitic plant.

He died on Feb. 8, 1941. (V. C. As.)

TÜBINGEN, a town of Germany, the capital of Baden-Württemberg, on the banks of the Neckar, at its junction with the Xmmer and Steinlach. 22 mi. S. of Stuttgart by road. Pop. (1950) 37,506. Tübingen is mentioned as a strong fortress in 1078, and was ruled from 1148 by counts palatine. In 1342 it was purchased by the count of Württemberg, whose descendants afterward acquired the title of duke.

The town was captured by the Swabian league in 1519, by Turenne in 1647, and again in 1688 by the French, who destroyed the walls.

The most conspicuous building is the old ducal castle of Hohentiibingen, built in 1507–35 on a hill overlooking the town, and now containing the university library and the observatory. The quaint old *Stiftskirche* (1469–83) is a Gothic building containing the tombs of the rulers of Wurttemberg; the town-hall dates from 1435 and was restored in 1872. Tubingen's chief claim to attention lies in its famous university, founded in 1477 by Duke Eberhard of Wurttemberg. Melanchthon was a lecturer here (1512–18). The university adopted the reformed faith in 1534, but in 1817 a Roman Catholic theological faculty was added to the other faculties. The leading faculty was long that of theology.

The university was attended in 1937 by about 1,500 students and had a teaching staff of 200. In the neighbourhood is the former Cistercian monastery of Bebenhausen, which was founded in 1183'.

TUBULIDENTATA, an order of placental mammals, including only the African aardvark or African ant bear. *Orycteropus,* representing the family Orycteropodidae. The aardvark was formerly associated with the true anteaters, sloths and armadillos (order Edentata) because, feeding on termites, it has a longish snout, a long, extensile tongue, a small gape, no teeth in the fore part of the jaws and cheek teeth defective in enamel and of persistent growth. In no other respects does it resemble the edentates; and although it is like the scaly anteaters or pangolins (order Pholidota) in certain internal anatomical features, these are characters common to many orders of mammals. *See* also EDENTATA; PHOLIDOTA.

The aardvark is a burrowing, heavily built animal, about six feet long (including body and tail), scantily covered with hair. with a long narrow head carrying huge rabbitlike ears and ending in a swollen mobile snout with terminal valvular nostrils closed with long hair. The tongue, although long, is not wormlike as in edentates and pangolins. The feet are powerful and very much alike except that the forefoot has no first toe; the toes are long, armed with huge flattened claws, and the second and third, which are the longest, are united by a deep and wide web. The tail is about two feet long, stout and tapering; and the external genital organs are situated on a preanal eminence containing a pair of scent glands opening in the male at the sides of the short penis and in the female at the sides of the vulva, which is provided with a cordate flaplike clitoris.

The teeth of the permanent set are unlike those of other mammals in being traversed by many tubules radiating from a central pulp cavity. They represent molars and premolars, the latter having milk predecessors; but in the newly born young traces of incisors and canines that never cut the gum have been discovered.

Aardvarks are found in Africa south of the Sahara both in deep forest and in the open. It is doubtful if more than one species is still in existence. Conservative estimates trace the tubulidentate line back to about 60,000,000 years. A species, O. *gaudryi*, nearly allied to the living forms, occurs in Lower Pliocene deposits of Bessarabia and the Greek island of Samos; and a distinct genus. *Palaeorycteropus,* has been recorded from the Upper Eocene deposits of southern France. The relationships of the Tubulidenta to other orders is still undetermined.

See AARDVARK.

TUCKER, ABRAHAM (1705–1774), English philosopher whose utilitarian theory of ethics anticipated William Paley's, was born in London on Sept. 2, 1705, the son of a wealthy city merchant. He was educated at Merton college, Oxford, and after traveling in England, Scotland, France and Flanders, he settled in 1727 on his estate at Betchworth castle, near Dorking, where he died, Nov. 20, 1774.

Tucker's chief work was a long series of disquisitions on metaphysics. psychology and ethics, *The Light of Nature Pursued,* of which the first four volumes were published in 1765 under the pseudonym Edward Search and three more posthumously (complete edition by Sir H. P. St. John Mildmay, 7 vol., 1805).

Simplicity and frankness characterize Tucker's manner of exposition, and he readily allows himself to digress from his main themes and to engage in some rather naive speculation. The general style of the work led to his being called "the Montaigne of metaphysics."

Tucker's contention that "every man's own satisfaction" is the ultimate end of action and that it is connected, through the will of God, with the "general good, the root where out all our rules of conduct and sentiments of honour are to branch," was later adopted by William Paley (*q.v.*) and presented systematically by him in his classic statement of the "theological" form of utilitarianism.

TUCSON, a city of southeastern Arizona, U.S., 125 mi. S.E. of Phoenix; the seat of Pima county. The city lies at an elevation of 2.400 ft., in a broad valley rimmed by mountains. The population in 1960 was 212,892, an increase of 368.4% since 1950 (part of which is accounted for by the annexation of suburbs); that of the standard metropolitan statistical area (Pima county) was 265,660, an increase of 88.1%. The metropolitan area includes several small settlements and one town, Ajo, built around a large open pit copper mine. (For comparative population figures *see* table in ARIZONA: *Population.*)

History. — Known as the Old Pueblo because of its interesting history, the story of Tucson goes back to Spanish colonists and missionaries. Padre Eusebio Kino, the great Jesuit, founded the mission San Xavier del Bac, 15 mi. from the modern city, in 1700. Later the Franciscan order built the beautiful church there which is a historic treasure of the southwest.

In 1776 the Spanish created a walled presidio of the adobe village Tucson (the Indian place name). When Spanish rule was superseded by that of Mexico, the walled town continued to be military headquarters of the province. Four flags have flown over the Old Pueblo: those of Spain, Mexico, the Confederate States of America and the United States.

Tucson was the territorial capital of Arizona from 1867 to 1877. The Southern Pacific railway reached Tucson from the west in 1880, and in 1910 it made connections with the Southern Pacific of Mexico, which gave direct service to Guadalajara and Mexico City. In 1900 Tucson became the see of a Roman Catholic bishop and the diocese maintains a cathedral; the Sisters of St. Joseph maintain St. Joseph's academy and the Franciscan fathers maintain San Xavier mission for Indians.

American pioneers changed the Spanish character of town life, although the majority of the inhabitants were Mexicans. Always a bilingual community with a large Spanish-speaking population, Tucson people have retained some customs and festivals from the Spanish past. Close relations are maintained with the Mexican state of Sonora, only 65 mi. S. Pioneers came from many states, as do modern inhabitants. Tucson mas chartered as a city in 1883 and has a council-manager form of government, in effect since 1930.

The Economy. — Climate was an asset in the development of Tucson. Its very dry air and bright sunshine attracted health seekers and visitors and tourism soon became important in the economy.' Recreation areas of unique desert vegetation, picnic grounds in the canyons and a ski run on Mt. Lemmon made Tucson a popular winter resort. The Arizona-Sonora Desert museum in the foothills of the Tucson mountains is a living museum of wildlife and vegetation in the Sonoran desert.

Good flying weather has made Tucson a natural focus for aircraft activities, and transcontinental and regional airlines serve the city. The U.S. air force maintains Davis-Monthan base on the outskirts of the city for jet fighters and bombers. International service with Aeronaves de Mexico began in the fall of 1960. The largest industry and largest employer is a company concerned with missile design and manufacture and with electronics. Several additional firms are engaged in electronic research and manufacture and some others in aircraft modification. The Southern Pacific has its division headquarters and repair shops in the city. Tucson is also the centre of one of the oldest agricultural districts of the state and there are many irrigated farms in its area.

Education and Cultural Activities. — The University of Arizona, situated in the city, serves the state and city in many fields (see also ARIZONA: *Education).* Tucson has an excellent public school system and several private ranch schools, and the U.S.

bureau of mines maintains a field office and experiment station in the city.

Artists, writers and other professional people have made their homes in or near the city. Art exhibitions, musical events and little-theatre programs provide varied cultural entertainment.

(A. M PE)

TUCUMÁN, a northern province of Argentina, surrounded north by the province of Salta, east by Santiago del Estero and south and west by Catamarca. Pop. (1960) 780,348. Area 8,697 sq.mi. The provincial capital is Tucumán (*q.v.*). The high Sierra de Aconquija occupies the western fringe of the province, but in the east the country is flat. alluvial and fertile. Tucumán owes its prosperity to the Aconquija range, nhich catches the warm moist winds from the east, with the result that there is abundant rain (about 37 in. yearly) and a number of permanent streams descend from the sierra to join the Rio Sali, a tributary of the Rio Dulce. Thus irrigation can be effected easily, and in some districts in normal years it is not even necessary. Moreover, because of the clouds in the proximity of the mountains, the province is free of frost. These favourable conditions have made possible the planting of sugar cane, the main source of wealth from the end of the 19th century. The second chief crop is maize and alcohol is manufactured. There are local railway lines to bring the cane to the sugar mills and national railways connect the province with other parts of the republic. (GE. P.)

TUCUMÁN (SAN MIGUEL DE TUCUMÁN), a city of Argentina, capital of the province of Tucumán (*q.v.*), located on the Sali river at the foot of the Sierra de Aconquija, approximately 700 mi. N.W. of Buenos Aires. Pop. (1960) 287,004. Although Tucumin is in a mountainous region, the climate is subtropical with moderate rainfall and infrequent winter frosts. The area is ideally suited to the major crop of sugar cane. for which the city is a processing and shipping centre. Tucumán was founded in 1565, moving to its present site after several inundations. It prospered due to its key position on the route from Córdoba to the Spanish mines in Bolivia. In 1776, with the creation of the viceroyalty of La Plata, control of the city passed from Peru to Buenos Aires. On July 9, 1816, a convention of delegates from the provinces of La Plata meeting in Tucumán signed the declaration of independence from Spain. The National University of Tucumán (1914) is a 20th-century addition to a rich colonial heritage. Construction of railroads in the 1880s further linked Tucumán to the coast and increased the importance of sugar production in the province.

(JS R. S.)

TUDOR. The house of Tudor, which gave five sovereigns to England, is derived by all the Welsh genealogists from Ednyfed Vychan of Tregarnedd in Anglesey, who is named in 1232 as steward of Llywelyn, prince of North Wales, and, seven years later, as an arbitrstor in a convention to which Davydd, the son of Llywelyn, was a party.

His descendant Tudor Vychan ap Gronw of Trecastell had four sons, of whom the eldest, Gronw Vychan, was in favour with the Black Prince and with Richard II. He was forester of Snowdon and steward of the bishop of Bangor's lordship in Anglesey. He died in 1382. an infant son being heir to his lands in Penmynydd, whose sister carried them to her husband Gmylym ap Gmffydd of Penrhyn.

Gronw's brothers Gwylym and Rhys served Richard II as captains of archers. Their youngest brother, Meredydd ap Tudor, escheator of Anglesey in 1392 and, like Gronw, an officer of the household of the bishop of Bangor, is said to have slain a man and fled to the wild country about Snowdon. He was the father of the handsome Owen ap Meredydd, commonly called Owen Tudor. a squire who appeared at the court of the infant king Henry VI and attracted the admiration of the queen mother. About 1428 or 1429. it must have been common knowledge that Owen Tudor and Queen Catherine were living as man and wife. There is no direct evidence for their marriage. Richard III denounced his rival Richmond as the son of a bastard, but it must be remembered that Richard was ready to foul the memory of his own mother in order to say the same of the young Edward V.

Five children were born to them, the sons being Edmund and Jasper and another son who became a monk. In 1436, a date which suggests that Bedford had been Owen's protector, the influence of Gloucester was uppermost. In that year the queen dowager was received within Bermondsey abbey, where she died in the following January. Her children were taken from her, and Owen Tudor was ordered to come into the king's presence. He had already seen the inside of Newgate gaol, and he would not obey without a safe conduct. When he had the safe conduct sent him he came up from Daventry and went at once to sanctuary at Westminster. Allowed to go back to Wales, he was retaken and lodged again in Newgate. He broke prison again and returned to his native Wales. When Henry VI came of full age he made some provision for his stepfather, who fought on the Lancastrian side. At Mortimer's Cross (Feb. 4, 1461) Owen fell into the hands of the Yorkists, who beheaded him in Hereford market place.

His eldest son, Edmund of Hadham (b. *c.* 1430), was knighted in 1449, and in 1453 he was summoned as earl of Richmond. He was declared of legitimate birth, and in 1455 he married Lady Margaret, daughter of John Beaufort, duke of Somerset. His only child, afterwards Henry VII, was born three months after his death.

Edmund's younger brother, Jasper Tudor, survived him many years. Jasper was knighted in 1449 and, about the date of Edmund's patent, was created earl of Pembroke. He bore the royal arms of France and England, differenced with a blue border charged with the royal martlets of the Confessor's fabulous shield, and the same was formerly to be seen upon his Garter stall plate of 1459. He fought at St. Albans in 1455 for the king who had advanced him, and two years later we find him strengthening the defences of Tenby. In 1460 he seized Denbigh, where the queen joined him after Northampton. He shared the defeat at Mortimer's Cross and left the country in 1462. In 1465 he made a last descent upon Wales, to be driven off by William Herbert, who was rewarded with his earldom of Pembroke, already forfeited by attainder. He came back again with Warwick in 1470 and was hurrying to join the queen when Tewkesbury was fought and lost. After many adventures he carried off his young nephew Richmond to Brittany. The two came back together in 1485. After Bosworth, Jasper was created duke of Bedford and restored to his earldom, the earl-marshalship being given him in 1492. He lived to fight at Stoke in 1487 against Lincoln and Simnel his puppet and to be one of the leaders of the host that landed in France in 1492.

He died in 1495 leaving no issue by his wife Catherine, the widow of the second duke of Buckingham and a daughter of Richard Widvile, Earl Rivers. But his bastard daughter Ellen is said to have been mother of Stephen Gardiner, bishop of Winchester.

TUDOR, ANTONY (1909–), English choreographer who worked extensively in the United States. In his dramatic ballets, *Lilac Garden*, *Pillar of Fire*, *Undertow* and *Romeo and Juliet*, he extended the range of classic ballet as an instrument of human expression.

Born in London on April 4, 1909, Tudor studied with Marie Rambert and for her company created his first ballet, *Cross-Gartered*, in 1931. When the American Ballet Theatre was founded in 1939 he joined it as dancer and choreographer. He was choreographer of the Royal Swedish Opera. 1949–50, and the Metropolitan Opera, New York city, 1950–51. After 1950 he directed the Metropolitan Opera Ballet school. (LN. ME.)

TUDOR PERIOD, in English architecture and the decorative arts, a loose term covering the final phase of the Perpendicular period (*q.v.*) and the earlier phases of the Elizabethan style (*q.v.*) or even the Jacobean style (*q.v.*), from which it is usually differentiated by the fact that those examples in which the Gothic influence predominates are termed Tudor, while those in which classic influence is more noticeable are known as Elizabethan or Jacobean. Since the Gothic tradition persisted in various parts of England and especially in Oxford and Cambridge until late in the 17th century, it is difficult to assign date limits to the Tudor style. In ecclesiastical architecture the Tudor period saw the climax of Perpendicular development. The characteristics in exterior secular work are: large groups of rectangular windows; rich oriel or bay windows; interesting and sometimes fantastic chimney treatments; complex roofs with many gables; much brickwork, frequently in patterns and lavish half-timber work (*q.v.*). In interior secular work this period saw an extraordinary development of wood paneling which was frequently used to cover all four sides of a room, and often enriched with linen fold decoration and occasional naïve travesties of classic forms and the lavish use of molded plasterwork for ceilings, cornices and walls.

Examples of the style are: the older portions of Hampton Court palace (1515–25); Layer Marney (1522–25); Moreton Old Hall, Cheshire (1550); Compton Winyates (c. 1520); Burton Agnes (1602–10); Ford's hospital, Coventry (begun 1529); at Oxford, Corpus Christi college (1516), the Founder's tower (1492–1505) and the hall (1541) at Magdalen. the tower of the old examination schools (c. 1620) and the chapel of Oriel (1637); at Cambridge, Queens' college (*c.* 1450), the two earliest courts of St. John's (between 1511 and 1600), and the King's gateway and Great Court at Trinity (built between 1518 and 1605). See GOTHIC ARCHITECTURE. (T. F. H.)

TUFF, a rock formed by induration of volcanic ash or dust. The loose fragmental ejecta of volcanoes are classified by size into (1) volcanic dust, less than 0.5 mm.; (2) ash, from 0.5 mm. to 4 mm.; (3) lapilli, from 4 mm. to 32 mm.; (4) bombs and blocks, larger than 32 mm. Bombs are plastic while blocks are solid when erupted. By compaction and cementation, volcanic dust yields dust tuff and ash yields tuff. If lapilli predominate over the finer constituents, a lapilli tuff results. Rocks composed chiefly of bombs are termed agglomerate (*q.v.*) and those consisting mainly of angular blocks are classed as volcanic breccia (*q.v.*).

Among the products of explosive eruptions, some form by expulsion of liquid magma as clots and spray. These are referred to as essential or juvenile ejecta. Other fragments are discharged in a solid state, being torn from the crater walls, from the tops of cones or the roofs of the underlying reservoirs. These are termed accessory ejecta. Still other ejecta are described as accidental, since they include pieces of any kind of rock torn from the subvolcanic basement. Many of these are intensely baked or wholly recrystallized, such as the limestone blocks periodically blown out by Vesuvius. The pipes of many extinct volcanoes are almost completely filled with accidental debris made up of pulverized sandstone and shale, as in the Navajo region of New Mexico. It is the violent expansion of uater vapour released from deep-seated bodies of magma that blasts these pipes through the overlying formations.

Tuffs may be grouped as vitric, crystal or lithic, according as they are composed principally of glass, crystal chips or the debris of pre-existing rocks. During some explosions, like that of Krakatoa in 1883, the ejecta consist mainly of pumice (*q.v.*), that is, of extremely porous, glassy fragments light enough to float on water, and of finely divided glass dust or pumicite, which, like pumice, has found use as a lightweight aggregate in the construction industry. Volcanoes fed by siliceous magma, such as rhyolite, dacite and trachyte (*qq.v.*), tend to produce the most voluminous and extensive deposits of this kind. However, some of the world's largest deposits of vitric tuff are produced by eruptions through a large number of narrow fissures rather than from volcanic cones. Foaming magma wells to the surface as an emulsion of hot gases and incandescent particles, and the material spreads swiftly even over gentle gradients as glowing avalanches. Such eruptions occurred in 1912 in the Valley of Ten Thousand Smokes (*q.v.*), Alaska. After coming to rest, the ejecta may be firmly compacted by adhesion of the hot glass fragments, and so form streaky, welded tuffs like those covering vast areas in New Zealand, Guatemala, Peru and Yellowstone National park, U.S.

Even fluid basaltic magma, such as that of Kilauea and Mauna Loa in Hawaii, may be inflated by expanding gas and tossed out as delicate glass threads and blebs, known respectively as Pele's hair and Pele's tears. But the chief fragmental products of basaltic volcanoes are the dark, porous, glassy lapilli and bombs which, from their superficial resemblance to the residues of burning coal, are spoken of as cinders. If the lapilli and bombs are sufficiently plastic when discharged, they assume rounded and ropy forms, partly in response to rotation during flight. More viscous clots fall to earth as subangular lumps with cracked, glassy skins that resemble bread crusts.

During other eruptions, the volume of ejected crystals exceeds that of glassy material, as at La Soufrière, West Indies, in 1902. Light crystals of leucite may accumulate by flotation close to the top of the conduit of Vesuvius during intervals of quiet, to be hurled out when activity revives; or clusters of heavy olivine and augite crystals may be expelled from lower levels. If the temperature of eruption is low, the explosions simulate steam blasts and none but angular, lithic fragments of old rock are expelled, as at Bandai-san, Japan, in 1888.

Fine ash and dust may aggregate into pellets or mud balls by falling through an eruption-cloud in which water vapour is condensing. Somewhat similar accretionary lapilli develop by the action of rain and wind on newly fallen ash.

In response to the dictates of gravity, the coarser and heavier volcanic ejecta tend to fall close to the source, while the finer and lighter particles are carried afar. Hence, in extensive deposits, tuff may vary greatly not only in texture but also in chemical and mineralogical composition.

Some ejecta fall directly into lakes or into the sea; others, having been deposited on land, are later washed into bodies of water and are there mixed with normal sediment. The ashy clays and sands thus produced may subsequently be converted to tuffaceous shales and sandstones.

When explosions take place underground the fragmental material may be forced violently into the surrounding rocks, forming intrusive tuffs or peperites.

There has probably been no geological period entirely free from volcanic eruptions. Tuffs therefore range in age from Pre-Cambrian to Recent. Usually, the older ones have lost all original textures and are thoroughly recrystallized. Many old basaltic tuffs are now represented by green chlorite and hornblende schists, and many rhyolitic tuffs by sericite schists.

From A.D. 1500, the world's volcanoes have discharged about 80 cu.mi. of fragmental ejecta, as against 16 cu.mi. of lava. The most voluminous explosions are generally associated with gas-rich magmas of volcanoes in mountain belts on the continents and adjacent islands, and follow long periods of quiescence. Among the most violent explosions of recent times are those of Tamboro, East Indies, in 1815; Coseguina, Nicaragua, in 1835; Krakatoa, Netherlands Indies, in 1883; and Katmai, Alaska. in 1912. Respectively, these volcanoes erupted approximately 8, 12, 5 and 6 cu.mi. of fragmental material. See also VOLCANISM; VOLCANO.

(H. Ws.)

TU FU (712–770), Chinese poet, whom most critics take to be China's greatest, was born in 712. His grandfather was an official and poet, his father attained medium rank in his official career, and through his mother he was remotely related to the imperial house. Tu Fu started his life in close accordance with the pattern of every educated Chinese but failed in the imperial examinations of 736. Much of his youth he spent traveling, and on his travels and during his sojourns at the capital he soon won renown as a poet and consorted with the other poets of the period, above all with Li Po.

During the 740s Tu Fu was also a highly regarded member of a group of high officials, even though he was without official position himself and failed a second time in an imperial examination. Between 751 and 755 he attempted to attract imperial attention by submitting a succession of literary products in which political advice was offered couched in a language of ornamental flattery, and this eventually resulted in a nominal position at court. Probably in 752, Tu Fu married and acquired some farmland, but already at that time he showed signs of a lung affliction. In 755 he was caught in the rebellion of An Lu-shan and experienced extreme personal hardships. He succeeded in escaping, however, and in 757 joined the exiled court, being given the position of Reminder. His memorials to the emperor, however, do not appear to have been particularly welcome. He again went through a period of poverty and hunger, wandered around and arrived late in 759 at Chengtu, where, with the help of friends, he was able to build himself a thatched hut and to experience a modicum of happiness.

For a time Tu Fu served a local war lord as military adviser. Then he started drifting again and in the mid-760s found himself at K'uei-chou in the service of another local war lord which enabled him to acquire some landed property and to become a gentleman-farmer. By that time he must have been sick; he even gave up drinking for a period because of his health. In 768 he again started traveling aimlessly toward the south, and he died late in 770, probably at T'an-chou.

Throughout his life the trenchancy of Tu Fu's political ambitions contrasted sharply with his lack of political acumen. His official biography calls his political comments "high-sounding rather than practical."

Tu Fu's varied but undistinguished life is matched by the broad but undistinguished range of his attitudes and passions. which are almost exclusively dictated by the tenets of a somewhat commonplace Confucianism. There is no reason to doubt the sincerity of his patriotism or of his affection toward his family and friends. Also, the depth of his compassion for human suffering is always genuine.

His poetic expression, however, is confined almost entirely to the dramatic, the general and the typical. and rarely ventures into the field of real lyricism. With all his ambitions and his self-pity, he is humane rather than personal. The poems written between 755 and 759, the period of extreme personal and national turmoil. are thus without doubt his most impressive.

Tu Fu's paramount position in the history of Chinese literature rests on his superb classicism. By his time, the development of poetic form had reached the acme of perfection. Tu Fu was a very erudite man. His intimate acquaintance with the literary tradition of the past was equaled only by his complete ease in handling the rules of prosody.

The wealth of his language makes use of all the connotative overtones of a phrase and of all the intonational potentials of the individual word. qualities that no translation ever will reveal. He was an expert in all poetic genres current in his day: but his mastery is at its height in the so-called regulated poem. particularly the seven-word regulated poem, the extreme formal restraint of which calls for the gift of a Tu Fu for being refined to the point of glowing intensity.

TUGELA, the largest river in Natal. South Africa. its basin being about 11,500 sq.mi. in extent. It rises on Mont aux Sources, in the Drakensberg, at over 10.000 ft. above sea level. After a mile or two it plunges over the great escarpment forming the most rugged and picturesque scenery. and then flows as a dignified stream in a broad, open valley to a point a few miles below Colenso, about 60 mi. eastward from the source. Here the valley becomes steeper and narrower, owing to rejuvenation. This character persists until within a few miles of its mouth, the river being sometimes 2,000 ft. below the neighbouring plateau. The Tugela is quite unnavigable. Its volume has great seasonal fluctuations. being easily fordable in many places in winter, and often quite impassable during summer rains. The Tugela receives as tributaries on its right bank the Little Tugela, rising near Cathkin Peak, and the Bushman and Mooi rivers, which both originate near Giant's castle.

On its left bank it receives the Klip river, which flows past Ladysmith, the Sunday's river from the Biggarsberg, and the Buffalo river. which rises near Majuba and flows not far from Isandhlwana, at which place, and also at Rorke's Drift, on the Buffalo. memorable actions were fought in the Zulu War. The boundary between Natal proper and Zululand follows the Tugela from its mouth to the confluence with the Buffalo river, and then runs up the latter to its junction with the Blood river, so called on account of the defeat of Dingaan's impi by the Boers in 1838.

TUGGURT (TOUGGOURT), town in Oasis *département,* Algeria, 127 mi. S. of Biskra. with which it is connected by a railway. Pop. (1961) 26.117. Just within the northern of two gates is the market place and the chief mosque. The surrounding oasis contains about 200,000 date palms. Temacine, with a holy lake, seat of a branch house of the extensive Moslem religious brotherhood of the Tijani, is nearby.

From the city a road 75 mi. long leads across the desert northeast to El Wad.

TUGUEGARAO, a municipality and capital of the province of Cagayan. Luzon. Philippines, on the Cagayan river, about 60 mi. from its mouth, and near the southern boundary of the province. Pop. (1960) 43,044. The river is navigable to Tuguegarao for vessels of light draught. The surrounding region is the most productive of tobacco in the archipelago. Ibanag is the principal vernacular. (C. S. L.)

TUKE, the name of an English family, several generations of which were celebrated for their philanthropic efforts.

WILLIAM TUKE (1732–1822) was born at York on March 24, 1732. His name is connected with the humane treatment of the insane, for whose care he projected in 1792 the Retreat at York, under the management of the Society of Friends, which became famous as an institution in which a bold attempt was made to manage the inmates without the excessive restraints then regarded as essential. His son HENRY TUKE (1755–1814) co-operated with his father in his reforms.

Henry's son SAMUEL TUKE (1784–1857) continued the work begun by his grandfather. and published a *Description of the Retreat near York,* etc. (York. 1813). He also published *Practical Hints on the Construction and Economy of Pauper Lunatic Asylums* (181j). He died at Tork on Oct. 14, 1857.

Samuel's son JAMES HACK TUKE (1819–1896) is chiefly remembered for his philanthropic work in Ireland, which resulted from a visit to Connaught in 1847, where he witnessed much distress. Letters descriptive of the state of things he saw when he was distributing relief in 1880. were published in the *Times,* and in his pamphlet. *Irish Distress and its Remedies* (1880), he pointed out that Irish distress was due to economic rather than political difficulties, and advocated state-aided land purchase, peasant proprietorship. light railways. government help for the fishing and local industries, and family emigration for the poorest peasants. From 1882 to 1884 he superintended the emigration of poor families to the United States and the colonies. To his reports on the distribution of seed potatoes in 1885, and his letters to the *Times,* which were reprinted under the title *The Condition of Donegal* (1889), were due in a great measure the bill passed for the construction of light railways in 1889 and the Irish Land act which established the Congested Districts board in 1891. He died on Jan. 13, 1896.

DANIEL HACK TUKE (1827–189j), younger brother of James Hack Tuke, abandoned a solicitor's career to undertake work at the York retreat. After studying medicine in London, he graduated M.D. at Heidelberg in 1853. In 1858, in collaboration with J. C. Bucknill. he published a *Manual of Psychological Medicine,* which was for many years regarded as a standard work on lunacy. In 1853 he visited a number of foreign asylums, and later returning to York he became visiting physician to the York' retreat and the York dispensary. In 1859 he retired, but he resumed practice in London in 1875 as a specialist in mental diseases. In 1880 he became joint editor of the *Journal* of *Mental Science.* He died on Xfarch j. 189j.

Among his works were *Illustrations of the Influence of the Mind on the Body* (1872); *Insanity in Ancient and Modern Life* (1878); *History of the Insane in the British Isles* (1882); *Sleepwalking and Hypnotism* (1884); *Past and Present Provision for the Insane Poor in Yorkshire* (1889); *Dictionary of Psychological Medicine* (1892).

TUKHACHEVSKY, MIKHAIL NICOLAEVICH (1893–1937), Russian soldier. was born in the region of Smolensk. He was educated in the corps of cadets and at the Aleksandrovsky military school, graduating in July 1914. In Feb. 191; he was taken prisoner by the Germans. but escaped to Russia in 1917, and in June 1918 received the command of an army. He commanded successively the I. VIII and V armies and then the Caucasian front. After the successful conclusion of operations against Denikin, Tukhachevsky was given the command of the western front. After the Civil War he became chief of the military academy, and in April 1924 was appointed assistant chief of staff. On June 11, 1937, after a secret trial for espionage and high treason, he. together with seven other generals, was shot.

TUKULOR, a tall, long-headed, well-proportioned and muscular people with long faces, incorporating Serer: Wolof, Mandinga, Soninke and Fulani elements in Senegal and the French Sudan. They call themselves *Futankobe* or *Futanke;* the Wolofs call them *Tokoror* or dwellers in the Tekrur or Senegalese Futa, or Tukolor, the name adopted for them by the French. Their language resembles Fulani and is related to Wolof and Serer. The Tukulor organized a theocratic elective monarchy, with a religious chief *(Almamy),* a functionary whose office was abolished in 1881. Their modern organization is by territorial groups. The Tukulor are Moslems. They are skilled cultivators and cattle raisers.

TULA, an *oblast* of the Russian Soviet Federated Socialist Republic, U.S.S.R., surrounded by those of Smolensk, Moscow, Ryazan and Orel, and not coinciding with the pre-1917 province of the same name. Area 9,305 sq.mi. Pop. (1956 est.) 1,498,000 (urban 746,000; rural 752,000), mainly Great Russians. It consists of plateau land (950 to 1,020 ft.), deeply entrenched by the Don and its tributaries, the Cpa and Sosna. About 9% is forested, the northern region having coniferous trees, and the south small and scattered patches of birch, ash and oak. The south is in the steppe black earth region, but the north is poorer gray forest soil. The climate is extreme, with five months' winter frost, an average July temperature of 66° F. and 16–18 in. of rain per annum.

The chief crops include rye and oats. Buckwheat, potatoes, wheat, millet, grass, hemp and sugar beet are grown, while along the Oka in the northwest of the region, apples, cucumbers. cabbages and onions are cultivated. Coal is mined along the railway extending eastward from Aleksin on the Oka through Tula to the region of Ryazan.

TULA is also the name of the chief town of the above region, in the broad but low, marshy valley of the Upa, in 54° 12' N. 37° 37' E. Pop. (1956 est.) 320,000. Tsar Boris Godunov founded the first Russian gun factory there in 1595, and in 1632 a Dutchman, Winius, established an iron factory. The factories were rebuilt on a larger scale in 1705 and 1714 and toward the end of the 18th century a marked expansion of the industry took place. Industries developed there include the manufacture of samovars (tea urns), sugar refining, smelting, the making of cutlery, leather and sewn goods and flour milling. The town is first mentioned in 1147, but its former site seems to have been higher up the Tulitsa, an affluent of the Upa. Its wooden fort was replaced in 1514–21 by a stone *kreml* (old kremlin) or citadel, which was restored after World War II.

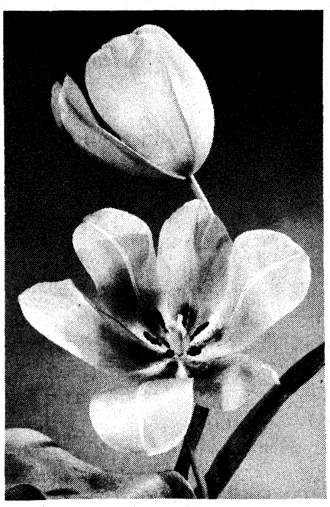
TULAREMIA is an acute infectious disease that resembles plague (*q.v.*) but is much less severe. It was described in 1912 in Tulare county, Calif., from which the name is derived. The causative agent is the bacterium *Pasteurella tularensis* (classified by some as *Brucella tularensis),* a minute microorganism cultivable only with difficulty. The disease is primarily one of wild animals, and human infections are only incidental to its life history. It occurs naturally in 48 species of vertebrates, of which the rabbit, especially the cottontail: *Sylvilagus,* is the most important source of human infection. Water-borne epidemics of the disease in man have occurred in the U.S.S.R. and Turkey; and naturally occurring infections in beavers and muskrats in the northwestern United States are well known. The disease is acquired by man from the animal reservoir of infection, in 90% of cases from the rabbit, either directly by handling the carcasses of infected rabbits, or indirectly through an insect vector. The most common vector transmitting the disease to man is the deer fly, *Chrysops discalis;* the human disease is also known as deer fly fever. Various ticks of the genera *Dermacentor*, *Haemaphysalis* and *Ixodes* may be largely responsible for maintenance of the animal infection. In addition, the infection is transmitted from the adult tick to the egg, and both larvae and nymphs are infectious and form an insect reservoir of infection.

The disease in man occurs in two forms, the more common glandular or ulceroglandular form, and the less common typhoidal type. Local lesions occur in the first, usually beginning with a papule at the site of initial infection, commonly a finger, that breaks down to form an ulcer. The infection then spreads to the lymph glands in the arms and armpits which become painful and swollen so that the glands may also break down with the discharge of purulent material. The general symptoms common to both forms of the disease are headache, bodily aches and fever. The disease persists for two to four weeks, and the case fatality is low, usually less than 5%. About 2,000 cases are reported each year in the United States; cases have been found in all the states and in the District of Columbia. Prophylactic immunization is relatively ineffective. The sulfonamides have little or no chemotherapeutic activity, chloramphenicol has slight activity, but the tetracyclines are reasonably effective. Streptomycin is the most effective chemotherapeutic agent, but the microorganism rapidly becomes resistant to it, often within the first two or three days of therapy. (W. Bu.)

TULCEA, a town of Rumania, in the region of Constanta, picturesquely situated on the right bank of the Danube, 42 mi. from its mouth at Sulina. Pop. (1956) 24,639. There is a large water-borne trade in cereals.

TULIP, a genus (*Tulipa*) of bulbous herbs belonging to the lily family (Liliaceae). The species are found wild along the northern shores of the Mediterranean, in the Levant, Armenia, Caucasus, northern Africa, Iran, and sporadically across north and central Asia to Japan. The cup-shaped flowers have six regular segments in two rows, as many free stamens, and a three-celled ovary with a sessile stigma, which ripens into a leathery many-seeded capsule. The species are numerous, and are distinguished one from another by the scales of the bulb being woolly or smooth on the inner surface, by the character of the flower stalks, by the filaments being hairy or otherwise, and by other characters. Owing to the great beauty of the flowers they have long been favourites in European and American gardens, and have been crossed and recrossed till it has become almost impossible to refer the plants to their original types.

The early flowering "Van Thol" tulips, the segments of which are mostly scarlet with yellow edges, are probably derived from T. *suaveolens,* a native of the Caspian region. T. *gesneriana,* a native of Armenia and central Russia, is the origin of most of the later flowering varieties. *T. oculussolis* and *T. clusiana* are lovely species, natives of southern Europe and *T. sylvestris,* with elegant yellow flowers, is a doubtful native of England. Owing to the exertions of Russian naturalists, a large number of new species were discovered in Turkistan and introduced into Europe. Some of these are very beautiful, and render it probable that by intercrossing with the older species still further difficulties will be presented in the way of identification. These difficulties are further enhanced by the fact that, quite apart from any crossbreeding, the plants, when subjected to cultivation, vary so greatly in the course of two or three years from the original species from which they are directly descended that their parentage is scarcely recognizable. This innate power of variation has enabled the florist to obtain, and ultimately to fix, many remarkable varieties. Millions of bulbs are cultivated in Holland for export every year; many are also grown in the Channel Islands, especially Guernsey, in the fen district of England, around Belfast, Ireland, and in the United States. Tulips were



ROCHE

COTTAGE TULIP (TULIPA), A LATE SINGLE FLOWERING KIND OF THE GEISHA VARIETY introduced into the Low Countries from Constantinople and the Levant in the 16th century; about 1637 they became the subject of an extraordinary speculation known as tulipomania in which prices for single roots rose to as much as 2,600 guilders. Thousands became bankrupt when the bubble burst.

Tulips, which have sprung from *Tulipa* gesneriana, are arranged in separate classes. Of these the most important are early, breeder, cottage and Darwin tulips. There are, in addition, various secondary groups, named bizarres, bybloemens, parrots, Rembrandts and striped tulips, according to their colour and marking. Tulips are readily raised from seeds, and the seedlings when they first flower (after about seven years' cultivation) are of one colour — that is, they are self-coloured. Judged by the florists' rules, they are either good or bad in form, and pure or stained (white or yellow) at the base; the badly formed and stained flowers are thrown away, while the good and pure are grown on, these being known as breeder tulips.

The breeder bulbs and their offsets may grow on for years producing only self-coloured flowers, but after a time, which is varied and indefinite, some of the progeny break, that is, produce flowers with the variegation which is so much prized. The flower is then said to be rectified; it is a bizarre when it has a yellow ground marked with purple or red, a bybloemen when it has a white ground marked with violet or purple, or a rose when it has a white ground marked with rose colour.

Tulips flourish in any good garden soil that has been deeply dug or trenched and manured the previous season. To secure perfect drainage and greater warmth a fair quantity of sand or grit should be present. Fresh manure should be avoided, but the remains from an old hotbed or mushroom bed may be incorporated. The best time to plant is in October and Sovember, the bulbs being buried about four to five inches deep and somewhat farther apart. The best effects are produced in formal beds by planting the same variety in each, to insure the plants being of the same height and in flower simultaneously.

Propagation. — Tulips are usually increased by offsets, which most varieties produce in fairly large numbers. These are taken off and sown in drills, like seed. They are usually strong enough to flower the third year from this sowing. Some varieties produce offsets sparingly and must be increased by seed—a slow and uncertain method. New varieties are raised from seed. (The colour variation in the flowers of seedlings is discussed above.) Seeds are sown in boxes or cold frames, in light sandy soil, and the young plants are allowed to remain undisturbed until the second year. They are then lifted and treated like offsets, being sown thinly in beds out of doors. They usually flower in about the seventh year. The soil in which tulips are propagated should be sandy, free working and thoroughly drained. A warm sheltered position is a necessity.

Forcing. — The early flowering varieties should be potted as early in September as practicable, later batches for succession being potted during October. Pots five and six inches in diameter are the most convenient for the early-flowering kinds, but seven-inch pots give the better results for the Darwin section of the May-flowering kinds which are now used for gentle forcing. Five or six bulbs are put in each pot and the tops should be covered with half an inch of soil and half an inch left for water. The soil should be a light and fairly rich compost, comprising about two parts loam, one part decayed manure or horse droppings that have been thoroughly sweetened, one part leaf mold and half a part of sand. Pot firmly: and plunge the pots in several inches of ashes out of doors, to protect the bulbs from frost! but it must be remembered that all garden tulips require a thorough winter chilling to bloom the next spring. As soon as growth commences at the top and a fair amount of roots are formed they may be introduced into the cool greenhouse, in batches according to the need and amount of stock available.

For market a slightly different method is adopted. The bulbs are placed in long shallow boxes, plunged in soil or ashes in semidarkness, and are afterwards transferred to benches in the forcing houses where they flower. Bulbs which have been forced are of no further value for that particular purpose. If planted in borders and shrubberies, however, they will continue to bear fairly good blossoms in the open air for several seasons.

Varieties.— —Many thousands of varieties are offered by dealers. The most generally useful fall into the following groups:

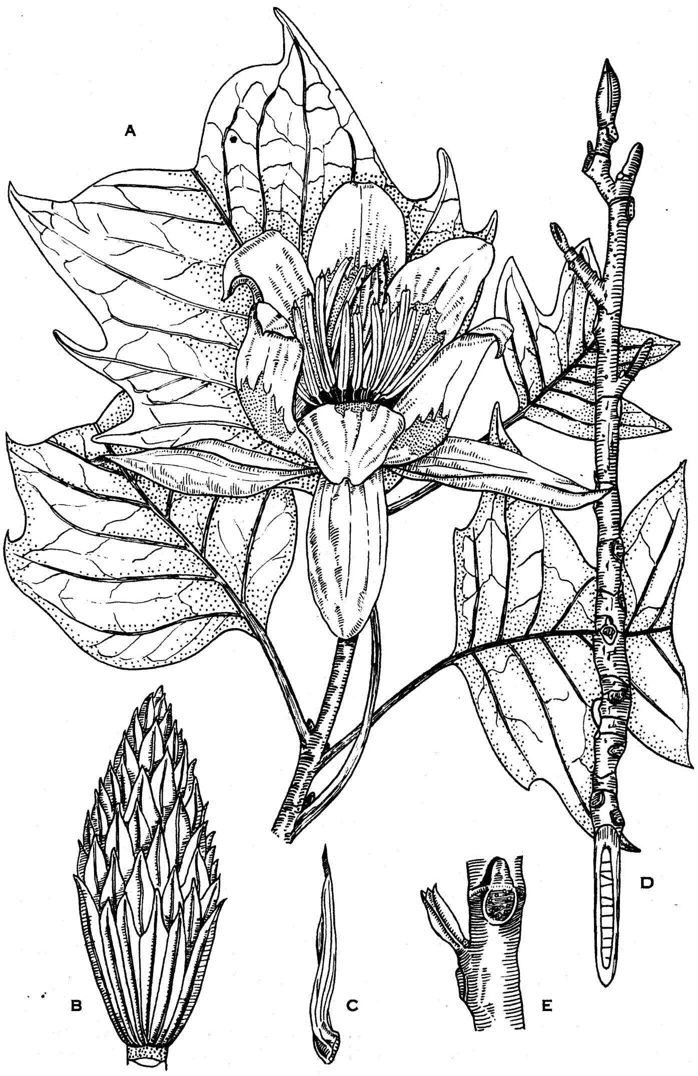
Early Single (or Double) *Flowering* Kinds are the most useful for bedding and pot culture.

Late Single Flowering Kinds. — These are all tall-growing hardy kinds suitable for growing in herbaceous borders where they can be left undisturbed; or for producing massed colour effects in flower beds. They include (a) Cottage or May-flowering tulips, so named because they were discovered in the gardens of old cottages, mansions, abbeys and monasteries throughout England, Scotland. Ireland, Belgium and France; (b) Darwin tulips which are a distinct race: having a wide range of large self-coloured flowers, but no yellows. The so-called black tulip belongs here.

Parrot Tulips. — This late flowering group is supposed to be derived from the curious green and yellow striped T. *viridiflora*. The flowers are mostly heavy and drooping, petals brightly coloured, the edges being curiously notched and wavy.

TULIP TREE (YELLOW POPLAR; Liriodendron tulipifera), an important timber tree of eastern North America, is one of two surviving species belonging to the genus Liriodendron, which! prior to the Glacial epoch, embraced at least 16 species..

Ranging from southern New England to Michigan and southward to Florida and Louisiana, the tulip tree or yellow poplar is



FROM HARRAR AND HARRAR, "GUIDE TO SOUTHERN TREES": REPRODUCED BY PERMISSION OF MCGRAW-HILL BOOK COMPANY, INC. DRAWN BY HELENE S. MILLAR

DENDROLOGICAL FEATURES OF THE TULIP TREE OR YELLOW POPLAR (LIRIODENDRON TULIPIFERA): (A) FOLIAGE AND FLOWER: (B) AGGREGATE OF SAMARAS; (C) SINGLE SAMARA: (D) TWIG; (E) LEAF SCAR most frequently encountered in mixed hardwood forest stands. Best development is attained on deep, rich, moist but well-drained soils of light texture. Second in girth only to the sycamore, and taller than all other American broad-leaved trees, it not infrequently surpasses a diameter of 6 ft. and a height of 190 ft. Its leaves, which bear no resemblance to those of other deciduous trees, are bilaterally two- to four-lobed with truncate or broadly notched apices; yellowish-green tuliplike blossoms, conelike clusters of terminally winged fruits and aromatic, purplish-brown twigs with winter buds resembling a duck's bill are also diagnostic.

Among the hardwoods, the annual harvest of tulip-tree timber is exceeded only by the oaks and the sweetgum. The light yellow to greenish-yellow wood is readily machined and utilized in prodigious quantities in the manufacture of furniture parts and plywood panels. It is also used in the production of paper, millwork, cooperage, boxes ,and crates.

Open-grown trees develop a crown of pleasing symmetry, but commonly begin to shed their leaves in early August, and the use of the tulip tree for a street or lawn tree is not recommended.

See also Forests and Forestry. (E. S. Hr.)

TULL, JETHRO (1674–1741), one of the greatest improvers of British agriculture, was born at Basildon, Berkshire, in 1674. He entered St. John's college, Oxford, in 1691, then Grays Inn, made the grand tour and was called to the bar in 1699. Necessity, however, compelled him to farm. For ten years he occupied Howberry farm, Cronmarsh near Wallingford, Oxfordshire, where he invented his seed drill which sowed the seeds in rows, thus allowing of cultivation in between. This treatment reduced the need for fallowing and incidentally for farmyard manure. In 1709 he moved to Mount Prosperous, in Shalbourne, Wiltshire. Two years later ill-health compelled him to travel in France and Italy. He was greatly struck by the remarkable effects of cultivation in the vineyards and on returning home in 1714 he developed some ingenious theories of plant nutrition and made a horse hoe to put them into practice. He was so successful that in 1731 he published *The New Horse Houghing Husbandry: or, an Essay on the Principles of Tillage and Vegetation,* expanding it greatly in 1733. Because of their novelty, his methods and ideas were violently attacked, and this, with ill-health and domestic worries, made his life unhappy. His many mechanical inventions were less important than his ideas on how cultivation should be done and what results it could achieve. His methods saved seed and kept down weeds; they were eventually taken up by the large landowners and formed the basis of modern systems of British agriculture.

Tull died Feb. 21, 1741. (E. J. R.)

TULLAMORE, a market town and the county town of County Offaly, Ire., on the Grand canal 60 mi. W. of Dublin by road. Pop. (1956) 6,147. A farm produce trade from a wide area is augmented by malting, distilling, bacon-curing and woolen industries.

The neighbourhood contains many Bronze Age and early Christian monuments. The adjacent ruined Sraith Ui Chatharnaigh castle dates from 1588; the modern hospital from 1942. (S. O. M.)

TULLE, a town of central France, capital of the *département* of Corrèze, 58 mi. S.S.E. of Limoges by rail. Pop. (1954) 15,813. Tulle (Tutela) owed its importance in the middle ages to the abbey of St. Martin, founded in the 7th or 8th century. The abbacy was raised to the rank of bishopric in 1317. The town was taken by the English in 1346. It was again conquered by the English in 1369; but, when the inhabitants succeeded in freeing themselves, they were exempted from all imposts by Charles V. The Protestants seized Tulle in 1585. The town extends along the narrow valley of the Corrèze, its streets here and there ascending the hill-slopes on either side by means of stairways. Of its 12th century cathedral, once attached to an abbey, only the porch, nave and a tower of the 13th century, with a fine stone steeple of the 14th century, remain. The neighbouring cloister (12th and 13th centuries) has been restored. The abbot's house (15th century) has a carved doorway and well-preserved windows. Tulle is the seat of a bishop, of a prefect, of tribunals of first instance and of a chamber of commerce and a board of trade-arbitrators. Its principal industry is the manufacture of small arms, established in 1690, and now carried on by the state. There are other minor industries. The well-known cascades of Gimel formed by the Montane are near Tulle.

TULLOCH, JOHN (1823–1886), Scottish theologian, notable for his efforts to arouse a spirit of liberal orthodoxy in the Church of Scotland, was born at Bridge of Earn, Perthshire, in 1823, and received his university education at St. Andrews and Edinburgh. In 1845 he becameminister of St. Paul's, Dundee, and in 1849 of Kettins, in Strathmore, where he remained for six years. In 1854 he was appointed principal of St. Mary's college, St. Andrews. At St. Andrews, where he held also the post of professor of systematic theology and apologetics, he lectured on comparative religion and treated doctrine historically, as being not a fixed product but a growth. In 1862 he was appointed one of the clerks of the general assembly, and from that time forward he took a leading part in the councils of the Church of Scotland. In 1878 he was chosen moderator of the assembly. Tulloch did much to widen the national Church of Scotland. He was deeply interested in the reorganization of education in both school and university, and acted as one of the temporary board that settled the primary school system under the Education act of 1872. He died at Torquay on Feb. 13, 1886.

Tulloch's most important works include *Rational Theology and Christian Philosophy in England in the Seventeenth Century,* 2 vol. (1872); *Modern Theories in Philosophy and Religion* (1884); *Movements of Religious Thought in Britain During the Nineteenth Century* (1885).

See Oliphant, M. O. W., *Memoir* (1888).

TULLUS HOSTILIUS, third legendary king of Rome (672–640 B.C.). His successful wars with Alba, Fidenae and Veii shadow forth the earlier conquests of Latian territory and the first extension of the Roman domain beyond the walls of Rome. It was during his reign that the combat between the Horatii and Curiatii, the representatives of Rome and Alba, took place. He is said to have been struck dead by lightning as the punishment of his pride. Tullus Hostilius is simply the duplicate of Romulus. Both are brought up among shepherds, carry on war against Fidenae and Veii, double the number of citizens, organize the army, and disappear from earth in a storm. As Romulus and Numa represent the Ramnes and Tities, so, in order to complete the list of the four traditional elements of the nation, Tullus was made the representative of the Luceres, and Ancus the founder of the Plebs. The distinctive event of this reign is the destruction of Alba, which may be regarded as a historical fact. But when and by whom it was destroyed is uncertain—probably by the Latins.

See Livy i, 22–31; Dion. Halic. iii, 1–35; Cicero, *De Republica,* ii, 17; and Rome: *Ancient History.*

TULSA, a city of northeast Oklahoma, U.S., on the Arkansas river about 200 mi. S.W. of Kansas City; the seat of Tulsa county. Tulsa calls itself the oil capital of the world. Nearly 800 oil companies of all types with investments throughout the world have offices there, and much of the city's economic activity is concerned with exploration, drilling, production, refining, transportation, marketing, financing, supply and research for the petroleum industry. The aviation industry is next in importance, and in addition there are approximately 700 firms in the Tulsa area manufacturing a wide variety of products. The city is also the commercial and financial centre of a rich agricultural area.

Tulsa began in the 1830s as a village of Creek Indian refugees, including many of mixed blood, from Alabama; the name of a Creek community in their former home was given to the new settlement. After the St. Louis-San Francisco railway reached the Creek Nation in 1882 a white community developed. It was incorporated in 1898. The population was only 1,390 in 1900, but with the discovery of oil at nearby Red Fork in 1901 and Glenn Pool in 1905, and the subsequent development of the mid-continent oil and gas region, Tulsa's growth was phenomenal. In 1960 the population of the city was 261,685, an increase of 43.2% in the decade; that of the standard metropolitan statistical area (Creek, Osage and Tulsa counties) was 418,974, an increase of

27.8%. (For comparative population figures for the city see table in OKLAHOMA: *Population.)*

The national headquarters of United States Junior Chamber of Commerce are in Tulsa and the International Petroleum exposition is held there. Educational facilities include the University of Tulsa, a Presbyterian institution founded at Muskogee as Henry Kendall college in 1894 and moved to Tulsa in 1907. The Tulsa Philharmonic orchestra; the Tulsa Opera, Inc.; the Philbrook Art centre; and the Thomas Gilcrease Institute of American History and Art are other significant cultural institutions.

The water system, which brings water by gravity flow from two lakes on Spavinaw creek, more than 50 mi. away. is one of Tulsa's greatest assets. The city has over 3,000 ac. in parks, the largest of which has golf courses, a zoo, picnic and recreation areas and a lake. Residents also have easy access to the numerous lakes of eastern Oklahoma. (W. A. SE.)

TULSI DAS (1532–1623), the greatest and most famous of Hindi poets, was a Sarwariya Brahman, born, according to tradition, in 1532, during the reign of Humayun, most probably at Rajapur in the Banda district south of the Jumna. His father's name was Atma Ram Sukal Dube; that of his mother is said to have been Hulasi. A legend relates that, having been born under an unlucky conjunction of the stars, he was abandoned in infancy by his parents and was adopted by a wandering *sadhu* or ascetic. with whom he visited many holy places in the length and breadth of India; and the story is in part supported by passages in his poems. He studied, apparently after having rejoined his family. at Sukarkhet, a place generally identified with Soron in the Etah district of the United Provinces, but more probably the same as Varahakshetra on the Gogra river, 30 mi. W. of Ajodhya (Ayodhya). He married in his father's lifetime, and begot a son. His wife's name was Ratnawali, daughter of Dinabandhu Pathak, and his son's Tarak. The latter died at an early age, and Tulsi's wife, who was devoted to the worship of Rama, left her husband and returned to her father's house to occupy herself with religion. Tulsi Das followed her, and endeavoured to induce her to return to him, but in vain; she reproached him (in verses which have been preserved) with want of faith in Rama, and so moved him that he renounced the world, and entered upon an ascetic life, much of which was spent in wandering as a preacher of the necessity of a loving faith in Rama. He first made Ajodhya (the capital of Rama and near the modern Fyzabad) his headquarters, frequently visiting distant places of pilgrimage in different parts of India.

During his residence at Ajodhya the Lord Rama is said to have appeared to him in a dream, and to have commanded him to write a *Ramayana* in the language used by the common people. He began this work in 1574, and had finished the third book (*Aranya-kand*) when differences with the Vairagi Vaishnavas at Ajodhya. to whom he had attached himself. led him to migrate to Benares, where he settled at Asi-ghat. There he died in 1623, during the reign of the emperor Jahangir, at the great age of 91.

The period of his greatest activity as an author synchronized with the latter half of the reign of Akbar (1556–1605) and the first portion of that of Jahangir, his dated works being as follows: commencement of'the *Ramayan,* 1574; *Ram-satsai,* 1584; *Parbati-mangal,* 1586; *Ramagya,* 1598; *Kabitta Ramayan,* between 1612 and 1614. A deed of arbitration in his hand, dated 1612, relating to the settlement of a dispute between the sons of a landowner named Todar, who possessed some villages adjacent to Benares, has been preserved, and is reproduced in facsimile in G. A. Grierson's *Modern Vernacular Literature of Hindustan,* p. 51. Todar (who was not, as formerly supposed, Akbar's finance minister, the celebrated Raja Todar Mall) was his attached friend. and a beautiful and pathetic poem by Tulsi on his death is extant. He is said to have been resorted to. as a venerated teacher, by Maharaja Man Singh of Jaipur (d. 1618). his brother Jagat Singh, and other powerful princes; and it appears to be certain that his great fame and influence as a religious leader, which remain pre-eminent to this day, were fully established during his lifetime.

Tulsi's great poem, popularly called *Tulsi-krit Ramayan* but named by its author *Ram-charit-+%pas,*"The Lake of Rama's Deeds," is perhaps better known among Hindus in upper India than the Bible among the rustic population in England. Its verses are everywhere, in this region, popular proverbs.

The poem is a rehandling of the great theme of Valmiki. but is in no sense a translation of the Sanskrit epic. Besides the *Lake of Rama's Deeds,* Tulsi Das was the author of five longer and six shorter works, most of them dealing with the theme of Rama, his doings, and devotion to him. The former are (1) the *Dohabali,* consisting of 573 miscellaneous *doha* and *soratha* verses —of this there is a duplicate in the *Ram-satsai,* an arrangement of seven centuries of verses, the great majority of which occur also in the *Dohabali* and in other works of Tulsi; (2) the *Kabitta Ramayan* or *Kabittabali,* which is a history of Rama in the *kabitta, ghanakshari chhappai* and *sawaiya* metres—like the *Ram-charit-manas,* it is divided into seven *kands* or cantos and is devoted to setting forth the majestic side of Rama's character; (3) the *Git-Ramayan,* or *Gitabali,* also in seven kands, aiming at the illustration of the tender aspect of the Lord's life—the metres are adapted for singing; (4) the *Krishnawali* or *Krishna gitabali,* a collection of 61 songs in honour of Krishna, in the Kanauji dialect —the authenticity of this is doubtful; and (5) the *Binay Pattrika,* or "Book of Petitions," a series of hymns and prayers of which the first 43 are addressed to the lower gods, forming Rama's court and attendants, and the remainder, no. 44 to 279, to Rama himself.

Of the smaller compositions the most interesting is the Vairagya Sandipani, or "Kindling of Continence," a poem describing the nature and greatness of a holy man, and the true peace to which he attains. This work has been translated by Grierson in the *Indian Antiquary,* xxii, pp. 198–201.

A manuscript of the *Ayodhya-kand,* said to be in the poet's own hand, exists at Rajapur in Banda, his reputed birthplace. One of the *Bal-kand,* dated Sambat 1661 (A.D. 1604), 19 years before the poet's death, and carefully corrected, it is said, by Tulsi Das himself, is at Xjodhya. Another autograph is reported to be preserved at Malihabad in the Lucknow district, but has not, so far as known, been seen by a European. Other ancient manuscripts are to be found at Benares, and the materials for a correct text of the *Ramayan* are thus available. Good editions have been published by the *Khadga Bilas* press at Bankipur (with a valuable life of the poet by Baijnath Das), and by the *Nagari Pracharini Sabha* at Allahabad (1903). The ordinary bazar copies of the poem, repeatedly reproduced by lithography, teem with interpolations and variations from the poet's language. An excellent translation of the whole into English was made by the late F. S. Growse, of the Indian civil service (5th edition, Cawnpore, 1891).

The best account of Tulsi Das and his works is contained in the papers contributed by Grierson to vol. xxii of the *Indian Antiquary* (1893). In Growse's translation of the *Raw-charit-Manas* will be found the text and translation of the passages in the *Bhaktamala* of Nabhaji and its commentary, which are the main original authority for the traditions relating to the poet. In the introduction to the edition of the *Ramayan* by the *Nagari Pracharini Sabha* all the known facts of Tulsi's life are brought together and critically discussed. For an exposition of his religious position, and his place in the popular religion of northern India, *see* Grierson's paper in the *Journal of the Royal Asiatic Society,* July 1903, pp. 447–466. (C. J. L.; X.)

See Sir G. A. Grierson, *Notes on Tulsi Das* (1921).

TULU LANGUAGE, also known as TULUVA. a language of the Dravidian family. spoken on the west coast of India in the South Kanara district of the state of Mysore. At mid-20th century there were estimated to be about 800.000 speakers. It has no literature. It is an independent language of the family and close affiliation with any one of the other languages is not yet clear. It has borrowed many words from Kanarese (*q.v.*) because of close political associations with this language. *See* also DRAVIDIAN LANGUAGES.

See *Linguistic Survey of India,* vol. iv (1906); Bishop R. Caldwell, *Comparative Grammar of the Dravidian Languages* (1913).

(M. B. E.)

TUMACO, a seaport city of southwestern Colombia in the department of Nariño. the southernmost of Colombia's port cities and, next to Buenaventura, the most important Colombian port on the Pacific side. Tumaco is located on an island on the south side of the bay of Tumaco. It is served by a short railroad line which goes only as far as Diviso, by the Barranquilla-Guayaquil air line and by a road which joins the Simón Bolivar highway between Pasto and Ipiales. Pop. (1951) 12,692. Tumaco and the region around it were visited by Francisco Pizarro, and the city later gained some importance because of its port facilities during the period when Colombia was attempting to win its freedom from Spain.

Tumaco is a shipping centre for goods sent down the Rio Patía, which drains into the bay of Tumaco.

TUMBES, a department of Peru, is situated on the' Pacific coast in the extreme northwest between Ecuador on the east and the department of Piura on the south. Formerly a littoral province, it was given departmental status in 1942. It is the country's smallest department, with an area of 1,827 sq.mi. Pop. (1954 est.) 33,700. Its capital is the city of Tumbes (pop. 8,602), on the Tumbes river 7 mi. from its port of Puerto Pizarro, with which it is linked by rail. The district was an ancient Inca stronghold, and Tumbes was a prosperous city when Francisco Pizarro made his initial landing nearby (1527) and used it as his base for the conquest of the Inca empire. The region's ready accessibility brought modern development early. In 1863 an oil well was sunk near Zorritos, marking the beginning of the important oil industry. The Zorritos-Chira oil fields (partly in Tumbes and partly in Piura) account for most of Peru's oil production and have reserves estimated at more than 5,000,000,000 bbl. Fishing, especially for lobster, is important. Other products include sugar, tobacco, coffee and cacao, along with salt and some gold. (L. W. Be.)

TUMBLEWEED, in the U.S. a common term for a plant which breaks loose at the ground line when dry, and is rolled about by the wind, scattering its seeds along the way. Tumbleweeds are most abundant and often noxious in semiarid regions. Examples are: tumbling pigweed (Amaranthus *graecizans*), Russian thistle (*Salsola kali*), winged pigweed (Cycloloma *atriplicifolium*), bugseed (*Corispermum hyssopifolium*), tumbling mustard (*Sisymbrium altissimum*) and witch grass (*Panicum* capillare).

TUMBLING MUSTARD (Sisymbrium *altissimum*), an annual tumbleweed of the mustard family (Cruciferae. *q.v.*), native to Europe and extensively naturalized in North America, especially in the northern states and adjacent Canada. It is tall, freely branching and has deeply cut leaves. The small pale-yellow flowers produce long, narrow, spreading seed pods. One plant may ripen more than 500,000 seeds.

TUMKUR, a town and district of southern India, in the west of Mysore state. The town (pop., 1951, 35,999), which is a health resort on the Devarayadurga hills, has a station on the Madras and Southern Mahratta railway, 43 mi. N.W. from Bangalore. The area of the district is 4,093 sq.mi.

It consists chiefly of elevated land intersected by river valleys. A range of hills rising to nearly 4,000 feet crosses it from north to south, forming the water parting between the systems of the Krishna and the Cauvery. The principal streams are the Jayamangala and the Shimsha. The population in 1951 was 1,151,362. The cultivated products consist chiefly of millets, rice, pulses and oilseeds.

TUMMEL, a river of Perthshire, Scot. It flows eastward from Rannoch moor to its junction with the Garry and then southeast to fall into the Tay near Logierait, a course of 58 mi. It drains a succession of basins in which the streams expand into lakes (Lochs Ericht, Rannoch and Tummel). The descent from each basin to the next is abrupt and marked by rapids or falls in the river. The falls of Tummel are much visited by tourists. Hydroelectric power stations have been constructed at several of these points where the river course is interrupted, *e.g.*, at Tummel bridge (1933) and at Pitlochry. (T. Her.)

TUMOUR. In its broad sense the word "tumour" may be applied to any localized swelling irrespective of origin, location or composition. In its restricted sense, however, it denotes an abnormal growth of new tissue, arising by unknown cause from preexisting body cells, having no purposeful function and being characterized by a tendency to autonomous and unrestrained growth. Thus we may recognize two main groups of swellings: false tumours or nonneoplastic swellings, and true tumours or neoplasms, conforming to the restricted definition just mentioned.

The essential basis for this distinction lies in the cellular composition of all living tissues, normal and abnormal. Only by a recognition of the distinctive appearance and characters of the individual cells forming a tissue or swelling can we attempt to define accurately the nature, origin and entity of a tissue mass. Swellings may be composed of (1) normal body cells, (2) abnormal body cells, or (3) foreign cells, introduced from without the body. Cells of the second variety differ from the first in having undergone alterations in appearance, character or arrangement as follows.

Hypertrophy denotes an increase in the size of individual cells. This feature is occasionally encountered in true tumours but occurs commonly in other conditions.

Hyperplasia denotes an increase in the number of cells within a given zone. In some instances it may constitute the only criterion of tumour formation.

Anaplasia denotes a regression of the physical characteristics of a cell toward a more primitive type. This is an almost constant feature of malignant tumours, though it occurs in other instances both in health and in disease.

True tumours in general are characterized by a growth of cells exhibiting one or more of these three variations from normalcy.

FALSE TUMOURS

These form a heterogeneous group. In most instances the cause and origin of the swelling is known and well understood.

Inflammatory Swellings. — These are formed in the normal course of the reaction of the body to irritants. The mass of the swelling is composed mainly of cells of normal body type which, in response to a noxious stimulus, are incited to multiply and concentrate in the zone that is the seat of the attack. The two common causes of inflammation are trauma and bacterial infection. Traumatic swellings of an acute nature include such conditions as a bruise, a haematoma (viz., a black eye), or a sprain. Examples of chronic traumatic swellings are calluses, bursitis (viz., housemaid's knee), or an overgrowth of bone after an inaccurately healed fracture. Infectious swellings of an acute nature include boils, abscesses, felons, and inflamed lymphatic glands. Those of chronic type result from tuberculosis, syphilis, actinomycosis, leprosy, etc.

Hypertrophic Swellings. — The essential feature of these is an increase in the size (hypertrophy) and number (hyperplasia) of the cells constituting the organ or part concerned. The excessive muscular development of the calves of the legs of some ballet dancers is an example, likewise the enlargement of the breasts and uterus in pregnancy. All such swellings result from normal physiological processes and as such do not constitute true disease.

Parasitic Swellings. — These result from the multiplication within the body of living cells introduced from without. The only common example is hydatid disease which gives rise to the formation of cysts in the internal organs. Both the wall and the contained fluid are derived from the foreign cells. They evoke a variable amount of inflammatory response on the part of the adjacent body cells.

Cysts. — These constitute a heterogeneous group since some cysts are true tumours, which happen to develop in spherical form with a central space occupied by degenerative fluid products of their own cells. Other cysts result from cystic degenerative changes occurring within the solid substance of true tumours. Many, however, are not related to tumours at all, the following being specific examples: retention cysts, dilated glands whose effluent ducts are blocked, *e.g.*, sebaceous cysts (wens); distention cysts, formed by the dilatation of closed sacs which normally contain but little fluid, *e.g.*, hydrocele; congenital cysts, which do not necessarily appear at birth but are all derived from embryological structures which have persisted fortuitously, *e.g.*, thyroglossal, branchial cysts; parasitic cysts (described above); degenerative cysts, *e.g.*, a ganglion of the wrist, blood cysts.

All cysts contain fluid free within a closed cavity. The nature of the fluid may be bloody, mucoid, milky, etc. Clear fluids such as lymph, in cysts near the surface of the body, will transmit light and hence are translucent. Aspiration of the contents is frequently practised as a means of diagnosis. Treatment consists in surgical removal where and when indicated.

Degenerative Swellings. — These result from distention of hollow organs or tissues following an abnormal weakness of their walls or their investing membranes. Examples include aneurysms, varicose veins, hernias, diverticula.

False Swellings. — Deeply seated organs or structures may become abnormally prominent because of the wasting of their superimposed coverings. A false impression of enlargement may therefore appear.

Swellings of Unknown Origin. — This group embraces a few swellings whose nature and origin is the subject of doubt and debate. They may or may not be true tumours, inflammations or degenerations. The outstanding example is Hodgkin's disease of the lymphatic glands.

Phantom Tumour is a term applied to the apparent enlargement of the lower abdomen that occurs in women who suffer from an hysterical conviction that they are pregnant. It is not infrequently accompanied by alleged concomitant accessory signs of pregnancy.

The "tumour" promptly disappears under the influence of hypnosis or anaesthesia.

TRUE TUMOURS

These are composed of masses of tissue cells developed from pre-existing body cells. In some instances the tumour cells are normal in appearance, faithful reproductions of their parent types; such tumours are generally benign. Other tumours are composed of cells slightly different from normal adult types, different in appearance, size, shape and structure; these tumours are usually malignant, and the specific changes in cell type are those of anaplasia.

Cause. — We have seen that the false tumours are initiated by a definite and in many instances a specific cause, but in the case of true tumours, the cause is unknown. The method by which a tumour grows; *i.e.,* the proliferation of body cells, is a process that normally occurs in health. Body cells, like men, have their allotted span of life, varying from a period of days to years, whereupon they are replaced. New cells do not arise *de* novo but by fission, one (mother) cell dividing into two (daughter) cells; the daughters (twins) are identical with each other and with their late mother. When tissue is lost, as by a burn of the skin, the defect is reconstituted by the multiplication of adjacent body cells. This process proceeds until the defect is properly repaired, and then it ceases. We can see the necessity and logic for the initiation of such a process but we can only marvel at the mechanism which finally throttles the cellular proliferation at the exact moment of normalcy. It is presumed that the reparative process of cell proliferation is initiated by a normal stimulus and is stopped by a similarly normal stimulus.

Tumours arise by a proliferation of body cells in the absence of a normal stimulus, or, alternatively, in the presence of an abnormal stimulus; the precise nature of both processes still defied elucidation at mid-20th century. Without any discernible cause, the cells of a tissue start to multiply as though to fill a defect that does not exist. One important difference from the normal reparative process is a tendency for the daughter cells to assume characters of a nature more primitive than that of their predecessors, hence becoming anaplastic.

Certain factors are generally believed to favour the initiation of tumour formation in isolated instances, and outstanding among these is chronic irritation. Employment in certain trades and occupations predisposes to the development of certain tumours; these occupations are associated with long continued exposure to mild irritation of various parts of the body. Experimental production of tumours by irritational methods has been accomplished in animals, but it is unlikely that these methods are identical with those that cause the spontaneous origin of tumours in otherwise normal human beings.

Among other factors is heredity. There is some evidence that inherited characteristics may predispose the development of tumours, particularly of the malignant type. Many experimental studies with mice demonstrate the possibility of breeding, by planned selection, a strain of animals that will show almost 100% cancer production. The extremely high incidence of human cancer in certain family groups is well known, but appears to constitute only a minor subfactor in the propagation of the disease.

Infection by micro-organisms has not been proved as a cause. Certain experimental tumours of fowl have been shown to be transmitted by a filterable virus. The only possible instance of this mode of tumour formation in man would appear to be the "crops" of "soft" warts commonly occurring in childhood, but there is some doubt that these warts are true tumours.

Trauma is a factor occasionally imputed, notably in instances coming to the attention of workmen's compensation boards. It would seem that in some instances certain tumours, usually of a sarcomatous nature, may be causally related to trauma, but definite proof was far from established at mid-century, since the experimental production of a tumour in this manner had yet to be demonstrated conclusively.

The Vicious Autonomy of Turnours. — Natural inflammatory swellings are primarily beneficial to the body since they constitute one phase of the protective response of the body to noxious stimulus. True tumours, on the other hand, serve no such useful function. In many instances their only role is to kill the patient. They grow for their own sakes alone, and at the expense of the body economy.

The capacity of inflammatory tumours to form and function depends upon the general healthiness of the body. In people who are poorly nourished or ill, the inflammatory response may be poor or absent. True tumours on the other hand observe no such compliance with the general body resources. Even though a person be so physically exhausted that a recently sustained wound may fail to show any attempt at healing, a true tumour currently present will continue to grow by cell proliferation, ignoring the ebbing vitality of the patient. In this respect tumours behave as parasites.

Whenever normal cellular proliferation is required to carry out body repairs, the multiplying cells tend to reconstruct as faithfully as possible the normal architecture of the part lost or destroyed. Proliferating tumour cells on the other hand follow no plan or deviate grossly from the original tissue pattern. This of course is at least consistent with their utter lack of function since no structural specification is therefore required. Indeed their perversity is sometimes manifested by the development of abnormal symptoms through their overproduction of malicious ferments, as in certain tumours of the thyroid gland and pancreas.

Clinical Manifestations. — The mass of newly formed tumour cells usually constitutes a definite localized swelling. Should such a mass occur on or near the surface of the body, it can be felt or seen as a lump. But since tumours may develop in any organ or tissue, however deeply placed, the swelling may not always be palpable.

Some tumours, notably those of the malignant variety, may assume physical characteristics other than that of lumps. Thus they may appear as ulcers, indurated cracks or fissures, wartlike projections, or as a diffuse ill-defined infiltration of what appears to be an otherwise normal organ or tissue. The tumour cells may replace completely the normal cells of the part and should the processes of proliferation of new cells and the destruction of normal cells both proceed at the same pace, there may be only little gross change in the size of the part, though there will usually be an alteration in the consistency of the tissues. In other cases the normal cells may disappear more quickly than the tumour cells appear, so that the affected part may actually shrink in size. This is seen in certain cancers of the breast and in the annular type of cancer of the bowel.

Tumours which arise in the tubular structures of the body; *e.g.,* the intestinal, biliary or urinary tracts, are prone to cause obstruction since the normal contents of these tubes are no longer free to pass along their lumina. Thus intestinal, biliary, etc., obstruction may be produced. Furthermore, such tumours, being located in the walls of these various tubes, actually may bleed into the tract concerned, and the blood subsequently appears at the natural body orifices; viz., the vomiting of blood resulting from cancer of the stomach, or the passage of bloody urine in cases of tumours of the kidney or bladder. Again, the tumour by virtue of its mass as a foreign body may initiate the production of pus or mucus and these substances likewise are passed to the surface of the body.

Tumours arising within the bony cages of the body; *e.g.*, chest, skull and spinal column, may cause symptoms by exerting direct pressure on adjacent vital structures such as the heart, brain and spinal cord. Those developing within the interior of a bone may so weaken the bone as to cause a collapse, bending or actual fracture. The destruction of specific tissue in which the tumour develops may so interfere with local function as to cause specific symptoms; *e.g.*, loss of vision in the case of an intraocular tumour.

Pain is a variable symptom. It may result from direct pressure on, or irritation of, adjacent nerve tracts. *e.g.*, the spinal cord, or by producing increases of pressure within a rigid cavity, *e.g.*, headache in the case of brain tumour; or by producing obstruction of a muscular tube with concomitant colic, *e.g.*, tumours of the intestine. Thus, in their early stages all tumours tend to be painless, and even though they grow to a large size, should there be no interference with local function, they may remain painless. Later, however, the malignant variety commonly causes pain by the direct invasion of nerve trunks or by destruction of bone. Tumours themselves are largely devoid of nerve fibres, excepting, of course, those that are composed of nervous tissue.

Classification of **Tumours.**—When we recall that tumours may arise in any part of the body and from every type of cell and tissue in the body, that they may possess the phenomenon of malignancy in any degree, we must realize that an accurate, all-embracing classification has yet to be achieved.

The fact that we are still uncertain of the identification of some of the precursor cells from which tumours arise serves only to augment the difficulty.

Since all tumours are composed of cells, we try to classify them according to the specific type of cell predominating in any particular instance. This constitutes the histologic basis of classification, the microscopic study of cellular structure. In general two main types of body tissue are recognized: (1) epithelial tissue, which forms the surfaces of the body and its tubular cavities and glands and (2) connective tissue, whose function is essentially supportive. It is therefore possible for tumours to be composed of three types of tissue, namely, epithelial tissue, connective tissue and tissues of mixed or uncertain type. The introduction of the last group adds a note of variability characteristic of all biologic processes.

Classification of Tumours

Classification according to behaviour	Classification according to tissue of origin		
	Connective tissue	Epithelial tissue	Tissue mixed or indefinite
Benign	lipoma fibroma angioma chondroma osteoma myxoma neuroma myoma fibromyoma osteochondroma glomus tumour	papilloma adenoma implantation dermoid	odontoma fibroadenoma adenomyoma fibropapilloma
Malignant	sarcoma	carcinoma	specific adrenal tumours
Variable malignancy or locally malignant	giant cell glioma endothelioma chordoma	rodent ulcer	melanoma mixed salivary tumour carcinoid tumour embryological tumours

Long before the advent of the microscope as an aid to histologic study, medical men classified tumours on the basis of their ultimate effect on the patient; *i.e.*, the clinical classification. While the histologic picture of a tumour is of interest to the pathologist, the effect of the tumour on the life and happiness of the patient is of far more importance to the patient himself. Hence the ancient clinical classification of tumours into the benign and the malignant types. The malignant tumours are those that, in general, always kill the patient eventually if left untreated or if not drastically eradicated at an early stage of development. This distinction of the clinical behaviour of tumours holds good only up to a point, for it is known that some benign tumours; *e.g.*, a lipoma, may readily cause death purely by virtue of location by exerting pressure on the spinal cord. Other tumours appear to fall between the two main clinical divisions in that they may be only locally malignant, destroying all normal tissue in their vicinity, but not spreading widely from their point of origin. Thus we may classify tumours on a clinical basis as benign, malignant, or of local or variable malignancy. Again the acknowledgment of a third group, while typifying the vagaries of biologic processes, serves also to enhance the difficulties in formulating a satisfactory classification of tumours.

Malignancy of Turnours.—Malignancy refers to the tendency of a tumour to produce death. But we have seen that any tumour, of any type, may produce death by local effects if appropriately situated.

Thus the specific definition of malignancy implies an inherent tendency, on the part of the cells composing it, to invade the body widely and relentlessly, to become disseminated by subtle means, and eventually to kill the patient unless all the malignant cells can be drastically and completely eradicated.

The outstanding gross characteristic of malignancy is the property of tumour cells to wander from their site of origin. Though the tumour may arise from one site in one tissue or organ, it may eventually establish metastases in almost every tissue and organ of the body.

In contrast, the cells of a benign tumour invariably remain in contact with each other in one solid mass centring at the site of origin. This gross physical continuity of the benign tumour cells enables them to be removed completely by surgical means, providing the location is suitable. But the dissemination of malignant cells, each one individually possessing the facilities and tendency to give rise to new masses in new and distant sites, precludes complete eradication by a single manoeuvre in all but the earliest period of growth.

The question frequently arises, does a benign tumour ever become malignant? In other words, is malignancy a property that may be acquired by benign tumour cells? We know that normal body cells, if subjected to the appropriate (and unknown) stimulus, may form tumours and these tumours may be either benign or malignant ab *initio*. Both types of tumour rarely are found in the same individual at the same time. Still more rarely does a primarily benign tumour appear to become transformed into a malignant one. It is not easy to be certain concerning the acquisition of malignant transformation; it is possible for a primarily malignant tumour to remain quiescent, mimicking a benign one clinically, for a long time.

Of the group of tumours in which malignancy is variable, some are benign from the start and remain so; others are apparently malignant from their moment of origin; and finally, a few appear to change from innocent to malignant type. In the latter case the histologic picture of the tumour before and after malignant transformation may show no differences. Thus, acquired malignancy is not necessarily dependent upon discernible changes in the appearance of the tumour cells.

To sum up, a benign tumour may undergo malignant transformation but the cause of such change is unknown. The regression of a malignant tumour to benign type is, lamentably, unknown.

For a discussion of malignant tumours *see* under CANCER; CANCER RESEARCH.

BENIGN TUMOURS

Characteristics.—Benign tumours tend to occur in younger people, most of them appearing before the age of 40. Histologically their cells show no great variation in detail from those of normal tissue, in contrast to the appearance of cancer cells. The arrangement of the new cells may suggest an abortive attempt to reproduce the normal structure of the part but this effort is usually crude and ineffectual. All tend to remain localized at the site of origin.

They enlarge by accretion, pushing aside the adjacent tissues without involving them intimately. Malignant tumours, on the other hand, invade the surrounding structures, thereby becoming fixed to them.

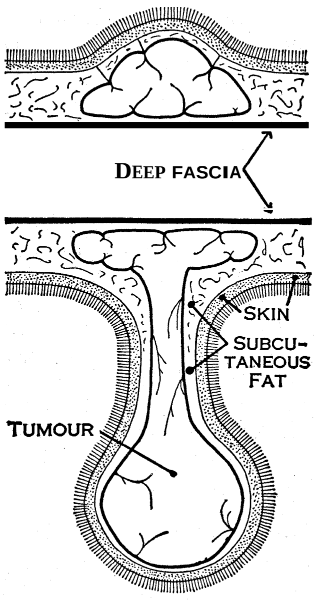
Many benign tumours are encapsulated. The capsule consists of a connective tissue derived from the structures immediately surrounding the tumour. While it serves to demarcate the tumour it does not act as a limiting membrane. Malignant tumours, as a rule, do not possess a capsule though some of the sarcomas arising from soft tissues may have a pseudocapsule in their early stages. The chief effect of the capsule is to lend the physical property of mobility to the tumour mass. Well-encapsulated tumours are not anchored to their surrounding tissues. It may be possible to bounce the tumour about in the part; *e.g.*, a fibroadenoma of the breast or, should the tumour arise from a bone (an osteoma), the enveloping muscles and tendons will move freely over and around the mass.

Benign tumours of any one type are frequently multiple, several arising in different parts of the body either simultaneously or in succession. In such'cases all the tumours are identical. It is most unusual for more than one malignant tumour to arise primarily, but, should this primary tumour give rise to metastases, these secondary masses tend to differ from the primary growth in their gross physical characteristics, though remaining identical histologically.

Benign **Tumours** Arising from Connective Tissue,

Lipoma.—This is the commonest of all neoplasms and consists of fat cells which are microscopically indistinguishable from normal fat cells. They are invariably ensheathed in a delicate transparent capsule which sends fine septa through the body of the tumour making it lobulated. Thus are explained the two outstanding characteristics of the tumour; namely, lobulation and a firm demarcated edge. Small lipomas tend to be plaque-shaped, larger ones hemispheroidal, while others may become pedunculated. Since normal fat is a soft structure, so too are most lipomas, though in their infancy they are frequently firm. Pain is a most unusual feature and suggests the rare complication of calcification. Since fat at body temperature is a clear fluid, prominent tumours near the surface of the body may be translucent in a strong beam of light.

They tend to occur in all situations where normal fat is found and thus may be classified according to site; namely, subcutaneous, subfascial, subserous, submucous, subsynovial, with rarer occurrence in the subperiosteal and subcapsular regions. By far the commonest site is the subcutaneous plane, immediately deep to the skin (see fig. 1). While commonly single, they may be present in scores. They vary from the size of a pea to that of a football and while they may arise at any age they are rare in the first decade of life. It is generally conceded that they are not subject to malignant change, those so-called malignant lipomas being liposarcomas from the start.



FROM "THE CLINICAL DIAGNOSIS OF SWELLINGS' (THE WILLIAMS AND WILKINS COMPANY) BY COURTESY OF DR. C. E. CORRIGAN

FIG. 1.—SUBCUTANEOUS LIPOMAS

Treatment consists of removal of the tumour by surgical excision, the indications being cosmetic defect or interference with the function of local structures; *e.g.*, when the tumour is located within the bowel or is exerting pressure on the spinal cord. Complete removal is usually effected quite easily and is never followed by recurrence.

Diffuse lipomas are characterized by absence of a limiting capsule. They are probably not true neoplasms but rather result from disturbances of metabolism.

Fibroma.—This is a rare tumour composed of white fibrous tissue enclosed in a thick tough capsule. It is usually spherical in shape, hard, painless, freely movable and varied in size but it seldom exceeds the dimensions of an orange. A "soft" variety is described but is uncommon. They are found in the bones—chiefly about the gums of the jaws and the nasopharynx; in the tendon sheaths—chiefly on the back of the wrist; in certain glands of the body (breast, ovary, testicle); and in the nerves.

The latter site is the commonest. Here the tumours spring from the fibrous sheath of the nerve rather than from the conducting tissue—hence they contain no nerve elements. The eighth cranial nerve is especially prone to be affected, giving rise to the so-called acoustic neuroma.

Von Recklinghausen's disease consists of multiple small fibromas affecting the subcutaneous nerves of the body and is accompanied by a patchy discoloration of the skin. The condition tends to be inherited and of familial proportions. Molluscum fibrosum, plexiform neuroma and elephantiasis neuromatosa are other clinical manifestations of multiple fibromas. Two complications are observed, myxomatous degeneration and malignant transformation to sarcoma, the latter supervening particularly on the "soft" variety of fibroma.

Treatment consists of early excision of the single types. There is no uniformly satisfactory method of dealing with the disease in its multiple form.

Angioma.—This tumour is composed of vessels of which there are two types (1) haemangiomas, or tumours of blood vessels and (2) lymphangiomas, tumours of lymphatic vessels.

The haemangiomas are of three varieties, depending on the type of blood vessel forming the tumour.

The capillary haemangioma is the commonest form of birth mark. It consists of a mass of fine capillary vessels stuffed with circulating blood. It is seen most commonly in the skin but may affect deeper structures as well. In its typical form it consists of a reddish, roughened, raised patch, painless, often with an ill-defined border. The colour is due to the concentration of blood and frequently this can be expelled partially by pressure with a finger tip, causing the zone so pressed to blanch. It does not possess a capsule.

The tumours, either single or multiple, appear shortly after birth and tend to increase in size for a few months. Many of them disappear spontaneously.

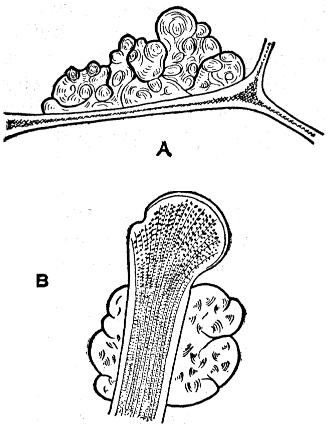
The only serious complication is haemorrhage, which in some instances may be fatal. Treatment consists of excision if feasible, if not, in radiation by means of X-ray or radium. They do not tend to recur.

The cavernous haemangioma consists of a growth of blood vessels of the character of veins. Hence they appear, when near the surface, as soft, painless, bluish, wormy masses which can be emptied by compression and will refill by dependency. If located close to the trunk of the body, they may show an impulse on coughing. They occur in the subcutaneous plane, in the muscles, in the solid viscera and in the bones—one tumour only being the rule. In the bones they are prone to erode their parent site and cause collapse or fracture. Frequently they possess a partial capsule of thin connective tissue.

Treatment is best effected by excision if possible, otherwise as in vertebral sites—by radiation.

The plexiform haemangioma consists of a mass of large vessels of arterial type and calibre. Not infrequently large venous channels are present as well. The temporal region of the head is the only common site, where the swelling appears as a pulsating mass which may erode the skin and the underlying bone. Treatment consists of complete and careful excision,

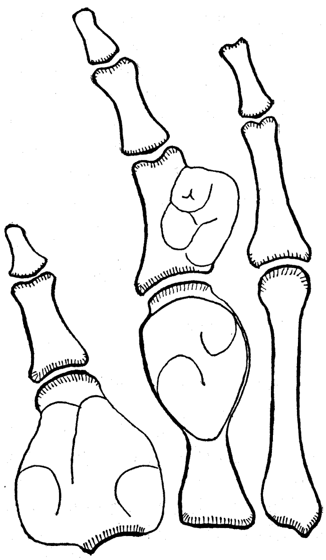
The lymphangiomas are rare tumours and, like their haemal cousins, are of three types. Capillary lymphangiomas consist of tiny pearly vesicles the size of pinheads, affecting chiefly the lips and tongue. The cavernous type, also known as cystic hygroma, consists of large, thin-walled, translucent lymphatic cysts, usually found in the neck. The plexiform type consists of a wormy mass of grossly dilated lymphatic vessels and, like the capillary type with which they are frequently associated, they tend to affect the lips and the tongue. All lymphangiomas may be treated by excision or radiation. None possesses a well-defined capsule.



OF SWELL- INGS" (THE WILLIAMS AND WILKINS COM- PANY) BY COURTESY OF DR. C. E. CORRIGAN
FIG. 2.— (A) ECCONDROMA OF THE SCAPULA, (B) ECCONDROMA OF THE HUMERUS

Chondroma.—This is a tumour composed of hyaline cartilage which is the embryologic precursor of bone. While normally confined to bony sites, these tumours occasionally are encountered free in soft tissue sites. They form firm lobular masses enclosed in a thick capsule. Two types are described. The *ecchondromas* (fig. 2) grow outward from the surface of their parent bone—commonly the flat bones of the skeleton. They may attain the size of a coconut and they push aside the overlying structures. They are usually single. The *enchondromas* (fig. 3) develop within the interior of bones—usually the smaller long bones of the hands, feet and digits. They are commonly multiple and bilaterally placed. As they grow they expand and thin the cortex of their parent bone, producing considerable deformity. They may erupt through their bony covering and project outward into the surrounding soft tissues.

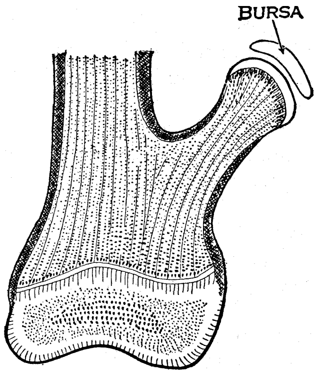
All chondromas tend to be painless, but are subject to myxomatous degeneration and sarcomatous change. All should be treated by complete surgical excision.



FROM "THE CLINIC DIAGNOSIS OF INGS" (THE WILLIAMS AND WILKINS COMPANY) BY COURTESY OF DR. C. E. CORRIGAN
FIG. 3.—ENCHONDROMAS OF THE SMALL BONES OF THE HAND

Osteoma.—This is a tumour composed of bone. Two varieties are distinguished. The *cancellous* osteoma (fig. 4) is made up of all the elements of the shaft of a long bone, including both the spongy medulla and the firm compact cortex. Its gross appearance suggests a ballooning outward of a portion of the parent bone at one point. They form hard painless masses deeply attached to the skeleton; displacing the soft tissues about them. Not infrequently they are capped by a bursa which may be the seat of periodic inflammation, thus causing pain overlying the swelling. These tumours probably form as the result of an accidental deviation from the normal pattern of growth in a long bone, for they arise only during the period of bone growth—under the age of 2j, and they cease to enlarge when their parent bone reaches maturity. Both single and multiple varieties occur. Treatment is effected by surgical excision.

The *compact* osteoma (fig. 5) consists of a proliferation of the dense cortical layer only of a bone. They are usually single tumours and constitute the hardest substance the human body is capable of producing. They occur on the surface of the flat bones of the body. notably the vault of the skull and the lower jaw. In the case of the skull they may grow from either the external or internal surface, or both, thus occasionally projecting into the cranial cavity and exerting pressure on the brain. When growing externally they form a hard circumscribed boss over which the scalp rides freely. They occur at any age. Treatment consists of removal by sectioning the normal bone close to the periphery of the mass, since no instrument is sufficiently staunch to attack the tumour itself without fracturing the adjacent portion of the skull.



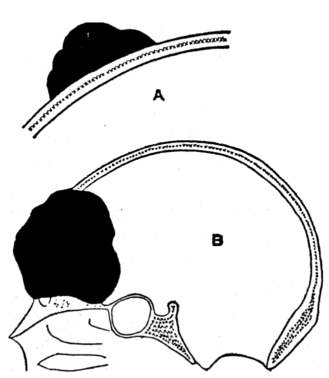
FROM "THE CLINICAL DIAGNOSIS OF SWEL INGS" (THE WILLIAMS AND WILKINS COM. PANY) BY COURTESY OF DR. C. E. CORRIGAN
4.—CANCELLOUS OSTEOMA OF THE LOWER END OF THE FEMUR

Myxoma is a rare tumour consisting of a mass of jellylike primitive connective tissue.

Neuroma is an equally rare tumour formed of nerve cells and fibres, usually derived from the autonomic nervous system.

Myoma, in pure form, is again a rare tumour consisting of muscle tissue only.

The *leiomyoma* is derived from smooth muscle fibres, the rhabdomyoma from striated muscle fibres.



FROM "THE CLINICAL DIAGNOSIS OF SWELL. INGS" (THE WILLIAMS AND WILKINS COM. PANY) BY COURTESY OF DR. C. E. CORRIGAN
FIG. 5.—COMPACT OSTEOMAS OF THE SKULL: (A) PROJECTING FROM THE EXTERIOR ONLY, (B) ENCROACHING ON THE CRANIAL CAVITY

Fibromyoma.—This is a tumour composed of two elements of connective tissue—fibrous tissue and smooth muscle tissue. It is a Common tumour, occurring much more frequently than either of its composites in pure form. Its site of election is the uterus, where it is colloquially termed a "fibroid." It is also the commonest of all tumours of the uterus and develops there in three situations—either projecting outward from the womb, enlarging the body of the womb, or projecting into the cavity of the womb in which case it is prone to bleed. These tumours may grow to a colossal size, are frequently multiple and are liable to undergo simple degenerations and malignant change. Treatment consists in surgical removal which, owing to their multiplicity and their deep-seated location, may demand the complete removal of the uterus.

Osteochondroma is the hybrid of the two "pure" tumours, osteoma and chondroma. They occur in sites common to the chondromas and clinically resemble the latter tumours closely. They should be treated by surgical removal.

Glomus Tumour.—This peculiar swelling consists of a mass of blood vessels, nerve cells and fibres and epithelioid cells. It occurs chiefly on the extremities; the hands, feet and digits are the common sites. It usually presents as a single, exquisitely tender, tiny reddish patch immediately deep to the skin or a finger nail. It is seldom as large as a grain of wheat when first discovered, the attention of the patient being focused by the inordinate pain which results from any manipulation of the part. It is believed to arise by proliferation of the local nervous mechanism of the lateral capillary "shunts." Treatment consists of surgical excision.

Benign Tumours Arising from Epithelial Tissue.—Pupil*loma* consists of a sprouting projecting mass of new tissue derived from a surface epithelium. Three histologic types are described, based on the type of epithelium composing the tumour. None are encapsulated.

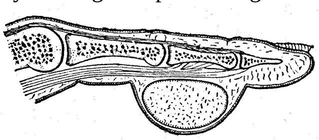
Squamous papilloma arises from a stratified squamous epithelium. The skin is the commonest site; there the process results in a wart. These are frequently multiple and in some instances may not be neoplastic at all. Other sites include the tongue, mouth and vocal cords. All may be treated by surgical excision or radiation.

Transitional papillomas are confined to the urinary tract, the kidneys, ureters and bladder. They contain a rich arborization of blood vessels surrounded by a delicate layer of epithelium. Hence their usual complication is haemorrhage, which is manifest by the painless passage of blood in the urine. In addition they may give rise to urinary obstruction and infection. All transitional papillomas are prone to become malignant and should therefore be eradicated as soon as diagnosed. If they occur in the bladder they may be cauterized with an electric current.

Columnar cell papillomas spring from and project into the interior of the gastrointestinal tract, the larger ducts of the breast and the walls of certain cysts. They have a tendency to bleed easily, thereby producing bloody effluxes, and all are prone to undergo cancerous change. They should be removed surgically when diagnosed.

Adenoma in pure form is an uncommon tumour derived from the secreting cells and tubules of glands. They occur in the alimentary tract, mucous and cutaneous glands and in the glands of internal secretion. In the latter situation they have been known to elaborate an excess of secretion, thus producing symptoms of overactivity of their parent gland; namely, thyroid, pituitary, parathyroid or pancreas. Elsewhere they tend to bleed and in the intestine they may produce obstruction. They are usually small spherical painless masses surrounded by a definite capsule. Treatment consists in surgical removal.

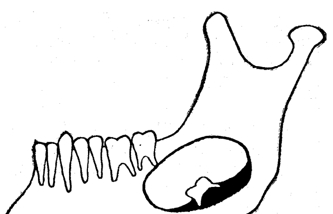
Implantation dermoid (fig. 6) is a tumour which assumes the form of a cyst. The common sites are the palms of the hands and the fingers. The popular theory of origin implies the growth of a bit of skin transplanted to a depth in the subcutaneous tissues. The wall of the cyst is formed of stratified squamous epithelium and the contents consist of epithelial debris. They usually grow to the size of a pigeon's egg, are painless and frequently translucent. They are readily treated bv excision.



FROM "THE CLINICAL DIAGNOSIS OF SWELLINGS" (THE WILLIAMS AND WILKINS COMPANY) BY COURTESY OF DR. C. E. CORRIGAN

FIG. 6.—IMPLANTATION DERMOID OF THE FINGER

Benign Tumours **of** Mixed Tissue **Origin.**—*Odontoma* (fig. 7) is a tumour derived from the elements of teeth and is therefore encountered only in the jaws. Since the teeth are derived from both epithelial and connective tissue elements, many varieties of odontoma may occur but man, in contrast to animals, is subject to few types but those of epithelial origin. As the process of tumour formation may afflict the teeth at any stage of their development three main types of epithelial odontoma are recognized; namely, fibrocystic disease of the jaw, dentigerous cyst and dental cyst. All these cause swelling of the jaw with considerable pain. All may be satisfactorily treated by excision.



FROM "THE CLINICAL DIAGNOSIS OF SWELLINGS" (THE WILLIAMS AND WILKINS COMPANY) BY COURTESY OF DR C E CORRIGAN

FIG. 7 —A DENTIGEROUS CYST OF THE LOWER JAW

Fibroadenoma is a hybrid which, like fibromyoma, is of more common occurrence than each of its two "pure" composites. It consists of a mixture of white fibrous tissue and epithelial cells of a secreting gland. It is often multiple, usually painless, spherical in shape, firm in consistency and carries a thick capsule. Only two locations are commonly noted, the breast and the prostate gland.

It is the commonest tumour of the breast. where it must be differentiated from carcinoma—and vice versa. One or more tumours may be present in one or both breasts. It tends to develop before the age of 3j. An outstanding clinical feature is the great mobility of the tumour aithin the breast tissue. Three varieties are described, hard, soft and cystic. The latter two may reach the size of a football but the hard type seldom exceeds the size of an orange.

Fibroadenomas have a small but definite tendency to become malignant. They should always be removed surgically as soon as they are diagnosed.

Adenomyoma and *fibropapilloma* are examples of rare hybrids. They assume the clinical features of one or the other of their constituent tumour tissues.

Diagnosis of Turnours.—Two main methods are commonly employed.

The first and oldest is that of clinical examination, an appreciation of the physical characteristics of the swelling, the symptoms it initiates, its site, its mode of growth and spread if any, and its effect on local and adjacent structures and functions. The success of this method depends essentially on the experience, skill and judgment of the physician. It may frequently be supplemented by X-ray studies of the part, notably in the case of tumours of the bones. intestinal tract and the more deeply seated lesions that cannot be directly seen or palpated.

The second method employed is the more scientific and accurate means of biopsy. Since all tumours consist of a new growth of cells, the microscopic study of these cells will give a true picture of the nature of the tumour. A bit of tumour tissue is therefore removed from the patient and submitted to histologic examination. This manoeuvre is employed where the diagnosis is in doubt, where the necessity of an extensive operation is being debated or where the method of treatment is in doubt. Some subvarieties of any one specific tumour may best be treated by operation, others by radiation or by a combination of both methods. Biopsy will usually provide the answer. While it constitutes the mainstay of accurate diagnosis it must be admitted that in some instances, notably in the case of near-malignant tumours, it may fail to clarify the diagnosis.

Occasionally adjuvant methods of diagnosis are employed. While there is no constant biochemical criterion by which tumours can be diagnosed. some of them, particularly of the adenoma group, will at times produce substances that alter the chemical and physical processes of the body in such a manner that the presence of a tumour may be inferred indirectly. By the study of these secondary effects alone the diagnosis may be established with certainty and an operation initiated for the purpose of searching for and removing the offending tumour, for example, an adenoma of the pancreas or the parathyroid gland.

The early diagnosis of tumours depends primarily on the patient who harbours one. Once having cause to suspect an abnormality he should pursue the matter of investigation as soon as possible. As mentioned above, some normally benign tumours tend to become malignant but this feature obtains only in cases where the tumour has been present for a long time. It is therefore obvious that early diagnosis is an essential factor in successful treatment.

Tumour Research.—The appalling loss of life caused by malignant tumours alone spurred world-wide efforts to unravel the mysteries of tumours. All aspects of the problem received meticulous investigation. the causation of tumours, their method of spread, factors which influence their growth and methods designed to eradicate them. The various fields of research include histology, biochemistry, physical chemistry, tissue culture, bacteriology, radiology, animal experimentation, surgery, clinical research, vital statistics and public health surveys. While notable advances were being made by mid-20th century, a satisfactory understanding of the problem was still lacking. It was not clear as to where the answer might be. The discovery of the cause, *e.g.*, might not yield the answer to the treatment, and vice versa.

BIBLIOGRAPHY.—E. T. Bell (ed.), *A Text-Book of Pathology*, 6th *ed.* (1947); William Boyd, *Surgical Pathology*, 6th *ed.* (1947); R. A. Willis, *Pathology of Tumours* (London, *1948).* (C. E. CG.)

TUMULUS, an artificial mound of earth or stone, usually conical in shape, erected either as a memorial, or over the grave of a royal personage, noble or hero, or the relic of a saint. Funerary tumuli are sometimes known as barrows (*q.v.*).

TUNA, any of several fishes of the mackerel family, belonging to the subfamily Thunninae. They are typically large fishes, of very robust body form, with a keel on each side of the caudal peduncle and with the pterotic bone excluded from the brain chamber by a deep pit or infolding behind the pro-otic bone. They are remarkable for maintaining their body temperature above that of the surrounding water and for having a peculiar vascular system, which is characterized by a large plexus along each side of the body. Most tunas inhabit warm seas and many of them are circumtropical. They are believed to migrate extensively. In the Atlantic ocean tunas spawn in the region of the Mediterranean.

They are among the most valuable food fishes in the world. The best-known types are bluefin, or tunny (Thunnus), the albacore (*Germo*), the yellowfin (Neothunnus) and the skipjack, or striped tuna (*Katsuwonus*). (See also TUNNY.) (L. A. WD.)

TUNBRPDGE WELLS (ROYAL), a municipal borough (1889) and inland watering place in the Tonbridge parliamentary division of Kent, Eng., 36 mi. S.E. of London by road. Pop. (1951) 38,400. Area 9.4 sq.mi. It owes its popularity to its chalybeate spring and its beautiful situation in a hilly wooded district. The wells are situated by the Parade (or Pantiles), a walk associated with fashion since the wells were discovered, and paved with pantiles in the reign of Queen Anne. A new assembly hall was opened in 1939. The town is built in a picturesquely irregular manner, and a large part of it consists of districts called parks occupied by villas and mansions. The medicinal springs were discovered by Dudley, Lord North, in 1606. After the Restoration it was visited by Charles II and Catherine of Braganza. It was a favourite residence of the princess Anne before her accession to the throne, and from that time became one of the chief resorts of London society. It reached its height in the second half of the 18th century, and is associated with Colley Cibber, Samuel Johnson, Richard Cumherland the dramatist, David Garrick, Samuel Richardson, Sir Joshua Reynolds, Beau Nash and Mrs. Thrale (Hester Piozzi). The Tunbridge Wells of that period is sketched in William Thackeray's Virginians. The industry known as Tunbridge Wells ware continued during 300 years, but the factory closed and the small existing supply comes from the spare time work of old hands. The mare includes tables, boxes, toys, etc., made of hard woods, such as beech, sycamore, holly and cherry, and inlaid with mosaic. Five miles southeast is Bayham abbey, founded in 1200, where ruins of a church, a gateway and dependent buildings adjoin the modern Tudor mansion. The vicinity of Tunbridge Wells is largely residential.

TUNDRA, the cold, desert, treeless plains which form the arctic lowlands of Europe and Asia. The name is also generally applied to a similar area in North America. The prevailing low temperatures are consequent on high latitude and proximity to the frozen northern ocean and result in very scanty vegetation.

TUNGABHADRA, a river of southern India, the chief tributary of the Kistna. It is formed by two streams, the Tunga and the Bhadra. which rise in Mysore in the Western Ghats.

T'UNG-CHOU (TUNGCHOW), a former town of Hopeh province. China. since 1958 included within the expanding city limits of Peking (*q.v.*). It is situated on the northernmost branch of the Grand canal, which there utilizes the channel of the Pai Ho. During the Mongol dynasty a canal was built connecting T'ung-chou with the national capital, enabling rice and other commodities to be shipped there from southern China. Later, when the canal fell into disuse, T'ung-chou was the river port of Peking. After the coming of railroad transportation to China, the importance of T'ung-chou declined. It was the headquarters of the Japanese puppet regime of East Hopeh set up in 1935, and the scene .of early fighting in the Chinese-Japanese war in 1937. T'ung-chou is connected with Peking's city centre by a light railway and by a suburban bus line. It was called T'ung Hsien from 1913 to 1954 when it reverted to its earlier name T'ung-chou. Pop. (1953) was more than 50,000. (T. SD.)

T'UNG-KUAN (TUNGKWAN), town in Shensi province, China, on the border of Honan province, 75 mi. E.N.E. of Sian. The town is situated at T'ung Kuan (T'ung pass), a historic gateway between the Yellow river and the Hua Shan, an eastern outlier of the Tsinling Shan. At T'ung-kuan, the Yellow river, flowing due south along the Shansi-Shensi border, receives the Wei Ho on the right, and makes a right-angled turn eastward through a valley hemmed in by great loess walls. The T'ung Kuan mas a strategic gateway throughout China's history, and a political division between the provinces of Shensi and Honan. The pass is used by the Lunghai railroad. China's main east-west trunk transportation line; and, in 1958, a bridge completed across the Yellow river established a link between the Lunghai line and the railroad station of Feng-ling-tu, the terminus of the railroad system of Shansi province. Completion of the bridge converted T'ung-kuan into one of China's leading railroad hubs. During the Chinese-Japanese War, T'ung-kuan was the westernmost point of the Japanese advance in central China. (T. SD.)

TUNG OIL has the valuable property of drying rapidly to a film that is hard, waterproof and highly resistant to acids and alkalies. Because of these characteristics the oil is used in the manufacture of high-grade protective coatings, such as paints and varnishes, for waterproofing and for many other industrial purposes. The Chinese first manufactured and used tung oil. In China it is expressed by primitive methods from the seeds of two native tree species, Aleurites fordii and A. montana. A. montana is tropical and grows only in areas that are practically frost-free. A. fordii is semitropical; it requires a long warm summer, but does not thrive without some cold weather in winter and when fully dormant can withstand a temperature of about 8" F. Each species is now grown in many areas of the world to which it is climatically suited. A. fordii was introduced into the United States in 1905. About 200,000 ac. of orchard in six southeastern states produce about 140.000 tons of whole fruit. From this crop, 15 to 20 modern mills process about 40,000,000 Ib. of oil, nearly enough for U.S. domestic requirements. (G. F. P.)

TUNGSTEN. The name tungsten (A. F. Cronstedt, 1755) means "heavy stone" (Sw. *tung*, "heavy"; *sten*, "stone".) and directs attention to the high specific gravity of the element and its ores (symbol W; atomic number 74; atomic weight 183.86). Up to the middle of the 18th century the mineral then known as tungsten, but now called scheelite, together with wolfram (or woliramite) were both considered minerals ,of tin. In 1781 K. W. Scheele showed that the mineral tungsten contained a peculiar acid which he named tungstic acid, combined with lime as a base. In the same year T. Bergman advanced the opinion that the new acid was a metallic calx or oxide. Two years later two students of Bergman, the Spanish brothers Juan José and Fausto d'Elhuyar, found the same tungstic acid in a black wolframite from the tin mines of Zinnwald. They heated this acid with carbon and isolated the metal tungsten.

Tungsten occurs in nature in the form of tungstates of iron, manganese and calcium, which may be divided according to their crystalline form into two groups. The iron and manganese tungstates, crystallizing in the monoclinic system, form the wolfram group, while calcium tungstate or scheelite belongs to the tetragonal system. Pure iron tungstate ($FeWO_4$) is known as ferberite and pure manganese tungstate ($MnWO_4$) as hubnerite. The mineral wolframite is normally a mixture of these two compounds in varying proportions. Waliramite generally occurs in columnar, bladelike or massive forms, though sometimes it is found in well-formed prismatic or tabular crystals. It breaks up readily into thin flakes and its specific gravity ranges from 7.0 to 7.5. The colour may vary from nearly black to a brownish tinge characteristic of specimens rich in manganese. Scheelite or calcium tungstate ($CaWO_4$) may occur in the form of well-developed crystals which are usually double tetragonal pyramids, but frequently it is found in a massive form with four good cleavages. The specific gravity is about 6.0 and the colour variable. It is generally gray, pale yellow or pale brown, rarely green or reddish, with a waxy lustre. The world's principal supplies of tungsten ores have come from China, Burma, Australia, Bolivia, Portugal, Korea and the United States.

In 1946 P. B. Nye and C. L. Knight reported on the deposit of scheelite at Grassy on King Island, Tasmania, one of the largest in the world, the reserves exceeding 2,000,000 tons at an average WO_3 content of 0.64%. It is a pyrometasomatic deposit formed by the replacement and alteration of beds of limestone interbedded with a series of hornfels. Within the mineralized zone the typical assemblage is garnet, diopside and epidote. Most of the scheelite occurs as grains less than 0.2 mm. in diameter. In the quartz veins the grains are relatively coarse.

Extraction and Manufacture.—The tungsten content of the ore mined is usually 0.5%-2.0%, so that a concentration process is necessary for extraction. The wolframite in the ore is associated with quartz and other gangue material, but it can be readily separated from these impurities because of its high density. To separate wolframite from cassiterite (SnO_2), which is present in a large proportion of the ores, magnetic methods are employed. Wolframite which contains iron is fairly magnetic, while cassiterite is not attracted even by powerful magnets. With the nonmagnetic scheelite, fortunately, the association of cassiterite is not common; otherwise, chemical processes would have to be employed to effect the separation.

Modern tungsten mills employ flotation as well as leaching methods to enhance the recoveries of tungsten from the ores. Tungsten concentrates throughout the British commonwealth are standardized at 65% WO_3 as against 60% WO_3 in the United States.

The tungsten industry employs two distinct methods of extracting the metal from these tungsten-ore concentrates. More than 80% of the tungsten produced in the world is used in special steels (see below and TUNGSTEN STEEL). The standard raw material for these steels is ferrotungsten with approximately 80% tungsten and very little carbon. This is exclusively made in the electric furnace. The fundamental reaction is:

$$FeWO_4 + 2FeSi = 2Fe + FeW + 2SiO_2$$

Since the melting point of 80% ferrotungsten is about 1,900° C. it is not poured from the furnace. Accordingly, upon completion of the reduction, the slag is tapped, the FeW alloy allowed to solidify in the furnace, the latter dismantled, the alloy cake removed and broken into small pieces suitable for tungsten-steel manufacture. The clcctric-power consumption ranges between 4,000 kw.hr. and 8,000 kw.hr. per ton of 80% FeW alloy.

For the production of tungsten metal to be used in tungsten lamps and vacuum tubes the wolframite concentrates are introduced into fused sodium carbonate (goo° C.–1,000° C.) in an oxidizing atmosphere. Sodium tungstate is thereby produced, and the iron and manganese present are converted to oxides:

$$4FeWO_4 + O_2 + 4Na_2CO_3 = 4Na_2WO_4 + 2Fe_2O_3 + 4CO_2,$$
$$6MnWO_4 + O_2 + 6Na_2CO_3 = 6Na_2WO_4 + 2Mn_3O_4 + 6CO_2$$

The soluble sodium tungstate is extracted with boiling water and on treatment with boiling hydrochloric acid an amorphous yellow precipitate of tungstic acid (H_2WO_4) is obtained which yields WO_3 on calcination In the preparation from scheelite the finely ground ore is decomposed with hydrochloric acid, whereby calcium chloride passes into solution, and tungstic acid. together with insoluble impurities like silica, remains as a sludge:

$$CaWO_4 + 2HCl = CaCl_2 + H_2WO_4$$

To purify the tungstic acid produced in these processes, it may be dissolved in ammonia and crystallized out as ammonium paratungstate, $5(NH_4)_2O$, $12WO_3xH_2O$. This is decomposed by hydrochloric acid to yield purified tungstic acid, or ignited in air to tungstic oxide (WO_3).

The above procedures may be repeated several times to attain a tungstic acid of the high specified purity from which the metal wire suitable for the lamp and vacuum-tube industry is obtained. The pure WO_3 thus produced is coarsened by heating at 1,350° C. for several hours. It is next reduced to metal (850° C.) by hydrogen: $WO_3 + 3H_2 = W + 3H_2O$. The metal powder obtained is converted into tungsten-metal bars by powder-metallurgy (*q.v.*) methods. It is not possible to melt tungsten in a crucible and cast it into rods simply because no crucible material melts at temperatures higher than tungsten (3,387' C.). Graphite heated to 3,387' C. disintegrates rapidly and/or forms carbides of tungsten.

Accordingly, the tungsten-metal powder is compressed into bars in a tungsten-steel mould at about one ton per square inch. The bars are then carefully removed and heated in a hydrogen atmosphere at about 1,300° C. Each sintered bar is then mounted in turn in a water-cooled metal bell jar filled with hydrogen. An electric current is passed through the bar until it almost melts. It is then allowed to cool in hydrogen and is now hot swaged (1,500° C.) and hot drawn (600° C.) down to the desired size. Short bearing dies are used in the swaging machine; tungsten-carbide and diamond dies are used in the hot drawing of the tungsten wire. The only serviceable lubricant for hot drawing is colloidal graphite (aquadag).

Physical and Chemical Properties.— Tungsten excels all other metals in having the highest melting point (3,387° C.—M. Pirani); the highest' tensile strength (600,000 lb. per square inch); the highest musical note; the lowest coefficient of expansion (4.4×10^{-6}); and the finest wire. There are five stable isotopes with mass numbers 180, 182, 183, 184 and 186. Nine radioactive isotopes, 176, 177, 178, 179, 181, 183, 185, 187 and 188, have been prepared. On the basis of the relative abundance of each stable isotope F. W. Aston calculated an atomic weight of 183.94 (Proc. Royal *Soc.*, A 132, p. 487 [1931]). Tungsten crystals are isometric and by X-ray analysis are fpund to be body-centred cubes with a lattice constant of 3.1592 A. The specific gravity of tungsten is about the same as that of gold. It is 19.3 in the annealed condition and as high as 21.4 in the wrought condition. The boiling point is 6,970° K. (6,700° C.).

Tungsten is paramagnetic. Magnet steels contain 4% tungsten but these permanent magnets have been largely superseded by the aluminum-nickel-cobalt-iron alloys.

Chemically, tungsten is a relatively inert metal. The distribution of electrons in the incomplete orbits (O and P) is: js^2, $5p^6$, $5d^4$, $6s^2$. Compounds have been prepared in which the element has positive oxidation numbers of 2, 3, 4, 5 and 6, the latter being of the greatest importance. Tungsten is not readily attacked by the common acids and alkalies nor by aqua regia. It reacts with a mixture of concentrated nitric and hydrofluoric acids. Very finely divided tungsten dissolves in hydrogen peroxide. The best solvent is fused potassium nitrite, the reaction being almost explosive. At incandescence tungsten reacts with all gases, including nitrogen, but excepting the noble gases helium, neon, argon, krypton and xenon. Tungsten alloys readily with the ferrous metals, with molybdenum, thorium, chromium, etc.

Applications.— The most important application of tungsten is in the production of tungsten steels and high-speed cutting tools. Tungsten steels are used for armament, for automobiles, for high-pressure equipment, etc. The Taylor high-speed steel contains approximately 18% tungsten, 5% chromium and 1% vanadium. The Stellite high-speed tools contain tungsten, chromium and cobalt. Aside from the use of tungsten metal in lamps and vacuum tubes it is used in electric contacts, X-ray tubes and fluorescent light tubes. The barium oxide-strontium oxide-coated tungsten cathode in these light tubes is one of the best electron emitters known. Scheelite is used as a phosphor in many of the fluorescent lamps. Tungsten carbide, WC, has replaced diamond in large drawing dies and rock drills; it is one of the best cutting tools, exceeded in hardness only by diamond and boron carbide (B_4C). An alloy of 90% tungsten, 4% copper and 6% nickel is used as protection in radium-beam therapy.

TUNGSTEN STEEL. The earliest alloy of this type is Mushet steel. It contains from 5.5% to 9.0% of tungsten and also carries enough manganese to give it air-hardening properties and to class it as a quaternary alloy. This article considers principally commercial ternary alloys of tungsten. High carbon steels containing tungsten up to 6% are essentially water-hardening steels. *(See* IRON AND STEEL: *Metallography and Heat Treatment;* METALLOGRAPHY.) The atoms of tungsten, being so much larger and heavier than those of iron, diffuse comparatively slowly in solid metal, so that a high temperature is required for solution before the quench. Accumulation of carbide particles upon tempering is also slow, hence the ability of tungsten steels to hold their hardness at high temperatures. Tungsten carbide also has a very high intrinsic hardness, approaching that of the diamond. For keen-edged tools tungsten in the alloy seems to prevent small particles from being torn away during use, and thus retards dulling.

Steel containing 0.9% carbon or more together with 1% to 2% tungsten is used for hack saw blades and for reamers. broaches and other tools which must show a minimum change in dimension after heat treatment. Steels with 1% ccabon or more. and 3% to 7% tungsten, are much used for "fast-finishing" tools to cut hard metals or to make a fine smooth cut on softer tough metal. Dies for cold drawing wire and other shapes are made of higher carbon steels (2%) with tungsten ranging from 1% to 12%. Dies with the higher tungsten percentages are used for the harder metals or the finer wires. Chromium is often added to facilitate the diffusion of tungsten. When 0.5% or more is present the alloy may crack during water hardening. An oil quench, however, will harden it through to the centre. Chromium also causes the useful hardness to be retained at higher working temperatures. For working hot metal, tools mould be made of 0.3% carbon steel with 10% tungsten and $3\frac{1}{4}$% chromium (known as "semi-high-speed"). Permanent magnets for electric meters, magnetos, radio and telephone equipment absorb annually several thousand tons of steel containing 0.7% ccabon and 5% to 6% tungsten.

In tungsten-iron alloys, substantially free from carbon, tungsten has the property of lowering the temperature at which delta iron changes to gamma iron and also of raising the temperature at which gamma changes to alpha iron. Consequently, the American metallurgist W. P. Sykes was able to show that no gamma iron is formed in carbon-free alloys containing more than 7% tungsten. Such an alloy is permanently austenitic, and cannot be hardened or tempered by heat treatment. In the alloys containing more tungsten the compound Fe_3W_2 appears; its solubility decreases with the temperature, and it is precipitated throughout the metal at a slow rate. To harden such an alloy it is necessary to anneal or "age" it at a moderate temperature for several hours or days. Brinell hardness numbers indicate the extent of this action:

	Brinell
Carbon free iron	70
Carbon free solid solution alloy, 80% iron, 20% tungsten	160
Above after aging	330
Carbon free aged alloy, 78% iron, 22% molybdenum .	530

Such aged alloys of iron and tungsten and of iron and molybdenum (tungsten and molybdenum being very similar chemically) form excellent wire drawing dies, and have given 10 to 40 times the service that can be had from best high speed steel before the edge needs re-dressing. (See IRON AND STEEL; HIGH SPEED STEEL) (E. E T.)

TUNGUSES, a widespread north Asiatic people. They are the *Tung-hu* of the Chinese, probably a corrupt form of *tonki* or *donki,* that is, "men" or "people." The Russian form *Tungus,* wrongly supposed to mean "lake people," appears to occur first in the Dutch writer Massa (1612) ; but the race has been known to the Russians ever since they reached the Yenisei. The Tungus domain stretches from long. 60° E. to the Pacific ocean and from the Arctic to the Chinese frontier. The Tunguses are known to the Samoyedes by the name of *Aiya* or "younger brothers." The Oroches, Chapogir, Golds, Lamut, Manjour, Manegre and Oroke are partly in Manchuria and are Tungusic. The Tungus type is essentially Mongolic, with broad flat features, small nose, wide mouth, thin lips, small black and somewhat oblique eyes, black lank hair, dark olive or bronze complexion, low stature, averaging not more than 5 ft. 4 in. The square shape of the skull and the slim, miry, well-proportioned figure are features especially of the typical Tunguses. They are classed according to their various pursuits, as Reindeer, Horse, Dog, or Sedentary, Nomadic and Wandering Tunguses. A few have become settled agriculturists; but the great bulk of the race are still essentially forest hunters, using the reindeer both as mounts and as pack animals. Nearly all lead nomad lives in pursuit of fur-bearing animals, whose skins they barter in exchange for provisions, clothing and other necessaries of life. The national costume shows in its ornamentation and general style Japanese influence, due to intercourse at some period previous to the spread of the race to Siberia. Many of the Tungus tribes are reckoned as "Greek Christians"; but most of them are still Shamanists and nature worshippers, secretly keeping the teeth and claws of wild animals as idols or amulets, and observing Christian rites only under compulsion. Family and exogamic clan organization is relatively strong. Intercourse begins before marriage as soon as a portion of the bride price has been paid. Some practise polygamy. Exchange marriages occur. The levirate is common. A man may take his son's widow. Cousin marriage occurs and tree burial (*q.v*) is found among them.

See M. Czaplicka, *Aboriginal Siberia* (1914).

TUNICATA. Tunicates are exclusively marine animals, related to vertebrates and therefore sharing with man a common but primevally ancient lineage. They are common, cosmopolitan, frequently seen but rarely noticed since for the most part they are fixed growing organisms resembling more a potato than a fish. Yet, at some time in the career of each individual it is provided with the forerunner of a backbone, a uniquely dorsal tubular spinal cord found nowhere among invertebrate animals, and similarly distinctive gills. Of these features, equally typical of the early human embryo, only the last usually survives into the adult animal, and mature tunicate animals in general are permanently attached forms with no capacity for locomotion, using an enlarged and elaborate gill system as a means of filtering large volumes of sea water for the sake of its contained microscopic life. As the name implies, a tunic is secreted by the skin which not only helps to anchor the animal to some solid structure but gives rigidity to its outer form, and allows the delicate inner organism to suck in and filter sea water to its heart's content. Many tunicates are solitary individuals growing to the size of an orange, but like most kinds of animals that have given up freedom of movement for a sedentary life, many have become colonial forms in which the individual becomes subordinated to an organic community.

Tunicates virtually are universally distributed throughout the seas of the world, from the intertidal zones down to the deep abyss, and inasmuch as certain types have given up a fixed existence for a drifting. floating life, the vast expanses of the open ocean are also inhabited by these forms. The more primitive group. associated with the sea bottom, is known as the ascidians. or sea squirts, and may be found along or near the shore of all the seven seas, growing on seaweeds, on or under rocks, in submerged sand flats, on coral reefs. submarine cables, ship bottoms, wharfpiles, and even on the shells of elderly lobsters and sea snails. They abound from polar regions to the tropics. Some species are cosmopolitan, found from Spitsbergen to Cape Cod. Naples to Singapore, others so limited as to be known only from grottos on a Brittany beach, or the Kerguelen Islands of the southern Indian ocean.

The group has many peculiar and fascinating features. Alone among animals it secretes its coat of *tunicin,* a substance almost identical with the ever-present cellulose of the plant kingdom. It has a heart similar to that of a chick embryo a few days after the onset of incubation, but unlike the chick heart the tunicate's reverses the direction of its beat periodically. Its blood is unique. While the blood has no respiratory pigment and can carry no more oxygen than a similar amount of sea water, it is frequently rich in both sulphuric acid and the rare element *vanadium*, substances more associated with the production of steel than body fluids. Not only are individuals hermaphrodite, that is, possess both ovaries and testes, but in many cases the same final organism can be produced either by a fertilized egg or by the growth and reconstruction of a fragment of adult tissue. Lastly, as the name of one genus, *Pyrosoma* or firebody, implies, some are brightly luminous at night, *Pyrosoma* appearing as a glowing candle-shaped body drifting through the surface waters of warm oceans.

The great French anatomist, Georges Leopold Cuvier, at the beginning of the 19th century placed ascidians with his "headless molluscs" the bivalves, and the class was named and defined by the evolutionist Jean Baptiste Lamarck in 1816, although the chorddte nature and therefore the relationship with vertebrate animals was not recognized until many years later. Only after Charles Darwin's great theses on evolution had been published and become widely known, was it discovered that the sedentary sea squirts produced eggs that developed not directly into miniature sea squirts, but into tiny tadpoles of the same basic organization as the tadpole of the frog.

Life Cycle.—Ascidians are hermaphrodite animals, each individual producing both eggs and sperm, in many cases being able to fertilize their own eggs, in others unable to do so and cross-fertilization is obligatory. Most solitary ascidians produce small eggs in large numbers, each being surrounded by buoyant follicle cells which enable it to float away in the currents while development proceeds. The early developmental patterns, while on a small scale and also condensed in time, resemble closely those of primitive vertebrates and are unlike those of any invertebrate animals. This development leads directly to the formation of a minute swimming tadpole. In the case of these widely disseminated eggs the tadpoles are quickly formed—long before they are capable of feeding. They are equipped for swimming to the sea surface, at least for a few critical hours. Each possesses a tail for swimming consisting of a central supporting rod of cells, the notochord, which all vertebrates, including man, possess at some stage in their individual development as the immediate precursor of a vertebral column. In the case of ascidians, however, the development stops there. On either side of the notochord is a band of muscle fibres equivalent to the locomotory muscles of a fish, while a narrow tubular spinal cord overlies the notochord throughout its length. These features and their combined organization are distinctive of all vertebrate and chordate animals and definitely link ascidians and other tunicates with the main evolutionary line leading eventually to man himself, in spite of the obscure and bizarre appearance of the adult forms.

In the tadpole, the nerve tube expands in front as a small brain vesicle typically containing two sense organs. These enable the tadpole to orientate and swim towards the source of light, the sea surface, and away from the centre of gravity, away from the sea bottom. They represent an eye and an organ of balance in their simplest form.

The existence of such a tadpole ensures a wide dispersion of the species, compensating for the immobility of the adult. This purpose is served, however, after a few hours, and then degenera-

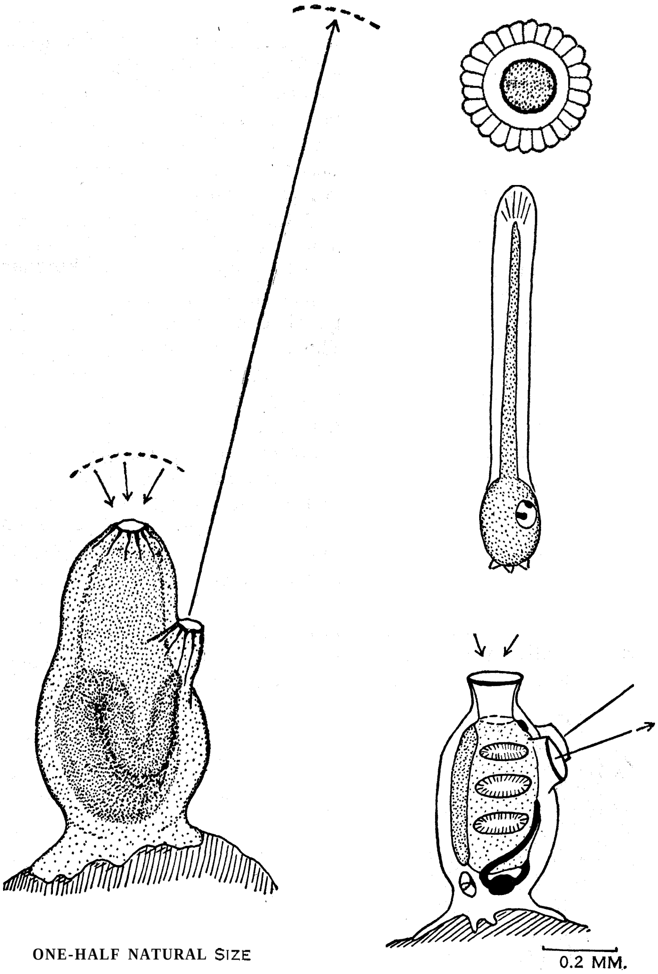

FIG. 1.—THE LIFE HISTORY OF AN ASCIDIAN

At the left an adult solitary ascidian of the genus Ascidia attached to a rock. The gill chamber and looped intestine show through the translucent protective tunic. The solid arrows indicate the direction and extent of the ingoing and outgoing water currents. At the right is the egg with its outer layer of buoyant flotation cells, the tadpole that develops from it with swimming tail, orienting sensory apparatus, and three adhesive papillae; and, beneath, the organism following the metamorphosis of the tadpole, namely, a young ascidian with three pairs of gill siits, intestinal loop and heart below, and brain lying between the siphons

tive changes commence in the tadpole organization. It sinks toward the sea bottom, the tail becomes immobile, and the tadpole becomes attached by three adhesive structures on its nose to any solid structure sufficiently clear of soft mud. With the tadpole anchored, the tail absorbing somewhat as in the case of the frog, development continues through this period of metamorphosis to form the first stage capable of feeding. This consists of a small barrel-shaped animal attached by what was originally its chin region, with a large funnel-like mouth facing upwards and allowing water to flow into a capacious pharynx or throat. This bears gill slits on each side through which the water passes into a surrounding chamber opening externally by another funnel. These funnels are called siphons, inhalent siphon and exhalent siphon respectively, and are characteristic of tunicates in general.

In essentials the adult ascidian differs from the newly attached feeding individual in little more than increased size and the acquisition of sex glands. The existence of tno such different types of organism as the ascidian tadpole and the ascidian adult has afforded the basis of much argument. Either the tadpole is a relic of a more aristocratic chordate ancestry and the adult represents a degenerate sacrifice of motility, or the attached adult is the more primitive type and the tadpole the newcomer. The first of these interpretations was the first to be adopted and is the orthodox view, the other is more recent and in many ways more plausible, but its implications concerning the origin of vertebrates are startling.

The typical ascidian is essentially a large sac corresponding to the throat region of a fish, into which leads the large inhalent siphon or mouth opening. The water taken in is strained through innumerable gill slits on each side of the sac, escaping into an external chamber leading to the exterior by way of the exhalent or atrial siphon. The remainder of the digestive canal is narrow and leads from the lower end of the gill chamber. It consists of an oesophagus, a simple stomach, and an intestine looped up to open close to the outlet of the exhalent siphon. In its loop the hermaphrodite sex gland is usually to be found. Close to the loop is a simple heart. A solid nerve mass, or "brain" lies between the two siphons, with nerves extending to each.

The reactions of the animal are practically limited to a swift closing of the siphons. At the base of the inhalent siphon a ring of tentacles prevents the passage of any particles too big to be managed, contact with the grid of tentacles producing the contraction reflex, and such a particle is rejected. Otherwise reactions are limited to mild responses to light stimulation.

Feeding Mechanism and Other Systems.—The mechanism for obtaining food is remarkable, both for its elaborate efficiency and for its ultimate evolutionary fate. The feeding mechanism consists essentially of two components, the production of mucus for the entanglement of food particles. and the production of a water current bringing in those particles. The water current streaming in through the inhalent siphon is produced by the outward-beating cilia (protoplasmic hairs) lining the numerous gill slits in the wall of the pharynx. On passing through these minute slits the water converges in the surrounding atrial cavity toward the exhalent siphon. It shoots out through this opening to a considerable distance, so that the water exhaled is not drawn in again

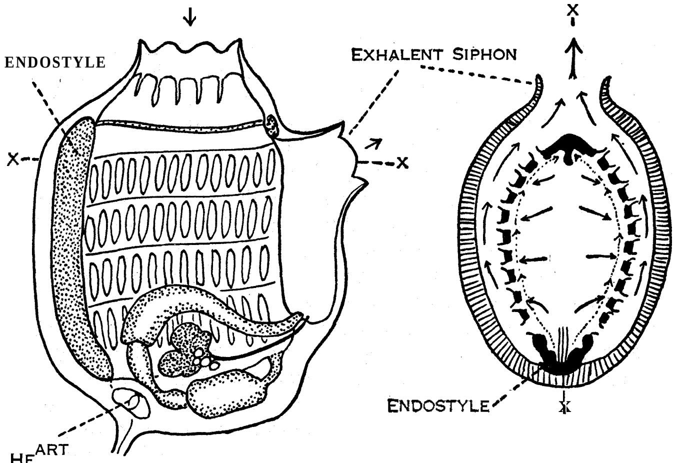

FIG. 2.—STRUCTURE AND FEEDING MECHANISM OF AN ASCIDIAN (GENUS PEROPHORA)

Solid arrows show direction of water currents, dotted arrows the direction of mucus transfer. Diagram at right represents a horizontal section at the level x —— x of the individual shown at the left. Water flows in through the mouth past tentacles into the gill chamber and flows out through four rows of gill slits in each wall into the surrounding protective outer chamber, finally to the exterior by the exhalent siphon. Food particles are trapped by mucus, secreted by a deeply-grooved band (the endostyle, the forerunner of the thyroid gland of man), which passes up the inner walls of the gill chamber. The particles are passed into and digested by the looped intestine lying at the base of the gill sac. The combined reproductive gland, ovary and testes, lies within the loop formed by the intestine

through the mouth. The water entering the gill chamber contains small living plant and animal organisms suitable for food. These are trapped by the endostylar mechanism. The mechanism consists of a mid-ventral groove, the endostyle, extending the whole length of the gill chamber, and a band of similar tissue extending around the anterior end immediately behind the anterior ring of tentacles. The groove and band consist of glandular tissue secreting mucus or slime in strands into the main cavity. Food particles encountering the strands are entangled and the cords of slime and organisms are wafted toward the upper side of the chamber. Along the mid-dorsal line the cords are rolled into a single cord with the aid of the dorsal membrane, and the cord passes back to the oesophagus. Passing through the oesophagus the cord reaches the stomach, is mixed with digestive enzymes and travels slowly through the looped intestine until the indigestible remnant emerges near the base of the exhalent siphon. Here the strong outgoing current carries away the faecal matter to a safe distance.

The food collecting apparatus as just described may become more elaborate in some, simplified in other forms of tunicates, but basically the system is the same in all. The same system is well developed in another chordate, *Amphioxus,* and even more significantly in the young of the lamprey, a true vertebrate. The adult lamprey, however, feeds in an entirely different manner and the greater part of the endostylar apparatus degenerates when the lamprey is about 6 in. long, except for the middle region of the endostylar groove itself, which emerges as the thyroid gland, the metabolic governor of all later vertebrates.

The blood and its circulation is of interest for several reasons. The pattern of blood vessels foreshadows that of the fishes. A large vessel passes from the heart forward beneath the endostyle, lateral vessels leave this and pass up the sides of the gill chamber to meet above in another longitudinal vessel. The heart itself is a tube folded lengthways within itself and has the unique property of periodically reversing the direction of its beat. After waves of contraction pass along it in one direction about 50 or 60 times, it slows to a stop and a new set of contractions begins, starting from the opposite end. The reversal is independent of any external nervous control. The blood is free to circulate in either direction owing to the absence of any valves limiting direction as they do in all vertebrates.

The blood itself is also peculiar. It transports no more oxygen than an equivalent amount of pure sea water and contains even less carbon dioxide. No respiratory pigment is present or necessary owing to the relatively enormous surfaces exposed to flowing water. At the same time pigmented cells are usually present in the circulating fluid and contain oxides of vanadium and free sulphuric acid. In certain solitary ascidians vanadium oxides may amount to as much as 15% dry weight of the blood, in spite of the fact that vanadium can barely be detected in sea water even by the most modern methods. How it is extracted by the animal and what part it plays in the activities of the organism are unknown. The sulphuric acid is also puzzling. Its presence is apparently associated—and probably its function as well—with that of vanadium. Apart from this it is difficult to understand how cells can tolerate within themselves a strong acid in a concentration sufficient to kill animal tissues in general.

Excretion of waste materials, especially the breakdown products of protoplasm itself, is managed in strange ways. Urates are deposited as solid concretions in sacs isolated within the body either single and large, or small and numerous, as permanent depositories. Other waste substances are eliminated at the external surface of the tunic. The tunic itself consists of tunicin, a substance closely allied with cellulose and secreted by cells characteristic of the middle body layer that have actually migrated through the outer skin to form a connective tissue in a most unusual place.

A tunicate could not be itself if it were not ambiguous. To complete the picture, there is a duct which passes from a glandular mass situated beneath the brain and opens by a ciliated funnel at the front and dorsal corner of the gill chamber. The structure of this apparatus and the nature of the cellular material passed down the duct to mix with the incoming water current indicate clearly that it is the homologue of the pituitary gland of vertebrates, the master gland of the body governing the endocrine glandular system as a whole. What the function is in the tunicates nobody knows.

Reproduction.—Tunicates have evolved in various directions not only as mature adult organisms but also in two other ways. The tadpole larvae vary remarkably in detail, while the faculty of reproducing nonsexually by the production of buds of various kinds has been evolved in some forms to a remarkable extent. The more elaborate types of tadpoles are relatively large with a relatively complex nervous system, beating heart and complex gill chamber almost ready for active life. In spite of such complexity, however, these tadooles may have a free-swimming life of oniy a few minutes, being designed primarily for the selection of limited and specialized habitats upon which to settle, in the immediate neighbourhood of their parents. They are also associated with viviparous forms, that is, the eggs are retained in the atrial chamber or in some special brood pouch and develop there safely at least until the tadpole stage is reached. Wide dispersion of the species by the usual means of oceanic currents is sacrificed to a maintenance of the population in local territory together with the selection of a specialized niche. The brevity of free-swimming existence not only limits the extent of distribution but greatly reduces the chances of any particular tadpole being eaten. In other words a relatively small number of large eggs are given a high degree of protection in several ways that ensure their survival to a comparatively advanced stage. This is in contrast to disseminating large numbers of small eggs to develop unprotected over a protracted period in the currents of the sea.

Viviparity, generally speaking, is usually associated with types able to reproduce also by budding. The plantlike method of reproduction, asexual reproduction or gemmation, is characteristic of many ascidians and has apparently arisen within the sea squirts on at least three separate occasions. It is a reproductive method very usual among nonmotile animals. If the tunicates as a whole are included, a fourth case of independently evolved budding should be added.

Budding is essentially a separating off, either physically or physiologically of a fragment of a mature or of a developing individual itself. The processes involved are essentially those in-

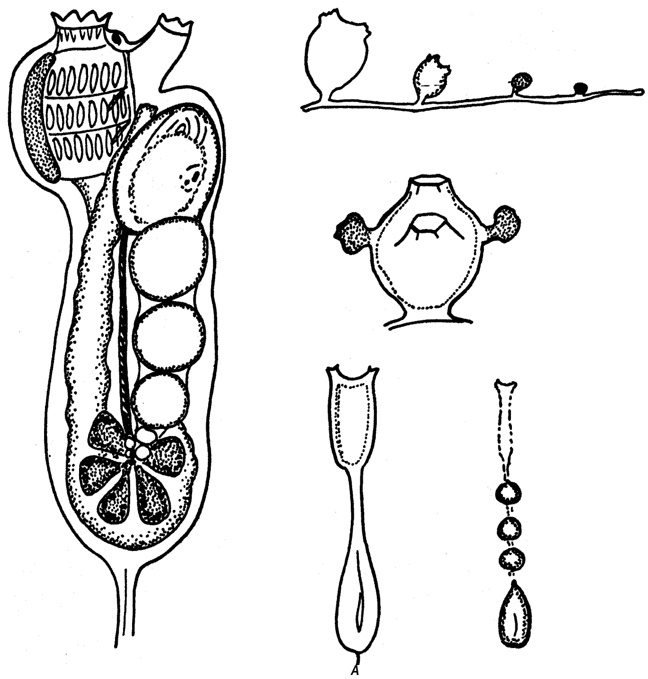

FIG. 3.—**VIVIPARITY** AND **BUD** FORMATION

Left: an individual (genus *Eudistoma*) with its intestinal loop extended posteriorly from the gill chamber shown with its ovary and testes still in the bend of the intestine, although the eggs are shown developing to the tadpole stage within the expanded oviduct. Upper right: buds are shown developing from a creeping stolon (Perophora), at the middle right buds develop from the lateral body wall of the parent (*Botryllus*), and at the lower right are two individuals (*Diazona*), one in functional form and one transformed into a string of living beads, each one of which is destined to form a new individual

volved in the regeneration of missing parts, a capacity tunicates have to a very marked degree. The nature of budding varies considerably among the different orders of tunicates, but in virtually every case it is due to some form of constriction by the epidermis which divides the contained tissues into separate masses, the nature of the whole isolated mass depending on the nature and part of the particular tunicate involved. The process is usually associated with the presence of reserve food storing cells known as trophocytes. These are produced in large numbers especially in those forms that undergo a winter regression. The main growing season naturally coincides with the spring and summer when the microscopic food organisms are abundant in the sea. In the early winter the food supply dwindles and many ascidians degenerate. In such as these the disintegrating tissues are absorbed by wandering reserve cells which subsequently migrate toward the base of the individual. There the epidermal constrictions divide the congested contained mass of reserve tissue into small masses or buds capable of surviving the winter and developing into new individuals in the spring. This type of budding leads to the formation of the group known rather loosely as the social ascidians, where many individuals of a common egg parentage are closely clustered together and may even become imbedded in the same glutinous external tunic. In others the buds may remain partly attached to the parent and either in connection with their parents or with other individuals of their own bud generation develop community systems of blood vessels and exhalent siphons. These are true animal colonies in which the individuals are actually subordinated to the activity of the whole.

Tunicates can be large and solitary, or small and aggregate or colonial; that is, growth can be expressed in either of these two ways but not both ways at the same time. It is the small individuals of the social and colonial forms that have departed from the production of large numbers of widely disseminated small eggs, and have evolved to a high degree the practice of viviparity or bearing their young alive.

Viviparity in ascidians is apparently easily attained and there is no doubt that among them it has been acquired independently on many occasions. All openings of the body proper, namely gill slits, anus, oviduct and sperm duct, open not directly to the exterior but into the atrial cavity, reaching the outside finally by way of the exhalent siphon. In egg-laying forms the reproductive ducts together with the intestine reach almost to the base of the exhalent siphon, and the outgoing stream of water carries all the products immediately away from the body. Accordingly all that is necessary for the retention of the eggs is a shortening of the oviduct so that they remain in the lower part of the atrial cavity, bathed by the water flowing through the gill slits. Increase in individual egg size ensures that under these circumstances the eggs will not be carried away by the water current, while the fact that the animals are hermaphrodite ensures fertilization and subsequent development of the retained eggs. When the tadpole stage is reached they swim away. This description applies to the majority of viviparous ascidians, but some are more specialized, such as *Distaplia,* and fertilized eggs are actually retained within the oviduct, which may bulge out from the side of the body as a distinct brood pouch. While in *Botrylloides* the egg is fertilized actually within the ovary, the tadpole escaping finally by bursting through the body wall.

While in many cases the presence of budding is little more than a process of reproduction, that is, increasing the number of individuals in a local population, in others there is a considerable degree of organic continuity and co-operation so that a superorganism is formed and the individuals are subordinated to it. The secretion of the external collagenous tunic plays an important part in this phenomena. The outer epidermis of different individuals remains distinct as in other forms of animal life, but the tunic secreted by adjacent individuals, if close enough together fuses into a compact whole. Budding therefore is always likely to result in numerous individuals becoming imbedded in a common mass of tunic material. This is the basis for a true colonial system. Individuals arrange themselves into systems or groups with, for example, all exhalent siphons converging toward a common centre to unite in forming a cloacal chamber and outlet. This condition frequently occurs. In a few types, as in *Botryllus* or *Symplegma,* buds remain in functional continuity with the circulatory system of the parents so that a colonial circulatory blood system is formed. Such a circulatory system within a mass of tunic survives though individuals associated with it may come and go as they each live through their individual cycles.

Selection of Habitat. — The form of solitary and colonial ascidians is closely adapted to the various types of possible habitats, or, to put it conversely the various special marine habitats are populated by ascidians that are able to survive in and exploit such niches.

Solitary ascidians are generally relatively large as individuals, with all three spatial dimensions well represented. They need plenty of room. They are to be found chiefly either attached to the surfaces of rocks, piles or ship bottoms, or imbedded in submerged sand or mud flats. Attachment is made by the grouing external coat of tunicin, aith its contained vascular processes. In quiet, more or less protected waters, such as harbours, estuaries, or relatively deep water, attachment is usually by the posterior end with the siphons reaching out into the water, as for example, *Ciona intestinalis,* the most cosmopolitan example of them all. Where there is considerable wave action, attachment is usually by the whole of one side. Some species are of but one habit or the other and are consequently limited in their range, while others, of which *Ciona* is as good an example as any, vary their attachment according to circumstances and occur in a diversity of habitats. In two families of ascidians, however, species have forsaken an attached abode for the sifting sand, mud, or shell gravel of the sea floor of the continental shelf. These are molgulids and polycarps, and in order to maintain their anchorage in such an unstable environment, they are large, more or less spherical, and have innumerable hairlike extensions of the tunic to which sand grains or shell particles adhere, the whole being submerged in the sand except for the emergent siphons. Sand or shell particles adhere also to the siphons and the animals are in consequence perfectly camouflaged. At certain depths of the continental shelf and coastal inlets extensive beds of mud, sand, or shell gravel of suitable consistency occur and these large and more or less globular species of the genera *Polycarpa* and *Molgula* are found in enormous numbers. The sea bottom habitat and its great extent has apparently made it less desirable to send tadpoles wriggling to the surface of the sea, and in these genera the tadpoles have independently allowed their eye to degenerate, being responsive only to the force of gravity, while in many species of sand-living molgulae, not only the eye of the tadpole, but its gravitational organ, the otolith, and the tail itself are lost. The effect is that large numbers of developing eggs are scattered over the sea floor nhere there is abundant room.

Budding or compound ascidians on the other hand are conspicuously unable to survive in such places, and for the most part are attached to relatively flat surfaces over which a good but not violent supply of clean water is assured.

Reproduction by budding, while leading to the formation of a colony unit rather than many separate individuals, has naturally an effect on the size of the individuals. An individual ascidian can either remain solitary and grow to a large size, or its growth is expressed in the formation of numerous individuals which repeat the budding process, thus increasing in number but hardly at all in individual size. If the process of budding is not too highly developed the individuals of a colony may be of a moderate size and number, and usually separate from though in contact with one another. These are often grouped together as the "social" ascidians to distinguish them from the "compound" forms that are more truly colonial. This grouping is not a natural one and brings together such distantly related types as *Clavelina* and *Stolonica,* genera which belong to different orders of ascidians. The individuals being, however, of fair size need a corresponding amount of space, and in general this group is found attached to protected submerged rock ledges, to the anchoring processes of large laminarian seaweeds, or to the surface of corals and sea fans.

Where budding is more active, the individual size is reduced and the numbers increased, tending to create a virtually two-dimensional colony. Colonies such as these are often large in area though of little thickness, with relatively minute constituent individuals. Together with bryozoans and certain sponges they tend to form an encrusting film over the underside of rocks, coral crevasses, stalks and fronds of seaweeds, and solitary ascidians, for the most part in the highly diversified environment of coastal waters, lagoons, mangrove swamps, rocky shores, estuaries and the intertidal zone itself. As long as the water flows freely bringing life-sustaining oxygen and microscopic food organisms this type of ascidian colony in general occupies a two-dimensional world of highly specialized niches. In relation to this and to the small size of the composing individuals, such organisms produce a comparatively elaborate form of tadpole larvae. The small hulk of a colony and particularly of an individual results in a correspondingly reduced capacity to produce eggs. When egg numbers are reduced below a critical value it becomes increasingly important to ensure the survival of an adequate number of those that can be produced. If large numbers cannot be produced it is better to produce a very few with a great chance of surviving to maturity than a moderate number with little chance. In any case the compound ascidians characteristically form a very small number of relatively large eggs that 'develop to the tadpole stage within the protection of the parental atrium or oviduct. Once liberated the best chances of the tadpoles of survival is attachment to surfaces similar to that of the parent and therefore in the near neighbourhood. Again in any case the tadpoles are not only good swimmers because of their relatively large size, but are also better equipped with sensory and hold-fast mechanisms so that some selection of a particular type of abode is possible; limiting their range to local territory, the length of the free-swimming period is reduced from the more primitive duration of one or several days to a mere few minutes. This form of adaptation has taken place in a number of unrelated families of ascidians independently, for example, *Botryllus, Perophora, Amaroucium, Clavelina* and *Didemnum.*

Colonial ascidians in particular are frequently brightly coloured with yellow, brown, red, green, and even blue pigments, while in some the constituent individuals become grouped in small star-shaped systems. *(Botryllus),* ladderlike rows *(Botrylloides)* or rosettes (*Polyclinum*).

CLASSIFICATION

The ascidians are but one of three orders of tunicates, the remaining two being oceanic orders.

Ascidians have been classified in various ways, but primarily with regard to the position and nature of the reproductive glands, and according to the nature of the branchial or gill structure. If the primitive type is considered to be relatively small with a moderately elaborate gill apparatus and an intestine looped beneath it and up one side toward the exhalent siphon, diversification within the order has been mainly in two directions. The intestinal loop may remain in this position while the branchial region is elaborated, or the branchial region may remain simple, but the intestinal loop together with the heart and reproductive glands descend down the attachment stalk.

Edmond Perrier divided the ascidians into Enterogona and Pleurogona, the Enterogona having the gonads or reproductive glands situated either within the intestinal loop or extending posteriorly from it, but in any case only a single unit of ovary and testis being present; the Pleurogona having gonads on each side of the body and extending into the outer wall of the atrial cavity. The division according to branchial structure was made by Fernando Lahille and later by Oswald Seeliger into three suborders, the Phlebobranchia with accessory longitudinal blood vessels internal to the branchial mall, the Haplobranchia without such vessels, the two suborders corresponding to the Enterogona; and the Stolidobranchia, corresponding to the Pleurogona, with internal longitudinai bars, in place of tubular vessels, the branchial wall usually being thrown into a series of folds.

The following is a synopsis of the group.

Class TUNICATA

Order I. ASCIDIACEA. Attached forms with dorsal exhalent siphon; branchial region (pharynx) with transverse rows of ciliated gill slits.

Section Enterogona. Gonads on one side only, either within loop of intestine or projecting beyond it posteriorly.

Suborder 1. PHLEBOBRANCHIA (DICTYOBRANCHIA). With internal longitudinal tubular vessels. Families: Cionidae, Perophoridae, Ascididae, Corellidae, Diazonidae.

Suborder 2. HAPLOBRANCHIA (KRIKOBRANCHIA). No internal longitudinal vessels or bars. Intestinal loop always extends posteriorly into stalk. Families: Clavelinidae, Polyclinidae, Didemnidae.

Section Pleurogona. Gonads usually paired, and in atrial wall.

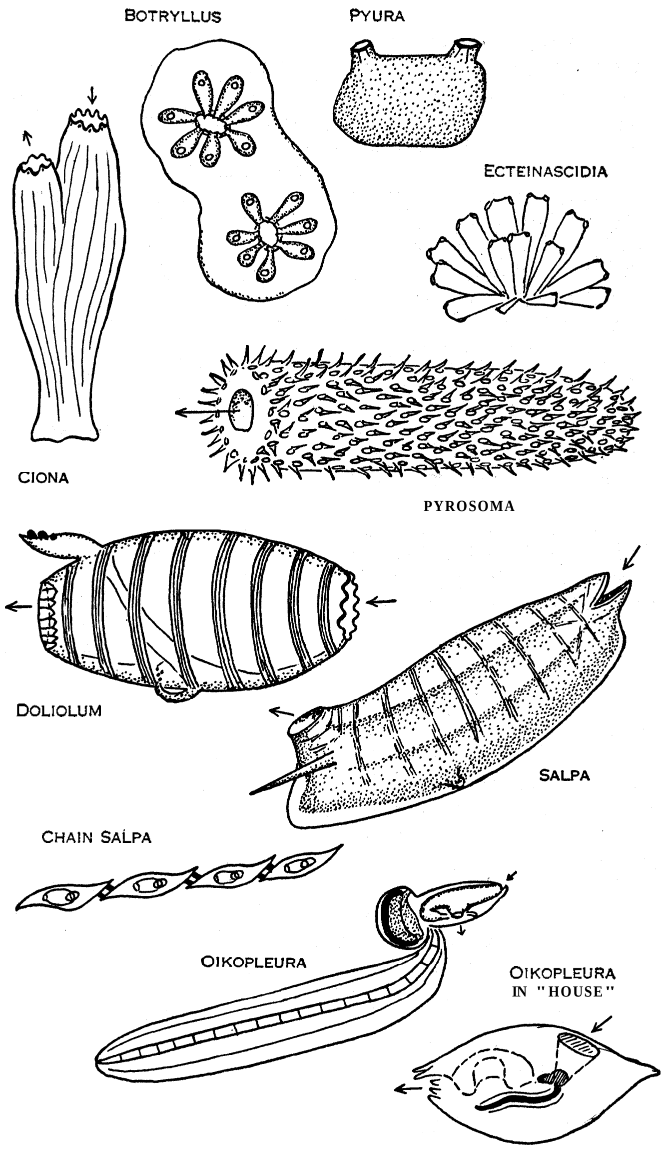

FIG. 4.— TUNICATES

Examples representing the classes Ascidiacea (all attached forms — the solitary Ciona and Pyura, and compound Botryllus and *Ecteinascidia),* Thaliacea (floating oceanic forms — the colonial Pyrosoma, both solitary and chain forms of Salpa, and *Doliolum* with buds forming on its dorsal spur), and Copelata (permanent tadpolelike forms — Oikopleura, with and without its temporary feeding "house"). Arrows show direction of ingoing and outgoing water currents

Suborder 3. STOLIDOBRANCHIA (PTYCHOBRANCHIA). With internal longitudinal bars and wall of pharynx folded longitudinally to create greater filtration surface. Families: Pyuridae, Molgulidae, Styelidae, Botryllidae.

In addition to the order Ascidiacea, the tunicates comprise two others, the order Thaliacea and the order Copelata. These are unattached forms inhabiting the oceanic currents, delicate transparent organisms not often seen but occurring in great numbers. The first of these is divided into three suborders, all members of which reproduce by budding to form colonies at some period of their life. The Copelata never bud and are permanently tadpole-like.

Order II. THALIACEA. Oceanic (pelagic), with inhalent and exhalent siphons at opposite ends of body; with long simple gill slits instead of rows of small gill slits.

Suborder 1. PYROSOMATA. Colonies form hollow floating tubes open at one end only, individuals being imbedded in the wall of the tube with their inhalent siphons extending from the outer surface and their exhalent siphons opening into the hollow interior of the colony. Eggs large, no tadpole larva being found. Family: Pyrosomatidae.

Suborder 2. DOLIOLIDA. Primary individual nonsexual, reproducing by budding. Budded individuals become sexually mature. Recognizable tadpole stage formed, but is temporary. Families: Doliolidae, Doliopsidae.

Suborder 3. SALPIDA. Primary individuals nonsexual, reproducing by budding. Buds form a long chain, sometimes in form of wheel, and function before being liberated. Eggs attached to parent and tadpole stage absent. Families: Salpidae, Cyclosalpidae.

Order III. COPELATA. Small oceanic forms with permanent tail; internal structures simplified; peculiar tunic house formed in relation to feeding mechanism. Families: Appendiculariclae, Fritillaridae, Kowalevskidae.

Both the Thaliacea and Copelata show adaptation to a pelagic existence in the upper layers of the ocean. *Pyrosoma* is the least modified and is essentially an unattached, floating colony, and is highly luminous. It glides slowly through the water by means of the water currents passed by each constituent individual into the hollow interior of the colony. The accumulating water escapes through the open end of the tube and the colony moves slowly in the opposite direction by a weak form of jet propulsion.

The Salps and Doliolids have given up producing water currents through their interior by means of ciliary activity and have substituted muscle contraction. Bands of muscle more or less encircle the body of an individual and their contractions force water through the barrel-shaped organism, thereby drawing the animal through the water.

The Copelata on the other hand retain the tadpole tail as the organ of locomotion. At times the action of the tail causes the animal to swim through the water, but most of the time there is present an external "house" of tunicin—secreted by the epidermis—which floats or drifts along, and the activity of the tail causes water to flow through it and from which microscopic food organisms can be filtered.

The relationship of the tunicates to chordate animals as a whole, and therefore to vertebrates and finally man, has been the subject of much speculation ever since the existence of a chordate tadpole mas first discovered. The first and Haeckelian interpretation was that the tadpole represented a relic of an ancient descent from an early vertebrate animal. the adult tunicate being in a sense highly degenerate, the tadpole being retained in the course of the development of the egg in conformation with the theory of recapitulation or biogenetic law. This view was universally held until the 1920s, and was relatively comfortable, for it accounted vaguely for the existence of the tunicates themselves as a byproduct and at the same time threw no slanderous aspersions on the origin of the chordate-vertebrate group of animals as forms which from the beginning swam in the light of the sun near the ocean surface, never descending for an apprenticeship on the plebian sea floor. Such a habit was supposed to account for the uniquely dorsal position of the nerve cord in vertebrates in contrast to the ventrally placed cord of belly-crawling invertebrates.

An alternative interpretation, however, appears to fit the facts better, a view first presented strongly and plausibly by Walter Garstang in 1928. This considers the attached ascidians to be of primitive habitat. Not present-day ascidians, but their ancestors of very ancient times, probably more than 1,000,000,000 years ago in the upper pre-Cambrian era, are thought to have been relatively small simple forms attached to the sea floor. There they evolved a dorsal nerve mass for controlling the siphons; gill slits evolved for the escape of the food-bearing current, and a ventral heart to pump the blood. Their eggs developed at first into simple larvae swimming by means of cilia like the larvae of most primitive marine groups. From this originally simple larva the ascidian tadpole gradually evolved.

No direct evidence can ever be obtained concerning the evolution of the tiny delicate organisms of pre-Cambrian times, but circumstantial evidence abounds and strongly supports this later theory concerning the origin of tunicates. If valid, then not only are the thaliacean tunicates colonial forms that have abandoned a sessile for a pelagic life, but the Copelata, which at one time were thought to be the most primitive of tunicates. are considered to be descendants of the Thaliacea and in no way primitive forms.

If the tunicates were merely an isolated group of animals with no self-important relatives, the more plausible of tno theories would be readily and more or less indifferently accepted. But somewhere near the level of tunicate organism are the remote beginnings of human evolution itself and the last theory directs the line of descent into and through the group instead of making a detour around into the great unknown. In effect, the great group of vertebrate animals would have their origin in the enterprising young of a group of tiny water filterers cemented posteriorly to the sea floor.

This is not implausible. Evolution does occur in relation to any stage in the life cycle of' an animal, and larval types are known to have become the sexually mature adults. Tadpole-like larvae could have evolved from simpler larvae within the tunicate group, and such larvae could have suppressed their metamorphosis into an old-fashioned tunicate, and continued to grow into a sexually mature swimming chordate organism from which the vertebrates eventually evolved.

It could have happened and such evidence as can be culled from living forms suggests that it did.

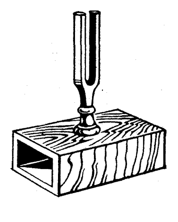
In other words, we can trace the dorsal position of our brain and spinal cord to the upward reaching siphons of a primitive attached tunicate, our heart and basic pattern of blood vessels to that of the same organism, our ear passage to a respiratory gill slit of an early shark and in turn to a water-escape passage of the sessile ascidian, our pituitary gland (the master gland of our endocrine system) to the subneural gland and hypophysial tube of the same form, while our tubular spinal cord and brain, our backbone and trunk muscles derive from the tail of the swimming larva the ascidian evolved and managed to make permanent.

Since the time primeval events such as these took place, the tunicates have had just as much time as all other surviving groups have had to become specialized in various ways, in their case to elaborate the gill-filtration system, budding and colony formation, etc., and there is no suggestion that in tunicates as they now exist we recognize our contemporary ancestors.

BIBLIOGRAPHY.—J. Hopkinson, "Bibliography of the Tunicata," Ray Society, London (1913). This is a complete list of publications from 1469 to 1911. There is no recent general account of the tunicates in English, but excellent German texts by J. Huus, I. E. W. Ihle, H. Lohmann and G. Neumann are included in the *Handbuch der* Zoologie of Kukenthal and Krumbach, vol. 5, second half (1933–37). Articles in English written from more limited points of view, consult W. Garstang, "The Morphology of the Tunicata," *Quart. Jour. Microscopical* Science, vol. 72 (1928); and N. J. Berrill, "Studies in Tunicate Development," Philos. Trans., Royal Soc., London, vols. 218–225 (1929–36).

(N. J. B.)

TUNING FORK, a two-pronged instrument of high-grade steel, which by the vibration of its prongs gives out a single pure musical tone of constant pitch. The pitch depends upon the natural period of vibration of the prongs, that is, upon their length and thickness.



BY COURTESY OF MESSRS. BOOSEY AND CO., LTD.

THE TUNING FORK, INVENTED IN 1711

Tuning forks may be made for all musical pitches in the audible range, and the fork which gives the A above middle C is usually taken as the musical standard. For laboratory purposes the forks may be mounted upon hollow boxes to increase the volume of sound by resonance. They may be set in momentary vibration by a light blow, or kept in constant vibration by the action of an intermittently energized electromagnet upon one of their prongs. The tuning fork was invented by John Shore in 1711. (See PITCH, MUSICAL.)

TUNIS, capital of Tunisia, in lat. 36° 48' N. and long. 10° 12' E., is situated on an isthmus separating two salt lakes, the marshy Sebkha-el-Sejumi and the Bahira (Lake of Tunis), the west bank of which it occupies. Tunis stands, as Carthage did, on the threshold of the western bay of the Mediterranean, at the natural outlet of the western bay of the Tunisian Tell and in easy communication with the south. But its topographical situation differs profoundly from that of the ancient town. Built at the end of the shallow Bahira, it uses an intermediate town, Goletta (*q.v.*) or La Goulette, for a part of its sea trade. In 1893 a sea channel, 6 mi. long and 7.5 m. deep was cut through the Rahira to connect Goletta with the city of Tunis making the capital a seaport.

Tunis consists of two towns side by side. The old native town lies between the Bir Kassa and the Ras Tabia hills, on a slope down to the Bahira; the new town developed on the flat, low-lying ground between old Tunis and the lake. European Tunis is built on a regular, somewhat monotonous plan; the blocks of houses are bordered by rectilinear avenues, some of which are planted with trees. On one avenue, nearly a mile long, laid out from east to west, stand the ministries! surrounded by gardens, the cathedral, the casino-theatre, the banks and the principal hotels and cafés. It is the centre of the city's life.

The old town includes three distinct parts. The Medina, or central city, which represents the primitive settlement) several gates of which are still standing; the suburb of Bab-el-Suika on the north, where the Jews live; and that of Bab-el-Jezira on the south. The Jamaa-ez-Zituna, or mosque of the Olive Tree, is the seat of an important Moslem university, founded in 732 by the Omayyad governor Obeid-Allah and reconstructed by the Aghlabites (9th century); most of its buildings date from the 13th to the 1 jth centuries.

Behind the Zituna are the *suks,* which are the most interesting feature of the native town. They are composed of little shops opening on to narrow, tortuous streets, covered by arches or roofs of planks, where only foot passengers can go. Each kind of trade, each group of craftsmen, has its special quarter. Tunis possesses many mosques, notably those of the Kasba (13th century) and Sidi-Mahrez (17th century).

Tunis and Goletta together form the major port of Tunisia. Tunis is the centre of a rich farming region. Its industrial products include beer, soft drinks and syrups, chocolate, canned vegetables and fruits, tobacco, leather, textiles and chemicals; the manufacture of carpets is an old-established craft. The industrial suburbs lie to the southeast.

The population of Tunis and its suburbs, 410,000 (1956 census), included 119,500 Europeans and 32.000 Jews.

Southeast of the city, along the valley of the Melain, are magnificent remains of the Roman aqueduct from Jebel-ez-Zaghuan to Carthage. Carthage is on the coast to the north.

Tunis existed in the Carthaginian epoch, but its importance dates only from the Moslem conquest. It became the capital city toward the end of the 9th century, under the Aghlabites, and reached its greatest prosperity in the Hafsid period, when it is said to have surpassed Cairo. Charles V took possession of it in 153j; the Spaniards were driven out in 1569, retook it in 1573, but ceded it to the Turks in 1574. Thereafter the history of Tunis merged with that of Tunisia (*q.v.*).

TUNISIA (Arabic AFRIKIYA), an independent republic (until July 1957 a beylicat, or kingdom) in north Africa bounded on the west by Algeria, on the north and east by the Mediterranean, on the southeast by Libya. The country, halfway between the Straits of Gibraltar and the Suez canal, forms, with Sicily, the barrier between the eastern and western Mediterranean. This situation and the possession of nearly 900 mi. of coast line gives economic and political importance to Tunisia.

PHYSICAL FEATURES

The mountains are formed of Secondary and early Tertiary rocks, while later Tertiary and Quaternary rocks cover the plains. The folds are Miocene in the main, as in the Atlas, but movement continued long after that period. There are numerous short discontinuous chains of varying orientation and a number of small circular or elliptical domes.

North of the concatenation of the Dorsal mountain ranges, which lies across the country from Tebessa to Ras Addar (Cap Bon), the chains of the Tell tend from southwest to northeast. Farther north rise the wooded sandstone mountains of the Khmir or Kroumirie (Fr. "Kroumir") country (3,000 ft.) and the Mogods, where the coast is hroken and wild. Next. standing round the alluvial plains of the middle and lower Mejerda (Medjerda) and of Bizerta and Tunis itself, there are mountains and hills of chalk and marl used for pasturage or cultivation. Relief is heightened in the High Tell, betneen Kef and Tebursuk (Titbomsouk), and in the Dorsal mountains (Chambi or Shambi, 5,065 ft.); but between the massifs there are wide depressions, varying in elevation from 1,300 to 2,600 ft., which are under crops.

South of the Dorsal, in the steppes, the barren mountain chains are not so high and tend southwest-northeast, west-east (Gafsa) and south-north; they are also further apart, with wide alfa-covered spaces between them. To the east the plains of the lower steppe. with Qairwan (Kairouan) and Sfax, are watered in the north by the aadis Marguellil and Zerud (Zeroud) but are characterized elsewhere by closed depressions nith sebkhas (salt lakes).

Finally, to the south of Gafsa, the Sahara begins with the clayey depression of the *shats* (Fr. "chotts") Gharsa, Jerid (Djerid) and Fejej (Fedjedj), the dunes of the eastern Erg and the plateau of the Matmata tribes and of the Dahar. The Dahar has on its eastern side the semiarid plain of the Jeffara (Djeffara), which borders the Gulf of Gabes. In the gulf itself are the islands of Jerba (Djerba) and Kerkena.

With a Mediterranean climate, Tunisia shows fewer contrasts in its different regions than do the Tell, the steppe and the Sahara in Algeria. The average January temperature at Tunis is 52.7° F.; the hottest month has an average of 79.2°.

The winds are chiefly northwest in winter and northeast in summer; the rainy season runs from October to May. Rain is heaviest in the winter. The distribution of rain is, however. highly irregular from region to region and from year to year; North Africa. in general, is in a zone of climatic discontinuity, and a small change of the winds may mean great changes in rainfall. One zone gets more than 24 in. of rain per year, and this includes the massifs of the Khmir country and the Mogods; the next zone, with 16–24 in. of rain, includes central Tunisia, the valley of the Mejerda, Cap Bon and the region of Tunis (Tunis 16 in., Tebursuk 20, Kef 19); a zone with 18–16 in. south of the Tunisian ridge includes the region of Qairwan and the Sahel (coast belt stretching from the Gulf of Hammamet to the south of Sfax); there is a zone with less than 8 in. in the south and extreme south (Gabes 4 in , Gafsa 6, Médenin 5). Despite the meagre precipitation there, the hills of the Sahel, the coastal plains of Sfax and even of the Jeffara and the islands of Kerkena and Jerba grow olives thanks to the humidity of the atmosphere, which condenses in the sandy soils.

The principal river is the Mejerda, rising in Algeria near Souk-Ahras and flowing into the Mediterranean near Porto Farina. It is 261 mi. long; its affluents are the wadis Melleg, Tessa and Siliana, which come down from the High Tell. In floodtime the volume of the Mejerda may be 35,315 cu.ft.; in drought it may go down to 35 cu.ft. This river has formed large alluvial plains, filling up the ancient Gulf of Utica and joining a series of shore islets. The rivers of the eastern slope (Zerud, Marguellil) dry up in basins of the lowland which communicate with the sea only when rains are exceptionally heavy.

The northern coast is much dissected. Standing out to sea is the island of La Galite; the Lake of Bizerta has kept its depth because the alluvium is deposited in another one above it.

Beyond the Cap Bon peninsula, the eastern limit of the Gulf of Tunis, the east coast is low and sandy, bordered by lagoons in several places and shelving slowly into shallow water around the Kerkena archipelago and Jerba Island.

Flora for the most part is Mediterranean; 1,350 out of 2,000 plant species occur also in Italy. Forest, scrub and steppe are the characteristic formations. The cork oak and the *zean* oak cover the Khmir country and the Mogods (400,000 ac.). The woods of the centre are less compact. The Aleppo pine (2,000,000 ac.) and the thuja are the chief forms. In the south one finds, chiefly, the juniper. with some Aleppo pines and pistachio nuts. Bled-Tala has a forest steppe with gum trees (Acacza tortila), the most northerly occurrence of a species found from Senegal to Arabia. The scrub is usually degraded forest, and its most characteristic tree is *Zizyphus* lotus, the spiny jujube tree. The steppe is covered by grasslike types such as the alfa or esparto grass and by species of Artemisia.

The fauna is much like that of Algeria, with European species. Mammalian fauna is mainly Eurasiatic, but among reptiles and fish some Africano-Brazilian forms persist. Stag (Cervus *elaphus barbus*) is found in Kroumirie and the sleeved mouflon in the mountains. (J.-J. Ds.)

HISTORY

The history of Tunisia begins with the establishment of the Phoenician colonies (see CARTHAGE; PHOENICIA). The Punic settlers Semitized the coast but left the interior almost untouched. Under the Romans, Punic speech and civilization gave way to Latin.

Rich in corn, herds and, in later times, oil, and possessing valuable fisheries, mines and quarries, the province of "Africa,': of which Tunisia was the most important part, attained under the empire a prosperity to which Roman remains in all parts of the country still bear witness. Carthage was the second city of the Latin part of the empire, "after Rome the busiest and perhaps the most corrupt city of the west, and the chief centre of Latin culture and letters." The emperor Septimius Severus and the philosopher Apuleius were Africans. Moreover, in the early history of Latin Christianity Africa holds a more important place than Italy; in Africa Christian Latin literature took its rise, and to this province belong the names of Tertullian and Cyprian, of Arnobius and Lactantius and, above all, of Augustine. Lost by Rome to the Vandals, who took Carthage in 439, the province was recovered by Belisarius (533–534) and remained Roman till the Arab invasions of 648–669. The conqueror, Okba ibn Nafi, founded the city of Qairwan (671), which was the residence of the governors of "Afrikiya" under the Omayyads and thereafter the capital of the Aghlabite princes, the conquerors of Sicily, who ruled in merely nominal dependence on the Abbasids.

Arab and Berber Dynasties. — The Latin element in Africa and the Christian faith almost disappeared in a single generation; the Berbers of the mountains, who had never been Latinized and never really Christianized, accepted Islam without difficulty, but showed their stubborn nationality not only in the character of their Mohammedanism — which has always been mixed with the worship of living as well as dead saints (marabuts) and other peculiarities — but also in political movements. The empire of the Fatimites (*q.v.*) rested on Berber support, and from that time until the advent of the Turks the dynasties of North Africa were really native, even when they claimed descent from some illustrious Arab stock. When the seat of the Fatimite empire was moved to Egypt (972), the Zeirids, a house of the Sanhaja Berbers, ruled as their lieutenants at Mahdia, and about 1050 Mu'izz the Zeirid, in connection with a religious movement against the Shi'ites, transferred his very nominal allegiance to the Abbasid caliphs. Sent in vengeance by the Fatimite caliph, a vast horde of Bedouins from Upper Egypt (Beni Hilal and Sulaim) ravaged all North Africa. Unable to found an empire or overthrow the settled government in the towns, the invaders made order and prosperity almost impossible in the open parts of the country until its effective occupation by the French. The Zeirid dynasty was finally extinguished by Roger II of Sicily, who took Mahdia in 1148 and established his authority over all the Tunisian coast. Even Moslem historians speak favourably of the Norman rule in Africa; but it was brought to an early end by the Almohade caliph of Morocco, Abd ul-Mumin, who took Mahdia in 1160.

The Almohade empire soon began to decay, and in 1336 Abu Zakariya, prince of Tunis, proclaimed himself independent and founded a dynasty which subsisted till the advent of the Turks. The Hafsids (so called from Abu Hafs, the ancestor of Abu Zakariya) assumed the title of "prince of the faithful," a dignity which was acknowledged even at Mecca when. in the days of Mustansir, the second Hafsid, the fall of Baghdad left Islam without a titular head. In their best days the Hafsids ruled from Tlemcen to Tripoli, and they received homage from the Merinids of Fez; they held their own against repeated Frankish invasions, of which the most notable were that which cost Louis IX of France his life (1270) and that which Louis II of Bourbon led (1390), when English troops took part in the unsuccessful siege of Mahdia. The Hafsids adorned Tunis with mosques, schools and other institutions, favoured letters and in general appear to have risen above the usual level of Moslem sovereigns. Their rule was troubled by continual wars and insurrections and later by family dissensions.

Turkish Rule. — The conquest of Algiers by the Turks gave a dangerous neighbour to Tunisia, and after the death of Mohammed the Hafsid in 1525 a disputed succession supplied Khair ed-Din Barbarossa with a pretext for occupying the city in the name of the sultan of Constantinople. Hasan, the son of Mohammed, sought help from the emperor and was restored in 1535 as a Spanish vassal, by a force which Charles V commanded in person, while Andrea Doria was admiral of the fleet. But the conquest was far from complete. The interior was a prey to anarchy and civil mar until, in 1570, Ali Pasha of Algiers utterly defeated Hamid, the son and successor of Hasan, and occupied Tunis. In 1573 the Turks again retreated on the approach of Don Juan, who had dreams of making himself king of Tunis; but in the next year Sultan Selim II sent a strong expedition which drove the Spaniards from Tunis and reduced the country to the status of a Turkish province. Nevertheless, the Spanish occupation left a deep impression on the coast of Tunis.

Within a few years after the Turkish conquest, a military revolution (1590) transferred the supreme power to a dey elected by the janissaries, who formed the army of occupation. The government of the deys lasted till 1705. The beys, whose proper function was control of the tribes and who from 1631 onward had overshadowed the deys, took full control when Hussein ben Ali was proclaimed sovereign by the troops under the title of "bey." Being a prince of energy and ability. he was able to establish the hereditary sovereignty which lasted without change of dynasty.

Under deys and beys alike Tunisia was essentially a pirate state. Occasional acts of chastisement (of which the bombardment of Porto Farina by Robert Blake in 1655 was the most notable) and repeated treaties, extorted by European powers. checked from time to time but did not eliminate the habitual piracies, on which indeed the public revenue of Tunis was mainly dependent. The powers were generally less concerned for the captives than for the acquisition of trading privileges, and the beys took advantage of the commercial rivalry of England and France to play them off one against the other. The definite abandonment of piracy may be dated from the presentation to the bey in 1819 of a collective note of the powers assembled at Aix-la-Chapelle. The government had not elasticity enough to adapt itself to so profound a change in its ancient traditions. No attempt was made to improve conditions in the country, except perhaps under Mohammed VI es-Sadik, who succeeded to the throne in 1859. In the third quarter of the 19th century not more than a tenth part of the fertile land was under cultivation. Taxation was ruinous, and borrowing in Paris increased the public debt enormously. The yearly charges on the debt exceeded the whole annual revenue. Discontent flamed into insurrection under attempted constitutional and military innovations, and the inevitable revolution was postponed only by the rivalry of the European powers and interests in the country. The French had come to regard Tunisia as the natural extension of Algeria, although after the Crimean War Turkish rights over Tunis were revived. After the Franco-German War, the bey turned toward Great Britain for advice, and a British protectorate was not an impossibility under the remarkable influence of Sir Richard Wood, British diplomatic agent at the court of Tunis from 1855 to 1879. The railways, lighthouses, gas and waterworks and other concessions and industries were placed in British hands. But in 1878, at the Congress of Berlin. Lord Salisbury agreed to allow France a "free hand" in Tunisia in return for French acquiescence in the British lease of Cyprus.

The French Protectorate. — After 1862, however, the kingdom of Italy began to take an interest in Tunisia. Italian residents outnumbered other European groups. Italians were the commercial and industrial leaders. In 1879. of the 683 vessels entering the port of Goletta, more than 500 mere Italian. When the country went bankrupt in 1869, a triple control mas established over Tunisian finances, with British, French and Italian "controllers." In 1880 the Italians bought the British railway from Tunis to Goletta. This and other actions excited the French to act on the understanding effected with the British at the Berlin congress. In 1881 a French force crossed the Algerian frontier and. advancing on the capital. compelled the bey to accept the French protectorate. The conquest of the country mas not effected without a serious struggle with the Tunisians. especially at Sfax; but all Tunisia was brought eventually under French control.

Mohammed VI signed the treaty acknowledging the protectorate at the Bardo palace on May 12. 1881. He died in Oct. 1882, and a new agreement, defining the protectorate, mas signed at La Lfarsa (June 8, 1883) by his brother and successor. hfohammed es-Sadik Ali IV. From 1884 onward the French, under a resident-general, carried out a thorough reform of the administration. Great Britain early recognized the protectorate, as did most of the other powers. Turkey did not, and though the boundary between Tunisia and Tripolitania was established by the treaty of May 19, 1910, between France and the Ottoman empire. it was not until the treaty of Lausanne (1923) that Turkish claims to the regency were finally renounced. Italy, however. was more deeply concerned by the establishment of the French protectorate, having looked forward to the acquisition of Tunis. The Italian government renounced its consular tribunals in Tunisia in 1884. as the other powers had done in 1883, but insisted on its other capitulatory rights (under a treaty of 1868) till 1896. By the terms of a convention then concluded the right of Italians in Tunisia to maintain their nationality was guaranteed. British subjects had the same right; this affected chiefly the Maltese settled in the country. The persistence shown by Italians and Maltese in maintaining their nationality, however, was a cause of annoyance and some practical inconvenience to the French. Decrees issued in 1921 declaring that British and Italian subjects, born of parents who were themselves born in Tunisia, would be deemed to be of French nationality provoked resentment: especially among the Italians. As to the British (*i.e.,* Maltese) an arrangement was reached in 1923 whereby the persons affected were entitled to decline French nationality. The Laval-Mussolini agreements of 1935, providing for the termination of Italy's special privileges, were never applied. They were to be denounced in 1938 by Mussolini, who made the acquisition of Tunisia one of the aims for which Italy declared war on France in 1940.

The nomad tribes in the south gave occasional trouble, but French rule was generally accepted. By the agreement of Sept. 12, 1919, the territory south of Tunisia forming salients between the oases of Ghadames and Ghat and between Ghat and Tummo was transferred to Libya.

Tunisian Nationalism. — Nationalism arose in Tunisia before World War I under the leadership of "Young Tunisians" influenced by European education and thought. The movement increased in importance under the stimulus of postwar movements in the middle east; in 1920 various groups united to form a Destour (Constitutional) party, whose program had the objective of securing democratic forms of government. In 1925 the French deported the leaders and broke up the movement.

The economic depression of the early 1930s and the appearance of younger leaders facilitated the revival of nationalism. These leaders, headed by Habib Bourguiba (*q.v.*), formed the Neo-Destour party with a program of vigorous action involving organization of the masses and the assistance of French leftist leaders and nationalists in Morocco and Algeria. The Neo-Destourians expected much from the French popular front government of 1936, which. however. added only minor reforms in 1937 to those granted in 1933 and 1935. After clashes with the police in April 1938, 200 nationalists were arrested and both the Destour and the Neo-Destour were dissolved. (P. W. I,; X.)

After the Franco-German armistice and Italy's entry into World War II (June 1940), Tunisia, like the rest of French North Xfrica, came under Vichy rule. Trade was paralyzed, and there was an acute shortage of imports, particularly of fuel and textiles. The day after the Allied landings in North Africa (*see* WORLD WAR II) the Germans, unopposed by the resident-general, Adm. J. P. Esteva, occupied the country (Nov. 1942). For six months Tunisia was a battleground; then in May 1943 the German and Italian armies collapsed. Esteva fled, and the bey, Mohammed el-Moncef, was deposed by the French and replaced by the heir apparent, Mohammed el-Xmin. Italian privileges were abolished by an ordinance of June 22. 1944. duly recognized by the Italian government.

Some political reforms were promised by the French but economic difficulties aggravated Moslem discontent, and nationalist agitation was resumed. A repressive policy was adopted, and in April 1945 Bourguiba, the leader of the Neo-Destour, fled to Cairo. In Aug. 1946 Salah ben Youssef, the secretary general of the Neo-Destour. summoned a meeting in Tunis of all the nationalist parties and groups, which unanimously passed a resolution condemning the protectorate and demanding complete independence. The principal nationalist leaders were then arrested, but were released a few weeks later.

In Feb. 1947, Jean Mons, the French resident-general, tried to form a nationalist ministry but failed because both the Destour and the Neo-Destour refused to accept either the continuance of the protectorate or the entry of Tunisia into the French union. In Aug. 1947 Mons therefore formed a Tunisian ministry composed of moderate elements with no definite party leanings. But whereas previously there had been only three Tunisian ministers, all departments of state being under French directors, all French directorships except those of education, finance and public works were now abolished and five more ministries given to Tunisians. These ministers were assisted by French councillors, whose agreement to ministerial propositions had to be obtained, differences between them being resolved by a "cabinet council" partly Tunisian and partly French. hlohammed Kaak, a lawyer, was prime minister and minister of justice.

In spite of great difficultiessome progress was made in education. But land-settlement plans came to nothing. health services lagged, and there was little diminution of the controlling power of the French in local as in central administration.

The nationalists were therefore very restive. Bourguiba (with official French sanction) returned to Tunisia in Sept. 1949 and for the next six months campaigned throughout the country for the abolition of the protectorate and for the grant of autonomy. In April 1950 he went to Paris and published a program in which, while renouncing the claim to complete independence and showing willingness to admit Frenchmen to elected Tunisian councils, he yet asked for a progressive transfer of sovereignty, for a new treaty and for internal autonomy.

In June 1950, Louis Périllier, the new French resident-general, admitted that substantial reforms were necessary and that direct administration should be ended within the framework of the treaties establishing the protectorate. In August a ministry was led by Mohammed Shenik in which the Tunisians participated in equal strength with the French and in which, for the first time, the Neo-Destour was represented by Salah ben Poussef. Because of pressure by the French settlers. no reform was achieved, but the Tunisian ministers' French advisers were removed. Another step toward internal autonomy, however, was taken in Feb. 1951, when it was decided that the council of ministers was henceforth to be under the chairmanship of the premier instead of that of the resident-general and that the certificate of the secretary-general of the residency was no longer required to validate ministerial decisions.

While French settlers made known their fear that Tunisian emancipation would end in the eviction of the French, Bourguiba tried to stir world opinion and sharply criticized the slowness of French policy. A nationalist agitation began in December and at the beginning of Jan. 1952 Jean de Hauteclocque succeeded Périllier as resident-general, The Shenik ministry made a complaint against France to the United Nations but this was ruled out of order by the Security council. Disorders increased after Bourguiba and 11 other Neo-Destour and Communist leaders had been arrested.

In March 1952 the French government proposed partial self-government for Tunisia but this proposal was criticized in the French national assembly as going too far and was rejected in August by the bey as insufficient. The situation deteriorated gravely as a result of the murder on the night of Dec. 4–5, 1952, of Ferhat Hashed, secretary general of the General Union of Tunisian Workers, a prominent supporter of Bourguiba. Terrorist activities of the *fellaghas* (rebels) spread throughout the country.

Independence. — Events took a dramatic turn when on July 31, 1954, Pierre Mendès-France, French premier, went to Tunis and told the bey that the French government was determined to give Tunisia internal autonomy, with an all-Tunisian government. Only foreign policy and defense were to remain under French control. The reciprocal obligations were to be decided by negotiation. On Aug. 7, Tahar ben Ammar, a Tunisian of moderate views, formed a ministry in which the Neo-Destour party was represented. At the beginning of December Gen. Pierre Georges Boyer de la Tour du Moulin, the French resident-general, agreed that a full amnesty should be given to all the *fellaghas* surrendering to the authorities and handing over their arms. By the end of 1954 almost all the rebels, about 2,500, had surrendered.

The Franco-Tunisian negotiations, initiated to implement the July promise of internal autonomy, ended on June 3, 1955, when a series of nine agreements was signed in Paris. Bourguiba, freed from internment, received an enthusiastic reception when he landed in Tunis on June 1. He told a crowd of 200,000 that "internal autonomy was only a step toward independence."

As a result of the French recognition of Morocco's independence (Nov. 6, 1955), the Tunisian government reopened the negotiations with France and on March 20, 1956, Tahar ben Ammar and Christian Pineau, the French foreign minister. signed a protocol abolishing not only the treaty of 1881, but the 1955 agreements as well. France recognized Tunisia's independence and its right to conduct its own foreign policy and to form its own army. Both countries recognized their "interdependence," which was, however, to be defined in further negotiations.

On March 25, the country's first general election resulted in complete victory for Bourguiba's National front, which won all the 98 seats of the constituent assembly. On April 25 Bourguiba formed a new government. Salah ben Youssef, however, opposed Bourguiba's policy, describing it as pro-French. He was to have been arrested in Jan. 1956 on a charge of treasonable conspiracy but succeeded in escaping to Libya and later moved to Cairo. There was a revival of *fellagha* activities which were carried out in co-operation with those of the Algerian insurgents.

A republic was proclaimed in July 1957, and the assembly elected Bourguiba as president.

SOCIAL AND ECONOMIC CONDITIONS

Area and Population. — The republic covers-an area of 48,332 sq.mi.

The natives of Tunisia belong to two stocks, which may be roughly classified as the Berber and the Arab. about two-thirds being of Berber descent. Arabic is spoken everywhere and only about 1% speak Berber. The population is mainly Sunni Moslem but the inhabitants of the island of Jerba are mostly of the Ibadhite sect of Islam. The towns contain some primarily urban elements such as the Andalusian Moors and the Jews.

Among the Europeans Italians were in absolute majority in 1906; by 1955 that majority became decisively French not so much through immigration as through naturalization. (See Table I.) Of the European population, 85% live in the towns, 60% in Tunis alone. Europeans are predominantly Roman Catholics; there are, however, about 3.500 Protestants.

TABLE I.—Population of Tunisia

Nationalities	1906*	1921	1936	1956
Moslems				
Tunisian	1,750,000	1,826,545	2,265,750	3,383,213
Non-Tunisiant	40,000	62,843	69,873	86,149
Total Moslems	1,790,000	1,889,388	2,335,623	3,469,362
Jews	68,000	48,436	59,485	57,786
Europeans				
French	34,600	54,476	108,068	180,450
Italians	81,200	84,799	94,289	69,909
Maltese	10,300	13,520	7,279	7,973
Other.	2,800	3,320	3,569	
Total Europeans	128,900	156,115	213,205	255,332
Total	1,986,900	2,093,939	2,608,313	3,782,480

'Estimates. †Mainly Algerians and Libyans.

Tunis is the country's capital; between 1926 and 1956 its population rose from 185,996 to 410,000. Other important towns are (pop. 1926 census; 1956 census in parenthesis): Sfax 16,301 (65,63j); Sousse or Susa, 28.718 (48.172); Bizerta 19,529 (44,-681); Qairwan 32,299 (33,968); Gabès 22,512 (24,420). Other towns exist as ports, oases or agricultural centres.

Agriculture. — About 3,400,000 ha., out of a productive area estimated at 9,000,000 ha.. are held to be arable. The returns are generally poor. (See Table II.) Vineyards cover about 36,000 ha. (1954), mainly in the regions of Tunis and Grombalia. The average annual production in 1950–54 was 740,000 hl. The eastern part of Tunisia is particularly suited to olive growing. In 1954 there were 26,000,000 trees of which four-fifths were full-bearing. For livestock see Table III.

Asses	130	137	168	164	160	162

Forests (2,500,000 ac.) provide firewood and timber (railway sleepers, pit props and stakes for vineyards), as well as cork for export. Alfa (70,000 tons in 1954) is exported chiefly to England, for the manufacture of paper pulp. Sea fishing is carried on in Tunisia under more favourable conditions than in Algeria. The fish are also more varied in kind. There are 13,000 fishermen, of whom 12,000 are natives and 1,000 Italians. The catch consists mainly of tunny, sardines and sardinella. Sponge fishing is carried on along the whole of the east coast, from Monastir to the frontier of Tripoli, especially at Sfax and in the Kerkena Islands; production in 1954 was 180,100 tons.

Industry. — Tunisia possesses practically inexhaustible deposits of phosphates. The chief exploitation is carried on in the Gafsa region and exports go through Sfax. The phosphates of Kalaa-es-Senan and Kalaa-Jerda, found as a prolongation of those of Tebessa, are exported through Tunis. Iron ares, abundant and of good quality, are found, especially to the south of Kef and not far from the Algerian frontier, at Duaria. at Jerissa and at Nefzas in the Mogods. Lead and zinc came from the country round Béja and the High Tell. Other minerals are mercury, manganese, copper, iron pyrites and salt; petroleum has been sought at various places. (See Table IV.) From 1954 natural gas from Cap Bon was being used in Tunis. Between 1938 and 1954 production of

TABLE IV.—Mineral Production

Mineral	1950	1951	1952	1953	1954
Phosphate rock	1,525	1,679	2,265	1,719	1,823
Iron ore (55% Fe content)	758	923	977	1,057	950
Lead ore	30.7	3	36.5	37.9	41.6
Zinc ore	5.7	7.3	7.5	6.6	9.5

electricity rose from 66,965,000 kw.hr. to 203,475,000 kw.hr. Important industries include flour milling, oil refining, lead melting and distilling; after World War II, moreover, there was considerable industrial development. comprising preserved food, building materials and light engineering workshops.

Foreign Trade. — Tunisia is in customs union with France, but for wine an annual quota system was being applied; *i.e.*, only a certain quantity was allowed free into France. Of the imports 80% came in 1954 from the franc area, 3% from the sterling area and 4% from the dollar area; of the exports, 68%, 10% and 2% went to the same areas, respectively. Tunisia imports textiles and clothing (20% of the total value of imports); foodstuffs(18%; *e.g.* sugar, tea and dairy produce); raw materials and unfinished goods (21%); supplies for building and development (21%); and fuel. Principal exports are olive oil and minerals. (See Table V.)

TABLE V.—*Foreign Trade*
(In millions of francs)

Item	1951	1952	1953	1954	1955
Imports	63,819	64,879	60,121	59,268	63,199
Exports	37,536	40,060	38,840	44,214	36,984

Finance. — Tunisia is in monetary union with France and the Tunisian franc was at par with the metropolitan franc. The Banque d'Algérie acted as bank of issue for Tunisia. The note circulation between 1941 and 1954 rose from 1,635,000,000 fr. to 24,836,000,000 fr. For revenue and expenditure see Table VI.

TABLE VI.—*Budgets*
(In millions of francs)

Item	1951–52	1952–53	1953–54	1954–55	1955–56
Revenue	47,120	48,244	51,680	53,024	53,275
Expenditure	47,111	51,596	54,136	55,524	57,175

Transport and Communications. — In 1955 Tunisia had 14,714 km. of roads and tracks. including 7,210 km. motor roads. On Dec. 31, 1954, there were 52,275 registered motor vehicles, including 30.854 cars, 13,553 lorries, 696 buses and 7,172 motor cycles. State railways in 1954 amounted to 1.529 km.. including 483 km. of standard gauge (1.44 m.). The latter. in the north, are a section of the Algerian railways. In the centre and the south the lines have a gauge of 1 m. The privately owned Sfax-Gafsa system (455 km.) had the same narrow gauge.

The major ports are: Tunis (with Goletta as its foreport). Sfax, Susa and Bizerta (also an important naval base). In 1951–56 the annual average of goods unloaded in all ports amounted to 974,200 metric tons (incl. 722,000 tons in Tunis-Goletta) and of goods loaded to 3,585,000 tons (incl. 1,417,000 in Tunis-Goletta).

The Tunis airport is an important link between Europe, Africa and the east. In 1954 2,022 aircraft landed there (incl. 356 foreign) with 54,556 passengers, 875 tons of freight and 187.1 tons of mail.

By Dec. 31, 1954 there were 92,987 licensed wireless receiving sets.

BIBLIOGRAPHY.—Maps on the scales of 1:500,000, of 1:200,000, of 1:100,000 and of 1:50,000 are issued by the Institut géographique national (Paris); there are also geological maps on the same scales. *See* J. Despois, *L'Afrique du Nord* (Paris, 1949), with bibliography; the collection *Initiation à la Tunisie* (Paris, 1950), with bibliography; the volume *Tunisie* in the *Encyclopédie coloniale*, 2nd ed. (Paris, 1947); *Annuaire Statistique de la Tunisie*, annual (Tunis, 1946 *et seq.*).

(J.-J. Ds.; X.)

TUNNEL.

A tunnel is a subterranean passageway, horizontal or nearly horizontal in direction, excavated without removing the overlying rock and soil, and, as constructed by man, is of a symmetrical geometric form or roughly so. Tunnels are used for many purposes; in mining for removing of valuable mineral deposits; in transportation for the passage of canals, railroads, automobiles and all types of vehicles, as well as pedestrians; in urban development for sewers, water mains and various means of communication. Underground passageways formed by natural forces are very common and are frequently called tunnels if horizontal or nearly so, but may be more precisely termed caves. The process by which they are formed is called cavitation; the most common type is the removal of soluble minerals by water percolating through the underground or flowing in subsurface streams. In Asia Minor one of the rivers on the route of the Mersina railway extension passes through a hill by means of such a natural tunnel. The Mammoth cave of Kentucky, the caverns at Carlsbad, N.M., and the Peak caves of Derbyshire have been formed by such cavitation.

There are numerous terms closely associated with tunnels and sometimes used interchangeably. A partially completed tunnel is called a heading, and in mining operations small passageways are termed galleries, drifts or adits. If the passage leading underground is vertical, it is called a shaft; if inclined, it is called a slope or inclined shaft; if the shaft or slope is started at the surface, the operations are known as sinking; and if worked upward from a previously constructed heading or gallery, the opening is called a rising or stope. Fig. 1, an old engraving by Georg Agricola from mining operations early in the 17th century, illustrates several of these terms common in mining operations, and also indicates some of the hand methods by which early mining was done.

Tunnelling is the term used to designate the act or method of constructing a tunnel; it refers to the construction of such a subsurface passageway without the removal of the overlying cover of rock or earth. In the construction of modern subways and in many

FIG. 1.—EARLY MINING METHODS IN "DE RE METALLICA" (1566) BY GEORG AGRICOLA
A. Shaft. B, C, *D. Drifts. E. Tunnel. F. Tunnel mouth*

other types of subsurface utilities, it has become common practice to build the subsurface structures or tubes in an open cut and subsequently replace the excavated earth as backfill, re-establishing the original surface of the ground. When this "cut-and-cover" method of construction is used, it is subsequently difficult to differentiate clearly between the finished subsurface structures or passageways and a true tunnel. For the purpose of definition it may be desirable to refer to such construction as a subway, a conduit, aqueduct, water main or sewer, with particular reference to the purpose for which the particular subsurface structure is to be used.

HISTORICAL DEVELOPMENT

Prehistoric Tunnels. — Unquestionably the first tunnels built by man were during prehistoric times. It would be only natural that the earliest cave man must have at some time enlarged his abode or connected nearby caves by tunnels in the strictest sense of the word. How extensive such improvements for access, safety and convenience of the cave dwellers were is only a matter of speculation, but that such things were done is a logical certainty. Up to the era of recorded history there are also many examples of tunnelling for dwellings and tombs, water supply, drainage and other utilitarian objectives.

Ancient Tunnels. — One writer lists the earliest tunnel of recorded history as that built by a Babylonian king about 2180–60 B.C. This tunnel passed under the Euphrates river to provide a passage connecting the royal palace with the Temple of Jupiter on the opposite bank. Another very early tunnel was credited by legend to King Hezekiah of Judah and was constructed in the 8th century B.C. for the purpose of providing water to the city of Jerusalem during anticipated sieges. An early Greek tunnel was built on the Island of Samos in 687 B.C., also for the purpose of providing water supply. This tunnel was reopened in 1882 and found to be in a remarkable state of preservation.

The tomb of Mineptah, at Thebes, was driven at a slope for a distance of 350 ft. into the hill, when a shaft was sunk and the tunnel projected a farther length of about 300 ft., and enlarged into a chamber for the sarcophagus. Tunnelling on a large scale was also carried on at the rock temples of Nubia and of India and to some extent by the Aztecs in America.

Sir William Flinders Petrie traced the method of underground quarrying followed by the Egyptians opposite the pyramids. Parallel galleries about 20 ft. square were driven into the rock and cross galleries cut, so that a hall 300–400 ft. wide was formed. with a roof supported by rows of pillars 20 ft. apart. Blocks of stone mere removed by the workmen cutting grooves all round them, and. where the stone was not required for use, but merely had to be removed to form a gallery, the grooves were wide enough for a man to stand erect. Where granite, diorite and other hard stone had to be cut the work was done by tube drills and by saws supplied with corundum, or other hard gritty material. and water—the drills leaving a core of rock exactly like that of the modern diamond drill.

As instances of ancient tunnels through soft ground and requiring masonry arching, reference may be made to the vaulted drain under the southeast palace of Nimrod and to the brick arched tunnel 12 ft. high and 1j ft. wide, under the Euphrates, previously mentioned. In Algeria, Switzerland and wherever the Romans went, remains of tunnels for roads, drains and water supply are found. Pliny refers to the tunnel constructed for the drainage of Lake Fucino as the greatest public work of the time. It was then by far the longest tunnel in the world, being more than 3.j mi. long. It was driven under Monte Salviano, which necessitated shafts no less than 400 ft. in depth. Forty shafts and a number of cuniculi or inclined galleries were sunk and the excavated material was drawn up in copper pails of about 10 gal. capacity by windlasses. The tunnel was designed to be 10 ft. high by 6 ft. wide, but its actual cross section varied. It is stated that 30,000 labourers were occupied for 11 years in its construction. With modern appliances and a small percentage of men such a tunnel could be driven from the two ends without intermediate shafts in far less time.

Following the fall of the Roman empire and for about ten centuries thereafter there was a complete cessation of tunnel-building activities. Immediately following this period the first record of renewed activity in tunnel building includes the dungeons and passages which were unearthed in the subsequent construction of the Moscow subway and of which there was only legendary record. These tunnels are believed to have been built by Ivan "the Terrible" about 1565 and were found to constitute a fantastic underground city, which might be compared with the catacombs of Rome. Other tunnels of this period include the irrigation tunnels built by the Moors during their occupation of Spain. However, as a matter of well-documented record, the first substantial project of tunnelling after the middle ages was started in 1450 in the Maritime Alps to provide a road between Nice and Genoa. This attempt was abandoned for several centuries but was resumed in 1794 and carried on to a length of about 8,200 ft., when it was again abandoned and never completed. It was subsequently replaced by a surface highway built by Napoleon Bonaparte through the Col di Tende pass.

Up to this time more extensive tunnelling projects had been handicapped by the crude hand methods of excavation in rock and by the failure to develop adequate means of bracing and support in tunnels in earth. Further difficulties were encountered in ventilation of the tunnels and in the drainage of the large quantities of ground water frequently encountered. No practical advance was made in tunnelling methods of the Romans until gunpowder came into use. Old engravings of mining operations early in the 17th century show that excavation was still accomplished by pickaxes or hammer and chisel, and that wood fires were lighted at the ends of the headings to split and soften the rock in advance. (See fig. 1.) Crude methods of ventilation by shaking cloths in the headings and by placing inclined boards at the top of the shafts are also on record. Gunpowder was first used for subsurface excavation in connection with mining operations sometime about 1600, the exact date not being recorded. Explosives were first used in 1679 in the construction of the Languedoc canal in France. That canal was 510 ft. long, 22 ft. wide and 29 ft. high, and was driven through soft limestone.

TUNNELS FOR TRANSPORTATION

Canals. — Tunnels for the diversion of streams or canals are of early date. South of Seleucia, in Turkey in Asia, a river flows through a tunnel 20 ft. wide and 23 ft. high. excavated in the 4th century A.D., through rock so hard that the chisel marks are still discernible. In 1766 a tunnel 9 ft. wide, 12 ft. high and 1.63 mi. long was begun on the Grand Trunk canal, Eng., and completed 11 years later. This was followed by many others. The Languedoc canal ushered in an era of tunnelling in connection with canal building which continued until canals were gradually replaced by railroads, early in the 19th century. Inasmuch as canals require a level grade, tunnels became a contingent necessity wherever hills or mountains were encountered. Canal building in Europe centred in England and France and was carried to America where several early tunnels mere built in eastern Pennsylvania. The first tunnel of any kind built in the United States was a canal tunnel known as the Auburn tunnel in Schuylkill county, Pa. It was begun in 1818 and opened in 1821 and was 20 ft. high, 18 ft. wide and about 450 ft. long. It was subsequently converted into an open-cut waterway. Thereafter the oldest existing tunnel in the United States was to be found on the route of an old Pennsylvania canal near Lebanon, Pa. This tunnel mas completed in 1828.

Canal building was a rather temporary phase of transportation, as history goes, as it was barely under way in the early 19th century when railroads took the spotlight and soon replaced canals as a transportation facility. As a result, except for a few early tunnels of historic importance, there are few notable tunnels as a result of an obvious association with canal transportation. An exception to this statement was the tunnel built in connection with the Rove canal; the latter; largest of its kind. was completed in 1927, connecting the port of Marseilles. Fr.. by canal with the Rhône river. It is 72 ft. wide (width of water 60 ft.) and jo ft. high inside and 4.53 mi. long. The cross-sectional area is about six times that of the average double-track railway tunnel. Its construction occupied 1j years. and its cost was about 135,000,000 fr., paid by the French government, the chamber of commerce and the city of Marseilles. The entire cost was to be returned by tolls. The quantity of material excavated was greater than any other tunnel in Europe, about 2,250,000 cu.yd., or 25% more than the Simplon tunnel. It is lined with masonry, has a tow path 6 ft. wide on each side in the form of a series of small arches and has a large masonry portal at each end. This tunnel is 1.7 mi. longer than a similar canal tunnel between the Marne and the Rhine.

Railway Tunnels.––What is said to be the first railway tunnel in the world was started in 1826 near St. Étienne in France, known as the Terrenoire (Black Earth) tunnel. It was built on a horse railroad in operation prior to the advent of steam locomotives. Another very early railway tunnel was the Allegheny portage railroad tunnel in the U.S., built between 1831 and 1833. It was 20 ft. wide, 19 ft. high and 900 ft. long, and was built to serve as a portage through a spur of the Allegheny mountains about 4 mi. above Johnstown, Pa., on the Conemaugh river. Oddly enough, this first among American railway tunnels was later abandoned when railroads took over "through" transportation from the canal

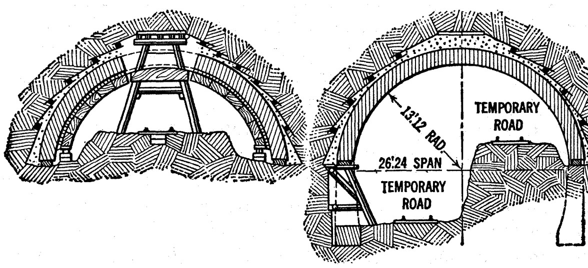

FIG. 2.—METHOD OF EXCAVATION OF ST. GOTTHARD TUNNEL

systems of that day and led to the abandonment of the Allegheny portage tunnel, which was nothing more than a link in one of the older routes of water-borne traffic.

Many of the most famous tunnels in the world were built in connection with the extension of railways of Europe through the Alps. In 1857 the first blast was fired in connection with the Mont Cenis work in the Alps; in 1861 machine drilling was introduced, and in 1871 the tunnel was opened for traffic. Located between Modane, Fr., and Bardonecchia, It., it is a single tunnel 7.98 mi. long, with a "horseshoe" section 26 ft. 3 in. by 24 ft. 7 in. The material penetrated was granitic and the average progress 7.7 linear feet per 24 hours. The approximate cost mas £7 j for each linear foot. With the exception of about goo linear feet the tunnel is lined throughout with brick or stone. During the first four years, by hand labour, the average progress was not more than 9 in. per day on each side of the Alps, but with compressed air drills progress at the end was five times greater.

In 1872 the St. Gotthard tunnel was begun, and in 1881 the first locomotive ran through it. Lying between Goschenen and Airolo, Switz., it is 9.3 mi. long and of the same dimensions as the Mont Cenis. The material also was granitic.

Mechanical drills were used from the beginning. Tunnelling was carried on by driving in advance a top heading about 8 ft. square, then enlarging this sideways and finally sinking the excavation to invert level. (See details in fig. 2.) Air for working the rock drills was compressed to seven atmospheres by water turbines of about 2,000 horsepower. The two inclines leading to the summit, which total about 36 mi., are 28% tunnel, which required seven spirals forming almost complete loops within the mountains in order to gain altitude and distance.

Driving of the Arlberg tunnel was begun in 1880, and the work was completed in little more than three years. It is a single tunnel. 25 ft. 3 in. wide and 6.36 mi. long. between Innsbruck and Bludenz, in the Tirol. The average progress in 24 hours mas 27.2 linear feet, and the approximate cost was F36 per linear foot. The main heading was driven along the bottom of the tunnel and shafts were opened to the upper heading 75 to 210 ft. apart, from which smaller headings were driven right and left. The tunnel was enlarged to its full section at different points simultaneously in lengths of 24 ft., the excavation of each occupying about 30 days and the masonry 14 days. Ferroux percussion air drills and Brandt rotary hydraulic drills were used, the performance of the latter being especially satisfactory. After each blast a fine spray of water was injected, which assisted the ventilation materially. In the St. Gotthard tunnel the discharge of the air drills was relied on for ventilation. In the Arlberg tunnel more than 8,000 cu.ft. of air per minute was thrown in by ventilators. To keep pace with the miners, 900 tons of excavated material had to be removed and 350 tons of masonry introduced daily at each end of the tunnel, which necessitated the transit of 450 wagons. The cost per linear foot varied according to the thickness of masonry lining and the distance from the mouth of the tunnel. For the first 3,000 ft. from the entrance the prices per linear foot were £3 16s. for the lower heading; £2 11s. for the upper one; £10 3s. for the unlined tunnel; £15 for the tunnel with a thin lining of masonry; and £41 8s. with a lining 3 ft. thick at the arch, 4 ft. at the sides and 2 ft. 8 in. at the invert.

The Simplon tunnel, begun in 1898 and completed in 1905, lies between Brigue, Switz., and Iselle, It.; it has a length of 12.3 mi. and is more than 30% longer than the St. Gotthard. The greatest depth below the surface is 7,005 ft. A novel method was introduced by driving two parallel headings. 56 it. apart, connected at intervals of 660 ft. by oblique galleries, which greatly facilitated ventilation and resulted in increased economy and rapidity of construction, while also ensuring the health of the men. One of the headings was enlarged at once to 16 ft. 5 in. wide by 19 ft. 6 in. high, for a single track railroad, but the second was left to be enlarged and similarly used at a later date. This was undertaken in 1918, during World War I, and completed a few years later. Had one wide tunnel been made instead of two narrow ones, it would have been difficult to maintain its integrity. Even with the narrow cross section employed, the floor was forced up at points in the solid rock from the great weight above, and had to be secured by building heavy inverts of masonry. About 2.5 mi. from the portal at Iselle, the "Great Spring" of cold water was struck. It yielded 10,564 gal. per minute at 600 lb. pressure per square inch, and reduced the temperature to 55.4° F., the lowest point recorded. A spring of hot water was met on the Italian side which discharged into the tunnel 1,600 gal. per minute with a temperature of 113° F. The maximum flow of cold water was 17,081 gal. per minute, and of hot water 4,330 gal. per minute. These springs often necessitated a temporary abandonment of the work. Water power from the Rhône at the Swiss and from the Diveria at the Italian end provided the power for operating all plants during construction of most of the work. The material penetrated was gneiss, mica schist, limestone, and disintegrated mica schist. The average progress per 24 hours was 35 linear feet and the approximate cost £49 7s. per linear foot. Among the able engineers connected with this work must be mentioned Alfred Brandt, who developed the drills which were used with much success.

A group of tunnels—the Tauern, Barengraben, Wocheiner and Bosruck—was undertaken by the Austrian government in connection with new Alpine railroads to increase the commercial territory tributary to the seaport of Trieste, which at one time was greater than Hamburg.

The Lotschberg tunnel, in the Alps of Switzerland, between Kandersteg and Goppenstein, is 9 04 mi. long and the maximum grade is 0.38%. It is a double-track railway tunnel, and its construction was begun in Oct. 1906 and completed in Sept. 1911. It was originally planned to be 8.5 mi. in length and straight. It passed beneath the ancient glacial gorge now filled with detritus and occupied by the Kander river, but at a great depth, and it was supposed it would be in solid granite. After driving the heading for nearly 2 mi., it broke through into the gorge, which was filled with sand, boulders and water under great pressure. In the space of a few moments about 8,000 cu.yd. of the material was carried into the heading. Twenty-five men, the drills and all equipment were lost. It was bulkheaded off. the line bent to throw it farther into the mountains and beneath the gorge, and it was then successfully completed, the length being increased one-half mile. The tunnel is operated electrically, using 15,000 v., single phase, alternating current of 16 cycles.

The Connaught tunnel at Rogers pass on the Canadian Pacific railuay pierces the Selkirk range of the Canadian Rockies. It is 5 mi. long and replaces a surface line 540 ft. higher up. Its construction saves 5 mi. of distance and replaces 5 mi. of snowsheds in a distance of 13 mi. It is a double-track tunnel, operated electrically, and has a maximum grade of 2.2%. It was built between 1913 and 1916 and was the first American tunnel in which a parallel pioneer tunnel was used. Progress on the pioneer heading reached as high as 817 ft. in 30 days

Much important tunnel construction has been done in Japan by the Japanese government railways. Probably the most notable is the Tanna tunnel between Atami and Mishima which was started in 1918 and not completed until 1934. Extraordinary difficulties were encountered, including great quantities of water under high pressure of 275 lb. per square inch, unstable soil and rock which collapsed, crushing heavy timbering, and, in fact, practically all of the difficulties that had been encountered on previous tunnels. Every method for combating these difficulties known to modern tunnel builders was employed, including cement grouting, compressed air, tunnel. shields, parallel drainage tunnels and the heaviest concrete lining ever employed, amounting to a maximum of $6\frac{1}{4}$ ft. in thickness at the top of the arch. The determination of the builders finally prevailed and the tunnel was completed after 16 years of unparalleled effort, but only after a cost of 70 lives and expenditures far in excess of anything anticipated.

The Moffat tunnel. on the Denver and Salt Lake railroad, replaced a surface line with 4% grades, crossing the continental divide about 50 mi. W. of Denver, Colo. At the time of construction it was the longest railroad tunnel in America. It lies at an elevation of 9,200 ft. above sea level, as compared with 11.660 ft. on the surface line at the summit of the divide. The work was begun in 1923, and the first train was run through in Feb. 1928. The work consists of two parallel tunnels, 75 ft. apart, one for a single-track railroad, 16 ft. by 24 ft., and one for a water tunnel, 8 ft. by 8 ft.. which may be used for the water supply of Denver. The work was done by the Moffat Tunnel commission, and paid for by a bond issue by a district of the state in the vicinity and Denver. The railroad tunnel is leased to the Denver and Salt Lake railroad. Its length is 6.1 mi., and the cost including the water tunnel was about $15,470,000. The grades of the railroad tunnel rise from the ends toward the centre, on rates of 0.3% from the east and 0.9% from the west. The construction of both tunnels at one time was taken advantage of to use the water tunnel as a pioneer heading with cross connections to the main railroad tunnel at intervals of about 1,500 ft., as was done in the Simplon tunnel and the Connaught tunnel. which offered advantages in speed and ventilation. Chloride of lime dumped in one of the lakes, 1,400 ft. above, was found in the tunnel water two hours later.

The Cascade tunnel of the Great Northern railway, between Berne and Scenic, in the state of Washington, is almost 8 mi. long (see fig. 3.) — fifth longest railway tunnel in the world and the longest railway tunnel in America in the 1950s. The alignment is straight and the grade 1.565% downward to the nest from Berne. Work mas started in Dec. 1925. The tunnel was driven from the two portals and a shaft, 622 ft. deep, 2.41 mi. from the east end, by the centre heading method, to allow radial drilling. A pioneer

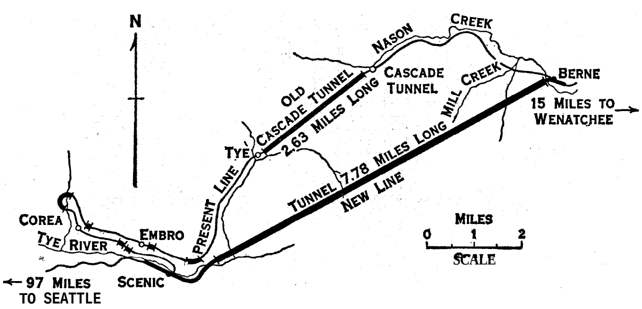

FIG. 3.— MAPSHOWING NEW AND OLD TUNNEL IN THE CASCADE MOUNTAINS, STATE OF WASHINGTON, U.S.

tunnel, 66 ft. to one side and parallel with the main tunnel, was also driven, from which cross drifts were driven at 1,500 ft. intervals. This provided a number of points of attack and ensured proper ventilation and drainage. The pioneer heading has a width and height of 10 ft. and was advanced 984 ft. in one month. The pioneer heading was holed through in May 1928 and the main tunnel was completed during the same year and put in operation Jan. 12. 1929. The power used in construction was 2,300 v., 60-cycle, 3-phase current. The total compressor capacity was 10,450 cu.ft. of free air per minute. Haulage in the headings was by 6-ton, 250-v. trolley locomotives, and for the full section 20-ton locomotives. The locomotives were equipped with gathering reels, which allowed their working 500 ft. beyond the suspended trolley. The line speed of the skip hoists at the shaft was 900 ft. per minute. A total force of about 1.800 men was employed, and because of the site's distance from any settlement, complete camps with cottages, schools, recreation halls, stores and shops were provided, equipped with water supply, electric lights, sewers and modern plumbing.

Notable English railway tunnels of early date include those under the Thames, the Severn and the hfersey rivers. In 1825 Marc I. Brunel began and in 1843 completed, after several suspensions of operations, the Thames tunnel between Rotherhithe and Wapping. It mas constructed for a highway. but was never used for that purpose. It was sold in 1866 to the East London railway, which operated its trains through it. This early tunnel, built of brick in the form of two arches with frequent openings between them, has a length of 1.200 ft. and required an excavation opening 27 ft. in width, which is still one of the widest ever built under such conditions. Brunel employed a peculiar form of shield, made of timber. in several independent sections. Part of the ground penetrated was almost liquid mud, and the cost of the tunnel was about £433 per linear foot.

The Severn tunnel. 4.33 mi. in length for a double line of railway, was begun in 1873 and finished in 1886. At the lowest part the depth of water was 59 ft. at low water and 104 ft. at high water, and the thickness of sandstone over the brickwork was 45 ft. Under a depression in the bed of the river on the English side there is a cover of only 30 ft. of marl. Much water was met throughout. In 1879 the works were flooded for months by a land spring on the Welsh side of the river and on another occasion from a hole in the river bed at the Salmon pool. This hole was filled with clay and the work completed beneath. The total amount of water raised at all the pumping stations was about 27,000,000 gal. in 24 hours.

The length of the railway tunnel under the Mersey between Liverpool and Birkenhead is 1 mi. between the pumping shafts on each side of the river. From each a drainage heading was driven through the sandstone with a rising gradient toward the centre of the river. This heading was partly bored out by a Beaumont machine to a diameter of 7 ft. 4 in. and at a rate attaining occasionally 195 ft. per week. All of the tunnel excavation, amounting to 320,000 cu.yd., was done by hand labour because heavy blasting would have shaken the rock. The minimum cover is 30 ft. betneen the top of the arch and the bed of the river. Pumping machinery is provided for 27,000,000 gal. per day, which is more than double the usual quantity of water. The firm of Brunlees and Fox was the engineers and the firm of Waddell the contractors. The work took six years and was completed in 1886.

The earliest of what was to become a maze of tunnels in and around New York city was built in 1837 as part of the New York and Harlem railroad. The actual tunnel was only about three blocks long at 91st street and can no longer be distinguished from New York's Park avenue tunnel, which was mostly open-cut but was later covered through the metropolitan area. Another historic American tunnel is the Hoosac tunnel, built in connection with the proposed construction of a canal from Boston to the Hudson river and later developed as a railroad. This tunnel, on the line of the Fitchburg railroad, was the first prominent tunnel in America and for many years the longest (4.73 mi.). It was begun in 1855 and finished in 1876 after many interruptions. It was memorable for the original use in America of compressed air drills and nitroglycerin, mechanical drilling being adopted in 1866.

Perhaps the most famous American railway tunnels of all are the Hudson river tunnels, the earliest of which uere constructed for'railways coming into New York city. The first of the Hudson river tunnels was started by D. C. Haskin and ran from Hoboken, N.J., to Morton St., New York city. This tunnel mas to be of two tubes, each 16 ft. wide by 18 ft. high. In June 1880 the northerly tube had reached 360 ft. from the Hoboken shaft. The compressed air blew a hole through the soft silt of the roof at this spot, and the water entered, drowning 20 men. With British capital and largely under the direction of British engineers, Sir Benjamin Baker and E. W. Moir, the northerly tunnel was extended 2,000 ft. to about three-fourths of the way across, but in 1891 the tunnel was allowed to fill with water and it so remained for ten years. Both tubes were completed in 1908, under the direction of Charles M. Jzcobs, engineer. In the meantime two others were started crossing under the Hudson from beneath the Pennsylvania railroad station in Jersey City to Cortlandt St., New York, and connecting tubes on the New Jersey side paralleling the Hudson river. These tunnels, forming parts of the Hudson and Manhattan railroad system, were put in operation in 1910 under electric traction by third rail. In addition to these Hudson river tunnels, a number of other tunnels of marked importance have been built under the East and Hudson rivers at New York. They are divided into two groups, those built as part of the Pennsylvania-Long Island railroad system, and those forming parts of the rapid transit system built by the city of New York.

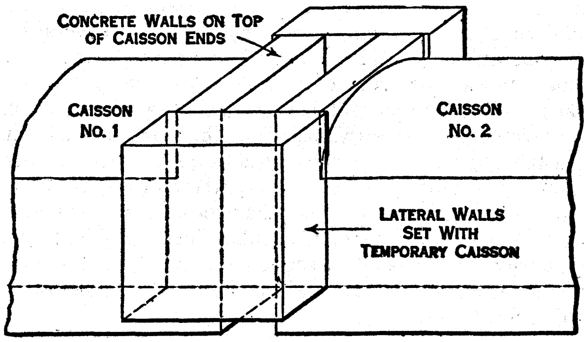

FIG. 4.— PERSPECTIVE SHOWING MANNER OF ENCLOSING SPACE BETWEEN TUNNEL CAISSONS FOR THE METROPOLITAIN UNDER THE SEINE AT PARIS

Railroads created the major demand for tunnels. It has been estimated that probably 4,000 or 5,000 railway tunnels had been built by mid-20th century, including some of the longest tunnels in the world, such as the Mont Cenis, St. Gotthard, Simplon and Lotschberg in the Alps, the Hoosac, Moffat and Cascade in the mountains of the United States. On mountain railways, tunnels often form a large percentage of the length; on one Mexican railway in a distance of 66 mi. there are 21 tunnels; on the Southern Pacific, 11 tunnels in 2j mi., including a spiral tunnel; and many other examples of this kind could be cited.

Subways and Rapid Transit. — With the growth of the modern city and the tremendous concentration of population, mass transportation became a great problem. While there are several forms of mass transportation, none has been more important in the large cities than the subways or rapid transit lines below the surface. This form of transportation is sometimes difficult to differentiate from railroad transportation, but the modern subway is so much a distinctive part of the modern city that it seems to deserve a special consideration. London was the first great city to recognize the advantages of subways, and its first underground line represented the beginning of the subway era. The first project of this nature for city traffic was authorized by parliament in 1856, and the first section of tunnel opened for traffic in Jan. 1863. It consisted of $3\frac{3}{4}$ mi. of 4-track railway in a tunnel of brick construction, 17 ft. high and $28\frac{1}{2}$ ft. wide. Many more such projects were to follow, and by 1939 the London underground network included about 96 mi. of tunnels for railways, mostly operated by electric traction. Most of those constructed after 1890, comprising about 50 mi. of double-tube railways, were tunnelled through clay by the use of cylindrical shields and have linings of cast-iron plates. The tubes are generally small, from 10 to 12 ft. in inner diameter, but shields about 23 ft. in diameter were used in constructing the stations on the Central London railway, and one 32 ft. 4 in. in diameter and only 9 ft. 3 in. long was used for a short distance on the Clapham extension of the City and South London railway. The first of the London tube railways to be built was 3.5 mi. of the City and South London, from the Bank under the Thames to Stockwell, built by J. H. Greathead and started in 1886. It was on this project that Greathead first combined the use of the shield and compressed air as a method of earth tunnelling, a combination almost universally used thereafter. When this first section went into operation in Dec. 1890, it added another first to its other distinctions, that of being the first electrically operated underground railway in the world.

The District subway of Glasgow, Scot., consists of a double-tube line in the form of a loop, connecting Partick and the northern districts with the centre of the city. It has a length of 6.5 mi. and consists in large part of circular tubes, 11 ft. internal diameter, built as tunnels, lined with cast iron and driven with a shield and compressed air. The line crosses twice beneath the Clyde. Work was begun in 1891 and the line opened to traffic in 1897.

Paris, Berlin and Moscow are other large European cities with extensive and well-known subway systems, many built as tunnels or subsurface cut-and-cover construction. Paris has an extensive system of underground railways, the Métropolitain, approximately 100 mi. in length in the 1950s, portions of which were built as tunnels and a considerable number of which were constructed under the engineering direction of F. Bienvenue. The first line was built in 1898, from Porte Maillot to Porte de Vincennes, and other lines followed at later dates. Instead of using completely cylindrical shields and cast-iron walls as in London, roof shields (*boucliers* de voute) were employed for the construction of the upper half of the tunnel and masonry walls were adopted throughout. In general, the upper half of the tunnel was executed first and the lower part completed by underpinning.

The tunnels of the Métropolitain of Paris under the two arms of the Seine, between Place du Chdtelet and Place St. Michel, tvere made by means of compressed-air caissons sunk beneath the river bed. They were built of plates of sheet steel and masonry, with temporary steel diaphragms in the ends, filled with concrete, making a cross wall with a level top about even with the outside top of the tunnel and about 2 ft. below the bottom of the Seine. The

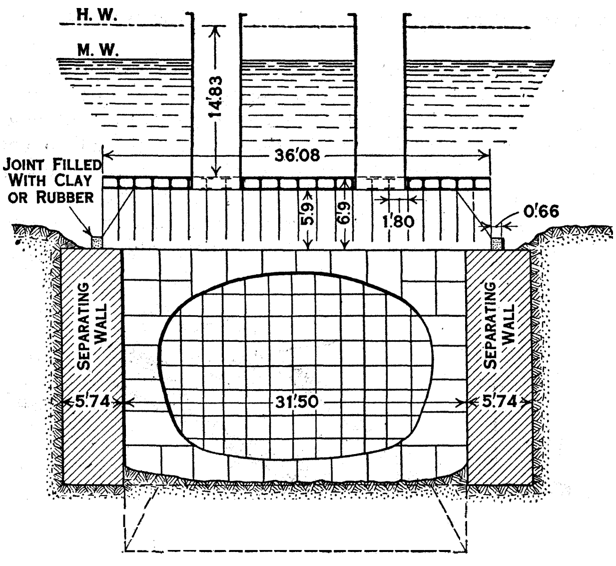

FIG. 5.— TRANSVERSE SECTION OF COFFERDAM SUPERIMPOSED OVER JOINTS BETWEEN CAISSONS IN TUNNELS FOR THE MÉTROPOLITAIN UNDER THE SEINE

caissons were sunk on the line of the tunnel so that adjacent ends and the walls just described were nearly 5 ft. apart (at that stage), with a core of earth between them. Side walls joining the end walls, and thus enclosing the earth core on four sides (fig. 4), were next made, by the aid of temporary small caissons sunk through about 26 ft. of earth under the river. The tops of the side walls were made even with the end walls. A steel rectangular cofferdam (figs. 5 and 6) was sunk to rest with rubber or clay joint on these surrounding walls. The cofferdam had shafts reaching above the surface of the water, so that the earth core was easily taken out in free air, after removing the water. The adjacent chambers under the caissons were then connected. Three caissons, of a total length of 396 ft., were used under the large arm and two, of an aggregate length of 132 ft., under the smaller arm of the Seine. Construction was started in 1905, and operation was begun in Jan. 1910.

New York, Boston, Philadelphia and Chicago are among large U.S. cities with subway systems. Boston was the first, starting in 1895 with the first section of its subway system, which consisted of 1½ mi. of mostly double-track and some four-track construction. Part of this was tunnel with roof shields, but large portions of it were cut-and-cover construction. It was opened to operation in 1898. New York is said to have the biggest subway network of any city in the world. The development of this great system began with an experiment, the old Beach tunnel of 1869 and 1870, although it was not until 1900 that the first contract was awarded for the construction of an actual underground line. There followed several decades in which New York city was the centre of the greatest tunnel building program that the world has ever seen. By 1937, there were 9 individual tunnels under the Hudson river and 1 under construction, 7 under the Harlem river, 26 under the East river and 2 under construction. These figures include not only rapid transit tunnels but also railroad, highway, large gas and water tunnels.

Next to New York, Philadelphia probably has the most extensive subway system in the United States. This was started with the Market street subway, a section of which began in 1903 and was completed in 1908. The Broad street subway followed, constructed over the period from 1915 to 1930. One of the unusual features of the Philadelphia subways is the extensive pedestrian passageways and concourses connecting the various subway stations and downtown office buildings, stores, hotels and banks, so that it is possible to traverse Philadelphia's underground city for six or seven blocks in any direction in the central business district.

Highways and Vehicular Tunnels. — The coming of the automobile brought on the most modern phase of land transportation and an unparalleled highway building program which in the latter 1950s was only mounting up to a peak. While highways do not have the limitations on grade which characterized canals and even railways, there have been many tunnels built in connection with road construction. However, it is one of the later phases of highway development, the superhighway, designed to handle large volumes of traffic at high speed. that again promised to make tunnel building a major consideration.

The earliest tunnel in recorded history, that built by a Babylonian king under the Euphrates river, would have to be classified as a highway tunnel, as it provided for the passage of chariots and pedestrians beneath the Euphrates river. Likewise, the first attempt at tunnelling the Alps was for a highway tunnel, a considerable length of which was built; and, even though it was never completed, it should also be considered in this classification. The earliest tunnel in London, started by M. I. Brunel in 1825, was intended for a highway, but was never used for such, being converted in 1866 to a railway tunnel.

In 1890–93 a shield-driven vehicular tunnel was constructed of sand and gravel across the Clyde in Glasgow, Scot. It consists of three parallel cast-iron tubes with an internal diameter of 16 ft., the centre one being a footway and the outer tubes for vehicles in each direction. The footway is reached by inclined ramps and stairs, but the vehicles are lowered and raised by elevators in shafts of 76 ft. inside and 80 ft. outside diameter. The distance between shafts is 700 ft. The cost was £287,000. The tunnel was not at first a financial success because of competition from a municipal ferry but its use, though interrupted, was later resumed.

The Blackwall tunnel, under the Thames about 6 mi. below London bridge, was built in 1892–97 through clay and 400 ft. of water-saturated gravel. The tunnel is about 3,116 ft. long, the external diameter 27 ft. and the internal diameter 24 ft. 3 in. The shield, 19 ft. 6 in. long, contained a bulkhead with movable shutters, as foreshadowed in Baker's proposed shield (fig. 8). There are a roadway 16 ft. wide for vehicles and two footwalks 3 ft. wide. The maximum grade is 2.78%.

The Rotherhithe tunnel, under the Thames about 2.25 mi. below London bridge, provides for a vehicular roadway 16 ft. wide and two footwalks 4 ft. 8 in. wide. It has a length of 4,863 ft. between portals, of which about 1,400 ft. are directly under the river. The exterior diameter of the tunnel is 30 ft. and the interior 27 ft. The maximum grade is 2.7%. It is constructed of cast-iron rings and concrete lining, and a shield and compressed air were used. It was begun in 1904 and finished in 1908. The top of the main

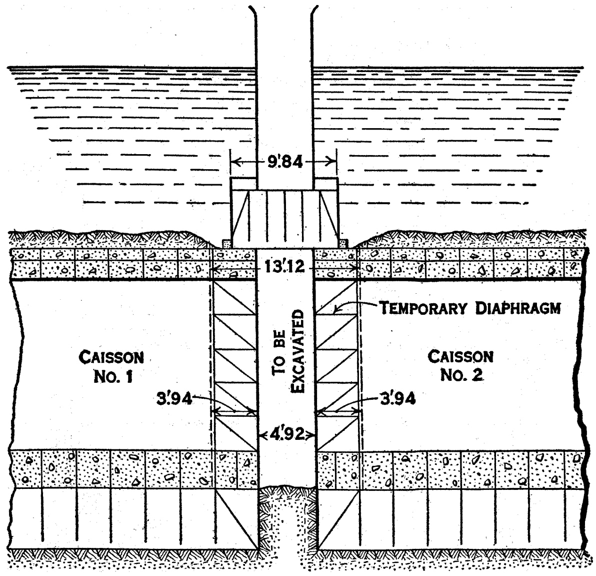

FIG. 6.—LONGITUDINAL SECTION OF COFFERDAM SHOWN IN FIG. 5

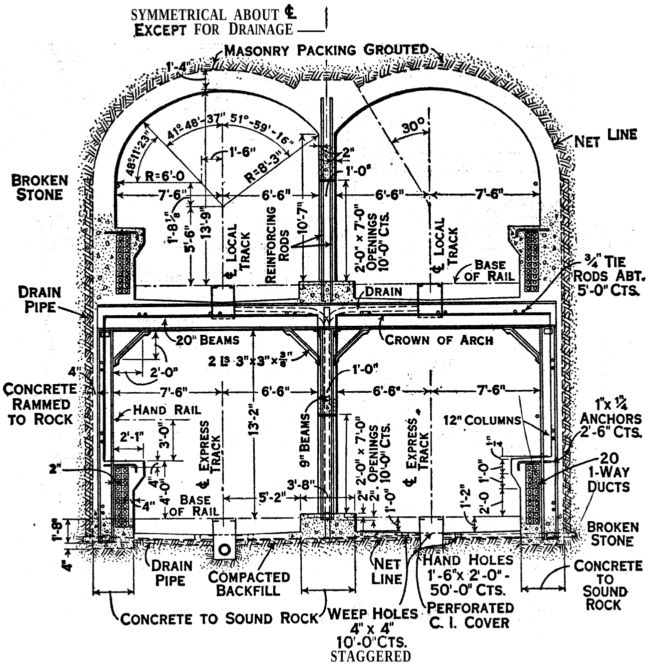
tunnel excavation in the middle of the river was only 7 ft. from the bed of the Thames, and a temporary blanket of filled earth, usual in similar cases, was prohibited because of the close proximity of the docks.

In 1914 a highway tunnel, started in 1907 and very similar to that at Glasgow, was completed in sand beneath the Elbe river at Hamburg, Ger. Access is here also obtained by elevators, in shafts 1,471 ft. between centres. The shafts are 72 ft. inside and 84 ft. outside diameter and each contains four elevators for vehicles and two for foot passengers. The lift is 78 ft. Each of the two tubes between shafts provides for a single roadway 6 ft. uide and two footwalks 4 ft. wide. The tubes are of cast iron, 19.7 ft. external diameter and the clear width inside is 14.8 ft. The lining is concrete faced with decorative tiles.

The notable Holland tunnels connect Canal street, New York city, with Twelfth street, Jersey City, passing beneath the Hudson river (see HOLLAND AND LINCOLN VEHICULAR TUNNELS). They comprise two tubes 1.61 mi. in length between the portals. Except for land approaches, they consist of circular cast-iron rings, 29 ft. in exterior diameter. They are solely for motor-propelled vehicular traffic, and each tube provides for two lines of traffic in one direction only, with a roadway width of 20 ft. The tubes beneath the river were driven with shields under compressed air. The maximum grade with traffic is 4%, and against traffic, 3.6%, both on the New York side of the river. The roadways are paved with granite blocks, and the clear headroom is 13 ft. 6 in. The interior walls are covered with glazed ceramic tile, and the tubes are brilliantly lighted by electricity. The entrance and exit portals are separated at each end by two city blocks, and large plazas are provided to prevent traffic congestion. Artificial ventilation is provided. The tunnels have fire fighting equipment, water lines, sand boxes, telephones, traffic signals, wrecking equipment, etc. A footwalk is provided for policing and inspection, but the tunnels are not open to pedestrians. Power for the equipment is obtained from two independent sources on each side of the river and three independent cables from each source of supply. Each cable has a capacity sufficient to carry the full load. It was estimated that the tunnels would have a traffic capacity of 1,900 vehicles per hour for each tube. About 52,000 vehicles have used the tunnels in a single day, without reaching their capacity. Construction began in 1920, and the tunnels were dedicated on Nov. 12, 1927. The cost of construction and real estate was about $48,000,000. Tolls are collected.

The Mersey river vehicular tunnel between Liverpool and Birkenhead, Eng., is the largest subaqueous tunnel in the world, having an outside diameter of 46 ft. 3 in. and inside diameter of 44 ft. The main roadway is formed at about the diameter line of the tunnel and provides for four lines of mechanically propelled traffic



BY COURTESY OF N.Y. CITY BOARD OF TRANSPORTATION

FIG. 7.— TYPICAL FOUR-TRACK TUNNEL IN ROCK

on a width of 36 ft. A narrow footwalk for patrol purposes is provided on each side. The whole of the upper part of the tunnel is exposed to view, there being no separate duct for the exhaust air, experiments having established this as unnecessary except near each exhaust shaft. Below the main roadway, in the portion of the tunnel under the river, there is space for a future roadway for two lines of traffic. The fresh air supply ducts are also located under the roadway. The bottom of the under-river tunnel at its deepest point is 170 ft. below high water. The distance between shafts on each side of the river is 1,735 yd., and the total length of main tunnel and branch tunnels is 2.62 mi. The branch tunnels have an inside diameter of 26 ft. 6 in., and only provide for two lines of traffic. They have a length of .6 mi. The gradient is 1 in 30. The capacity of the tunnel is 4,150 cars per hour, 100 ft. apart and moving at 20 m.p.h. At this speed the time required to pass through the tunnel is 6½ min. About 82,000 tons of cast iron were used in lining the tunnel, which was opened to traffic July 18, 1934. The total cost of construction, including land, but excluding interest charges during construction, was £6,919,000.

The vehicular tunnel beneath the Detroit river, from Detroit, Mich., to Windsor, Can., was started in 1928. It consists of one tube, 0.95 mi. long between portals, with an inside diameter of 28 ft. 4 in. The portion beneath the river, 2,500 ft. long, was built by the subaqueous trench method as in the case of the Michigan Central tunnel at Detroit and the second Harlem river tunnel at New York. The land portions, 1,000 ft. and 500 ft. in length, were shield-driven. The estimated cost was $10,000,000. Because of the international character of this tunnel, it was necessary not only to provide for collection of tolls but for customs and immigration inspection, which requires unusual plaza facilities at both ends of the tunnel.

The largest-diameter tunnel built by the subaqueous trench method is the Oakland-Alameda estuary tube, in California. It is a single tube, 0.67 mi. in length between portals, of which 2,436 ft. is made up of 12 sections of tubes, each 203 ft. long, sunk in a dredged trench, with a depth of water over the tubes of 42 ft. The tube sections present the novelty of being made of reinforced concrete, 37 ft. external diameter, with a shell thickness of 30 in., and they are enveloped with a membrane of three-ply waterproofing. They were cast in forms in a dry dock at San Francisco, then floated to position and sunk. The tunnel has a roadway for vehicles that is 23 ft. wide and also has footwalks that are protected by railings. The cost was estimated at $4,500,000 or about one-half the estimated cost if done by the shield method.

The Liberty, Pa., vehicular tunnels penetrate the south hills at Pittsburgh and, connect with the Liberty bridge over the Monongahela river. They consist of two parallel tunnels, 59 ft. between centres, each 26 ft. 7 in. wide, and 1.1 mi. long. Each tunnel provides a single line of street railway track not installed and two lines of vehicular traffic on a roadway 21 ft. wide. There is also a footwalk, 4 ft. wide, in each tunnel. The tunnels are lined with concrete 24 in. thick. The alignment is straight and the grade continuous at the rate of 0.392%. The work was begun in 1919 and completed about three years later. The total cost was about $6,000,000. For tunnels of their size, unusually rapid progress was made in excavating, largely because of a bonus system of paying the workmen. Eleven hours' pay was allowed for 9 ft. advance of excavation and 12 hours' for 10 ft., whether consumed or not. There was also sharp rivalry between the forces in the two tunnels, and the men completing their shift first were allowed to display an American flag at the entrance the following day, while their competitors were compelled to display a black flag. The average rate of advance per day in the tunnels was more than 10 ft. for a period of several months.

On superhighways, large volumes of high-speed traffic necessitate better alignment and flatter grade, approaching the requirements imposed by canals and railroads. The first section of the Pennsylvania turnpike made use of abandoned railroad tunnels through several ridges of the Allegheny mountains. The Goat Island tunnel linking the East bay and West bay crossing of the San Francisco bay bridge deserves special mention. This tunnel provides for a double-deck, two-lane highway and was 76 ft. high and 58 ft. wide in the rough, being 52 by 66 ft. inside its concrete lining. It has the largest cross section of any tunnel in the world, although its width is exceeded by the Rove canal tunnel. Another large highway tunnel of the western United States is the Waldo tunnel, 46½ ft. wide, 29 ft. high inside the concrete lining, and 4 mi. long, designed to provide for three northbound traffic lanes on route 101 in Marin county, Calif.

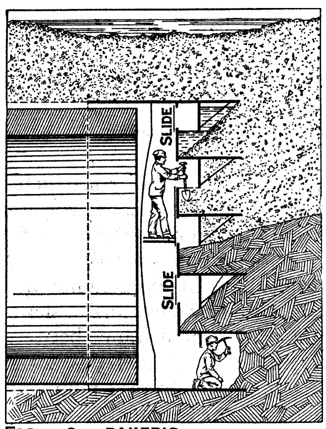


FIG. 8.—BAKER'S PNEUMATIC SHIELD

Aqueducts and Utilities.— Tunnels for conveying water are among the earliest tunnels of which there are any records. Reference has already been made to the tunnel built by King Hezekiah to supply water to the city of Jerusalem and to the water tunnel on the Island of Samos, both of which antedate the Christian era. Examples of the Roman aqueducts and drainage tunnels have also been previously noted; remains of Roman aqueducts are still scattered through Europe and Asia. In more modern times the use of tunnels for water supply and for disposal of municipal waste has become such an everyday occurrence that it is virtually impossible to compile anything like a complete record either as to the amount of tunnelling activity or the magnitude of the various projects. Many cities, both large and small, have become involved in such projects as a necessary part of supplying the public service required in any modern city. Many miles of tunnels have been built under the Great Lakes by Chicago, Detroit, Cleveland, Milwaukee and other cities. Gen-

erally speaking, these tunnels are to serve as raw water conduits from intakes well out in the lake. or they serve as outfall sewers for disposing of municipal waste far enough from shore to eliminate nuisance and health hazards. Many of these tunnels, particularly those in plastic clay, were built by ordinary mining methods in the early days, nith or without the use of compressed air. Later, shield-driven tunnels became the more common, but they too may involve a combination of both shield and compressed air.

Both the largest and longest aqueduct tunnels are those supplying water to the city of New York. They also present the novelty of sinking to great depths below the hydraulic grade line and rising again to that line to pass beneath river gorges, which are crossed at many points, and also to pass beneath the entire length of Manhattan Island. This introduces an internal or bursting pressure in the tunnel, which is called "a pressure tunnel."

The Croton aqueduct, from the Croton dam to the gatehouse at 135th street, constructed 1885–90, forms a tunnel 31 mi. long and includes an inverted siphon or pressure tunnel, passing beneath the Harlem river. A number of short sections were built in open excavation and then covered over.

The Catskill water-supply system, extending from the Catskill mountains to New York city, a distance of about 160 mi., consists in large part of tunnels which at the time of their construction were both the largest tunnels for such purpose and the longest tunnels for any purpose in the world. All are concrete lined. There are 25 tunnels on the hydraulic grade with a total length of 32 mi., including the tunnel beneath the Shanddken mountains, 18.1 mi. long, about 40 mi. S.W. of Albany, N.Y., built by the city of New York (1917–24). It has a horseshoe section 11 ft. 6 in. high by 10 ft. 3 in. wide and was then the longest continuous tunnel in the world for any purpose. Seven shafts were used in constructing this tunnel. There are also seven pressure tunnels crossing beneath river valleys. including that beneath the Hudson river from Storm King to Breakneck mountain, at a depth of 1,114 ft. below sea level. It is 14 ft. internal diameter and 3,022 ft. between the shafts on either side of the river. (See fig. 9.) The total length of the Catskill aqueduct pressure tunnels exclusive of the city aqueduct tunnels is 17 mi., and they are from 14 ft. to 17 ft. 6 in. in diameter. The city aqueduct tunnel extends from Hillview reservoir, beneath the Harlem river and nearly the entire length of Manhattan Island and the East river, to shafts in Brooklyn. a distance of 18 mi. To provide resistance to the bursting pressure of the water and also watertightness, it was placed in the rock from 200 to 750 ft. below the surface of the streets beneath which it was built. It was driven from 25 shafts: averaging 4,000 ft. apart. The work of constructing the Catskill aqueduct system, including the reservoirs, the City tunnel and the Shandaken tunnel, occupied from 1905 to 1926.

In 1920, a tunnel 4.j mi. long, 9 ft. wide and 9.5 ft. high was begun in the Alps of Switzerland to convey water to a hydroelectric plant. The Nevada irrigation tunnel is 4.1 mi. long and has a cross section 9 by 9 ft. It was completed in May 1928 at a cost of $1,500,000.

One of the most unique tunnel systems in the world developed in connection with public utilities are the little-known freight subways under the city of Chicago. These tunnels were first undertaken for communication tunnels to carry telephone and telegraph lines beneath the surface, but being too expensive for this purpose, were later taken over by the Illinois Tunnel company and devoted to the transportation of freight between the large buildings in the business district. Ultimately, the system included 62 mi. of such tunnels with a rolling stock of about 3,300 small cars and 150 electric locomotives. It is a little railroad empire all its own, busily shuttling its freight and express back and forth under the city.

Tunnel activities of the western United States include such projects as the Gunnison irrigation canal: the Boulder (Hoover) dam diversion tunnels. and the power development tunnels of southern California and other Pacific coast aqueducts, including the famous Hetch Hetchy water supply project for the city of San Francisco. The Gunnison tunnel, built between 1905 and 1910, is about 6 mi. long and is 11 ft. wide and 10 ft. high inside the concrete lining, and somewhat larger in unlined rock portions of the tunnel. The Boulder diversion tunnels were really unusual in dimensions and the quantities of rock excavation and concrete involved in their construction. There were four such diversion tunnels, 56 ft. in diameter and approximately $\frac{3}{4}$ mi. long, which is a cross section exceeded only by the Rove canal tunnel and the Goat Island tunnel. The Boulder dam conversion tunnels were built in 1931 and 1932. Another noteworthy tunnel project was the Ward tunnel built by the Southern California Edison company in connection with a gigantic water power project. It included six large dams, eight tunnels and five power plants, including the $13\frac{1}{2}$ mi. Ward tunnel, which was 15 ft. in diameter, built between 1920 and 1925.

Of the Pacific coast aqueducts, those built in connection with the Hetch Hetchy water supply project for the city of San Francisco are the most impressive. This project, started in 1914 and completed in 1934, involved several series of tunnels through coastal mountain ranges. One division, known as the Mountain division. contained 19 mi. of tunnel: the Foothills division, $15\frac{3}{4}$ mi.; and, the Coast Range division. $28\frac{1}{2}$ mi. including a 25-mi. tunnel which, when built, was the longest continuous tunnel in the world. These tunnels mere mostly in rock, approximately $13\frac{1}{2}$ by 14 ft. unlined. Another large project of the Pacific coast is the Colorado river aqueduct built by the city of Los Angeles, which includes a total of 392 mi. of aqueduct, of which 108 mi. is tunnel, with an additional 55 mi. of cut-and-cover construction.

DESIGN AND CONSTRUCTION

Tunnel building as it has developed over the centuries since the first tunnels of recorded history may be regarded as an art rather than a science. representing. as it does, a gradual accumulation of experience gained in actual construction. The first tunnelling was in rock or other materials which were largely self-supporting and presented few problems other than the excavation to provide room for passage or other uses to which the tunnel was put. However, as tunnel projects became more and more ambitious, tunnel builders became aware of definite limitations imposed by the character of the material which was being excavated and other environmental conditions that were encountered.

Tunnels in Rock.—Early tunnels were in rock or earth masses of sufficient resistance to permit open mining, which for many years was carried on by crude and slow hand methods. Tunnelling through great mountains brought out a number of problems that the earlier tunnel builders had scarcely realized. Even in rock, temporary bracing and permanent linings were sometimes required to resist the great pressures, and tremendous quantities of ground water at high temperatures were encountered at great depths under the mountains. In the longer tunnels, ventilation became a serious problem. both during construction and the later operation of the tunnels. Gradually it was realized that even the most rigid materials would tend to flow like a plastic solid, provided the pressures exerted were sufficiently high. Even at mid-20th century there was much remaining to be done in the solution of the problem of stresses around such rock cavities, and the fundamental principles involved have not been well established.

There are two general approaches to the problems of the stresses around a tunnel, either in rock or in the less resistant earth masses. The first approach, which may be considered more highly theoretical, is based on the classical theory of elasticity and treats the earth or rock mass as an elastic medium in which it is assumed that the stresses are independent of the depth of overburden or weight above the tunnel. The second approach, which may be referred to as the rational method of design, considers that the weight of the overlying rock is a controlling consideration, and the equivalent vertical pressure acting on the horizontal projected area of the tunnel must be redistributed without exceeding the resistance of the mass surrounding the tunnel. Any pressure in excess of this limit must be carried by the lining. either temporary or permanent as the case may be. As in all problems of plastic flow, the rate of squeezing or displacement may be sufficiently slow as to permit a much lighter temporary lining than will be required to resist the pressure of the earth over much longer periods of time involved in the case of the permanent lining.

Tunnels in Earth.— The major difference which is immediately apparent in earth tunnelling is the relatively low resistance to the induced stresses and the almost universal necessity for continuous support placed concurrently aith the excavation operations. It is only in relatively shallow tunnels through the stiffest clays that unsupported tunnel openings may be made, even for short periods of time. The earliest methods of support included tunnel liner and bracing of timber. cast iron. steel or masonry, and permanent linings usually of brick, masonry or monolithic concrete. The introduction of shields and compressed air, used sometimes separately but usually in combination, made it possible for tunnelling to be successfully carried out even in the softest silts and clays. In cases of sand or gravel, or other permeable materials, ground water becomes a very serious problem, but here, too, shields and compressed air are effective means of protecting the tunnel excavation. In all tunnels, but particularly in earth tunnels, natural gases which may be encountered must be recognized as a contingent hazard. and there have been many examples of serious accidents from explosions or from lethal gases which may be encountered in the underground.

From the standpoint of design, earth tunnels present the same problems in principle, but the magnitude of the pressures dealt with may be much greater than those encountered in comparable rock tunnels. Both the theoretical and rational approaches referred to above are employed, and, while the modern science of soil mechanics has made considerable progress with these problems, much further development is needed. However, it should be emphasized that what is referred to by some writers on tunnels as "that most peculiar and dreaded phenomenon known to tunnel men as swelling ground" or squeezing rock, is not nearly as much of a mystery as may have been indicated in the past. This phenomenon is nothing more or less than the necessary result of a combination of pressures which are much too great to be redistributed by the materials involved. While the problems are difficult, they are not mysterious and uncontrollable as one might be led to believe.

Construction Methods.—In the history of tunnel-building (above) much has been said about construction methods. Some of the more important methods, with some examples not previously presented, are now summarized below.

Shields and Compressed Air.—In 1818 *M.* I. Brunel took out a patent for a tunnelling process which included a shield and mentioned cast iron as a surrounding wall. His shield foreshadowed the modern shield which is substituted for the ordinary timber work of the tunnel, holds up the surrounding earth during excavation, affords space within its shelter for building the permanent lining in telescope fashion, and is moved forward by pushing against the front ends. The advantages of cast-iron lining are that it has great strength in small space as soon as the segments are bolted together and its joints can be caulked watertight.

In 1830 Lord Cochrane, afterward the 10th earl of Dundonald, patented the use of compressed air for shaft sinking and tunnelling in water-bearing strata. Water under any pressure can be kept out of a subaqueous chamber or tunnel by introducing sufficient air of a greater pressure, and men can breathe and work therein—for a time—up to a pressure exceeding four atmospheres. To confine the compressed air, it is necessary to provide a substantial bulkhead across the workings. To pass men and materials through the bulkhead, there is a mechanical device (lock)—a large steel tube with doors at each end, both of which open inward toward the working chamber, and both of which can never be opened at one time because of the difference in air pressure between that in the working chamber and that back of the bulkhead. Valves are provided to admit compressed air to the lock from the working chamber, and also to exhaust it from the lock to back of the bulk. head, in order to manipulate the doors. Compressed air was first used in tunnel work by Hersent, at Antwerp, Belg., in 1879, in a small drift with cast-iron lining. In the same year compressed air was used for the first time in any important tunnel by D. C. Haskin in the famous first Hudson river tunnel from Hoboken, N.J., to Morton street, New York city.

The use of compressed air in the first Hudson tunnel and of annular shields and cast-iron lining in constructing the City and South London railway (1886–90) by Greathead became widely known and greatly influenced subaqueous and soft-ground tunnelling thereafter. The pair of tunnels for this 'railway from the Bank under the Thames to Stockwell, from 10 ft. 2 in. to 10 ft. 6 in. interior diameter, were constructed mostly in clay and without the use of compressed air, except for a comparatively short distance through water-bearing gravel. In this gravel a timber heading was made, through which the shield was pushed.

The St. Clair river tunnel from Sarnia, Ont., to Port Huron, Mich.. was built in 1889–90 through clay, and for a short distance through water-bearing gravel. It is 1.14 mi. in length and 21 ft. external diameter. This tunnel was the first one completed in America in which were used all the essential elements for successful subaqueous work; *i.e.,* a shield, compressed air and cast-iron rings.

In 1891 the tunnel of the Ravenswood Gas company in New Tork cıty was started beneath the East river and Blackwell's Island from betneen 70th and 71st streets in Manhattan to Ravenswood in Long Island City. It was expected to be a rock tunnel throughout, and the section was to be 8 ft. 6 in. high and 10 ft. 6 in. wide, to provide room for two gas mains, 3 ft. and 4 ft. respectively. Soft ground mas encountered, and great difficulty was found because of the depth and ·water pressure. Compressed air was adopted, the pressure at times reaching as high as 46 lb. per square inch. Eventually, it was necessary to line the soft ground sections with cast-iron rings of 10 ft. 2 in. internal diameter. The work was completed in 1894

The East Boston tunnel, built in 1901, was the first important example of a shield-built monolithic concrete arch; it extends from the Boston subway to East Boston. It is 1 4 mi. long, 3,400 ft. being under the harbor. One mile was excavated by tunnelling with roof shields about 29 ft. wide through clay containing pockets of sand and gravel. The shields reacted against iron bars set in the concrete and moved forward on the masonry side walls.

Subaqueous Trench *Tunnels*.—In the course of adjusting methods of tunnelling to meet the wide variety of conditions that have been encountered, there has arisen one type of construction which is not tunnelling in the strictest sense of the word, but the final result is so closely related to tunnelling that it seems desirable to include it in a general discussion of the subject. This may best be described as subdqueous trench tunnels.

In 1845, De la Haye, in England. doubtless having in mind the tedious and difficult work of the Thames tunnel, proposed to make tunnels under water by sinking large tubes on a previously prepared bed and connecting them together. Thereafter many inventors proposed similar schemes. In 1866 M. F. Belgrand sank twin-plate iron pipes. 3.28 ft. in diameter and 512 ft long, under the Seine at Paris for a sewer siphon. and there have since been numerous examples of sunk cast-iron subaqueous water pipes.

It is believed that the first tunnel of this class, large enough for men to move upright in. was by H A. Carson (in 1893–94), in the outer portion of Boston harbour. for the metropolitan sewer outlet. The tubes mere about 9 ft. exterior diameter, in sections each 52 ft. long and weighing about 210,000 lb., made of brick and concrete with a skin of wood and watertight bulkheads at each end. A trench was dredged in the harbour bed and saddles were accurately placed to support the tubes. The latter. made in cradles above the water alongside a wharf, were lowered and towed $\frac{1}{2}$ to $\frac{3}{4}$ mi. to their final positions. After sufficient water had been admitted. they were lowered to their saddles by travelling shears on temporary piles. The temporary joints betneen consecutive sections were made by rubber gaskets between flanges which were bolted together by divers. The later operations were backfilling the trench over the pipes and, in each section, pumping out the water. removing its bulkheads and making good the masonry between consecutive bulkheads, this masonry being inside the flanges. This work, about 1,500 ft. in length. was done without contractors. by labourers and foremen under the immediate control of the engineers, and was found perfectly sound.

The double-track railroad tunnel at Detroit, Mich.. made in 1906–09 for the Michigan Central railroad, is 1.5 mi. long, with a portion of 0.5 miles directly under the river. A trench was dredged nith a depth equal to the vertical dimension of the tunnel below the river bed and about 70 ft. below the river surface, and grillages were accurately placed in it to support the ends of thin steel tube forms, inside of which concrete was to be moulded and outside of which deposited. These tubes, each about 23 ft. in diameter and 262.5 ft. long, were in pairs (one tube for each track) and nere joined together at intervals of 12 ft. by thin steel diaphragms surrounding the tubes. The planking, to limit the concrete, nas secured to the outside edges of the diaphragms. The tubes were made tight, bulkheaded at their ends, floated into place, sunk by admitting water, set on the grillages, and the ends of successive pairs connected together by bolts through rubber gaskets and flanges.

The first subaqueous highway tunnel in the United States was that at Washington street, beneath the Chicago river in Chicago. It is not properly a tunnel, having been built in a cofferdam. It was constructed in 1866–69 with two roadways each 11 ft. wide and 13 ft. high, and a footway 10 ft. wide and 10 ft. high. It was twice rebuilt to provide a deeper waterway. the original depth being only 14 ft. After the great fire of 1871, it formed the only means of communication between the west side and the business district pending the reconstruction of the bridges. In 1869–71 a similar roadway tunnel was constructed at La Salle street and in 1889–94 one at Van Buren street, both beneath the Chicago river. These also required rebuilding at later dates to provide deeper waterways.

Tunnelling by *the* Freezing Method.—Tunnelling by freezing the water contained in the soil and then excavating through the frozen material in a manner similar to rock has often been proposed. The method has been used for sinking shafts with a fair degree of success in a number of cases. Siberian miners have for years taken advantage of low temperatures to penetrate saturated ground to reach mineral deposits. F. H. Poetsch applied the method in 1883 in sinking a shaft in Saxony for the Archibald mine.

While fairly successful as applied to shafts, the method has rarely been used for driving tunnels. and then not with entire success. In 1884–86 in Stockholm, Swed., a tunnel for pedestrians was driven in part by the freezing method. The length of the tunnel was 758 ft., and it passed beneath a ridge dividing two parts of the city. The cross section was 12 ft. 8 in. high and 13 ft. 2 in. wide, and the material was coarse gravel with large stones and some clay. It contained water and had very little cohesion. The material was frozen by using a dry air (Lightfoot) machine delivering 25,000 cu.ft. of air per hour. The temperature of the air at the machine was $-55°$ C.

VENTILATION OF TUNNELS

Ventilation of Steam Railway Tunnels.—The simplest method for ventilating a railway tunnel is to have numerous wide openings to daylight at frequent intervals. If these are the full width of the tunnel, at least 20 ft. in length, and not farther apart than about 500 ft., a tunnel can sometimes be naturally and adequately ventilated. Such arrangements are, however, seldom practicable, especially in long and deep tunnels, and then recourse must be had to mechanical means. Not only long tunnels, but often those relatively short, require artificial ventilation when on a steep gradient, as the smoke and gases have a tendency to travel up the grade with the locomotive, which is then working at full capacity. Natural ventilation depends for its action upon the difference of temperature within the tunnel or ventilation shaft, and the outer air. In winter the draught is upward and in summer often downward. In the spring and autumn there are often periods when there is little difference in temperature and, in consequence. little circulation of air. Most steam railway tunnels are poorly ventilated, except where the difference in elevation of the ends or the prevailing winds create a natural draught through them. The need for ventilation is far greater with steam locomotion than with electric motors.

The first application of mechanical or fan ventilation to railway tunnels was made in the Lime street tunnel at Liverpool, which has since been replaced by an open cutting. At a later date fans were applied to the Severn and Mersey railway tunnels.

Where possible, the principle ordinarily acted upon, where mechanical ventilation has been adopted, is to exhaust the vitiated air at a point midway between the portals of a tunnel, by means of a shaft with which is connected a ventilating fan of suitable power and dimensions. In the case of the tunnel under the Mersey river such kind of shaft could not be provided, because of the river's being overhead, but a ventilating heading was driven from the middle of the river (at ahich point entry into the tunnel was effected) to each shore. where a fan 40 ft. in diameter was placed. In this way the vitiated air is drawn from the lower point of the railway, while fresh air flows in at the stations on each side to replenish the partial vacuum.

The principle was that fresh air should enter at each station and "split" each way into the tunnel, and that thus the atmosphere on the platforms should be kept pure. In the Mersey tunnel there are five fans; two are 40 ft. in diameter by 12 ft. wide and two 30 ft. in diameter by 10 ft. wide, one of each size being erected at Liverpool and at Birkenhead respectively. In addition there is a high speed fan, 16 ft. in diameter, in Liverpool, which throws 300,000 cu.ft. per minute. The ventilation of this tunnel was satisfactory up to a train schedule of 300 trains per day, or one each way every five minutes. As the traffic increased the air

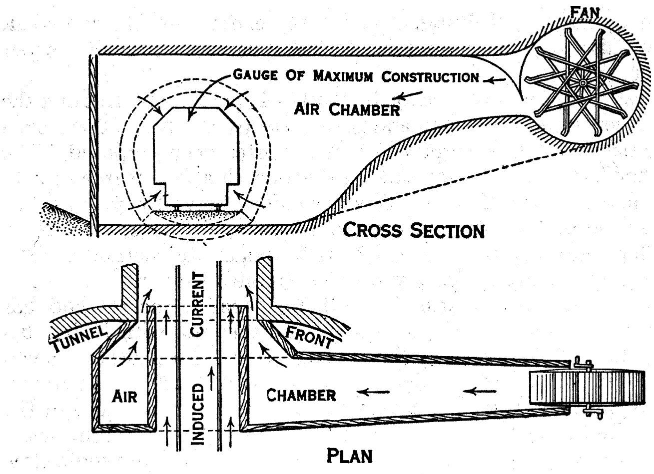

FIG. 10.— DIAGRAM ILLUSTRATING THE SACCARDO SYSTEM FOR VENTILATING TUNNELS

shaft became coated with soot several inches thick and arrangements were made to install electric power.

The central point of the Severn tunnel lies toward the Monmouthshire bank of the river and ventilation is effected from that point by means of one fan placed on the surface at Sudbrooke Monmouth, at the top of a shaft which is connected with a horizontal heading leading to the centre of the tunnel. This fan, which is 40 ft. in diameter by 12 ft. in width, removes from the tunnel some 400,000 cu.ft. per minute, and draws in an equivalent volume of fresh air from the two ends.

About 1896 an excellent system was introduced by Saccardo, an Italian engineer, which to a great extent minimized the difficulty of ventilating long tunnels under mountain ranges where shafts are not available. This system, which is not applicable to tunnels in which underground stations exist, is based upon the principie of the ejector, and is illustrated in fig. 10, which represents its application to the single-line tunnel through the Apennines at Pracchia. This tunnel is one of 52 single-line tunnels, with a gradient of 1 in 40, on the main line between Florence and Bologna. built by Thomas Brassey. There was a great deal of traffic which had to be worked by heavy locomotives. Before the installation of a ventilating system, under any condition of wind, the state of this tunnel, about 9,000 ft. in length, was bad; but when the wind was blowing in at the lower end at the same time that a heavy goods or passenger train was ascending the gradient the condition of affairs became very much worse. The engines, working with the regulators full open, often emitted large quantities of both smoke and steam, which travelled concurrently with the train. The goods trains had two engines, one in front and the other at the rear. and when, from the humidity in the tunnel due to the steam, the wheels slipped and possibly the train stopped, the state of the air was indescribable. A heavy train with two engines conveying a royal party and their suite, arrived on one occasion at the upper exit of the tunnel with both enginemen and both firemen insensible; when a heavy passenger train came to a stop in the tunnel, all the occupants were seriously affected.

In applying the Saccardo system, the tunnel was extended for 15 or 20 ft. by a structure either of timber or brickwork, the inside line of which represented the line of maximum obstruction of the tunnel, and this was allowed to project for about 3 ft. into the tunnel (fig. 10). The space between this line and the exterior constituted the chamber into which air was blown by means of a fan. Considering the length of tunnel, it might at first be thought there would be some tendency for the air to return through the open mouth, but nothing of the kind happened. The whole of the air blown by the fan, 164,000 cu.ft. per minute, was augmented by the induced current yielding 46,000 cu.ft. per minute, making a total of 210,000 cu.ft.; and this volume was blown down the gradient against the ascending train so as to free the driver and men in charge of the train from the products of combustion at the earliest possible moment. Prior to the installation of this system the drivers and firemen had to be clothed in thick woollen garments, pulled on over their ordinary clothes, and wrapped round and round the neck and over the head.

The Saccardo system was installed in 1899 at the St. Gotthard tunnel with most beneficial results. The ventilating plant is situated at Goschenen at the north end of the tunnel and consists of two large fans operated by water power. The quantity of air pressed into the narrow mouth of the tunnel is 413,000 cu.ft. per minute at a velocity of 686 ft., this velocity being much reduced as the full section of the tunnel is reached. After installation, a sample of the air taken from a carriage contained only 10.19 parts of carbonic acid gas per 10,000 volumes.

In the Simplon tunnel (12.3 mi. long), where electricity is the motive power, mechanical ventilation was installed at the time of construction at each end of the tunnel, both for construction purposes and to serve as permanent equipment. It is based on a different principle than the Saccardo system. A steel sliding door is arranged at each entrance to be raised and lowered by electric power. After the entrance of a train the door is lowered and fresh air forced into the tunnel from the same end at considerable pressure by fans. After completion of the second tunnel following World War I an additional ventilation plant was built at the north end of the tunnel.

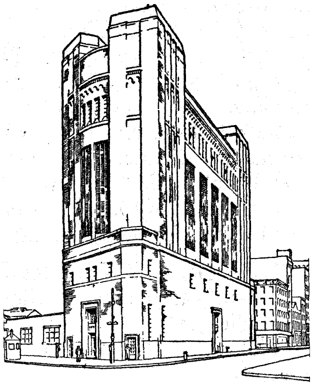
The Moffat tunnel in Colorado (6.1 mi. long) is ventilated by a mechanical plant based on the principle of forced or induced draught created at one end of the tunnel. A building was erected at the east portal which forms an extension of the tunnel and provides a fan chamber on each side. A vertical lift gate is provided to close the portal. Two fans are provided, which differ for experimental reasons. Each has a diameter of 9 ft. and a width of 6 ft. The motors are of 750 and 500 h.p. with capacities of 450,000 and 350,000 cu.ft. per minute, at velocities of 14 and 10 m.p.h., respectively. Only one fan is operated, the other held in reserve. The ventilation is by forced draught for eastbound trains and induced draught for westbound trains, which forces the smoke back along the train.

Other railway tunnels partially or completely ventilated by mechanical draft are the Giovi tunnel, in Italy; Hoosac tunnel, in Massachusetts; East Mahanoy tunnel, in Pennsylvania; Big Bend tunnel, in West Virginia; Elkhorn tunnel, in West Virginia; and the Gallitzen tunnel, in Pennsylvania.

Volume of Air Required for Ventilation of Steam Locomotive Tunnels.— The consumption of coal by a locomotive during the passage through a tunnel having been ascertained, and 29 cu.ft. of poisonous gas being allowed for each pound of coal consumed, the volume of fresh air required to maintain the atmosphere of the tunnel at a standard of purity of 20 parts of carbon dioxide in 10,000 parts of air is ascertained as follows: The number of pounds of fuel consumed per mile, multiplied by 29, multiplied by 500 and divided by the interval in minutes between the trains, will give the volume of air in cubic feet which must be introduced into the tunnel per minute.

Ventilation of Tunnels for Electric Traction.— The introduction of electric traction has simplified the problem of ventilating intra-urban railways laid in tunnels at a greater or less distance below the surface, since the absence of smoke and products of combustion from coal and coke renders necessary only such a quantity of fresh air as is required by the passengers and staff. For ventilation the shallow tunnels which form the underground portions of the Metropolitan and District railways in London, open staircases, blowholes and sections of uncovered track are relied on. When the lines were worked by steam locomotives they afforded notorious examples of bad ventilation, the proportion of carbonic acid gas amounting to from 15 or 20 to 60, 70 and even more parts in 10,000. Since the adoption of electricity as the motive power the atmosphere of the tunnels has very much improved. Samples taken from the cars in 1905 after the adoption of electricity gave as low as 11.27 parts in 10,000.

When deep level tube railways were first constructed in London, it was supposed that adequate ventilation would be obtained through the lift-shafts and staircases at the stations, with the aid of the piston action of the trains which: being of nearly the same cross section as the tunnel, would, it was supposed, drive the air in front of them out of the openings at the stations they were approaching, while drawing fresh air in behind them at the stations they had left. This expectation, however, was disappointed and it was found necessary to employ mechanical means. On the railway running from the Bank of England to Shepherd's Bush, a distance of 6 mi., the ventilating plant installed in 1902 consists of a 300 h.p. electrically driven fan, which is placed at Shepherd's Bush and draws in fresh air from the Bank end of the line and at other intermediate points. The fan is 5 ft. wide and 20 ft. in diameter, and makes 145 revolutions a minute, its capacity being 100,000 cu.ft. a minute. It is operated from 1 to 4 A.M. and, the openings at all the intermediate stations being closed, it draws fresh air in at the Bank station. The tunnel is thus cleared out each night, during the period when trains are not operated, and the air is left in the same condition as it is outside. The fan is also worked during the day from 11 A.M. to 5 P.M., the intermediate doors being open. In a number of the later tube railways in London—such as the Baker street and Waterloo, and the Charing Cross and Hampstead lines—electrically driven exhaust fans are provided at about half-mile intervals; these each extract 18,500 cu.ft. of air per minute from the tunnels and discharge it from the tops of the station roofs.



"COURTESY" N.Y. STATE BRIDGE AND TUNNEL COMMISSION

BUILDING FOR THE HOUSING OF THE MACHINERY BY WHICH FRESH AIR IS FORCED INTO THE HOLLAND TUNNEL AND USED AIR WITHDRAWN

The Boston system of electrically operated subways and tunnels is ventilated by electric fans capable of completely changing the air in each section about every 15 minutes. Air admitted at portals and stations is withdrawn midway between stations.

In the southerly 5 mi. of the first rapid transit subway at New York city, constructed between 1900 and 1904, which is a four-track structure of rectangular section, having the area of 650 sq.ft. and built as close as possible to the surface of the streets, ventilation by natural means through the open staircases at the stations was at first relied upon. The results were satisfactory as regards the proportions of carbonic acid gas found in the air, but when intensely hot weather prevailed the tunnel air was sometimes 5° hotter because of the conversion of electric energy into heat. Ventilation chambers were added on each side of the subway at points between stations, and the condition became much improved. These chambers are beneath the sidewalks and covered by gratings, and they have been incorporated in the construction of all subways built later. In addition. a partition wall separates trackways for trains running in opposite directions and the piston action of the trains induces a satisfactory circulation of the air.

Ventilation of Vehicular Tunnels.—The need of mechanical ventilation of vehicular tunnels is a development resulting from the advent of vehicles propelled by internal-combustion engines. The exhaust from such engines contains smoke and gases, which are irritating to the eyes and also contains a considerable percentage of carbon monoxide, a highly poisonous gas. The first studies of the need of ventilation for vehicular tunnels were undertaken in connection with the construction of the Holland tunnel, at New York, because of its length and the large volume of traffic which was expected to use it. At that time (1920) natural draught was relied upon for the ventilation of all such tunnels in operation, including the Blackwall and Rotherhithe tunnels in London. The traffic in them, however, was only about 100 motor vehicles per hour for each tunnel, compared with an estimated traffic of 1,900 motor vehicles per hour in each tube of the Holland tunnel. Research studies and exhaustive tests were made for this tunnel with the co-operation of the U.S. bureau of mines to determine first, the amount and composition of exhaust gases from motor vehicles; second, the physiological effects of these gases; and, third, the friction losses and power required to handle large quantities of air through concrete ducts.

In the Holland tunnel, the transverse system of ventilation was adopted. The fresh air is introduced continuously along each tube, from conduits provided for the purpose, and taken off at frequent intervals at opposite points. The air therefore travels a course transverse to that of the vehicles and there is a practically equal degree of purity at all points in the tubes. Because carbon monoxide is lighter than air and the exhaust motor gases are warmer than the fresh air introduced in the tunnel and therefore tend to rise, the fresh air ducts are placed beneath the roadways and the exhaust ducts above the roadway ceiling but all in the same tunnel tube. The fresh air is introduced in each roadway by continuous slots along each side above the floor, and the vitiated air is exhausted through louvers in the roof at 15 ft. intervals. The entire tunnel atmosphere is completely changed every $1\frac{1}{2}$ minutes or 40 times per hour, but so uniformly and gently that the current is hardly perceptible. This eliminates the fire hazard incident to a longitudinal circulation of draught. There are four ventilation shafts, one at each pierhead line and one about midway between the pierhead and portal on each side of the river. The fans are located in the shaft buildings and there are 84 in all, one-half blowers and one-half exhausters.

The Liberty tunnels were the first long vehicular tunnels in which artificial ventilation was used. The method adopted is the longitudinal draught system, based on Saccardo's, with modifications by C. S. Churchill. The flow of air in each tunnel is with the traffic. and is induced from a shaft near the centre of each tunnel. Each shaft is divided into two compartments, one of which is used to exhaust the air which enters at the portal from the first half of the tunnel, and the other to blow fresh air into the tunnel at the centre and force it forward to the exit portal. Suitably designed nozzles at the centre of the tunnels, at the shafts, prevent the mixing of the air being introduced and ejected. The flow of air is continuous in each tube in opposite directions and wind pipes are provided at the exit of each tube to prevent interference with the ventilation by adverse winds. The ventilating plant and fans are on the hilltop near the ceptre of the tunnels, at the shafts. The plant was designed to provide for a double line of motor cars in each tube, spaced 100 ft. apart, moving at 15 m.p.h. and a proportion of carbon monoxide at 6 parts in 10,000 at the point of exit, the average, therefore, being 3 parts in 10,000. This required the supplying of 280,000 cu.ft. of air per minute in each tube at a velocity of six miles per hour. (See also AQUEDUCTS; TRANSPORT; etc.)

TUNNY or BLUEFIN TUNA (*Thunnus thynnus*), the largest of the tunas. It grows to a large size, in some parts of the world reaching a length of more than 10 ft. and a weight of 1,500 lb. It is robust in form, has a short pectoral fin. is bluish above, gray spotted with silver below. It is world-wide in distribution and generally is found in more temperate waters than are the other tunas.

It is excellent as food and the object of important fisheries in the Mediterranean, in California and in Japan. Anglers, ranking this fish among the greatest trophies obtainable, pursue it in many parts of the world with rod and reel. Large specimens are often called horse mackerel. (*See* also TUNA.)

TUNSTAL (or TONSTALL), **CUTHBERT** (1474–1559), English prelate, natural son of Thomas Tunstal of Thurland castle, Lancashire, studied at Oxford, at Cambridge and at Padua. Having held several livings in succession, he became chancellor to William Warham, archbishop of Canterbury, in 1508 or 1509. He was employed on diplomatic business by Henry VIII and by Cardinal Wolsey, being sent to Brussels in 1515 and to Cologne in 1519, while he was at Worms during the famous Diet of 1521. In 1516 he had been made master of the rolls; and he became dean of Salisbury in 1521, bishop of London in 1522 and keeper of the privy seal in 1523. He represented Henry in the negotiations with Charles V after his victory at Pavia in 1525 and he helped to arrange the peace of Cambrai in 1529. In 1530 he succeeded Wolsey as bishop of Durham. Tunstal adhered firmly to the traditional teaching of the Church, but after some hesitation he accepted the royal supremacy and publicly defended this position. In 1537 the bishop was appointed president of the new Council of the North, but although he was often engaged in treating with the Scots he took part in other public business and attended parliament, where in 1539 he participated in the discussion on the bill of Six Articles. Although he disliked the religious policy pursued by the advisers of Edward VI and voted against the first Act of Uniformity in 1549, he continued to discharge his public duties without molestation until after the fall of the protector Somerset; then in 1550 he was put under house arrest; and in Dec. 1551 he was committed to the Tower of London. A bill to deprive him of his see was introduced, but the house of commons refused to pass it; and the earl of Warwick obtained his deposition by a special commission in Oct. 1552. On the accession of Mary in 1553 he was released and the next year he was reinstated as bishop of Durham. He assisted at the trial and deposition of John Hooper and other Protestant bishops. When Elizabeth I came to the throne he refused to take the oath of supremacy, and he would not help to consecrate Matthew Parker as archbishop of Canterbury. He was placed under arrest at Lambeth, where he died on Nov. 18, 1559.

See C. Sturge, *Cuthbert Tunstal* (London, 1938).

TUPIAN (TUPÍ, TUPÍ-GUARANÍ), a linguistic stock of South American Indians of the Macro-Tupi-Guarani phylum. Aboriginally, they occupied the lower Amazon, Tapajoz, Xingu and Tocantíns rivers and the Brazilian coast south to Uruguay. Far-flung prehistoric and postnhite migrations carried them to eastern Paraguay (the Guarani), the Bolivian Andes (the Chiriguano) and the middle and upper Amazon. After white settlement, Tupi became the *lingua geral* of much of Brazil, especially on the Amazon.

The Tupians were tropical rain forest farmers, rivermen and coastal navigators. By slash-and-burn cultivation they grew manioc, sweet potatoes, maize, beans, peanuts, cotton and dyes. They took turtles and turtle eggs and from large dugout canoes caught fish and river mammals with arrows and harpoons. They also used vegetable drugs for fishing. Wild game was secondary.

Tupian society consisted of an extended, usually patrilineal family occupying a single large thatched house, but some Tupians had patrilineal clans. On the lower Amazon and the coast, palisaded, multihouse villages of several thousand persons occurred. These villages warred incessantly, capturing, torturing and eating their victims. Religion was largely shamanistic with little village ceremonialism.

See Alfred Métraux and others, "The Coastal and Amazonian Tupi" in *The Tropical Forest Tribes*, 3.57–191, *Handbook of South American Indians* (Julian H. Steward, ed.), Bur. Amer. Ethnol. Bul. 143 (1948).

TUPOLEV, ANDREI NIKOLAEVICH (1888–), Russian army officer and aircraft designer, was born on Nov. 10, 1888, in Pustomazovo, Russia, and educated at the Moscow Higher Technical school, graduating in 1918. In that year, together with N. Zhukovski, he organized the Central Aerohydrodynamic institute (TsAGI), of which he was assistant director from 1918 to 1935 and head of its design bureau from 1922. Under his direction, over 100 types of passenger aircraft and medium- and long-range bomber aircraft were designed and built. Some of the better known of these are the tno-engine TB-1, three-engine ANT-9, four-engine TB-3, and ANT-25, which flew in 1937 from Moscow across the north pole to San Jacinto, Calif. Other planes designed later by Tupolev were the twin-engine attack bomber TU-2, four-engine bomber TU-4 (a copy of the U.S. B-29). tactical twin-jet bomber TU-10 (1948), six-turbojet-engine TU-75 (1950), TU-104 (1955), TU-104.4 (1957) and TU-114 (1957). Of these, the TU-104 and 104A twin-jet airliners (transport versions of TU-10) were widely used on commercial air routes. In 1938 Tupolev was arrested as an "enemy of the people" but five years later was freed and restored to favour. He was made a lieutenant general during World War II, received several Stalin prizes and was elected to the Academy of Sciences of the U.S.S.R. in 1953. In 1957 Lieut. Gen. Tupolev was awarded a Lenin prize for designing the TU-104.

(D. CR.)

TUPPER, SIR CHARLES, BART. (1821–1915), Canadian statesman, was born at Amherst, Nova Scotia, on July 2, 1821, and studied medicine at Edinburgh university, where he received the diplomas of M.D. and licentiate of the Royal College of Surgeons.

In 1855 he was returned to the Nova Scotia assembly for Cumberland county. Tupper was a member of the executive council and provincial secretary of Nova Scotia from 1857 to 1860 and from 1863 to 1867. He became prime minister of Nova Scotia in 1864, and held that office until the Union act came into force on July 1. 1867. Tupper was leader of the delegation from Nova Scotia to the Union conference at Charlottetonn in 1864, and to that of Quebec during the same year; and to the final colonial conference in London, which assembled to complete the terms of union, in 1866–67. He was sworn a member of the privy council of Canada. June 1870, and was president of that body from that date until July 1, 1872, when he was appointed minister of inland revenue. This office he held until Feb. 1873. when he became minister of customs under Sir John Macdonald, resigning with the ministry at the close of 1873. On Sir John's return to power in 1878, Tupper became minister of public works, and in the following year minister of railways and canals. Tupper was the author of the Public Schools act of Nova Scotia. and had been largely instrumental in molding the Dominion Confederation bill and other important measures. Sir Charles represented the county of Cumberland until 1884, when he was appointed high commissioner for Canada in London.

Shortly before the Canadian federal elections of Feb. 1887, Tupper re-entered the Conservative cabinet as finance minister; he resigned in May 1888, when he was reappointed high commissioner for the Dominion of Canada in London.

Tupper was one of the British plenipotentiaries to the Fisheries convention at Washington in 1887. When the dominion cabinet, under Sir Mackenzie Bowell, was reconstituted in Jan. 1896 Tupper accepted office, and in the following April he succeeded Bowell in the premiership. At the general election in the ensuing June the Conservatives were severely defeated, and Tupper and his colleagues resigned, Sir Wilfrid Laurier becoming premier. At the next general election, in 1900, Tupper sustained in his own constituency of Cape Breton his first defeat in 40 years. He wrote *Recollections of Sixty Years* (1914).

See E. M. Saunders, *Life and Letters of Sir Charles Tupper*, 2 vol. (1916).

TUPPER, MARTIN FARQUHAR (1810–1889), English writer, the author of *Proverbial Philosophy*, was born in London on July 17, 1810, the son of a doctor of Huguenot descent. He was educated at Charterhouse and at Christ Church, Oxford. He was called to the bar at Lincoln's Inn, but never practised. He began a long career of authorship in 1832 with *Sacra Poesis* and in 1838 he published *Geraldine, and Other Poems*. For 50 years he was fertile in producing both verse and prose, but his name is indissolubly connected with his long series of didactic moralizing in blank verse, the *Proverbial Philosophy* (1838–67), which for about 25 years enjoyed an extraordinary popularity. The first part was, however, a comparative failure. and N. P. Willis, the American author, took it to be a forgotten work of the 17th century.

Tupper died at Albury, Surrey, on Nov. 29, 1889.

TURA, COSIMO (1430–1498), Italian painter, founder of the Ferrarese school, was born at Ferrara and spent most of his life there, being court painter to the dukes Bono and Ercole. Between 1465 and 1467 he decorated the library of the Pico della Mirandola uith allegorical figures, since destroyed. The decorations of Duke Borso's chapel at Belriguardo also have perished. The Kaiser Friedrich museum, Berlin, has one of the most important of Tura's works, "The Madonna and Child Enthroned With Saints." Another notable work is the "Madonna and Child Enthroned Surrounded by Six Angels Playing on Musical Instruments" (National gallery, London), the central panel of an altarpiece of which the lunette representing the "Pietà" is in the Louvre and one of the wings, representing "A Monk Kneeling and Two Saints," is in the Colonna collection. Rome. Other notable works are the "Madonna and Child in a Garden," in the National Gallery of Art, Washington, D.C.; the "Pietà," in the Civico Museo Correr, Venice; and a "Virgin and Child," in the Accademia Carrara, Bergamo.

TURBELLARIA, a class of flatworms or Platyhelminthes (*q.v.*) in which the body is unsegmented and covered with a ciliated epidermis, and an alimentary canal is generally present. Almost all the group are free-living.

General Morphology. — The body is either subcylindrical or flattened and leaflike or ribbonlike. In length the species range from a fraction of a millimetre to about 20 cm. (7.87 in.) In many forms there is a flat creeping (ventral) surface. At or near the anterior end there may be a pair or more of tentacles, and a

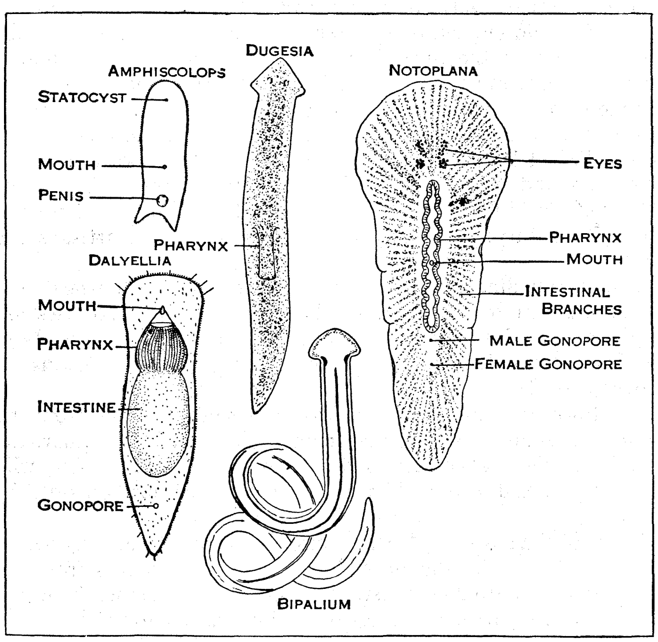

Fig. 1.—Some types of Turbellaria, not to scale. Upper left, *Amphiscolops*, example of the order Acoela; lower left, *Dalyellia*, example of the order Rhabdocoela, section Dalyellioida: upper centre, *Dugesia*, common fresh-water planarian, order Tricladida, suborder Paludicola; lower centre, *Bipalium* kewense, tropical land planarian often found in greenhouses, order Tricladida, suborder Terricola; right, Notoplana, common marine flatworm, order Polycladida, suborder Acotylea, family Leptoplanidae

pair of eyes, or numerous eye spots. The margins of the body, in some of the leaflike aquatic forms, are very mobile and can be thrown into undulations, enabling the animal to swim. The dorsal surface of the body is often pigmented, and the colours and markings, especially in terrestrial forms, may be very striking and brilliant. In certain aquatic species a green or brown colour is produced by the presence in the tissues of symbiotic green or brown algae.

The body is clothed in a cellular or syncytial epidermis, which mhy be completely ciliated but often lacks dorsal cilia. It gives off a mucoid slime that comes from gland cells sometimes situated in the epidermis but more often located in the parenchyme. The epidermis also contains elongated densely staining bodies, the rhabdites, believed to contribute to slime formation. Below the epidermis is a basement membrane, and below this various layers

FIG. 2.—RHABDOCOELAN TURBELLARIAN (MICROSTOMA LINEARE) THE PROCESS OF REPRODUCTION BY DIVISION

of muscle fibres (circular, longitudinal and usually also diagonal). As in the other classes of Platyhelminthes, the internal organs are embedded in parenchymatous tissue.

The mouth may be located anywhere along the midventral line but is usually more or less central. It leads, usually through a muscular pharynx, often more or less protrusible, into the intestine, except in the order Acoela, which primitively lack an intestine and in which food is taken into the interior parenchymatous mass. The intestine may be a simple sac or may be lobed or highly branched and as a rule, has no opening to the exterior except the mouth.

The nervous system consists of paired anterior ganglia lying ventrally to the gut, and giving off various lateral, dorsal and ventral fibres which are interconnected by other fibres. Tactile organs are generally distributed over the skin. and may take the form of special hairlike cilia. Other sensory organs also occur in the form of statocysts, ciliated cephalic pits or grooves, and eyes. The eyes are usually pigment cups containing the bulbous free ends of the retinal cells, notable for their rod border. An excretory system of the platyhelrninth type, with flame cells, is usually present. The external opening may be single or paired, ventral or terminal, or there may be multiple excretory pores on either surface. Almost all the Turbellaria are hermaphrodite, and the reproductive organs are usually complex. There may be separate male and female pores or a common gonopore, situated almost anywhere along the midventral line. Sometimes the sex ducts open by the mouth.

Classification. — The conservative classification here adopted follows Bresslau (Handbuch der *Zoologie,* vol. 2, 1928).

Order 1. **Acoela.**—Small marine flatworms with mouth and often simple pharynx but no digestive cavity. Usually with a statocyst and a frontal cluster of glands. Without excretory system. Gonads consist of strands of differentiating sex cells not delimited from the parenchyme. Oviducts absent but male ducts and simple penis present. The chief families are the Proporidae without, and the Convolutidae with, a seminal bursa, *i.e.,* a sac for receiving the partner's sperm.

Order 2. **Rhabdocoela.**—Small worms, marine, brackish or fresh-water with complete digestive tract; intestine a simple blind sac or tube. With excretory system and usually with oviducts. Seldom with a statocyst. Gonads few, mostly compact.

Suborder 1. CATENULIDA.—Fresh-water forms with simple pharynx, single median nephridium, no yolk glands. Asexual reproduction by fission. One family, Catenulidae, represented by the very common Stenostomum.

Suborder 2. MACROSTOMIDA.—Fresh-water or marine, with simple pharynx, paired nephridia, no yolk glands. Two families, Macrostomidae without, and Microstomidae with, asexual reproduction by fission (fig. 2).

Suborder 3. LECITHOPHORA.—Fresh-water, marine or terrestrial rhabdocoels with bulbous pharynx and yolk glands more or less distinctly separated from the ovaries. Reproduction exclusively sexual. Includes numerous families.

Section 1. *Dalyellioida.*—Rhabdocoels with a doliiform (cask-shaped) pharynx, oriented parallel to body surfaces. Chief family, Dalyelliidae, with complicated male apparatus.

Section 2. *Typhloplanoida.*—Rhabdocoels with a rosulate (spherical) pharynx oriented at right angles to body surfaces. Chief family, Typhloplanidae with genera Mesostoma, *Typhloplana,* Castrada, Phaenocora, etc.

Section 3 *Kalyptorhynchia.*—Mostly marine rhabdocoels with a protrusible food-catching proboscis at the anterior tip (in addition to the usual pharynx). Represented by *Gyratrix, Polycystis, Acrorhynchus,* etc.

Suborder 4. TEMNOCEPHALIDA.—Ectocommensal fresh-water rhabdocoels of dalyellioid affinities living on crayfish and other fresh-water animals. Found only in tropical and subtropical countries. The body has 2 to 12 fingerlike tentacles and one or more adhesive disks.

Order 3. **Alloeocoela.**—Slightly larger worms mostly of plump, cylindroid form, with simple or slightly lobulated intestine. Mostly with two ovaries and numerous testes. Chiefly marine, a few in fresh water. Represented by *Prorhynchus, Plagiostomum, Cylindrostomum, Monocelis, Bothrioplana,* etc.

Order 4. **Tricladida.**—Larger worms of flattened elongated form with plicate pharynx and three-branched intestine (fig. 3). With two ovaries, few to many testes, distinct yolk glands, copulatory sac for receiving sperm, and single gonopore behind the mouth.

Suborder 1. MARICOLA.—Marine planarians with copulatory sac behind the male apparatus. *Procerodes,* free-living, and *Bdelloura, Syncoelidium, Ectoplana* epizoic on the horseshoe crab, *Limulus.*

Suborder 2. PALUDICULA.—Fresh-water planarians with copulatory sac anterior to the penis. Familiar animals of ponds and streams; *Planaria, Phagocata, Dendrocoelum,* etc.

Suborder 3. TERRICOLA.—Terrestrial planarians of tropical and subtropical jungles, sometimes reaching great lengths, often with bright colour patterns. *Geoplana, Bipalium, Rhynchodemus,* etc.

Order 5. **Polycladida.**—Marine, often large, much flattened and leaflike flatworms with numerous eyes and much-branched intestine radiating from the pharynx to the periphery.

Suborder 1. ACOTYLEA.—Without a ventral sucker. Pharynx mostly ruffled, mouth not near anterior end. Tentacles when present borne near the brain. Stylochidae, Leptoplanidae, Planoceridae, etc.

Suborder 2. COTYLEA.—With a ventral sucker behind the genital pores. Pharynx ruffled or cylindrical, mouth anterior. Tentacles when present occur on the anterior margin. Pseudoceridae, Eurpleptidae, Prosthiostomidae, etc.

The classification proposed by Meixner (*Die Tierwelt der Nord-und Ostsee,* Teil iv b) differs in that the first three suborders of the Rhabdocoela are raised to the rank of orders and the Tricladida are made a suborder under Alloeocoela. While there are justifications for these changes, it seems best to adhere to the older classification.

Occurrence and **Habits.**—Most Turbellaria are aquatic. They are abundant on the seashore and in fresh water, where they lurk among weeds or under stones, and in the crannies of rock pools. They creep by a gliding movement caused in the smaller forms by ciliary action, in the larger ones by muscular waves; some are able to swim. Many species of triclads are terrestrial. These occur in damp localities and chiefly in tropical or subtropical countries, though a few are known in temperate latitudes. They are somewhat sluglike in form and habits. A few Turbellaria, mostly dalyellioid rhabdocoels, are parasitic. These are marine, and are found in such animals as sea-urchins, holothurians and molluscs. The free-living forms are almost all carnivorous, feeding either on microscopic organisms or on worms, molluscs and insects. The protrusible pharynx is used either to engulf the prey whole or to pierce it and suck up its juices after it has been enveloped in a coating of mucus.

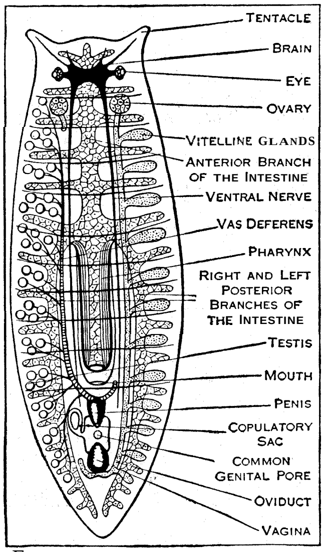

FIG. 3.—GENERAL STRUCTURE OF A TRICLADID TURBELLARIAN. THE THREE-BRANCHED INTESTINE IS CHARACTERISTIC OF THIS GROUP

Development and **Life** History.—The development of most of the Turbellaria is direct (*i.e.,* without metamorphosis). In certain polyclads, however, the embryo develops into a swimming larva ("Müller's larva") provided with eight ciliated lobes, and somewhat resembling the trochophore larvae of certain annelids. In the Rhabdocoela the eggs are generally enclosed in shells, each being provided with a number of separate yolk cells. In the Acoela and Polycladida the ova themselves may contain yolk granules, and the eggs are usually laid in clumps surrounded by a gelatinous envelope. The ova of triclads are laid, several together, surrounded by amoeboid yolk cells, in a cocoon.

A form of asexual multiplication occurs in certain rhabdocoels (Microstomidae) and triclads. In the former the body becomes constricted in the middle and forms two complete animals, each of which again subdivides, and so on, until a whole chain of individuals is formed, head to tail, eventually breaking up into separate organisms. In some of the triclads spontaneous fragmentation may occur, with regeneration of the parts to form complete animals. But even forms which at one season reproduce in this manner, do so at another by means of eggs. In certain rhabdocoels (e.g., *Mesostoma*) two distinct types of eggs are produced according to the season. During warm weather the eggs laid are thin-shelled "summer eggs" which develop rapidly, while thick-shelled "winter eggs," whose contents remain longer in a resting condition, are laid in cold weather. In other cases the eggs are apparently similar at all seasons, but develop more rapidly in warm water than in cold. Thus in shallow pools subject to sudden and frequent changes of temperature, the population increases rapidly during warm weather, while during cold spells the survival of the race is assured. (*See* PLATYHELMINTHES.) (H. A. B.; L. H. H.)

TURBERVILLE (or TURBERVILE), **GEORGE** (1540?–1610?), English poet, second son of Nicholas Turberville of Whitchurch, Dorset, belonged to an old Dorsetshire family, the D'Urbervilles of Thomas Hardy's novel, *Tess.* He became a scholar of Winchester college in 1554, and in 1561 was made a fellow of New college, Oxford. In 1562 he began to study law in London, and gained a reputation, according to Anthony a Wood, as a poet and man of affairs. He accompanied Thomas Randolph in a special mission to Moscow to the court of Ivan the Terrible in 1568. Of his *Poems describing the Places and Manners of the Country and People of Russia* (1568) mentioned by Wood, only three metrical letters describing his adventures survive, and these were reprinted in Hakluyt's *Voyages* (1589). His *Epitaphs, Epigrams, Songs and Sonets* appeared "newly corrected with additions" in 1567. In the same year he published translations of the *Heroycall Epistles* of Ovid, and of the *Eglogs* of Mantuan (Gianbattista Spagnuoli, called Mantuanus), and in 1568 *A Plaine Path to Perfect Vertue* from Dominicus Mancinus. The *Book of Falconry or Hawking* and the *Noble Art of Venerie* (printed together in 1575) may both be assigned to Turberville. He probably died before 1611.

TURBET I HAIDARI, a town in the province of Khurasan in Iran, situated at an elevation of 4,400 ft., about 76 mi. S. of Meshed, on the motor road to Zahidan (Duzdab), via Qain and Birjand.

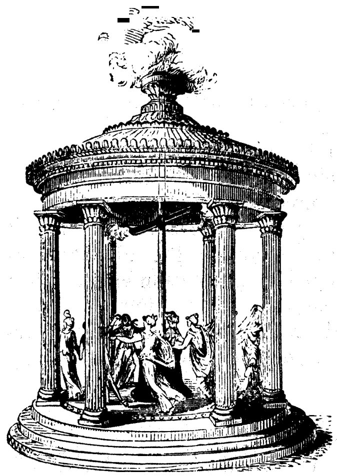
The town is a centre of many roads. In the northeast are the ruins of an old citadel, or the Ark of Ishaq Khan; but the principal feature of the town is its bazaar formed of four dome-vaulted streets radiating from a larger central dame. Before the famine of 1871, Turbet i Haidari was populous, but the population was, it seems, reduced by 20,000. The town had recuperated before World War I owing to increased trade between Russian Turkistan and Afghanistan; the population (1956) is 19,807, chiefly of Turki Qarai stock. who were settled there by Timur in the 14th century; but many of the merchants and artisans are Yazdis.

The surrounding district is very fertile and much wheat and barley are sent to other parts. The chief trading activities are wool buying, silk production (now greatly declining), carpet buying from the Baluch nomads round about, and the making of copper utensils.

The town. formerly known as Zavah, derives its name from the *turbeh,* or tomb, of a holy man named Qutb ud Din Haidar, the founder of the ascetic sect of dervishes known as Haidaris, who died *c.* 1230 and is buried in a domed building just outside the town.

TURBINE: GAS. A gas turbine is a form of heat engine for producing work with the aid of heated gases. It differs from the conventional internal-combustion engine in the manner in which the heated gases are employed. In the internal-combustion engine. air and fuel are drawn into cylinders fitted with movable pistons connected to a crankshaft by means of connecting rods. By exploding the mixture of air and fuel in the cylinders, the pistons are forced to move back and forth, causing the crankshaft to turn. A flywheel is attached to the crankshaft to smooth out irregularities. The mechanism of internal-combustion engines is complicated and subject to inertia and vibrational forces that are difficult to eliminate.

The gas turbine is an attempt to achieve the advantages of internal-combustion engines without the complications associated with reciprocating motion. Its principle of operation is to direct a continuous stream of hot gases against the blading of a turbine rotor. In modern units. the air is first compressed in an axial-flow compressor before being directed into combustion chambers. In these. fuel is mixed with a portion of the air and burned. Some of the air is bypassed around the burner and subsequently mixed again with the products of combustion to prevent excessive temperature of the gases leaving the combustion chambers. The emerging gases are directed through nozzles and against the blading of the turbine rotor. furnishing sufficient power to drive the compressor with enough left over for useful purposes. The result is a smooth-running machine, incorporating the advantages of Internal combustion without the disadvantages of reciprocating pistons.



REPRINTED FROM THE 9TH EDITION OF "ENCYCLOPAEDIA BRITANNICA"

FIG. I.— SKETCH OF HERON'S GAS TURBINE (ABOUT 130 B.C.)

HISTORY

Early. — The earliest known device which might be classified as a gas turbine is believed to be that suggested by Heron of Alexandria (*q.v.*) about 130 B.C. An early sketch of Heron's gas turbine is shown in fig. 1. It consisted of a circular rotating platform. not unlike that of a present-day merry-go-round, on which live persons could stand. Rotation of the platform was to be accomplished by means of air drawn through bent tubes, leading into a long central vertical tube culminating in the hearth of an altar fire located on the roof. The exact manner of operation was not clearly explained by Heron, but there is no doubt that the intention was to employ heated air as the motivating force.

Another early device called the smokejack is illustrated in fig. 2. It was designed to operate with the aid of hot combustion gases rising from a fireplace. The smokejack is believed to have first been sketched by Leonardo da Vinci. It was later more fully described in a book by John Wilkins, an English clergyman, later bishop of Chester, entitled ,*Mathematical Magick*, published in 1648. The device consists of a number of horizontal sails similar to those of a modern windmill, attached to a vertical shaft and placed in the chimney of a fireplace. The hot gases rising past the sails caused the device to rotate. With the aid of a simple gearing system it was possible to employ the smokejack for turning a spit, or to perform other simple tasks.

A somewhat similar device was later patented by John Dumbell of England. His device. shown in fig. 3, employed a large number of sails, one above the other, all attached to a hollow drum. In addition, he supplied his own furnace underneath, with means for supplying air and fuel and for keeping the component parts from melting. In his patent he stated that he "would apply whatever produces steam, smoke, rarefied air, or spirit. or which produces an inflammable vapour, either in combined or single state, or which may be drawn by distillation, or which possesses an explosive or combustible power effect." Some authors have interpreted the latter part of the sentence to mean that the device was a forerunner of the explosion-type gas turbine. In view of the patent drawings this view is difficult to substantiate since the drawings do not reveal anything like a constant-volume. explosion-type combustion chamber.

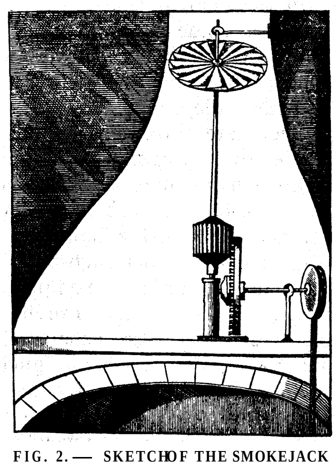


FIG. 2.— SKETCH OF THE SMOKEJACK TURBINE

The first patent for a gas turbine operating on a cycle resembling present-day units was issued to John Barber of England in 1791. A sketch of Barber's turbine. taken from the patent dranings, is shonn in fig. 4. The principle of operation was as follons: air and fuel from a gas producer, after being compressed in separate cylinders, were directed into a combustion chamber and burned. The products of combustion were released through a small nozzle onto a turbine wheel. The power thus produced was supposed to be sufficient to compress the air and fuel and to leave enough over for external work. From our modern knowledge of the cycle, and from the sketch supplied by Barber, it is known that his machine could not have operated successfully. It did, however, represent an ingenious invention and included most of the essential elements found in present-day gas turbines.

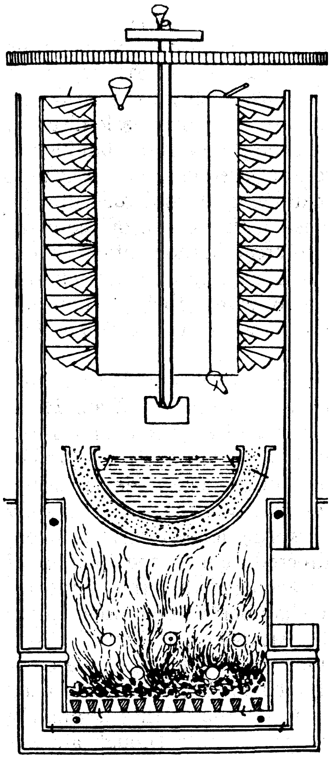

FIG. 3.— PATENT DRAWING OF JOHN DUMBELL'S TURBINE

Modern. — In the years following the issuance of John Barber's patent, many novel devices were proposed, but it was not until 1872 that a really significant advance in the art was made. This came with the granting of a patent to F. Stolze of Germany for his so-called fire turbine. Stolze's turbine consisted of a separately fired combustion chamber, a heat exchanger and a multistage axial-flow compressor directly coupled to a multistage reaction turbine. Operation was as follows: air, after being compressed, was directed into the heat exchanger where it was heated by means of combustion gases from a separately fired furnace. From the heat exchanger the compressed air passed into the turbine through which it was expanded back to the atmosphere. Even though Stolze's gas turbine embodied almost every feature of a modern, simple open-cycle gas turbine, it was unsuccessful. The reason was that the compressor and turbine lacked the necessary efficiency to sustain operation, using maximum turbine inlet temperatures permissible at that time.

The first successful gas turbine was built by R. Armengaud and C. Lemale for the Société des Turbomoteurs in Paris in 1903. This unit consisted of a three-cylinder multistage Rateau compressor followed by a combustion chamber in which liquid fuel was burned with air supplied from the compressor. The hot gases issuing from the combustion chamber, after being cooled to some extent by the injection of water, were expanded through a two-row impulse turbine wheel. The unit was capable of operating with an efficiency of about 3%. Although by later standards this was an unimpressive performance, it was nevertheless a significant achievement at the time. It is believed to be the first gas turbine capable of delivering work on a scale suitable for commercial purposes.

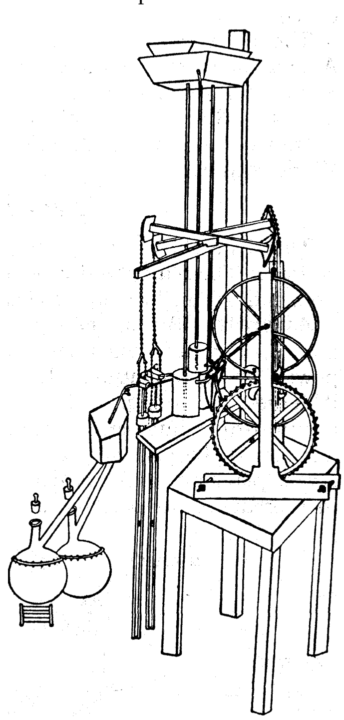

FIG. 4.— DRAWING OF JOHN BARBER,S TURBINE, PROBABLY THE FIRST TO USE A COMBUSTION CHAMBER

Two other contributions should also be mentioned. In these, a different principle of operation was employed, that of exploding a mixture of air and fuel in constant-volume combustion chambers and then allowing the products of combustion to flow through nozzles onto a turbine wheel.

The first of these was a two-horsepower, 10,000-r.p.m. unit built by M. Karavodine in Paris in 1908. It consisted of a simple De Laval impulse-type turbine wheel (see TURBINE: STEAM) about six inches in diameter with four explosion chambers arranged around the periphery of the wheel. each leading to a nozzle directed against the wheel. When in operation the products of combustion from the four explosion chambers were released in sequence against the wheel. An ingenious method of drawing air and fuel into the chambers was provided. After explosion, the inertia of the gases leaving the chambers was employed to create a momentary partial vacuum inside the chambers capable of sucking in a new charge. During tests the device was reported to have a fuel consumption of about 2.24 kg. of gasoline per horsepower-hour, corresponding to a thermal efficiency of about 2.5%.

The second and more important of the two contributions historically was the explosion-type turbine developed by Hans Holzwarth of Germany. who began a long series of experiments in 1905. His turbine consisted of a constant-volume combustion chamber into which a charge of fuel and air was introduced under pressure. Following ignition. the pressure was increased to approximately 49 times the original value, causing a spring-loaded valve to open, admitting the gases into nozzles directed against the blading of the turbine. The mechanism was so arranged that the valves remained open until the combustion chamber was emptied, after which a new charge was introduced. Although an air compressor was employed in the Holzwarth turbine, the efficiency of the compressor was not extremely important. This is because the air need be supplied at a pressure of only about one-fourth that ultimately achieved during explosion. and also because only enough air was required to furnish oxygen for combustion.

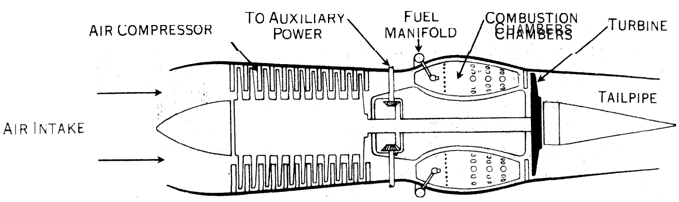
Over a period of about 30 years Holzwarth and various collaborators continued development of the turbine. Although now superseded by the constant-pressure combustion gas turbine, the Holzwarth explosion turbine represented a unique and important contribution.

The modern gas turbine is due to the work of many individuals. Among the most important was Sir Frank Whittle of England, who was among the first to recognize its application to jet propulsion aircraft. His efforts in this regard led to its development and use in military aircraft in America and the United Kingdom during World War II.

APPLICATIONS

The gas turbine is a versatile prime mover and has many applications. These may be divided into aircraft, electric power generation, industrial, locomotive, marine and automotive.

Aircraft.— By far the most important present-day application is in military aviation where the gas turbine provides the motive power for jet propulsion. In this application, illustrated in fig. j, it serves as a jet propulsion engine consisting of an axial-flow compressor. a number of combustion chambers arranged in parallel around the periphery of the engine, a turbine and a tailpipe. As the plane moves forward air is drawn into the compressor where its pressure is increased by several atmospheres. It then flows into



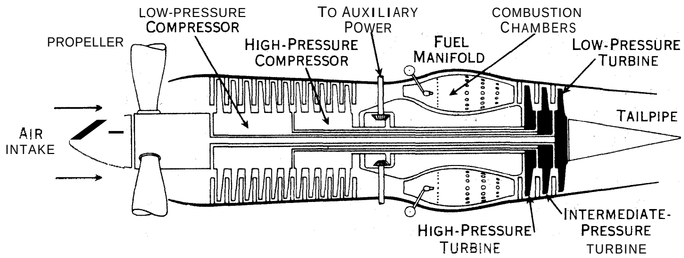
BY COURTESY OF PRATT & WHITNEY AIRCRAFT

FIG. 5.— CUTAWAY DRAWING OF A JET PROPULSION ENGINE

the combustion chambers where a special grade of kerosene fuel is injected and burned, raising the temperature of the products of combustion to approximately 1,600° F. From the combustion chambers the hot products pass through the turbine, surrendering sufficient energy to drive the compressor. The gases then exhaust through the tailpipe at high velocity. The increase in velocity of the gases issuing from the tailpipe over that of the air entering the compressor provides the reactive force needed to drive the plane forward.

Modern military jet propulsion engines are capable of producing tremendous power. In emergencies this can be augmented still further with the aid of an afterburner, the purpose of which is to add heat to the gases just before exhausting from the tailpipe. This increases their velocity and adds to the forward thrust of the engine.

Another gas turbine application for aircraft is the turboprop, illustrated in fig. 6. In this application the gas turbine serves a dual purpose, that of driving a conventional propeller and that of producing additional thrust by means of the reactive force of the exhausting gases. This type of engine has the advantage of lower fuel consumption than a straight jet propulsion engine when operating at speeds and altitudes suitable for commercial flying. At the same time it offers some advantages over conventional reciprocating aircraft engines such as higher speed, smooth flight and less vibration.



BY COURTESY OF PRATT & WHITNEY AIRCRAFT

FIG. 6.— CUTAWAY DRAWING OF A TURBOPROP ENGINE

Electric Power Generation.— In the field of electric power generation the gas turbine must compete with the diesel engine and steam turbine. Gas turbines are limited in capacity by the fact that the pressure involved is low, making it necessary to employ large turbines and compressors in order to handle the huge volumes of air required. For this reason no serious attempt has been made to design a gas turbine power plant capable of competing with the modern central station steam power plant in which single units as large as 450,000 kw. have been built.

In the field of small power plants, a number of installations had been made in the United States and in Europe by the mid-1950s, but insufficient information was available to draw accurate conclusions as to just where the gas turbine would ultimately find its widest adoption.

There are three applications which deserve special mention. These are: (1) operation in combination with steam power plants as a means of increasing the over-all efficiency of the plant; (2) for stand-by and peak load service; and (3) for portable power plants. A promising combined steam turbine-gas turbine power plant is one in which high-temperature exhaust gases from a conventional gas turbine are employed to supply oxygen to the furnace of a steam boiler in lieu of preheated combustion air. This is feasible because the gases exhausted from a gas turbine still contain about 80% of the oxygen originally in the air supplied to the compressor inlet. Such an arrangement is capable of increasing the over-all efficiency of the plant by a substantial amount. It also offers savings in size and weight of the boilers required? less building volume: quicker starting of the boiler and elimination of the forced and induced draft fans normally required by the boiler.

Other ways in which the gas turbine can be employed to improve the efficiency of a steam power plant are to use the exhaust gases for feed-water heating or for the generation of steam in an exhaust heat boiler.

In the hydroelectric power field the gas turbine offers an attractive means of providing additional peak load and stand-by power. It can often be installed for this purpose at lower cost than additional steam or hydro capacity. Furthermore, it offers the advantages of virtually automatic operation, simplicity, small space requirements and minimum maintenance. Another similar application is for end-of-the-line voltage booster service on long-distance transmission lines. A third application is for portable power plants. Here the gas turbine can be mounted on railroad cars for emergency use by the military or other agencies.

Industrial Applications. — An early and still important application of the gas turbine in industry is in connection with the Houdry process of refining oil. In this application, air under pressure must periodically be passed over a catalyst for the purpose of burning off carbon accumulated during the refining process. The air employed thus becomes heated in the same manner as it would in a combustion chamber, and can therefore be passed through a turbine to perform useful work, including that of driving the compressor employed for supplying the air to the catalyst. The result is a gas turbine with the carbon burn-off operation substituted for a combustion chamber. A large number of these units had been manufactured in the Cnited States and were rendering satisfactory service by the mid-1950s.

Another industrial application is for natural gas pipeline compressor stations. For this purpose the gas turbine is ideally suited since natural gas is an excellent fuel and is available at low cost, making fuel economy of secondary importance. By using a regenerator, satisfactory efficiencies can easily be obtained and stations can be located anywhere along the line since no water supply need be available. Furthermore, fully automatic stations can be built which require practically no supervision and only a minimum of maintenance.

A third industrial application is in the steel industry. Here large volumes of air under pressure are required for reducing iron ore in blast furnaces. In present installations the hot blast-furnace gases leaving the furnaces are utilized as fuel for generating steam in a boiler. The steam so generated is used in steam turbines or large reciprocating engines which in turn drive large rotary blowers or compressors supplying air to the blast furnaces. This equipment occupies a great deal of space and is also quite expensive. In addition a large quantity of condensing water is required for the turbines or steam engines.

With the gas turbine it is possible to replace all this equipment with a single unit designed to operate with blast-furnace gas as fuel. In such an installation a portion of the air compressed is directed to the blast furnace while the remainder flows through the combustion chamber and turbine. The exhaust gases leaving the turbine can be passed through a regenerator to preheat the air flowing to the combustion chambers. thereby increasing the efficiency. The blast-furnace gas supplied to the combustion chamber as fuel can be compressed with the aid of a small compressor driven off the shaft of the turbine.

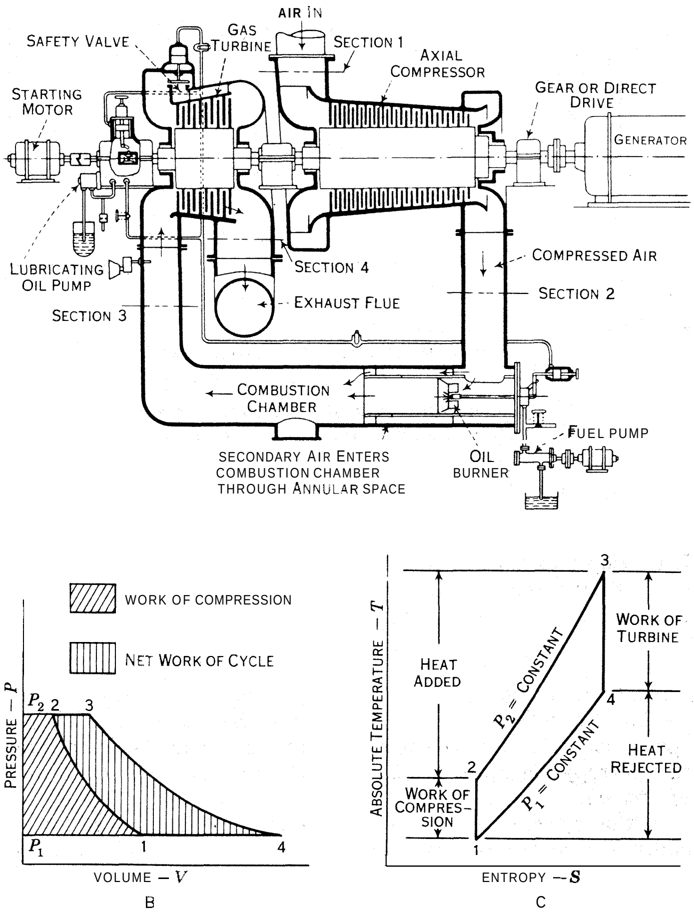
Locomotive. — A field of application receiving considerable attention in the 1950s was the railroad locomotive. Advantages of the gas turbine for this service are its smoothness of operation, simplicity and lack of need for water. 4 number of oil-burning gas turbine locomotives were built in the United States and Switzerland and were giving satisfactory service. Because of economic considerations, however, they were unable to replace the diesel locomotive. because they were less efficient thermally. Attempts were made to overcome this economic disadvantage by developing a coal-burning gas turbine locomotive, but the engineering difficulties are great, and much work remained to be accomplished before a successful unit could be built.

Marine. — In the field of small ship propulsion. the gas turbine offers advantages of lighter weight and less space requirement than a corresponding boiler and steam turbine plant. However, progress had been slow by the mid-1950s, and few units had been built. For marine service the advantage of intercooling can be utilized to obtain increased efficiency. (See *Theory* below.)

Automotive. — There is much speculation as to the future of the gas turbine for automotive applications. In the mid-1950s it appeared that the disadvantages outweighed the advantages, and that there was little likelihood of the gas turbine replacing the reciprocating engine in the near future. The principal advantages of the gas turbine over the conventional reciprocating automotive engine are its smooth vibrationless operation, flat torque versus speed characteristic, light weight, small space requirements, lack of need for a cooling system and the possibility of burning a cheaper fuel than gasoline. Its disadvantages are high cost of manufacture and materials. high fuel consumption, high speed and high noise level. Although no one could predict what will ultimately occur, it appeared that the gas turbine would eventually find important applications in the automotive field, even though it might never replace the reciprocating engine entirely.

Future of the Gas Turbine. — The many applications for which the gas turbine is especially well suited seem to assure an attractive future. In the fields of military and commercial aviation its status as the leading contender among all types of power plants is unchallenged. In the industrial field, there seem to be an increasing number of possible applications indicating continued growth in this area. The same growth can be confidently predicted for its use in all forms of transportation including marine, locomotive, truck and even automotive.

In the utility field it is unlikely that the gas turbine will supersede the large central station steam turbine. The reason for this is inherent in the gas turbine cycle, which requires that all air passing through the turbine must first be compressed. This means that a large portion of the work output of the turbine must be employed to drive the compressor, leaving only a fraction for driving the electric generator. Should the work of compression, for example, require half that of the turbine output, one would obtain only one-half unit of power for two units of rotating machinery. In the steam turbine, on the other hand, one would obtain essentially one unit of power for one unit of rotating machinery.



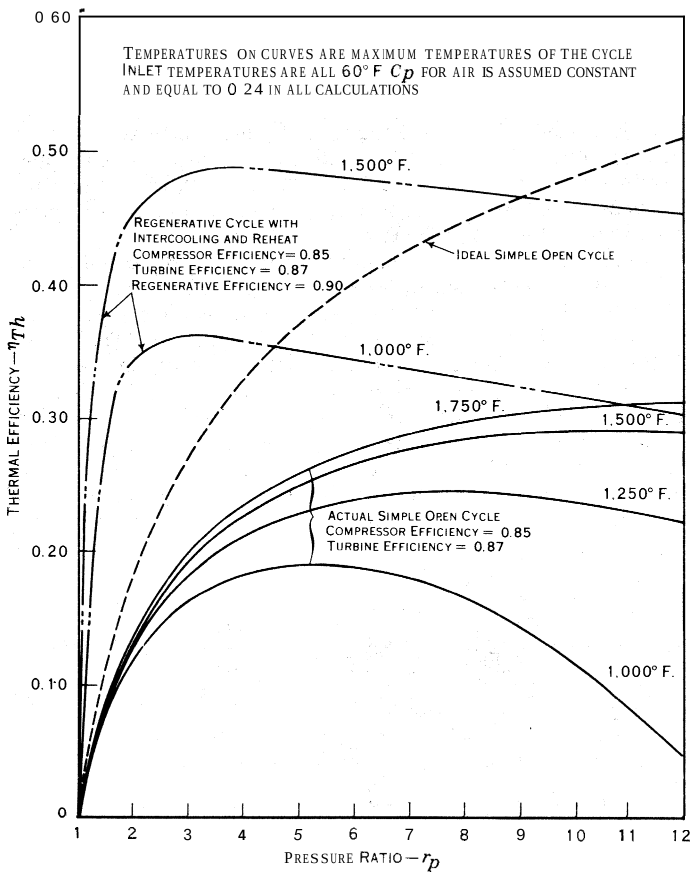
(A) ADAPTED FROM AN ORIGINAL DRAWING BY ALLIS-CHALMERS MANUFACTURING CO.; (B AND C) BY COURTESY OF R. A. BUDENHOLZER

FIG 7 — (A) IDEAL SIMPLE OPEN-CYCLE. CONSTANT-PRESSURE COMBUSTION GAS TURBINE: (B) PRESSURE-VOLUME AND (C) TEMPERATURE-ENTROPY RELATIONSHIPS FOR SUCH A TURBINE

This is because in the steam cycle, the only work of compression required is that of the boiler feed pumps, an almost insignificant portion of the turbine output.

Still another factor in favour of the steam turbine is its ability to expand steam through pressure ratios as high as 10,000 to 1 or more. This permits the use of very high initial pressures, resulting in relatively small turbine components. With the gas turbine, pressures are always low, making large components essential for high power output.

One method of partially overcoming this difficulty is to employ



BY COURTESY OF R A BUDENHOLZER

FIG. 8.— THERMAL EFFICIENCY OF VARIOUS CYCLES

a pressurized cycle in which the unit is first charged with air or other gases and then operated under a pressure level of several atmospheres. Although this has the advantage of reducing the size of the rotating machinery, it requires a cooling medium capable of lowering the turbine exhaust gases back to compressor inlet temperature before they can be reintroduced into the compressor. It is also necessary to add heat to the compressed gases in a separately fired furnace, or to continuously add sufficient new air and fuel to the cycle, under pressure, to maintain combustion.

THEORY

Nearly all modem gas turbines operate on the constant-pressure combustion cycle. In fig. 7 is shown a sketch of an idealized simple open-cycle unit with accompanying pressure-volume and temperature-entropy diagrams (see STEAM: *Steam* Engine and Properties of *Steam).*

In this cycle air enters the axial-flow compressor at section 1 under normal atmospheric pressure and temperature P_1 and T_1. It is then compressed adiabatically and reversibly (isentropically) to section 2 where the pressure and temperature are now P_2 and T,. From section 2 the air flows into the combustion chamber where fuel is iniected and burned at constant pressure, raising the temperature t o - . ~ ~From the combustion chamber the heated gases enter the turbine where expansion occurs to atmospheric pressure.

The amount of work obtainable from the unit is the difference between that required to compress the gas and that obtained from the turbine. 'This may be represented on the pressure-volume diagram by areas and on the temperature-entropy diagram by ordinates, as indicated in fig. 7(B) and 7(C).

The energy relations involved in each portion of the cycle can best be analyzed by using the steady-flow energy equation between any two sections a and b. (For a discussion of the theory concerning the equations, see THERMODYNAMICS: Thermodynamics and Heat Engines.) This equation is

$$\frac{Z_a}{J} + \frac{V_a^2}{2gJ} + h_a \pm {}_aQ_b \pm {}_aW_b = \frac{Z_b}{J} + \frac{V_b^2}{2gJ} + h_b \qquad (1)$$

where

$_a$ = subscript representing section a
$_b$ = subscript representing section b
$\frac{Z}{J}$ = energy possessed by the working fluid by virtue of its elevation above an arbitrary datum elevation, B.Th.U per pound
$\frac{V^2}{2gJ}$ = kinetic energy possessed by the working fluid by virtue of its velocity, B Th.U. per pound
h = enthalpy of the fluid, B.Th U. per pound
${}_aQ_b$ = heat added or abstracted from the fluid between sections a and b, B Th U. per pound
${}_aW_b$ = work done by or on the fluid between sections *a* and b, B.Th.U. per pound
$\pm$ = plus if heat or work is added; negative if taken away

If, in the ideal cycle, air is assumed to behave as a perfect gas one may replace h with C_pT, where C_p is the specific heat at constant pressure for air. Also, if it is assumed that changes in elevation are not great and that velocities entering and leaving various components of the unit are small, the terms $\frac{Z}{J}$ and $\frac{V^2}{2gJ}$ may be neglected. On this basis the equation becomes

$$C_pT_a \pm {}_aQ_b \pm {}_aW_b = C_pT_b. \qquad (2)$$

Applying equation (2) to the various components of the gas turbine gives:

Work of compression, in which ${}_1Q_2 = 0$ and ${}_1W_2$ is positive,

$$W_c = {}_1W_2 = C_p(T_2 - T_1). \qquad (3)$$

Heat added in the combustion chamber, in which ${}_2Q_3$ is positive and ${}_2W_3 = 0$,

$$Q_A = {}_2Q_3 = C_p(T_3 - T_2). \qquad (4)$$

Work done by the turbine, in which ${}_3Q_4$ is zero and ${}_3W_4$ is negative,

$$W_t = {}_3W_4 = C_p(T_3 - T_4). \qquad (5)$$

In the above equations W_c represents the work required to compress and deliver the air, Q_A the heat added to the air in the combustion chamber and W_t the work done by the turbine, all in B.Th.U. per pound of air.

Using the above equations, the net work of the cycle per pound of air passing through the turbine is,

$$W_{cycle} = W_t - W_c = C_p[(T_3 - T_4) - (T_2 - T_1)]. \qquad (6)$$

The heat added is $Q_A = C_p(T_3 - T_4)$ so that the thermal efficiency, representing the ratio of the work done to heat added, is

$$\eta_{Th} = \frac{W_{cycle}}{Q_A} = 1 - \left(\frac{T_4 - T_1}{T_3 - T_2}\right) = 1 - \frac{T_1\left(\frac{T_4}{T_1} - 1\right)}{T_2\left(\frac{T_3}{T_2} - 1\right)}. \qquad (7)$$

It is easy to show from the laws of thermodynamics that for a perfect gas undergoing the processes involved, $\frac{T_4}{T_1} = \frac{T_3}{T_2}$. The equation for the thermal efficiency of the ideal cycle therefore becomes

$$\eta_{Th} = 1 - \frac{T_1}{T_2}. \qquad (8)$$

It is also well known that when any two states of a perfect gas, 1 and 2, are joined by an isentropic process,

$$\frac{T_2}{T_1} = \left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}} = r_p^{\frac{k-1}{k}}. \qquad (9)$$

Where k is the isentropic exponent for the gas and r_p is the pressure ratio $\frac{P}{P_1}$ Substitution of this relationship into equation (8) gives the-thermal efficiency in terms of pressure ratio.

$$\eta_{Th} = 1 - \frac{1}{r_p^{\frac{k-1}{k}}}. \qquad (10)$$

A curve illustrating the variation of thermal efficiency with pressure ratio, derived in accordance with equation (10), is shown by the dotted curve in fig. 8. According to this curve, which represents only the ideal cycle, the efficiency increases with pressure ratio until a maximum value of unity is reached at infinite pressure ratio.

Actual Simple Open-Cycle Gas Turbine. — The principal difference between the ideal cycle described above and the actual cycle is that the compression and expansion processes cannot be carried out isentropically as assumed. Instead. the work of compression is increased and that obtained by expansion is decreased. The net result is a drastic reduction in thermal efficiency.

The reasons for this are illustrated in the temperature-entropy diagram of fig. 9. Here the actual processes are shown as solid lines and the ideal processes as dotted lines. As a result of inefficient comoression the actual amount of work reauired to compress the air becomes $W_c = \frac{C_p(T_2-T_1)}{\eta_c}$ where η_c is the efficiency of the compressor. Similarly, because of the inefficiency of the turbine, the work of expansion is reduced to $W_t=\eta_t C_p(T_3-T_4)$ where η_t is the efficiency of the turbine. The net work of the cycle therefore becomes

$$W_{\text{cycle}}=W_t-W_c=\eta_t C_p(T_3-T_4)-\frac{C_p(T_2-T_1)}{\eta_c} \tag{11}$$

The heat added in the actual cycle is that required to raise the temperature of the air leaving the compressor to T,; namely,

$$Q_A=C_p(T_3-T_2'). \tag{12}$$

By simple algebra and the thermodynamic relations for a perfect gas, it can be shown that the thermal efficiency becomes

$$\eta_{Th}=\frac{\eta_c\eta_t\left(\frac{T_3}{T_1}\right)-r_p^{\frac{k-1}{k}}}{1-\eta_c+\left(\frac{T_3}{T_1}\right)\eta_c-r_p^{\frac{k-1}{k}}}\left(1-\frac{1}{r_p^{\frac{k-1}{k}}}\right) \tag{13}$$

where the term in parentheses is equal to the thermal efficiency of the ideal cycle and the remaining portion represents a correction factor for inefficiency of the actual cycle. Curves showing the thermal efficiency of several typical actual cycles. similar to that depicted by the temperature-entropy diagram of fig. 8, are illustrated by the solid lines in fig. 7. In these. the efficiency of the compressor is taken as 85% and that of the turbine 87%. Maximum cycle temperatures. ranging from 1,000° F. to 1,750° F., about the maximum permissible with modern alloys, are employed.

The curves show that the thermal efficiency increases nith maximum temperature of the cycle T_3 and that there is an optimum value of pressure ratio r_p for each value of T_3. From these curves it is easy to verify that the maximum temperature must be high if a satisfactory efficiency is to be obtained. From the temperature-entropy diagram it is also evident that the lower the efficiencies of the compressor and turbine, the lower will be the net work output of the cycle. These facts explain the failure of Stolze's turbine and of all similar early models. They also explain the reason for Holznarth s efforts in attempting to perfect the explosion-type turbine. in which the efficiency of compression is less important.

Reheat, Intercooling and Regeneration. — There are three basic ways in which the efficiency of the simple gas turbine cycle can be increased. These are. (1) to increase the work output of the turbine; (2) to decrease work input to the compressor; (3) to decrease the amount of heat added by the fuel.

The first of the above objectives may be realized by dividing the expansion process into two or more steps. This is usually accomplished by employing a high-pressure and low-pressure turbine with a combustion chamber in betneen for reheating the air and combustion products. The effect is to increase the volume of the gas undergoing expansion, thus increasing the work of the turbine.

The second objective may be accomplished by compressing the air in a manner as near isothermal (constant temperature) as possible. The closest practical approach to this objective is to employ intercooling. This consists of compressing the air in tno or more steps with arrangements for cooling back to inlet temperature between steps. The purpose here is to maintain the volume of air as low as possible in order to reduce the power required for compression.

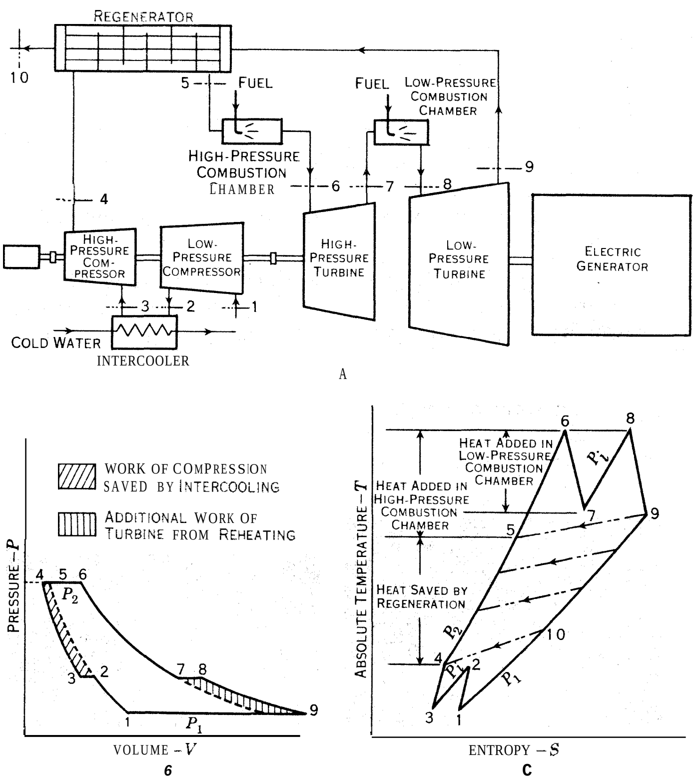
FIG 9 — TEMPERATURE-ENTROPY DIAGRAM FOR ACTUAL SIMPLE OPEN-CYCLE GAS TURBINE

With respect to the third objective, examination of the temperature-entropy diagram in fig. g reveals that the hot gases leaving the compressor at temperature T_4' are higher than the temperature



BY COURTESY OF R A BUDENHOLZER

FIG. 10.— (A) SCHEMATIC DIAGRAM OF ACTUAL CYCLE EMPLOYING INTERCOOLING, REGENERATION AND REHEAT; (B) PRESSURE-VOLUME AND (C) TEMPERATURE-ENTROPY RELATIONSHIPS OF SUCH A CYCLE

of the air leaving the compressor at T_2'. By employing a heat exchanger it should be possible to warm the air on its way to the combustion chamber, by transferring excess heat from the exhaust gases to the air. In practice this is accomplished by means of a regenerator in which the hot exhaust gases are passed counterflow to the air leaving the compressor in a manner such that the heat surrendered by the turbine exhaust gases is absorbed by the compressed air before entering the combustion chamber. This reduces the amount of heat added by the fuel.

FIG. 11.— CURVES OF WORK OUTPUT PER POUND OF AIR FOR CYCLES OF VARIOUS COMPLEXITY

Fig. 10 is a schematic diagram of a cycle incorporating all three of the features described above. Also shown in fig. 10 are the corresponding pressure-volume and temperature-entropy diagrams. With the aid of the pressure-volume diagram it is easy to represent, by crosshatching, the increased work of the turbine resulting from reheat and the decreased work of compression resulting from intercooling.

From the temperature-entropy diagram the transfer of heat from the hot exhaust gases to the cooler compressed air is illustrated together mith the consequent saving in heat added by the fuel. Although there is additional heat added in the reheat combustion chamber. the amount is not as great as the gain in work of the turbine. Therefore, reheating is an advantage from the standpoint of over-all thermal efficiency.

In fig. 8 are shown thermal efficiency curves for a regenerative cycle employing both reheat and intercooling, and having the same compressor and turbine efficiencies as before. For computing the efficiencies. frictional. pressure drop in the cycle was neglected and the regenerator was assumed to have an effectiveness of 90%. The advantage of the cycle is readily apparent insofar as thermal efficiency is concerned. However, the disadvantages of added complexity and first cost often outweigh the advantages.

Work Obtainable. — The work obtainable per pound of air passing through the cycle varies greatly with pressure ratio, maximum temperature and complexity of the cycle. In fig. 11 are presented curves showing the work obtainable, plotted opposite pressure ratio, for the various cycles discussed in the previous section. The point of maximum efficiency is marked on the curves representing the actual simple open cycle in order to indicate that the point of maximum work does not necessarily correspond to that of maximum efficiency. The curves are computed for a compressor efficiency of 85% and a turbine efficiency of 87%. When intercooling and reheat are employed each is assumed to occur at the optimum intermediate pressure for maximum efficiency, namely, $P_i = P_1\left(\frac{P_2}{P_1}\right)^{0.5}$. Pressure drop in the cycle is neglected and the specific heat of air is taken as constant and equal to 0.24 B.Th.U. per pound per degree Fahrenheit. Reheat and intercooling are assumed to restore the temperatures to their original values.

The curves clearly show the advantage of reheat, intercooling and regeneration on the work output of the cycle.

Design Features. — Although a detailed discussion of the many design features of gas turbines cannot be undertaken here, enough can be included to give the reader an idea of the arrangement of essential components. In fig. 12 is shown a cross section of an 8,750-r.p.m., 1,800-h.p. gas turbine. At the left is the axial-flow compressor where intake air is compressed to a pressure equal to about four or five atmospheres. In the centre are a ring of combustion chambers into which fuel is injected and burned, raising the temperature of the air and combustion products to a value of approximately 1,250° F. From the combustion chambers the hot gases are directed into the multistage reaction turbine which is directly connected through a central hollow shaft to the compressor. During expansion of the gases through the turbine, sufficient work is performed to drive the compressor and still leave a substantial amount for other purposes.

Fig. 13 is a view of the exposed compressor and turbine rotor. The blading is clearly visible on both compressor and turbine elements. (For a discussion of turbine blading see TURBINE: STEAM.)

In fig. 14 is shown a sectional scale model of a 5,000-h.p. gas turbine plant equipped with a regenerator. Air is first compressed

in the axial-flow compressor and then directed into the regenerator where it absorbs heat from the turbine exhaust gases. From the regenerator it returns to the combustion chambers to be heated further by the combustion of fuel before flowing into the high-pressure turbine. The latter is connected to the coniрressor by a hollow shaft and supplies the power required to drive it. From the high-pressure turbine the hot gases flow through the low-pressure turbine and out through the regenerator to the exhaust. The low-pressure turbine furnishes the power to drive an electric generator or other equipment. The arrangement of elements for a

jet propulsion engine is illustrated schematically in fig. 5. In the jet propulsion engine only a portion of the energy in the gases is employed by the turbine to drive the compressor. The remainder is reserved for building up velocity of the gases issuing from the tailpipe, thus providing the reactive force required for propulsion.

A turboprop engine with propeller, double-rotor compressor and triple-rotor turbine is illustrated schematically in fig. 6. In this unit the propeller is driven by the low-pressure turbine. The low-pressure section of the compressor is driven by the intermediate-pressure turbine. and the high-pressure section by the high-pressure turbine. Such an arrangement provides a wide degree of flexibility with respect to speed of both propeller and compressor elements.

TURBINE: STEAM. A steam turbine is a machine for converting thermal energy stored in steam into work. It consists of a shaft or rotor resting in bearings and enclosed in a cylindrical casing. The rotor is made to turn smoothly by means of jets of steam issuing from nozzles located around the periphery of the turbine cylinder and impinging upon blades or buckets attached to the shaft. Thus, a steam turbine is a prime mover nhich generates motive power in the same manner as a windmill except on a vastly greater scale. Instead of a current of air being used to rotate the shaft. steam is employed as the working agent.

Because of its ability to develop tremendous power within a comparatively small space. the steam turbine has superseded all other prime movers except hydraulic turbines for the generation of large quantities of electrical energy (see TURBINE: WATER). The economic importance of the steam turbine has provided an incentive for continued development, resulting in units capable of generating over 250,000 kw. of power on a single shaft and over 450,000 kw. in other combinations.

History. — The earliest proposed steam turbines were of the reaction type in which rotation was achieved by steam issuing from curved tubes or nozzles, much as in the case of water issuing from a lawn sprinkler. The first such device is attributed to Heron of Alexandria about the year 130 B C. It consisted of a hollow sphere mounted betneen two hollow tubes through which steam was supplied. Attached to opposite sides of the sphere, in a plane perpendicular to the axis of the two tubes, were two curved nozzle outlets through uhich steam issued, imparting rotation in a manner similar to that of the familiar pinwheel employed for fireworks displays.

The first steam turbines having any commercial significance appear to be those built in the United States by William Avery in 1831. Their turbine consisted of two hollow arms about $2\frac{1}{2}$ ft. long, attached at right angles to a hollow shaft through which steam was supplied. The arms were of rectangular cross section about $\frac{1}{2}$ in. by 34 in. measured on the outside. At the extremity of each arm was a small opening about $\frac{1}{8}$ in. by $\frac{1}{4}$ in. in cross section through which the steam could issue. The openings were at the trailing edge of the arms so that rotation was achieved by the reactive-force of the steam. About 50 of these turbines were built for sawmills and wooduorking shops and at least one was tried on a locomotive. Although an efficiency approximately equal to that of contemporary steam engines was claimed. the turbines were abandoned because of their high noise level, difficult speed regulation and frequent need of repair.

It was not until the latter part of the 19th century that further significant contributions were made. Probably the most prominent among a number of early inventors in the steam turbine field was Sir Charles Parsons of England. He is recognized as the first to employ a large number of stages in series so that the energy release by the expanding steam could take place in small steps. It was this principle that opened the way for the development of the modern steam turbine. He also developed the reaction stage principle, in which pressure drop and energy release are equal through both the stationary and moving blades. Turbines- employing this principle are frequently called Parsons turbines in honour of the inventor.

Parsons' original ten-horsepower steam turbine was built in 1884 using a rotor and casing with attached multiple-stage blading, characteristic of modern turbines. Steam entered at the centre and flowed toward the ends.

Another prominent pioneer in the development of the steam turbine was Carl G. P. De Laval of Sweden. who first built a small 42,000-r.p.m. reaction turbine in 1883. Although several of these were later employed for driving cream separators. he did not consider them practical for commercial application. De Laval turned his attention to the development of reliable single-stage simple-impulse turbines similar to those with which his name is still associated. He is credited with being the first to employ a convergent-divergent type nozzle in a steam turbine in order to realize the full potential energy of the expanding steam in a single-stage machine.

During the period from 1889 to 1897 De Laval built a large number of turbines ranging in size from about 5 h.p. to several hundred. In 1892 he built a 15-h.p. turbine for marine applications uith two turbine wheels, one for forward motion and the other for astern operation. An early model similar to this was exhibited at the world's fair held in Chicago in 1893.

In addition to Parsons and De Laval two other pioneers in the field, C. E. A. Rateau of France and Charles G. Curtis of the United States, made important contributions. Rateau started his nork in 1894. He developed the multistage-impulse principle, now commonly known as pressure staging, in which pressure drop occurs only in the stationary nozzle elements and not in the moving blades. With this design, fewer stages are required than for a corresponding reaction-type turbine operating under the same steam conditions. Curtis began his work on steam turbines in 1897. He is responsible for the development of the velocity-compounded impulse stage in which two rows of moving blades are employed. In his design an intermediate row of stationary blading was inserted between the two moving rows in order properly to direct the steam from the first to the second moving row. He also developed the use of several velocity-compounded stages in series.

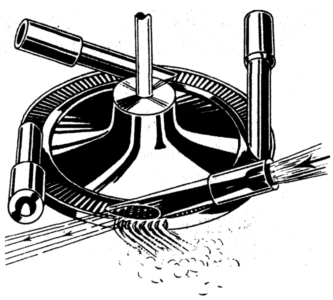

FIG. 1.—DE LAVAL WHEEL AND NOZZLES SHOWING DEVIATION OF THE STEAM JETS BY THE BUCKETS

Shortly after the turn of the century steam turbines began to replace steam engines as the principal prime mover in central station power plants. As a result developments were rapid and became associated chiefly with large companies rather than individuals. Improvement in both size and efficiency of units followed, leading to the commanding position now occupied by the steam turbine in the field of electric power generation.

Principal Components. — The principal components of a steam turbine are: (1) the rotor which carries the blading employed for converting energy of the steam into rotary motion of the shaft; (2) the casing or cylinder. inside which the rotor turns and which carries fixed nozzle passages through which steam is accelerated before being directed against the rotor blading; (3) the speed regulating mechanism by which the speed of rotation is governed;

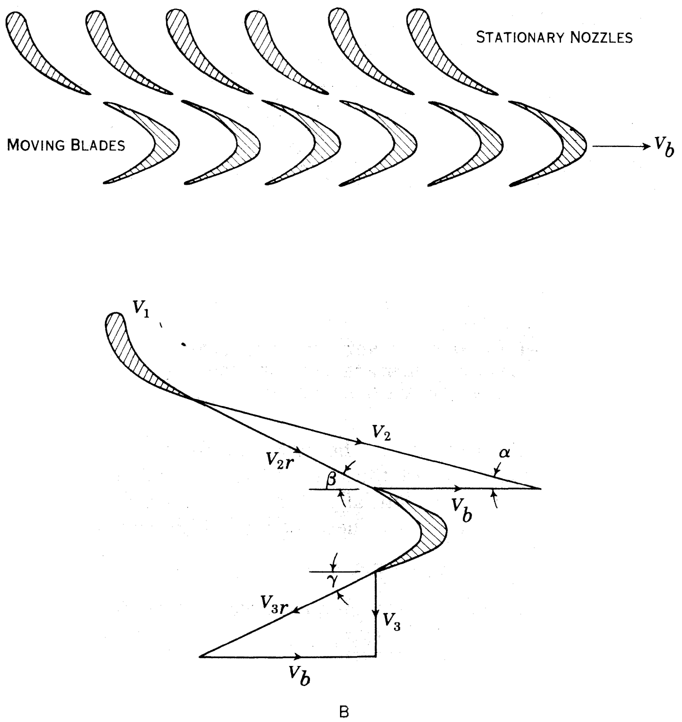
(4) the lubrication system for bearings and other apparatus associated with the turbine.

Of the various elements of the turbine, perhaps the most difficult to design properly is the blading, since it must have adequate strength and the correct aerodynamic shape to convert the energy of the steam into shaft work efficiently. Various types of blading and blading arrangements have been proposed but all are designed to take advantage of Newton's principle that when a given mass of substance suddenly changes its velocity, a force is exerted by the mass in direct proportion to the rate of change of velocity.

Two types of blading have been developed to a high degree of perfection. These are impulse blading and reaction blading.

The principle of impulse blading may best be illustrated by referring to fig. 1. This is a simplified diagram of a turbine rotor wheel showing four fixed nozzles directing high-velocity steam against blades mounted around the periphery. If there were no blades in the path of the steam, it would proceed in a straight line as indicated. However, the blades catch the impinging steam and turn it in the opposite direction, thus changing its velocity from a high value at entrance to a low value at exit. This decrease in velocity of the mass of steam produces a force on the rotor blading, causing the shaft, to which the blading is attached, to turn.

Proper operation of an impulse wheel similar to that illustrated in cross section in fig. 1 requires that the blading be of approximately symmetrical design and that it move past the nozzles with a speed approximately equal to one-half that of the steam issuing from the nozzles. A velocity diagram for such an arrangement is shown in fig. 2(B). In this diagram both magnitude and direction of steam velocity (V) at entrance and exit to the moving blades is indicated. When only a numerical subscript is employed, the velocity is relative to a stationary element of the turbine such as the fixed nozzles or casing. When the subscript r is added, the velocity is relative to the moving blades. Thus in fig. 2(B) the velocity of the moving blades is equal to V_b ft. per second while



BY COURTESY OF R. A. BUDENHOLZER

FIG. 2.— (A) ARRANGEMENT OF NOZZLES AND BLADING FOR A SIMPLE-IMPULSE TURBINE STAGE; (B) VELOCITY DIAGRAM FOR SIMPLE-IMPULSE TURBINE STAGE

that of the entering steam is equal to V_2 ft. per second. The relative velocity of the steam entering the moving blades is V_{2r}. Upon leaving the moving blades the steam has a relative velocity with respect to the moving blades equal to V_{3r} and a velocity V_3 with respect to the stationary elements of the turbine. It will be noted that V_2 is the vector sum of V_{2r} and V_b and that V_3 is the vector sum of V_{3r} and V_b. As indicated in the diagram, the blading turns the steam through a sharp angle, releasing it with about the same velocity, relative to the moving blades, as it had at entrance, but in the opposite direction. The result is that at exit the velocity component of the steam in the direction of the moving blades is approximately zero relative to the stationary elements of the turbine.

When reaction blading is employed the rotor is designed to turn at a speed approximately equal to that of the steam issuing from the nozzles, instead of half the velocity, as employed in an impulse stage. The steam thus enters the moving blades with almost zero relative velocity, as indicated in fig. 4(B). Also, the blades of the rotor of a reaction turbine are unsymmetrical and have a profile such that the space between blades forms nozzle passages. As the steam flous through these passages, it expands, thereby increasing its velocity relative to the blading. The acceleration of the steam creates a reactive force, turning the rotor in a direction opposite to that of the exit steam.

If the blading is designed to provide nozzle passages capable of building up an outlet relative velocity equal but opposite in direction to that of the moving blades, the steam will leave the moving blades with a component in the direction of movement approximately equal to zero relative to the stationary elements of the turbine.

It should be noted that with either type of blading, the over-all principle is the same, namely, that the velocity relative to stationary reference co-ordinates is first built up in the stationary nozzles, after which it is decreased in the moving blades. Energy stored in the steam is thereby first converted into kinetic energy and then into rotational shaft work.

Power Developed.—As already indicated, the magnitude and direction of steam velocity at entrance to and exit from the various passages in a turbine stage can conveniently be illustrated by means of a velocity diagram. With the aid of the velocity diagram illustrated in fig. 2(B) it is easy to compute the force of the steam acting on the blading of a simple-impulse stage. Employing Newton's law, one may write

$$F_b = \frac{w}{g}(V_{2r}\cos\beta + V_{3r}\cos\gamma) \tag{1}$$

where F_b is the component of force acting in the direction of the blade velocity, in pounds; w is the rate of flow of steam, in pounds per second; and g is the gravitational constant, in feet per second squared.

If the blading is symmetrical γ will equal β. Also, since the passages are not designed as nozzles, V_{3r} will equal V_{2r} and both may be replaced by $V_2\cos\alpha - V_b$, so that

$$F_b = \frac{2w}{g}(V_2\cos\alpha - V_b). \tag{2}$$

The power developed by the stage in foot-pounds per second will equal the force acting on the blading multiplied by the velocity with which the blades are moving. Hence,

$$P = F_b \times V_b = \frac{2w}{g}(V_2\cos\alpha - V_b)V_b. \tag{3}$$

To obtain the value of blade velocity resulting in maximum power output, equation (3) may be differentiated with respect to V_b and equated to zero. Thus

$$\frac{dP}{dV_b} = \frac{2w}{g}(V_2\cos\alpha - 2V_b) = 0. \tag{4}$$

Therefore

$$V_b = \frac{V_2\cos\alpha}{2}. \tag{5}$$

Substituting into equation (3) gives the maximum power of the stage

$$P_{\max} = \frac{wV_2^2\cos^2\alpha}{2g} = \frac{2wV_b^2}{g} \tag{6}$$

To express this in terms of horsepower, one need only divide by 550, the number of foot-pounds per second in one horsepower. Thus

$$hp_{\max} = \frac{2wV_b^2}{550g}.$$

To obtain greater power per stage with impulse blading the principle of velocity compounding may be employed. In this arrangement, the steam first passes through a row of nozzles and blades much as in the case of the simple-impulse stage but with a sufficient velocity to allow the steam to be redirected into a second row of moving blades as illustrated in fig. 3.

It can be shown by the use of Newton's law and trigonometric calculations similar to those carried out for the simple-impulse stage that a blade velocity equal to $\frac{V_2 \cos \alpha_1}{4}$ is required for maximum efficiency of this type of stage.

On this basis the maximum power obtainable is

$$P_{\max} = \frac{8wV_b^2}{g}. \tag{8}$$

This is four times as great as the power obtainable from a simple-impulse stage employing the same blade velocity. The reason for the increased power is that the velocity of the steam jet V_2 is tuice as great as for a simple-impulse stage. Its kinetic energy is therefore four times as great permitting the development of four times as much power.

It should be pointed out that although four times as much power is obtained with velocity compounding. four times as much thermal energy has to be expended in order to achieve this greater power. Velocity compounding, therefore, does not achieve more power for the same expenditure of thermal energy but merely permits a greater jet velocity for the same blade velocity. Since blade velocity is limited by the allouable centrifugal force, the use of velocity compounding permits a greater release of thermal energy per stage and hence fewer stages are required to accommodate a given thermal energy.

With impulse blading, an increase in velocity of the steam is achieved only in the stationary nozzle passages. In the case of reaction blading it is achieved in both the stationary nozzle passages and in the passages between the moving blades. This increase may be observed by referring to fig. 4(B), which is a velocity diagram for a 50% reaction-type stage. The term 50% reaction has reference to the fact that only 50% of the energy of the stage is released in the stationary nozzle passages, the other 50% being reserved for release in the moving blades. It will be noted from fig. 4(A) that both stationary and moving blades have the same profile. and that both form nozzle passages. This blading is in contrast with that of impulse stages in which the moving blades are symmetrical in shape and do not form nozzle passages.

In fig. 4(B) it will be noted that, just as in the impulse stage, the velocity in the stationary nozzles is built up to a value equal to V_2. However, since the blades are moving with the velocity V_b, the steam enters these with a relative velocity equal to V_{2r}, having no component in the direction of movement of the blades. In passing through the blading, the steam is accelerated to the velocity V_{3r}. In the ideal case V_{3r} is made approximately equal to V_2 so that the steam leaves the moving blades with a relative exit velocity component equal but opposite in direction to that of the moving blades.

Hence the velocity of the leaving steam, relative to stationary elements of the turbine, is V_4. This velocity has no component in the direction of rotation of the blading and is therefore correct to enter smoothly into the next row of stationary nozzles. In the reaction blading shown, the velocity component of the steam in the direction of rotation has been changed during passage through the moving blades from zero at entrance to $V_{3r} \cos \alpha = V_b$ at exit. This change creates a reactive force against the moving blades given by the equation

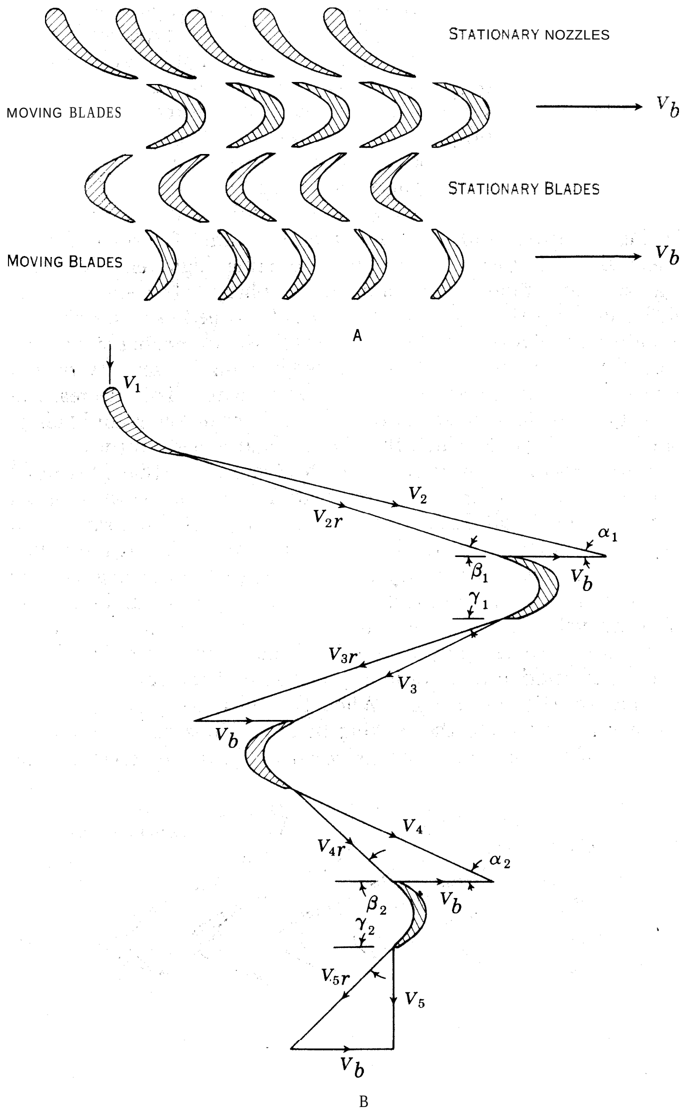
$$F_b = \frac{w}{g} V_b \tag{9}$$

where, as before, w is the flow through the blading in pounds per second. The maximum power developed by the stage will therefore be

$$P_{\max} = \frac{wV_b^2}{g}. \tag{10}$$

This is just half the power capable of being developed in a single-impulse stage having the same blade velocity and one-eighth that capable of being developed in a velocity-compounded stage of the same blade velocity.

Stage Efficiency.—The efficiency of a turbine stage may be defined as the power output divided by the energy expenditure required to produce that power. If it is assumed that between



BY COURTESY OF R. A BUDENHOLZER

FIG. 3.—(A) ARRANGEMENT OF NOZZLES AND BLADING IN A VELOCITY-COMPOUNDED IMPULSE TURBINE STAGE WITH TWO ROWS OF MOVING BLADES: (B) VELOCITY DIAGRAM FOR A VELOCITY-COMPOUNDED IMPULSE TURBINE

impulse stages the velocity of the steam is essentially zero. the velocity V, at the outlet of the nozzles must be achieved at the expense of thermal energy initially stored in the steam. The required energy is equal to the kinetic energy of the steam leaving the nozzles, $\frac{wV_2^2}{2g}$ ft.lb. per second.

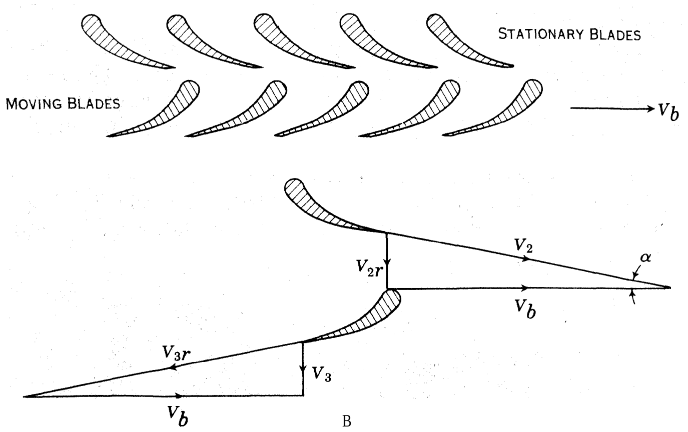
The maximum efficiency of a simple-impulse stage is therefore

$$e_s = \frac{P_{\max}}{\frac{wV_2^2}{2g}} = \frac{\frac{2wV_b^2}{g}}{\frac{wV_2^2}{2g}} = \frac{4V_b^2}{V_2^2} = \cos^2\alpha. \tag{11}$$

Similarly, for a velocity-compounded impulse stage the maximum efficiency will be

$$e_s = \frac{P_{\max}}{\frac{wV_2^2}{2g}} = \frac{\frac{8wV_b^2}{g}}{\frac{wV_2^2}{2g}} = \frac{16V_b^2}{V_2^2} = \cos^2\alpha. \tag{12}$$

In the 50% reaction stage the velocity V_2 must first be achieved by expansion through the stationary nozzles after which the velocity V_{3r} must be attained by expansion through the moving blades. Thus, two expansions are required at a sacrifice of stored



BY COURTESY OF R A BUDENHOLZER

FIG. 4.— (A) ARRANGEMENT OF NOZZLES AND BLADING IN A 50% REACTION-TYPE TURBINE STAGE; (B) VELOCITY DIAGRAM FOR A 50% REACTION-TYPE TURBINE STAGE

energy in the steam equal to $\dfrac{w(V_2^2+V_{3r}^2)}{2g}$ ft.lb. per second.

Since for this type of stage, V_{3r} is equal to V_2, the input is $\dfrac{wV_2^2}{g}$ and the efficiency is

$$e_s \equiv \frac{P_{\max}}{\dfrac{wV_2^2}{g}} = \frac{\dfrac{wV_b^2}{g}}{\dfrac{wV_2^2}{g}} = \frac{V_b^2}{V_2^2} = \cos^2\alpha. \tag{13}$$

It will be noted that the efficiency for all three types of stage is $\cos^2\alpha$, indicating that regardless of the type employed, the theoretical maximum efficiency is the same. In all types the smaller the angle α, the closer will the efficiency approach its maximum value of unity which occurs when a is zero. Normally the smallest value of a that will permit adequate flow through the blading is between 12° and 20°, making an efficiency of unity a physical impossibility. Also. in actual turbine stages there are numerous other losses such as wall friction, eddy current, turbulence and leakage losses. All serve to reduce the efficiency to well below $\cos^2\alpha$. Efficiency of turbine stages also varies nith the ratio of blade velocity to steam jet velocity. The manner in which this change occurs can be observed by referring to fig. 5 illustrating the variation of stage efficiency with velocity ratio for three different types of stage. The curves shonn are typical of actual stages and therefore incorporate the various losses mentioned above. It will be noted that the maximum efficiency of the velocity-compounded stage nith two rows of moving blades tends to be less than that of the simple-impulse stage, and that both tend to have a loner maximum efficiency than the reaction-type stage. In general, velocity-compounded stages are avoided except for the first control stage of turbines.

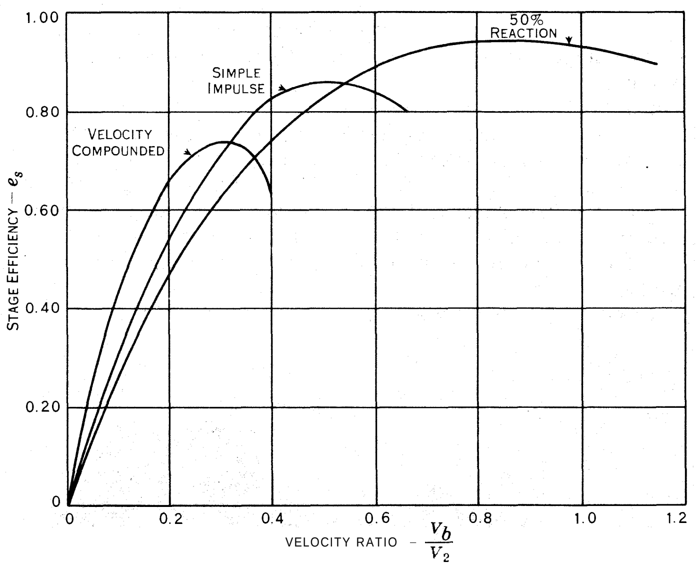
Turbine Staging.— In modern turbines a large number of stages arranged in sequence are required because the total energy release per pound of steam cannot be achieved in a single stage. There are several reasons for this, the most important of which are the folloning. (1) Steam in expanding through a modern turbine often enters under a pressure in excess of 2,000 lb per square inch and exhausts under a pressure below 1 lb. per square inch absolute. This means a several-hundredfold increase in volume of flon betneen entrance and exit. Such large expansions cannot be accommodated efficiently by a single stage because the cross-sectional area perpendicular to the flow would have to increase several hundred times through a single row of nozzle passages and one or two roms of moving blades. (2) By breaking the expansion into small steps, more efficient nozzle and blade passages can be designed. In this manner the proper velocity relationship can be realized to best accommodate conversion of energy in the steam into shaft work. (3) Centrifugal and other forces acting on the blading limit its maximum tip velocity to values that will not permit the efficient use of as few as one stage, even if all of the other factors were favourable to such an arrangement.

In modern steam turbines, three types of staging are often employed, either separately or in combination. These are velocity-compounded staging, pressure staging and reaction staging.

Velocity-Compounded Staging.— Velocity-compounded staging is well suited for small turbines in which the steam, after passing through the turbine, exhausts to a heating system or to some other use in which the pressure is atmospheric or higher. Such a turbine is illustrated in the cutaway view of fig. 6. This view clearly shows the admission valve which is controlled by a governing mechanism capable of rationing steam to the nozzles in accordance with power and speed requirements. The path of the steam through the admission valve, nozzles and turbine blading is clearly illustrated.

In addition to its use in small single-stage machines, velocity-compounded stages are frequently employed as the first of a number of stages in large industrial and central station type turbines. In this application the velocity-compounded stage serves as a control stage, and offers a powerful means of quickly changing the turbine output in response to the slightest change in steam flow as dictated by the governing mechanism. Velocity-compounded staging also permits a large drop in pressure and temperature before the steam enters the first moving blades of the turbine. This drop makes possible the use of higher initial temperatures and pressures without the use of special heat-resistant alloys that are very expensive and difficult to machine. In addition, the specific volume of the steam flowing through the blading is greater, allowing the use of longer blades, which results in lower frictional losses between the steam and the retaining walls of the blading and casing.

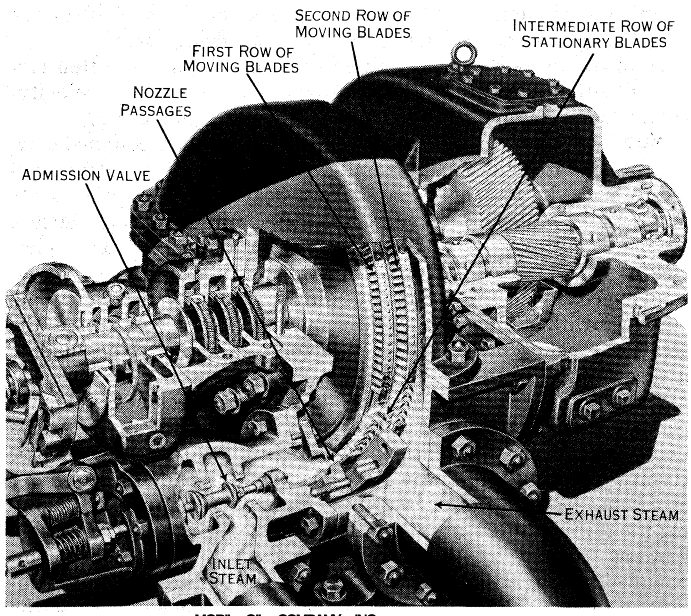
Pressure Staging.— The second type of staging mentioned, pressure staging, is simply the use of a large number of simple-impulse stages in sequence. Turbines using this principle employ a large number of stages, each contributing a small fraction to



BY COURTESY OF R A BUDENHOLZER

FIG. 5.— RELATIONSHIP OF STAGE EFFICIENCY AND VELOCITY RATIO FOR VARIOUS TYPES OF TURBINE STAGES

the total power output. A large central station turbine employing this type of staging is illustrated in fig. 7. The particular design shown is built in sizes from 50,000 to 100,000 kw. rated load, with steam inlet pressures ranging from 1,450 to 1,800 lb. per square inch gauge and temperatures ranging from 1,000° to 1,050° F. Typical of most modern machines, the turbine is equipped for return of the steam to the boiler for reheating after expansion through the first few high-pressure stages. Following reheat, the steam is again returned to the turbine where it continues its expansion through the intermediate-pressure section and on into



BY COURTESY OF SOCONY MOBIL OIL COMPANY, INC

FIG. 6.—CUTAWAY VIEW OF A SINGLE-STAGE VELOCITY-COMPOUNDED TURBINE

the low-pressure section. Here it is divided into two paths, each flowing in opposite directions to opposite ends of the exhaust hood. From the exhaust hood the steam passes into a condenser where it is liquefied and returned to the boiler for re-evaporation into steam.

Reaction Staging.—Reaction staging is similar to pressure staging except that a number of reaction stages are employed in sequence. Turbines using this principle require about tnice as many stages as corresponding machines employing pressure staging. The cost, however, is about the same because blading for pressure staging must be stronger and therefore more rigidly constructed.

In fig. 8 is shown a sectional view of a reaction turbine with the various important parts designated. Also shown is a view of the exposed turbine rotor and another of the steam chest and multiple steam admission valves. It will be noted that in this machine the first stage is a velocity-compounded stage rrith two rows of moving blades. The two rows are clearly discernible in the exposed view of the rotor. This is a typical arrangement for turbines of this size.

Flow Characteristics.—In fig. 9 are presented blade cross sec-

FIG. 7.—TANDEM-COMPOUND, DOUBLE-FLOW, REHEAT STEAM TURBINE

tions illustrating the variation of pressure, temperature, specific volume and velocity through the three types of staging discussed above. Each diagram is drawn employing the number of stages required to produce the same theoretical power output when using the same blade velocity. In every case ideal theoretical velocity ratios are employed and the same jet angle α is used.

Fig. 9(A) is a velocity-compounded stage in which the entire pressure drop occurs in the stationary nozzle passages. The result is a large drop in pressure and temperature and a large increase in specific volume and velocity. As the steam flows through the remainder of the stage its pressure. temperature and specific volume remain constant but its velocity is decreased in two steps as shown. In the first row of moving blades the velocity drops to about half its initial value. Through the stationary blading

(B) Exposed turbine rotor. (C) Steam chest showing multiple admission valves

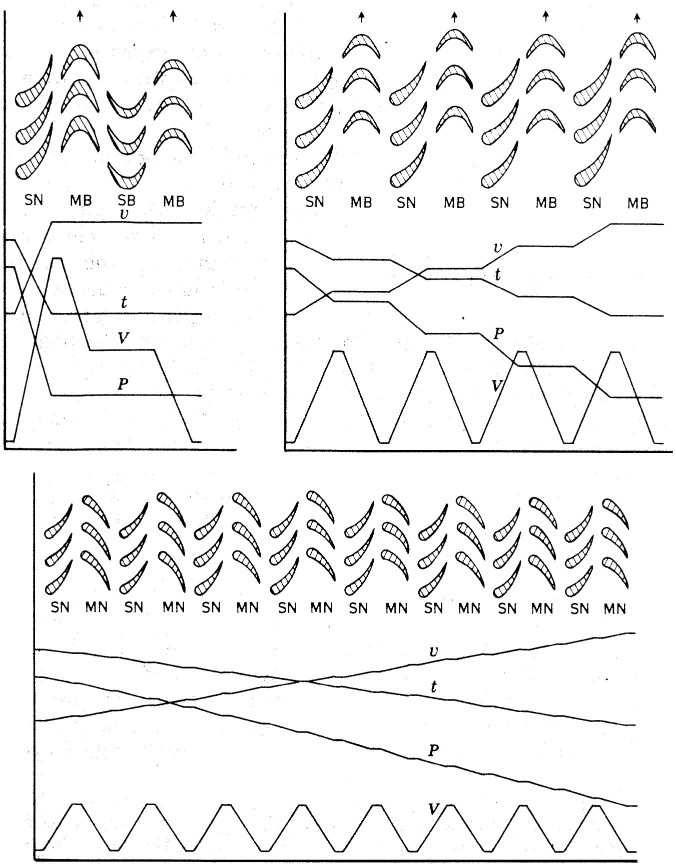
the magnitude of the velocity remains unchanged but its direction is altered.

After entering the second row of moving blades its value is decreased to almost zero at exit. Thus the kinetic energy stored in the steam, after leaving the stationary nozzles, is converted into work in two steps, each in a different velocity range. Hence the term velocity-compounded stage.

Fig. 9(B) is a diagram of the flow pattern through a group of four simple-impulse stages in series theoretically capable of developing the same power as the single velocity-compounded stage of fig. 9(A). In this case the velocity is built up in each row of stationary nozzles and reduced in each row of moving blades. As indicated, the over-all pressure and temperature drop and overall increase in velocity are the same as for the single velocity-compounded stage. It will be noted that the pressure drop occurs in four approximately equal steps, giving rise to the name pressure staging by which this type of arrangement is most commonly known.

A group of eight 50% reaction stages equivalent to the single velocity-compounded stage of fig. 9(A) or the four pressure stages of fig. 9(B) is illustrated in fig. 9(C). Here it will be noted that pressure and temperature drop occurs across the moving blades as well as the stationary nozzles. Although the specific volume increases, the velocity relationship of the moving blades relative to the stationary nozzle is such that the velocity relative to the stationary elements of the turbine is alternately built up and decreased as indicated. This alternation is true even though an expansion takes place relative to the moving blades as illustrated in fig. 4(B).

Performance Characteristics.— The performance of a steam turbine is measured in terms of the "turbine heat rate." which is a measure of the heat that must be supplied to the steam in order to produce a specified power output. For central station applications the turbine is always connected directly to an electrical generator and the combination is called a turbogenerator. The turbine heat rate for this type of machine is defined as the number of British thermal units (B.Th.U.) of heat that must be added to the steam in order to produce one kilowatt-hour of electrical power output.



SN= STATIONARY NOZZLES MB= MOVING BLADES P= PRESSURE V= VELOCITY

FIG 9 — VARIATION OF PRESSURE TEMPERATURE. SPECIFIC VOLUME AND VELOCITY RELATIVE TO STATIONARY ELEMENTS OF THE TURBINE FOR THREE DIFFERENT TYPES OF STAGES

(A) Velocity compounded stage, (B) group of four simple-impulse stages (pressure staging), (C) group of eight 50% reaction stages. Each group develops the same amount of power

In the case of a turbine not connected to an electrical generator, the heat rate is usually expressed in terms of B.Th.U. per horsepower-hour output.

The turbine heat rate depends upon a large number of factors. the most important of which are the following: (1) pressure and temperature of the inlet steam: (2) exhaust pressure; (3) internal efficiency of the turbine, a measure of effectiveness with which the energy in the steam is converted into work; (4) exhaust loss, the kinetic energy loss associated with the high velocity of exhaust; (j) mechanical losses; (6) generator losses. With the exception of the first two factors. the above all depend to some extent upon the fraction of rated load being carried by the turbine.

In general. the turbine heat rate increases with decrease in load. This inverse relation means that more steam is required to generate a unit of output at low load than at high load.

A diagram illustrating the heat supplied to each pound of steam passing through a typical turbine. and its ultimate disposition. is shown in fig. 10. The diagram is plotted with the heat content per unit mass (enthalpy) of steam as ordinates and entropy as abscissas (see STEAM: Properties of Steam). The chart is commonly called a Mollier chart and has the advantage of showing heat and energy quantities in terms of length of lines measured parallel to the direction of the ordinate. Thus difference in enthalpy quantities are representative of heat and work insofar as operation of the turbine is concerned.

For simplicity, a turbine operating on the simple Rankine cycle (see STEAM: Steam *Power* Plants) has been chosen. In this type of cycle no steam is extracted from the turbine for heating feed water on its way to the boiler.

Referring to the diagram, various efficiencies of the turbine may be defined as follows:

$$\text{Generator efficiency} = \eta_g = \frac{\text{generator output}}{\text{mechanical output}} = \frac{h_1 - h_2''''}{h_1 - h_2'''}$$

$$\text{Mechanical efficiency} = \eta_M = \frac{\text{mechanical output}}{\text{mechanical input}} = \frac{h_1 - h_2'''}{hi - h_2''}$$

$$\text{Internal efficiency} = \eta_i = \frac{\text{steam output}}{\text{available energy}} = \frac{h_1 - h'_2}{h_1 - h_2}$$

$$\text{Engine efficiency} = \eta_e = \frac{\text{generator output}}{\text{available energy}} = \frac{h_1 - h_2''''}{h_1 - h_2}$$

$$\text{Thermal efficiency} = \eta_t = \frac{\text{generator output}}{\text{total energy input}} = \frac{h_1 - h_2''''}{h_1 - h_2}$$

It should be pointed out that in the above equations and in fig. 10 the symbols h_2''' and h_2'''' do not represent true enthalpies of the steam at the points indicated, but are energy quantities per pound of steam which can be used in lieu of enthalpy in order to make possible easy representation of the mechanical and generator losses both in the equations and on the Mollier chart. The quantity h_2'' represents the enthalpy which the steam exhausting from the condenser would have if its kinetic energy were converted into enthalpy and added to h_2'. The term h_2' is the enthalpy actually possessed by the steam exhausting to the condenser.

In turbines designed for central station power plants provision is made for withdrawing portions of the steam supplied to the turbine at several locations along the path of flow from inlet to condenser. This steam is used for feed-water heating. When steam is withdrawn in this manner the generator output per pound of throttle steam is obtained by summing up values of the flow between extraction points multiplied by the corresponding enthalpy drops between extraction points.

For central station steam turbines the following efficiencies are typical:

Generator efficiency	0.97–0.99
Mechanical efficiency	0.98–0.99
Internal efficiency	0.83–0.87
Engine efficiency	0.75–0.80
Thermal efficiency without extraction	0.25–0.35
Thermal efficiency with extraction	0.30–0.40

The heat rate of a turbogenerator may readily be found by dividing 3,413 by its turbine thermal efficiency. Thus for a turbine having a thermal efficiency of 0.30 the heat rate will be $\frac{3{,}413}{0.30} = 11\ 378$ B Th U. per kilonatt-hour.

Classification of Steam Turbines.— Turbines may be classified as condensing or noncondensing, depending upon whether or not the steam is exhausted to a condenser. Noncondensing turbines are those in which steam, after expsnding through the turbine, is exhausted to the atmosphere, to a heating system or to some other type of equipment. Their most frequent application is in industrial plants where steam is needed at low or intermediate

withdrawal of variable quantities of constant-pressure steam from one or more extraction points along the path of flow. regardless of how much load is being carried by the turbine. Such turbines are widely used in industrial power plants where steam is needed at one or more pressures for process work. Since it is desired to hold both extraction pressure and speed constant, regardless of power requirements, a complicated system of governing is required. This makes the turbines more expensive than either bleeder or straight-through turbines. Automatic-extraction turbines may be designed for either condensing or noncondensing operation.

Modern Trends.— The ever-increasing demand for electrical energy, together with the soaring cost of fuel. has stimulated the building of larger and larger turbines with higher and higher efficiencies. To secure the highest possible thermal efficiency, it is necessary to raise the pressure and temperature of the inlet steam to very high values.

During the decade 1930 to 1940, typical pressures and temperatures were around 1,200 lb. per square inch gauge and 900° F. In the following decade. 1940 to 1950, steam conditions of the order of 1,800 lb. per square inch became common, and temperatures as high as 1,050° F. were introduced. The decade 1950–60 witnessed the introduction of supercritical pressure plants, some operating with initial pressures beyond 6,000 lb. per square inch gauge and temperatures of the order of 1,100° F. These units are built with provisions for interrupting the flow of steam through the turbine and returning it to the boiler for reheat at least once and often twice during its passage from inlet to exhaust. In addition to reheat provisions, the turbines are also equipped with a large number of openings for extraction of steam for feed-water heating as required in a modern regenerative cycle plant.

pressures and where by-product power can be generated economically by inserting a noncondensing turbine between the steam generator and the equipment requiring steam.

Condensing turbines are those in which steam, after passing through the turbine, is exhausted into a condenser. Condensation is effected by the circulation of large quantities of cold water through the tubes of the condenser. The circulating water absorbs the latent heat of the steam and carries it away. The process of continuous condensation maintains a low pressure in the condenser, thus increasing the expansion ratio of the steam and the consequent efficiency and work output of the turbine. Because of the necessity of maintaining the highest possible efficiency, all central station power plants employ condensing turbines. These are connected directly to large electrical generators capable of generating power at high voltage. The power is carried by high-tension lines to substations where it is reduced in voltage and distributed to the consumer.

An additional classification of turbines may be made on the basis of whether or not a portion of the steam is extracted from the turbine during passage through the machine and in what manner the extraction takes place. On this basis turbines may be classified as (1) once-through turbines; (2) bleeder turbines; (3) automatic-extraction turbines.

Once-through turbines are those in which there are no bleed points and all steam supplied to the admission valves passes all the way through the turbine and out the exhaust. The energy breakdown contained in fig. 8 is for this type of turbine.

Bleeder turbines are those in which provisions are made for feed-water heating. This is accomplished by the withdrawal of steam at various locations along its path of flow through the turbine for the purpose of heating feed water on its way to the boiler. In bleeder turbines no attempt is made to control the pressure of the steam extracted. Because of this. extraction pressure automatically varies in almost direct proportion to the load being carried by the turbine. The principal advantage of a bleeder turbine over a once-through turbine is that steam bled from the turbine for the purpose of feed-water heating does not flow to the condenser. Its latent heat is therefore retained in the cycle. Another advantage is that the exhaust area of the turbine can be smaller because less steam flows to the condenser.

The use of bleed-point steam for feed-water heating is universal in central station power plants because it increases the thermal efficiency of a plant by 10% to 15%. In most cases the fraction of steam withdrawn is about 30% of the steam initially supplied at the turbine inlet.

Automatic-extraction turbines are machines designed for the

TURBINE: WATER. Modern hydraulic turbines may be divided into two classes, impulse, and pressure or reaction turbines. Of the former the Pelton wheel, and of the latter the Francis turbine or one of its modifications, are the only types used in recent important installations.

In an impulse turbine, the whole head of the supply water is converted into kinetic energy before the wheel is reached. The water is supplied to the wheel through a nozzle which delivers a high velocity jet at atmospheric pressure on to the vanes or buckets mounted on the periphery of the wheel.

In the pressure or reaction turbine, the wheel or runner is provided with vanes into which water is directed by a series of guide vanes extending around the whole periphery. The water on leaving these guide vanes is under pressure, and supplies energy partly in the kinetic and partly in the pressure form. In its passage through the runner the pressure energy is utilized in increasing the relative velocity of flow between the vanes, and the water finally leaves the runner at the pressure obtaining in the discharge pipe or draft tube.

In the earliest of these turbines, the Fourneyron, the guide vanes were inside the runner, and the water flowed outward. This was followed by the Jonval turbine, in which the guide vanes are

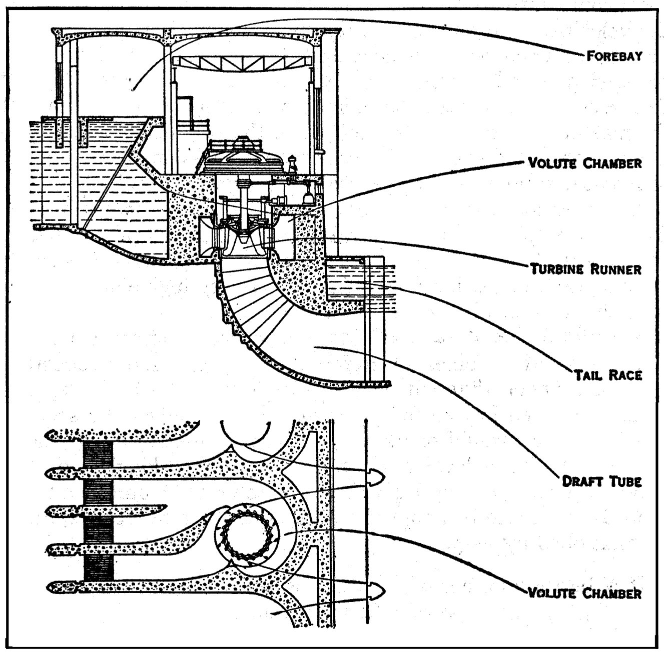
above the runner and the water flows axially into and through the wheel. Both types are now obsolete, and one or other modification of the Francis or inward-flow turbine, in which the guide vanes surround the outer periphery of the runner, is now in general use.

The supply of water to the runner depends upon the opening between the guide vanes. These are pivoted on stems which project through stuffing boxes in the turbine casing. Each stem carries a lever. These are all coupled to a regulating ring whose position is regulated by the governing mechanism, so that all the guide vanes are opened or closed simultaneously.



FROM GIBSON, "HYDRO-ELECTRIC ENGINEERING" (BLACKIE & SON)

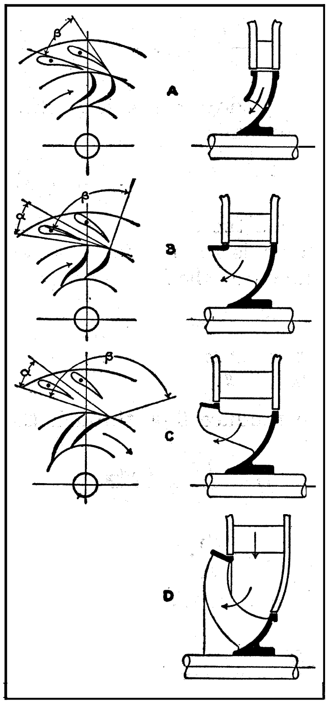
FIG. 2.— DETAILS OF HIGH HEAD FRANCIS TURBINE WITH CAST IRON VOLUTE

In a low-head installation the turbine may be erected in the open forebay or supply canal. This method has the disadvantage that the guide-vane mechanism is submerged and cannot be inspected or repaired without draining the wheel pit, and in most recent installations, even of the low-head type, the guide-vane ring is surrounded by a spiral volute chamber, from which the pressure water is delivered with uniform velocity around the entire periphery of the guide ring. For heads not exceeding about 100 ft., modern practice favours the moulding of the volute chamber in the concrete of the substructure (fig. 1). For higher heads, considerations of strength necessitate a metal casing, to which the water is supplied through a pressure pipe line (fig. 2). The turbine runner is usually of cast iron, although where corrosion or erosion is to be anticipated, it may be made of cast steel if large, and of phosphor bronze if small.



FROM GIBSON. "HYDRO-ELECTRIC ENGINEERING" (BLACKIE & SON)

FIG. 3.— TYPES OF TURBINE RUNNER

A. For high heads and comparatively low speeds. B. For medium heads and moderate speeds. C. For medium heads and high speeds. D. For low heads and high speeds

The general changes in the shape and proportions of the runner which have accompanied recent development of the low head high-speed turbine are indicated in fig. 3. The change has been generally in the direction of increasing the axial depth of the buckets, and at the same time of maintaining or increasing the ratio of the discharge area at exit to that at entrance. At the same time the width of the buckets in the direction of flow has been reduced. An extreme example is shown in fig. 3D, in which flow through the wheel itself is almost axial. In many recent low-head turbines the runners are of the propeller type. They are characterized by the fewness of the vanes, as few as three or four in many cases, and are in appearance very like the ordinary ship's propeller.

The Draft Tube.—In order to avoid the flooding of the turbine house by any raising of the tail race level in time of floods it is usually necessary to instal the turbines at some higher elevation, and if the turbines were provided with open discharge pipes, freely discharging into the atmosphere, the proportion of head represented by the elevation above tail water level would be lost. By arranging the discharge, or draft tube, so that the outlet is always submerged, it becomes possible, however, to place the turbine above tail water level without loss of head. The pressure at the point of discharge from the runner into the draft tube is now less than atmospheric by an amount which depends upon the elevation above tail water level.

The draft tube also, if well designed, serves a further purpose in that it enables a large proportion of the kinetic energy of discharge from the runner to be converted into pressure head, and so to be utilized. For this the tube must be designed with a gradually increasing diameter, so that the velocity is gradually reduced from v_1 to v_2 before discharge (fig. 4). The velocity of discharge from the draft tube should not exceed about 4 f.s.

Hydraulics of the Reaction Turbine. — In the following discussion let ω =angular velocity of the runner in radians per second ($\omega = 2\pi N \div 60$ where $N=$ revolutions per minute); $u=\omega v=$velocity of wheel at point indicated by a suffix; $v=$absolute velocity of water; $w=$tangential component of v; f =radial component of v; $v=$relative velocity of water and vane; $\alpha=$ guide vane angle; β =wheel vane angle at entrance; γ =wheel vane angle at exit; Q=flow in c.f.s.; W=weight of 1 cu.ft. of water; suffix (2) refer to inlet to wheel vanes; suffix (3) refer to exit from wheel vanes.

For entry without shock, the direction of the relative velocity of water and vane at the entrance to the wheel must be parallel to the vane tips, and a consideration of the diagram of velocities (fig. 4) shows that if the angles are correctly proportioned:

$$f_2 = w_2 \tan\alpha = (w_2 - u_2)\tan\beta;\ \therefore\ u_2 = w_2\left(1 - \frac{\tan\alpha}{\tan\beta}\right).$$

$$f_3 = (u_3 - w_3)\tan\gamma;\ 2v_r = f_2 \operatorname{cosec}\beta;\ 3v_r = f_3 \operatorname{cosec}\gamma.$$

The change of the moment of momentum in the wheel = turning moment $\left\{ -\frac{WQ}{g}(w_2 r_2 - w_3 r_3)\right.$ ft. lb.

$\therefore$ Work done per second on runner $= \frac{WQ}{g}(w_2 u_2 - w_3 u_3)$ ft. lb.

In an ideal wheel, with no friction or eddy losses, neglecting changes of level in the wheel, we should have

$$\frac{p_2}{W} + \frac{v_2^2}{2g} = \frac{p_3}{W} + \frac{v_3^2}{2g} + \text{work done per pound between (2) and (3).}$$

The efficiency will be a maximum when the energy rejected in the discharge is a minimum, *i.e.*, when v_3 is a minimum, or when w_3 is zero, in which case $v_3 = f_3$. Assuming the wheel to be designed for this state of affairs,

$$\frac{p_2}{W} + \frac{v_2^2}{2g} = \frac{p_3}{W} + \frac{f_3^2}{2g} + \frac{w_2 u_2}{g}.$$

Writing H as the head available to produce flow through the wheel, so that

$$H = \frac{p_2}{W} + \frac{v_2^2}{2g} - \frac{p_3}{W},\ \text{we have}\ H = \frac{f_3^2}{2g} + \frac{w_2 u_2}{g},$$

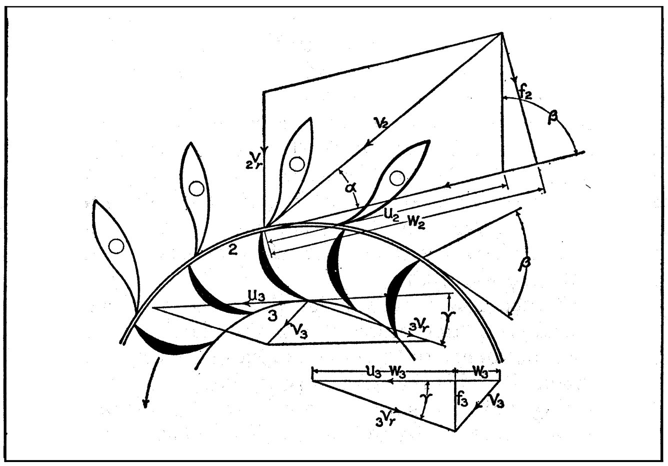
from which, writing $f_3 = f_2 \frac{b_2 r_2}{b_3 r_3} = w_2 \tan\alpha \frac{b_2 r_2}{b_3 r_3}$,

where b and r are the breadth and radius of the wheel, we get, on substitution,

$$w_2 = \sqrt{\left[\frac{2gH}{2 + \left(\frac{b_2 r_2}{b_3 r_3}\tan\alpha\right)^2 - 2\frac{\tan\alpha}{\tan\beta}}\right]}$$

while $u_2 = w_2\left(1 - \frac{\tan\alpha}{\tan\beta}\right)$, and $Q = A_2 f_2 = A_2 w_2 \tan\alpha$.

Thus in a wheel of given design, the peripheral speed for maximum efficiency, and the volume of discharge, each vary as $\sqrt{H}$,



FROM GIBSON, "HYDRO-ELECTRIC ENGINEERING" (BLACKIE & SON)

FIG. 4.— VELOCITY DIAGRAM FOR ENTRANCE AND EXIT OF FRANCIS TURBINE

while the output of the turbine, being proportional to the product QH, varies as $H^{\frac{3}{2}}$.

The hydraulic efficiency, $\eta = \frac{\text{work done per pound}}{H} = \frac{w_2 u_2}{gH}$.

By suitable adjustment of the vane angles α and β the, peripheral speed for a given head may be varied between wide limits. For high speeds the vane angle should be large. As β is increased the value of f_2 and hence the volume of water passing a wheel of given size diminishes, so that to obtain the same output the size of the wheel must be increased. If, as is usually the case in low-head plants, a high rotative speed is required, the inlet area is increased by increasing the depth of the runner. Such a turbine has a comparatively large ratio of inlet area to discharge area, and the velocities of discharge are relatively high. For high heads β may be between 60° and 90°, and, for medium and low heads, between 90° and 135°. Similarly, while the hydraulic efficiency decreases as α increases, the volume of flow increases with a , and the maximum output is obtained when the product of Q and η is a maximum. For high efficiency α should be as small as mechanical considerations permit, generally between 12° and 18°.

In one modern turbine, the Kaplan, the wheel vanes are not fixed but are pivoted on a central drum, and their leading angle β can be adjusted while running so as to suit any variations in the working head or discharge. In this way a very high efficiency may be maintained at all loads.

Specific Speed of a Turbine.— In order to afford a basis of comparison of turbines of different diameters and proportions operating under different heads, the term known as "specific speed" has been introduced. This may be defined as the speed at which a runner would operate if reduced geometrically to such a size that it would develop 1 h.p. under unit working head. The figures for specific speed given below refer to a unit head of 1 foot. If the metre be adopted as the unit, these figures require to be multiplied by 4.45.

If N be the number of revolutions per minute,
„ P „ „ horsepower of the turbine,
„ H „ „ working head in feet,

the specific speed $N_S = \frac{N\sqrt{P}}{H^{\frac{5}{4}}}$ revs. per minute.

The specific speed of a reaction turbine may be varied by varying the diameter of the runner, the angle of the guide vanes and the angle of the wheel vanes. By modifying the design as indicated in the sketches of fig. 3 it is possible, while maintaining high efficiencies at full load, to increase the specific speed from about 15, its minimum value with the type shown in fig. 3A, to about 125 with the type shown in fig. 3D. Specific speeds as high as 150 are possible with some sacrifice in efficiency, and it is probable that further developments will see the value increased still farther. These high specific speeds are extremely valuable for low-head installations since they enable the size and cost of the turbine and of the generator to be greatly reduced. In fact, many existing low-head installations would have been commercially impracticable but for the development during recent years of the high-speed turbine.

High specific speeds are, however, attended by some disadvantages. The part-gate efficiency in general falls off as the specific speed increases. Also if the speed is unduly high it becomes very difficult to avoid very high local velocities and centres of low pressure in the runner, which invariably give rise to severe corrosion. At the present stage of design, the maximum specific speeds to be used under normal circumstances with various heads are approximately as follows:

Head (feet)	20	40	60	80	100	150	200	300	400	600
Specific speed r. p. m.	125	100	85	75	65	50	43	33	30	25

The reaction turbine may be built either as a horizontal or vertical shaft machine. The latter type, having the weight of the rotating parts supported by a thrust bearing of the Michell or Kingsbury type, has been gaining in popularity of recent years.

The Pelton Wheel.— This is usually built as a horizontal shaft machine and consists of a runner carrying a series of buckets around its periphery on which impinge one—or in exceptional cases two—high velocity jets from a nozzle or nozzles at the end of the supply pipe line (fig. 5). The buckets are spoon shaped and have a central sharp ridge which divides the impinging jet into two halves which are deflected backwards by the buckets through about 165°. The modern Pelton wheel is always fitted with a circular nozzle, with an axial needle or spear for regulating the size of the jet. The maximum diameter of jet as yet adopted is about 12 inches. The axial position of the needle in the nozzle is regulated by the governing mechanism in all important installations.

The Pelton wheel, being essentially a high head turbine, is usually supplied through a comparatively long pipe line, and any

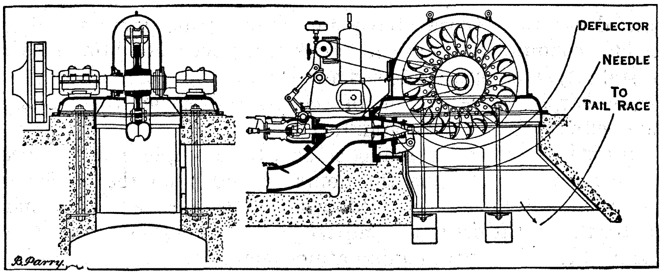


FIG. 5.— PELTON WHEEL WITH SINGLE NOZZLE

rapid closing of the nozzle such as might occur if the load were suddenly thrown off, would set up severe surges of pressure in the pipe line which would not only prevent close speed regulation but might be dangerous. To prevent this, modern Pelton wheels are also fitted with a jet deflector, consisting of a curved plate pivoted between the nozzle and the buckets, which is operated by the governor and which when in action cuts into the jet and deflects it either wholly or partially into the tail race. The governing mechanism is so arranged that when load is thrown off the wheel, the deflector at once comes into play, deflecting the jet from the buckets. The needle then begins to move slowly towards the closed position, and at the same time the deflector moves slowly back towards its idle position. Ultimately both come to rest with the deflector just clear of the jet, and with the diameter of the latter so adjusted as to give the required supply of water to the wheel.

Hydraulics of the Pelton Wheel.—If H be the pressure head behind the nozzle, in feet, the velocity of efflux is $C_v\sqrt{2gH}$ ft. per second, where C_v, the coefficient of velocity, in a well-formed needle nozzle is approximately ·99. Calling this velocity V_1, the horsepower of the jet is equal to

$$\frac{62{\cdot}4aV_1^3}{550\times 2g}$$

where a is the area of the jet in square feet.

Let u = peripheral speed of buckets at pitch circle, in ft. per second.
„ V_2 = final absolute velocity of water leaving the buckets.
„ ${}_1v_r$ = relative velocity of jet and bucket at entrance.
„ ${}_2v_r$ = relative velocity of jet and bucket at discharge.
„ α = mean angle between jet and tangent at point of contact.
„ γ = total angle of deflection of buckets.

Then the initial velocity of jet in direction of tangent at point of impact $= V_1\cos\alpha$.
The component, parallel to the tangent at discharge, of final velocity relative to bucket $= {}_2v_r\cos\gamma$.

∴ Absolute velocity in this direction at discharge $= u+{}_2v_r\cos\gamma$.

∴ Change of tangential momentum per second per pound

$$=\frac{1}{g}(V_1\cos\alpha-u-{}_2v_r\cos\gamma).$$

∴ Work done per pound of water per second

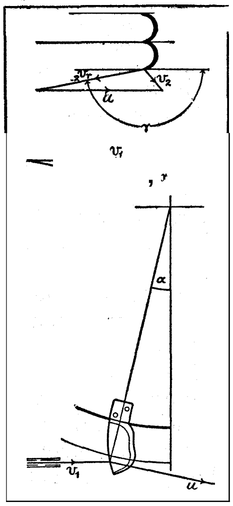
$$=\frac{u}{g}(V_1\cos\alpha-u-{}_2v_r\cos\gamma)\text{ ft. lb.}$$

∴ Efficiency $$=\frac{u}{gH}(V_1\cos\alpha-u-{}_2v_r\cos\gamma).$$

The loss due to friction and eddies in the buckets $=\dfrac{{}_1v_r^2-{}_2v_r^2}{2g}$ ft. lb. per pound, where ${}_1v_r^2=V_1^2+u^2-2V_1u\cos\alpha$.

The loss due to rejection of kinetic energy in the discharge $=\dfrac{V_2^2}{2g}$ ft. lb. per pound, where $V_2^2=u^2+{}_2v_r^2+2u_2v_r\cos\gamma$.

Tests show that in an average wheel ${}_2v_r$ may be as low as from ·5 to ·6 ${}_1v_r$. In a well-designed bucket, however, having a ratio of bucket width to jet diameter not less than about 3.3, this ratio approximates to ·75 or even ·8. If the angle of deflection were 180°, and if the buckets were frictionless, the value of the peripheral speed of the wheel for maximum efficiency would be $V_1\cos\alpha\div 2$, or approximately $V_1\div 2$, since α is small. When account is taken of the various losses and of the fact that γ is less than 180°, the best peripheral speed lies between ·44 and ·48V_1.



FROM GIBSON, "HYDRAULICS" (CONSTABLE & CO.)

FIG. 6.—VELOCITY DIAGRAMS FOR PELTON WHEEL BUCKETS

Comparison of Impulse and Reaction Turbines.— The peripheral velocity of a Pelton wheel for maximum efficiency is slightly less than one-half the velocity of the jet (usually approximately $\cdot 46\sqrt{2gH}$, where H is the head), while that of the reaction turbine varies from about $\cdot 65\sqrt{2gH}$ to $1{\cdot}05\sqrt{2gH}$, depending on the design. Because of this, the Pelton wheel is well adapted for very high heads, which may then be utilized with moderate speeds of rotation. On the other hand the relatively high speed of the reaction turbine enables reasonably high rotative speeds to be obtained with low heads.

The Pelton wheel cannot well be designed to utilize efficiently more than two jets on a single wheel, and as the maximum practicable jet diameter is not large, the volume of water which can be handled and the output of the turbine become small under low heads. The reaction turbine with its full peripheral admission on the other hand is well adapted for large volumes. It is not suited for small powers under high heads, since the volume of water is then small, the waterways are of very small sectional area and easily become choked by floating debris, and the fluid friction losses become relatively high.

The Pelton wheel cannot easily be adapted to the use of a suction or draft tube, and, where the tail-race level may vary appreciably, must be installed above the highest probable tail-water level with some sacrifice of head. The efficiency of the reaction turbine is not so sensitive to changes of head as that of the Pelton wheel, but if operated under constant head and at constant speed, the efficiency of the Pelton wheel does not fall off so rapidly at part loads as that of the reaction turbine. On the other hand, the modern reaction turbine has a slightly higher full-load efficiency, so that the average efficiency from half to full load is sensibly the same in a well-designed machine of either type. The following table shows typical values of the part-load efficiencies of modern turbines of both types of large size, installed under equally favourable conditions.

Proportion of maximum discharge	·2	·3	·4	·5	·6	·7	·8	·9	1·0
Efficiency of reaction turbine	·60	·70	·75	·79	·82	·87	·90	·91	·89
Efficiency of Pelton wheel	·70	·78	·82	·83	·84	·85	·86	·85	·83

The possibilities of accurate speed regulation are about equal in the two types.

For large units the reaction turbine is generally preferable for heads up to 400 feet. For heads above 750 ft. the Pelton wheel is more suitable, while between these limits the choice depends largely upon local circumstances and on the power required. The greater simplicity and accessibility of the parts requiring replacement due to natural wear and tear renders the Pelton wheel more suitable when the supply is taken from a stream carrying an appreciable amount of grit.

The reaction turbine has been built in units capable of developing 65,000 H.P. The most powerful Pelton wheel yet constructed develops about 30,000 H.P., but these outputs could be largely extended if necessary.

(A. H. G.)

TURBOT *(Rhombus maximus)*, a flat fish of the Mediterranean and the Atlantic coast of Europe, is distinguished by a large terminal mouth, eyes on the left side, a very deep body and a naked skin, with conical bony tubercles scattered on the eyed side.

The brill, a related species, is not so deep and is scaly. The turbot is a valued food fish; it feeds mainly on other fishes; it attains a weight of 30 lb.

It has a longer larval life than most flat fishes; and specimens nearly an inch in length, with an eye on each side, may be found swimming at the surface.

TURBULENCE, ATMOSPHERIC. The motion of a fluid, whether liquid or gas, can be one of two main types: laminar, in which the individual particles of the fluid follow well-defined, smooth paths; or turbulent, in which the motion is extremely irregular and, in general, no two particles follow the same path. Most natural motion is turbulent, and this is especially true of the wind near the earth's surface, although even there, there is, on occasions, an approach to laminar motion, as will be seen below. The turbulence of the natural wind exhibits itself as a succession of gusts and lulls, with simultaneous random oscillations in direction, so that when speaking of the speed and direction of a wind one must necessarily refer to averages taken over a period of many minutes.

The amount of turbulence present in a wind varies considerably with the time of day, state of sky and the nature of the surface over which the air is passing. Meteorologists usually measure the turbulence of the wind by its gustiness, defined to be half the difference between the maximum and minimum speeds during a specified period divided by the average speed. Thus a wind whose average speed is 20 m.p.h. would have a gustiness of 0.25 if its speed varied between 15 and 25 m.p.h. during the period of measurement. Oscillations of direction are usually 15° or more on either side of the mean direction, but this figure also can vary considerably.

Mixing.—The importance of turbulence in meteorology lies in the fact that it is the agent that causes the atmosphere to be churned up and thoroughly mixed. In other words, turbulence is the main cause of the diffusion of water vapour, smoke and the lighter seeds. The evaporation of water from land and sea, and hence the hydrological cycle, depends very much on turbulence, which may be pictured as the irregular movements of small and large masses of air, usually called eddies, from one level to another. In this respect eddies may be likened to molecules whose incessant motion also causes diffusion, but eddy diffusion is on a vastly greater scale than molecular diffusion and takes place in a rather different way. As a consequence of these differences the mathematical theory of diffusion by turbulence is considerably more complicated and less exact than that of molecular diffusion. In particular, it is impossible to speak of the atmosphere having a definite "diffusivity"—that is, to associate with diffusion in the atmosphere a single quantity corresponding to the familiar diffusion coefficient encountered in molecular diffusion—although many attempts have been made to do so.

Lower Atmosphere.—In considering atmospheric turbulence it is essential to distinguish between conditions in the lower atmosphere, say within a few hundred feet of the surface, and those prevailing in the upper atmosphere, many thousands of feet above the ground. In the lower atmosphere the turbulence of the wind usually exhibits a marked diurnal variation. If the sky is clear, turbulence reaches a maximum in the hours around noon. This is because the surface of the earth is heated by the sun's rays, and masses of warm air continually rise and are replaced by cooler air from above.

This vertical motion, which is accompanied by a marked fall of temperature with height, called a lapse, together with disturbances in the wind caused by obstacles such as trees, houses and hills, keep the whole motion extremely irregular. Diffusion is at its highest level during lapse conditions, and smoke from domestic or industrial chimneys is quickly scattered.

As the sun sets, the earth cools rapidly because of radiation to space. As a result, the layers of air near the surface become more dense than those above and temperature increases with height, a condition known as an inversion. Such a condition makes for stability. and both the speed and the gustiness of the wind decrease sharply. The motion of the air approaches the laminar state, with marked effects on diffusion.

This is best seen by watching smoke, for example, from a weed fire in a garden. During the hours around noon the smoke is scattered in all directions by the vigorous turbulence of the wind, but after sunset it drifts in compact plumes that show little or no mixing with the surrounding atmosphere. The concentration of smoke, that is, the amount of smoke in unit volume of the air, is very much increased during the inversion period which lasts, on a clear night, until dawn. When the sky is overcast, the turbulence of the air remains at much the same level day and night. The cloud sheet reduces the intensity of solar radiation during the day and at night acts as a blanket which prevents the surface from losing heat to space.

Inversions of the type described above occur on every clear night and are usually confined to relatively shallow layers near the ground. On occasions, however, inversions may extend to 1,000 ft. or more above the surface. Such large-scale inversions are usually caused by the slow descent of air in an anticyclone. When this occurs there is a strong possibility that smoke-polluted fog (smog) will be formed, especially in winter, by the breakdown of the natural ventilation of the atmosphere. The outstanding example of such a smog is that which occurred in London in Dec. 1952, which was estimated to have caused the deaths of over 4,000 people from respiratory ailments such as bronchitis. Other examples of respiratory epidemics caused by pollution are those which occurred in Donora, Pa., in 1948 and in the Meuse valley, Belg., in 1930. It is clear, therefore, that turbulence is a valuable property of the wind, for without it life in great cities would not be possible.

Detailed studies of turbulence near the surface show that the oscillations of velocity have periods varying from a fraction of a second to many minutes, and that the gustiness of the wind depends very much upon the roughness of the surface. The difference between the total velocity at any instant and the mean velocity is called the eddy velocity; this has components in the average direction of the wind, across wind and vertically. Turbulence is also mainly responsible for the internal friction of the atmosphere. All motion of the air (wind) is caused by horizontal differences of pressure, but in the lower levels of the atmosphere the speed of the wind is considerably reduced by the friction of the ground. This frictional effect is spread upward by turbulence. The eddies in the wind, by mixing the slow-moving air near the ground with the faster-moving air from above, cause a general leveling out of velocity differences, with the result that over flat country the speed of the wind increases rather gradually from the surface value to that of the frictionless flow at about 2,000 ft

The stratum of air in which this transition occurs is usually called the friction layer of the atmosphere. Near the ground the cross-wind component of eddy velocity is considerably greater than either of the other components, but at heights exceeding about 100 ft. all three components are equal. Considerable attention has also been given to the cognate problem of the transfer of heat from the ground upward by the eddies in the friction layer.

In relation to atmospheric pollution, it has been established mathematically that the concentration of smoke at ground level from a typical industrial stack varies inversely as the square of the height of the stack, so that increasing the height of a stack from say, 100 to 200 ft., reduces the concentration of smoke at ground level by a factor of 4. It is therefore a considerable advantage to ensure that noxious fumes are emitted at as great a height as possible. These and other studies of turbulence in the regions of the atmosphere in which life is most abundant. that is, within a few hundred feet of the ground, are part of the science known as micrometeorology.

Upper Atmosphere.—At heights above 2.000 ft. or so over flat country, the frictional effect of the surface on the wind is greatly reduced, and much of the small-scale turbulence characteristic of the lower atmosphere disappears. However, although upper winds are usually much less turbulent than surface winds, they sometimes exhibit a degree of turbulence which is significant for aviation. In certain meteorological conditions, such as those which favour strong surface heating and high humidity, there is much upward movement of the air (convection) accompanied by the formation of cumulus clouds towering to considerable heights. In the vicinity of such clouds flying is usually rough or bumpy. The bumps are most severe in thunderstorms, in which upward currents of up to 100 ft. per second have been measured, and the interior of a thundercloud is a region of very intense turbulence. An aircraft flying through such rough air experiences severe vertical accelerations, sometimes sufficient to throw out of his seat a passenger who has not fastened his safety belt.

Pilots try to avoid cumulus clouds for this reason, but in recent years another type of turbulence, less easily forecast, has become prominent with the advent of high-speed aircraft operating at great heights. This is clear-air turbulence, which is only found in the high atmosphere. In many instances the sole effect on the aircraft is to give one the impression of riding in a solid-tired vehicle over cobblestones; but at times clear-air turbulence can be of sufficient intensity to strain the structure of the aircraft, especially at high speeds. This type of turbulence is often found near jet streams. the very high-speed winds which blow in narrow belts near the tropopause (30,000 ft. or above), but precisely how the wind becomes so violently disturbed at these great heights remains to be explained.

TURDIDAE: see THRUSH.

TURENNE, HENRI DE LA TOUR D'AUVERGNE, VICOMTE DE (1611–1675), marshal of France, second son of Henri, duke of Bouillon and sovereign prince of Sedan, by his second wife, Elizabeth, daughter of William the Silent, prince of Orange, was born at Sedan on Sept. 11, 1611. He was educated in the doctrines of the Reformed religion and received the usual training of a young noble of the time; but physical infirmity, and particularly an impediment of speech (which he never lost), hampered his progress. though he showed a marked partiality for history and geography and especial admiration of the exploits of Alexander the Great and Caesar. After his father's death in 1623, he devoted himself to bodily exercises and in a great measure overcame his natural weakness. At the age of 14 he went to learn war in the camp of his uncle, Maurice of Nassau. and began his military career (as a private soldier in that prince's bodyguard) in the Dutch War of Independence. Frederick Henry of Nassau, who succeeded his brother Maurice in 1625. gave Turenne a captaincy in 1626

The young officer took his part in the siege warfare of the period and won special commendation from his uncle. who was one of the foremost commanders of the time, for his skill and courage at the celebrated siege of Hertogenbosch (Bois-le-Duc) in 1629. In 1630 Turenne left Holland and entered the service of France. Cardinal Richelieu at once made him colonel of an infantry regiment. He still continued to serve at frequent intervals with the prince of Orange, who was the ally of France. In 1635 Turenne served under Cardinal de la Valette in Lorraine and on the Rhine. The siege of Mainz was raised, but the French army had to fall back on Metz from want of provisions. In the retreat Turenne measured snords with the famous imperialist, General Gallas, and distinguished himself greatly by his courage and skill. The reorganized army took the field again in 1636 and captured Saverne (Zabern), at the storming of which place Turenne was seriously wounded.

In 1637 he took part in the campaign of Flanders and was present at the capture of Landrecies (July 26) and in the latter part of 1638, under Duke Bernhard of Saxe-Weimar (1608–39), he directed the assault of Breisach (reputed the strongest fortress on the upper Rhine), which surrendered on Dec. 17. He had now gained a reputation as one of the foremost of the younger generals of France, and Richelieu next employed him in the Italian campaign of 1639–40 under "Cadet la Perle," Henri de Lorraine, count of Harcourt (1601–66).

On Nov. 19. 1639, he fought in the famous rearguard action called the battle of the "Route de Quiers" and during the winter revictualled the citadel of Turin held by the French against the forces of Prince Thomas of Savoy. In 1640 Harcourt saved Casale and besieged Prince Thomas's forces in Turin, which were besieging in their turn another French force in the citadel. The latter held out. while Prince Thomas was forced to surrender on Sept. 17. 1640, a fourth army which was investing Harcourt's lines being at the same time forced to retire. The favourable result of the complicated operations of this campaign was largely due to Turenne, who had by now become a lieutenant-general.

He himself commanded during the campaign of 1641 and took Coni (Cuneo), Ceva and Mondovi. In 1642 he was second in command of the French troops which conquered Roussillon. At this time the conspiracy of Cinq-Mars (*q.v.*), in which Turenne's elder brother, the duke of Bouillon, was implicated, was discovered (see FRANCE: History).

The earlier career of Turenne was influenced by the relations of the principality of Sedan to the French crown; moreover his steady adherence to the Protestant religion was an element of difficulty in Turenne's relations with the ministers. Cardinal Richelieu nevertheless entrusted him with the command in Italy in 1643 under Prince Thomas (who had changed sides in the quarrel).

Turenne took Trino in a few weeks but was recalled to France toward the end of the year. He was made a marshal of France (Dec. 19) and was soon sent to Alsace to reorganize the "Army of Weimar"—the remnant of Duke Bernhard of Saxe-Weimar's troops—which had just been severely defeated at Tiittlingen (Nov. 24–25, 1643).

He was 32 years old at this time and had served under four famous commanders. The methodical prince of Orange, the fiery Bernhard, the soldierly Cardinal de la Valette and the stubborn and astute Harcourt had each contributed much to the completeness of Turenne's training; and he took the field in 1644 prepared by genius and education for the responsibilities of high command.

The work of reorganization over, Marshal Turenne began the campaign in June by crossing the Rhine at Breisach but was almost instantly joined by an army under the duc d'Enghien (afterwards the great Condé), who, as a prince of the royal house. took the chief command of the united armies of "France" and "Weimar." The four famous campaigns which followed brought to an end the Thirty Years' War (*q.v.*). The chief event of the first of these was the desperately-fought battle of Freiburg against Count Mercy's Bavarians (Aug. 3, 5 and 9, 1644), after which Philipsburg was successfully besieged. Before the capitulation Enghien withdrew and left Turenne in command.

The marshal opened the campaign of 1645 with a strong forward movement but was surprised and defeated by Mercy at Mergentheim (Marienthal) on May 2. Enghien was again sent to the front with the army of France, and Turenne's army was greatly increased by the arrival of a Swedish force and a contingent from Hesse-Cassel The Swedes soon departed, but Enghien was at the head of 20.000 men when he met the Bavarians in a battle even more stubbornly contested than Freiburg. Mercy was killed and his army beaten at Allerheim near Nordlingen (Aug. 3, 1645).

Ill-health forced Enghien to retire soon afterwards, and Turenne was for the third time left in command of the French army. He was again unfortunate against the larger forces of the imperialists, but the campaign ended with a gleam of success in his capture of Trier (Trèves). In the following year (1646) he obtained more decided successes and, by separating the Austrians from the Bavarians, compelled the elector of Bavaria to make peace (signed March 14, 1647). In 1647 he proposed to attack the thus weakened army of the emperor but was ordered into Flanders instead. Not only was the opportunity thus lost but a serious mutiny broke out among the Weimar troops, whose pay was many months in arrear. The marshal's tact and firmness were never more severely tried nor more conspicuously displayed than in his treatment of the disaffected regiments, among whom in the end he succeeded in restoring order with little bloodshed. He then marched into Luxembourg but was soon recalled to the Rhine, for in 1648 Bavaria had returned to her Austrian alliance and mas again in arms. Turenne and his Swedish allies made a brilliant campaign, which was decided by the action of Zusmarshausen (May 17), Bavaria being subsequently wasted with fire and sword until a more secure pacification was obtained.

The peace of Westphalia (1648) was no peace for France, which was soon involved in the civil war of the Fronde. (See FRANCE: *History.*) Few of Turenne's actions have been more sharply criticized than his adhesion to the party of revolt. The army of Weimar refused to follow its leader and he had to flee into the Spanish Ketherlands, where he remained until the treaty of Rueil put an end to the first war of the Fronde. The second mar began with the arrest of Condé and others (Jan. 1650), among whom Turenne was to have been included; but he escaped in time and with the duchesse de Longueville held Stenay for the cause of the "Princes"—Condé, his brother Conti and his brother-in-law the duc de Longueville. Love for the duchess seems to hare ruled Turenne's action, both in the first war and, now in seeking Spanish aid for the princes. In this war Turenne sustained one of his few reverses at Rethel (Dec. 1j, 1650); but the second conflict ended in the early months of 1651 with the collapse of the court party and the release of the princes.

Turenne became reconciled and returned to Paris in May, but the trouble soon revived and before long Condé again raised the standard of revolt in the south of France. In this, the third war of the Fronde, Turenne and Condé were opposed to each other, the marshal commanding the royal armies, the prince that of the Frondeurs and their Spanish allies. Turenne displayed the personal bravery of a young soldier at Jargeau (March 28, 1652), the skill and wariness of a veteran general at Gien (April 7), and he practically crushed the civil war in the battle of the Faubourg St. Denis (July 2) and the reoccupation of Paris (Oct. 21). Condé and the Spaniards, however, still remained to be dealt with, and the long drawn out campaigns of the "Spanish Fronde" gave ample scope for the display of scientific generalship on the part of both the famous captains. In 1653 the advantage was with Turenne, who captured Rethel, St. Menehould and Muzon, while Condé's sole prize was Rocroy. The short campaign of 1654 was again to the advantage of the French; on July 25, the Spanish were defeated at Arras. In 1655 more ground mas gained, but in 1656 Turenne was defeated at Valenciennes in the same way as he had beaten Condé at Arras. The war was eventually concluded in 1658 by Turenne's victory at the Dunes near Dunkirk, in which a corps of English veterans sent by Cromwell played a notable part (June 3–14); a victory which, followed by another successful campaign in 1658, led to the peace of the Pyrenees in 1659.

On the death of Cardinal Mazarin in 1661 Louis XIV took the reins of government into his own hands and one of his first acts was to appoint Turenne "marshal-general of the camps and armies of the king." He had offered to revive the office of constable of France (suppressed in 1627) in Turenne's favour if the marshal wonld become a Roman Catholic. Turenne declined. Born of Calvinist parents and educated a Protestant, he had refused to marry one of Richelieu's nieces in 1639 and subsequently rejected a similar proposal of Mazarin. He had later married a daughter of the Protestant Marshal de la Force, to whom he was deeply attached. But he sincerely deplored the division of the Christian church into two hostile camps. How closely both he and his wife studied such evidence as was available is shown by their correspondence, and, in the end, two years after her death, he was prevailed upon by the eloquence of Bossuet and the persuasions of his nephew, the abbé de Bouillon, to give in his adhesion to the Orthodox faith (Oct. 1668). In 1667 he had returned to the more congenial air of the "Camps and Armies of the King," directing, nominally under Louis XIV, the famous "Promenade militaire" in which the French overran the Spanish Netherlands. Soon afterwards Condé, now reconciled with the king, rivalled Turenne's success by the rapid conquest of Franche Comté, which brought to an end the War of Devolution in Feb. 1668.

In Louis XIV's Dutch War of 1672 (see DUTCH WARS) Turenne was with the army commanded by the king which overran Holland up to the gates of Amsterdam. The dikes were opened and the country round Amsterdam flooded. This heroic measure completely checked Turenne, whom the king had left in command. Turenne now fought a successful war of manoeuvre on the middle Rhine while Condé covered Alsace. In Jan. 1673 Turenne assumed the offensive, penetrated far into Germany and forced the Great Elector of Brandenburg to make peace; later in the year, however, he was completely outmanoeuvred by the famous imperial general, Montecucculi, who evaded his opponent, joined the Dutch and took the important place of Bonn. In June 1674, however, Turenne won the battle of Sinzheim, which made him master of the Palatinate. Under orders from Paris the French wasted the country far and wide. In the autumn the allies again advanced, and though Turenne was again outmanoeuvred, his failure on this occasion was due to the action of the neutral city of Strasbourg in permitting the enemy to cross the Rhine by the bridge at that place. The battle of Enzheim followed; this was a tactical victory but hardly affected the situation, and at the beginning of December the allies were still in Alsace. The old marshal now made the most daring campaign of his career. A swift and secret march in mid-minter from one end of the Vosges to the other took the allies by surprise. Sharply following up his first successes, Turenne drove the enemy to Turkheim, and there inflicted upon them a heavy defeat (Jan. 5, 1675). In a few weeks he had completely recovered Alsace. In the summer campaign he was once more opposed to Montecucculi, and after the highest display of "strategic chess-moves" by both commanders, Turenne finally compelled his opponent to offer battle at a disadvantage at Sassbach. Here, on July 27, 1675, he was killed by almost the first shot fired. The news of his death was received with universal sorrow. Turenne's most eloquent countrymen wrote his *éloges,* and Montecucculi himself exclaimed: "Il est mort aujourd'hui un homme qui faisait honneur à I'homme." His body was taken to St. Denis and buried with the kings of France. Even the extreme revolutionists of 1793 respected it; and, when the bones of the sovereigns were thrown to the winds, the remains of Turenne were preserved at the Jardin des Plantes until Sept. 22, 1800, when they were removed by order of Napoleon to the Church of the Invalides at Paris, where they still rest.

Turenne was one of the great captains whose campaigns Napoleon recommended all soldiers to "read and re-read." His fame as a general was the highest in Europe at a period when war was studied more critically than ever before, for his military character epitomized the art of war of his time (Prince de Ligne). Strategic caution and logistic accuracy, combined with brilliant dash in small combats and constancy under all circumstances of success or failure may perhaps be considered the salient points of Turenne's genius for war. Great battles he avoided. "Few sieges and many combats" was his own maxim. And, unlike his great rival Condé, who was as brilliant in his first battle as in his last, Turenne improved day by day. Kapoleon said of him that his genius grew bolder as it grew older; and a modern author, the duc d'Aumâle (*Histoire* des princes *de* la *maison* de *Condé*), takes the same view when he says: "Pour le connaitre il faut le suivre jusqua'à Sulzbach. Chez lui chaque jour marque un progrès." In his personal character Turenne was little more than a simple and honourable soldier, endowed with much tact, but in the world of politics and intellect almost helpless in the hands of a skilful intriguer or casuist. His morals, if not beyond reproach, were at least more austere than those prevalent in the age in which he lived. He was essentially a commander of regular armies. His life was spent with the troops; he knew how to win their affection; he tempered,a severe discipline with rare generosity and his men loved him as a comrade no less than they admired him as a commander. Thus, though Condé's genius was far more versatile, it is Turenne whose career best represents the art of war in the 17th century. For the small, costly and highly trained regular armies and the dynastic warfare of the age of Louis XIV, Turenne was the ideal army leader.

The most notable of the numerous portraits of Turenne are those of P. de Champagne at Versailles and of Senin (dated 1670) in the Jones collection at South Kensington, London. Of the older memoirs of Turenne the most important are those of "Du Buisson," *La Vie du vicomte de Turenne—the* author is apparently Gatien de Sandraz de Courtilz (Paris, the Hague and Cologne, 1688–95); Abbe Raguenet, *Histoire do viconzte de Turenne* (Paris 1741) and especially Ramsay, *Histoire d'Henri de la Tour d'Auvergne, vicomte de Turenne* (Paris 1735), the second volume of which contains the marshal's memoirs of 1643–58. These memoirs, of which the Prince de Ligne wrote that "ce ne sont pas de conseils, ce sont des ordres . . . 'faites' . . . 'allez,' etc."—were written in 1665, but were first published (*Mémoires sur la guerre, tirés des originaux*, etc.) in 1738, reprinted in Michaud, *Mémoires sur l'histoire de France*, 3rd series, vol. iii, and Liskenne and Sauvan's *Bibliothèque historique et militaire*, vol. iv (Paris 1846). A manuscript, *Maximes de M. de Turenne* (1644), exists in the Staff archives at Vienna; and of other documentary collections may be mentioned Grimoard, *Collections de lettres et mémoires trouvés dans le portefeuille de M. de Turenne* (Paris, 1782); *Recueil de lettres dcrites au viconzte de Turenne par Louis XIV. et ses ministres*, etc. (Paris 1779); *Correspondance inédite de Turenne avec Le Tellier et Louvois*, ed. Barthélemy (Paris 1874). *See* also the *Observations on the Wars of Marshal Turenne*, dictated by Napoleon at St. Helena (1823); Puységur, *La Guerre par principes et règles* (Paris 1748): Précis in *Bibliothèque internationale d'hist. milit.* (Brussels 1883); Duruy, *Histoire de Turenne* (Paris 1880); Roy, *Turenne, sa vie et les institutions militaires de son temps* (Paris 1884); Hardy de Périni, *Turenne et Condé* (Paris 1907); Neuber, *Turenne als Kriegstheoretiker und Feldherr* (Vienna 1869); Sir E. Cust, *Lives of the Warriors of the 17th Century* (London, 1867); T. O. Cockayne, *Life of M. de Turenne* (founded on Ramsay's work; London, 1853); G. B. Malleson, *Turenne. Marshal Turenne*, by "the author of the Life of Sir Kenelm Digby" (London 1907), is a valuable work by a civilian and is based in the main on Ramsay's work, the memoirs of Cardinal de Retz, James, duke of York, etc., and on Napoleon's commentaries. A remarkable parallel between Turenne and Condé, in Saint-Evremont's *éloge* of the latter, will be found in Carrion-Nisas, *Essai sur I'histoire général de l'art militaire*, ii, 83 (Paris 1824); C. G. Picavet, *Les dernières années de Turenne 1660–1675* (1910), p. 513; General Weygand, *Turenne* (1929). (C. F. A.)

TURFAN, the name of a remarkable depression in the Tarim region south of the Tien-shan, here over 10,000 ft. in height. This oasis lies 980 ft. below sea level at the lowest point. The'town of Turfan, just 30 mi. to the north, stands some 250 ft. above sea level, and the general level around the depression rapidly reaches over 2,500 feet. The depression is loess covered and would be fertile if it could be irrigated. The town of Turfan is a double settlement, part Chinese and part Turki, with a population of 15–20 thousand. In the depression, the temperature varies from 90° for July, calculated at Lukchun, to 13° in January and the daily fluctuations are very great.

TURGAI, a former province of Russian central Asia, now included in the Kazakstan (*q.v.*) A.S.S.R.; *see* also AKTUBINSK.

The Turgai strait, a narrow passage over the watershed separating the Tobol and the Irgiz, between the east of the southern Urals and the west of the plateau region of the Kirghiz steppe, is of great structural importance. Through it came the marine transgressions of previous geological epochs; the upper Cretaceous advanced into the southwest only, but those of the upper Eocene and Oligocene extended along the east of the Urals and the Lower Oligocene sea of Germany reached the Arctic ocean. During the age of the amber forests the Strait of Turgai was closed, and no sea again entered Siberia by that route. The course of the Tobol river marks the direction of the ancient marine connection. At a recent epoch the present Turgai river, which enters Lake Chalkarteniz and which receives the Irgiz as a tributary, flowed into the Sea of Aral, its volume being then much increased by tributaries which now lose themselves in the sand before reaching it.

See Suess *The Face of the Earth*, vol. III (1908).

TURGENEV, IVAN SERGEYEVICH (tōōr-gān'yĕv) (1818–1883), Russian novelist, was born at Orel of a family of provincial gentry. His father had married for money a woman older than himself, who made up for her thwarted affections by making herself a domestic tyrant to her children, as well as to her serfs. Turgenev was educated at home, at the Universities of Moscow and St. Petersburg and finally (1839–40) at Berlin, where, in contact with young Russian intellectuals, he became a Westernizer. In 1843 he published *Parasha*, a tale in verse, which was favourably reviewed by Belinsky. Turgenev deserted the civil service for letters and was infatuated with the famous singer, Pauline Garcia (Mme. Viardot); this caused a breach with his mother, who cut off his allowance. He lived as a Bohemian until her death (1850) made him a rich man. His lifelong affection for Mme. Viardot, who merely tolerated his presence, met with no response but left a deep impress on his work. Turgenev abandoned poetry for the drama (which he also abandoned after 1852) and for prose fiction. His first great success was *A Sportsman's Sketches* (started 1847, in book form 1852), in which the peasants appeared more attractive than their masters. It was received as a protest against serfdom. In 1852 Turgenev was exiled to his estate for a while because of his laudatory obituary on Gogol.

His masterpieces included short stories like *The Backwater, Asya, First Love* and the more ambitious novels *Rudin* (1856), *A Nest of Gentlefolk* (1858), *On the Eve* (1860) and *Fathers and Sons* (1862), in which the love plot was interwoven with current social issues. All were commented on at great length by the leading critics. His attempt, however, to draw a strong man in the person of the agnostic and materialist—"nihilist"—Bazarov was resented by the Radical press as a caricature. Turgenev, being sensitive to criticism, was embittered against his countrymen and settled abroad, and his later works are mainly retrospective. The two novels in which he tried to deal with actuality, *Smoke* (1867) and *Virgin Soil* (1877), only show the depth of his bitterness and his complete loss of touch with contemporary Russia. However, his last visit to Russia (1880) was a triumphant progress. He died in 1883, at Bougival, near Paris.

Turgenev was the first Russian author to be read and admired by Europe. During his last years he lived in close touch with the French literary world, contracted intimate friendships (especially with Flaubert) and was regarded as a master by younger men like Maupassant. He was very popular in this French circle, but much less so among his Russian compeers: Tolstoy, Dostoyevsky and Nekrasov all sooner or later came to detest him.

Turgenev is the most poetical (in the 19th century acceptance of the word) of the Russian realists. He had undergone the profound influence of Pushkin (as well as of Lermontov and George Sand). His novels are largely variations on the theme of *Eugene Onegin.* His character drawing does not depend on analysis and psychology but on a subtly-woven poetic atmosphere that accompanies the characters like an aura. This applies mainly to his women; they are invariably stronger and more attractive than his men, who (with the single exception of Bazarov) are neurasthenic weaklings. His style is marked by a careful simplicity and elaborate naturalness that answered to the highest ideals of 19th century taste. Delicately-drawn landscape passages are among its most outstanding features.

TURGEON, PIERRE FLAVIEN (1787–1867), archbishop of Quebec, was born in Quebec on Nov. 12, 1787. He was ordained in 1810 and became director of the Quebec seminary in

1821 after visiting England and Rome, 1819–20. He was instrumental in obtaining settlement of the status of the Catholic church in Canada. After serving as administrator from Nov. 1849, he became archbishop of Quebec in Oct. 1850 and in that capacity brought about the organization of the province; and under him the first and second councils of Quebec convened in 1851 and 1854, respectively. He was the founder of Laval university, which opened on Sept. 1, 1852, and of La Maison du Bon Pasteur. He held office until 1855 when ill health compelled him to resign. He died on Aug. 25, 1867.

TURGOT, ANNE ROBERT JACQUES, BARON DE LAUNE (1727–1781), French statesman and economist, was born in Paris on May 10, 1727, the youngest son of Michel Étienne Turgot, "provost of the merchants" of Paris. He was educated for the church; and at the Sorbonne, to which he was admitted in 1749 (being then styled abbC de Brucourt), he delivered two remarkable Latin dissertations, *On the Benefits which the Christian Religion has conferred on Mankind* and *On the Historical Progress of the Human Mind.* In 1750 he decided not to take holy orders, giving as his reason, according to Dupont de Nemours, "that he could not bear to wear a mask all his life." In 1752 he became *substitut* and later *conseiller* in the parlement of Paris. and in 1753 *maîtres des requites.* In 1754 he was a member of the *chambre royale* which sat during an exile of the parlement; in 1755 and 17j6 he accompanied Gournay, then intendant of commerce, in his tours of inspection in the provinces and in 1760, while traveling in the east of France and Switzerland, visited Voltaire, who became one of his chief supporters. In Paris he frequented the salons, especially those of Mme. Graffigny—whose niece, Mlle de Ligniville, afterwards Mme. Helvétius, became his lifelong friend—Mme. Geoffrin, Mme. du Deffand, Mlle. de Lespinasse and the duchesse d'Enville. It was during this period that he met the leaders of the "physiocratic" school, Quesnay and Gournay, and with them Dupont de Nemours, the abbC Morellet and other economists. All this time he was studying various branches of science and languages, both ancient and modern. In 1753 he translated the *Questions sur la commerce* from the English of Josias Tucker and wrote his *Lettre sur la tolérance* and a pamphlet, *Le Conciliateur,* in support of religious tolerance. Between 1755 and 1756 he composed various articles for the *Encyclopédie* and between 1757 and 1760 an article on *Valeurs et monnaies,* probably for the *Dictionnaire du commerce* of the abbC Morellet. In 1759 appeared his *Éloge de Gournay.*

In August 1761 Turgot was appointed intendant of the *généralité* of Limoges, which included some of the poorest and most over-taxed parts of France; here he remained for 13 years. He was already deeply imbued with the theories of Quesnay and Gournay *(see* PHYSIOCRATIC SCHOOL) and set to work to apply them as far as possible in his province. He continued the work on the *cadastre,* or new official survey, begun by his predecessor Tourny in order to arrive at a juster assessment of the *taille;* he also obtained a large reduction in the contribution of the province. He published his *Avis sur l'assiette et la re'partition de la taille* (1762–70) and as president of the *Société d'agriculture de Limoges* offered prizes for essays on the principles of taxation. Quesnay and Mirabeau had advocated a proportional tax (*impôt de quotite'),* but Turgot, a distributive tax (*impôt de répartition*). Another reform was the substitution for the *corvée* of a tax in money levied on the whole province, the construction of roads being handed over to contractors. In 1769 he wrote his *Mémoire sur les prêts à intérêt,* in which the question of lending money at interest was for the first time treated from a scientific, not from a moral standpoint. Among other works written during Turgot's intendancy were the *Me'moire sur les mines et carrières* and the *Mémoire sur la ma-que des fers,* in which he protested against state interference and advocated free competition.

During the famine of 1770–71 he enforced on landowners "the obligation of relieving the poor" and especially the *métayers* dependent upon them and organized in every province *ateliers* and *bureaux de charité* for providing work for the able-bodied and relief for the infirm. Turgot made the *curés* the agents of his charities and reforms when possible. In 1770 he wrote his famous *Lettres sur la liberté du commerce des grains* addressed to the comptroller-general, the abbC Terray. Three of these letters have disappeared, having been sent to Louis XVI by Turgot at a later date and never recovered.

Turgot's best known work, *Réflexions sur la formation et la distribution des richesses,* written in 1766 for the benefit of two young Chinese students, appeared in 1769–70 in Dupont's journal, the *Ephémérides du citoyen,* and was published separately in 1776. After tracing the origin of commerce, Turgot develops Quesnay's theory that the land is the only source of wealth and divides society into three classes, the productive or agricultural, the salaried (*stipendiée*) or artisan class and the land-owning class *(classe disponible).* He advocates the *impôt unique; i.e.,* that only the *produit net* of the land should be taxed, and the complete freedom of commerce and industry.

On July 20, 1774, Turgot was appointed minister of marine through the influence of Maurepas; and on Aug. 24 he became comptroller-general. His first act was to submit to Louis XVI his guiding principles: "No bankruptcy, no increase of taxation, no borrowing." Turgot's policy, in face of the desperate financial position, was one of rigid economy in all departments. He contemplated a thorough-going reform of the *ferme générale* and, meanwhile, imposed certain conditions on the leases as they were renewed—such as a more efficient personnel and the abolition for the future of the abuse of the *croupes* (the name given to a class of pensions) and annulling certain leases, such as those of the manufacture of gunpowder and the administration of the *messageries,* the former of which was handed over to a company with Lavoisier as one of its advisers and the latter superseded by a better service of diligences which were nicknamed "turgotines." He also prepared a regular budget.

Turgot's measures reduced the deficit and raised the national credit to such an extent that in 1776, just before his fall, he was able to negotiate a loan with some Dutch bankers at 4%; but the deficit was still so large as to prevent him from attempting to realize his scheme of substituting for indirect taxation a single tax on land. He suppressed, however, a number of *octrois* and minor duties.

Turgot's edict for free trade in corn signed on Sept. 13, 1774, was strongly opposed in the *conseil du roi.* Turgot was hated by many in high places who had been interested in the speculations in corn and was opposed by Linguet and by Necker, who in 1775 published his treatise, *Sur la législation et le commerce des grains.* But Turgot's worst enemy was the poor harvest of 1774, which led to a slight rise in the price of bread in the winter and early spring of 1774–75 and to those extraordinary bread-riots known as the "guerre des farines." Turgot showed great firmness and decision in repressing the riots and was loyally supported by the king throughout.

Turgot's famous "Six Edicts" were finally presented to the *conseil du roi* (Jan. 1776). The two which met with violent opposition were, firstly, the edict suppressing the *corvées,* and secondly, that suppressing the *jurandes* and *maitrises,* the privileged trade corporations. Turgot announced in the preambles to these his intention to subject the noblesse to taxation and to establish as a principle the right of every man to work without restriction.

He obtained the registration of the edicts by the *lit de justice* of March 12; but by that time he had won the hatred of the nobles and the parlements, the court, the "financiers," the clergy, the rich bourgeoisie of Paris and others. The queen disliked him for opposing the grant of favours to her protégés, and he had offended Mme. de Polignac in a similar manner. Malesherbes and Maurepas ceased to support him, and Maurepas became reconciled with the queen and her party. About this time, too, appeared a pamphlet, *Le Songe de M. Maurepas,* generally ascribed to the comte de Provence (Louis XVIII), containing a bitter caricature of Turgot.

Before relating the circumstances of Turgot's fall it might be well to summarize briefly his views on the administrative system. With the physiocrats, he believed in an enlightened absolutism and looked to the king to carry through all reforms.

As to the parliaments, he opposed all interference on their part in legislation, considering that they had no competency outside the sphere of justice. He recognized the danger of the recall of the old parliament but was unable effectively to oppose it since he had been associated with the dismissal of Maupéou and Terray and seems to have underestimated its power. He was opposed to the summoning of the states-general advocated by Malesherbes (May 6, 1775), possibly on the ground that the two privileged orders would have too much power in them. His own plan is to be found in his *Mémoire sur les municipalités,* which was submitted informally to the king. In Turgot's proposed system landed proprietors alone were to form the electorate, no distinction being made between the three orders; the members of the town and country *municipalités* were to elect representatives for the district *municipalités,* which in turn would elect to the provincial *municipalités,* and the latter to a *grande municipalité,* which should have no legislative powers but should concern itself entirely with the administration of taxation. With this was to be combined a whole system of education, relief of the poor, etc. His large reforms amounted to a complete revolution and Louis XVI recoiled at the prospect.

Such a fundamental difference of opinion between king and minister was bound to lead to a breach sooner or later. Turgot's only choice, however, was between "tinkering" at the existing system in detail and a complete revolution; and his attack on privilege, which might have been carried through by a popular minister and a strong king, was bound to form part of any effective scheme of reform.

The immediate cause of Turgot's fall is uncertain. Some speak of a plot, of forged letters containing attacks on the queen shown to the king as Turgot's, of a series of notes on Turgot's budget prepared, it is said, by Necker and shown to the king to prove his incapacity. Others attribute it to the queen, and there is no doubt that she hated Turgot for supporting Vergennes in demanding the recall of the comte de Guines, ambassador to London, whose cause she had ardently espoused. Others attribute it to an intrigue of Maurepas. On the resignation of Malesherbes (April 1776), whom Turgot wished to replace by the abbé Véry, Maurepas proposed to the king as his successor a nonentity named Amelot. Turgot, on hearing of it, wrote an indignant letter to the king, in which he reproached him for refusing to see him, pointed out in strong terms the dangers of a weak ministry and a weak king and complained bitterly of Maurepas's irresolution and subjection to court intrigues; this letter the king is said to have shown to Maurepas, whose dislike for Turgot it still further embittered.

With all these enemies, Turgot's fall was certain; but he wished to stay in office long enough to finish his project for the reform of the royal household. This, however, he was not allowed to do. On May 12, 1776, Turgot was asked to resign. He retired to la Roche-Guyon, château of the duchesse d'Enville, returning shortly to Paris, where he spent the rest of his life in scientific and literary studies, being made vice-president of the Académie des Inscriptions et Belles Lettres in 1777. He died on March 18, 1781.

In character Turgot was simple, honourable and upright, with a passion for justice and truth. He was an idealist, his enemies would say a doctrinaire, and certainly the terms "natural rights," "natural law," etc., frequently occur in his writings. His friends speak of his charm and gaiety in intimate intercourse, but among strangers he was silent and awkward and produced the impression of being reserved and harsh. Many of the reforms and ideas of the Revolution were due to him; the ideas did not as a rule originate with him, but it was he who first gave them prominence. Oncken looks upon him as a bad physiocrat and a confused thinker, while Léon Say considers that "though he failed in the 18th century he triumphed in the 19th."

Bibliography.—G. Schelle, *Turgot* (Paris, 1909); and Marquis de Ségur, *Au Couchant de la monarchie* (Paris, 1910), contain much that is based on recent research. The principal older biographies are those of Dupont de Nemours (1782, enlarged in his edition of Turgot's *Works,* 1807–11) and Condorcet (1786); the best modern ones are those of A. Neymarck (Paris, 1885), Léon Say (Paris, 1887) and W. W. Stephens (London, 1895). See generally, Oncken, *Geschichte der Nationalökonomie,* vol. ii, ch. 1; Schelle, *Dupont de Nemours et l'école physiocratique* (1888); Henry Higgs, *The Physiocrats* (1897); R. P. Shepherd, *Turgot and the Six Edicts* (1903), in Columbia Univ. Studies, vol. xviii, no. 2; *Oeuvres de Turgot et documents le concernant, avec biographie et notes par G. Schelle,* 5 vol. (1913–23).

TURI, a Shi'ah Moslem tribe which holds the Kurram valley in West Pakistan and enjoys increasing prosperity. Divided into five clans, all apparently of Turki origin, the Turis probably wrested the valley from the Bangash Pathans after 1700, distributing its lands as conquered so that every original settler's family now holds fields all over it. A sturdy race, whose "fathom" is reputed to be 6½ ft., they are distraught by faction but hospitable; and a Turi escort (*badragga*) is famed for its fidelity.

They threw in their lot with the Sunnite Pathans (1851–56) but in the second Afghan War furnished Sir Frederick Roberts with supplies and in 1890 accepted British protection.

TURIN (Ital. Torino), a city of Piedmont, Italy, and capital of the province of Torino. It is built upon alluvial soil 784 ft. above sea level and stands largely upon the left bank of the Po river, by its junction with the smaller Dora Riparia, 75 mi. S.W. of Milan. Turin was the capital of the kingdom of Sardinia until 1861 when it was made the capital of united Italy, and so remained until the removal of the seat of government to Florence in 1865. Pop. (1951) 717,245 (city); 719,300 (commune); (1957 est.) 889,249 (commune). The area of the commune is 50 sq.mi.

The streets and avenues of Turin, almost all of which are straight, intersect at right angles and many of them are arcaded. The Via Roma, almost bisecting the city to link the Porta Nuova railway station with the Piazza Castello, was imposingly rebuilt between 1931 and 1936. In general Turin has a modern aspect, but its regularity of form is derived from the ancient Roman town of *Augusta Taurinorum,* which formed its nucleus.

The cathedral of St. John the Baptist (the see became an archbishopric in 1510) is a cruciform Renaissance building, dating from 1492–98, by the Florentine architect, Baccio Pontelli, with Meo del Caprino as the contractor. Behind the high altar of the cathedral is the chapel of SS. Sudario or SS. Sindone, a brilliantly original baroque edifice built (1668–94) by Guarino Guarini as a royal burial place. The "sudario" from which it takes its name is asserted to be the shroud in which Joseph of Arimathea wrapped the body of Christ. La Consolata, another of Guarini's baroque works (1679) richly completed by P. Juvara (1714), has an 11th-century tower which belonged to the monastery church of S. Andrea, founded by monks from Novalesa in 942.

Other churches of note are La Gran Madre di Dio, erected to commemorate the return of the court in 1814, and S. Filippo (1672–1772), the largest church in Turin. The dome of S. Filippo fell in just as it was approaching completion under the hands of Guarini and was restored by Juvara. Waldensian church, the first Protestant church in Turin, was built in 1848.

The Palazzo Madama was built by William VII of Montferrat at the close of the 13th century on the Roman east gate of the town; remains of the gate towers were incorporated in it. It owes its name to the widow of Charles Emmanuel II, who added the west façade and the handsome double flight of steps from Juvara's design (1718). The extensive Palazzo Reale or royal palace was begun in 1646. Many of the baroque palaces have fine pillared courtyards; some of them are the work of Guarini. The tower of the citadel (1565) contains the artillery museum. The Castello del Valentino is partly in the French style of the 16th century. It contains the polytechnical schools, the geological, mineralogical and industrial museums and the university botanical garden.

The hill of Superga (Suporga, Soperga), about 3 mi. E. of Turin and 2,205 ft. above sea level, is crowned by a basilica, Juvara's masterpiece, erected for Victor Amadeus II in memory of the liberation of Turin from the French in 1706. King Charles Albert and other Savoy princes are buried in the crypt. The hill is ascended by a twisting road and by a funicular railway. From its summit in fine weather the visitor can look down on Turin across the river to the west, or at the wide semicircle of the snow-crested Alps that rise like a wall at a radius of 30 mi. or more and sweep from beyond the pyramidal Monte Viso on the southwest around to the massif of Monte Rosa to the north. In clear weather the mountains are visible from Turin itself. The summit of Superga, with its several restaurants, is a favourite excursion place of the Torinese. It is also the scene of football's first air disaster, when on May 5, 1949, the aircraft carrying the Torino team from a game in Lisbon struck the hill in a storm with the loss of all aboard.

Not far from Turin are the royal castles of Moncalieri, Stupinigi, Rívoli, Racconigi, Aglie, and Venaria Reale.

Besides Turin university, founded about 1405 by Louis of Savoy-Acaia, there are schools of agriculture, architecture, medicine and engineering and an institute of commerce and economics. The old university buildings, erected in 1713, contained the national library which was partially destroyed by fire in 1904. The academy of sciences, founded in 1757, is in a building erected in 1679 by Guarini. This building also houses a museum of local antiquities of Piedmont and of Egyptian treasures, some of which were excavated at Thebes and Assiut. The picture gallery has paintings by Dutch, Flemish and north Italian masters. There is a natural history museum in the Palazzo Carignano, another of Guarini's buildings. The Palazzo Reale contains the royal armoury (a fine collection begun by Charles Albert in 1833) and the Royal Albertine library with a rich manuscript collection and 20,000 drawings. Turin also contains the Museo Nazionale di Montagna, devoted to the history of mountaineering.

Turin is noted for many modern public monuments including those to Emmanuel Philibert (1838), Charles Albert (1861) and Pietro Micca (1834). The Mole Antonelliana, started by Alessandro Antonelli in 1863, is used for the Risorgimento museum. It is perhaps the highest (548 ft. including the Stella d'Italia) brick edifice in Europe; the dome is raised upon a hall with three galleries, one above the other. The newer parts of the city, extending toward the south beyond the stadium (1911) are well laid out.

Among the hospitals is that called by the name of its founder, St. Joseph Cottolengo (1786–1842), a vast institution providing for more than 7,000 persons.

Communications and Industries — Turin is the nearest railway centre to Mont Cenis in French Savoie, while the line through Cuneo over the Col di Tenda affords direct communication with the French Riviera. In the late 1950s there were plans for a Mt. Blanc and other tunnels. Lines connect Turin with Milan, Genoa and other Italian towns. At Caselle is a large airport.

After Milan, Turin is the chief industrial city of Italy. The industries comprise metallurgy, especially the making of precision tools and ball bearings; silk (exported) and cotton weaving; tanning and leather-working; the manufacture of synthetic fibres, plastics, matches, rubber, furniture, paper, cosmetics, glass; also damasks, velvets, woolen goods and ready-made clothing; chocolate, wines (exported), liqueurs and vermouth are other notable products. The manufacture of automobiles became of great importance in the 1950s; airplanes are also made as well as railway freight cars, bicycles, motorcycles, radios and television sets. Electric power is widely developed because of the proximity of the Alpine valleys; and the hydroelectric plants of Mont Cenis, the Val d'Aosta and the Toce valley all concentrate on Turin.

History. — The ancient Augusta Taurinorum (or Taurasia) was a city of Gallia Cisalpina and the chief town of the Taurini. The natural advantages of its site and its position with relation to the Mont Genèvre pass over the Cottian Alps (*see* COTTII REGNUM) made it important; though Hannibal, after crossing the Alps in 218 B.C., was able to take the town after a three days' siege. It was partly burned in A.D. 69, but continued to be prosperous.

The Roman town formed a rectangle 2,526 by 2,330 ft. (770 by 710 m.). This measurement was questioned by F. Haverfield, *Ancient Town-Planning* (Oxford, 1913), but was confirmed by an article by U. Savoia in *Town-Planning Review*, xii (Liverpool, 1927). The walls, which were 21 ft. high, 7 ft. thick at ground level and 3 ft. at the top, were standing until about 1600; and the north gate, the Porta Palatina, still remains. The interior of the town was divided by seven streets from east to west and eight from north to south into 72 blocks (*insulae*). The ancient pavement and the drains below it are frequently found under the streets of the central portion of the modern town, indicating that they follow the ancient lines. Remains of a theatre were discovered in the palace garden.

Turin was made the chief town of Piedmont by Amadeus, first duke of Savoy. (*See* SAVOY, HOUSE OF.) Between 1536 and 1562 Turin was occupied by the French, and in 1630 it lost 8,000 of its citizens by the plague. The French were masters once more from 1640 to 1706, and again from 1798 until 1815, when Piedmont was restored to the house of Savoy. The town was heavily bombed in World War II by the Allies, but by the latter 1950s the work of restoration was well advanced.

BIBLIOGRAPHY.—C. Promis, *Storia dell' antica Torino* (Turin, 1869); A. d'Andrade, *Relazione dell' ufficio regionale per la conservazione dei monumenti del Piemonte e della Liguria*, 7 *seq.* (Turin, 1899); M. Bernardi, *Torino ed i suoi dintorni* (Rome, 1950).

TURINA, JOAQUIN (1882–1949), Spanish composer, was born at Seville on Dec. 9, 1882. He studied under Paul d'Indy, in Paris, 1905–14, where he wrote an encyclopaedia (*Enciclopedia abreoiada de la música*, Madrid, 1917). His principal works are: *Procesidn del Rocio* for orchestra; music for the morality play, La *adziltera penitente;* a dramatic work, *Jardín de oriente* (1923); a pianoforte quintet, a string quartet, *Escena Andaluze,* for viola, pianoforte and string quartet; *Poema de una Sanluqueña,* and songs. He died Jan. 14, 1949, in Madrid.

TURKESTAN: *see* TURKISTAN.

TURKESTAN (HAZRET, YASI), a town in the Kazakhstan Soviet Socialist Republic. in 43° 8′ N., 68° 18′ E., on the Orenburg-Tashkent railway 20 mi. E. of the Syr-Daria river. altitude, 833 ft. Population about 30,000. Its main industry is cotton, and it acts as a depot for the collection of hides and wool. It is an ancient town and in 1397 a Persian architect was commissioned by Timur (Tamerlane) to build a mosque in honour of the Kirghiz patron Hazret Yasavi.

TURKEY, a republic of the near east, with an area of 296,185 sq mi., comprising 9,068 sq mi. in Europe (Eastern Thrace) and 287,117 sq.mi. in Asia (Anatolia). The total includes 451 sq.mi. of swamps and marshes and 3,256 of lakes. A survey in 1955 established the area of the country as 301,380 sq.mi. It is bounded on the east by the U.S.S.R. (367 mi.) and Iran (Persia) (292 mi.); on the south by Iraq (235 mi.) and Syria (490 mi.) and the Mediterranean sea; on the west by Greece (127 mi.) and Bulgaria (124 mi.) and on the north by the Black sea.

Turkey in Europe is separated from Anatolia by the straits—the Bosporus. the Sea of Marmara and the Dardanelles—which form the only sea passage between the Black sea and the Mediterranean. It is bounded on the northeast by the Black sea, and on the southwest by the Aegean sea. The western frontier with Bulgaria and Greece was determined by the treaty of Lausanne (July 24, 1923). It runs from Ayastafanos on the Black sea along the valley of the small river Rezvaya, across the Istranca mountains and continues westward to the river Tundzha (Tunja), which it crosses about 15 mi. N. of Edirne (Adrianople). From this point it turns southwest to the river Maritsa (Meric) which it strikes about 15 mi. upstream from Edirne. There the frontier with Bulgaria ends and that with Greece begins. The border follows the Maritsa to Edirne (Adrianople), where on the right bank the suburb of Karagach (Karaagac) and a small part of the railway are included in Turkey; then the river is followed to its mouth near Enos (Enez).

The islands of Imroz (Imbros) and Bozcaada (Tenedos) off the Dardanelles belong to Turkey; otherwise the Aegean and the Mediterranean coast line is the boundary to a point just south of the mouth of the Orontes (Asi) river where the frontier with Syria begins. The line runs irregularly east and north through mountainous country, enclosing Antakya (Antioch) and its lake, to Meydaniekbez, where it turns east across the Baghdad railway, which it crosses again at Cobanbey (see *Communications,* below). It then runs about one yard south of the railway to Nusaybin (Nisibis), where it again crosses it and turns slightly north to Cizre (Jezirat ibn Omar) on the Tigris which it follows in a southerly direction to its confluence with the Khabur (Habur). The frontier with Syria, which ends at this point, was originally defined when the French withdrew from Cilicia in the Franco-Turkish agreement of Oct. 20, 1921, and was confirmed by the treaty of Lausanne (1923). Under the terms of this treaty the Antakya-Alexandretta district known as the sanjak of Alexandretta (Iskenderun) came within the French mandate for Syria but enjoyed a special administration by virtue of its large Turkish population. In 1939, when the grant of independence to Syria (*q.v.*) appeared imminent, the district was annexed to Turkey and became the Hatay province, the boundary of which, from the mouth of the Orontes to Cobanbey, became the western section of Turkey's frontier with Syria.

The question of the frontier with Iraq, in accordance with article 3 of the treaty of Lausanne, came before the council of the League of Nations and was defined in the Ankara convention of June 5, 1926. Delimitation was completed in 1928. The frontier starts from the junction of the Khabur with the Tigris about 80 mi. N.W. of Mosul, follows the Khabur and its tributary the Hazil Su northeastward into the mountains, then turns east and traverses the difficult Kurdish highlands to the Ruhar-i-Shin where it turns south across the Semdinan Su to the Rubar-i-Haji Bey and follows this river in a northeasterly direction to its source in the Persian watershed.

A frontier commission was delimiting the boundary between Turkey and Persia when World War I broke out in 1914. In order to put an end to frontier incidents which had occurred, an *accord* de *délimitation* was signed on Jan. 23, 1932, and a further rectification of the line in the neighbourhood of Paki and Eli was settled on May 27, 1937. From the junction with the Iraqi frontier the line runs in a general northerly direction in mountainous country to a point about 25 mi. S. of Mount Ararat (the Agri Dag), where it turns east for about 20 mi. and then north to enclose this mountain until the river Aras (Araxes) is reached. There the frontier with Iran ends and that with the U.S.S.R. begins.

The frontier with the U.S.S.R. was defined in an annex to the treaty of Moscow (March 16, 1921) and by article 4 and three annexes of the treaty of Kars (Oct. 13, 1921). From a point roughly east of Ararat the boundary line follows the Aras to its junction with the Arpa, which it then follows, skirting the Alagoz volcano, to a point about 10 mi. W. of Leninakan (Aleksandropol). There the line swings in a great bow, northwestward over the Transcaucasian mountains and then westward, enclosing Kars, Ardahan and Artvin; crossing the river Coruh (Chorokh), it reaches the Black sea less than 10 mi. S. of Batum.

Physiography. — Turkey has been described as a bridge between Europe and Asia. Though the western end of the bridge has been broken down toward the Aegean and is interrupted by the straits, the customary division into European and Asiatic Turkey is an arbitrary one derived from the strategical and political importance of the straits. European Turkey is no more than the western continuation of the northern coast land of Anatolia. The geological upheavals which determined the formation of the land surface had not ended in the 20th century, as the disastrous earthquakes of modem times testify.

Turkey in Europe, a rough triangle with its apex on the Bosporus, has a northern and southern fringe of mountains, the Istranca and Tekirdag ranges, and a central undulating plain through which run the valleys of the Maritsa and the Ergene, draining the landward slopes of both highlands. East of the Maritsa and Tundzha rivers the central lowland is the only avenue from the west to Istanbul. About 25 mi. W. of Istanbul, a transverse ridge 600 ft. high crosses the peninsula from Terkos lake to Buyuk Cekmeca. This ridge is the foundation of the defensive system known as the Chatalja (Catalca) lines.

Asiatic Turkey (Anatolia) is roughly rectangular in outline, almost three times as long from east to west (about 900 mi.) as from north to south (about 300 mi.). Its main features are: (1) a central plateau extending nearly 500 mi. eastward from the latitude of Istanbul; (2) a mountainous girdle encircling the plateau on north. west and south and (3) an almost entirely mountainous region which becomes progressively wilder and more rugged up to the frontiers of the U.S.S.R. and Iran.

The central plateau is elevated to an average height of 3,000 ft. above sea level. Most of it is semidesert or steppe with scanty pasture except where the rivers flow through it with strips of fertile land bordering them. There are numerous depressions where marshes, shallow lakes or mud flats have been formed. Some of these are brackish because of the solubility of the rocks over which the water has reached them. The largest of these basins is a salt lake, Tuz Golu, in the centre of the plateau, about 60 mi. S. of Ankara (Angora). West of Ankara much of the country is rolling upland, between 3,500 and 4,500 ft. above sea level, with a few rounded summits nearly 6,000 ft. high. To the south and east of the capital is a region of rolling uplands with the remains of extinct volcanoes and, particularly in the neighbourhood of Kayseri (Caesarea Mazaca), lava and ash from them. To the north and northeast toward Sivas the level of the plateau rises, falling again in the direction of Amasya (Amasia) and Chorum (Corum). Near Sivas the Kizil Irmak (Red river) is at about 4,500 ft., and the central plateau is enclosed by mountain ranges on the east, northwest and southwest.

The Black sea coast between the Bosporus and the Soviet frontier is about 750 mi. long and has, throughout most of its length, steep, broken country near the seaboard. The breadth of the coast land is less easy to define. There is no clear dividing line between it and the central plateau in the western part, though to the east the character changes and there is a sharp division between the high mountain ranges on the coast and the hinterland. There is a fertile plain, the delta of the Sakarya river, between the gulf of Izmit and Eregli. Between Eregli and Inebolu the mountains rise to 3,000 ft. close to the sea and peaks inland to more than 6,000 ft. The hills are well forested, and the valleys between them, running from north to south, with branches parallel to the coast, are extensively cultivated. Coal is mined between Eregli and Cide. East of Inebolu the coastal range rises steeply from the sea and then falls abruptly about 30 mi. S. of the coast. Inland of Sinop, at Bafra where the Kizil Irmak reaches the sea and also east of Samsun are areas of coastal plain. Generally speaking, the inland belt is well-wooded, and the rounded mountains form a series of plateaus with fertile depressions between them. From Ordu to the Soviet frontier the features are a coastal range about 20–30 mi. from the shore, between which and the higher volcanic ranges to the south run the Kelkit and Coruh valleys.

Western Anatolia may be defined as the region west of long. 30° E., which comprises the Aegean coastland up to the central plateau. The coast line is deeply indented and has many natural harbours. The country bordering the Sea of Marmara is relatively low with streams running north or south, for which the hills around Balikesir are the collecting ground. The valley of the Simav separates these hills from the higher country to the east in which the forest-clad Ulu Dag (the Mysian Olympus of the ancients) stands about 8,000 ft. above the fertile slopes around Bursa (Brusa); ranges average more than 5,000 ft. to the Egrigoz Dag (7,000 ft.), about 50 mi. to the south. The fertile coastal region of Bergama (the ancient Pergamum) lies between the Simav valley and the three east-west valleys of the Gediz and the Kucuk and the Buyuk Menderes (the Little and the Great Maeander). The region to the east of Izmir (Smyrna), which is watered by the last two rivers, is bounded by two semielliptical chains of mountains, the western one of which rises to an average of 4,000–5,000 ft. with peaks reaching more than 7,000 ft. Between this and the eastern range, 200 mi. inland at its furthest point, is a rich alluvial plateau. To the south are rugged highlands which end abruptly at the Mediterranean coast west of the Dalaman valley.

The southern edge of the central plateau is followed by the railway from Afyon (Afyon Karahisar), which traces a wide curve southeastward through Konya (Konia) to Karaman and then northeast to Kayseri. Between this line and the sea lie the Taurus mountains. From the Dalaman valley on the west to Silifke on the east a bundle of ranges, not always continuous and sometimes ill-defined, enclose the Adalia (Antalia) plain. The main Taurus, an irregular chain to the northeast, dominates the Seyhan and Ceyhan coastal plains in which lie Mersin and Adana. It is broken by the

Cakit gorge which leads to the famous Cilician Gates, the route from the central plateau to the sea. The Taurus, rising to more than 12,000 ft. southwest of this gorge, ends south of Kayseri, which is overlooked by the separate volcanic group. the Erciyas (the Mount Argaeus of the ancients). East of the Seyhan lowland is the narrow strip of lowland along the sides of the Gulf of Alexandretta, at the head of which a gap between two parallel ranges forms the ancient Amanus Gates, the Kalekoi pass between the Misis Dag on the west and the Gavur Dag (classical Amanus) on the east. Beyond the Taurus to the east is a group of seven ranges, the Anti-Taurus, all of which have a general trend to the northeast. The Kurt Dag, the Gavur and the Misis are the southernmost of the group, but none has an inclusive name. The central ranges are much cut up by tributaries of the Seyhan and Ceyhan rivers. There are numerous peaks with heights between 7,000 and 8,000 ft., and the Nuruhak Dag, southwest of Malatya, is 10,100 ft.

Southeastern Turkey may be defined as the belt bounded on the south by the frontiers with Syria and Iraq, on the east by the frontier with Iran and on the north by the mountain ranges which form the watershed of the Euphrates and the Tigris. The Euphrates basin, on the west, is an irregular strip through which the river runs between precipitous banks. Most of the villages are on tributaries well back from the river. Between it and the Tigris valley is a barren, undulating plain, north of which rise the rugged heights of the Kurdish Taurus. The Tigris rises near the Hasar lake, flows on an erratic course southeast to Diyarbakir and then east, fed by numerous tributaries on the way. It passes there between deep gorges turning south and then east to Cizre, where it meets the frontier with Syria.

East of the Tigris to the Iranian frontier lie the Kurdish mountains, with summits rising to more than 13,000 ft. On the west the country is wild, and rivers and their tributaries cut erratically between the crests. In the centre the ranges end in precipitous cliffs facing southwestward; further to the east the country is lower and becomes milder to the Iranian frontier. The Great Zab (Buyuk Zap Su), the tributaries of which drain the extreme southeastern comer of Turkey, passes through deep gorges in wild and difficult country and, cutting through the Cilu range, crosses the Iraqi frontier.

Eastern Turkey north of this region to the Kelkit and Coruh valleys is largely volcanic, with cones rising to 11,000 ft. or more surrounded by lava fields. Some ranges of nonvolcanic origin vary an otherwise monotonous landscape. The Murat Su, which rises north of Lake Van, almost in the shadow of Mount Ararat, crosses the area from east to west to join the Euphrates 250 mi. away. Lake Van, which lies at 5,643 ft. above sea level, is about 80 mi. long from east-northeast to west-southwest and about 35 mi. across at its widest point; it has no outlet. Mount Ararat, a volcanic cone rising to 16,916 ft., is the loftiest of the Agri Dag group on the frontier of Soviet Armenia, south of Erivan.

Climate.—The structure of Turkey—a central plateau surrounded by coastal belts of mountains—gives regional variations in climate which generally follow the divisions described above, although local differences due to latitude, altitude and topography occur. The central plateau has hot, dry summers and cold winters with rain or snow between November and May. The eastern part of the plateau is colder than the western in winter; the summers are cool in the north, but hot in the south. The change in climate is rapid from the Black sea coastlands to the plateau. In this region the winters are mild on the coast; the summers are hot and damp. Fog and mist are frequent throughout the year. Winter temperatures fall rapidly and rainfall increases from the coast to the mountain heights inland. In western Anatolia the change in altitude from coast to plateau is less abrupt and the climatic change is more gradual. The summers are hot and dry; the winters near the coast are mild and damp but become colder inland with frost and some snow. Rainfall is moderate (20–30 in.) on the coast and decreases inland. On the southern coastlands the temperature in winter is moderate, and this is the warmest part of Turkey. The summers are hot and, particularly in the eastern coastal lowlands, oppressive because of the high humidity. In the southeastern region the summers are extremely hot but the winters are milder than on the central plateau. Eastern Turkey has wide variations of temperature because of its mountainous character, and the northeastern district (Erzurum-Kars), where snow lies for four months of the year, has the coldest winter in Turkey. The summers are hotter in the south than in the north, but reliable records are scanty for this region. See Table I.

Table I.—Temperatures and Rainfall

Station	Absolute maximum and minimum recorded temperatures (degrees Fahrenheit)			Mean annual rainfall	
	Max.	Month	Min.	Month	Inches

(K. C. B.)

HISTORY

The first appearance of the Ottoman Turks in history dates from the early 13th century. According to the official tradition of the Turkish historiographers, Ertughrul, the father of the first sultan, Osman, was a member of the tribe of Kayi, the most exalted branch of the Ghuzz (Oghuz) Turks, who had been driven from their home in central Asia by the advancing Mongols. He and his small band of tribesmen found their way into Anatolia, where the Seljuk sultan Ala ud-Din Kaikobad I, in gratitude for their timely intervention when he was hard pressed by a superior Mongol army, gave the gallant stranger a grant of lands around Soghut. Modern research (notably by Paul Wittek; see *Bibliography)* proved the greater part of this romantic story false. The weight of evidence is against Ertughrul's exalted Kayi genealogy. Nor was it tribal loyalty that held his followers to him, any more than it retained men's allegiance to his descendants for nearly seven centuries.

From at least the early 9th century, there are record: in the Moslem east of organizations of ghazis, (fighters for the faith), men sworn to wage ceaseless war on the infidel, through motives of religious zeal or greed for loot or both. Such were the followers of Ertughrul. Ertughrul was not the only ghazi leader to establish a dynasty; the beyliks (principalities) of western Asia Minor —Menteshe, Aidin (Aydin), Karesi, Sarukhan—were all founded by ghazis. So also was the Saffarid dynasty which ruled in Persia between 860 and 1000. When a ghazi organization settled down in a conquered territory, there was always a hard core of warriors who, remaining true to their purpose, refused to become peaceful citizens. These would naturally move on to any place where the fight against the infidel was still being fought. In this fact lies the reason for the extraordinary success of the line of Ertughrul; their field of operations was on the frontiers of Byzantium, where in fighting the Christian a ghazi might best fulfill his destiny. The Ottoman power was therefore perpetually strengthened by an endless stream of recruits from the more settled lands to the south and east.

In assigning to Ertughrul the lands around Soghut, the Seljuks were only recognizing a *fait accompli.* Soghut remained his headquarters. and when he died in 1281, at the age of 90, it was there that he was buried.

THE OTTOMAN SULTANATE

Osman I (1281–?1325).—Ertughrul was succeeded by his son Osman (b. 1258), the first sultan of the dynasty to which he gave his name ("Ottoman" is a barbarism for "Osmanli"). In 1284 he mas confirmed in his dominions by the Seljuk sultan Masud. He proceeded steadily with the work of enlarging his territories, taking Karajahisar in 1291, Bilecik and Yarhisar, and then Inegol in 1299. About 1308 the Seljuk sultanate came to an end, and the

Mongol Ilkhanids of Persia and Mesopotamia, to whom the Seljuks had been tributary, entrusted Anatolia to a Mongol prince, Timurtash. who tried with no great success to bring all the principalities under his sway. The main opposition to him came from the bey of Karaman, a powerful state which later gave the Ottomans a great deal of trouble. The fall of the Seljuks is generally regarded by Ottoman historians as marking the beginning of Ottoman independence, but it is known that Osman's successor continued to pay a yearly tribute to the Ilkhanids.

Toward the end of Osman's life, infirmity compelled him to depute his authority to his son Orkhan by 1324. By the time of his death (1325 or 1326), his dominions extended over the triangle contained by Hendek in the north, Eskisehir in the south and Lake Apolyon in the west.

Orkhan (?1324–62).—Orkhan had won the succession through his military ability, his elder brother Ala ud-Din being a man of pacific and scholarly temperament (he is generally identified, on no good authority, with the Ala ud-Din Pasha who served as vizier to the first two sultans). In 1.326 the Ottoman forces captured Bursa, which had been under siege since 1315. In 1329 a Byzantine army under the personal command of the eastern Roman emperor Andronicus III was defeated at Pelecanon (Maltepe); and Nicaea (Iznik) fell shortly afterward. In 1336 Orkhan profited by a dynastic quarrel in the neighbouring beylik of Karesi to annex a portion of its territory, including Pergamum. This acquisition placed a number of experienced seamen at the disposal of the Ottomans. The next year Nicomedia (Izmit) was wrested from the Greeks, and by about 1340 the Byzantine possessions in Asia Minor had been reduced to a few coastal towns near Constantinople.

A period of consolidation followed, until 1345, when dissension among the Greeks gave the Turks a bridgehead in Europe. In that year the usurper John Cantacuzenus appealed to Orkhan for aid against the rightful emperor John V Palaeologus. An Ottoman force was promptly dispatched which penetrated into the Balkans, inflicted a heavy defeat on the loyalists and returned laden with booty. John Cantacuzenus gave Orkhan his daughter in marriage; then, in 1352, as a reward for further help, he permitted the sultan to garrison the fortress of Chimpe on Gallipoli. He soon realized his mistake when the Ottomans advanced from this base to occupy the rest of the peninsula; his suggestion that Orkhan should sell Chimpe back to him and evacuate Gallipoli was not accepted. After the usurper's downfall in 1355, John Palaeologus was obliged to recognize Orkhan's territorial acquisitions in Rumelia. The sultan did not neglect his eastern frontiers; in 1354 an army commanded by his son Suleiman Pasha took Ankara from the son of Ala ud-Din Ertena, an Ilkhanid governor-general who had established himself at Sivas. Orkhan died in 1362 and was succeeded by his son Murad, Suleiman Pasha having predeceased his father by three years.

***Murad I* (1362–89).**—The reign opened brilliantly with the capture of Adrianople and Philippopolis by Lala Shahin Pasha. The efforts of the Greek emperor, in alliance with the doge of Venice, to expel the Turks from Europe came to nothing, in consequence of the Ottoman policy of settling nomads from Anatolia in the conquered territories. Although the exact date is not known, it was probably about this time that the corps of janissaries (*q.v.*) was founded, with Christian youths captured in the wars. In 1363 an allied army of Serbs, Bulgars, Walachians, Bosnians and Hungarians, headed by Louis I of Hungary, was routed on the Maritsa. Two years later Murad made Adrianople his capital and began to enrich it with palaces and mosques. By 1369 the conquest of eastern Thrace was completed. The Serbian ruler of Kyustendil, an important iron-mining centre, became tributary to the Turks in 1372, and Lazar I Hrebelyanovich of Serbia was soon obliged to follow his example. During the subsequent lull in hostilities the flow of Turkish settlers to the newly acquired lands continued and the foundations of Ottoman administration were firmly laid there.

The temporary peace did not interrupt the enlarging of the Ottoman territories. Murad married his son Bayezid to Devlet Khatun, daughter of the bey of Germiyan (Kermian), his southern neighbour. Her dowry consisted in the major portion of her father's lands, including the city of Kutahya. From this convenient base Murad intimidated the bey of Hamid into selling him a large part of his principality, contiguous to the frontiers of Karaman. Ali Bey of Karaman, probably in league with the ruler of Hamid, persuaded Stephen I Tvrtko, king of Bosnia, to attack the Turks in Rumelia and then took advantage of Murad's absence in Europe to occupy the former Hamidian provinces. Murad left Jendereli Khair ud-Din Pasha to deal with the situation in Rumelia and returned to Anatolia, with Byzantine and Serbian auxiliaries, to crush Ali Bey at Konia (1387). An Ottoman force under Timurtash Pasha invaded Bosnia but was totally defeated by a combined Bosnian and Serbian army. The princes and kings who had consented to pay tribute were encouraged to rebel by this success. Murad appealed for help to the Anatolian beys; some complied, including those of Germiyan and Hamid, but not Karaman. Murad then returned to Europe with a large force and sent Chandarlizade Ali Pasha northward; the fortresses of Shumla, Pravadi, Trnovo, Nicopolis and Silistria were taken by him. Ivan Shishman III, the rebel king of Bulgaria, was punished and his country once more subjugated. Ali Pasha then joined his master at Kosovo. There Lazar of Serbia had collected an army of 100,000 Serbs, Hungarians, Moldavians, Walachians and others. On Aug. 27, 1389, the greatest of the battles of Kosovo was fought. Lazar was captured and his army cut to pieces, but after the battle Murad was slain. Serbian tradition tells that he was assassinated by Milosh Kobilovich, a Serb who approached him on the plea of submission.

Murad was succeeded by his eldest son, Bayezid. His second son, Savji, had plotted with Andronicus, son of the emperor John Palaeologus, to dethrone their respective fathers. The attempt failed; Andronicus was ordered by his father to be blinded and Savji was put to death (1385).

Bayezid I* (1389–1403).**—After being proclaimed on the field of Kosovo, Bayezid ordered the execution of his remaining brother Yakub. There is some evidence that in killing his brother the new sultan was following the example set by his father on his accession. Lazar II, otherwise called Stephen, Lazar I's son and successor on the throne of Serbia, made haste to conclude peace with Bayezid; he acknowledged his suzerainty and gave him his sister in marriage. Turks and Tatars were settled between Nish and Uskub Skoplje. The sultan then returned to meet a grave threat in Anatolia. The bey of Karaman, on hearing of Murad's death, had roused the beys of Aidin, Sarukhan and Menteshe against the Ottomans. Independently of these, Yakub of Germiyan was resolved to take back the lands that had gone to make his sister's dowry. Bayezid acted with great promptness. In the winter of 1390 he overran Aidin and Menteshe and then marched east to occupy Germiyan. In his retinue was Manuel, son of the emperor John V Palaeologus. Kara Timurtash Pasha was appointed ***beylerbeyi (governor-general) of Anatolia, with his headquarters at Kutahya. In the spring of 1391 the Ottomans invaded Karaman. Hearing that the Walachians, in league with the dispossessed beys, were in revolt, Bayezid made peace with Karaman and, by a brilliant march to the Danube, put down the rebellion. Meanwhile Manuel Palaeologus, learning of his father's death, hastened to Constantinople to claim the throne as Manuel II, without obtaining leave from the sultan. Bayezid therefore blockaded the city. At the end of seven months, the new emperor not only agreed to pay an increased tribute but also consented to the building of a mosque in the capital and to the appointment of a kadi to judge between Moslems residing there. The reason for the sultan's willingness to lift the blockade was that Sigismund of Hungary, later western emperor, had, with Walacbian help, entered Bulgaria, capturing Nicopolis from the Turkish garrison. At the news of Bayezid's approach, Sigismund withdrew and the sultan returned to Anatolia to crush the turbulent ruler of Kastamuni (1392). At the end of 1394 Bayezid sent envoys to Egypt, requesting that the caliph should recognize him as sultan of Rum; and this was done.

In the same year Pope Boniface IX had proclaimed a crusade against the Turks. The attack came in 1396, when armies from many European countries assembled in front of Nicopolis. So elated were the allies by some minor initial successes that Sigismund even spoke of going on to the conquest of Jerusalem. The speed of Bayezid's advance was such that the crusaders at first refused to believe the reports of his proximity. Their over-confidence resulted in their annihilation. After this victory the siege of Constantinople was resumed, and about this time the fortress of Anadolu Hisari, on the Asiatic side of the Bosporus, was built. It seems that the Ottoman plan was to starve the city, rather than to take it by assault, but as the Turkish naval forces were negligible the Byzantines had no difficulty in obtaining supplies and reinforcements by sea. Bayezid overran Thessaly in 1397 and, until the spring of 1402, carried out a series of raids on the Morea, leaving colonies of Turks to hold the captured districts. In 1397 the sultan also took Konya after a siege and killed the bey of Karaman, who had attacked Ankara and captured Timurtash Pasha while Bayezid was fighting Sigismund at Nicopolis. The Ottoman territories were also extended in the northeast, to march with the empire of Trebizond.

Meanwhile Timur (Tamerlane) had started from Samarkand on his victorious career. After devastating Georgia in 1400 he marched against the Turks. Some of the dispossessed princes of Asia Minor had begged Timur to reinstate them. Bayezid replied to a request to this effect from Timur in terms which made war inevitable. An attack in force was postponed by Timur's activities in Syria and Mesopotamia. But in 1402 in a great battle near Ankara the Turks were defeated and Bayezid was taken prisoner. Eight months later he died at Akshehir. probably by his own hand. This disaster checked the Ottoman advance for more than a decade. Timur reached Bursa and looted it, although Suleiman, Bayezid's eldest son, who fled after the battle, had forestalled him in carrying off the Ottoman treasury. One after another the Anatolian cities of the Ottomans were seized and plundered by the Tatars. (G. L. L.)

Mohammed I (1413–21).—Timur had sent letters after the fugitive sons of Bayezid promising to confer on them their father's dominions and protesting that his invasion had been due merely to the insulting tone adopted toward him by Bayezid and to the entreaties of the dispossessed princes of Asia Minor. He did not cross into Europe, but moved eastward after capturing Smyrna and restoring the dispossessed beys. For some time further, disputes between the sons of Bayezid delayed the Turkish revival. However, Mohammed I (*q.v.*), the youngest, was recognized as sultan in 1413 and recovered nearly all his father's territories in his reign of eight years. Two years after his accession he compelled the prince of Karaman to yield up a number of his cities and then, turning northward, forced Mircea, voivode of Walachia, to pay tribute. The Turkish dominions in Asia Minor were extended, Amasia, Samsun and Janik being captured, and an insurrection of dervishes was quelled. In 1421 the sultan died. His services in the regeneration of the Turkish power were great. Amid the cares of state he found time for works of public utility and for the support of literature and art; he is credited with having sent the first embassy to a Christian power, after the Venetian expedition to Gallipoli in 1416. He was succeeded by his son Murad.

Murad II (1421–51).—Shortly after his accession the emperor Manuel, having applied in vain for the renewal of the annual subsidy, paid him by the late sultan for retaining in safe custody Mustafa, an alleged son of Bayezid (see MOHAMMED I), released the pretender. After ruling in Rumelia for more than a year he was defeated and hanged at Adrianople (1422), and Murad thereupon laid siege to Constantinople to avenge himself on the emperor. The siege was raised because the appearance of another pretender, in the person of Murad's 13-year-old brother Mustafa, under the protection of the revolted princes of Karaman and Germiyan, called the sultan to Asia. Mustafa, delivered up by treachery, was hanged (1424); but Murad remained in Asia, restoring order in the provinces, while his lieutenants continued the war against the Greeks, Albanians and Walachians. Constantinople withstood a siege in 1422, but by the treaty signed on Feb 22, 1424, shortly before his death, the emperor Manuel II, in order to save the remnant of his empire, agreed to the payment of a heavy annual tribute and to surrender all the towns on the Black sea except Selymbria and Derkos and those on the Struma (Strymon) river. Peace was also made at the same time with the despot of Serbia and the voivode of Walachia, on the basis of the payment of tribute. By 1426 the princes of Germiyan and Karaman had submitted on honourable terms, and Murad was soon free to continue his conquests in Europe. Of these conquests the most conspicuous was that of Salonika. Garrisoned by 1,500 Venetians, the city was carried by storm (March 1, 1430); the merciful precedent set by Mohammed I was not followed, the greater part of the inhabitants being massacred or sold into slavery and the principal churches converted into mosques.

By this time it was widely recognized that a further Turkish advance could be prevented only by the combined action of the northern peoples now definitely threatened. In 1442 a force of Slavs and Magyars under the voivode Janos Hunyadi (*q.v.*) drove the Turks from Nagyszeben (Sibin). In the following year they were expelled from Smederevo, which they had conquered a few years previously. Meanwhile, again confronted by a rebellion of the prince of Karaman, Murad had crossed into Asia and obtained his submission, granting him honourable terms in view of the urgency of the peril in Europe. On July 12, 1444, a ten years' peace was signed with Hungary, whereby Walachia was placed under the suzerainty of that country. Conscious of failure, Murad abdicated in favour of his young son Mohammed and retired to Manisa (Magnesia) in 1444. Pope Eugenius IV urged the king of Hungary to take advantage of this favourable opportunity, and 19 days after the truce had been concluded a large army headed by Wladyslaw I of Hungary, Hunyadi and Cardinal Cesarini crossed the Danube and reached Varna. In this emergency Murad was implored to return to the throne. After some hesitation he agreed and, crossing over with his Asiatic army from Anadolu Hisari, hastened to Varna and routed the allies. Murad is said to have abdicated a second time and to have been again recalled to power because of a revolt of the janissaries. In 1446 Corinth, Patras and the north of the Morea were added to the Turkish dominions. The latter years of Murad's reign were troubled by the successful resistance offered to his arms in Albania by Skanderbeg (*q.v.*). In 1448 Hunyadi, now governor of Hungary, collected the largest army yet mustered by the Hungarians against the Turks, but was defeated on the famous field of Kosovo. In 1451 Murad died at Adrianople, being succeeded by his son Mohammed.

Mohammed II the Conqueror (1451–81).—After suppressing a fresh revolt of the prince of Karaman, the new sultan gave himself up entirely to the realization of the long-cherished project of the conquest of Constantinople. After building in 1452 the Castle of Europe (Rumeli Hisari) Mohammed began the siege in 1453. Constantine XI Palaeologus, the last emperor, failed to obtain support from the west, the defenders of the city were vastly outnumbered by the Turks and on May 29, 1453, it was carried by assault. The sultan triumphantly entered the palace of the emperors, and the next Friday's prayer was celebrated in the church of St. Sophia.

Secure in his possession of Constantinople the sultan proceeded northward and entirely subdued the southern parts of Serbia. A siege of Belgrade was unsuccessful, because of the timely succour afforded by Hunyadi (1456). Two years later internal dissensions in Serbia brought about the conquest of the whole country by the Turks, only Belgrade remaining in the hands of the Hungarians. Walachia was next reduced to the state of a tributary province. Because Venice adopted a hostile attitude after Turkey's conquests in the Morea, greater attention was devoted to the fleet; Mytilene was captured and the entrance to the straits fortified. The conquest of Bosnia, rendered necessary by the war with Venice, was next completed, in spite of the reverses inflicted on the Turks by the Hungarian king Matthias Corvinus, the son of Janos Hunyadi. The Turks continued to press the Venetians by land and sea; Albania was overrun; and Venice was forced to agree to a treaty by which she ceded to Turkey Scutari (Shkoder) and Kroia, and consented to pay an indemnity of 100,000 ducats (Jan. 25, 1478). The Crimea was next conquered and bestowed as a tributary province on the Tatar khan Mengli Ghirai. Mohammed now endeavoured to strike a blow at Khodes, the stronghold of the Knights of St. John, preparatory to carrying out his long-cherished plan of conquering Italy. A powerful naval expedition was outfitted but failed, though a land attack on southern Italy at the same time was successful, Otranto being captured and held for a time by the Turks. In 1481, setting out on campaign, the sultan died at Gebze. He is said to have been of a merry and even jocular disposition, to have afforded a generous patronage to learning and art and to have been master of six languages.

Mohammed II was the organizer of the fabric of Ottoman administration in the form which it retained practically unchanged until the reforms of Mahmud II and Abdul-Mejid. He raised the regular forces of the country to a total exceeding 100,000. Under him the independent princes of Asia Minor were finally subjugated. Many educational and benevolent foundations were endowed by him, and it is to Mohammed II that the organization of the ulema, or legist and ecclesiastical class, is due.

Bayezid II (1481–1512).—Bayezid reached the capital before his brother Jem and ascended his father's throne. To win over the followers of his brother he paid an accession present to the janissaries: this became an established custom. Jem's attempts to seize the throne were defeated. He took refuge with the Knights of Rhodes, but they were paid to keep him in custody. He was removed to Europe and, after 13 years' captivity, died in Naples. He was said to have been poisoned by Pope Alexander VI, who received 300,000 ducats from Bayezid, but from *Taj-ut-Tevarih,* the most reliable history of the period, his illness sounds like erysipelas.

Bayezid was a man of peace by nature and quite incapable of directing the warlike tendencies of the young empire. He abandoned Otranto and exempted Venice from her yearly tribute by imposing instead a 4% customs duty on Venetian goods imported. In 1492 the armies of the Turks invaded Laibach in Carniola and Cilli in Styria. In 1494 they were driven out of Styria by the emperor Maximilian. While Bayezid was fighting against his brother's claims, Moldavians attacked Turkish territory in Walachia and he was forced to lead another Turkish army into Moldavia. The khan of the Crimea, Mengli Gherai, fought in this army, and through his influence political correspondence was opened between Russia and Turkey, and the first Russian ambassador, Mikhail Belsechev, arrived in Constantinople. Moldavia became a vassal state after two years of war. John Albert, king of Poland, invaded Moldavia in 1496; and this was followed by a counterinvasion of the Turks, but they were forced to return by the severe winter. In 1496 Hercegovina was annexed to the empire, and in 1500 the Polish wars ended with an armistice. Rome and the Italian states had encouraged the sultan to crush the Venetian republic. The Turks gained over Venice their first great naval victory at Lepanto on July 28, 1499, and concluded peace on Dec. 24, 1502; a part of Morea and a few islands passed to Turkey, Venice retaining Cephalonia. On the Asiatic side Ismail Safavi, the shah of Persia, inspired with religious zeal for the propagation of Shi'ite doctrines, raided the empire (1501). The sultan attempted a pacific solution but failed to restrain his warlike son Selim from fighting the Persians. Shah Ismail's propaganda rooted the Shi'ite doctrines so firmly in Anatolia that in spite of the sanguinary repressions during the reign of Selim I, and the republican law of 1925 abolishing the dervish orders, adherents of the Kizilbash and other Shi'ite sects remain there to this day. Bayezid had also to fight the Egyptian armies under the Mamelukes who had invaded Adana, and he drove them out.

Selim then turned upon his father and, having won the janissaries to his side with promises of conquest, forced him to abdicate. Bayezid died on his way to his retreat at Dimotika. The political influence of the janissaries on the frequent change of sultans dates from this episode.

Selim I the Grim (1512–20).—True to his promise Selim kept the janissaries in action throughout his reign. After defeating his brother's claims, he attempted to exterminate Shi'ism not only in Anatolia but in Persia which was its centre. In 1514 he annihilated Shah Ismail's forces at Chaldiran and conquered Azerbaijan and Kurdistan. His most important conquests were Syria and Egypt, which he added to the empire after defeating the Mamelukes in 1516 and 1517. According to most Turkish and western historians he obtained from the last of the Abbasid caliphs, Mutawakkil, the title of caliph. (After the fall of the caliphs of Baghdad in 1258, the descendants of the Abbasids took refuge in Cairo and enjoyed a purely titular authority under the protection of the Egyptian rulers.) But the important authority of the *Taj-ut-Tevarih* implies that Selim did not base his Pan-Islamism on the prestige of the caliphate, for the *Fetih-Name* (the declaration of conquest) of Selim himself, as there quoted, has no reference to caliph or caliphate. Another contemporary historian, Hasan Tulun, a Mameluke and an admirer of Selim, in his *History of Egypt,* also implies that Selim meant to realize Pan-Islamism through force rather than through the assumption of the title of caliph. He assembled the ulema in Egypt and, referring to the fact that the Mamelukes always had their sultan consecrated by the caliph, asked whether this was necessary: the ulema declared that the sultanate depended on force rather than on consecration. The sherif of Mecca, Abu'l-Baraka, sent his son with the holy relics and the keys of holy places to Selim. But though these relics are the emblems of the caliphate it is probable that Selim wished virtually to abolish it. Not until 1774 did a sultan claim also to be caliph.

An important revolt, led by Jelal who pretended to be the mahdi, broke out at Yozgad in Anatolia, but was at once suppressed and from this date *Jelali* came to be a general term for "rebel."

Selim, who died in 1520, never fought against the Christian west. Possessed by the ideal of uniting the Moslem east, he directed his campaigns accordingly. During his reign of eight years the empire nearly doubled its extent. Although he uprooted corruption and the people enjoyed a severe but just administration, his cruelty in executing eight grand viziers is alluded to in the popular saying: "May you be vizier to Sultan Selim." He was a distinguished poet, but wrote almost exclusively in Persian. His love of culture and learning was shown by his preference for the company of the learned. Although among his subordinates he punished small offenses with death, his sheikh ul-Islam, Ali-Jemali Efendi, who was fearless and outspoken, was able to make him desist from his plan of converting the Greeks to Islam by the sword if necessary, by reminding him of the conqueror's (Selim's grandfather's) firman, which gave religious freedom to the Greeks. At one time Selim tried to make Arabic the official language, to further his Pan-Islamic policy.

Suleiman I the Magnificent (1520–66).—Suleiman (Soliman) I, known as the "Magnificent" in the west and the "Lawgiver" in Turkey, being an only son, was saved from the wars of succession which his predecessors had to fight. He began his reign with the magnanimous act of freeing all the prisoners of war and restoring the goods confiscated from the merchants who traded with Persia in Selim's time. But this record is marred by the execution of two of his sons. That of the older, Mustafa, was thought due to the influence of his wife, the famous Khurrem Sultan, known as Roxelana (the daughter of a Russian priest), in order to leave her own sons without a rival. With her began the influence of women in affairs of state. She was also believed to have influenced the execution of the able grand vizier Ibrahim Pasha in order that his power might pass to Rustem Pasha, her son-in-law.

Suleiman's conquests were mostly in the west, though he had some Asiatic campaigns. He first marched into Hungary in 1521 ostensibly because his envoy had been slighted and because he received no congratulations on his accession. But actually he was resuming the northwestward march of his house that had been blocked by Hunyadi in 1456 He captured Belgrade, which remained a base throughout the Turkish wars in Europe. In 1522 Rhodes and Cos were conquered. In 1526 the Hungarians were severely defeated at the battle of Mohacs (*see* HUNGARY: *History*), their king. Louis II, killed and the greater part of Hungary including Budapest taken. The Turks appointed John Zapolya, the voivode of Transylvania, to be king of the Magyars. The sultan then left Hungary to put down a Shi'ite rising in Tabriz.

Ferdinand, the brother of the emperor Charles V, then claimed the Hungarian throne as the brother-in-law of Louis II, invaded Buda and drove out Zapolya, who naturally appealed to Suleiman. In 1529 Suleiman with Zapolya marched into Hungary, seized Buda and defeated the Austrians, and Zapolya was reinstated. Encouraged against Charles V by Francis I of France,, Suleiman laid siege to Vienna, but after three weeks was obliged to abandon it. Part of the Turkish army went as far as Regensburg in Germany. In 1532 Suleiman again marched against Charles V and approached Vienna, but in 1538 a truce was signed and Hungary was divided between Zapolya and Ferdinand.

During his Persian wars Suleiman retained the friendship of Ferdinand; but in 1540 Zapolya died and Ferdinand marched on Buda. Suleiman decided to uphold the claims of Zapolya's son and of his widow Isabella. He marched into Hungary, defeated Ferdinand and placed the young king on the throne under the regency of his mother. Suleiman refused all overtures of peace and war continued both on land and sea. In 1542 an alliance between Francis I and Suleiman led to a combination of the Turkish and the French fleets against Charles V. On land, Suleiman took Esztergom, Vizegrad, Szekesfehervar and a part of Hungary that became a Turkish province consisting of 12 sanjaks. On June 15, 1547, a truce of five years was signed in Adrianople between Suleiman, Charles V and Ferdinand which recognized the Turkish conquests and bound Ferdinand to pay a yearly tribute of 30.000 ducats to Turkey for the territory left to him. John Sigismund, the son of John Zapolya, was recognized as the independent prince of Transylvania and of the 16 adjacent Hungarian counties, Queen Isabella to act as regent during his minority.

The terms of the treaty were soon ignored. Ferdinand being in league with Frater Gyorgy (see MARTINUZZI, GEORGE) to free Transylvania from the Turkish suzerainty, Suleiman sent a large army under Sokollu Mohammed Pasha into Hungary. Lippa and Temesvar were taken but a victory of the Persians in the east forced Suleiman to sign an armistice in 1553 and invite Austrian delegates to Constantinople to negotiate for peace. The negotiations failed and war continued with atrocities on both sides till 1561. On June 1, 1562, peace was concluded between Suleiman and Ferdinand, who had been crowned emperor. Ferdinand undertook to pay all his arrears of tribute to Turkey and to continue a yearly payment of 30,000 ducats, to leave Temesvar and other towns to Suleiman, to recognize the independence of John Sigismund in Transylvania and to withdraw all his Habsburg claims to interference in Hungary.

In 1564 Ferdinand died and Maximilian II succeeded him. Maximilian attacked Tokay, which was in Turkish possession, and let the tribute fall into arrears. Sokollu Mohammed Pasha, the new Turkish grand vizier, desired to wipe out the disgrace of a naval defeat in Malta which had ended in the death of Adm. Torgut, and Suleiman in 1566 led an army into Hungary, although 72 years old. He died during the siege of Szigetvar, but his death was kept secret by Sokollu till the fortress fell. Thus Suleiman, after ruling 46 years in life, ruled 46 days after his death, until his son Selim ascended the throne and reached Belgrade.

On the Asiatic frontier in 1526 Shah Tahmasp of Persia had taken Tabriz from the Turks while Suleiman was fighting at Mohacs. On his return Suleiman set out for Persia with an army, conquered the Armenian plateau and joined another Turkish army commanded by Ibrahim Pasha which had already recaptured Tabriz. The Persians retreated without fighting and in 1534 Suleiman took Baghdad.

In 1536 the French ambassador, Jean de la Foret, negotiated a treaty between France and Turkey by which certain judicial and economic privileges were granted to France. This marks the beginning of the capitulations which, started when Turkey was a powerful empire, were at first regarded only as the means of procuring an easy market for Turkish goods in France. They led, however, to serious and enduring political complications and became the pretext for exploiting Turkey in her decadent days. In 1555 Suleiman concluded a treaty of peace with the Persians at Amasia after conquering Georgia, the Armenian plateau and Erzurum.

Murad II had begun the building of the Turkish navy but it was during Suleiman's reign that Turkey became a first-rate sea power. At no other time did Turkey have such a large number of famous admirals. Suleiman had conceived the idea of using the renowned corsairs who raided the Spanish and Irish coasts and he had engaged Khair ud-Din Barbarossa (see BARBAROSSA). Barbarossa was the son of a Turkish spahi, Yakub, a Macedonian, and his mother was Greek, his native place being Mytilene. He presented to Turkey Algiers, which he had personally conquered, and he formed what was called Garb Ojaklari (the states of Barbary). This was a military organization which administered Algiers, Tunis and Tripoli. Barbarossa took Tunis but was driven out by the fleet of Charles V, who devastated Tunis and destroyed mosques and valuable libraries because the Turks had converted churches into mosques in Hungary. Barbarossa's greatest naval victory was in 1538 when he defeated the combined fleets of the emperor, the pope and Venice under the command of Andrea Doria, off Prevesa. He took Castelnuovo and a few islands of the archipelago and he restored Morea to the Turkish empire. Torgut (known as Dragut in the west) was another famous corsair who had ravaged the Italian and Spanish coasts and was now engaged by Suleiman. He captured Tripoli from the Knights of Malta and was appointed its governor. He died in 1565, after an unsuccessful attack on Malta. Suleiman sent an expedition by sea to India in 1537, which conquered Aden on the homeward voyage. Piale Pasha, Piri Reis, Salih Reis, Seydi Ali Reis, were other renowned admirals of this period. Piri Reis and Salih Reis conquered the coasts of Yemen and Aden as far as the gulf of Basra. Piri Reis compiled a detailed sea atlas (Bahriye) of the Aegean and Mediterranean. He also conquered Muscat but was finally executed on the grounds that he had accepted bribes from the Portuguese to lift the siege of Ormuz. Seydi Ali Reis, a distinguished mathematician, succeeded him in the command of the fleet and was also defeated by the Portuguese. He escaped to the Indian ocean with three ships on which he lived for three years; then he landed and reached Turkey by land. He wrote his travels (*Mirat* ul-Memalik), a mathematical book on the astrolabe and a book called *Muhit* (Ocean) on the navigation of the Indian seas.

The Ottoman State in the 16th Century.—The Ottoman state evolved gradually from a society whose institutions were fundamentally nomadic. The power was divided between two classes: the military class representing force and the ulema representing religion. The judges belonged to the latter class, but their judgments were executed by the military. All executive power centred in the military. The sultan himself, whose autocratic person was the symbol of this power, was a soldier, as were the viziers, the leading administrators. During war the governing body accompanied the army, this being characteristic of a nomadic system. The most remarkable feature of the Ottoman state was that, down to the 18th century, the holders of almost every important post were slaves, most of them acquired by the impressment of Christian boys. The majority of the *kapikullari* (slaves of the Porte) were trained as janissaries in barrack schools. Those who showed promise of suitability for high office were sent to a school attached to the palace, where they were taught the Moslem humanities (Persian and Arabic), music and practical arts and crafts. (See Barnette Miller, The Palace School of Muhammad the Conqueror [1941].)

Suleiman's administration was one of the best of his time. The Christian population in Morea preferred the Turkish rule to that of the Venetians, and some Hungarian villages chose Turkish rule of their own accord. Financially Turkey was in a good position; it had been enriched by the addition of prosperous lands, the revenue was 183,000,000 aspres (though expenditure was 6,000,000 more) and no new tax was levied during this reign. The countries belonging to the empire were administered in two different ways. One part was ruled by the central government and consisted of 24 vilayets (provinces), 4 of which were in Europe and 20 in Asia and Africa. The second part was more or less self-governing under the suzerainty of the sultan and consisted of the kingdoms of Hungary and Transylvania, the principalities of Moldavia and Walachia, the khanate of Crimea and the sherifate of Mecca, which was ruled by the descendants of the prophet. The *Garb Ojaklari* (the states of Barbary), consisting of the provinces of Tripoli, Algiers and Tunis, had semi-independent governors who selected their own administrative bodies and later were empowered to make independent treaties.

After the conquest of Constantinople and the transfer of the capital to the imperial city, the Turkish system was somewhat influenced by that of the Byzantine empire. The affairs of state were discussed at the imperial divan over which the sultan presided until the reign of Mohammed the Conqueror, after which the sultans thought it more in keeping with their imperial dignity to hear the proceedings from behind a grating. The permanent members of the imperial divan consisted of three or more viziers (pashas with three horsetails), the grand vizier being the chief of these and invested with supreme power by the signet of the sultan. He held the title of *serdar-i-ekrem* (generalissimo) when in command of the army, in which case one of the other viziers remained behind as *kaymakam* (lieutenant). The viziers in the divan were called *kubbe vezirleri* (viziers of the dome), because of the nature of their meeting place. Their deliberations were attended by the following dignitaries: the *kazaskers* of Rumelia and Anatolia (the two highest judges of the empire); the *kadi* (judge) of Istanbul; the *defterdar* (minister of finance); the *nishanji* (keeper of the great seal); the *yenicheri aghasi* (commander of the janissaries); the *kaptan pasha* (lord high admiral) and the *reis ul-kuttab* (chief secretary, later the foreign minister).

Each vilayet was governed by a pasha (two horsetails) called a *beylerbeyi*. These provinces were divided into *sanjaks*, each being governed by a pasha (one horsetail) called *sanjakbeyi*. The *sanjaks* were divided into *kazas*, each being governed by a *kadi*.

The Turkish army during Suleiman's reign probably numbered between 200,000 and 300,000, and was one of the best disciplined and best equipped of the time. The main elements of the army were the janissaries and the spahis, the latter comprising feudal cavalry and standing cavalry divisions. Other important units were the *jebeji* (armourers), the *topju* (artillery) and the *bostanji* (originally gardeners, later police).

The land was divided into several categories: *vakuf*, *yurtluk-ojaklik*, *timar*, *ziamet* and *khas*. The revenues of vakuf-lands provided for the upkeep of mosques, schools, hospitals and other pious purposes. *Yurtluk-ojakliks* were lands in frontier districts, the revenues of which went to the frontier guards. The other three terms denoted fiefs whose revenues amounted to 2,000–20,000 aspres, 20,000–100,000 aspres and more than 100,000 aspres respectively. Some of these fiefs provided incomes for members of the imperial house and for successive holders of the great offices of state, while others were assigned to spahis. Only the latter sort were hereditary.

Selim II (1566–74).—Selim II, after pacifying the janissaries with payments, tried to undermine the power of Sokollu, the grand vizier, but finally found himself obliged to let the country be ruled by that great statesman. The conquest of Samos was completed and the risings is Yemen suppressed by Sinan Pasha. In 1568 the peace between Austria and Turkey was renewed for eight years. With the idea of joining the rivers Don and Volga by canal so that a fleet might be sent to the Caspian sea, Sokollu attacked Astrakhan but failed in his project. Turkish historians credit him also with the intention of opening a Suez canal. Cyprus was invaded by the Turkish army under the command of Lala Mustafa Pasha, who violated the capitulations of Famagusta (1571) by executing the Venetian commander Marco Antonio Bragadino, and aroused strong feeling against the Turks. Venice, Spain and the pope united in a holy league against Turkey and their combined fleets under the command of Don John of Austria severely defeated the Turkish fleet at Lepanto (1571). A year later the advance of a new Turkish fleet commanded by Kilij Ali Pasha caused Venice to break from the league and conclude a treaty with the Turks (March 7, 1573). In 1574 Sinan Pasha and Kilij Ali Pasha recaptured Tunis and ravaged Sicily. Selim died in 1574.

Murad III (1574–95).—Murad, Selim's eldest son, opened his reign by murdering his five younger brothers. He also tried to undermine Sokollu's power and in spite of his advice opened a war with Persia which lasted 12 years. The Turks conquered Shirvan, Tiflis and Daghistan and peace was concluded when Abbas, the successor of Tahmasp, was firmly established as shah of Persia. Sokollu's efforts to build an observatory in Istanbul were opposed by fanatical opinion; and his assassination, which soon followed, is said to have been ordered by the sultan. This threw the country into disorder, for there was no man who had Sokollu's strength and authority to oppose the harem intrigues and corruption. The janissaries, refusing to accept a debased coinage that was called "Jewish money," mutinied throughout the empire. This mutiny had scarcely been suppressed when in 1593 the uncertain peace between Austria and Turkey degenerated into a regular war which is known as the "long war." This began when Hasan Pasha, the governor of Bosnia, raided the Austrian frontiers and attacked Sisak. The Austrians and the Hungarians together routed the Turks in Kulpa with great slaughter. Sinan Pasha, the grand vizier, marched on Hungary with a large army, and war continued for 14 years. Bribery, which had become widespread in the country, corrupted the army as well, and there was no office which was not susceptible to the bribe of the highest bidder. Shemsi Pasha, one of Murad's counsellors, openly boasted of having made a sultan take bribes for the first time. Veszprem and Gyor were conquered by the Turks but the Moldavian and Walachian revolts checked further victories. The sultan's Venetian wife, Safiye Sultan (Baffo), ruled for many years as his only wife, accepted bribes and interfered in state affairs, influencing the Porte's relations with Venice, although in later years she had rivals. Murad, who died in 1595, is said to have had 130 children. The capitulations with France were renewed in 1581, those with Venice in 1589. Capitulations were signed with the grand duke of Tuscany for the first time in 1578, and with Great Britain for the first time in 1580. The first British ambassador sent to Turkey was William Harborne. Elizabeth I in her letter to the sultan urged as a special claim to his friendship their common mission to fight the "idolaters," an interesting example of diplomacy.

Mohammed III (1595–1603).—Safiye Sultan, who had wielded such a strong influence as wife, continued to do so as mother during this reign. The new sultan began by murdering 19 of his brothers. The war in Hungary became chronic and intrigues bet een Sinan Pasha and Ferhad Pasha for the position of grand vizier led to frequent changes of command in the army, with disastrous results. Sinan persuaded the sultan to command the army in person, with good results at first, for in 1596 the Turks recaptured Eger (Erlau) and in three days defeated the allied armies at Keresztes. Because the sultan was anxious to return to his easy life in the capital and because the undue severity of Chighala Sinan Pasha was causing the Anatolian troops to desert, the Turks did not gain much by their victory. Ibrahim Pasha, Safiye Sultan's favourite, became grand vizier through her influence and she sold by proxy all the high offices of state. In 1598 Gyor, Tata, Veszprem and Papa were lost by the Turks. In 1599 overtures for peace were made by all sides without result. The unique military achievement of this campaign was that of Tiryaki Hasan Pasha, who in 1600 captured Kanizsa. A year later the attempt of the archduke Ferdinand to retake it at the head of 30,000 men was defeated. Military mutinies and Jelali insurrections broke out in the interior and Shah Abbas marched on Tabriz and Erivan. The sultan died in 1603.

Ahmed I (1603–17).—Ahmed I succeeded his father at the age of 14. The war with Persia continued fitfully during his reign. The Turks recaptured Esztergom in Hungary. Transylvania passed to the suzerainty of Turkey of its own accord; Stephen Bocskay, a member of its own aristocracy was appointed king. But the continual mutinies of the janissaries and the reverses in Persia forced Turkey to sign for the first time at Zsitvatorok a treaty of peace on terms of equality with Austria. Austria was freed from future tribute to Turkey by paying 200,000 ducats down, and for the first time the emperor was referred to as *padishah* in the official Turkish documents. A treaty of peace was also concluded between Turkey and Persia in 1611, Persia giving to Turkey as indemnity 1,000,000 lb. of silk. Kuyuju ("pitman") Murad Pasha, so called because he threw the bodies of rebels into pits, suppressed the Jelali risings in Anatolia. Friendly relations with Poland were restored.

Ahmed I was of a religious disposition, and left the affairs of the state to his grand vizier. In this reign it was decided to relax the custom of killing the brothers of every new sultan. They were, instead, to be confined each in a separate pavilion enclosed in a walled garden, known as kafes (cage). The evil result of this humane decision was that when a sultan was succeeded by a brother and not by a son the new ruler was inevitably a man with no experience of the world or of state affairs. At Ahmed's death his sons were minors and, as it was contrary to custom for a minor to succeed, his brother Mustafa became sultan (1617).

Mustafa I and Osman II (1618–22).—Sultan Mustafa being an imbecile was after three months declared incompetent to rule and Osman II, son of Ahmed, ascended the throne. Sokollu's idea that friendship with Persia would be politically to the advantage of the empire was adopted by the sultan and peace was concluded with that country. Moldavia revolted and joined the Poles, and Osman marched on Hotin. The expedition was a failure and diminished the prestige of the sultan. From his contact with them he knew how utterly degenerate and useless a body the janissaries had become and decided to discipline and reform them. He pretended to go on a pilgrimage to Mecca with the intention of marching back to the capital with a loyal and well-disciplined army which he hoped to raise in Syria and Arabia. When a rumour of this reached the janissaries they revolted. After marching the sultan through the streets of Istanbul and exposing him to ignominious insults they killed him.

Mustafa I (1622–23), Murad IV (1623–40), Ibrahim I (1640–48).—Mustafa I was once more dragged to the throne by the janissaries but he soon abdicated in favour of his nephew Murad IV, still a minor. Till the sultan was of age the empire was in the hands of his mother, Kosem Sultan, who had to cope as well as she could with the mutinous army and the corrupt state. The army chose the grand viziers and massacred them when it wanted a change. Kosem Sultan had to open the treasury to appease these revolts, which depleted the finances still more. When Murad IV was of age he restored order by one of the bloodiest reigns of history. Marching on Baghdad and Erivan he recaptured them from the Persians, repeating the atrocities which the Persians themselves had committed. He concluded a peace with Persia which fixed the Turko-Persian frontiers. On his return he murdered all his brothers with the exception of Ibrahim and continued to terrorize his officials by frequent executions. He died in 1640.

The decline in the Ottoman power continued during the reign of Murad's eccentric brother and successor, Ibrahim I. Ibrahim devoted himself to pleasure and was ruled by the women in the palace while his mother Kosem Sultan once more took the reins of power. It is not surprising that complete anarchy reigned throughout the empire, the capital included. A campaign against Crete, which belonged to the Venetians who had burned some Turkish ships, began during this reign, but continued for 25 years. For the first time the Dardanelles were closed by Venetian ships, which caused a famine and led to a revolt. Ibrahim wanted to massacre the Christians, but the ulema were able to restrain him. The change of the residence of the ambassadors from Istanbul to Pera dates from this event. Ibrahim was dethroned during a mutiny and killed.

Mohammed IV (1648–87).—Mohammed IV, the seven-year-old sultan, succeeded his father and for another eight years the affairs of state were in the hands of Kosem Sultan, his grandmother. The janissaries had supreme power, monopolizing everything, even the sale of bread. Mohammed's mother, Turhan Sultan, tried to get the power into her hands and the period of anarchy and mismanagement was prolonged by the struggle between the two women, each depending on a different military party. Turhan Sultan accused her mother-in-law of trying to poison the boy sultan and one evening she contrived that her party should invade the palace and surprise Kosem Sultan in her room. Kosem Sultan's great oratorical powers, which had enabled her to control janissary risings, failed to save her life and she was strangled with the cords of her bed curtain. Turhan Sultan now put Kuprili Mohammed into power as grand vizier, the first of five from the same family of Kuprili (*q.v.;* properly Koprulu) who did much to restore the empire. He restored order in the srmy by very drastic measures, rebuilt an efficient navy, defeated the Venetians and recaptured the island of Lemnos and other islands, The improved condition of the army led to the pacification of Transylvania which was in revolt. Kuprili Mohammed Pasha died after being in officefive years and his son Ahmed became grand vizier. In 1663 disturbances in Transylvania caused the Turks to attack the Austrians. At first Turkish arms were victorious; but the French, who had been alienated by the haughty demeanour of the Kuprilis, sent help to the Austrians under Raimando Montecucculi, the Austrian general, and the Turks were defeated at the battle of Szent Gotthard abbey. They lost little in the treaty of Vasvar (Aug. 10, 1664), by which a truce of 20 years was agreed upon. Transylvania was evacuated but remained tributary to Turkey. The Turks retaliated on the French by depriving those Catholics who were under French protection of some of their privileges in the holy places and granting them instead to the Orthodox church. The Cretan campaign was still in progress and the French were helping the Venetians, but the Turks took Candia and a treaty was signed in 1669 between the Venetians and the Turks which left Crete in the possession of Turkey while the island fortresses of Suda, Spinalonga and Grabusa remained Venetian.

Events in the Ukraine led Turkey into war with Poland in 1672. The Turks captured Kamenets, Lemberg and Lublin. The Poles sued for peace and a treaty was signed in 1672 at Buczacz whereby Podolia was ceded to Turkey and the Ukraine left to the Cossacks; Poland consented to pay Turkey an annual tribute of 22,000 sequins. But John III Sobieski, who ascended the Polish throne, refused to abide by the terms of this treaty and war was renewed and continued till 1676, when the treaty of Zurawno was signed, both parties abrogating the tribute clause.

Kuprili Ahmed having died, Kara Mustafa succeeded him as grand vizier. A man of great military ambitions, he led Turkey into a series of unnecessary wars. The first was against the Russians, and although the Turks were successful at the beginning, their losses were so great that they signed a treaty at Radzin (Jan. 8, 1681) ceding the disputed territory to Russia. The internal disputes in Austria caused by Protestant persecution caused Kara Mustafa in 1683 to violate the truce signed by Kuprili Ahmed and lead a vast army against Austria which laid siege to Vienna. The emperor and his court fled from the capital, but John Sobieski of Poland saved the Austrian cause by attacking the Turks in the rear and defeating them. The failure at Vienna marks clearly the beginning of Ottoman decline. It kindled the crusading spirit in Europe against Turkey and an alliance between Austria, Venice, the pope, Poland, Russia, Malta and Tuscany was formed. The Austrians made conquests in Hungary, the Venetians in Greece, the Russians in Crimea and the Poles in Podolia. Turkey tried in vain to get France to join it against this general alliance. The janissaries mutinied and Mohammed IV abdicated.

Suleiman II (1687–91), Ahmed II (1691–95), Mustafa II (1695–1703).—Mohammed's brother Suleiman II succeeded to the throne. Kuprili Mustafa was made grand vizier, and true to the tradition of his illustrious family, he restored order in the army and in the fleet, and by wise and tolerant administration won the sympathies of the non-Moslem subjects. The Austrians captured Erlau, entered Transylvania and reached Belgrade and Uskub, but Kuprili Mustafa drove them out and recaptured Belgrade. He also defeated the Russians in Crimea. Mustafa went as far as to distribute seeds for the crops of the people of the recaptured countries. In 1691 while the Turkish army was fighting in Morea Suleiman II died and was succeeded by his brother Ahmed II.

The Turks were defeated at Slankamen (Szalankemen) in Croatia in Aug. 1691 and Kuprili Mustafa was slain on the battlefield. An attack on Petrovaradin was equally a failure and the Venetians captured the island of Chios. In 1695 Ahmed died and was succeeded by his nephew, Mustafa II, Mohammed IV's son, who resumed leadership in the field of war.

Chios was recaptured and the war with Austria continued. The Turks conquered Lippa and defeated the Austrians and the Austrian field-marshal Friedrich von Veterani was killed. But the Russians took Azov and in 1697 the Austrians under Prince Eugene defeated the Turks at Zenta on the Tisa (Tisza). The war was ended, on the pressure of Venice, Holland and England, by a series of treaties with Austria, Poland and Venice concluded at Karlowitz (Jan. 1699). By the terms of these treaties Turkey retained the Banat; Austria kept Transylvania; Poland restored the places captured in Moldavia but retained Kamenets, Podolia and Ukraine; Venice retained the Morea and Dalmatia and a two years' truce was signed with Russia. In 1700 Azov was ceded to Russia by a separate treaty. During this time Husein, another Kuprili, was grand vizier, but his efforts to introduce order into the country were frustrated. He was driven out of office and a fresh revolt of the janissaries forced the sultan himself to abdicate. He was succeeded by his brother Ahmed III.

Ahmed III (1703–30).—Ahmed began his reign by conceding the demands of the janissaries and accepting their chosen grand vizier. Charles XII of Sweden, having been beaten by the Russians at Poltava, took refuge in Turkey and was invited to reside at Bender. This involved Turkey in another war with Russia, which had already sent troops across the frontiers in pursuit of Charles XII (1710). Baltaji Mohammed, grand vizier in command of the Turkish army, was induced by diplomacy to grant the tsar Peter a peace less to Russia's disadvantage than his army's defeat on the Pruth merited (1711). By this peace Azov was left to Turkey, Russian fortresses on Turkish frontiers were razed, Russia consented to the return home of Charles XII and renounced all claims over the Tatars in Crimea and in Polish territory. Because the hospodars of Moldavia and Walachia had assisted Russia during the campaign they were punished, and Phanar Greek notables (see PHANARIOTES) governed these principalities till the Greek insurrection of 1821. Venice was next to be punished for having incited the Montenegrins to revolt, invaded Bosnia and captured Turkish ships in the Mediterranean. In 1715 Turkey declared war against Venice, quelled the Montenegrin revolt, captured Modon and Coron and with its fleet took the islands of Tinos and Cerigo, as well as the remaining Venetian fortresses in Crete. Austria intervened, urging Turkey to cede to Venice certain places in Dalmatia as compensation for its losses in Morea. This led to a declaration of war against Austria in 1716. The Turkish army was routed near Petrovaradin and pursued by the Austrian army led by Prince Eugene, which took Belgrade and overran the Banat (1717). The Turkish army then retreated to Adrianople. By the mediation of England and Holland the treaty of Passarowitz was signed on July 21, 1718: Belgrade, a part of Walachia and Banat passed to Austria, and strongholds in Albania and Dalmatia to Venice. This treaty was signed by the grand vizier Ibrahim Pasha, who is accused of having betrayed Turkey by accepting it. The craze of the time in the capital was the cultivation of tulip gardens and has given to this period of Turkish history the name of the "tulip period." It created a definite literary school under Nedim, the greatest Turkish lyric poet. But popular murmurings against these costly pleasures became such that the grand vizier had to seize the occasion of the Persian defeat by the Afghans to annex several parts of Daghistan in Persia in order to appease the bellicose spirit of the janissaries. This led to a complication with Russia, but the intervention of France resulted in the treaty of Constantinople between Russia and Turkey (June 30, 1724) which allotted Baku and Derbend on the Caspian coast to Russia.

The news of the defeat of the Turkish army by the Persian army under Nadir Kuli Khan led to a rising of the mob under the leadership of Patrona Khalil. a bath waiter. The grand vizier was killed and the sultan forced to abdicate (1730). His nephew, Mahmud I, Mustafa II's son, succeeded. This was the only Turkish rising which did not originate in the army. The printing press first came into use in Turkey at this time.

Mahmud I (1730–54).—Patrona Khalil was killed and his followers dispersed after the accession of Mahmud I. The war continued with Persia, and Nadir Kuli Khan, after his successes in Iraq and Erivan, seized the Persian throne. In 1736 a Turco-Persian treaty was signed whereby all territory conquered since the reign of Murad IV was returned to Persia. Russia also returned the Persian territory it had annexed, thus laying the basis of a Russo-Persian alliance against Turkey.

The question of the Polish succession once more led Turkey into war. France had put forward as its claimant to the Polish throne Stanislas Leszczynski, while Austria and Russia supported the claims of Augustus III (the elector Frederick Augustus II of Saxony) although Russia had bound itself by the treaties of 1711 and 1720 to abstain from interfering with Poland. The Russian candidate was forced upon Poland (1733), whereupon France declared war on Russia and Austria and then urged Turkey to join it. Turkey had a grievance in that Russia had refused to allow the Crimean troops to march through Daghistan during the Persian campaign, so Turkey declared war in spite of the joint efforts of England and Holland. Before waiting for a declaration of war a Russian army under Marshal B. C. Münnich stormed the isthmus of Crimea, devastated the peninsula and captured Azov and Kilburun in 1736 and Ochakov the next year. The sea powers of the west mediated to restore peace and the representatives of the belligerents met in Niemirow in 1737 to arrange terms. Austria, however, put forward new claims to the principalities and the Balkan peninsula which were refused by Turkey, whereupon Austria revealed the existence of a secret alliance with Russia and threatened to fight for its new claims. Accordingly Austria's army marched on Bosnia and Walachia, capturing Nish in Serbia. But the tide of war turned against both Russia and Austria when Ochakov and Kilburun were recaptured by one Turkish army while another crossed the Danube and penetrated as far as the Banat. In 1739 Turkey consented to negotiate peace and a conference opened in the camp of the grand vizier who was marching on Belgrade. The preliminaries were signed under the mediation of the French ambassador, Louis Sauveur Renaud, marquis de Villeneuve, for whose services the Porte reaffirmed the capitulations which France had already obtained. After the entrance of the grand vizier into Belgrade the definitive treaties of peace were concluded with Austria and Russia (Sept. 18, 1739). Austria gave up Belgrade and the rest of the territory south of the Save which it had gained by the treaty of Passarowitz. The treaty with Russia provided that the forts of Azov should be razed and that Russia should have no warships on the Sea of Azov or on the Black sea. The Kabardias were to remain independent as a buffer state between Turkey and Russia. Turkey consented to discuss the question of recognizing the tsar's claim to the imperial title of padishah and admitted his right to send representatives to Constantinople.

Two years after the treaty of Belgrade, war broke out with Persia because of Nadir Kuli Khan's attempt on Mesopotamia. It continued from 1743 to 1746 with varying fortunes, and when peace was signed Turkey retained the frontier fixed at the time of Murad IV and Persia procured a few privileges for its pilgrims to the Holy Places. Turkey refrained from taking part in the War of Austrian Succession in spite of the efforts of France, and maintained a peaceful attitude during the disorders which followed the death of Nadir Kuli Khan in Persia. The sultan died in 1754 and was succeeded by his brother Osman III (1754–57). The only noteworthy events of the latter's reign were the first Wahhabi rising and the issuing of the first order for veiling women's faces.

Mustafa III (1757–73).—Koja Raghib, the grand vizier at the accession of Ahmed III's son, Mustafa III, sent an envoy to Berlin, and a treaty of friendship and commerce was signed on March 12, 1761. While he was alive Koja Raghib kept the sultan out of war. He controlled Turkey's foreign affairs while the sultan, who was of a fanatical disposition, concerned himself with the dresses and the veils of women. He projected an alliance between Turkey and France; but since France and England had differences over the Indian possessions such a treaty might have affected the English interests among the Moslems, and in consequence Sir James Porter, the British ambassador in Istanbul, used his influence against it.

Before long, events in Poland drew Turkey into war in 1768. Catherine II of Russia tried to put her favourite, Stanislas Poniatowski, on the Polish throne on the death of Augustus III.

The Poles complained to the Porte and urged Turkey to fight Russia. The sultan at first contented himself with protests, but Russia had violated the neutrality of the Kabardia, while in Serbia, Moldavia and Montenegro the Russian monks carried on seditious propaganda against Turkey. Turkey issued an ultimatum to Russia demanding that Russia withdraw its army from Poland. On Russia's refusal war was declared. Turkey procured the neutrality of England, Holland and Sweden in this war, and Austria undertook to remain neutral in return for certain privileges. Nevertheless Turkey had entered the war without preparations. The Turks were first defeated by the Russian forces in Georgia. Crimea and Kabardia and on the Dniester; the Russian Baltic fleet under Alexis Grigorievich Orlov reached Morea, and incited the inhabitants to revolt. In 1770 the Turkish fleet was burned near Cheshme (Cesme, west of Smyrna) by the Russian fleet under the direction of a Scottish admiral. The Turks were defeated in Bessarabia, and the Russians invaded the principalities and reduced the fortresses on the delta of the Danube and on the Dniester. In 1771 the Crimea was conquered by the Russians. Although the Austrians had undertaken to mediate and to assist the Turks, they preferred to take a share in the partition of Poland. After a fruitless conference at Focşani, the Russian representative at the conference of Bucharest (1773) issued an ultimatum demanding the free navigation of the Black sea and the Aegean sea for Russian trading vessels and warships, the cession of Kilburun and the right to protect the Orthodox subjects of the sultan. Turkey refused these terms, and the war continued, the Turks fighting hard in Silistria and Varna. Mustafa died in 1773 and was succeeded by his brother. Abd ul-Hamid I.

Abd ul-Hamid I (1774–89).—Abd ul-Hamid had been kept in seclusion for 43 years and was weak in his mind. The abuses and disorders in the army and the palace were at their worst, and the situation at home gave no hope of retrieving the external misfortunes of the state. Turkey refused the mediation of Prussia, but when the Russian army reached Shumla it was forced to negotiate peace. The treaty of Kuchuk Kaynarji was signed on the anniversary of the treaty of Pruth (July 21, 1774) which had been disastrous to Russia. This was the most humiliating treaty the Turks had yet signed. The treaty was the first political manifestation of the Eastern Question (*q.v.*). The Tatars from Poland to the Caspian sea were given their independence, the sultan merely retaining his religious leadership as caliph. Russia retained Kilburun, Kerch and Yenikale, while Akkerman, Ismail, Ochakov and Bessarabia were restored to Turkey. Moldavia and Walachia became semi-independent states under Turkey, Russia, however, having the right to intervene in the appointment and dismissal of the hospodars. The imperial title of padishah was definitely conceded to the Russian tsars. The Black sea and the Mediterranean were made free for commerce and navigation to both countries, and Turkey was to pay an indemnity of 15,000 purses to Russia. The most important clause from the Turkish point of view was that which gave Russia the right to protect the Orthodox subjects of Turkey. Originally this treaty only accorded to Russia the right to build a church in Constantinople and the right of making representations for the protection of the officials of this church. and Turkey undertook to protect the Christians (article 7). This clause was later interpreted as an inclusive protection of the Orthodox Christians and played a disastrous part in the subsequent history of Turkey. Poland, the original cause of the war, was not mentioned, having been partitioned for the first time in 1772.

Turkey took advantage of the respite to strengthen its frontier defenses and to reform the janissaries. Russia soon tried to annex Crimea, but a rupture was averted by French mediation and also by the fact that Turkey was not ready for war. Turkey signed the convention of Ainali-Kavak, March 10, 1778, whereby the Russian partisan Shahin Gherai was recognized as the khan of Crimea, and the terms of the treaty of Kaynarji reaffirmed. Five years later Russia annexed Crimea and Kuban, and Turkey was forced to sign the convention of Constantinople on Jan. 8, 1784, the stipulations as to the independence of the Tatars in the treaties of Kaynarji and Ainali-Kavak being abrogated. Catherine II's triumphant entry into the Crimea and her interview with her ally the emperor Joseph II to discuss the partition of Turkey, together with the seditious Russian propaganda in Moldavia, Walachia and Morea created a war party in Constantinople which was sustained and encouraged by the British and Prussian ambassadors. War was declared. The Austrians joined the Russians but were driven back from Mehadia by the Turks, who overran the Banat (1789). The Russians captured Hotin and Jassy and Ochakov, all of whose inhabitants were massacred, including the women and children, by the order of Gen. Alexander Suvorov. The news affected Abd ul-Hamid I so deeply that he died.

Reform had become so urgent and inevitable that of the two young sultans who succeeded Abd ul-Hamid I, one gave up his life for it and the other had to carry out his designs for westernization by the most sanguinary measures. The ignorance, the despotism or the weakness of most of the sultans disorganized both the autonomous and the centrally governed provinces. Between the treaty of Karlowitz and the treaty of Kaynarji, the absence of discipline among the janissaries and their interference in the internal policy of the state upset the administrative machinery. The partially self-governed states of Barbary (Tripoli, Tunis, Algiers) had become almost independent, keeping only a nominal connection with the empire and choosing their own chiefs, called *dayi*. The Mamelukes who were allowed to stay in Egypt by Selim the Grim had become stronger and, with the help of the janissaries, were taking up a hostile attitude to the Porte. The pashas in Baghdad did the same. The recurrence of the Jelali insurrections brought forward headstrong governors who ruled the country like feudal lords. In European Turkey the locally elected notables, called *ayan*, interfered in the administration. This general disorganization had been partially remedied by the grand viziers belonging to the Kuprili family, but it continued worse than ever after them. The system of land tenure of the time of Suleiman was violated. The *khas, timar* and *ziamet* were seized by the central government, apportioned to the favourites of the sultans or the viziers and sometimes even sold to the highest bidder and to people who were not able to cultivate them or to perform the military duties of the former spahi fief holders. The number of the officials increased, and their short terms of office led to continual disorder.

During the "long war" of the time of Murad III the army increased disproportionately, but its individual units were no longer trained in the barracks and their military value was next to nothing. The sultans isolated themselves in their palaces and led lives of pleasure, thus losing contact with the army. They appointed incompetent commanders and executed them if they were defeated, which paralysed the initiative of those with a genuine ability to command. As the supply of provisions and ammunition was also in disorder, many deserted from hunger and lack of munitions. Although the army decreased in numbers after the treaties of Karlowitz and Passarowitz, the leaders of the janissaries would mark any man in the street as a regular soldier, register his name and put the pay in their own pockets, while the man himself went on with his own work. All attempts so far had failed to remedy these abuses. To make matters worse, the frequent change of sultans, often brought about by the janissaries themselves, meant accession presents which at times depleted the treasury. Then the treasury was refilled by debasing the coinage.

Science and industry which were far advanced at the time of Suleiman had taken no part in the progress of the 17th and 18th centuries but had remained hopelessly mediaeval. The official class was mostly illiterate, and the *kadis* who meted out justice were ignorant. The Turks refused to learn any European languages and knew very little of what was going on in the world. When necessity arose they used Christians and Jews as interpreters and became correspondingly dependent on them. Few books on philosophy, mathematics and history were printed in Ahmed III's reign. Only literature, especially poetry, flourished during this decadent age, and many of the great Turkish poets were of this time. Textile industries, being patronized by the sultans, also flourished. The manufacture of implements of war and ammunition continued, partly because of the artisans who inherited their craft and partly because of the experts who were brought from the west for the purpose.

Selim III (1789–1807).—Selim III, the son of Mustafa III, was the only Turkish prince of the last centuries who had not been caged, which gave him an opportunity of greater knowledge and a more normal view of the world. A passionate admirer of French culture, he wanted Turkey to be equal with the western powers in every branch of progress. It was in Selim's mind that the new Turkey originated, and with him the struggle for reform and progress began seriously, at the price of so many Turkish martyrs. He hoped to bring the war to a victorious end and so acquire the necessary prestige for his reforms. When the news of the Russian victory of Kalas reached Constantinople, he called a council, enumerated the causes of defeat and disaster and proposed internal reform as the only remedy. He insisted that the people should elect their own *kethudas* (mayors) and *ayans* (notables) without the interference of the governors, that an end should be put to the unlawful tribute which the *rayas* were made to pay, that the army and the administration should be organized on a western basis.

In the meantime one Austrian army defeated the Turks in Serbia and captured Belgrade, while another in conjunction with the Russian army captured Focşani. On Aug. 4, 1791, the new Holy Roman emperor, Leopold II, who was unfavourable to the Russian alliance, made a peace with Turkey at Sistova through the mediation of England, Prussia and Holland, by which Belgrade was restored to Turkey. But Russia, after defeating the Swedes, who were Turkey's allies with Prussia, was free to carry out its policy of extension in Turkey, and the war continued. It was about this time that William Pitt in England proposed the policy of preserving the integrity of the Turkish empire. It appeared first in the form of friendly advice to Russia to make peace with Turkey, which was rejected by Catherine II. Turkey, after several reverses on the field, made peace with Russia in 1792 at Jassy, the Dniester becoming the Turkish frontier in Europe.

Selim continued his reforms, especially in the army. He formed a new corps, but in order to disarm the jealousy of the janissaries he affiliated the new corps to them. Military schools were opened, the fleet reorganized, and instructors brought from Europe. But his progress was interrupted by the war with France (1798). Bonaparte attacked Egypt, more as a move against England than against Turkey, as his aim was to open a French route to India. Turkey fought against France in alliance with England and Russia. Napoleon was beaten in Syria, the French feet destroyed by Nelson at Aboukir, and the Ionian islands captured by the Turkish and Russian fleets. Peace was concluded with France in 1802. The reactionary governors whose interests were injured by the new reforms continued to cause disorder in every part of the empire. Pasvanoglu, the governor of Vidin, drove the peaceful *rayas* to revolt by his persecutions, and the insurgents chose Karageorge (George Petrovic) as leader and succeeded in taking Belgrade. An army was sent to punish Pasvanoglu, without result. The revolt of the Wahhabis in Nejd became another source of anxiety which continued till the time of Mahmud II. A marked renewal of trouble broke out with Russia over the principalities. Constantine Ypsilanti and Alexander Murusi, hospodars of Walachia and Moldavia, two instruments of Russia, had caused risings against the Porte which had led Turkey to dismiss them without the consent of Russia, thus violating the agreement of 1802. Russia and England protested, and the two were replaced. But, encouraged by the French ambassador, H. F. B. Sébastiani, Turkey declared war against Russia, although the British ambassador threatened to join Russia against Turkey (Nov. 6, 1806). The British fleet passed the straits, anchored off Constantinople and delivered an ultimatum, ordering Turkey to dismiss the French ambassador within 24 hours and to make peace with Russia. The Porte, encouraged by Sébastiani and by popular indignation at the presence of the ships, decided to resist. The entire population of Constantinople helped to range a thousand guns along both sides of the Bosporus in one day. The British fleet retired considerably damaged.

In the meantime the reforms and the progress of the new army were leading the janissaries and the corrupt officials to make desperate efforts in opposition, and they were supported by most of the reactionary governors. In 1807 the garrisons on the Black sea rose, under Kabakjioglu, and killed their officers and all those who were known to be reformists. The rebellion became general and the abolition of the new troops was demanded. The concessions made by the sultan in the hope of preventing further bloodshed only encouraged the rebels to make greater demands, and finally they dethroned him. Sébastiani is charged by the Turkish historians with inciting the janissaries.

Mustafa IV (1807–08).—Selim's successor Mustafa IV, son of Abd ul-Hamid I, abolished all the reforms, and anarchy continued during his reign of 14 months. In 1807, during the negotiations between Tsar Alexander I and Napoleon at Tilsit for the partition of Turkey, Napoleon undertook to mediate peace between Russia and Turkey if Alexander would withdraw his troops from Walachia and Moldavia. An armistice was signed in Aug. 1807, the Turkish army retiring to Adrianople. In the winter of 1807 a committee composed of the adherents of reform in Ruschuk (Russé), persuaded Bairaktar Pasha, who had distinguished himself in the Russian war, to march on Constantinople with an army of 20,000 Kirja-Ali troops with the object of reinstating Selim and his reforms. Selim was killed by the janissaries before Bairaktar's army could enter the palace (1808). His nephew, Mahmud, Mustafa IV's brother, a youth brought up in the tradition of reform, was saved by Jevri Kalfa, a woman in the palace who threw ashes in the eyes of the murderers and enabled the future sultan to escape by the roof. Mustafa IV was dethroned and Mahmud II, the last survivor of his line, ascended the throne.

Mahmud II (1808–39).—Mahmud II appointed Bairaktar grand vizier and issued a royal proclamation ordering him to treat the people and their *rayas* with justice and to re-establish order. As the Russian question was not settled and the principal governors were all trying to instigate revolts by declaring the reforms to be antireligious and thereby exciting fanatical resistance, Mahmud II based his arguments on religious grounds and demonstrated the necessity of education and reform in the name of Islam. Bairaktar Pasha called a council in Constantinople to which he invited notables and influential men from all over the country. The council decided that the new troops, under European instructors, were to be re-established under the name of *seymen-i-jedid;* that the janissary organization was to be retained but reformed, those only nominally on the register and receiving pay without serving to be dismissed; and that the authority of the sultan was to be permanent. The new grand vizier managed to restore comparative order and began his reforms seriously, but while the Kirja-Ali troops who were loyal to him were on their Bairam leave the janissaries attacked his home at night. He pretended to parley with them asking to have his womenfolk removed to a safe place, after which he promised to give himself up. But when the women had been removed he opened fire on the rebels from his windows and fought them to the last shot, after which he blew himself up in the powder magazine under his house. The janissaries, once more masters of the situation, resumed their massacres of the new troops and forced the sultan to cancel all the reforms.

The truce signed with Russia in 1807 had had no result,, and the war continued fitfully. France had encouraged the Porte to resume the Russian wars but the misfortunes of these wars aroused public opinion in Turkey against France and turned it in favour of England. On June 5, 1809, a treaty was signed in Chanak between England and Turkey, the British representative being Sir Robert Adair. A peace with Russia was also concluded on May 28, 1812, in Bucharest by the mediation of Stratford Canning, who later as Lord Stratford de Redcliffe, British ambassador, played a great part in Anglo-Turkish friendship. The treaty gave Hotin, Bender and Akkerman to Russia and confined the eastern frontiers of Turkey to the lines of the Prut river. The clause which restored Serbia to Turkish suzerainty was vague and gave rise to disputes. The Turkish army marched into Serbia and appointed one Milosh Obrenovich as the governor of his district; he, however, raised a successful revolt against Turkey and ruled Serbia in semi-independence. Karageorge, who had returned, was killed by him, and in 1817 he was designated hereditary prince of Serbia.

During the war with Persia, Russia had acquired the right from

Turkey to use temporarily the road from the Black sea to Tiflis by way of the valley of the Rion-Phasis. Russia desired to have this district ceded to it by a secret clause in the treaty of Bucharest, and the sultan had refused to ratify it. But within a few years Russia acquired the high land between the Caspian and the Black sea and the low lands along the coast between Xnapa and Poti, which were nominally under the suzerainty of the sultan.

Such was the situation when a European guarantee of integrity of Turkey was proposed at the congress of Vienna, in the belief that breakup of the Turkish empire would endanger the world's peace. It was decided, with the consent of the tsar Alexander, that England, France and Austria should trace clearly the frontiers of the Turkish empire, whose integrity the powers would undertake to guarantee. The Porte, deeming the proposal to be a humiliating foreign intervention, refused. The return of Napoleon threw the question into the background and the Turkish empire thus remained outside the European concert. This Eastern Question (*q.v.*) which occupied the political history of the 19th century can be summed up as the result of the conflict of the following desires: Russia's and Austria's desire to reach the Mediterranean; the British desire to prevent Turkey from obstructing the route to India and the desire of the non-Moslem Turkish subjects for independence, which was often concealed under the demands for reform.

Mohammed (Mehemet) Ali Pasha, the governor of Egypt, who had become known during the war with Napoleon, had proved his strength in 1811 by destroying the Mamelukes. His successful expedition against the Wahhabis in Hejaz had made him a popular hero as the saviour of the holy places. Another Ali Pasha of Janina (*see* ALI, called the Lion of Janina), originally from Tepeleni. nho kept order for a time in Greece and Albania, but who became rebellious, was slain in 1822.

The Greek Rising. — The Greeks found this an opportune moment to realize their ideal of national independence. Their hopes had begun at the time of Peter the Great and were considerably strengthened by the attitude of Catherine II (*see* GREEK INDEPENDENCE, WAR OF). Their secret revolutionary society, the Hetairia, was founded in Bucharest by the Greek poet and patriot, Constantine Rhigas; and, four years after his arrest and execution in 1798, it was revived in Odessa. The society passed into action with the help of Alexander Ypsilanti. son of hospodar Ypsilanti, a Greek who had become a general in the Russian army and used his forces to support insurgents in Moldavia in 1821. The emperor Alexander's aversion to supporting a revolutionary, even against the infidel Turks. together with the preference of the population of the Danubian principalities for the Turkish rule rather than that of the hated Phanariotes. considerably weakened the cause of the insurgents. This, the first serious rising was put down at the battle of Dragashani on June 19, 1821. The Greek rebels in Morea, however, had massacred almost to extermination the native Moslems and the sultan retaliated by executing the Greek patriarch in Constantinople on the charge of having instigated the slaughter. Russia, taking this up as an insult to the Orthodox Church, broke off relations with Turkey. The European powers used every effort to avert a Russo-Turkish conflict. Metternich hoped that with time and the moral and material assistance of European peoples the Greeks would of themselves achieve national independence. On March 2j, 1823, however, George Canning induced England to recognize the Greek insurgents as a belligerent party. The Russian emperor, jealous of this new influence in favour of the Orthodox Christians of the east, called as a counterpoise a conference in St. Petershurg in April 1824. Neither the Turks nor the Greeks would abide by its decisions and the sole outcome of the conference was an offer of the joint mediation of Austria and Russia, which the Porte refused. The sultan, finding himself unable to put down the Greek revolt, asked the aid of Mohammed Ali Pasha, the governor of Egypt, promising him the general governorships of Morea, Syria and Damascus in return. The well-disciplined Egyptian fleet and army approached the Morea under the command of Ibrahim Pasha, the son of Mohammed Ali. The Greeks were defeated in June 1827. Athens once more was in the hands of the Turks, and Ibrahim Pasha was sending crowds of Greeks as captives to Egypt and replacing them by the fellahin (Egyptian peasants). An isolated Russian intervention, for which Russia was concentrating in the south, was prevented by the death of the tsar Alexander in 1825. Canning persuaded the new tsar Nicholas I to call another conference in St. Petersburg on April 4, 1826, as a result of which England was empowered to offer Turkey a settlement of the Greek question based on the establishment of Greece as a vassal and tributary state. In case of refusal the two powers. whether separately or in common, would take the earliest opportunity of enforcing a settlement. Russia, meanwhile, issued a separate ultimatum to the Porte for the satisfaction of its other grievances. The Porte, though it resented new demands being made before the others were dealt with, was unable to resist and signed the convention of Akkerman accepting the Russian demands which were: the confirmation of the treaty of Bucharest; the opening of the navigation of the Black sea to Russian ships; seven years' term of office for the hospodars of Walachia and Moldavia, as well as the consent of the Russian ambassador in Constantinople before they could be dismissed and the recognition of the autonomy of Walachia and Moldavia, where no Moslem was to reside except in the fortresses.

Mahmud II, by a wholesale massacre on June 15, 1826, had crushed the janissaries, and the defense of the empire was now in the hands of the new army. Helmuth von Moltke was to be among the large number of French and Prussian instructors engaged for it. Mahmud also abolished what remained of the feudal system in the provinces. The taxes were to be gathered by the central government. The execution of individuals by the viziers without trial and the confiscation of the property of wealthy persons deceased, or of persons executed by the state, was forbidden by new regulations. Mahmud II himself discarded the turban and adopted the fez and European costume, and ordered all officials to do the same. The fez remained the official headgear of the Turks till the passing of the "hat law" by the Turkish republic in 1925.

The Greek question was still unsettled. In 1826, the Greeks formally asked for the mediation of England. Canning's objection to intervening unasked having thus been removed, he invited the co-operation of Russia in making representations to the Porte which should be based on the protocol of St. Petersburg and suggested measures of coercion in case of refusal; the tsar consented to this. The coercion was to take the form of a pacific blockade of Morea, so as to force Ibrahim Pasha to evacuate the country by cutting off his supplies. Austria and Prussia, in the conference of the five powers of the Grand Alliance in London in 1827, protested against coercion of the Porte for revolutionary purposes and withdrew. On the suggestion of France, however, the protocol was made into a treaty and, as the treaty of London, was signed by the three powers on July 6, 1827. By its public articles the powers agreed to secure the autonomy of Greece under the suzerainty of the sultan without any breach of friendly relations with Turkey. But by additional secret articles it was agreed that in the event of the Porte's not accepting the offered mediation, consuls should be established in Greece and an armistice proposed to both belligerents and enforced by the powers.

The armistice. accepted by the Greeks, was refused by Ibrahim Pasha, pending instructions from Constantinople, though he consented to keep his ships in the harbour of Navarino. In the meantime the Greeks destroyed a Turkish flotilla off Salona, and Ibrahim, taking this as a breach of the convention, set sail from Navarino northward. The Russian and French fleets joined the British fleet at Navarino and, on Oct. 20, attacked the Turkish and Egyptian fleets and destroyed them (*see* NAVARINO, BATTLE OF). Turkey broke off diplomatic relations with the three powers concerned. and the sultan issued a proclamation denouncing the cruelty and perfidy of the European powers and summoning the Moslems to a holy war. Canning had died and England had gone back to its policy of preserving Ottoman integrity, so the struggle that followed was restricted to Russia and Turkey. Russia declared war on Turkey April 26, 1828, England disapproving and France agreeing. Although Turkey was in the midst of confusion because of the destruction of the janissaries and the new army

was small and hardly formed, the resisting power of the Turks was raised to its utmost by the attitude of the powers. Russia had to fight two very hard and difficult campaigns before Gen. H. von Diebitsch could dictate terms of peace at Adrianople (Sept. 14, 1829). A protocol at London on March 22 had proposed boundaries for an autonomous Greece. The treaty of Adrianople between Turkey and Russia provided that the Danubian principalities were to become practically independent; that the districts of Anapa and Poti were to be ceded to Russia; and the Greek question was to be settled according to the terms of the protocol of March 22. But in order that Russia should not enjoy the prestige of having emancipated Greece unaided, the other powers decided to give further concessions to Greece, and this was expanded into the treaty of London of May 7, 1832, by which Greece became an independent kingdom under the Bavarian prince Otto (see RUSSO-TURKISH WARS; GREECE: History).

The Egyptian Revolt.—Turkey suffered a series of serious internal revolts after the reverses had reduced her prestige. Bosnia and Albania revolted. In 1830 the French occupied Algiers. Mohammed Ali Pasha, the governor of Egypt, was found to have intrigued in the revolt of Albania and in Damascus. He was recalled and replied by open revolt, sending his army under his son Ibrahim Pasha to invade Syria. Mohammed Ali Pasha's hope was to seize the sultanate and to start a new dynasty—a hope which seemed feasible when, after capturing Damascus and Aleppo and defeating the Turkish army in Konya, Ibrahim invaded Kutahia. As France was supporting Egypt, Turkey endeavoured to draw England into an alliance against Egypt. Palmerston refused in spite of the efforts of Stratford Canning, and Mahmud II in desperation asked for help from Russia. The treaty of Unkiar Skelessi (Hunkiar Iskelesi) was signed July 8, 1833, and the Russian army came to the Bosporus to help the Turks against the Egyptian army which was now threatening to march on the capital. England and France, suspicious of Russia, now mediated. They forced Mohammed Ali to stop the march of the Egyptian army and made the sultan accord the hereditary governorships of Adana, Crete. Tripoli and Damascus to him. This put a temporary end to the war. The treaty of Unkiar Skelessi had included clauses which permitted: (1) Russian warships to pass through the straits and to land troops if necessary and (2) the closing of the straits to warships of all the other powers. These clauses seemed to place Turkey in the power of Russia. After securing peace under these humiliating conditions Mahmud once more began to prepare his army while Mohammed Ali increased his with recruits from the provinces which had been given him. In 1839 Mahmud sent a Turkish army against the Egyptians in Syria but was badly beaten by the forces of Ibrahim Pasha at Nezib in the north of Syria. Mahmud died in Constantinople while the battle was actually in progress (July 1, 1839).

Internal Affairs.—Mahmud II's reign opened seriously the period of westernization in Turkey. In addition to the army reforms already mentioned. medical schools were opened by experts from Europe, and the civil service was organized on a modern basis. A number of students were sent to Europe for the first time, a newspaper and the first official printing press were established. The ministry of foreign affairs and the ministry of the interior were organized as well as the ministry of public works and the supreme council of legal affairs. The naval and military schools and the school of engineering founded by Selim III were reorganized, and in 1838 a council of public instruction was formed. The basis of compulsory elementary education was laid down by a royal proclamation which forbade children who had had no elementary education to take up any craft. And the pious foundations (evkaf) were unified and organized into a ministry.

Abd ul-Mejid I (1839–61).—Abd ul-Mejid succeeded his father at the age of 16 when Mohammed Ali Pasha of Egypt seemed on the verge of seizing Turkey and the empire seemed about to dissolve into its elements. The army, the government and the sultan were helpless and the Turkish fleet was handed over to Mohammed Ali Pasha by the treachery of Adm. Ahmed Pasha. But to prevent Russia from using the treaty of Cnkiar Skelessi for its own purposes the great powers decided to intervene in the Turko-Egyptian conflict and called a conference in London. France, who had supported Mohammed Ali Pasha, took no part in the final settlement. but Russia for the purpose of breaking the entente between England and France waived its claims under the treaty of Unkiar Skelessi and joined the concert. By the protocol de *clôture*, which was signed on July 15, 1840, the governorship of Egypt became hereditary in Mohammed Ali's family without undermining the sovereign rights of Turkey; Egyptian claims to Crete, Syria and the Holy Cities were abandoned. A year later, on July 15, 1841, five powers signed the protocol des *détroits*, by which the sultan was to close the straits to warships of all the powers.

The schemes for reform which Selim III and Mahmud II had only been able partially to realize were to be more fully worked out under Abd ul-Mejid I. Mustafa Reshid, the Turkish foreign minister and ambassador to London, returned. He was the greatest statesman and westemizer of the reform period, and he personally prepared a tanzimat or vast plan of reforms and made the sultan sign and issue it under the name of *Gulhane-hatti-humayouni* (royal decree of Gulhane). From this decree dates the fundamental change of Turkey from the old system based on nomadic principles to that of a modern state. Like the preceding decrees, in order that it might disarm fanatical opinion, it also emphasized that all progress was in accordance with Islam. It undertook to issue laws conforming with the age; to establish security of life, property and honour (no one was to be punished without trial); to remodel every branch of the administration and to accord perfect equality to all Ottoman subjects of whatever race or creed. This meant a great difference for the Christians. Though they had religious and communal freedom by the firman of the conqueror, the political complications caused by the separatist tendencies and the massacre of the Moslems in Morea by the Greeks had aroused intense hatred and made their position difficult and even dangerous. The attempt of the *tanzimat* to establish them as equal citizens helped to unite them with the ruling race and before long the Christians shared all the offices in the administration, even up to the rank of cabinet minister. Mustafa Reshid with a few convinced and westernized men around him made gigantic efforts to enforce the new principles in every department. The announcement of reforms, however, regularly ran far ahead of their performance.

Mahmud's military organization was extended by engaging more foreign instructors and opening more military schools. The most important change was the recruiting law, which reduced military service, hitherto for an indefinite time, to a limited period. The Christians were exempted from military service upon payment of a special tax. A body of gendarmerie was instituted.

In addition to the only existing educational institutions, that of the ulema and the schools maintained by private donations, with studies based on the Koran, the council of education founded and multiplied both primary and secondary state schools, and tried to unify and centralize education by sending superintendents to the provinces to carry out the state system. Commercial courts were opened. As the civil and penal cases were sent to the Sheria courts, a school for judges was opened and attached to the office of the sheikh ul-Islam.

Permanent ambassadors were appointed from among the best statesmen and sent to European capitals; this helped to create friendly relationships with the western powers. The promise of the reforms, which without resorting to terrorist methods appeared to be forming a centralized and efficient government, naturally aroused great sympathy for Turkey and hope for its future. The only international controversy arose when in 1848–49 Turkey, true to its traditions, refused to give up the Polish and Hungarian refugees. Turkey had England's support in this act. The difference with Persia over the frontier question was settled for the time being by the treaty of Erzurum (1848) by English and Russian mediation.

The Holy Places and the Crimean War.—The possibility of a strong and reformed Turkey made Russia uneasy. Since the time of Peter the Great and Catherine II it had considered itself the rightful heir to most of the lands of the declining Turkish state. Nicholas I, who went to London in 1844, proposed to England the partition of Turkey, which he called a "sick man." England was to receive Crete and Egypt, Constantinople was to be a free city, and the Balkan states were to be autonomous under Russia. Suspicious of the Russian designs, England refused to solve the Eastern Question by so drastic a measure. But the question came up again in 1850 through a quarrel between the Catholic and Orthodox monks about the Holy Places in Palestine.

The capitulations signed on May 28, 1740, by Mahmud I, according certain rights to the Roman Catholic (Latin) ecclesiastics in the Holy Places, had placed the French pilgrims, together with the pilgrims of the other Catholic nations, under the protection of the French flag. This stipulation of the treaty had fallen into desuetude during the French Revolution. In the meantime every advance of Russia had been marked by encroachments of the Orthodox Church on the Roman Catholic Church. The quarrels of the monks of the two churches would have passed unnoticed if Louis Napoleon had not in 1850 seized the opportunity to win over to his side the clericals in France: the French ambassador handed to the Porte a formal demand for the restitution to the Catholics of all their rights. The Ottoman government proposed a mixed commission of inquiry. and France agreed with the condition that no documents later than 1740 should be admitted as evidence. As this suggestion excluded the treaty of Kaynarji, the tsar demanded that nothing should be altered in the status quo. This was a contest between Russia and France for paramount influence in the east: England was inevitably involved and took the side of France and Turkey. The Porte arrived at a compromise in March 1852 by issuing a firman which accorded privileges to both sides, taking on itself the right of "protection." Neither France nor Russia accepted this as neither desired a settlement. Louis Napoleon, who became emperor as Napoleon III in Nov. 1852 and whose new title had been recognized only equivocally by the tsar, wanted a war for dynastic reasons, and the tsar thought the moment opportune to drive out the infidel from Europe. The tsar renewed the proposals of partition made in 1844.

In 1853 Prince Alexander Sergeievich Menshikov was sent to present the Russian ultimatum to Constantinople. He demanded the recognition of the status quo in the matter of the Holy Places end of the tsar's right under the treaty of Kaynarji to protect the Orthodox subjects. The Porte turned for advice to Lord Stratford de Redcliffe, the British ambassador, who was both popular and influeritial. He grasped the situation at once and persuaded Menshikov to present the two demands separately. On April 22, the question of the Holy Places was settled by the British, Russian and French ambassadors. Then when the question of the Russian protectorate over the Christians was raised, Menshikov found himself opposed by the ambassadors of the other powers. Menshikov demanded that the Porte should give a note reaffirming the Russian rights, and this the Turkish cabinet seemed inclined to accept. But that cabinet fell; Mustafa Reshid came into power and, advised by Lord Stratford de Redcliffe, refused the Russian demand. Menshikov left Constantinople on May 22. On June 22 the Russian army under Prince Mikhail Dmitrievich Gorchakov entered the Danubian principalities. It was explained, however, by a circular that this was not with the purpose of attacking Turkey but in order to obtain material guarantees for the enforcement of the existing treaties. In August a conference of the four powers assembled in Vienna, but the settlement proposed conceded everything to Russia except the protectorate, and the Porte would not agree to it. In October Turkey presented an ultimatum to Russia demanding the evacuation of the principalities, and the French and English fleets passed the Dardanelles. Lord Aberdeen, hoping to keep peace, informed Russia that as long as it abstained from crossing the Danube or attacking a Black sea port there would be no *casus belli*. But Russia bornbarded Sinop on the Black sea coast and destroyed a Turkish squadron (Nov. 30), and the French and English fleets entered the Black sea and demanded that the Russian fleet should retire.

The conflict at Sinop had been more like a slaughter than a battle, and the excellent behaviour and initial successes of the Turkish land forces aroused sympathy and admiration throughout Europe. The belief in the rejuvenation of Turkey seemed justified. On March 27, 1854, Great Britain and France declared war on Russia, with the strong support of public opinion; they were later joined by Sardinia. Austria put pressure on Russia to withdraw from the Danubian principalities and occupied them itself in agreement with Turkey. (See EASTERN QUESTION.)

The main operations of the Crimean War (*q.v.*) were confined to the Crimea. The allied troops landed on Sept. 14, 1854, and the campaign lasted till Dec. 1855, when the threatened intervention of Austria forced Russia to accept terms which were ultimately embodied in the treaty of Paris (March 30, 1856). Russia abandoned its pretensions to protect the Christians in Turkey and renounced her right of exclusive interference in the Danubian principalities, to which a fragment of Bessarabia was restored; the navigation of the Danube became free under the supervision of an international commission; the Black sea was to be open to commercial ships of all countries and closed to all warships except a limited number of small warships belonging to Turkey and Russia; Turkey was admitted to the European concert and the contracting parties were to respect its independence and the integrity of its territory; the tanzimat was reaffirmed and enlarged by a decree of the sultan called the *Hatt-i* Humayun, which was included in the treaty under insistence from the powers.

The new era following the Paris conference opened with several outbursts against the reforms. It is noteworthy that the Christians, even the clerical class, were opposed, either for fanatical reasons or at the instigation of Russia, which did not want Turkey to be strengthened. In 1859 the Danubian principalities, encouraged by France and Russia, united and, choosing Alexander John Cuza as their ruler, formed the principality of Rumania. (See RUMANIA.) In 1860 a disturbance in Lebanon involving the Druses and the Christians led to a French occupation, which Fuad Pasha, seconded by Ahmed Vefik Effendi, the Turkish ambassador in Paris, contrived to restrict and to terminate as soon as possible. A *réglement* was signed in Constantinople on June g, 1861, instituting an autonomy for Lebanon under a Christian governor to be chosen by the powers with the consent of the Porte. This agreement lasted till World War I.

Toward the end of Abd ul-Mejid's reign a secret committee was formed in Constantinople to propagate the idea of a constitutional regime for Turkey.

Abd ul-Aziz (1861–76).—Abd ul-Aziz became sultan on his brother Abd ul-Mejid's death in 1861 and reaffirmed by decree the principles of the *tanzimat*. Pan-Slavism, which had its centre in the University of Moscow, began to penetrate Montenegro and Hercegovina, which rose in revolt. These revolts were put down but the Serbs also revolted, demanding the expulsion of the Moslems who lived in the fortresses. In 1862 this revolt was pacified by ceding a few more fortresses to the Serbs; and five years later, through the mediation of England and Holland, the Turkish troops were withdrawn altogether. The Cretans, aided by Greece, revolted and declared their union with Greece. Thereupon Ali Pasha, the grand vizier, went to Crete with an army and quelled the revolt; the episode led to a diplomatic rupture with Greece and in 1869 a conference of ambassadors in Paris accorded local autonomy to Crete under Christian governors. Meanwhile, Ismail Pasha, who became governor of Egypt in 1863 and was a man given to unrestrained expenditure, had obtained loans from France and England, bribed a large number of influential men in the Porte and made the sultan agree to the establishment in Egypt of a succession from father to son, which he did by issuing the firman of May 27, 1866, and June 8, 1867, the latter according to the governor of Egypt the title of khedive. Abd ul-Aziz yielded so easily because he was desirous of bringing about the same alteration in the succession in Turkey in favour of his eldest son. Also, the introduction of a regular budget system for the first time revealed the deplorable state of the treasury. New loans, internal and external, had to be raised in order to pay the interest on the old debts.

The regime of Midhat Pasha, the father of the Turkish constitution, as the governor of Nish, was so popular with all races and creeds that his methods were introduced into other Rumelian vilayets. The people elected their provincial councils, and criminal and civil courts were first opened in those provinces. On March 10, 1870, a firman instituted the Bulgarian exarchate, thus severing the Bulgarian Church from the jurisdiction of the Greek patriarch of Constantinople. In 1871, Russia. taking advantage of the weakened state of France, declared itself no longer bound by the treaty of Paris, which had restricted the number of Russia's warships on the Black sea. An international conference which met in London in 1871 recognized this by abrogating the restrictions on both Russia and Turkey. The passage of the straits remained interdicted to warships.

A law promulgated on June 18, 1867, for the first time allowed foreigners to hold landed property throughout the empire except in Hejaz on condition of their being divested of their right to the protection of their own authorities concerning such property. The grand vizier, Ali Pasha, also made the first amendment to the capitulations by inducing the powers to accept Turkish jurisdiction over small cases for their subjects who lived at a distance from consular towns. In 1866 a Bulgarian insurrection, instigated by Russia, broke out in Trnovo on the pretext that the reforms promised by the firman quoted in the treaty of Paris had not been carried out. Although Midhat Pasha pacified the rising, its real motive, which was nothing less than a desire for national independence, remained unaltered. After the death of such able statesmen as Ali Pasha and Fuad Pasha, Abd ul-Aziz became despotic and began to exile people without trial. The palace expenses increased and financial conditions became worse. The world-wide depression which began in 1873 ended the process of borrowing to cover extravagance and meet deficits. Recourse was had to increased pressure for taxes, which were still payable in kind. Mahmud Nedim Pasha was obliged to declare that the government could pay only a 50% annuity on its debts; whereupon Europe considered Turkey bankrupt, and the state began to lose the prestige gained after the reforms. The agrarian conflict between the Moslem landowners and the Christian peasantry in Hercegovina now spread to the Serbs and Bulgars. A revolt of the latter people was punished with traditional Turkish severity. The Bulgarian atrocities committed by the Turks in the summer of 1876 turned public opinion in the west against Turkey still more.

A secret revolutionary society, formed at the time of Ali Pasha and called the Young Ottomans, was spreading its ideas and influencing public opinion. The great Turkish poet and patriot Namik Kemal Bey and another poet and satirist, Zia Pasha, fled to Paris and published pamphlets inciting the people to demand a constitutional government and succeeded in smuggling them into every part of Turkey. Midhat Pasha, who shared the opinions of the Young Ottomans, succeeded in winning over other members of the cabinet for constitutional change and obtained a *fetva* for the deposition of Abd ul-Aziz, who was accordingly dethroned on May 30, 1876, with the purpose of establishing a constitutional regime. A few days after his deposition he' committed suicide. His nephew Murad V, Abd ul-Mejid's son, who ascended the throne, became insane after reigning three months and was deposed. Murad's brother Abd ul-Hamid, believed to be liberal, but actually reactionary, was placed upon the throne (Aug. 31).

Abd ul-Hamid II (1876–1909).—In the autumn of 1876 Russia made preparations looking toward war with Turkey. With the hope of settling peacefully the Bosnian, Serbian and Bulgarian questions, the British government of Disraeli took the initiative in calling a conference at Constantinople. After assembling on Dee. 12, the conference appeared to be making progress, proposing that the Bosnian and Bulgarian areas should be given substantial autonomy under a governor-general named by the sultan and approved by the powers. But on Dec. 23 the sultan proclaimed a constitution, mainly modelled on the French system, which had been prepared by Midhat Pasha. The defeated conference dragged on for four weeks and then disbanded. Two weeks later, on Feb. 5, 1877, the sultan dismissed and banished Midhat Pasha. Russia in exasperation declared war on Turkey on April 24. The Rumanians joined Russia and Austria declared its neutrality. Public opinion in Europe was anti-Turkish, especially in England, because of the financial repudiation and the sanguinary repression of the Bulgarian revolt, and not a single voice was raised in favour of Turkey. The Turks were defeated both in Europe and in Anatolia (*see* RUSSO-TURKISH WARS), and the Russian army reached Adrianople where both a truce and the preliminaries of peace were signed on Jan. 31, 1878. A treaty was concluded in San Stefano on March 3, 1878. Rumania and Serbia were to become independent, while Bulgaria was to become a vast principality, its frontiers reaching both to the Mediterranean and the Black sea. The provinces of Kars, Ardahan and Bayazid were to be given to Russia as a war indemnity. England objected to the treaty as violating the terms of the international treaty signed in Paris and proposed a new congress. At first only Germany, France and Italy agreed, but when Austria, which was in a position to endanger the retreat of the Russian army, came in, Russia was obliged to do likewise. Turkey contracted a defensive alliance with England on June 4, 1878 at the price of leasing to that country the island of Cyprus.

On July 13, 1878, the congress of Berlin (*q.v.*) ended the Russo-Turkish conflict. It modified the treaty of San Stefano; recognized the independence of Rumania, Serbia and Montenegro; reduced the frontiers given by the treaty of San Stefano to Bulgaria and further divided the territory into two parts, one of which became a self-governing Turkish province named Eastern Rumelia. Turkey had the sanjak of Bayazid in Anatolia restored but was to pay an indemnity of 300,000,000 roubles to Russia. The most important clause of the treaty was the formal engagement of Turkey to introduce reforms in the Rumelian provinces as well as in the eastern provinces which had Armenian minorities.

Abd ul-Hamid II, who immediately after the congress engaged a number of European experts on the pretext of reorganization and reform, before long dismissed them. Apart from the occupation of Egypt by England (1881), (*see* EGYPT), the chief interest of Turkish history now lies in the steps by which Abd ul-Hamid secured his predominance. The power of the Porte was slowly transferred to the palace through the machinations of Said Pasha, the first secretary of Abd ul-Hamid, who before long was an absolute monarch. Midhat Pasha, the veteran reformer, was lured back by a free pardon and appointed governor of Smyrna. Before long he was arrested, charged with the death of Abd ul-Aziz, condemned, reprieved, exiled and finally executed in prison. Since the finances had become worse after the war and the payment of debts was falling into arrears, Said Pasha, now grand vizier, founded the Ottoman Public Debt administration which gave the control of the payment of debts to European delegates. By the decree of Muharrem, Dec. 1881, several categories of Turkish revenue were assigned to this administration, which exercised a weighty influence in Turkish finance until 1914.

In 1885 a rising took place in the province of Eastern Rumelia, which was united to Bulgaria. Turkey appointed Prince Alexander of Battenberg (the prince of Bulgaria) governor of Eastern Rumelia, a diplomatic way of accepting the annexation. Revolts in Crete had been in progress since 1890, and Greece hoped to annex the island. The series of independent non-Moslem governments which had been founded in succession within the empire raised the hopes of all the other national minorities. The Armenians in the eastern vilayets, who enjoyed freedom of education in their schools, succeeded in permeating all the Armenian communities with the desire for national independence. Two revolutionary Armenian committees, called Hinchak and Dashnaktsutiun, who were in close touch with European centres, were formed. Abd ul-Hamid's foolish patronage of the Kurdish communities encouraged them to persecute the Armenians. This, as well as the severity with which the taxes were collected, gave the Armenians two pretexts to rise in revolt in 1894. These revolts were repressed with such sanguinary measures that England and France prepared a program of reforms for the eastern vilayets and forced Turkey to accept it. No effect was given to the Turkish promises, and in 1896, when Lord Salisbury tried to enforce reform on those vilayets, the other powers would not agree to the coercion of Turkey. The Armenian revolutionaries in despair adopted a form of revolt which would force the attention of European political circles: they seized the Ottoman bank, a European institution in Istanbul. The repression was once more sanguinary.

On the ground that Greece had inspired the revolts in Crete, the

Porte declared war on April 17, 1897, and the Turkish army, after inflicting a severe defeat on the Greeks, marched on Domokos. The powers, becoming anxious, intervened and ended the war. A peace was concluded which involved a slight rectification of the frontier and the payment of an indemnity of £T4,000,000 by Greece. Crete was put under international control, en *dépôt,* and much of the capitulations which benefited Greek citizens was cancelled. In 1898 Prince George, the son of the king of Greece, was appointed governor of Crete and a national assembly called. The refusal of Austria and Germany to take part in the anti-Turkish settlement of the Cretan question emphasized a new attitude of Germany toward Turkey. As a result of its apparent pro-Turkish policy Germany obtained a concession to construct the Anatolian railway and in 1899 the Baghdad line. Abd ul-Hamid's preference for Germany was partly because of the friendly attitude of the German kaiser and partly because he feared the liberal influence which France and England would have over the intellectuals in Turkey.

During the latter part of Abd ul-Hamid's reign the Macedonian question became most important. The independent Balkan states carried on anti-Turkish propaganda among their own races in the Turkish Balkans and it is through this movement that the *comita*djis appeared in the Balkans. *Comitadjis* were armed bands of political partisans, such as have at various times worked in the Balkan peninsula. Their activities caused risings and slaughter, which were avenged by equal if not greater ferocity, thus adding to Turkish ill-repute in Europe. In 1903 after the Bulgarian insurrection in Macedonia, Turkey accepted the Miirzsteg program, which was prepared by Austria and Russia: the three vilayets of Salonika, Monastir and Uskub (Skoplje) were placed under a Turkish inspector general (Husein Hilmi Pasha) who in turn was under the supervision of Russian and Austrian civil agents. The gendarmerie was given an Italian commander, and French, English, Austrian, Russian and Italian instructors. In spite of these reforms Macedonia could not be pacified and the work of the comitadjis went on.

Rise of *the* Young Turks.—The Young Turks were the successors of the Young Ottomans, who after the closing of the first parliament had worked in secret for the restoration of the constitution by means of publications and secret societies both in Europe and in Turkey, mostly among the students in the military and medical schools. From 1882 onward Abd ul-Hamid had put the press under a strict censorship and by an elaborate network of spies had abolished freedom of speech. The obscurantist educational system was preventing the spread of modern ideas, the Christian schools alone not being affected by this system. Under these conditions Talaat Bey, a chief clerk of the Salonika post office and a student of law, and Rahmi Bey, a local notable, together with a few others, had formed the Secret Society of Union and Progress on the model of the Freemason lodges, to restore the constitution. The Turkish revolutionary societies in Europe were affiliated to the Salonika society through their leader Nazim. Then, provoked by reports that Edward VII of England and Nicholas II of Russia had planned the partition of Turkey at their meeting in Reval in June 1908, the officers of Macedonia such as Niazi, Enver, Mustafa Remal and Jemal Bey joined the society, bringing to it the command of an active force in the Macedonian army. In July 1908, Maj. Niazi first led an armed rising in Resna and the other conspirators followed. The revolt shot through the cities of the empire, and Abd ul-Hamid was informed that he had no alternative but to restore the constitution, which he did on July 24. This bloodless revolution aroused enthusiasm even among the Serbian, Bulgarian and Greek *comitadjis* and among the Armenian revolutionaries. Representatives of nearly all these came to Salonika and joined the Union and Progress, which ceased to be secret after the proclamation of the constitution. It seemed for the minute as though all the different racial elements of the empire would really unite in a constitutional Turkey. But the separatist and nationalist ideals of the different races were too deeply rooted to be swept away by momentary enthusiasms. The restoration of the constitutional regime postponed the Reval program. But both Austria, which thought Turkey an obstacle to its expansion toward the Aegean sea, and Russia, which found a strong Turkey a hindrance to its plans of expansion, felt uneasy. On Sept. 15, 1908, the Austrian and Russian foreign ministers A. L. von Aehrenthal and A. P. Izvolsky (*qq.v.*) met at Buchlau and agreed on a partition program by which the straits were to be in the Russian zone and Bulgaria a Russian sphere of influence; Macedonia was to be in an Austrian zone and Serbia an Austrian sphere of influence; Albania was to be in an Italian zone and Greece an Italian sphere of influence. Three weeks after this meeting Austria annexed Bosnia and Hercegovina (Oct. 5, 1908), and Bulgaria declared its complete independence. Turkey recognized the Bosnian annexation, for which Austria paid £2,200,000 and evacuated the sanjak of Novi Pazar. For Turkey's recognition of Bulgarian independence, Russia cancelled £5,000,000 of the Turkish indemnity of 1878, expecting to recover the greater part from Bulgaria. Before long these foreign blows were followed by the recrudescence of internal conflicts. The Albanians revolted against the new regime in Macedonia, and the Kurds attacked the Turks, the Armenians and the Nestorians in eastern Anatolia. In Adana the reactionaries attacked the Armenians, and Yemen rose in revolt. Izzet Pasha was sent to pacify the Yemen which he was able eventually to do by a friendly agreement with the imam Yahya (1912). The reactionary opposition in the capital incited fanatical opinion against the new regime. Finally the movement passed into a military revolt on April 13, 1909. Some officers and adherents of the new regime were massacred, and parliament was raided. Abd ul-Hamid pardoned the leaders of the revolt and formed a new cabinet. In reply an army under Mahmud Skevket, sent by the Young Turks from Salonika, marched on the capital and punished the insurgents. The evident desire of Abd ul-Hamid to restore absolutism led parliament to procure his dethronement by a fetva. His brother Mohammed V took his place.

Abd ul-Hamid had tried to revive the political influence of the caliphate in the hope of retaining the non-Turkish Moslem elements of the empire. This Pan-Islamic deal was favoured by the German emperor William II who, during his visit to Jerusalem in 1898, spoke of himself as the friend of the "caliph of three hundred million Moslems." Abd ul-Hamid constructed the Hejaz railway to further the same ideal.

Mohammed V (1909–IS).—Now that the government of the Young Turks was firmly established, the Committee of Union and Progress became a political party and efforts were made to stop the interference of the army in internal politics. In spite of the great losses of territory the empire over which the Young Turkish party was to rule extended from the Adriatic to the Indian ocean and from Mt. Ararat to Tunis. Thirty-three years of mismanagement under the despotic reign of Abd ul-Hamid had reduced Turkey to such a state that in any case a new government had a difficult task; and although the Young Turks were full of patriotic zeal and well versed in western culture, they had had no experience in governing. The army was put under intensive German instruction, the navy was put under instructors led by Adm. Sir Douglas Gambles. A French expert, Charles Laurent, was engaged for the financial department, though it was Javid Bey, the minister of finance, who first succeeded in establishing a finance department on European lines. A great change took place in public works through the concessions given to European companies, which brought foreign capital into the country. In every branch a serious and fruitful activity began.

The evacuation of Crete in 1909 by the four controlling powers led to an acute difference between Turkey and Greece. In 1910 the Cretans elected deputies to the Greek parliament in Athens, but Eleftherios Venizelos refused to admit them, an act which prevented war.

The Italian and Balkan Wars.—The Italo-Turkish War (*q.v.*) began in 1911. Italy, having been assured of the neutrality of the powers, gave the Porte an ultimatum of 24 hours on Sept. 28. On its rejection the Italian navy bombarded Preveza, and Italian troops landed at Tripoli and in Cyrenaica. Without a strong navy Turkey was unable to defend Tripoli, but Enver and Fethi Beys organized a defense by the natives, who were thoroughly roused and the invaders were confined to the coast. Rhodes and the Dodecanese were occupied in May 1912. The outbreak of the First Balkan War forced Turkey to make peace at Ouchy on Oct. 15, 1912. Tripoli and Cyrenaica were left to Italy, but the sultan was permitted to send a representative, called *naib-i-sultan.* The fate of the Dodecanese islands was not to be decided until the Lausanne conference of 1922–23.

In Aug. 1912, a faction in the army, opposed to the Union and Progress party, had brought about a change of government, and the cabinet formed was composed mostly of the members of the old regime, including Kiamil Pasha, the well-known Hamidian grand vizier. Russia offered to help Turkey in case of an attack on the Dardanelles on the condition that the Russian fleet be allowed to pass the straits. The Porte refused.

To stamp out the *comitadjis,* Turkey had embarked on an attempt to disarm the people in the Balkans. Greece, Serbia, Montenegro and Bulgaria in reply reconciled their conflicting interests in the Balkans and formed an alliance against Turkey (March–Oct. 1912). Turkey was unaware of this alliance for a long time, but on Oct. 8, 1912, Montenegro declared war on Turkey; and on Oct. 14, Greece, Serbia and Bulgaria issued ultimatums demanding reforms and the demobilization of the Turkish army in the Balkans. Turkey declared war on Serbia and Bulgaria on Oct. 17, and Greece declared war on Turkey the next day. The political dissensions which affected the command and the organization of the army proved disastrous to Turkey, and the army was defeated, though it made a fine and prolonged defense of Scutari (in Albania), Janina and Adrianople. Adrianople was still in the hands of the Turks when the advance of the Bulgarian army was stopped at the last defenses of Constantinople, the Chatalja lines. The Turkish cruiser "Hamidie," under the command of Rauf Bey, escaped through the lines of the Greek fleet at the straits and wandered in the Adriatic, Aegean and Mediterranean, bombarding enemy ports, hampering their transports and raising Turkish morale. At the beginning of the war the powers had declared that whatever the military results of the war might be the territorial *status* quo would be maintained in the Balkans. Turkey hoped that this declaration would apply as much in the event of Turkish defeat as of Turkish victory. The powers called a conference in London after the Turkish defeat. But since the status quo was clearly going to be changed in favour of the Balkan states, in spite of the declaration of the powers, and since Kiamil Pasha's government was about to cede Adrianople even before that city had fallen, the Young Turks determined to seize power again. They raided the Sublime Porte and forced Kiamil to resign. A Young Turkish cabinet was formed under Mahmud Shevket. Although at first the new cabinet refused the terms of peace of the London conference, the intervention of Russia and Austria and the fall of Adrianople enforced their acceptance by treaty at London on May 30, 1913. This brought the Turkish frontiers in Europe to the line Midia-Enos.

A month later the Second Balkan War broke out, with Greece and Serbia fighting Bulgaria over the division of territory. The Rumanians, with the purpose of annexing the Dobruja, also marched on Bulgaria. This moment was seized as opportune by the Turkish army to march on Adrianople, which was recaptured. A treaty of peace was signed with Bulgaria in Constantinople on Sept. 29, by which Adrianople passed to Turkey. On Nov. 13 peace was concluded with Greece, by which it was given Crete and the rest of the Aegean islands except Tenedos and Imbros and the Dodecanese islands, the latter of which were still under Italian occupation. On March 14, 1914, peace was signed with Serbia. The net result of the series of treaties contracted with the Balkan states was the loss to Turkey of all its possessions to the west of the Maritsa river. (See BALKAN WARS.)

Young Turkish Policy.—Mahmud Shevket Pasha then attempted a settlement of differences with England and France. Hakki Pasha, ex-grand vizier, was sent to London to come to an understanding over the Persian gulf controversy and to negotiate for the modification of the financial capitulations. Javid Bey, ex-minister of finance, was sent to France to settle the railway questions, to modify the financial capitulations and to raise a loan. But during these negotiations the opposition (the Liberal Union) murdered Mahmud Shevket, and the Young Turks passed repressive measures. A new cabinet was formed under Said Halim Pasha. A military mission was brought from Germany under Gen. Otto Liman von Sanders, who was also appointed commander of the army corps in Constantinople. The navy was under the Englishman, Adm. A. H. Limpus. A detailed program of reform for the eastern vilayets was prepared. As the powers refused to provide experts, inspectors were engaged from Sweden; the ministry of the interior, however, employed British inspectors.

The policy of the Young Turks had begun by being a policy of "Ottomanism," which aimed at uniting all the racial and religious elements of the empire. The risings in Macedonia had proved that the nationalism of each element, encouraged by outside powers, could not be assimilated by such a weak state as Turkey. Turkey through the Balkan War lost its Albanian, Bulgarian, Serbian and most of its Greek subjects, and the Arabs, incited by France, also manifested separatist tendencies, although to give the right to use Arabic officially in the courts in Arabia was the only decentralizing measure the Young Turks had taken. The failure of Ottomanism was followed by the revival of Abd ul-Hamid's Pan-Islamist policy, a decision encouraged by the sympathy which the Indian and the Egyptian Moslems had shown during the disasters of the Italian and Balkan wars. It was this Pan-Islamism which later led the Young Turks to proclaim jihad (holy war) in the hope of influencing the Moslem combatants in the Allied armies during World War I. This revival was led by Enver Pasha; it was opposed, in the name of pure nationalism by a larger group led by Ziya Gokalp, the poet and philosopher, who was helping the cultural-nationalist institutions called the "Turk Yurts" and the "Turk Ojaks" (opened 1912). The influence of Turkish refugees from Russia caused the nationalism of the Union and Progress party to take a Pan-Turanianist form.

The disagreement between England and Germany over the Baghdad railway and that between France and Germany over their respective railway spheres were settled by two agreements signed in Feb. 1914 between France and Germany and in June between England and Germany.

World War I.—In 1913 Enver Pasha, formerly Enver Bey, became minister of war. His policy was to give the high commands in the army to younger men. The military organization continued to be under the German mission. There were secret negotiations between Germany and Turkey known only to the grand vizier Prince Said Halim Pasha, Talaat Bey and Enver Pasha. A secret alliance was signed on August 2, 1914, when war was breaking out between Germany and Austria on one side and England, France and Russia on the other. Turkey declared its neutrality but mobilized at the same time. There were war and antiwar factions in the party. The antiwar faction tried to come to an understanding with the Allies, declaring that Turkey would remain neutral if the financial capitulations were modified and a loan granted. Javid Bey, the minister of finance, was at the head of the antiwar faction. The Allies made no promises, but they demanded the dismissal of the German commanders and the expulsion of the crews of two German cruisers which had taken refuge in the Dardanelles. The British government commandeered the two Turkish dreadnoughts which were then being constructed in England with the money raised by popular subscription, an act which, though legal, caused surprise and resentment. And when Germany offered the warships "Breslau" and "Goeben" to the Turkish navy the antiwar faction was weakened. The war faction argued that Turkey had lost by its political isolation since the Crimean War, that it should join Germany who was fighting against the hereditary enemy of Turkey, tsarist Russia, and that should Turkey become victorious, it might become free from the capitulations and even regain some of its lost territories. On Sept. 8, 1914, Turkey declared the capitulations abolished, which raised protests from all the powers, including its ally Germany. When the two German warships, which had become units of the Turkish navy though still under German command, attacked Russian ships and ports in the Black sea, Russia declared war, and England and France did the same. Turkey thus found itself at war with the

Allies on the Egyptian, Mesopotamian and Caucasian frontiers as well as at the Dardanelles (see DARDANELLES CAMPAIGN; MESOPOTAMIA, OPERATIONS IN; PALESTINE, OPERATIONS IN). The Dardanelles were successfully defended by Turkey, but the Russians took Trebizond, Erzurum and Erzinjan and marched toward Sivas; while Turkey failed in its attack on the Suez canal and the British took Mesopotamia including Baghdad. During the Turko-Russian battles on the Caucasian front, the Armenians created disturbances behind the Turkish lines and threatened to cut the lines of communications. The Turkish government began early in 1915 a general deportation in which atrocities were committed on a large scale. When Gen, Antranik, the Russo-Armenian general, entered eastern Anatolia, the Armenian soldiers under his command (so-called "Christian Army of Revenge") replied by similar atrocities, though on a far smaller scale. As Turkey had mobilized to its utmost limit it became almost impossible to sustain the army; the civil population suffered privation hitherto unknown; martial law was proclaimed everywhere. The Communist Revolution led Turkey and its Allies to conclude a peace treaty with Bolshevik Russia at Brest-Litovsk, March 3, 1918, by which all its lost territory was restored to it (even those districts which it had ceded to Russia in 1877). But the Arab nationalists, supported by England, drove out the Turks from Hejaz, except from Medina. The British army occupied Syria. On Oct. 30, 1918, an armistice was signed at Mudros, on the British warship "Agamemnon," between Adm. S. A. G. Calthorpe and Rauf Bey, the Turkish minister of marine. Although the armistice aimed at ending World War I, it did not end yet for Turkey who had to fight for four years more actually against Greece though virtually against the Allies themselves.

During the war secularization in education and other departments had taken place. The university had been extended and its principal chairs were occupied by German professors. The Sheria courts were taken from the sheikh ul-Islam and given to the ministry of justice. A family law issued in 1916 reformed marriage and divorce regulations. Women, who already had equal education with men, now filled public posts, and the university opened its doors to them.

Mohammed VI (*1918–22*).—Mohammed V had died in July 1918 and had been succeeded by his brother Vahid ed-Din, who took the name of Mohammed VI. In the early months of the reign the Turks welcomed the armistice as being the end to the great suffering of long years. But they soon forgot this suffering in the humiliation and persecution to which they became exposed. The Allied fleets and armies occupied the straits, Istanbul and even places outside the armistice line, and the terms of the armistice were stretched to the point of violation. Under these conditions the Turks had a bitter foretaste of the peace that they would receive at the hands of the Allies. Both in Istanbul and in the provinces, officers and intellectuals met in secret and began to discuss how to secure a tolerable peace, and as the nationalists appeared in the forefront of the general reaction against the Allies this agitation received the general name of the "nationalist movement." Meanwhile the Allies could not come to an agreement among themselves over the Turkish peace. Finally, on May 15, 1919, the Greek army was landed in Smyrna under the protection of the British, French and U.S. fleets, and the Greeks inaugurated their occupation by massacres committed in full view of the Allied fleets. (Italy, having retired from the peace conference for the moment, did not take part. By the interallied agreement of St. Jean de Maurienne in 1917, Smyrna and Adalia had been apportioned to Italy, and Italy had landed troops in Adalia in April 1918.) The Greek landing in Smyrna aroused general indignation in Turkey which ended in the national determination to resist to the last, even if this meant total disintegration. Mass meetings in Istanbul were the first manifestation of this feeling.

The National Pact.—Meanwhile Turkey was in a state of anarchy. The responsible leaders of the Union and Progress party had escaped to Germany, and the party was dissolved. Mohammed VI, a personal enemy of the Young Turks, forced Izzet Pasha's cabinet, which to some extent was able to keep order, to resign, and the Liberal Union came into power, Certain nationalist leaders wanted to save the country from disintegration by cooperating with the sultan and using his prestige as sultan-caliph. Among these was Mustafa Kemal Pasha. But Mohammed VI preferred to sacrifice the existence of his nation to his personal security, and this he did by bringing Damad Ferid Pasha into power and, through him, giving the reins of the government to the high commissioners of the Allies. In western Anatolia organizations for a national defense against the Greek invasion were rapidly arising. In eastern Anatolia, especially in Trebizond and Erzurum, associations, under the guidance of Kiazim Kara-Bekir Pasha, were preparing to oppose any attempt of the Allies to create an Armenia out of the territories which, even before the deportations and atrocities, they claimed to have been predominantly Turkish. The sultan with the Allies' assent, in order to control these organizations and disperse them if necessary, sent Mustafa Kemal Pasha to eastern Anatolia as the military inspector general. Kemal reached Samsun four days after the Greek landing at Smyrna. But as he was already in correspondence with these organizations, he met Rauf Bey, Ali Fuad Pasha and Col. Refet at Amasia on his way to Erzurum and signed the Amasia protocol on June 19, 1919; Kiazim Kara-Bekir Pasha also signed by telegram. This protocol is the first document that formally declared the national determination to resist both the Allies and the sultan, as the instrument of the Allies. A national congress assembled in Erzurum, on July 23, 1919, and Mustafa Kemal Pasha, having resigned from the army, presided. Another congress assembled in Sivas on Sept. 4, 1919, to which the national associations of western Anatolia sent representatives. This congress reaffirmed the decisions of the Erzurum congress, added plans for the defense of Eastern Thrace and chose a representative body to control the movement in Anatolia. No president was chosen. but Mustafa Kemal Pasha's leadership was generally recognized. This manifestation of the national will forced the sultan to dismiss Damad Ferid Pasha. A new cabinet with nationalist tendencies came into power. In Jan. 1920 a new parliament assembled in Istanbul, containing a nationalist majority. The parliament issued the national pact as accepted by the two congresses.

This national pact formulated the demands which the nationalists made during the whole struggle, and which they obtained eventually at Lausanne. It proposed self-determination for the Arab provinces south of the armistice line; it agreed to the opening of the straits to commerce and it proposed to grant to non-Turkish minorities the same rights as they had secured in Europe under various postwar treaties. The pact also demanded, either explicitly or implicitly, that Turkey should retain all territories inhabited by non-Arab Ottoman Moslem majorities, which meant not only Anatolia but eastern Thrace and the Mosul vilayet; that Istanbul should be given military security; that the capitulations should be abolished and that there should be a reasonable settlement of the public debts.

The Allies were watching with some anxiety the nationalist activities, which consisted mostly of smuggling in arms and ammunition and organizing the defense. Mustafa Kemal Pasha stayed in Anatolia to conduct these activities. The Allies, in conjunction with the sultan and the Liberal Union party, decided to strike at the nationalist movement through the persons of the leading deputies and intelligentsia in Constantinople. On March 16, 1920, the Allied forces in the capital seized a large number of nationalists, including Rauf Bey, the leader of the nationalist party in parliament, and Kara Vasif Bey, the head of the nationalist organization in Constantinople, arresting them in the parliament house itself. Parliament was then closed by the orders of the sultan. Some deputies and a few of the intelligentsia escaped to Ankara, which had become the nationalist centre.

The *Ankara* Government.—Mustafa Kemal Pasha had issued a proclamation inviting Anatolia to elect its deputies for a new assembly, which was opened in Ankara on April 23, 1920. Mustafa Kemal Pasha was elected president both of the assembly and of the government. Thus came into existence a new Turkish government over all territories not under foreign occupation. A new temporary constitution, known as the Law of Fundamental Organization, proclaimed the sovereignty to belong to the nation without restriction, and the great national assembly to be the sole and lawful representative of the nation, exercising sovereignty in its name. But Mustafa Kemal Pasha tried to make use of those who were still loyal to the sultan by declaring in his speeches that the sultan-caliph was a prisoner in the hands of the Allies and that he would be restored after the realization of the national ideal. The government of Istanbul, controlled by the Allies, condemned the leading nationalists to death by extraordinary courts and issued a fetva denouncing them as outlaws. The Anatolian government retaliated similarly. The sultan's government sent forces under the name of the caliphate army and roused counterrevolutionary outbreaks around Ankara, tvhich, however, were put down by the nationalists. When the Allies found themselves embarrassed by the nationalist success, they accepted the offer of Venizelos that the Greek army should advance beyond the area allotted to it in order to deal with the nationalists. In the months of June and July 1920 the Greek army occupied eastern Thrace and marched on to Bursa and Ushak. On Aug. 10, 1920, the Allies concluded the treaty of Sèvres with the sultan's government in Istanbul which aimed at destroying the independence of Turkey. In Europe, eastern Thrace nearly as far as the Chatalja lines, including Gallipoli, was assigned to Greece; and provisionally Greece was also given Smyrna and a zone around it. A tripartite agreement between England, France and Italy laid out French and Italian spheres of influence in parts of those Anatolian territories which under the peace treaty were nominally left to Turkey. The outlines of the Armenia which was to be formed in eastern Anatolia were left to Pres. Woodrow Wilson to define. The treaty strengthened the nationalist cause by arousing unanimous indignation. The British forces in Eskisehir withdrew under the pressure of Ali Fuad Pasha's forces. In Cilicia and Aintab the nationalist forces were struggling successfully against the French army.

The continual raids by the Armenians of the Armenian republic on the Turkish frontier villages, as well as the necessity for a direct route to Russia, led Turkey to attack the Armenian republic. The Turkish army captured Kars and Alexandropol, and a victorious peace was concluded with Armenia at Alexandropol on Jan. 3, 1921. A Turkish delegation sent by the Ankara government signed a treaty of friendship with Russia by tvhich Russia became the first country to recognize that government. The Menshevik government of Georgia was overthrown, and Turkey with the consent of Georgia occupied Ardahan, Artvin and Batum. When the Caucasian republics were federated to Russia, a treaty signed in Kars Oct. 13, 1921, between Russia, the government of Ankara, and the three Caucasian republics, left Kars, Ardahan and Artvin to Turkey and restored Batum to Russia.

The defeat of Venizelos in the general elections in Greece and the return of King Constantine alienated the Allies, especially France. The Greek army in Anatolia started a new offensive, but was twice checked by the Turkish army at Inonu (January–April 1921). The Allies called a conference in London to which representatives of both the government of the sultan and the government of Ankara were invited (January–February 1921). At this conference it became clear that the Allies realized the necessity of amending the treaty of Skvres: the Ankara delegates initialled agreements with the French and Italian governments which were not accepted by Ankara. These agreements nevertheless were the first signs of the difference of opinion between the Allies on the Turkish question. The Allied high commissioners at Istanbul as a result of this dissension announced the neutrality of their governments on May 18, 1921, and designated neutral zones forbidden to the belligerents on each shore of the Bosporus and the Dardanelles. On July 10, 1921, the Greek army once more passed to the offensive and drove the Turkish army east of the Sakariya. At the suggestion of a commission of inquiry sent by the great national assembly to the front, Mustafa Kemal Pasha was now appointed generalissimo. He fought during 20 days the decisive battle of the Sakariya, after which the Greeks retired westward. As a reward he was made marshal and was given the title of *ghazi* by the great national assembly.

Henri Franklin-Bouillon was delegated by France to negotiate an agreement which was signed in Ankara on Oct. 20, 1921. It recognized the Ankara government and traced the Turko-Syrian frontier, as later reaffirmed in the Lausanne treaty. On March 24, 1922, the Allies intervened in common to propose a truce between Turkey and Greece, but the Turks declared that they could only negotiate after the evacuation of Anatolia. However, the Ankara government sent to Europe first Yusuf Kemal Pasha, the commissary of foreign affairs, and then Fethi Bey, the commissary of the interior, to seek a peaceful solution. Fethi Bey arrived in London with especially conciliatory proposals, but during his three weeks' stay was not received by any cabinet minister. The Ankara government concluded that the question could be settled only by force of arms. The Greeks, to raise their morale, demanded permission to occupy Istanbul, which the Allies refused. On July 30, 1922, Aristeides Sterghiadis, the Greek high commissioner in Smyrna, proclaimed the autonomy of the Anatolian territory under Greek occupation, apparently with the intention of continuing the Anatolian war in the guise of a local Greek national movement, in case the Greek army should be compelled by diplomatic pressure to evacuate Anatolia. The Allies proclaimed their neutrality for the second time on August 10, 1922, by the decision of the supreme council of war.

The Turkish offensivebegan on Aug. 26 and the Greek army was completely routed. On its way from Ushak to Smyrna, it burned to the ground the most prosperous towns in the west of Turkey, and atrocities were committed on a large scale. Nearly a million people were made homeless. The Turkish army entered Smyrna on Sept. 9, and masses of the native Christians left the town in great disorder. The central part of the town was burned on Sept. 13.

The annihilation of the Greek army produced a dangerous situation. At first England and France agreed to act in concert in case of necessity by opposing any Turkish violation of the neutral zones. On Sept. 16, David Lloyd George further announced that the British dominions, Yugoslavia and Rumania had been asked to promise military support for maintaining the freedom of the straits. This announcement incited the Turks to action, both by its threatening tone and because it contained no reference to the nationalists' territorial demands in Eastern Thrace. In consequence the Turkish army advanced toward the neutral zone. France and Italy withdrew their troops, and Franklin-Bouillon was sent to Smyrna from Paris to mediate with Mustafa Kemal Pasha-and so arrest the march of the Turkish army. The British troops remained alone. On Sept. 23, Lord Curzon came to an agreement with M. Poincaré which accepted the British view regarding the temporary question of the neutral zones and the French view regarding the definitive peace terms. On the same day, in accordance with this agreement, the principal Allied powers invited the Ankara government to a peace conference on two bases: that Turkish sovereignty should be restored in Thrace up to the river Maritsa; and that during the interim period, pending the negotiations and entry into force of the peace treaty, the inviolability of the neutral zones should be maintained. Meanwhile the Turkish cavalry had advanced almost up to the British wire at Chanak, and only the tact and firmness of Gen. Charles Harington, as well as his desire to prevent war, averted a disaster. The nationalists accepted the Allied invitation and suggested a preliminary conference on Sept. 29. On Oct. 13 a military convention was signed at Mudania between the Ankara delegates, the Allied generals in Istanbul and Greek representatives.

The Allies had also invited the sultan's government to the peace conference. Tewfik Pasha, the last grand visier of the Ottoman empire, wrote to the great national assembly proposing joint action, and this made it necessary for the assembly to face the dilemma of having two governments in one country. In consequence the caliphate was separated from the sultanate; the sultanate was abolished, and the sovereignty of the nation without any restriction, already inserted in the new constitution, was reaffirmed on Oct. 1, 1922. It was decided, however, to keep the caliphate in the house of Osman. The governmental departments in Istanbul then passed to the Ankara government, tvhich formality was accomplished by Refet Pasha, that government's high commissioner for Thrace. Thus the house of Osman, which had reigned for seven centuries, came to an end through the treason of its last sultan, Mohammed VI, and for the first time in its history Istanbul was no longer the capital of the state to which it belonged. On Nov. 17, 1922, Mohammed VI took refuge in the British warship "Malaya" and escaped to Malta. The commissary of Sheria deposed the refugee caliph by a *fetva* and elected Prince Abd ul-Mejid. the son of Abd ul-Aziz, as caliph. The new caliph recognized the sovereignty of the great national assembly and gave up his claims to the sultanate by a written document. This was the last time the Turks used the *fetva*.

The Treaty **of Lausanne.**—The Lausanne conference met on Nov. 20, 1922, and after a recess from Feb. 4 to April 23, 1923, signed a peace treaty on July 24. By it the Turks procured the demands they had put forward in the national pact, except that concerning Mosul. The capitulations were abolished. To realize racial unity in new Turkey the Orthodox Greeks in Anatolia were to be exchanged for the Moslem Turks in Greek Macedonia; the Greeks of Istanbul and the rest of the Christian minorities were to have the same rights as were secured to other minorities in Europe under the postwar treaties. The tracing of the frontier with Iraq was to be discussed between England and Turkey at a future date and if necessary to be submitted to the League of Nations. Turkey also concluded treaties with the U.S. and Poland which restored diplomatic relations with these countries.

(**A. A. A.;** G. L. L.)

THE REPUBLIC

The Ottoman empire, which had tried to end the war in 1918 by the armistice of Mudros, was no more. The Turks, principal element of the defunct empire, had created a new independent Turkish state. The new Turkey had abolished the capitulations and contracted treaties with all the other states. Released from external troubles, it was free to begin a new era of progress and reconstruction. The new constitution was not complete, and the position of the president of the national assembly, who was the head of the state at the same time, was vague. Taking advantage of this, during a difficulty in forming a new council of commissaries, Mustafa Kemal Pasha proposed a constitutional amendment by which Turkey would become a republic (Oct. 29, 1923). This amendment was accepted, and Mustafa Kemal Pasha was elected the first president of the Turkish republic. Ismet Pasha, his right hand man, formed a cabinet.

Mustafa **Kemal's** Presidency.— Mustafa Kemal Pasha accepted the clause in the new constitution which declared the state religion to be Islam. But there was a growing conviction that radical reform would be possible only after freeing the state from religion. Turkey after adopting the republican form of government was determined to complete the partial secularization of the preceding regime and to prevent all interference by religious influence, which was regarded as having been the principal obstacle to modernization. The clause in the constitution declaring Islam the state religion and the position of the *fainéant* caliph were accordingly the first objects of attack. On March 3, 1924, the great national assembly passed three laws at one sitting: (1) expelling the Ottoman dynasty; (2) abolishing the caliphate, the commissariat of *sheria* (the recognized office for the religious affairs) and *evkaff* (pious foundations) and (3) attaching all the educational and scientific institutions, including the *medresses* (religious colleges), to the commissariat of public instruction. By these laws the Turkish republic put an end to Pan-Islamism in Turkey and also paralyzed the Khilafat movement in British India. The most important step in secularization was the clause of one of the three laws which withdrew the civil transaction section of the *sheria*, which so far had dominated the Turkish code through the *mejelle* (Turko-Islamic code). The dispatch of all concerns and cases which related to dogma and religion passed to an office called the presidency of religious affairs. Thus for the first time Turkey tried to separate religion from the state. Of the two classes, the ulema and the military, which had dominated the Turkish state, the ulema were no more. The military, from the time of the *tanzimat*, had nominally ceased to interfere in internal politics. But in spite of this the deposition of Abd ul-Aziz (1876), the re-establishment of the constitution (1908) and the nationalist movement (1918) were all brought about through the army. And although during the last and most important changes of regime, including state secularization, military influence was not obvious, the force behind the throne in the Turkish state was still the army. A month before the passing of these laws Mustafa Kemal Pasha assembled the commanders of the army in Smyrna and discussed these questions with them, thus diplomatically shifting the responsibility to the shoulders of the army in case of any public opposition. A new constitution which was extremely democratic in form was adopted on April 20, 1924. To win over the peasantry, who constituted the majority and who did not regard these radical measures favourably, the tithes, which lay heavily on the agricultural classes, were abolished and military service was reduced to 18 months. The deficit in the revenue resulting from abolition of the tithes was met by a heavier taxation of the urban population.

Although constitutionally the natural sovereignty was in the hands of the national assembly, Mustafa Kemal Pasha, through his personal prestige won in the field and through his hold over the army, showed decided tendencies toward a personal dictatorship. This created an opposition under Rauf Bey and Kiazim Kara-Bekir Pasha, which attempted to keep the republic on a democratic and liberal basis and was called the Republican Progressive party (Nov. 1924). Ismet Pasha's cabinet fell and Fethi Bey, a liberal and moderate statesman, formed a new cabinet. The Kurdish provinces revolted because they resented the extreme centralization and the harsh measures of the government in carrying out new reforms and because of the separatist tendencies of some of the leading chiefs. Mustafa Kemal Pasha seized this as a pretext to strike at the opposition. Pretending that the liberal clause in the Progressive program which advanced liberty of conscience had encouraged this rising, he forced the Fethi Bey cabinet to resign, on the ground that it had refused to carry out drastic measures in the peaceful parts of Turkey. Ismet Pasha formed a cabinet for the second time. The law of maintenance of order was passed.

With the passing of this law, the tribunals of independence, which had functioned during the nationalist struggle against the antinationalists, were revived. The opposition party was suppressed. The freedom of speech. which the new constitution had accorded to the Turkish nation was evaded through the very vague terms of the law. Mustafa Kemal was able to establish his dictatorship, despite a very democratic assembly, by the absence of any clause in the constitution which would place the president of the republic above parties. Therefore he, as the active president of his own party, could wield unbounded power. The Kemalist party (People's party), like Abd ul-Hamid and the Committee of Union and Progress, believed that the Turkish nation was not yet ready for a liberal regime. Although the Kurdish insurrection was put down by tribunals and military operations, the disturbances continued in Van, Bitlis and Diarbekr and led the republic to begin a partial deportation of the Kurds. The religious orders were abolished and the *tekkes* (monasteries) were closed as having influenced the Kurdish rising. A decree ordered the army to adopt a kepi and the civil servants to wear hats. A law passed in Nov. 1925 abolished the fez and obliged everybody to wear hats (women were not included). This law provoked several counterrevolutionary risings in the eastern provinces, which the tribunals suppressed by death sentences and imprisonments. On Feb. 17, 1926, the assembly adopted a new civil code which was almost a translation of the Swiss. By the adoption of this code Turkish legislation was wholly freed from Islamic influence. The laws concerning marriage, divorce and inheritance, which had been totally different from those of the west, were altered, and polygamy was legally prohibited. This radical secularization led the non-Moslem minorities to renounce of their own accord the minority rights which they had procured at the Lausanne conference. The secular republic had now only two points of contact left with religion: the clause in the constitution which stated that the religion of the state was Islam, and the law which attached the presidency of religious affairs to the prime minister's office. The former of these was broken on April 9, 1928, by an amendment to the constitution.

On the pretext of a conspiracy against Mustafa Kemal Pasha's life, "discovered" in the summer of 1926, all the members of the suppressed opposition party, both in and out of the assembly, as well as the leading members of the Union and Progress party, were arrested by the tribunal of independence. At the trial political opponents were assumed to be conspirators by the mere fact of their being in the opposition. Kiazim Kara-Bekir Pasha, Ali Fuad Pasha and Refet Pasha were acquitted by the pressure of the army. Several members of the assembly, whose parliamentary immunity was violated and who had been in the forefront of the nationalist movement, were executed. Javid, the foremost Turkish financier, Shukri, Nazim and Janpoulant, all ex-ministers of the Unionist regime and some of them deputies, were also executed. The ex-prime minister Rauf, who was in Europe at the time, was condemned to ten years' imprisonment.

A decree of 1928 discarded the Arabic alphabet for the writing of Turkish and imposed the Roman instead. This change was in accordance with the policy of modernizing the language itself and freeing it from its dependence on Arabic and Persian.

The year 1930 saw two advances in Turkey's political life: women received the vote for municipal elections; and on Aug. 13 the former prime minister, Fethi Bey, formed an opposition group, the Liberal Republican party. In the municipal elections of the same year his party polled about 25% of all votes, women were for the first time elected, and the Greek, Armenian and Jewish minorities presented their candidates. But by the end of the year the opposition party was dissolved.

Turkey did not escape the economic depression of the early 1930s. But that adversity did not arrest—although it curtailed—the economic reconstruction of the country. This was fostered by the formation of a number of state banks, to each of which was delegated the establishment and control of state industrial and mining enterprises and public utilities. A long-term credit of $8,000,000 was negotiated with the Soviet government for the acquisition of Russian cotton-spinning machinery. Many occupations, until then mostly exercised by foreigners, were reserved for Turks—partly to promote their education in trade and commerce. In 1932 a five-year industrial plan was promulgated and an important program of economic and educational reforms was launched. The metric system was adopted; and English replaced French, Arabic or Persian as the principal foreign language to be taught in the schools.

On Dec. 6, 1934, the great national assembly changed the constitution so that all Turkish men and women were henceforth entitled to vote in legislative elections as soon as they had reached the age of 23 and to become elected at the age of 31. At the same time it was also decided that the president was to be elected from among the deputies, his term of office being identical with the life of the assembly. During 1935 women were for the first time elected to the great national assembly. The international women's congress met at Istanbul in April of the same year. Sunday was introduced (in place of Friday) as the weekly rest day. The old Turkish titles—such as pasha—were abolished; and family names were introduced, as in the west. Mustafa Kemal received the surname of Ataturk;' the premier Ismet, that of Inonii. On Feb. 5, 1937, the assembly accepted the six principles of the Republican People's party—republicanism, nationalism, democracy, evolutionism, separation of state and religion and state supervision of the principal industries, public utility services and means of communication.

In Oct. 1937 Ismet Inonu, who had been prime minister for almost 15 years, resigned and was replaced by the former minister of economic affairs Celal (Jelal) Bayar. After the death of Kemal Ataturk on Nov. 10, 1938, at the age of 58, Inonii was elected president of the republic.

Foreign Affairs.—On May 19, 1924, a conference assembled in Istanbul to trace the Turko-Iraqi frontier, which had been left over by the Lausanne conference. No result was achieved and in accordance with the decision of the Lausanne conference, England and Turkey submitted the question to the League of Nations. On Dec. 16, 1925, the League decided to give most of the vilayet of Mosul to Iraq. To this the Turks would not at first consent. A treaty of mutual neutrality was concluded on Dec. 17 for three years with the U.S.S.R. Turko-Soviet relations, which had become distant since the Lausanne conference, once more became very close. The *Türk Ojaks* (national clubs) issued a declaration, stating that Turkish nationalism was cultural and local and had no Pan-Turanian aims. Finally in the early summer of 1926, the British, Turkish and Iraqi representatives met in Ankara and signed a treaty on June 5, which ceded the vilayet of Mosul to Iraq with a slight rectification of the frontier in favour of Turkey: for a period of 25 years from the coming into force of the treaty, the Iraqi government was to pay Turkey 10% on all royalties it received from the exploitation of the Mosul oil. On April 22, 1926, a treaty of neutrality had been concluded with Persia. A treaty of perpetual peace and friendship was signed with Afghanistan on May 27, 1928, and a treaty of nonaggression and arbitration with Italy on May 30.

In 1930, after an exchange of populations, treaties of friendship and arbitration were signed with Greece, initiating an era of co-operation between Greece and Turkey. Cordial relations were also maintained with the Soviet Union; and in Oct. 1931 the second Balkan conference met in Istanbul, with more than 150 delegates from Albania, Bulgaria, Greece, Yugoslavia, Rumania and Turkey attending. In July 1932 Turkey joined the League of Nations, and at about the same time initiated a rapprochement with Britain and France. A further step in Turkish policy was taken on Feb. 9, 1934, when under Turkish leadership the Balkan entente—which included Rumania, Yugoslavia, Greece and Turkey (but not Bulgaria) was established. In Nov. 1935 the existing treaties with the Soviet Union were prolonged for a further ten years. The treaties with Iran, Iraq and Afghanistan were consolidated by the signing, at Saadabad on July g, 1937, of an Asiatic pact of nonaggression with those states.

The rapprochement with Great Britain became more marked in 1936. Turkey promised to co-operate with Great Britain in case of a conflict with Italy in the Mediterranean; and a conference at Montreux removed (with British support) the limitations imposed upon Turkey by the treaty of Lausanne in respect of the militarization of the straits. The visit of King Edward VIII to Istanbul still further strengthened Anglo-Turkish relations.

By an agreement with France of July 3, 1938, the district of Alexandretta was established as an autonomous part of Syria, but conforming in most respects to the order prevailing in Turkey. It received the name Hatay, after the ancient Hittites, regarded by the modern Turks as their ancestors. In less than a year Hatay was ceded wholly to Turkey, at the signing of the declaration of mutual assistance with France.

World War II.—As president; Ismet Inönü followed, on the whole, the constructive and cautious policy of his predecessor. But his cabinet was soon faced with the imminence of war in Europe. In view of this crisis Turkey signed declarations of mutual assistance with Great Britain (May 12, 1939) and France (June 24), aiming at the maintenance of peace in the eastern Mediterranean.

Turkey's position seemed secure because of its friendship with the western democracies on the one hand and with the Soviet Union on the other. Turkey might indeed have become the connecting link between these two camps, both of which were then opposed to German aggression. But the pact of friendship between the Soviet Union and Germany of Aug. 1939 profoundly altered Turkey's position. Turkey tried to maintain its friendship unchanged, and the Turkish foreign minister visited Moscow in the autumn, but without result. On Oct. 19, therefore, Turkey concluded a treaty with Great Britain and France, and a series of staff talks between the general staffs of the western democracies and Turkey began. Turkey was unable however, to transform the Balkan entente into a military alliance.

Italy's entrance into the European war in May 1940 extended the area of the conflict into the eastern Mediterranean and thus created for Turkey a *casus* foederis. But the downfall of France and the complete uncertainty of the future of Great Britain made Turkey hold back. Although Turkey made every effort to increase the strength of its army it was largely a bayonet army, inadequately equipped with modern aircraft and armour. President Inonii, therefore, adopted a policy of neutrality. Nevertheless, although Turkey did not enter the war as an active ally of Great Britain. it continually stressed its solemn intention of remaining faithful to the alliance.

It was expected that Turkey would enter the war actively if the security of the straits or of the near eastern oil fields were threatened, or if Bulgaria and the Greek region of Salonika—which Turkey regarded as her security zone—were invaded. Accordingly, in Jan. 1941, Anglo-Turkish staff talks were held in Turkey and the British foreign secretary Anthony Eden visited the country. But fear of German military superiority kept the Turks inactive when the time for action came. Thus, when the German army occupied Bulgaria at the beginning of March, Turkey did not move, nor did it come to the help of Greece and Yugoslavia when they were attacked by Germany. The German conquest of Greece and the occupation of the Greek islands in the Aegean sea in the spring of 1941 isolated Turkey strategically and made its participation in the conflict impossible for the time being. By the end of 1941 the war had come near to Turkey on all sides. Bulgaria was in it on the side of the axis. Greece was completely occupied by Bulgarian, Italian and German forces. Greek and Italian islands held by the axis were being equipped for fighting. Syria, Iraq and Iran were thoroughly controlled by Great Britain, Free France and the U.S.S.R. The Balkan entente and the Asiatic pact had gone, and the Anglo-Franco-Turkish treaty for mutual aid was uneasily asleep. Turkey sat alone—a small neutral buffer state in the midst of mighty antagonists.

In general Turkey had nothing to lose and everything to gain by a policy of neutrality. It held no colonial territory and desired no extension of boundaries. Its economic surpluses were eagerly sought by both sides. Participation in the war would have meant heavy expense and renewed depletion of its manpower. During almost five years of World War II, therefore, Turkey maintained a firm and scrupulous neutrality. No concealment, however, was made of a determined intention to resist with all resources any invasion of its territory. The danger of invasions by axis forces was certainly great: in fact, Hitler's choice in June 1941 to attack the U.S.S.R. rather than to overwhelm the middle east probably saved Turkey from terrible disaster. A German drive might have rolled with comparative ease across Turkey to Egypt and the Persian gulf, to join forces with Japan in southern Asia. This danger was averted, but it was not removed so long as Germany was active in North Africa and advancing toward the Caucasus and Iran. But the resounding defeats of El Alamein and Stalingrad remove the "pincers" threat, and after Jan. 1943 Turkish fear of Germany diminished rapidly.

Under the circumstances Turkey's neutrality was convenient to both sides. The Germans, while fighting in the U.S.S.R., could feel secure against a thrust from the southeast. The Allies on the other hand possessed a neutral barrier on the north while they strengthened themselves in Egypt and improved the roads across Iran for transporting supplies to the Soviet Union. In particular, Turkey protected the Anglo-Iranian oil fields, which were of vital consequence to the whole eastern war.

In the midst of its tribulations the Turkish government had thought best to sign a two-year nonaggression pact with Germany on June 18, 1941, only four days before the German attack on the U.S.S.R. This was followed on Oct. g, after much haggling, by a commercial treaty: products to the value of £T100,000,000 on each side were to be exchanged during 1943 and 1944; Germany was to deliver to Turkey war material to the value of £T18,000,000, and in exchange Turkey agreed to provide Germany with 90,000 tons of chrome ore per year. Great Britain and the United States offered counter proposals: on Dec. 3, lend-lease advantages were promised to the Turks, and in March 1942 a first large shipment arrived. During the course of the war the Anglo-Saxon countries continued to provide Turkey with war material, naval vessels, locomotives, railway cars, wool, cotton yarn, mining machinery and foodstuff (military preparedness had caused shortages of foodstuffs by removing men from the farms). The supplies entered Turkey mainly at Mersine and Alexandretta, ports which were improved by wharves and jetties. While the western nations steadily increased their support of Turkey, Germany was less and less able to fulfill its promises and was reported to have received only 25,000 tons of chrome ore during 1943, paying four times the prewar price for it.

Relations with the Soviet Union were disturbed after an attempt in Feb. 1942 to assassinate the German ambassador Franz von Papen. Among 50 persons arrested five were Russians. Two of the latter—employees of the Soviet consulate in Istanbul—were convicted on June 17.

In July Shukru Saracoglu, who had long served successfully as Turkish foreign minister, became premier. In Feb. 1943 a new great national assembly was elected. Meeting in March, it re-elected Ismet lnonii as president for four years. The president confierred at the end of January with the British prime minister Winston Churchill at Cairo. He returned there in December to meet Churchill and Pres. Franklin D. Roosevelt. Both conferences appeared to be very cordial, but no visible changes of Turkish policy ensued.

The heavy war expenditure strained Turkish finances seriously. To meet the deficit a law of Nov. 11, 1942, created a form of capital levy tax called the *varlik vergisi;* the penalty for nonpayment was forced labour in the eastern provinces. The tax was fairly levied upon Moslem Turks and foreigners but it was unjustly and ruthlessly applied in the case of Jews, Greeks and Armenians of Turkish nationality—against whom considerable feeling had been aroused because of their alleged war profiteering. Within six months more than £T300,000,000 had been collected.

The year 1944 brought increasing successes to the Allies and discomfiture to the axis; and Turkish policy responded cautiously to the change. In January the Japanese Domei correspondent was expelled. In May a Pan-Turanian and fascist plot was uncovered in Istanbul; many arrests were made and martial law was proclaimed. In March, however, relations with Great Britain became strained because Turkey was still shipping chrome ore and other products to Germany and manifested no intention of joining in the war. Great Britain, therefore suspended shipments to Turkey of munitions and foodstuffs. In justification of its inaction Turkey claimed that it had not received the quantity of war material which had been promised.

Not until Aug. 2, 1944, did Turkey yield to pressure from the United Nations to fulfil its treaty obligations, and then it only broke off relations with Germany. Promptly thereafter German representatives left Turkish soil and commercial exchanges came to an end. Turkey, however, still refused to declare war and join in the final grand assault in Germany. It did not, indeed, make the formal declaration until Feb. 23, 1945 after the Allies had announced that only those states which had done so would be invited to take part in the United Nations conference at San Francisco.

Internal Affairs after World War 11.—The collapse of the Nazi regime and the close association of Turkey with Great Britain and the U.S. were bound to weaken Turkey's attachment to the one-party system established by Kemal Atatiirk. It came to an end in Jan. 1946 when the Democratic party—an opposition party founded by Celal Bayar, one of Turkey's most eminent statesmen—officially came into existence. The new party received the blessing of the president, the government and the press. The first election under the two-party system was held in July 1946, and resulted in a sweeping victory for the government. The opposition leaders charged the government agents with irregularities. The result, however, would probably have been much the same if the votes had been properly counted.

The great national assembly took westernization of its parliamentary system in its stride. The Democratic party followed the maxim that it was the duty of the opposition to oppose. It constantly criticized the government, and its effectiveness was out of proportion to its numbers. It continued to gain strength in the country, but it refused to contest any of the by-elections of 1948 and 1949 on the grounds that the amendments to which the government had consented in the electoral law had not gone far enough. Early in 1950, however, a new electoral law was passed by the assembly which provided all the safeguards demanded by the opposition (secret ballot, public counting, judicial supervision, etc.); and on May 14, a general election was held. It resulted in an overwhelming defeat for the Republican People's party, which had been in power continuously since 1923. The Democratic party won 408 seats against 69 for the Republican People's party, one Nationalist and 9 Independents. Celal Bayar was elected president of the republic. He invited Adnan Menderes to form a cabinet. A distinguished historian and university professor, Fuat Koprulu, became minister of foreign affairs.

Despite Republican and Nationalist attacks on the government (so vitriolic that modifications of the laws against libel and slander were made), the Democratic party again won a decisive victory at the general election in May 1954, securing jo3 of the 541 seats.

The Democratic party drew its leaders mainly from the middle class. Its domestic policy might be described as liberalism plus the nationalization of railways, power, coal, steel and other large-scale activities, but greater scope was promised for private enterprise.

Communism did not appear to be a serious problem in Turkey after World War II. Its doctrines would not ordinarily appeal to a prosperous Moslem peasantry, and the fact that it was sponsored by Russia, the historic enemy of Turkey, handicapped Communist agents and propaganda. Nevertheless, the government decided to prohibit Communist organizations. In 1946 out of jj suspects arrested, 44 were convicted of being members of an illegal organization, and several professors were dismissed from Ankara university for Communist sympathies. Further arrests were made in 1951. Despite Turkey's apparent prosperity, there was considerable internal discontent during 1954–55, caused by inflation resulting from overinvestment and also by the bitterness of the strife between the political parties and repressive government policy. Underground organizations took advantage of this, and the riots of Sept. 6–7, 1955 (*see* below), were evidence of unrest. At a special meeting of the national assembly (Sept. 12) martial law was imposed for a period of six months in Istanbul, Izmir and Ankara.

One of the most important measures adopted by the great national assembly was the land reform bill of 1945. It aimed at converting Turkey into a country of smallholders by distributing state and ecclesiastical lands, reclaimed and uncultivated lands and privately owned lands of more than 450 ha. among landless peasants and immigrants. The dispossessed owners were to receive 4% state bonds for their property, and the agricultural bank was to grant loans to the peasants, free of interest and repayable over 25 years, to assist them in stocking and equipping their farms. The bill also had provisions against the splitting of holdings through inheritance. After protracted discussions, the great national assembly decided in 1948 to introduce the teaching of Islam—but only in the two highest classes of the primary schools and outside the regular school hours.

Foreign Relations.—Until the establishment of the republic, Russia and Turkey had engaged in a succession of wars for nearly 300 years. Russia. therefore, came to be regarded by the Turks as the inveterate enemy. the inevitable aggressor, whose aim. down the centuries, remained the same: to possess Istanbul and the straits. In 1925, however, cordial relations were established by Lenin and Kemal, which endured until the signature of the Soviet-German "nonaggression" treaty of Aug. 23, 1939. Although the Soviet-Turkish treaty of friendship of Dec. 17, 1925, still remained in force, Turkey suspected (not without reason, as was subsequently proved) that the U.S.S.R. was bargaining with Germany at Turkey's expense.

The estrangement was no less pronounced on the Soviet side since Turkey continued to maintain its attitude of nonbelligerency, keeping the straits closed to Soviet and Allied warships. The ancient hostility was revived, and with it the ambition—dormant since the Russian Revolution—of gaining control over the straits. Early in 1945 Moscow launched a war of nerves against Turkey, which was not mitigated by Turkey's belated declaration of war against Germany. The subsequent denunciation, therefore, by the Soviet government on March 20, 1945, of the Soviet-Turkish treaty of friendship (due to expire on Dec. 17, 1945) did not come altogether as a surprise in Ankara. This was followed by a Soviet demand: (1) for a revision of the Montreux convention of 1936 which would permit the U.S.S.R. to share in the defense of the straits and (2) for the return of the old Turkish provinces of Kars and Ardahan, which had been annexed by Russia in 1878 and ceded back to Turkey by the treaty of Brest-Litovsk of March 3, 1918 (cession confirmed by the treaty of Kars of Oct. 13, 1921).

These demands were clarified by exchanges of notes in which the Soviet government proposed: (1) that the straits always be open for the passage of merchant vessels of all countries; (2) that they always be open for the passage of warships of the Black sea powers only; (3) that the passage of warships of non-Black sea powers not be admitted, except in special cases; (4) that the regime of the straits be the joint responsibility of the Black sea powers with Turkey; and (j) that the defense of the straits be carried out jointly by Turkey and the U.S.S.R. Turkey intimated in its replies that it might agree to the first three proposals, but pointed out that the regime of the straits was governed by the Montreux convention, which could not be revised except by its signatories. It refused to consider the suggestion that the U.S.S.R. be alloued to share in the defense of the straits, pointing out that this would mean granting bases on Turkish territory to a foreign power, which would be an infringement of Turkish sovereignty and a menace to its independence.

Great Britain and the United States supported Turkey on this issue. The visit in the summer of 1946 of the battleship "Missouri" to Istanbul aroused enthusiasm in Turkey and was followed by visits of successive squadrons of U.S. warships. These fleet movements were unmistakable hints to the U.S.S.R. that the United States would not tolerate any offensive move against Turkey. On March 12, 1947, Pres. Harry S. Truman recommended the employment of U.S. funds and military and civil equipment to assure the independence and economic stability of Turkey. Thereafter the United States pursued a policy of full support for Turkey's military. naval and economic strength. War material poured into Turkey. Important naval and military missions arrived from the United States, and U.S. experts were soon studying and preparing plans for the development of Turkey's agriculture, irrigation, coal, oil, banking, transport system, education, electrification and foreign trade. By 1950 work had begun on a number of schemes, and equipment had begun to arrive. In addition hundreds of U.S. technicians were engaged and hundreds of Turks went to the U.S. to receive military or technical instruction. In the spring of 1948 military aid alone was stated to have reached the value of $100,000,000. (A. A. A.; A. H. L.; A. C. Es.)

In its foreign policy Turkey remained steadfast through all changes of government. It resolved to play its full part in international organizations in favour of peace by mutual aid and felt disappointment that it was not allowed to be an original member of the North Atlantic treaty of April 4, 1949.

After the Communist aggression in Korea Turkey was first to announce its decision to join the U.S. armed forces there, and a brigade disembarked at Pusan in Oct. 1950. The Turks fought brilliantly at Kunuri, in Nov. 1950, under Brig. Gen Tahsin Yazici. The Turkish casualties during the Korean campaign amounted to 717 dead and 2.156 wounded—fourth largest casualties after those of South Korea, the United States and the United Kingdom.

The accession of Turkey to the North Atlantic Treaty organization was. on the initiative of Turkey itself, proposed to the other NATO powers by the United States on May 1j. 1951. The United Kingdom. though initially favouring a separate Mediterranean or middle eastern treaty, gave its support to the proposal. At its meeting at Ottawa, Ont., in Sept. 1951, the NATO council recommended to the member governments that an invitation be extended to Turkey (and Greece) to accede to the treaty, and a protocol was agreed to change the text of the treaty accordingly.

The Soviet government announced on May 30, 1953, that the Georgian and Armenian Soviet republics had renounced territorial claims to Kars. Ardahan and Artvin, and that, in consequence, "the Soviet Union had no territorial claims whatsoever on Turkey." The note also recalled that, at the time these territorial claims had been presented, the Soviet government had also raised the question of "the removal of the possible threat to the security of the U.S.S.R. from the side of the Black sea straits." The Soviet government had, however, reconsidered its opinion on this question and now deemed it possible to ensure the security of the U.S.S.R. on conditions acceptable alike to both countries.. In its reply the Turkish government expressed satisfaction that the U.S.S.R. had renounced all territorial claims on Turkey and pointed out that the question of the Bosporus and the Dardanelles was regulated by the Montreux convention of 1936.

Improved relations between Greece and Turkey reached a climax on Feb. 28, 1953, when a treaty of friendship and co-operation was signed at Ankara between Turkey. Greece and Yugoslavia. This was transformed into a military alliance by a treaty signed at Bled on Aug. 9, 1954. It was suggested that Italy should also become a signatory. but the alliance was seriously weakened during 19jj by the new relationship established between Yugoslavia and the U.S.S.R. by the Soviet leaders' visit to Belgrade in May and June; and by the crisis in Turko-Greek relations over Greek support for the movement toward self-determination for Cyprus. At the London conference on Cyprus (Aug. 29–Sept. 7, 1955) the Turkish foreign minister insisted that if Great Britain were to give up Cyprus) the island must revert to Turkey, its former owners. On Sept. 6–7 serious anti-Greek rioting. said to be Communist-inspired, broke out in Istanbul. Izmir and Ankara.

Progress was made, however, with the formation of a middle eastern defense system. On Feb. 19, 1954, an agreement was signed between Turkey and Pakistan, and on Feb. 24. 1955, a Turco-Iraqi defense treaty was signed at Baghdad. This was joined by Great Britain in April, by Pakistan in September and by Iran in November.

Lewis, *Turkey* (London, New York, 1955). (X.)

Population. — The earliest invaders of the present Turkey probably came from the Eurasian steppes around the Black and Caspian seas. The Hittite empire was established in Mesopotamia and in Anatolia by 1800 B.C., and the Turks of today take great pride in their Hittite ancestry. The Hittite empire on its fall gave place to Phrygian invaders and to refugees from Greece, who overran western Anatolia. They were followed by the Persians, by the Macedonians under Alexander, by Celtic tribes from the middle Danube (Galatians). by the Romans. by the Arabs (Saracens) and, by the Seljuk Turks. (See TURKS OR TURKIC PEOPLES.)

The history of the country is reflected in the variety of types found in modern Turkey, though generally the people are muscular and well-built, round-headed, with high cheekbones. brown eyes, square jaws and large, somewhat aquiline noses. The majority has Mediterranean colouring, but there is a fairer strain.

TABLE II.—*Population, 1927–60*

Date of Census	Total	Urban	%	Rural	%	Density per sq.mi.
1927 .	13,648,270	3,305,879	24.2	10,342,391	75.8	46
1935 .	16,158,018	3,802,642	23.5	12,355,376	76.5	54
1940 .	17,820,950	4,346,249	24.4	13,474,701	75.6	59

Bursa . .	61,690	77,598	85,919	103,812	128,875	153,574
Eskisehir .	32,341	60,742	80,030	120,092	120,092	153,190

It was estimated that the present people of Anatolia owe about 75% of their ancestry to the original inhabitants and 25% to the Seljuk Turks. The Kurds, living mainly in the eastern and south-eastern provinces, are differentiated from the rest of the people by their height (average j ft. 7 in.) and very long heads and by the high proportion with fair hair and blue eyes.

The growth of the population between 1927 and 1955, and the extent to which industrialization produced a shift from rural to urban population are shown in Table II. Growth of the chief towns during the same period is illustrated by Table III.

The greater part of the population lives near the coast, where

†Telecommunications workers only.

‡Before 1950 military men were classified under administration; in 1950 they were classified according to civil profession.

Turkey. the density is from 1 to 25 per square mile. On the edge of the plateau, in western Turkey and in the southern coastlands the density varies from 25 to 75 per square mile.

Population groupings according to language and religion are shown in Tables IV and V respectively.

The distribution of the population by occupational groups is shown in Table VI.

Education.——Primary education is, in theory, compulsory for both sexes between the ages of 7 and 12. Among the problems of primary education in the 1950s was the lack of teachers. Although great expansion had taken place, there was probably still a considerable number of children in the provinces receiving little or no education. The secondary schools provide a three-year course which may be followed by a three-year or four-year course at a *lycée.* Parallel with the secondary schools are the boys' technical schools, with three-year, five-year or six-year courses, where engineering, building and other trades were taught; girls' institutes giving training in home management, cooking, hygiene, etc.: and commercial schools in which general as well as commercial subjects are studied.. Technical and commercial instruction may be continued in a small number of *lycées* specializing in these subjects. Evening trade schools are also provided for men and women who have not had more than a primary education; the number of these in the mid-1950s was still small. The Istanbul Technical university, reorganized in 1941, is designed to give instruction, both practical and theoretical, in engineering subjects. The course lasts four years. With it is associated a technical department, with a two-year course in civil or mechanical engineering. Other universities include one at Istanbul. with faculties of law, medicine, science, letters and economics; one at Ankara, with faculties of languages, history and geography, science, medicine and law; and the University of the Aegean in Izmir (opened in 1955), with faculties of agriculture and medicine.

An interesting and successful experiment was the establishment of village institutes (koy *enstitülari*), at which boys and girls who have had primary education are given general and vocational training designed to fit them as teachers in village schools or as farmers able to apply modern agricultural methods to their work. The rural atmosphere is maintained in these institutes and the training is severely practical. A boy returning as a village schoolmaster is expected to be able not only to teach but to build and maintain a schoolhouse of a standard pattern, if necessary.

Education is free in all government schools; but board and lodging, where this is necessary, are not always provided, though many scholarships that cover all expenses at school or university are awarded. A number of Turkish private schools exist, as well as the schools for the minorities (Greek, Armenian or Jenish) and the foreign schools (of which the U.S.-supported Robert college in Istanbul is the best known). The Turkish government's insistence on the secularization of education throughout the country raised serious difficulties for the foreign schools. and some were forced to close. In 1947 the ban on religious instruction was relaxed, and Moslem schools were permitted to open in addition to, but not in replacement of the secular state schools.

The spread of education was enormously assisted after the Arabic alphabet was superseded by the modified Latin alphabet, introduced in 1928 by a nation-aide campaign in which Kemal Ataturk himself took a prominent part. At the same time efforts were made to reform the Turkish language by the substitution of pure Turkish words for Arabic or Persian words in general use. This led to some confusion and the effort was allowed to slacken.

Adult education was still much needed at mid-century. Apart from stationary and mobile schools for the illiterate, vocational and professional training schemes with day or evening classes had been developed. To help in filling the need for adult education, "people's houses" (*halkevleri*) were established all over the country; activities include language and literature, fine arts, drama and history. Libraries and museums were also established.

Table VII shows the increases in the number of schools and students between 193j and 1952, illustrating particularly the great importance attached to technical training. The budget allocation for the universities was trebled between 1950 and 1955.

TABLE VII.—*Education*

Year	Number of schools	Number of students	Primary schools	Secondary schools	*Lycées*	Vocational schools	Higher schools and faculties
1935–36	6,614	770,600	6,275	191	66	44	18

GOVERNMENT AND ADMINISTRATION

Before the Kemalist revolution, a "Turk" was generally taken to mean a Moslem subject of the sultan. In 1924 the meaning was established in article 88 of the organic law as follows:

The people of Turkey, regardless of religion and race, are Turks as regards citizenship.

The organic law, adopted on April 20. 1924, was a concise document showing the influence of U.S., French and British examples. It contained six chapters: (1) fundamental provisions; (2) legislative powers; (3) executive powers; (4) judicial powers; (5) general rights of Turkish citizens and (6) miscellaneous, containing articles relating to the administration and to the conditions for amendment of the constitution itself. Article 2 later underwent important amendments; in 1928 the provision that Islam was the religion of the state was deleted, and in 1937 the six principles of the People's Republican party (at that time the only political party) — republicanism, nationalism, state socialism (*étatisme*), sovereignty of the people, secularism and revolution — were inserted. These were regarded as fundamental principles and were accepted by all parties, though interpretation of them varied. "Nationalism" was not aggressive but looked inward with an educative and humanitarian aim; "state socialism" was designed to build up economy and industry on a Turkish foundation and to encourage social and cultural progress; "revolution," an expression of reaction to the slow and ineffective reforms of Ottoman times, signified the will to reform methodically the life and institutions of the country. Other important modifications to the organic law were the extension of the suffrage to women (1934); the alteration in the system of voting in parliamentary elections from indirect to direct (1946); and the introduction of the secret ballot (1948). Other important provisions were: that sovereignty belongs without restriction to the nation; that the grand national assembly is the sole and real representative of the nation: on whose behalf it exercises the right of sovereignty; that the legislative authority and executive powers are concentrated and manifested in the grand national assembly and that the grand national assembly exercises its executive authority through the person of the president of the republic, elected by it, and through a council of ministers chosen by the president. Under chapter 5 it was laid down that "Every Turk is born free and lives free. Liberty consists of any action which is not detrimental to others . . . All Turks are equal before the lams . . . Personal immunity, freedom of conscience, of thought, of speech and press, the right to travel. to make contracts, to work, to own and dispose of property, to meet and to associate, form part of the rights and liberties of Turkish citizens."

The assembly's term is four years, and it meets annually on November 1 without a summons; it must remain in session for at least six months every year, and the annual budget must be presented at the beginning of the session. The functions of the assembly include: the making, amending, interpreting and abrogation of laws; concluding treaties; declaring war; examining and ratifying laws drafted by the commission on the budget; coining money and accepting all contracts and concessions involving financial responsibility.

The president of the republic is elected by the members of the assembly from their own number for the four years of their own office. He is eligible for re-election. He may preside over the assembly on ceremonial occasions and, if he deems it necessary, over the cabinet. But he may take no part in debates or cast a vote. He is bound to publish laws passed by the assembly within a period of ten days; however, he may return for reconsideration with an explanation of his reasons laws of which he does not approve, except organic and budget lams. The president is the supreme commander of the army, personifying the assembly in which the office is vested. He selects the prime minister from the members of the assembly; other ministers are chosen by the prime minister and presented to the assembly after the president's approval.

Members of the council of ministers are responsible individually and collectively to the assembly for the policy and conduct of the department of state. The prime minister decides the number of ministers (usually 15) in charge of the following departments: justice! national defense, interior, foreign affairs, finance, education, public works, economy, health and social assistance, customs and monopolies, agriculture, communications, commerce, labour and state enterprises. In addition there is a minister of state who is deputy prime minister.

The council of state is both an advisory body and a judicial authority in administrative matters. It is attached to the office of the prime minister. and its members are chosen from prominent citizens with administrative and judicial experience. It may advise on draft laws submitted to it by the government.

The country is divided into 63 provinces (*ils,* formerly *vilayets).* Provinces are divided into districts *(ilces,* formerly *kazas)* and districts into communes *(bucaks,* formerly *nahiyes).* The highest administrative official in each is the *vali,* the *kaymakam* and the *bucak muduru.* The *vali,* who is appointed by the president of the republic on the recommendation of the minister of the interior, is the chief administrative officer of the province, representing all the departments (except those of war and justice) and co-ordinating their work in his province. He corresponds directly with each ministry and has a staff of advisers, who also form an administrative council under his chairmanship. The organization of the district *(ilce)* under the *kaymakam* and of the commune *(bucak)* under the *bucak muduru* follows the same pattern. The commune comprises a number of villages each of which has a headman *(muhtar)* and a council of elders, numbering from 5 to 12, according to the size of the village. A provincial council, elected for four years, debates questions of local administration, and its resolutions have legal effect; the *vali,* who is president of the council, may however refer proposals of which he does not approve to the council of state. In every headquarters town of a province or district and in all other towns of 2,000 inhabitants or more there is a municipality *(belediye).* At the head of the municipality is the mayor *(belediye reisi),* who is assisted by an elected municipal council and a committee composed partly of officials and partly of persons chosen by the council for a year's term of office.

Justice, Police and Gendarmerie. — Under articles 8–54 of the organic law, the courts of justice were made entirely independent of the assembly and the government. The highest court is the court of cassation in Ankara, which has civil, penal, commercial and bankruptcy chambers, each divided into special sections. Each court chamber has its president; the chambers together iorm the quorum of the court of cassation which has its own president and forms the highest court of appeal. Lower courts are: (1) peace courts, (2) courts of first instance, (3) central criminal courts and (4) commercial courts.

The most sweeping of the changes made by the revolution was the abolition oi the religious courts and the Moslem Shari code and the adoption, in 1926, of the Swiss civil code, the Italian penal code and a commercial code based on several European models.

The minister of the interior is responsible for the maintenance of order and the internal security of the country. He exercises his powers through the director-general of security and the general commanding the gendarmerie and, in case of necessity, by calling on the armed forces, although a decision of the council of ministers is necessary before the army can be employed. The police are divided into three groups: administrative (prevention of crime, maintenance of law and order, etc.), in which they are under the orders of the civil authorities; judicial, in which they are under the public prosecutor, and political (*i.e.,* for matters concerning the internal security of the state). In the capital the police are organized under a director-general. In the provinces the police subdivisions are attached to the valis, kaymakams or *mudurs.* A law of 1930 established the gendarmerie as a military force, administratively under the minister of the interior, which reinforces the police mainly in rural districts and is subject to the same local authorities, administrative or judicial. The gendarmerie is formed from men serving with the colours and is primarily a military formation, its training and instruction being supervised by the general staff.

Defense. — From Feb. 1952 Turkey was a full member of NATO. The result was the formation of the southeastern Europe command, the headquarters of which were fixed near Izmir (Smyrna). At the end of 195j it was estimated that Turkey had 427,000 men in the armed forces.

The ground forces, 375,000 in all, were organized into three armies (Istanbul, Izmir and Erzurum), 16 partly motorized infantry divisions, 3 cavalry divisions and 6 armoured brigades (two in each of the three armies). Each armoured brigade comprised 50 M-47 Patton tanks, a battalion of artillery mith 12 pieces (105-mm. and 1jj-mm. howitzers) and a battalion of motorized infantry.

The air force (29,000 strong) was responsible for 12 combat squadrons equipped with U.S. jet aircraft, assigned to the NATO Izmir command. The navy (23,000 strong) included one cruiser ("Yavuz," a modernized German battle cruiser), 10 destroyers and 12 submarines. Military service was compulsory for a period of 24 months.

Social Welfare. — The basic law relating to labour and social insurance was passed in 1936 and regulated conditions of employment (health and safety arrangements, hours of work, etc.) in establishments employing ten or more persons. It also prohibited strikes and lockouts. In 1946 a ministry of labour was established to supervise the laws relating to labour and social insurance; supplementary laws were passed in 1946, 1947 and each year from 1950 to 1954. Of the 300,000 persons covered by the law in 1949 about 74,000 were members of the 83 trade unions. Any trade union representing the majority of workers in an industry could, on the written demand of one-fifth of the total number of workers, initiate collective bargaining with an employer. Any employer wishing to make mass dismissals had to give a month's notice to the ministry of labour.

Insurance measures were introduced in 1946. They applied to all persons covered by the basic law of 1936, and others could be included. Workers and employers each contribute 4% of the wage paid, and men and women receive a pension at the age of 60, from £T400 to £T3,000 annually, according to the piemiums paid. In heavy industries the pensionable age is 55 and premiums are higher. Sickness and maternity benefits were provided under a law of 1951.

Although thought was given to the care of the sick during the middle ages, apparently even the elementary service of those days was allowed to decay, and it was not until the middle of the 19th century that any attempt at reorganization was made. Under the constitution of 1908 some reforms were introduced, but progress was slow and the government of the republic faced a formidable task when it established the ministry of public health and welfare in 1923. At that time there were only 54 hospitals and 30 provincial dispensaries to serve the needs of the whole country. In 1952, however, there were 328 hospitals with 27.366 beds, administered as follows: ministry of health, 96 (15,437 beds); provincial administration, 47 (3,500 beds); municipalities, 1; (2,268 beds); others (including those belonging to foreign organizations, minority communities, charitable associations and private doctors), 80 (5,2jr beds). There were also 90 health centres with 910 beds.

Campaigns against malaria, trachoma and syphilis were vigorously conducted with considerable success. Great efforts were made to reduce the very high infant-mortality rate (120–350 per 1,000 live births in 1918), but the shortage of nurses and midwives made this difficult.

Each province (il) has a director of health services, with doctors in the districts (ilces) and communes (*bucaks*) who not only supervise sanitary conditions but, in the bucaks, are the local medical practitioners, giving free advice and treatment. Each large town has its own municipal health organization. The state-controlled factories, moreover, have their own hospitals and staff.

ECONOMICS

Agriculture. — Agriculture is Turkey's most important industry, providing a livelihood for 75–80% of the population, largely on small farms. For some years the republic spent relatively small sums on the scientific development of agriculture in comparison mith its expenditure on industrial projects, but after World War II great efforts were made in soil conservation, irrigation, cattle breeding, and the improvement of farming methods and transportation facilities. U.S. aid enabled excellent results to be obtained.

Turkey's principal crops were cotton, tobacco, cereals, fruit (fresh and dried), nuts, oilseeds, olives, pulses and vegetables (see Table VIII). Besides grapes and figs (see Table IX), other fruits (*i.e.,* citrus fruit, apples, pears, quinces, peaches, apricots, melons and strawberries) grew in abundance. Only dried fruit (figs and raisins) was exported in quantity in the 1950s.

Olives are grown in western Anatolia and in the south. Although the country ranked fifth among world olive producers in the 1950s, most of the crop was used for domestic consumption. Turkey rose to first place in world production of raisins.

TABLE VIII.—*Principal* Crops: Areas and *Yield, 1934–54*

(In 000s)

Crop*	1934–38		1946–50		1954		1955

Sugar beet	34	394	4 6	718	70	1,065	98	1,497

*Cereals are grown principally in the central plateau, except maize, grown on the Black sea coast, and rice in the hdana-Iskenderun district and in southeastern Turkey.

†The cultivation of cotton is concentrated in the Aegean and Adana regions.

‡Most of the tobacco is grown in the Aegean district but there are important areas also on the Marmara coast and on the Black sea coast near Samsun

Hazelnuts, walnuts, pistachios, almonds and peanuts were grown, but only the hazelnut was exported in any quantity. Grown on the Black sea coast near Samsun, the yearly exports averaged nearly 30,000 tons. The pistachio crop rose to 10,000 tons in 1954.

The principal kinds of oilseeds grown included sunflower, linseed, cotton, sesame: poppy, peanuts and olives. Excluding the last two, the 1953 crop of oilseeds was aboyt 446,000 tons, of which more than one-half was cottonseed.

Vetches of various kinds came into increased use as fodder in the 1950s. Haricot, broad beans, lentils and chickpeas are plentiful, and potatoes are widely grown. Onions, garlic! leeks, eggplant, artichokes, tomatoes, cabbage, lettuce, cucumbers, carrots and turnips are extensively grown for local consumplion.

Tea growing mas started in 1931 in the Rize district on the Black sea coast. The approximately 7,800 ac. under cultivation in 1949 had grown to 9,500 by 1952. Production in the factory at Rize, a govern-

TABLE IX.—*Dried* Fruit: Tonnage and *Value* Exported*

*No reliable figures of total production were available in the early 1950s. The white seedless grape, *sultaniye*, grows in the valleys in western Anatolia. The best figs are grown in the Aydin district of western Anatolia and near Izmir (Smyrna).

ment monopoly, was 159 tons in 1949; by 1955 tea production amounted to about 700 tons.

Forestry.— The forests of Turkey, according to official statistics published in 1953, occupied about 40,200 sq.mi., or 13.4% of the total area of the country. Forests, however, had been diminishing for many years as a result of neglect, indiscriminate cutting, and destruction by goats. At mid-century a scheme of reafforestation was being carried out by which it was intended to increase the forest area to about 60,000 sq.mi. The principal species are pine and fir (western Anatolia and the Black sea coast), beech (Marmara region, western Anatolia and Black sea coast) cedar (southern coastlands) and oak; valonia oak grows only in western Anatolia. There are fringes of oak scrub on the Black sea, Marmara and Mediterranean coasts.

Livestock and Fisheries.— Except for a few state farms the care and feeding of livestock remained poor in the mid-1950s, and a large proportion of the grazing land (artificial pasture being almost non-existent) was bad. Sheep and goats are the most common stock since they can exist on poor grazing. The sheep are mostly oi the Karaman, fat-tailed variety; there are large numbers of ordinary goats, and the Angora goat, which thrives on dry, elevated plateaus, is bred extensively. Cattle are still largely used as draught animals, the Turkish gray cattle being especially suitable ior this. Crossbreeding with Swiss cattle was tried with some success after World War II. The horses are mainly oi Turkish origin, but breeding irom Hungarian stock was introduced on a small scale; the five government stud farms breed mostly English thoroughbred and Arab race horses. There are many fowl.

In 1952 the government set up the Et ve Ralik Kurumir organization to regulate the meat and fish industry and trade.

TABLE X.—*Livestock*

*No official census was taken before 1948. †1939. ‡1952.

Annual production of wool was about 36,000 metric tons in 1954. Production of mohair (from the Angora goat) amounted to about 7,500 tons; about one-half of this was exported.

Dairying was only a minor industry. Cow's milk was used to some extent in the cities; goat, sheep and water buffalo milk were more common in villages. Large quantities of yogurt and cheese and smaller amounts of butter were made. In 1955 a model dairy farm was established near Istanbul by Turkish and Danish interests.

The main fishing industry is in the Sea of Marmara and the Bosporus, but fishing is carried on in various forms all around the coasts. Bonito, tunny, swordfish, mackerel, herring and sardines constitute the principal catch. The only inland fishing centre is Lake Van though trout, pike, carp, eels and coarse fish are common in inland waters. About one-third of the catch of fish is consumed in the country, the remainder being exported salted, canned, dried or fresh.

Mining.—Turkey's principal minerals are coal, lignite, iron ore, chrome, copper, manganese, lead, zinc and emery, but only coal, lignite, iron and chrome are extensively produced, though important increases in production of copper, manganese and sulfur took place after 1950.

The Petroleum law of 1954 abolished the state monopoly in the exploitation of oil deposits and leading foreign companies began work by the end of the year. First drilling for petroleum took place under government auspices in 1947 at Ramandag in southeast Anatolia. A refinery at Batman. 40 mi. away, started production in 1955; the ultimate capacity was about 300,000 tons a year.

The only bituminous coalfield is around Zonguldak on the Black sea coast, about 150 mi. E. of Istanbul. Although output increased from about 700,000 metric tons in 1924 to nearly 6,000,000 metric tons in 1954 it did not keep pace with the internal demand, and there was no export trade in coal. Deposits of lignite are widespread; it is most abundant in western Turkey. The principal mines worked are at Soma, Degirmisaz and Tuncbilek. Other extensive coalfields, both bituminous and lignite, are known to exist but lack of transport facilities and power prevented their exploitation. Some progress was made possible by Marshall plan aid after World War II.

Industry.— The policy of *étatisme,* or state exploitation, had never necessarily involved 100% control of any particular industry, and "a very free interpretation was practised. Statism begins where private initiative stops." (A. Bonné, Stale *and Economics in* the *Middle* East, see Bibliography.) The Sumer bank was created in 1933 to take over some existing industries and to establish and administer new ones. It became responsible for some or all of the factories making cotton and woolen textiles, artificial fibres, iron and steel, paper and cellulose, cement and firebricks, and leather, shoes and glue. The Eti bank was founded in 1935 to exploit mineral resources and develop and control electrical power. Tobacco and cigarettes, alcohol and alcoholic drinks, matches and salt became state monopolies, but the manufacture of beer and w-ine and the import oi whisky and champagne were freed in 1955. Much of the beet sugar industry was developed by the state. Industrial development was slowed down during World War II, but the prospect of foreign credits and U.S. aid made possible large-scale plans ior development afterward. At the same time. the government adopted a more liberal policy toward private enterprise and foreign capital, particularly after 1950. The Industrial Development bank to help private enterprise was iounded in 1950 with the participation of private individuals, banks, the government, the International Bank ior Reconstruction and Developmect, and Marshall plan counterpart funds. In 1951 and 1954 further encouragement was given to foreign capital investment. (See Table XI.)

Textiles.—The principal cotton products in 1955 were cabot, white sheetings, prints. low-grade shirtings and cambrics. The "cottage industry" produced rough cotton fabrics on hand looms. In 1955 there were about 1,000,000 spindles and 19,000 looms. In addition to five woolen mills owned by the Sumer bank there were nearly 40 privately owned mills, some of them very small. There was a total of 199,000 spindles and 2,610 looms in 1955. There mas also a rayon factory producing about 450 tons annually. The long-established silk-weaving industry at Bursa was entirely in private hands. Production in 1948 was 200 tons of yarn and 1,500,000 m. of silk fabric.

Iron and Steel.—The iron and steel works at Karabuk were formerly operated on behalf of the Sumer bank. The iron ore was brought by rail from Diurigi, formerly an Eti bank enterprise (600 mi. away), and coal from Zonguldak. Plans to double the output were considered in the mid-1950s and a site ior a second iron and steel plant was sought. A new company to take over the whole industry was formed in 1955.

A sulphuric acid plant, installed at Karabuk by a German firm during World War II, produced about 11,000 tons of acid in 1949. The raw material is imported.

Paper.—The paper industry controlled until 1955 by the Sumer bank. centred at that time around two paper mills at Izmit, with yearly capacities of about 11,000 and 12,000 tons. In 1955 plans were made for the construction of a third mill at Izmit; all three mills were to be a part of the newly established Turkish Cellulose and Paper Factories enterprise. The Aegean Paper industry at Izmir, a joint effort of Turkish and U.S. investors, was also established in 1955.

Cement.—In 1949 six iactories produced 375,000 tons. Rapid expansion took place in the following years and in 1954 a Cement Industries company financed by private and government capital planned the building of additional plants which were expected to have a total capacity of 2,500,000 tons by 1958.

Sugar.—Before 1951 four factories controlled by the Sugar Monopoly organization, met domestic needs. Between 1950 and 1954 seven new factories were built. The total capacity of refined sugar was raised to 375,000 tons in 1956.

Tobacco.—In 1955 production was estimated at 22,010,000,000 cigarettes and 2,402 tons of processed tobacco. Tobacco and tobacco products were among Turkey's leading exports in value.

Electric Power.— Expansion of electric power capacity, both thermal and hydroelectric, was planned in the 1950s; it was designed to give 3,000,000,000 kw.hr. Production was 312,000,000 kw.hr. in 1938 and 1,452,200,000 kw.hr. in 1955. In 1953 industry used 64.3% of the output, and domestic customers 14.6%. Per capita consumption of electric power rose from 22 kw hr. in 1940 to 54 kw.hr. in 1953.

Communications.—*Railways.*—Before the constitution of the republic, Turkey was badly served by railways, nearly all of v hich were owned by foreign companies; their total length was 2,536 mi. The republican government put in hand a program of extensions which added 1,238 mi. in its first ten years. By the end of 1949 517 mi of line had been transferred to the state by conventions and treaties, 2,000 mi. had been bought from foreign companies and 2.250 mi. had been constructed by the government since 1923, bringing the total length of lines to 4,767 mi. During World War II the rate of construction had been slowed down because of rising costs and difficulties in the supply of materials. In 1947 a plan was worked out under which it was intended to add a iurther 1,435 mi. to the system by 1965. Between 1945 and 1954 rail traffic increased from 51,000,000 to 62,000,000 passengers, and from 7,000,000 tons to 11,000,000 tons of freight. Some diesel-electric units were imported, and locomotives were converted from coal to oil burning for use in eastern Turkey.

The directorate-general of the Turkish state railways (Devlet *Demir Yollari*), iormerly operated under the general control of the ministry of communications, became a state corporation in 1953. The office of railroads and ports, a division of the ministry oi public works, oversaw technical planning and construction.

Roads.—In 1923 the roads, surfaced and unsuriaced, amounted to only 8,073 mi. During the next 15 years an average of £T7,300,000 a year was spent on building and reconstruction. By 1935 the total length had almost been doubled, and in 1939 a comprehensive program was announced under which 19,872 mi. of modern roads were to be built in ten years at a cost of £T120,000,000. World War II put a stop to this work, and development was slow until, in 1948, an agreement was signed between the American Mission for Aid to Turkey and the ministry of public works, in which a nine-year program for the construction, reconstruction and improvement of a national highway system of 13,437 mi of all-weather roads was announced. The length of stabilized roads was increased from 9,578 to 16,875 mi. in 1950–54.

Ports and Shipping.—The railway administration was made responsible for the maintenance and exploitation of the terminal ports of Haydarpasa (Istanbul), Derince, Iskenderun (Alexandretta). Mersin, Samsun, Alsancak (Smyrna), part of the quays at Sirkeci (Istanbul) and the quays at Bandirma and Edrcmit. Istanbul, which handles 30% of Turkey's foreign trade, suffered from congestion. Improvements to it and extensive works at Samsun, Mersin Alsancak (Izmir) and Iskanderun were in progress in the mid-1950s.

In 1951 the state shipping lines were converted into a corporation under the Maritime Bank (*Denizcilik* Bankasi) but in 1955 this administration was superseded by an independent organization, the *Denizcilik Nakliyat* to manage a fleet of 30 passenger and cargo ships. The total commercial fleet, including vessels in private ownership, amounted in gross tonnage to 553,900 tons (passenger vessels. 110,500 tons) in 1955. There were also state-owned ferryboats and auxiliary craft.

Civil Aviation.—The state airlines operated an extensive network of internal services in the mid-1950s with services to Athens and Cairo also. The main civil airports were at Istanbul and Ankara. Civil air agreements were concluded by Turkey with the United States, Sweden, France, Italy, Denmark, Czechoslovakia, Greece, the Netherlands, Great Britain, Iraq, Brazil, Iran. Egypt. Israel and Yugoslavia.

Posts, Telegraphs and *Telephones.*—The republican administration claimed that the number of post and telegraph offices in Turkey increased from 688 to 2,216 by 1954. Work on the expansion of telephone and telegraph interurban services was begun in 1947, and a wide-scale training program to fit the staff to cope with new technical problems was initiated. In 1934 broadcasting was taken over by the government from a semiofficial body, its supervision being vested in the director-general of the press, publication, broadcasting and tourism. Three transmitting stations were operating in 195j, Radio Ankara, the main station on 1,648 m., 19.79 m., 16.48 m., 31.7 m. and 19.7 m., with 120 kw.; Radio Istanbul, on 428 m. and two short-wave transmissions. with 150 kw.; and Radio Izmir, a regional station of low power, on 45.53 m. Programs in Urdu, Serbian, Arabic. Persian, German, Bulgarian, Greek, Rumanian, Polish, French and English were being broadcast from Ankara. Receivers registered in Turkey numbered 990,000 in 1955, compared with 38.428 in 1938. The cost of broadcasting was met entirely from a grant out of the budget allocation for the director-general of the press.

Finance.—Continuous adverse trade balances caused the value of the Turkish pound (LT or TL.) to depreciate between 1923 and 1930, when the £ sterling reached the value oi £T11.00. Action by the Turkish government brought the rate to £T10.30, at which it remained until Great Britain went off the gold standard in Sept. 1931. From that date the Turkish pound was kept pegged to the French iranc at 12.06 ir. per £T1. In 1936 the iranc was devalued, and the Central bank, which had started operations in *1931*, maintained the old gold parity and exchange rates so that the pound sterling equalled £T5.20. This. however, was only a theoretical rate. as exports enjoyed a premium and imports suffered a surcharge. This situation was regulated in 1946. when the Turkish currency was devalued. When sterling was devalued in 1949, the old rate with the dollar mas retained. (Sea Table XII.)

Reduction in imports and competitive buying by the belligerents during World War II resulted in a considerable rise in Turkey's gold reserves and foreign-exchange assets betu-een 1939 and 1945. But when manufactured goods became more easily available and exports were artificially restricted, these balances were rapidly dissipated. The Marshall plan aid came to Turkey's rescue (1948), and further sub-

stantial assistance was given under the European Recovery plan, as well as both financial and technical help from the U.S. under the auspices of the Economic Cooperation administration.

The state budget and those of the para-statal bodies (state railways, steamship lines, etc.), and of the state-owned mining and industrial enterprises may be said to interlock in so much as some are subsidized or subsidize others. The final accounts of state finances showed deficits in all except two years between 1936 and 1950–51; with the exception of the Monopolies administration (tobacco and alcoholic liquors), deficits were also shown by the state-owned undertakings. The monopolies' profits could be regarded as the equivalent of excise duties in other countries. The financing of deficits was difficult since there was no organized capital market and the public became unwilling to subscribe to internal loans. In 1951, when 37% of the revenue was derived from direct taxes and 56.7% irom indirect taxes, the government promised to 'do its best to improve the state of affairs. The reformed income tax laws that came into force in 1950 had, moreover, failed to provide the expected amount of revenue because, it was believed, of evasion and ialse returns. (See Table XIII.)

Table XIV shows the more important departments' expenditures.

The Ottoman public debt, which had been contracted to meet the serious financial situation during the latter half of the 19th century, was administered by an international council until Turkey entered World War I in *1914*; payments under existing arrangements then ceased. By the treaty oi Lausanne (1923) part oi the indebtedness was transferred to the territories then detached from the Ottoman empire. Turkey remained responsible for a sum of £T84,590,000. Agreements with the bondholders were revised in Turkey's favour in 1928, 1933 and 1936, and the Turkish government assumed the liabilities and took over the management of the debt in 1940.

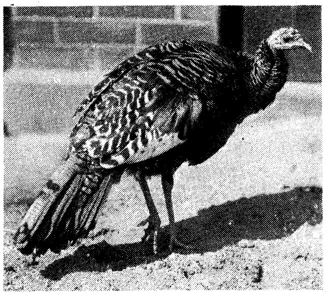
W SUSCHITZKY

FIG. 1.—DOMESTICATED NORTH AMERICAN TURKEY (MELEAGRIS GALLOPAVO)

TURKEY. Either of two species of gallinaceous (chicken-like) birds that, along with chickens, peafowl, pheasants, guinea fowl, quail, megapodes, curassows and guans, comprise the order Galliformes. Within this order the turkeys form the family Meleagrididae.

One species is *Meleagris* gallopavo, the North American turkey, which originally was native to the southwestern, midwestern and eastern United States, southern Ontario, Can., and nearly all of Mexico. This species is the source of all domesticated turkeys which are now found in almost all countries of the world.

The other living species is the ocellated turkey, *Meleagris ocellata* (or *Agriocharis ocellata*), of the tropical lowlands that make up the Yucatán peninsula of Mexico and adjacent parts of Guatemala and British Honduras. No subspecies of *ocellata* are knonn. The ocellated turkey is one of the most colourful of birds, displaying iridescent green, gold and reddish-copper bronzing over nings and back, with a purplish-blue ocellus (eyelike spot) in the tips of the gray-and-black-penciled main tail feathers and tail coverts. Males and females look alike and neither has a beard or breast tuft. *Ocellata*'s maximum weight is reported to be 18 lb. It has not been domesticated.



BY COURTESY OF NEW YORK ZOOLOGICAL SOCIETY

FIG. 2.—OCELLATED TURKEY (OCHARIS OCELLATA)

Turkey males are called toms or gobblers, the females are called hens and the young turkeys are called poults. The sparsely feathered head and upper neck of males are heavily caruncutated and are bright red, changeable to white overlaid with bright blue. The females are less heavily caruncutated and lack the blue colour. There is a single large throat wattle, or dewlap, in both sexes and a single fleshy head appendage, the snood. The beard is a tuft of coarse, black, hairlike feather structures in the centre of the crop region of all males and a few females of the North American species.

Wild Turkeys.—The North American wild turkey has produced seven distinct subspecies. The most widespread subspecies was the turkey of the Pilgrims, the Eastern wild turkey, *Meleagris* gallopavo *silvestris*, which became the U.S. symbol of Thanksgiving. This turkey originally ranged the United States and Canada south and east of a line extending approximately from Portland, Me., through Mitchell, S.D., and south to Houston, Tex., excepting southern Florida. The Florida wild turkey inhabited the lower three-fourths of that state. The Rio Grande turkey lived in south central Texas and northeastern Mexico. The Merriam turkey inhabited the mountains of Arizona, New Mexico, southern Colorado, southwestern Texas and north central Mexico. The Central Mexican, or Gould's, turkey ranged the mountains of central Mexico. The South Mexican turkey, *Meleagris gallopavo gallopavo*, was native to the mountains of southern Mexico from Michoacán through Oaxaca. Moore's turkey has been discovered on the western slopes of the Sierra Madre mountains of northwestern Mexico at elevations of 2,500 to 8,500 ft.

All these subspecies intergraded with each other where their ranges adjoined, and all have the same general colour pattern but differ from each other in details of plumage colour. The basic colour is black with red-green surface iridescence, copper-coloured bronzing on wings and tail, and black-and-white barred wing feathers. The lower body and tail feathers of both sexes and the breast feathers of females have chestnut-brown tips in the Eastern and Florida turkeys, cinnamon to buff tips in the Rio Grande and Merriam turkeys and almost-white to white tips in the three Mexican subspecies.

The North American turkey still exists in the wild state over most of its original Mexican range. In the United States it is found in varying numbers in about 21 states, including all those south of the Ohio river, as well as Pennsylvania, Maryland, Illinois, Missouri: Arkansas, Louisiana, Oklahoma. Texas, Colorado, New Mexico and Arizona. In certain states wild turkeys may be hunted legally.

Wild turkeys subsist on nuts. seeds, grasses, legumes, roots, tubers, leaf buds, fruits and insects along with occasional small amphibians, crustaceans and mollusks. They roost high in trees, preferably evergreens. When alarmed they may fly as far as a mile and at speeds estimated to be as high as 55 mi. per hour. The males, both wild and domesticated, practise gobbling and strutting, mostly during the breeding season, to attract the hens. Turkeys are polygynous but harems of more than six hens are rare in the wild state. The females build nests on the ground and their brown-speckled eggs are incubated for 23 days.

Domesticated **Turkeys.**—Turkeys had been domesticated by the Aztec Indians of southern Mexico prior to the European discovery and were taked to Spain about 1519. From Spain the stocks spread throughout Europe, reaching England about 1541. Some of these European turkeys were taken to North America by the early colonists and served as foundation stock, along nith the native wild turkeys, in the development of the six long-established standard varieties of the United States—Bronze. Narragansett, White Holland, Bourbon Red. Black and Slate.

Up to about 1935 turkeys were bred mainly for perfection of plumage colour, and some exquisitely beautiful exhibition strains were produced in the U.S. Emphasis then changed to meat qualities and some exceptionally well-meated strains. were produced. Large. heavily fleshed Bronze turkeys of Englis origin aided in this development.

These new strains! called Broad Breasted Bronze, dominated the turkey inarket in the U.S. and Canada by 1913'. Adult males of this variety commonly weigh 50 lb., or, rarely, up to 65 lb. The Beltsville Small White, a small broad-breasted turkey developed by the U.S. department of agriculture, became popular in the U.S. and was made a seventh standard variety in 1951. State experiment stations and private breeders developed a number of large. broad-breasted white strains. These strains rapidly achieved popularity until by the late 1950s about 18,000.000 were raised annually in the United States, compared to 48,000,000 large Broad Breasted Bronze. 15,000,000 Beltsville Small Whites and possibly 1,000,000 of all other varieties and crosses.

The turkey industry of the United States produced a gross annual income as high as $356,000,000 during the 1950s. The Canadian turkey industry is of sizable proportions; those of Mexico, Argentina! Brazil, most European countries and Australia are smaller but of measurable economic importance.

TURKIC LANGUAGES are considered to be related to the Mongolian and Tungusic languages in what is known as the Altaic group. In fact the links between the Turkic and other so-called Altaic languages are somewhat tenuous. Taken by themselves. the Turkic languages present a remarkable uniformity and interresemblance, only Chuvash and Yakut being strongly aberrant. They have changed little from the language in the earliest extant Turkish inscriptions, those found near the Orkhon river in the Mongolian People's republic and the Yenisei river in the U.S.S.R., which date from the 8th century A.D.

Classification.—The Turkic languages may be classified according to either the historical-geographic or the phonetic data. The former system, being the most generally accepted, is given below:

1. Old *Turkish:* The Turkish of the Orkhon and Yenisei inscriptions ; Uigur.

2. *Middle Turkish*: (a) *Western Group*: Kuman. Kipchak; (b) *Eastern Group:* Kara-khanid, Khwarezmian, Chagatai.

3. *Modern Turkish: a. Southwestern* (*Turkmen*) *Group:* (1) Pre-Ottoman. Ottoman, the Turkish of modern Turkey, Ottoman dialects of Anatolia and the Ealkans. Crimean Ottoman, Gagauz Turkish (of Rumania), Turkish dialects of Bulgaria, Bosnia and

Macedonia, and Chuvash; (2) Azeri (Azerbaijani), spoken in the Azerbaijan Soviet Socialist republic (S.S.R.), and in northwestern Iran; (3) Kashgai, Ainalu and Baharlu, spoken in southern Iran; (4) Turkmen, used in the Turkmen S.S.R. and extending into the Kara-Kalpak Autonomous Soviet Socialist republic (A.S.S.R.), the Uzbek S.S.R., Kazakh S.S.R., Iran and Afghanistan. Small groups of Turkmen are also found in Anatolia, Syria and Transcaucasia.

b. Southeastern (Ckagatai or Uzbek) Group: Eastern Turkistan (Turki) dialects are spoken in the Sinkiang Uigur Autonomous region; various dialects of Uzbek are used in the Uzbek S.S.R., the southern part of the Kara-Kalpak A.S.S.R., in the eastern part of the Turkmen S.S.R., in the northern and western parts of the Tajik S.S.R. and in the southern part of the Kazakh S.S.R. as well as in northern Afghanistan; the Chagatai literary language also belongs to this group.

c. Northwestern (Kipchak) Group: (1) Kirghiz, which is used in the Kirghiz S.S.R., overlaps into Chinese territory and is also found in Afghanistan, is, of all the languages of this group, most similar to Oirot and Teleut of the northeastern group and with them may form a subgroup linking the northeastern and northwestern groups; (2) Kazakh is used in the Kazakh S.S.R., in the Kara-Kalpak A.S.S.R. and to some extent within the Mongolian People's republic; (3) Kara-Kalpak, which is hardly more than a Kazakh dialect, is used in the Kara-Kalpak A.S.S.R., and also by the Kara-Kalpaks living in Afghanistan; (4) Nogai is spoken in three dialects—White Nogai, which is used in the Karachai-Cherkess Autonomous oblast (A.O.) and differs markedly from the other two, and Black Nogai and Central Nogai, which are used in the Dagestan A.S.S.R.; (5) Kumyk is also spoken in the Dagestan A.S.S.R.; (6) Bashkir is used in the Bashkir A.S.S.R.; (7) the Volga Tatar dialects such as Kazan Tatar are spoken in the Tatar A.S.S.R. and a number of other languages are used by Tatar elements in the Urals, Tobol and Irtysh river areas.

d. *Northeastern (Uigur) Group:* (1) Tuva (Uryankhai), spoken in the former Tannu Tuva republic (now Tuva A.O.), and Karagass, spoken on the northern slope of the Sayan mountains (the language of the Orkhon and Yenisei inscriptions and the old Kirghiz language are also sometimes placed in this group); (2) the languages and dialects spoken in the Abakan and Yüz steppes (most of them in the Khakass A.O.), and also Sarig Uigur (Sari Yogur) spoken in China; (3) the language spoken in the Baraba steppe and the languages spoken in the northern Altai and in the Altai proper, chiefly in the Gorno-Altai A.O., *i.e.,* Altai proper (now called Oirot), Teleut, Teleng, Tölös, Yakut. Further research is still required on the grouping of these languages.

Turkish is the primary language of approximately 60,000,000 people, of whom 25,000,000 are in the Republic of Turkey. 19,000,000 in the Soviet Gnion, 8,000,000 in China and 8,000,000 in Iran and Afghanistan.

Characteristics. — Phonetics. — The outstanding phonetic characteristic of the Turkic languages is vowel harmony. The vowels are of two kinds — "front vowels," produced at the front of the mouth (e, i, o and *ü*), and "back vowels," spoken from the back of the mouth (a, *ı* [like the *i* in the English "hit"], o and u). Purely Turkish words can contain only front or back vowels and all suffixes and infixes must conform to the vowel of the syllable preceding them in the word. Thus, ev "house:" evler "houses," *evlerim* "my houses," evlerime "to my houses"; but at "horse," atlar "horses," atlarzm "my horses," *atlarıma* "to my horses." The principle of vowel harmony has to some extent broken down in a few Turkic languages, notably in certain dialects of Uzbek, and it is usually not applied to foreign words incorporated into Turkish.

Although in their old form Turkic languages probably had both long and short vowels, long vowels are now rarely found except in loanwords from such languages as Arabic and Persian. Only Turkmen and Yakut have to a great extent preserved the original length of vowel sounds.

There are certain changes of consonants which are peculiar to Turkic languages; some consonants change when they are followed by a vowel. In particular, *p, ç* ("ch"), t and k change to b, c ("j"), d and **g** (*e.g.,* varlik to *varliği*). Certain consonants change by what is known as progressive assimilation when they follow certain other consonants. Thus in the Turkish of modern Turkey the past tense of gelmek ("to come") is geldi, but that of gitmek ("to go") is gitti. Initial 1 and r are not found in purely Turkic words.

Morphology and Syntax. — The morphology and syntax of the Turkic languages are governed by agglutination. *i* e., the expression of grammatical concepts by suffixes and infixes which themselves have no intrinsic meaning, rather than by independent words. Since the plural is expressed by a special suffix, case endings are not affected by number. The result is a remarkable regularity and facility of analysis. For example, the word *evlerimde* ("in my houses") is composed of: *ev* "house," ler = plural suffix, *im* = possessive suffix of first person singular and de = locative suffix "in." Attached to a word with back voweling, *e.g.,* oda "room," these suffixes change their vowels according to the law of vowel harmony to odalarzmda ("in my rooms").

The syntax of Turkic languages, although logical and regular in itself, presents many difficulties to the English-speaking student. This is due principally to the absence of any relative pronoun and a great wealth of participles and verbal nouns. Thus the sentence "I know that the person who had come went away" is rendered in Uzbek: Kelgan *kishining* ketganini *bilaman* (literally "Having-come person's having-gone-his know I").

Of the various parts of speech which present peculiar features, the Turkic verb deserves special mention:

1. One or more infixes may be inserted between the verbal stem and the grammatical suffix to indicate passivity, causation, reciprocity, negativity and impossibility. So the word *sevmek* ("to love") can be enlarged to *sevdirilememek* ("to be impossible to be caused to love"), with *-dir-* showing causation, *-il-* passivity, *-e* + me- negative possibility and *-mek* the infinitive suffix.

2. All Turkic languages have an unusually large number of tenses and combinations of tenses to express fine shades of meaning. However, future tenses hardly exist or are used at all except in the Turkish of modern Turkey.

3. In a sentence containing a series of verbs in the same tense and time, differing only in their stems, the requisite verbal suffixes are affixed only to the final verb in the series, while to the other stems the abbreviating suffix (*-ip* in the Turkish of Turkey) is affixed in their place. So *gelip, görüp, gittim* ("I came, I saw, I went") are written, instead of *geldim, gördüm, gittim.*

4. A characteristic of many Turkic languages, though only traces are found in the Turkish of Turkey, is the expression of a verbal concept by two or more successive verbs. Thus the concept "to bring" is expressed in Uzbek by two verbs meaning "having taken, come" (alib kel), but in the Turkish of Turkey by a single word.

Writing and Literary Languages. — The Orkhon and Yenisei inscriptions of the 8th century were written in the Turkic runic script, according to the description of Vilhelm Thomsen, who deciphered it in 1893. This is thought to have been derived from the Aramaic alphabet through the old Sogdian alphabet. It was eventually replaced by the Uigur script derived from one of the northern Semitic alphabets through Sogdian. This in turn was largely replaced by the Arabic alphabet in the 9th and 10th centuries, although it was used until the 15th century by the Golden Horde and by the Timurids for writing the Kipchak and Chagatai languages.

The Arabic script was generally used by all Turkic peoples writing Turkic languages until 1924, when a Latin script was introduced in Soviet Azerbaijan. After 1928 this Latin script was extended to most of the other Turkic languages in the U.S.S.R. in a modified form known as the unified Turkic Latin alphabet. But after 1939 it was replaced by modified forms of the Cyrillic alphabet. A different Latin script was officially adopted in Turkey after 1928, so since that time the Arabic script has not been officially used by any Turkic people.

Distinct Turkic literary languages did not begin to develop until the 14th and 15th centuries. The most important was Ottoman Turkish, which developed from the literary language of the Seljuk period and included heavy accretions of Arabic and Persian uords. It persisted in upper-class Ottoman society until it was gradually supplanted by the Turkish of modern Turkey in the 20th century. Second in importance was Chagatai, ahich had its origin in the literary language in the domains oi Chagatai, the second son of Genghis Khan, during the 13th century. It persisted from the 15th century until the emirate of Bukhara was incorporated into the U.S.S.R. in 1920, when it was replaced by the Uzbek literary language.

Of the other literary Turkic languages current in Russia before the Revolution the most important were Turkmen, Azeri and Crimean and Kazan Tatar, all of which used the Arabic script A limited amount of writing was done in Kazakh, Kirghiz and a few other languages, mostly in the Arabic script. After the Revolution about 18 literary languages were developed for most of the Turkic languages spoken in the U.S.S.R.

Outside Turkey and the U.S.S.R. a certain amount of writing in the Arabic script is done by Turkic communities such as those in Iranian Azerbaijan and the Sinkiang Uigur A.O. The Cypriot Turks use the Latin script of Turkey.

Linguistic Policies. — The people of the Turkish republic and the Soviet Union were subjected to official linguistic policies whose widely varying object, nature and scope tended to produce different results.

The Turkish policy, initiated by Mustafa Kemal Atatiirk in 1928, aimed at modernizing the language by adapting a Latin script and by replacing words of foreign origin—chiefly Arabic and Persian—with words of Turkish origin or at least formed according to the principles of Turkic morphology. This policy was only partially successful and the more familiar Arab and Persian words remain in use, especially for official administrative terms and abstract concepts. On the other hand the Soviet adoption of the Cyrillic script after 1939 was aimed at the cultural separation of the Soviet Turkic peoples from those of Turkey. It was designed to facilitate the introduction of Russian loanwords and to promote the study of Russian in order to assimilate the Turkic peoples into the Russian community. Whereas in Turkey the tendency was to draw on pre-Ottoman words to express new and particularly political concepts, the Soviet authorities preferred to draw on Russian. Thus; for the Arabic word *inkilap* ("revolution") an attempt was made in Turkey to substitute *devirme* ("a turning round"), while in the U.S.S.R. it was replaced by *revolyutsiya*. In addition to reforms of alphabets and vocabularies both Turkish and Soviet policy aimed at modification of syntax and phonetics, the former toward a simplified Turkish purged of Arabic and Persian accretions, the latter toward the Russian systems. *See* also TURKISH *LANGUAGE.*

TURKISH LANGUAGE. By this term is generally understood the language of modern Turkey, the offspring of Ottoman Turkish. With the tongues of Azerbaijan and Turkmenistan, it forms the southwestern or Turkmen group of the Turkic family.

Morphology. — It is an agglutinating language, adding suffixes to invariable roots to make words which may be the equivalent of a whole English phrase or sentence. Thus *parasızlıklarından,* "because of their poverty," is composed of: *para,* "money"; *-sız,* "-less"; *-lık,* "-ness"; *-ları,* "their"; *-n-dan,* "from."

A peculiarity of Turkish is a lack of grammatical gender even more complete than in English: the same pronoun *o* does duty for "he," "she" and "it."

The noun has five case endings: a definite accusative, a genitive, dative, ablative and locative; *e.g., deniz-i gördük,* "we saw the sea"; *deniz-in,* "of the sea"; *deniz-e,* "to the sea"; *deniz-de,* "on/in the sea"; *deniz-den,* "from the sea." The plural suffix *-ler/-lar* precedes these endings.

The verb has a present, an aorist, a future and two past tenses, one for facts and one for hearsay. Thus from *yapmak,* "to do": *yapıyor,* "he is doing"; *yapar,* "he does"; *yapacak,* "he will do"; *yaptz,* "he did/has done"; *yapmış,* "he is said to have done." The simple past *yaptz* has a special set of personal endings which it shares with the conditional mood; the other tenses are compounded by adding the present of the verb "to be" to the tense base, which is identical with the third-person forms given above. Additional tenses are formed with the past tense of the verb "to be." Thus *yapar* means "habitually doing." and this, with the addition of *-ız,* "we are." or *-dık,* "we were." gives respectively *yaparzz,* "we do," and *yapardık,* "we used to do."

Negative. passive, reflexive. reciprocal. causative, potential and necessitative suffixes may be added to the verb stem: *gel-me-di,* "he did not come"; *yap-zl-dz,* "it was done"; *yıka-n-dım,* "I washed myself"; *sev-iş-irler,* "they love one another"; *sev-dir-dim,* "I caused to love"; *gel-ebil-irsiniz,* "you can come"; *gel-meli-siniz,* "you ought to come."

The cardinal numbers are as follows: 1 *bir,* 2 *iki,* 3 *üç,* 4 *dört,* 5 *beş,* 6 *altz,* 7 *yedi,* 8 *sekiz,* 9 *dokuz,* 10 *on,* 11 *on bir,* 19 *on dokuz,* 20 *yirmi,* 30 *otuz,* 40 *kırk,* 50 *elli,* 60 *altmış,* 70 *yetmiy,* 80 *seksen,* 90 *doksan,* 100 *yuz,* 1000 *bin.*

Phonology. — Turkish is written in a Latin-based alphabet, whose letters have much the same values as in English, with these differences: *c* is pronounced like English *j; ç* like *ch; ğ* lengthens a preceding vowel; *j* is pronounced as in French; *ş* is pronounced like English *sh.* Undotted *ı* is like *i* in "Cyril"; *o* and *u* are pronounced as in German; the remaining vowels as in Italian.

Of fundamental ımportance in Turkish phonology is the vowel harmony based on the distinction between the back vowels *a, ı, o, u* and the front vowels *e, i, o, ü.* As a rule, all the vowels of a word belong to the same class: *sargz,* "bandage"; *sergi,* "exhibition"; *dolu,* "full"; *köprü,* bridge; *kolay,* "easy"; *borek,* "pastry." The vowels of suffixes vary according to the class of the root. Thus 1st, *birinci;* 3rd, *üçüncü;* 9th, *dokuzuncu;* 40th, *kırkıncı.*

Apart from this phonetic variation, the language has a regularity which at first sight seems almost artificial. this impression is heightened when we learn that the verb "to be" is anomalous and that there is one lone irregular noun.

Syntax. — The chief syntactical feature is the use of nouns as qualifiers, by adding the possessive suffix of the third person to the qualified word. *Türkiye Cumhuriyet-i* ("Turkey Republic-its"), "Turkish Republic"; *hava yollar-ı* ("air ways-its"), "airways."

The main part of a statement comes at the end of the sentence, preceded by ıts modifiers and qualifiers. English prepositions are represented in Turkish by postpositions. Thus *İngiltere konsolosluğuna yakzn otelde oturan arkadaşımız dun evimize geldi,* literally "England consulate-its-to near hotel-in living friend-our yesterday house-our-to came," means "Our friend who lives in the hotel near the British Consulate came to our house yesterday."

History. — From the time of the wholesale conversion of the Turks to Islam in the 10th century, their language was subjected to invasion by a stream of Arabic words, not only religious and ethical terms but also the whole vocabulary of Arab science and civilization. In the 12th century, when Persian became the literary language of western Asia, a second invasion began. Turkish writers felt themselves free to draw on Arabic and Persian and also to employ grammatical constructions peculiar to these languages. The imposition of vast numbers of Semitic and Indo-European nords on the basic Turkish stock resulted in Ottoman Turkish, a language as hybrid as the culture which gave it birth, but expressive, flexible and possessed of a rare majesty. It was, however, a purely administrative and literary language, used by fewer than one in ten of the population.

The beginnings of Turkish journalism, just after the middle of the 19th century, led to a simplification of the written language, and this trend was accelerated in the second decade of the 20th century by the nationalist and Pan-Turkish policies.

Cnder the republic. it became almost a matter of dogma that the language should be purged of alien elements. The first casualty in the ensuing campaign was the alphabet. The Arabic script, which had been adopted by the Turks at the time of their conversion to Islam, distinguishes only three vowels. Turkish has eight.

The consonants of the two languages are also dissimilar. In 1928 the Arabic alphabet was replaced by the Latin letters described above. Despite certain shortcomings, this new alphabet, which is now in full use, is far better suited to express the sounds of Turkish.

In 1932 Mustafa Kemal founded a Turkish Linguistic society, whose chief purpose was to find genuine Turkish substitutes for every single Arabic and Persian word in the language. The application of this principle often led the society to absurd lengths. We might sympathize with an English purist who urged us to say "beginning" instead of "commencement," but we should certainly balk at having to say "wapentake" instead of "constituency"; analogous suggestions by the Turkish language reformers cost them much popular support. They modified their policy and stopped advocating the abandonment of well-established words of foreign origin.

The Democratic party, which came to power in 1950, withdrew governmental support from the language-reform movement. But all the years of nationalist propaganda, the increase in literacy and the great expansion of popular journalism had left their mark on the written language. Arabic and Persian grammatical constructions had been almost entirely eliminated and there was a growing disinclination to use Arabic or Persian words for which Turkish synonyms exist. On the other hand, the westernization of Turkish life was subjecting the language to a third foreign invasion: the literary man who makes an adaptation of a work scorns to describe it by the Arabic term *iktibas*, preferring to call it an *adaptasyon*.

The attempt to reform by decree had been abandoned; further development depended on the good taste of the people using Turkish.

TURKISH LITERATURE. Three main periods can be discerned in the history of Turkish literature: first, the period before the conversion of the Turks to Islam, covering approximately the 8th to 11th centuries A.D.; secondly, the period of Islamic culture, extending from the 11th to the mid-19th century; and thirdly, the modern period, dating from the accession of Sultan Abdul Mejid in 1839, in which the influence of western thought and literature, following the reforms of that reign, became predominant.

THE PRE-ISLAMIC PERIOD

The oldest literary legacy of the pre-Islamic period is to be found in the Orkhon inscriptions (*q.v.*) in northern Mongolia, carved in 735 in the Turkish runic alphabet on two large stones, in memory of the Turkish prince Kiil (d. 731) and his brother King Bilge (d. 734). They relate in epic and forceful language the origins of the Turks, the golden age of their history, their subjugation by the Chinese and their liberation by Bilge Kagan. Their polished style suggests considerable earlier development of the language (see D. Ross, "Orkhon Inscriptions," Bulletin of the School of Oriental and African Studies, 1929). Excavations carried out in Chinese Turkistan have brought to light important specimens of writings of the Uigur Turks from the 9th to the 11th centuries. Mahmud Kashgari's comprehensive dictionary (1071) contains specimens of old Turkish poetry in the typical form of quatrains (*dörtlük*), representing all the principal genres, epic, pastoral, didactic, lyric and elegiac. They echo vividly the life and customs of the people, contrasting with the later, Persian-inspired, stylized and mannered poetry (see C. Brockelmann, "Alttiirkestanische Volkspoesie," Asia Major, i and ii, 1924).

THE ISLAMIC PERIOD

With the conversion to Islam, the Turks gradually adopted Arabo-Persian poetical metres and literary traditions. The first known work of Islamic Turkish literature is Kutadgu *Bilig* ("Knowledge That Gives Happiness"; 1069) by Yusuf Has Hacib, chamberlain to the sultan of Kashgar. An allegorical poem of more than 6,000 couplets on the art of government, it consists of a series of conversations between the prince, the vizier, his son and a friend, who symbolize justice, good fortune, reason and contentment. Many traditions of pre-Islamic Turkish poetry survive in this work.

Later in this period Turkish literature divided into three branches according to the three main dialects: Chagatai, Azeri and Anatolian or Ottoman.

Chagatai.—This, the literary language of the eastern Turks, was used mainly in central Asia by the Golden Horde (*q.v.*), in Egypt and in the Indian courts of the Mogul period. Lacking a political and literary centre, it was influenced by local spoken dialects. Alishir Nevai (*q.v.*), the Mogul emperor Baber (d. 1530) and Ebulgazi Bahadur Han (d. 1663), the author of *Shecere-i Türk* ("Genealogy of the Turks") are three of the great classical writers of this dialect. Baber's memoirs, the Babur-nama describing his adventurous life in a vivid and colourful style, are the masterpiece of eastern Turkish prose (see A. S. Beveridge, The *Babur-nama*, Eng. trans., 2 vol., 1922).

Azeri.—This, the literary dialect of eastern Oguz (a term denoting the Turks in western Persia, Iraq and eastern Anatolia before the Ottoman conquest) is very similar to Anatolian Turkish. Nesimi is its first outstanding representative. An enthusiastic mystic, he was executed for heresy (*c.* 1420). His poems have rare beauty and profound religious feeling.

Shah Ismail (d. 1524), founder of the Safawid dynasty of Persia and known by his pseudonym, Hatai, had a lasting influence on popular religious literature in Anatolia. His poems, a blend of religious emotion and political propaganda, preach the Shi'ite doctrine. Fuzuli (*q.v.*), the greatest representative of the classical school, influenced Azeri and Ottoman poets of all succeeding generations. Azeri has also bequeathed to posterity the *Oguzname* ("The Legend of Oguz Kagan"), the only surviving example of the old Turkish epic. It relates the conquests and exploits of the legendary Turkish king Oguz and his sons. Another important Azeri work which contains elements of the old Turkish epic is the *Kitab-i* Dede Qorqut. This consists of 12 epic tales named after the sage who appears in each. They have only a superficial trace of Islamic culture and relate the life and battles of the Oguz Turkish tribes in northeastern Anatolia during the 13th and 14th centuries. The repetition of certain rhyming or alliterative word sequences suggests that parts of old poems have been incorporated into the tales. Slightly altered versions of some of the tales still live on in modern Turkish folklore.

Anatolian **or** Ottoman. — This was the language of the Anatolian Seljuks and of the Ottoman empire after the 13th century.

Preclassical Period. — In this period, which spans the 14th and 15th centuries, the influence of the Persian classics was paramount. They provided the inspiration for Turkish lyrics and romances, and Turkish poets strove to adapt their language to the Arabo-Persian metrical system, However, the most prominent figure of the period is Yunus Emre (*q.v.*), a great mystic poet and saint, who wrote in simple language, using the traditional syllabic metre. Sultan Veled (d. 1312) also wrote in a simple style. Other representative figures of the period are Ashik Pasha (d. 1332), author of the mystic and didactic poem Garibname, and Ahmed Dai, whose narrative poem Chenkname discovered in recent times is most original.

Ahmedi (d. 1413), a court poet, wrote several romances in verse and a vast epic on the life of Alexander the Great, containing the earliest known chronicle of the Ottoman empire. Sheyhi (d. 1428) continued the work of Ahmedi, assimilating with greater inspiration Persian poetic forms. He wrote a romance, *Hüsrev ü Shirin*, and the famous humorous satire Harname. Suleyman Chelebi (*q.v.*) composed the popular verse panegyric on Mohammed, Mevlid, a masterpiece of religious literature.

The prose of this period is mainly represented by translations of religious or popular stories and semiepic accounts of battles.

The Classical Period. — From the middle of the 15th century onward, with the establishment of the Turks in Istanbul, the golden age of Turkish letters began. The Persian classics were no longer mechanically imitated, but fully assimilated, and this enabled Turkish poets to evolve a genuine classical poetry which bore the imprint of their own individuality. A price had to be paid, however, for this assimilation of Persian poetic forms. The Turkish language lost some of its purity by accepting a large number of Persian and Arabic words and constructions. A result of this was that Turkish literature was restricted to a small educated class and was largely isolated from the mass of the people. Outstanding poets of this period include Ahmed Pasha (d. *c.* 1497) who improved the technique of classical Turkish prosody; Necati (d. 1509), a more inspired poet and author of lyrics and elegies written in a refined and original style, which greatly influenced later poets; Zati (d 1546). author of the poem *Shem ü Pervane;* Tashlicali Yahya (d. 1573) who wrote a romance, *Yusuf ve* Zulehya, the story of Joseph and Potiphar's wife, and a famous elegy on Prince Mustafa, the son of Suleiman the Magnificent; Ruhi of Baghdad (d. 1605), remembered especially for his famous Terkib-i bend, a sarcastic satire on bigotry, hypocrites and flatterers; Fuzuli (*q.v.*); and Baki, known as the "king of poets."

In the 17th century Yahya, the sheikh ul Islam, with his gay and polished lyrics, forms a link between Baki and Nedim. Nef'i (*q.v.*) and Naili (d. 1668) were both influenced by the "Indian school" of Persian literature. Naili, with his delicate style and fresh and colourful images tinged with melancholy, introduced a new note into the hackneyed poetry of the established tradition. The refined and flowing verse of Nabi (d. 1712), very popular in his time, echoes eastern wisdom and has a stronger appeal to the intellect than to the emotions.

The prose of the classical period shows great variety with folk tales; half-religious, half-epic narratives; belles-lettres written in a rather heavy and artificial style; and particularly the work of the chroniclers, who were also masters of Turkish classical prose. The chronicles of Ashikpashazade (d. 1485) and Neshri have an epic character and are written in simple Turkish. Ibn Kemal (d 1535) and Hoca Sadeddin (*q.v.*) wrote in a flowery style. Other chroniclers of this period were Mustafa Ali (d. 1606), also author of many treatises; Pechevi (d. 1650), who is particularly interesting when he relates events he himself witnessed; Katib Chelebi (*q.v.*); Silahdar (d. 1723); and Mustafa Naima (*q.v.*), greatest of all Turkish historians. These all wrote in a comparatively straightforward style, free from the mannerisms of official documents. The same can be said of the style of the Seyahatname written by the great traveler Evliya Chelebi (*q.v.*) and of Kochi Bey's famous reports to Murad IV and to Ibrahim recommending reforms for the empire.

The Postclassical Period.—The 18th century witnessed a refreshing revival of classical poetry. During the first half of the century, Nedim (*q.v.*) sang in colourful, vivacious and gay poems of the Tulip age of Istanbul under Ahmed III. In the second half of the century Galib Dede (*q.v.*), the last of the great classical authors, wrote the original mystic romance *Hüsu ü Ashk.*

Prose, on the other hand, was in decline. After Naima, most prose writers gradually moved away from natural, spontaneous narrative and adopted a pompous and flowery style.

Folk Literature.—Apart from the poets of the learned classes there were a number of folk poets. The greatest of these was the 17th-century minstrel Karacaoglan who told of the life of the people in simple language in the old syllabic metre.

THE MODERN PERIOD

The Impact **of** the West.—In the 19th century the introduction of western reforms into Turkish life generally had its effect on literature. Mainly under French influence, pioneers like Shinasi (1826–71). his disciple Ziya Pasha (1825–80), Namik Kemal (*q.v.*) and Abdulhak Hamid (*q.v.*) began, from the middle of the century, to adopt and adapt western literary art forms, such as the novel. the drama and the essay, nhile the rigid forms and attitudes of classical poetry gradually went out of fashion.

About the end of the century, the novelist Halid Ziya (*q.v.*) and the poet Tevfik Fikret (*q.v.*), together with their friends, founded a literary school associated with the name of the periodical *Servetifünün.* They were more western in technique and conception than their predecessors, but they indulged in an overloaded and precious style. These mannerisms were eschewed by the novelist Huseyin Rahmi (*q.v.*) and the essayist Ahmet Rasim (1864–1932), who described Istanbul life at the turn of the century with power and realism. The same reaction in favour of simplicity and realism is to be seen in the poetry of Mehmed Emin (1869–1944) and of Riza Tevfik (1868–1949). After the revolution of 1908 the younger generation of writers, headed by the symbolist Ahmed Hashim (d. 1933), grouped themselves into the short-lived *Fecr-i* Ati ("Dawn of the Future") literary school.

Independent Trends.—At this time the neoclassicist Yahya Kemal (*q.v.*) began to exercise great influence upon the younger generation, while the popular Pan-Islamist poet Mehmed Akif (1873–1936) remained an independent figure. Author of the Turkish national anthem, Akif achieved a mastery of classical prosody while using mainly the everyday Turkish idiom. A fervent Moslem, he wrote mainly didactic poetry but reaches the heights of lyricism when he is inspired by great religious or national events.

Nationalist Literature.—The *Türk Yurdu* ("Turkish Hearth") movement? based on the review of that name which became the official organ of the Young Turks, and the sustained striving of the Salonica periodical *Gench Kalemler* ("Young Pens") for simplified language were followed by the evolution of a distinctively Turkish literature largely under the leadership of Ziya Gokalp (*q.v.*), who sought to base literature on the ideals and aspirations of Turkish nationalism and to give it inspiration by a study of the Turkish past. Writers looked for new subjects in the country and its people. The outstanding prose writers of this period are Fuad Köprülü (*q.v.*), who wrote on Turkish literary history and folklore; Omer Seyfeddin (1884–1920), language reformer and author of popular short stories; Yakup Kadri (*q.v.*); Halide Edib (*q.v.*); Refik Halid Karay (1888–). whose novels and short stories gave the first realistic glimpses of life in Anatolia; Falih Rifki Atay (1894–), a brilliant journalist and essayist; and Reshat Nuri Guntekin (*q.v.*), popular novelist and language reformer.

In poetry, Faruk Nafiz Chamlibel, whose unsophisticated, romantic poems on emotional and patriotic themes made him the most popular poet of the 1920s, Necib Fazil Kisakurek (1903–), a modern mystic, and a host of others wrote in the Turkish syllabic metre.

Literature Under the **Republic.**—Nazim Hikmet Ran (*q.v.*) introduced free verse and "unorthodox" poetry in the early 1920s, but his influence only began to be felt in the late 1930s. Poets who, without ignoring the conventions, also enriched Turkish poetry were A. H. Tanpinar (1901–) who, mainly concerned with form, achieved unusual musical effects in syllabic metre by his choice of words and delicate imagery; A. M. Dranas; and C. S. Taranci (1910–56) who, writing in a warm and flowing style, dwelt on the themes of human sorrow and melancholy.

Orhan Veli Kanik (*q.v.*) pioneered the new school of poetry, reintroducing free verse and widening the range of theme. Such was his influence that most poets of his generation adopted his language and technique. The greatest name, however, in 20th-century Turkish poetry is Fazil Hüsnü Daglarca (1912–), whose books have given a continuous revelation of his versatile poetic genius. His lyrics and epics express his unquiet spirit in a delicate, fresh and original style.

The outstanding prose genre of the republican period is the short story, developed as never before in Turkish literature. Themes vary, but the emphasis is on social problems. the life of simple people, workers and peasants, although there are also subjective, autobiographical, psychological and descriptive types of story. In the early 1930s Sebahattin Ali (1907–49) drew superficially realistic sketches of Anatolian peasant life, but it was Sait Faik (*q.v.*), a poet by nature, who pioneered the ne school in the short story, widening its scope and using slang and dialect.

Although of the preceding generation it was not until the 1940s that Abdulhak Shinasi Hisar (1888–) produced his best work. His stories recall the early days of the century. In the late 1940s most prose writers turned to the novel, a genre which had been long neglected. The life and problenis of the peasantry and small townsmen were successfully treated in both short stories and novels by Samim Rocagoz, Kemal Bilbashar and especially by

Orhan Kemal (1914–) and Kemal Tahir (1908–). Other leading modern writers include Haldun Taner, Salah Binsel, Sabahattin Batu, Nezihe Merich and Mahmut Makal (1930–) whose Bizim Koy, a powerful sketch of a central Anatolian village, made a sensation when it appeared in 1949. In Ince Memed (1956), another outstanding novel, Yashar Kemal Gokcheli (1922–) tells the story of a landowner's cruelty and its results.

Nurallah Atach (1898–1957), the language reformer, was the outstanding literary critic of his day. His flair for discovering talent launched many young poets and writers on their careers.

TURKISTAN (TURKESTAN), a name that has been conventionally employed to designate the regions of central Asia lying between Siberia on the north and Tibet, India and Afghanistan on the south, the western limit being the Caspian sea and the eastern limit Mongolia and the Gobi desert. Etymologically the term was intended to indicate the regions inhabited by Turkic peoples; however, the regions called Turkistan not only contained peoples who were not Turkic but excluded some who were; *e.g.,* the Turks of the former Ottoman empire. What was formerly commonly called Eastern (Chinese) Turkistan became mainly the southern portion of the Chinese province of Sinkiang (*q.v.;* see also TARIM); the former Western (Russian) Turkistan was included in the soviet socialist republics of Uzbekistan, Turkmenistan, Kazakhstan, Kirghizia (Kirghizstan) and Tajikistan (*qq.v.*). See also ASIA: Ethnology; TURKS OR TURKIC PEOPLES.

TURKMENISTAN. A soviet republic of west-central Asia, which in 1924 was separated from the former Russian Turkistan. It is bounded on the west by the Caspian sea, on the north and northeast by Uzbekistan, on the southeast by Afghanistan and on the south by Iran.

Physical Geography. — Turkmenistan consists largely of desert plains and low plateaus rising southward to the Kopet Dagh. The Ust Urt plateau projects into the republic in the north as an area of semiarid tablelands, containing some sandy and alkalifloored depressions, and giving way southward to the Kara Kum (Black Sands) desert. The latter area of vast desert lowlands comprises perhaps 90% of Turkmenistan. Of the several rivers which descend into the Kara Kum from the south, only the Amu Darya maintains sufficient volume to traverse the desert.

The shrinking Caspian sea, its surface 86 ft. below open sea level, bears witness to the region's aridity. The Gulf of Kara-Bogaz-Gol acts like a great evaporating pan, 30 ft. deep. drawing water from the Caspian to further concentrate its salts so that sodium sulfate, gypsum and sodium chloride may be extracted industrially. During the Pleistocene Age the Caspian and Aral seas were connected at a level *c.* 245 ft. above that of the present Caspian, and their waves cut widespread benches at this height. A system of disused channels links the lower Amu Darya and the Caspian. Just north of Khiva oasis, the Kunya Darya runs westward into the Sarykamysh basin and still occasionally carries flood water from the Amu to feed lakes in the basin. Only when the Aral sea stood about 12 ft. above its present level could its waters have joined the Caspian through the lowest gaps in the rim of the Sarykamysh basin. As the level of the Caspian progressively diminished, such water cut the Uzboi channel (now dry) for more than 800 mi. to the Balkhan gulf.

Extensive areas of the Kara Kum are covered with sand derived from the alluvium of former and present rivers. A good deal of it is fixed by vegetation. L. S. Berg described the various forms taken by the sand: crescentic *barkhans* up to 30 ft. high; the more stable "mound sands" of compacted sand bearing an appreciable cover of plants; the "ridged sands," possibly "fossilized" Pleistocene dunes, lying in elongated parallel north-south ridges. 80 yd. apart and up to more than 60 ft. high and separated by *takyrs,* troughs of clay and saline deposits; and the sandy plains, generally held by vegetation, which cover large areas east of the Murgab (Murghab) river in the south. Southward Kara Kum merges into a loess-covered piedmont plain 300–400 ft. above sea level, across which flow many small mountain streams which have built up alluvial fans along the mountain front. Only the Tedzhen and Murgab push any distance out into the desert.

Finally, forming the frontier with Iran and Afghanistan, the Kopet Dagh range belongs to the Alpine-Himalayan structural system. Within the republic the Kopet Dagh attains more than 9,650 ft., yet the Turkmenian slopes are so dry that only minor streams descend from it. Toward the Caspian the range is lower and more broken, ending possibly in the isolated Little Balkhan. The structures of the Great Balkhan (5,600 ft.) appear to be due to an earlier (Mesozoic) phase of mountain building.

Apart from the Kara-Bogaz-Gol salts, most of the useful minerals of the republic are found in the south. Petroleum in the region of Nebit Dagh, Vyshka and the Cheleken peninsula is the most important. Others include ozocerite, barites, witherite and bentonite, all in the Caspian coastal belt, and copper and salt in the eastern corner of the republic.

Turkmenistan has a continental desert climate. Winters are cold in the north (January mean 25° F.) to cool in the south (35°), but summers are very hot (July mean 90°) in the south and practically cloudless. In the lowland the rainfall amounts to only 4–8 in., while even on the most favourable mountain slopes the total is but 16 in. A spring maximum is the rule.

Natural vegetation is limited to drought-resisting types. Everywhere the spring rains produce a short-lived cover of grass and herbs. The semidesert vegetation of the Ust Urt differs only in density from that of the Kara Kum. In both there are plants that can tolerate the various saline areas; *e.g.,* boyalych shrubs (*Salsola* arbuscula), biyurgun (Anabasis salsa j, various Artemisia and black saxaul. More sandy areas bear plants adapted to a shifting soil and which can find moisture at depth; *e.g., juz-gun* (*Calligonum*) and white saxaul. Climbing into the foothills a thicker cover of desert sedges gives place to dry grass steppes. Pistachio thickets are found southwest of the Tedzhen. River courses, notably the Amu Darya, are lined by saline meadows and tugay jungle, including poplars, willow, tamarisk and Russian olive. The fauna include many species adapted to a sandy environment: lizards, jerboas, etc. Wild ass and antelope are becoming rare! but the tugay forests still contain Turkistan tigers. (B. L. C. J.)

History. — The Turkmens or Turkomans arrived in Transcaspia in the 11th century, as Seljuk Turks. They were, in fact, not eastern but western Turks, separated from the main stem geographically but not linguistically. Since they had always lived as nomads, they did not form a state. They often became subject to one of the neighbouring states, Persia, Khiva or Bukhara, but this dependence was limited to only a few oasis cities of the area. Like their forefathers who had built the Turkish state in Anatolia, they are good warriors, as the Russians discovered in the second half of the 19th century when they had decided to annex the land of the Turkmens to the governor-generalship of Turkistan. To conquer Kokand; Bukhara and Khiva the Russians had to start their progress from the north, because the western approach was barred by the desert of Kara Kum and by the Turkmens. Advancing from Krasnovodsk, the Russians took Kyzyl Arvat in 1877 and two years later stormed the Turkmen fortress of Geok Tepe but suffered a defeat. Lt. Gen. M. D. Skobelev took Geok Tepe on Jan. 24, 1881, No quarter was given, and about 8,000 persons were slaughtered.

After the Russian victory, Ashkhabad was occupied three days later and in March the leaders of the Turkmen *ulus* ('(tribes") declared their submission. Merv (Mary) was occupied without fighting on March 18, 1884, and the Transcaspian province (*oblast*) of Russian Turkistan was formed.

During World War I, when the tsarist government tried to conscript the Turkmen for auxiliary services, they revolted in Oct. 1916 under the leadership of Aziz Chapykov. Two years later, when a Turkish army under Nuri Pasha, coming to the help of Azerbaijan, captured Baku from the Red army, the British sent a small force to Turkmenistan and for a time Merv was occupied by a detachment under Gen. Sir Wilfrid Malleson. This was not meant to be an intervention in Russian affairs, but an operation to prevent a German-Turkish thrust in the direction of Afghanistan and India. By the end of 1920 the Red army occupied the Transcaspian province.

In the summer of 1919 a Bureau of Turkistan Moslem Communist Organizations, or Musburo for short, was formed in Moscow. It expressed the opinion that the Uzbeks. Kazaks. Kirghiz and Turkmens, as well as the Bashkirs, Tatars and other Turkic peoples of Russia, were members of one Turkish nation and should form one republic within a Soviet federation. The Moscow council of people's commissars was cautious enough not to agree to that, but also not to reject such a wish too abruptly. A Turkistan Autonomous Soviet Socialist Republic was formed within the Russian federation, but J. V. Stalin, the people's commissar of nationalities, started preparing the partition of Turkistan into five republics, allegedly according to the principle of nationalities. He did not want a single Turkish nation within the U.S.S.R. According to him, the crux of the matter was that the Turkic peoples had no industrial proletariat. Speaking to the 12th congress of the All-Union Communist party (April 23, 1923), Stalin said that conditions now existed enabling these peoples to establish. with the aid of the Russian proletariat, their own centres of industry. The master plan was to prepare a massive interpenetration of the Turkic peoples through industrialization.

On Oct. 27, 1924, Turkmenistan became a Soviet Socialist republic and on Jan. 29, 1925. it was accepted as a member of the U.S.S.R. The Musburo was disbanded in 1934. In Turkmenistan, as in other Turkic-speaking republics, the vigilant Russian political police discovered many "bourgeois nationalists," such as N. Aitakov, chairman of the supreme soviet of the Turkmen S.S.R., who was shot in 1937.

PRINCIPAL CITIES AND RAILWAYS OF TURKMENISTAN

Population.—The area of Turkmenistan, according to official Soviet sources?is 188,417 sq.mi. Between 1926 and 1939 its population increased from 998.154 to 1,253,985, and in 1959 it was 1.520.000. There were 811,769 Turkmens in the U.S.S.R. in 1939. and 1,004.000 in 1959. In Turkmenistan proper there were an estimated 762.300 (61%) in 1939 and 924,000 (61%) in 1959. The percentage of Russians during that period was 18%. The progress of industrialization was apparent in that the percentage of urban population, 13.7% in 1926, had risen to 33.2% in 1939 and to 46% in 1959.

The population of Ashkhabad, the capital, rose from 51.593 to 126,580, and that of Chardzhou from 13.950 to 54,739. In 1959 the population of Ashkhabad was 170.000. In 1959 Merv had a population of 48,000 and Krasnovodsk of 50.000. The Turkmens are Sunni Moslems. (See TURKS OR TURKIC PEOPLES,)

Education.—While before World War I about 99% of Turkmens were illiterate: by 1953 there mere 1,226 schools with 218,500 pupils: including 30 secondary vocational schools and 6 institutions of higher education with a total of 13,000 students. Journals and books are printed in Turkoman as opposed to the literary Turkish language. Between 1925 and 1928 the Arabic script was replaced by a Latin alphabet, not only in Turkmenistan but also in other Turkic-speaking republics. The idea of this reform was to isolate the Turkic-speaking peoples of the U.S.S.R. from the cultural influences of Turkey which was still using the Arabic script. But in 1928 Mustafa Kemal Atatiirk introduced the Latin script in Turkey and Moscow was faced with the potential danger of a cultural unity of all Turkic-speaking peoples. To build a new barrier, the Soviet government decided that a new "alphabetic revolution" was necessary. In 1938 the compulsory teaching of Russian in all non-Russian schools was introduced, and in 1939–40 the Cyrillic alphabet replaced the Latin in all Turkish-speaking areas. In Turkmenistan this created a barrier between the Russian Turkmens and those of Iran (c. 400,000 in Khurasan), but this was considered in Moscow a lesser evil.

Economy. — Before World War I Turkmenistan was a typical land of nomadic herdsmen. By the mid-20th century nomadism had been replaced by a settled way of life. Cotton growing and an oil industry were developed. In 1934 there were 138.800 head of cattle in the republic, 721,200 sheep and goats and 54,200 horses; *i.e.,* about one-quarter of the livestock there had been in 1914. By 1942 the livestock figures were 260,100 head of cattle, 2,213,300 sheep and goats, 56,500 horses, 133,100 mules and asses and 74,900 camels.

The area under cotton in the Murgab and Tedzhen valleys was increased between 1925 and 1945 from 151,000 ac. to 264,000 ac.; *i.e.,* from 25% to 31% of all arable land. Production of unginned cotton increased during this period from 44,730 metric tons to 171,600 tons, which was about 7% of the total Soviet production. The main ginning plants were at Chardzhou and Tashauz.

Petroleum was discovered in the country before World War I and the 1913 output was 129.500 metric tons; by 1941 the output amounted to 690,300 tons, and in 1953 to 3,255,000 tons. After Baku, the Bashkir, Tatar and Kuibyshev areas Turkmenistan was by the mid-20th century fifth in importance among the oil-producing areas of the U.S.S.R.

Soviet planners had given much attention to irrigation works in Turkistan in general and in Turkmenistan in particular. On Sept. 11, 1950, the decision was taken to construct the Great Turkmenian canal across the Kara Kum desert. linking the lower Amu Darya to the Caspian sea. The canal was to be 684 mi. long, and it was to irrigate nearly 3,200,000 ac. When completed it would permit the transport of cotton and other raw materials from Uzbekistan and Turkmenistan to central Russia and of grain and industrial goods in the reverse direction. This project would have restored in a modern setting the situation which existed until the mid-16th century, when the Amu Darya flowed into the Caspian. It was not known if construction of this canal was ever begun. but if so, the work was abandoned in 1953 and thereafter the Soviet press kept silent about the project.

See UZBEKISTAN: Bibliography. (K. SM.)

TURKOMAN (TURKMEN), the name of a people belonging to the southwestern or Oguz branch of the Turkic linguistic group. They live for the most part in Soviet Turkmen S.S.R. and in neighbouring parts of Soviet Central Asia (Kazakhstan and Uzbekistan). A large body live in Iran, especially in the north and in northeast and northwestern Afghanistan. Small pockets of Turkomans are found in northern Iraq and Syria. Larger groups live in central Anatolia, Turkey. The Turkomans speak a Turkic language most closely related to the Turkish of Turkey, Azerbaijani, Crimean Tatar, the Turkic dialects of the Balkans and Kashgai of Iran.

The territory of the Turkomans is almost. invariably arid. ranging from dry steppe to semidesert to desert. Turkmenistan proper is one of the most arid places in the world. Agriculture is possible only under conditions of intensive irrigation and artificial fertilization of the soil. The Turkomans were by tradition a nomadic pastoral people, an economic type well adapted to the arid conditions of their habitat, and lived in tent villages which were not fixed in one place. They raised sheep. goats, horses, camels. asses and cattle. Their nomadism was an annual round of movement from winter camp to summer pasture, and in the spring out onto the desert to give the herds and flocks access to the ephemeral desert plants. Most of their terrain is waterless;

most of their lakes are salt or brackish. With the help of irrigation and fertilization, the Turkomans of the Soviet Union have taken up agriculture; their stock-breeding is no longer nomadic but is based upon a fixed-village and permanent-dwelling pattern. The Turkomans of the countries outside the Soviet Union continue their traditional nomadic pastoral life. An important adjunct to the Turkoman economy is their manufacture of rugs.

The social organization of the Turkomans is heavily patiilineal. Genealogies, marriage, family life and inheritance of tangibles are based primarily upon the principles of descent in the male line and agnatic kinship. Turkomans live in extended families composed of parents, all unmarried children and families of the married sons. The rule of residence on marriage is patrilocality. Family authority is vested in the father and is patriarchal.

The traditional Turkoman social structures, larger than the extended family, were the kin village, composed of families related in the male line; lineages and clans, likewise based upon agnatic kinship; and confederations. the largest of the units of traditional organization. There were five chief divisions of the Turkomans. The most senior of these was a division composed of the Salor-Sarik-Teke-Yomud-Emrili lines; the most senior of this division was the Salor line. The pastoral and nomadic Turkomans reckoned seniority on the basis of primogeniture. and order of birth of the ancestors. Their descendants were ranked in their descent lines. The second of the great divisions, like the first. held itself to be the direct descendants of the Oguz Turks. The other three divisions held a subordinate position. These were the old non-Oguz Turkomans (Kokhurli. Ananli and others), the recent non-Oguz Turkomans (Ali-eli, Khizr and others', and Turkomanized Arabs (Ata. Khodja. Said and others).

Although most of the Central Asian Turks, such as the Kazakhs and Uzbeks, were divided into a noble stratum and a common stratum, the Turkomans had no such division. On the other hand, the Turkomans have a division according to economic function. The Yomud Turkomans. of the senior division, were divided into an agricultural group whom they called *Chomur,* and a pastoral group. whom they called *Clzorva.* The *Clzorva* were the prestige group, just as herding was, and is, the prestige occupation. *Chomurs* aspired to become pastoral *Clzorva;* and conversely *Chorvas,* becoming impoverished, became *Chomurs.* The cleavage between the two groups was functional and could be crossed. At the head of each division was a khan. This mode of organization exists no longer in the Soviet Union, but continues elsewhere.

The Turkomans are Moslem, of the Sunni sect, but, like most Turkic nomads, are not as deeply influenced by Islam as are the sedentary Turks. The majority live in the Soviet Union! where they numbered 1,004,000 in 1959. The number of Turkomans in the world is roughly estimated to be about 1,500,000.

TURKS AND CAICOS ISLANDS, a group in the West Indies, are geographically a part of the Bahamas but politically a British colony. The area is 169 sq.mi. Pop. (mostly Negro) (1943) 6,138; (1960) 5,716.

The Turks Islands, so named from a local cactus resembling a Turkish fez, are eight in number, but only two, Grand Turk (9.4 sq.mi.; pop. 2,346) and Salt cay (4 sq.mi.; pop. 441) are regularly inhabited. These two and Cockburn harbour on South Caicos are ports of entry. The Caicos group, northwest of the Turks, includes six principal islands. South Caicos and North Caicos being the most important. The mean temperature is 82° F., but because of the prevailing trades the climate is not oppressive. Rainfall averages only $29\frac{3}{4}$ in. annually and drinking water is scarce, being rationed at times. Hurricanes are not infrequent. An unusually violent one in 1945 caused great damage.

Salt raking is the staple industry. with an average annual export of 43,000 tons, about half from South Caicos. Conchs and crayfish are also exported. Grand Turk, the seat of government, is an important cable junction. with cables to Jamaica. Bermuda and Barbados. There is frequent shipping and air service to Kingston, Jamaica. The islands were discovered by Juan Ponce de Leon in 1512 but were uninhabited until 1678, nhen Bermudians arrived and began the salt-raking industry. They were expelled by the Spanish in 1710 but soon returned, remaining despite Spanish and French attacks. In 1799 the islands were given representation in the Bahamas assembly, but in 1848, on petition from the inhabitants, they were placed under Jamaica as a separate colony. In 1873 they were annexed by Jamaica. In 1960 the group became a separate colony of Great Britain. A small U.S. air base was maintained on South Caicos from 1944 to 1947 and a guided missile base on Grand Turk after 1952. (L. W. BE.)

TURKS OR TURKIC PEOPLES. The terms Turkic peoples and Turks have no clearly defined racial significance. They can be properly applied, however, to those communities historically and linguistically connected with the 'Iu-Kiu, the name given by the Chinese to the nomad people who in the 6th century A.D. founded an empire stretching from Mongolia and the northern frontier of China to the Black sea. Some authorities consider that the name Hiungnu, which appears in Chinese sources as far back as 2000 B.C., also referred to the Turks; but it was probably a generic term applied to Turkic, Mongol and perhaps Tungus peoples.

With some individual exceptions. notably in the European part of Turkey and the Volga region, the peoples corresponding to the foregoing definition are confined to Asia. They may be divided into two main groups, the western and the eastern. The former includes the Turkic peoples of Europe and those of western Asia inhabiting the Asiatic part of Turkey and the northwest of Iran (Persia). The eastern group comprises the peoples of the Soviet republics of Kazakstan (Kazakhstan). Turkmenistan, Uzbekistan and Kirghizia (*qq.v.*), the Altai region, the Yakuts and other scattered elements of eastern Siberia and of the Chinese province of Sinkiang. Linguistically the Turkmens are connected with the western group.

HISTORY

Nothing definite is yet known about the origin of the Turks and much of their history even up to the Mongol conquests is shrouded in obscurity. In its Chinese form of Tu-Kiu the word "Turk" first appeared in history in the 6th century as applied to the founders of the empire referred to above. This empire consisted of two parts founded by two brothers and known to the Chinese as the northern and western Turks. It submitted to the nominal suzerainty of the Chinese T'ang dynasty in the 7th century, but the northern Turks regained their independence in 682 and retained it until 744. It is to this empire that the Orkhon inscriptions, the oldest-known Turkic records, relate. These inscriptions refer to the Oguz which was apparently the name of a confederation of Turkic tribes, to the Uigur as inhabitants of the basin of the Selenga river in Mongolia and to the Kirghiz as living on the Yenisei river. In 745 the Uigur established themselves as the rulers of Mongolia. Driven out of Mongolia by the Kirghiz in 840, they founded two kingdoms, one in Kansu and the other in Bishbalik and Karakhoja (in what is now eastern Sinkiang), the latter persisting until the Mongol period. The Kirghiz were the last Turkic-rulers of Mongolia. They were driven out in 924 and established themselves first in the Upper Yenisei and later in the region now called Kirghizia.

In 699 the western Turks passed under the domination of the northern Turks but later freed themselves. At the end of the 7th century they became involved in the Arab conquest of Transoxiana, which during the next three centuries became part of the realm of the Persian Abbasid and Samanid dynasties. In 999 Bukhara and Samarkand, and the country stretching as far as the Amu Darya, again came under Turkic rule.

At the beginning of the 11th century there were two great Turkish migrations which were profoundly to affect the later history of the Turkic peoples. Before these migrations two Turkic peoples. who appear to have early separated from the bulk of the Turks, were active south and east of the Urals. The first were the Khazars who in the 7th century established an empire which stretched to the Caucasus and later to the Crimea. They were finally destroyed by the Kievan Rus (*see* RUSSIA) at the beginning of the 10th century. The second were the Pechenegs whose earliest-known habitat was in the Ural-Volga area. Toward the end of the 9th century they controlled the region embracing Bessarabia and Moldavia to the eastern Carpathians. They were overrun by the Oguz or Guzz in 1065 and had been virtually extinguished by the Byzantines by the beginning of the 12th century. The first great migration was of the Oguz from north of the Syr Darya. One branch, the Khalji, advanced into Afghanistan and were the forerunners of the Ghilzai tribe which ultimately founded a dynasty in India. Another branch was that of the Seljuks who by the end of the 11th century controlled an empire stretching from the Amu Darya to the Persian gulf and from the Indus to the Mediterranean. This empire began to disintegrate about 1100 and was finally destroyed by the Mongols in the 13th century.

The second migration was of the Kipchaks who appeared from the Irtysh river and advanced to the southwest as far as the Syr Darya where they established themselves in the territory formerly occupied by the Oguz. They also advanced into eastern Europe, conquering the region between the Danube delta and the Carpathians, the Crimea and the lower reaches of the Volga. They were known to the Byzantines as Kumans (Cumans; *q.v.*) and to the Russians as Polovtsy and disappeared from history on their destruction by the Mongols in 1239.

The Mongol conquests, which began at the beginning of the 13th century, spread eventually over almost all the areas held or inhabited by Turkic peoples. The Kipchak empire was overrun and extinguished, and the last remnants of the Seljuk empire, the sultanate of Konya and the realm of the shahs of Khorezm, were subjugated. But following the distribution of Jenghiz Khan's empire, which took place after his death, a process of Islamization and Turkification ensued which resulted in the virtual absorption by the Turks of the Mongols outside Mongolian territory. The influence of the khans diminished, particularly in what is now known as central Asia, and the real power passed to the Turkish governors. One of these, Timur, seized power in Transoxiana in 1369 and eventually extended his territory over the whole of the Golden Horde, over most of Persia, and as far south as Baghdad; he captured Delhi, Aleppo and Damascus; he also defeated in 1402 the Ottoman sultan Bayezid I near Ankara, the Ottoman empire having been founded at the end of the 13th century by Osman, the first sultan of the Osmanli dynasty. (*See* TURKEY.)

While Timur's empire remained, that is, until about the middle of the 15th century, and for a considerable time afterward, a large proportion of the Turkic peoples in Asia were ruled by men of Turkic stock. At the end of the 15th century and during the beginning of the 16th, the Uzbeks, who were a returning wave of Turkic peoples from the Kipchak region, rose to power in central Asia and in 1500 their ruler Mohammed esh-Shaibani deposed Baber, the last of Timur's successors. Shaibani was, however, defeated by the Persian Safavid shah Ismail in 1510, and the territory as far north as Merv (Mary) was nominally included in the Persian empire until the end of the 17th century. Persian rule as far as the Amu Darya was re-established for a short time by Nadir Shah in 1740. The Azeris of Transcaucasia were also included in the Persian empire until 1813, when Azerbaijan was partitioned between Russia and Persia. (*See* AZERBAIJAN.) Elsewhere in Asia the Turks were ruled by their own people until the rise of Imperial Russia, except during the Kalmuck domination of large areas of central Asia between 1603 and 1758 when the Kalmuck empire was destroyed by the Chinese.

In Europe, after the collapse of Mongol domination in 1480, rule over the Turkic peoples was divided between the Russian and Ottoman empires, except for Crimea, which remained nominally independent until 1783 when it was annexed by Russia.

After the defeat of the Uzbeks by Persia, Uzbek territory was confined to the lands north of the Amu Darya and Kopet Dagh and eventually became the emirate of Bukhara. At the same time the Uzbek khanate of Khorezm or Khiva was formed. Abdullah esh-Shaibani, the emir of Bukhara, succeeded in uniting these two states before his death in 1597; but they did not remain under one rule for long. In 1740 both states were invaded and temporarily occupied by Nadir Shah of Persia. After a period of disorder, the last Bukharan dynasty, the Manghyt emirs, came to power in 1753 and retained nominal independence until the Soviet occupation in 1gzo. (*See* UZBEKISTAN.)

The Turkmens remained in their present habitat during the Oguz migration of the 11th century and were one of the few Turkic peoples who were not merged in the hlongol empire. In the 15th century the Turkmen tribes of Kara Koyunlu (Black Sheep) and Ak Koyunlu (White Sheep) wielded considerable power, but although the Turkmens kept themselves independent from the neighbouring states they never formed a regular state of their own. They finally lost their independence to Russia in 1881. (*See* TURKMENISTAN.)

The khanate of the Mogul was the name given to the last Turkish kingdom to arise out of the Mongol empire in the middle of the 14th century. In spite of their name, these Moguls spoke a Turkic language, and part of them, the Sarig Uigur (Yellow Uigur) retained the Uigur script until the 18th century. This kingdom, which stretched from Kashgar to the then Chinese frontier, was destroyed by the Kalmucks in 1682.

The Mongol domination of Russia came to an end in 1480. It is from this date that the domination of Russia over most of the Turkic peoples in Asia began. The first expansion of the Russians into Asia was due east along the line of least resistance. To the south, however, they advanced into the Caucasus and by 1689 had occupied the eastern portion. At this time the Turkic peoples under Russian rule included the Turks of the northeastern Caucasus, the Volga region and Bashkiria, as well as the outlying Yakuts in eastern Siberia. By 1800 this rule had been extended to include the Crimea, and by 1878 the whole of the rest of the Caucasus had passed from Turkish and Persian into Russian hands. The Russian advance into what is now Kazakstan (*q.v.*) did not begin until 1801. By 1900 the whole of central Asia to the Chinese, Afghan and Persian frontiers had passed under Russian rule or suzerainty.

DISTRIBUTION

The position of the Turkic peoples as regards habitat and political dependence may be briefly summarized as follows:

Turkey. — The vast majority of the population of the Turkish republic, that is, about 20,000,000 (1954 est.), may be described as Turks. They are Turkish-speaking, but with the passage of time, the pure Turkic stock has become diluted with other elements.

Iran. — The whole of the Iranian province of Azerbaijan is inhabited by Azeris or Turkish-speaking Turks. There are other scattered Turkic elements, notably the Turkmen in Khurasan. In the south, the tribes of Kashkai, Ainalu and Baharlu are of Turkic origin and Turkish-speaking. In the absence of an official census, it is impossible to estimate precisely the number of Turks living in Iran. but it is probably not less than 2,000,000.

Afghanistan. — There are a few thousand Uzbeks and a smaller number of Turkmens living in northern Afghanistan.

China. — According to Soviet estimates, there are about 4,500,000 Turkic peoples in the Chinese province of Sinkiang (about 4,000,000 Uigurs, 350,000 Kazaks and 150,000 Kirghiz).

U.S.S.R.—The total number of the Turkic peoples living in the U.S.S.R. was not less than 19,000,000 (1939 est.). A detailed ethnic survey was published with the census of 1926. Subsequent population figures, including those of the census of 1939, did not always distinguish clearly between the indigenous and settled populations. The total population of Kazakstan (1939 census) was 6,145,937, of whom 80% were made up of Kazaks and Russians. (*See* Table.)

The 1939 census showed the total Turkic population of Kazakstan, Uzbekistan, Turkmenistan. Kirghizia and of Tajikistan (excluding Tajiks) to be about 10,000,000, that is, an over-all increase of only about 3% over the 1926 census figures. the Kazaks having apparently decreased by 869.525. The over-all increase in the Turkic population of the whole U.S.S.R. between 1926 and 1939 was approximately 12%.

After 1939 there were a number of changes of which details were still not available by the mid-1950s. There has evidently been some growth of population, but there has also been some dispersal of the Turkic peoples. For instance, as a result of their alleged collaboration with the Germans during World War II the Crimean Tatar, the Karachai and Balkar peoples were uprooted and their existence as ethnic units is no longer recognized. The Crimean A.S.S.R. (Autonomous Soviet Socialist Republic) and the Karachai A.O. (Autonomous province) have thus ceased to exist. and the name of the former Kabardino-Balkar A.S.S.R. changed to Kabardinian A.S.S.R.

Distribution of the Turkic Peoples in the U.S.S.R.

Area	Census of 1926	Census of 1939
A. Volga Region		
Tatars	3,308,116	4,300,336
Chuvash	1,117,419	1,367,930
Bashkirs, etc.	741,080	842,925
	5,166,615	6,511,191
B. Caucasus		
Azeris	1,706,605	2,274,805
Kumyk	94,549	113,500*
Karachay	55,123	75,737
Balkar	33,307	42,666
Karapapakh	6,316	7,500*
	1,895,900	2,514,208
C. Central Asia		
Kazaks	3,968,289	3,098,764
Uzbeks and Kurama	3,954,701	4,844,021
Kara-Kalpaks	146,317	183,[illegible]
Turkmen	763,940	811,769
Kirghiz	762,736	884.306
Others	169,877	203,900*
	9,765,860	10,028,535
D. East Siberia and Altai Region		
Yakuts	241,365	260,000*
Others	124,001	140,000*
	365,366	400.000
Total (A + B + C + D)	17,193,741	19,453,934

*Groups included in the 1926 but excluded from the 1939 census. An increase of 20% over 1926 has been estimated.

Source: F. Lorimer, *The Population of the Soviet Union* (New Tork, 1946). Comparison between the figures shown in the 1926 and 1939 censuses is complicated by the fact that many of the smaller ethnic groups mentioned in the 1926 census were not included in data of the 1939 census so far available.

As already indicated the main ties binding the Turkic peoples together are historical and linguistic rather than cultural. It is indeed difficult to speak of Turkish culture with any degree of precision. Insofar as there are any cultural links other than those of history and language which are strong and persistent, it is that of Islam. for—with the exception of the Turks of eastern Siberia (Yakuts) and the Altai region—all the Turks are Moslem. The Chuvash are Orthodox Christians. Little remains to indicate what the pre-Islamic culture of the Turks was. and it is hard to detect any common characteristics. The so-called "golden period" of literature, art and refined culture which flourished for about a century under Timur and his successors was Persian rather than Turkish. The same can be said of the culture of the Seljuk empire. Under the Turkish republican government efforts were made to revive the ancient culture of the Turks and to isolate it from Islam. Similar eiforts. although with a different purpose, were made by the Soviet government. The Turks of Iran, while retaining their language. had been considerably affected by Iranian culture, and no Turkic language was used as a medium of education in the schools.

Of the literature written in Turkic languages by far the most considerable is that of Turkey. In the U.S.S.R. the official tendency has been to discountenance much of the traditional oral literature as reactionary and to develop a new literature on Soviet and, to a large extent. Russian lines. A large number of translations and a smaller number of original works have been published in Turkic languages. In Iran and Afghanistan no translations or original works in Turkic languages had been published by mid-20th century.

Although the bulk of the Turkic peoples profess. Islam, they have been much affected by the appearance of laicism in the countries on which the great majority of them are politically dependent. In Turkey religious instruction had been discontinued in state schools but from 1947 the ban on religious instruction was relaxed. In the U.S.S.R. religious teaching forms no part of state education but is permitted in theological institutions.

TURKU (Swedish ABO). a seaport of Finland on the Gulf of Bothnia. Pop. (1950) 101.824. It is the second largest town in Finland, and has a shipbuilding and repairing industry. An icebreaker keeps the port open throughout the winter.

There are four entrances to the harbour. with lighthouses for each, and there are four patent slips capable of taking vessels up to 1,200 tons. The chief imports are salt. salt fish, pig iron. oils. coal. cotton, machinery and colonial goods, and the exports timber, grain, butter, bar iron. pork. beef and game. There is a considerable coasting trade. After the diet of Borga in 1809, Turku became capital of the Russian grand duchy of Finland. but in 1819 the government was moved to Helsinki. It was founded in 1229 and has been a centre of Swedish culture, having a Swedish as well as a Finnish college.

TURKU-PORI (ABO-BJORNEBORG), a department. in the southwest of the republic of Finland. Area (in English square miles) 8.886. Pop. (1950) 631.049. It is a lowland region containing much boulder-clay soil and a consequent imperfect drainage. The department, together with most of Finland. has not yet recovered from the effects of severe glaciation. Finnish and Swedish are spoken. The chief towns are Turku (Abo), pop. (1950) 101,824; and Pori (Bjornehorgj. 43,213.

TURMERIC, the tuberous rhizomes (underground stems) of *Curcuma longa*, an herbaceous perennial plant belonging to the family Zingiberaceae (*q.v.*). It is a native of southern Asia, cultivated on a large scale both on the mainland and in the islands of the Indian ocean. Turmeric has been used from a remote period both as a condiment and as a dyestuff, and was once employed to a more limited extent as a medicine. In Europe it is employed chiefly as a dye, also as an ingredient in curry powder and as a chemical test for alkalies. The rhizome is prepared by cleaning it and drying it in an oven. There are several varieties (Madras, Bengal, Gopalpur, Java, China and Cochin turmeric), differing chiefly in size and colour of the tubers and to a slight degree in flavour. All are hard and tough, but break with a short resinous or waxy fracture; the exposed surface varies in tint from an orange brown to a deep reddish-brown. The colour is due to curcumin, of which the drug contains about 0.3%. When pure it forms yellow crystals having a vanilla odour and exhibiting a fine blue colour in reflected light. On oxidation with potassium permanganate it gives vanillin, the flavouring and odorous material of vanilla (*q.v.*). It is soluble in alcohol, in chloroform, but only sparingly in water. Paper tinged with a tincture of turmeric exhibits on the addition of an alkali a reddish-brown tint that becomes violet on drying, thus providing a test for alkalinity discovered by H. A. Vogel in 1815.

TURNEBUS, ADRIANUS [ADRIEN TURNEBE] (1512–1565), French classical scholar, was born at Les Andelys in Normandy, and at the age of 12 was sent to Paris to study. After having held the post of professor of belles-lettres in the Cniversity of Toulouse, in 1547 he returned to Paris as professor (or royal reader) of Greek at the Collège Royal. In 1552 he was entrusted with the printing of the Greek books at the royal press, in which he was assisted by his friend, Guillaume Morel (*q.v.*). He died of consumption on June 12. 1565. His works chiefly consist of philological dissertations, commentaries (on Aeschylus, Sophocles, Theophrastus, Philo and portions of Ciceroj, and translations of Greek authors into Latin and French. His son. Etienne, published his complete works. in three volumes (Strasbourg, 1600), and his son Adrien his *Adversaria*, containing explanations and emendations of numerous passages in classical authors.

TURNER, FREDERICK JACKSON (1861–1932), noted historian of the C.S. frontier, mas born in Portage, Wis., Nov. 14, 1861. He attended local schools, was graduated from the University of Wisconsin in 1884, and returned. after a short interval as a reporter, to prepare for college teaching. Turner concentrated on history. working under the guidance of William Francis Allen. an effective teacher who stimulated students to analyze and criticize source materials and interrelationships in history. Studying at the State Historical society during this time, Turner probed the Lyman C. Draper collection of western Americana, with its wide spectrum of manuscript materials on the pioneer days of Wisconsin. After winning his master's degree in 1888, Turner went to Johns Hopkins university to continue graduate work in the famed seminar of Herbert Baxter Adams. There he met a number of first-rate scholars, including Woodrow Wilson, who became a lifelong friend. In 1889 he married Caroline Mae Sherwood of Chicago and returned to Wisconsin as an assistant professor: completing his doctoral dissertation the next year. Personable and handsome. with a quiet sense of humor, Turner was a teacher of unusual ability who encouraged independent thought on the part of his students. In 1892 he was made professor of American history, a position in which he brought distinction to his alma mater for 18 productive years. He moved to Harvard in 1910, following his election to the presidency of the American Historical association. After retirement in 1924, he was welcomed at the Henry E. Huntington library as a research associate, spending his final years studying and writing until his death Mar. 14, 1932.

Turner's doctoral dissertation on "The Character and Influence of the Indian Trade in Wisconsin" (1891) portrayed the trading post as a frontier institution that had evolved from antiquity, thereby disclosing the influence of Herbert Baxter Adams' emphasis on the evolution of institutions throughout history. Turner partly rejected, but never wholly abandoned, the concept that American institutions were products of European "germs," often called the germ theory.

"The Significance of the Frontier in American History," an essay that Turner read before a group of historians at the World's Columbian exposition in Chicago. Ill., on July 12, 1893, introduced a new hypothesis that promised to revise older interpretations of U.S. history. Teaching. developing a course on the history of the west, and further research preceded the publication of his first book of essays, *The Frontier in American History* (1920). A dozen additional essays appeared in his *Significance of Sections in American History* (1932), which was awarded the Pulitzer prize in 1933. Earlier Turner had written *The Rise of the New West, 1819–1829* (1906) for the American Nation series. An incomplete manuscript was published posthumously as *The United States, 1830–1850: the Nation and Its Sections* (1935).

Turner's eminence rests on the enormous influence his ideas had on subsequent interpretation of U.S. history. Whereas religious liberty. slavery. English tyranny, nationalism and the rise of democracy had occupied his predecessors, Turner emphasized the impact of a wilderness environment on a transplanted civilization. He wrote that frontier individualism had from the very beginning of American history promoted democracy. Free land on the frontier, drawing men away from European influences! helped build a new Americanism. Frontier traits of self-reliance, individualism, restless energy, and "that buoyancy and exuberance that conies with freedom," left their imprint on society. With Jefferson. Jackson and Lincoln as leaders, Turner viewed western democracy as an effective force in American life.

"The significance of the frontier" is a phrase with fundamental implications that has, at times, been used in connection with the expanding frontiers of Australia. and many nations of the western hemisphere. Within the United States the phrase gave meaning to the history of every town. county and state, lifting local history from the confines of antiquarianism. Turner's disciples were captivated by the phrase, and some of them saw the frontier philosophy as the whole key to America's past. At Harvard, away from his Wisconsin homeland. Turner had tempered some of his earlier generalizations, thus giving evidence of flexibility of mind and integrity as a historical thinker.

It is difficult to pin point the essence of Turner's thinking on the subject of the frontier in United States history because there are modifications of the frontier hypothesis throughout his writings. He did stress the significance of free land, the importance of environmental influences, and the persistence of older customs as the frontier moved westward and pioneer sections went through a process of social evolution. Primitive at first, the frontier areas were eventually supplanted by a modern civilization with sectional variations, caused in large part by physiographic factors. The new civilization that emerged after about three centuries was distinctly different from the old; and this difference could be largely traced to the influence of the passing frontier.

Despite its early general acceptance by historians, the frontier hypothesis, especially the famous essay of 1893, made Turner the centre of a bitter historical controversy. Scholars nevertheless have generally accepted Turner's frontier hypothesis as a suggested interpretation, rather than as a theory, and thus have abandoned needless bickering.

Detailed examination of Turner's writings, correspondence and lecture notes taken in his classes, reveals the concept of multiple hypothesis as one of his main contributions. He had borrowed this idea from the distinguished geologist and president of the University of Wisconsin. Thomas C. Chamberlin. It was appropriate that Turner would think in terms of multiple causation in history. for his researches ranged beyond the social sciences into the natural sciences. Turner's provocative essays on sectionalism, predicated on this concept, completely revised the old view of uncomplicated rivalries between the north, south, and west in U.S. history. His penetrating analysis revealed intricate economic, social and geographical forces that divided the nation into a number of distinct sections or regions, and demonstrated that a federation of sections nourished a complex American spirit. Sectional rivalries for control of pioneer areas, Turner pointed out, gave clues to the development of America's political party history. Although western American history was Turner's field of specialization, he was willing to consider any interpretation of United States history, few of which he failed to suggest in his lectures or published works.

TURNER, HERBERT HALL (1861–1930), English astronomer who pioneered some of the procedures universally used in measuring astronomical photographs, was born at Leeds on Aug. 13, 1861. A student, and later a fellow, at Trinity college, Cambridge, Turner in 1884 was appointed chief assistant at the Royal observatory. Greenwich, where he remained until 1893, when he was appointed Savilian professor of astronomy and director of the University observatory at Oxford. He published more than 200 papers and essays on astronomical and seismological subjects and is best remembered for his enthusiasm in pushing to completion the Oxford. and other, zones of the astrographic catalogue; his introduction of standard co-ordinates in the reduction of astronomical photographs and a series of notes, light in vein, contributed monthly to the periodical, *Obseraatory,* under the heading "From an Oxford Notebook." He died in Stockholm, Swed., on Aug. 20. 1930. (O. J. E.)

TURNER, JOSEPH MALLORD WILLIAM (1775–1851), English romantic landscape painter and pioneer in the study of light, colour and atmosphere, was born on April 23, 177.5. in London, the son of a barber, William Turner: who was a native of Devonshire, and Nary Marshall. Both families were traders; nothing is known about Turner's mother except that she died insane in 1804.

Life and Training.— At the age of ten Turner mas sent to live with an uncle at Brentford, Middlesex. where he attended school. Several drawings in the Turner bequest are dated 1787, when he was 12, and these are sufficiently professional to corroborate the tradition that his father used to sell the boy's work to his customers. After some instruction under Thomas Malton, Turner entered the Royal Academy schools in 1789 and exhibited a water colour the following year n-hen he was only 15. He used to spend the summer holidays touring the country in search of subjects, and visited Oxford in 1783, Bristol in 1791 and Wales in 1792. His sketchbooks, filled with drawings to be worked up later into finished water colours for commissions or for exhibition, are preserved in the British museum. His early work is topographical in character, imitating the best masters of the day—Thomas Malton, Edward Dayes and Paul Sandby. In 1794 he began working for engravers, supplying designs for *The Copperplate Magazine* and *The Pocket Magazine.* Engraved views of picturesque ruins of castles and abbeys were much in demand at the time. In the winters he attended the evening sessions at the house of Thomas Monro, the doctor and connoisseur, who had treated John Robert Cozens during his last illness and owned a number of his drawings. Turner, Thomas Girtin and other young artists were employed at making copies or elaborations of his unfinished drawings. The influence of Cozens and of Richard Wilson helped to broaden Turner's outlook and revealed to him a more poetic and imaginative approach to landscape, which he pursued to the end of his career with ever-increasing brilliance.

From 1796 Turner began to exhibit oil paintings as well as water colours at the Royal academy. The first one. "Fishermen at Sea" (on loan to the Tate gallery, London), is a moonlight scene and was acclaimed by a contemporary critic as the work "of an original mind." In 1799, at the age of 24. Turner was elected an associate of the Royal academy and in 1802 he became an academician, a dignity he was to enjoy for nearly half a century. He took his duties seriously, attended academic functions regularly, was helpful and encouraging to other artists and left £20,000 to the academy in his will, but when he was appointed professor of perspective in 1808, his lectures are said to have been difficult to follow, and in 1838 he resigned from this office.

His travels in 1797 took him to Yorkshire and the Lake district. in 1798 to Wales again, and in 1801 to Scotland, places he nas to revisit frequently in later years. He was now overwhelmed with commissions and the success of his career was assured By 1800 he had taken a studio at 64 Harley street. London, and later his father came to live with him and devoted the rest of his life to serving as a studio assistant and general agent. in fact giving his son every possible domestic and business help In 1804 Turner opened his private gallery. where he continued to show his latest work for many seasons. though toward the end of his life admission was difficult to obtain. As he never married, had no expensive habits and devoted his time entirely to his art. he was able to amass a considerable fortune. In order to be able to paint undisturbed he became secretive about his residence In 1812 he moved to Hammersmith and later built himself a house at Twickenham, Sandycombe lodge, uhich still stands. His father's death in 1829 broke up his domestic arrangement. At the end of his life he lived in Chelsea under the assumed name of Booth and was looked after by his old Margate landlady.

Development of his Painting.— -In 1802 Turner made his first journey to the continent. The crossing to Calais was rough and he has left a vivid record of his experience on arrival in his picture "Calais Pier" (National gallery, London), a composition in which he tried to rival the Dutch marine painters. In Paris he made detailed notes in the Louvre, where all the paintings brought from Italy by Napoleon were then displayed. He filled a sketchbook with copies and criticism of the paintings, showing that his taste was for the great Venetians and for Poussin, but not for Rubens, whose landscapes struck him as "one continual glare of colour."

From Paris he proceeded to Lyons, Grenoble. Geneva, around Mont Blanc to Courmayeur and Aosta, over the St. Bernard pass to Vevey, then to Interlaken, the St. Gothard pass. Zurich, Schaffhausen and back to Paris through Strasbourg and Nancy. He made over 400 drawings during the tour and continued for many years after to paint pictures of scenes that had impressed him, the most important being. three pictures of Bonneville. Savoy (1803 and 1812); "The Festival at Mâcon" (1803, Sheffield); water colours of the "Devil's Bridge" and the "Falls of Reichenbach" (Bedford); "The Fall of the Rhine at Schaffhausen" (1806, Boston. Mass.) and "Snowstorm: Hannibal Crossing the Alps" (1812, Tate gallery). His figure compositions. "Venus and Adonis' (*c.* 1803. Sir Raymond Quilter) and "The Holy Family" (1803 Tate gallery), show that he tried his hand in the Venetian manner.

The methodic endeavour to master every style he admired and the ease with which he accomplished this are seen in many of his early sea pieces in which he surpasses the Dutch marine painters, and in the exercises in the style of Claude Lorrain culminating in '(Dido Building Carthage" (1815), which he bequeathed to the National gallery together with "Sun Rising Through Vapour" (1807) on condition they were hung beside his two favourite Claudes. Other instances of similar rivalry are "Aeneas and the Sybil—Lake Avernus" (*c.* 1803) recalling Wilson, "The Garden of the Hesperides" (1806) recalling Poussin, a series of genre subjects such as "The Blacksmith's Shop" (1807) in the style of David Teniers and Sir David Wilkie (all at the Tate gallery) and "Dordrecht" (1818) in the style of Albert Cuyp (Farnley hall, Yorkshire).

In 1805 Turner exhibited "The Shipwreck" (Tate gallery), which was purchased by Sir John Leicester and was the first of many works to be engraved by Charles Turner. A list of subscribers to the plate is preserved in one of the "Shipwreck" sketchbooks and shows that by this time Turner had a wide public among the nobility and collectors as well as among fellow artists. This was the year of the battle of Trafalgar, and when the "Victory" returned with the body of Nelson on board, Turner went down the Thames to sketch the flagship and collect material for the picture of "The Battle of Trafalgar"—usually known as "The Death of Nelson"—(1806–08, Tate gallery). In 1824 he completed a larger picture of the same subject for King George IV, now in the National Maritime museum. Greenwich.

Engraved Work.——In 1807 Turner first began his great enterprise of publishing a series of plates known as the *Liber studiorum.* This may have been suggested by the success of the publication in 1777 of R. Earlom's engravings of Claude's *Liber veritatis,* but the purpose was quite different. Claude's book of drawings was kept as a record of pictures he had sold. Turner's aim was to perpetuate the great variety and range of his work; some of the subjects were taken from existing paintings and water colours. others were specially designed for the *Liber.* The publication was issued in parts consisting of five plates each, covering all the styles of landscape composition, such as historical, architectural, mountainous, pastoral and marine. The first part appeared in June 1807 and the last in 1819, when Turner evidently lost interest in the project and abandoned it. He had employed several engravers. including F. C. Lewis. Charles Turner and William Say, had supervised the work personally at every stage, etched some of the plates himself and made innumerable preparatory drawings. Though originally planned to consist of 100 plates, only 71 were in fact published. The technique was a combination of etching and mezzotint. In 1823 steel engraving superseded the copper plate and Turner embarked on a new project, *The Rivers of England,* for which he designed 16 plates. Other publications to which he contributed were W. B. Cooke's *Southern* Coast (1814–26), *England and Wales* (1829–38), Sir Walter Scott's *Provincial Antiquities* (1826) and *Works* (1833–34), Samuel Rogers' *Italy* (1830) and *Poems* (1834) and *The Rivers of France* (1833–35). At the height of his career Turner was regarded as the most desirable illustrator, his journeys were usually paid by the puhlishers and he received from 10–25 guineas for each subject. These include some of his most intricate and delicate water colours.

Paintings of the Middle Period, 1810–1835.—During the second decade Turner was much in demand as a painter of castles and country seats for their owners. Two examples are "Linlithgow Palace" (1810, Liverpool) and "Somerhill" (1811, Edinburgh). He continued to excel in marine painting, the two most ambitious works being "Spithead" (1808–09) and "The Wreck of a Transport Ship" (1810). The earl of Egremont had bought a sea piece in 1802 and became a regular patron and close friend. In later years Turner was often invited to stay at Petworth, Sussex. He probably paid his first visit to his other great friend and patron, Walter Fawkes, at Farnley hall, Yorkshire, in 1810, and used to spend some weeks staying there nearly every summer till the death of Fawkes in 1825.

In 1811 Turner made an extensive tour of Devonshire, Cornwall and Somerset and in 1813 he returned to Devon. In 1815 and 1816 he toured Yorkshire again for the purpose of supplying 20 water colours to illustrate T. D. Whitaker's *History of Richmondshire.* The following year he went to the continent, primarily to visit the field of Waterloo, of which he afterward painted a dark and romantic picture, then up the Rhine, as far as Mainz, returning through Holland. In 1818, 1822 and 1831 he went to Scotland.

His painting during these years was becoming increasingly luminous and atmospheric in quality. Even when painting actual places, as in the views of "Greenwich," "Windsor" (both 1809), "St. Mawes" (1812), "Abingdon" (1809) and "Oxford" (1811), the hard facts of topography are diffused behind pearly films of colour; pictures like "Frosty Morning" (1813) and "Bligh Sands" (1815) are entirely based on effects of light.

Turner had begun the series of fanciful Carthaginian subjects in 1815 with "Dido Building Carthage" and was to continue producing variations on that theme to the end of his life. By appending long poetic quotations either from James Thomson's *Seasons,* Byron, Milton. Shakespeare, Pope or from his own composition, *Fallacies of Hope,* he showed that he regarded the poetic interpretation as of paramount importance. Among the most ethereal dreams of this period are "The Lake of Geneva" (1810, Los Angeles County museum), "Crossing the Brook" (1815) and "-England; Richmond Hill, on the Prince Regent's Birthday" (1819, Tate gallery), one of his largest and most ambitious pictures. As if he felt that he had done all he could with the beauty of his native country, he set out in the summer of 1819 on his first visit to Italy. He spent three months in Rome, visited Naples Florence and Venice and returned home in midwinter. During his journey he made about 1,500 drawings and in the next few years he painted a series of pictures inspired by what he had seen. They show a great advance in Turner's style, particularly in the matter of colour, which becomes purer, more prismatic, with a general heightening of key. A comparison of "The Bay of Baiae" (1823) with any of the earlier pictures reveals a far more iridescent treatment resembling the transparency of a water colour. The shadows are as colourful as the lights and he achieves contrasts by setting off cold and warm colours instead of dark and light tones.

During the 1820s tours of the continent alternated with visits to various parts of England and Scotland. In 1821 he painted a series of delicate water colours of the Seine on blue paper; in 1825 he revisited Holland and Belgium, and the following year the Meuse, Moselle and the Loire. Notable among the pictures of this period are the views of "Cologne," "Dieppe" and "Mortlake Terrace" in the Frick collection, New York. In 1828 he went to Italy again and held an exhibition of some of his pictures in Rome. The previous year he had stayed with John Nash, the architect, at Cowes and painted the brilliant sketches of the regatta now at the Tate gallery. One of the finished pictures is at the Victoria and Albert museum. London. The splendid sketches of Petuorth probably belong to the early 1830s.

Late Works. — In the last 15 years of his life, Turner revisited Venice, Switzerland, Germany and France. Observers have recorded the untiring energy with which he sketched while abroad, and the drawings numbering nearly 19,000 in the Turner bequest bear witness to this labour. While his earlier paintings and drawings show the most accurate observation of architectural and natural detail, in his later work this is sacrificed to general effects of colour and light with the barest indication of mass. His composition tends to become more fluid, suggesting movement and space; some of his paintings are mere colour notations, barely tinted on a white ground, like "Norham Castle" and "Boat Between Headlands." It is reported that Turner used to send canvases in this state to the academy and add the detail, required by public taste. on varnishing day. This may account for the large number of slightly brushed-in canvases found in his studio at the time of his death. Or he may have realized that additional elaboration could only ruin the beautiful effect he had achieved. These colourful abstractions are far more appreciated now than the romantic subjects he exhibited.

Apart from fanciful reconstructions of ancient Rome and the scintillating Venetian subjects, which found ready purchasers in his day, the outstanding examples of his late work are: "Ulysses Deriding Polyphemus" (1829); "Hero and Leander" (1837), a daring composition of sunset and moonlight with visions of spirits rising from the waters; "The Fighting Téméraire Towed to Her Last Berth" (1839), a tribute to the passing age of sail; and "Rain, Steam and Speed" (1844)—all in the national collections. Actually the first picture to be hung in the National gallery was the opalescent "Venice From the Steps of the Europa" (1842), bequeathed by Robert Vernon in 1847 while Turner was still alive. Turner's preoccupation with the elements of fire and water appears in two pictures of the "Burning of the Houses of Parliament" (now in Cleveland and Philadelphia), in the large sketch "Fire at Sea" (National gallery) and in "Rockets and Blue Lights" (1840, Clark Art institute, Williamstown, Mass.). The "Snowstorm" (1842, National gallery) was painted from observations made when Turner crossed from Harwich in such a wild storm that he had to be lashed to the mast for four hours and did not expect to survive. The last pictures he exhibited in 1850 show some falling off of his powers, though the colour is still radiant.

Turner died in London on Dec. 19, 1851, and was buried in St. Paul's cathedral. By his will he intended to leave his fortune of £140,000 to found a charity for "decayed artists," and his pictures to the nation, on condition that a gallery was built to exhibit them. As a result of protracted litigation with his rather distant relatives, the money reverted to them, while the pictures and drawings became national property. The first selection shown to the public included only 34 paintings. Since then many more have ,been put on view, but it was not until 1908 that a special gallery was built by Sir Joseph Duveen to house them at the Tate gallery. All the drawings and water colours were transferred to the British museum for safety after the Thames flood of 1928, when the storerooms at the Tate gallery were inundated. At the time of his death. Turner's gallery was in such a state of neglect that many of his paintings were said to be mere shadows of what they had been originally. Fortunately the sketches. which were not then considered worthy of exhibition, have escaped the hands of unskilled restorers and have retained their original freshness and spontaneity.

The immense reputation that Turner enjoyed at the end of his life and for over half a century after was partly due to the enthusiastic championship of Ruskin, who published *Modern Painters* to prove Turner's superiority to all previous landscape painters and to extol his accurate rendering of natural appearance. The present attitude toward Turner is somewhat different. In his pursuit of light and pure colour Turner had anticipated the achievements of the French Impressionists, and when Monet and Pissarro saw his work in London in 1870 they were greatly interested, although few of his truly impressionist sketches were shown at that time. In the 1920s, when the Postimpressionist cult was at its height through the writings of Roger Fry, Turner's reputation suffered a temporary eclipse, but prices remained high in the market. In 1948. a representative collection of his work was shown at the Venice Biennale and afterward in the principal capitals of Europe, and abstract painters began to find a common purpose with their own in some of his late colour compositions. Thus each generation has been able to discover new sources of inspiration in his work. The important exhibition "Turner in America" held in Indianapolis in 1955 further strengthened his prestige, and the prices at the Lennox library sale in New York in 1956, when "Staffa: Fingal's Cave" (1832) reached $47,000 and "Fort Vimieux" (1831) $56,000, caused a sensation. The record price remains 29,000 guineas, paid in 1927 for "Venice: Dogana and Salute" (1843) at the Ross sale, while the highest price for a water colour was 11,000 guineas paid for "The Lake of Lucerne" at Christie's in 1959. *See* also PAINTING: *Great Britain;* WATER-COLOUR PAINTING; LANDSCAPE PAINTING.

TURNER, NAT (1800–1831), Negro leader of a slave insurrection in Virginia. known as the "Southampton insurrection," was born in Southampton county. Va., in 1800. From his childhood he claimed to see visions and hear voices, and he became a Baptist preacher of great influence among Negroes. In 1828 he confided to a few companions that a voice from heaven had announced that "the last shall be first," which was interpreted to mean that the slaves should control.

On the night of Aug. 21, 1831, with seven companions, he entered the home of his master, Joseph Travis, and murdered the inmates. After securing guns, horses and liquor they visited other houses, sparing no one. Recruits were added, in some cases by compulsion, until the band numbered about 60. About noon on Aug. 22 they were scattered by a small force of whites, hastily gathered. Troops were hurried to the scene, and the Negroes were hunted down. In all 13 men. 18 women and 24 children had been butchered. Turner was captured on Oct. 30 and was tried and hanged, having made, meanwhile, a full confession. Nineteen of his associates were hanged and 12 were sent out of the state. The insurrection led to the enactment of stricter slave codes.

TURNHOUT, town in the province of Antmerp, Belg., 26 mi. N.E. of that city. Pop. (1955 est.) 34.061. It carries on an active industry in cloth, playing cards and other manufactures. There is a leech breeding establishment.. The town hall was formerly a palace of the dukes of Brabant. Two miles west of Turnhout is the curious penal or reformatory colony of Merxplas. The system of this establishment is to allow certain approved prisoners to follow their usual occupations within a defined area.

TURNIP (*Brassica rapa*), a hardy biennial, of the family Cruciferae. which has been cultivated from a remote period for its fleshy roots. The tender growing tops are also used widely as a green vegetable. The so-called "root" is formed by the thickening of the primary root of the seedling together with the base of the young stem (hypocotyl) immediately above it. The great mass of the "root" consists of soft "wood" developed internally by the cambium layer and composed mainly of thin-walled, unlignified, wood-parenchyma.

The stem remains short during the first year, the leaves forming a rosettelike hunch at the top of the root; they are grass green and bear rough hairs. In the second season the bud in the centre of the rosette forms a strong erect branched stem bearing somewhat glaucous smooth leaves. The stem and branches end in corymbose racemes of small, bright yellow flowers, which are succeeded by smooth, elongated, short-beaked pods.

The turnip probably originated in middle and eastern Asia and by cultivation has spread throughout the temperate zone.

The varieties of turnip are classified according to their shape as (1) long varieties, with a root three or more times as long as broad; (2) tankard or spindle-shaped varieties. with a root about twice as long as broad; (3) round or globe varieties with an almost spherical root; (4) flat varieties with a root broader than long; there are also many intermediate forms. Turnips are also grouped according to the colour of the upper part of the root, which comes above ground, and according to the colour of the flesh, which is white or yellow.

The yellow-fleshed varieties, which are not hybrids between the turnip and Swedish turnip, are more robust, of slower growth and superior feeding value to the white-fleshed turnips and are less injured by frost. The foliage turnip produces no enlarged root but only a profusion of leaves which are used as a potherb. A variety of this form called Seven-Top is widely grown in the southern United States.

The Swedish turnip (*Brassica napobuassica)* or rutabaga differs from the turnip proper in having the first foliage leaves glaucous, not grass green, in colour and the later leaves smooth and glaucous; the root bears a distinct neck with well-marked leaf scars. the flesh is firmer and more nutritious. and the roots keep much better during winter. The white-fleshed forms have a rough, green skin, firm white flesh and are of irregular form. The flowers are of a bright canary colour. The yellow-fleshed Swedish turnips have a firm yellow flesh, a smooth skin of a green. purple or bronze colour. The flowers are buff yellow or pale orange. The Swedish turnip has 38 chromosomes, the true turnip 20.

Cultivation and Trade.—Both the turnip and rutabaga are cool-season crops. The rutabaga grows less rapidly, requiring a longer season. In the lower latitudes turnips are sown either in early spring or in late summer, developing rapidly enough to make a crop before extremes of summer or late fall weather occur. Rutabagas, however, are sown only as a main or late crop and are more hardy to cold. Rutabagas are little grown in the United States except in the northernmost states. but are grown extensively in Canada, Great Britain and northern Europe. Both species are grown as livestock feed in northern climates but in the U.S. are grown almost entirely as a vegetable.

Extensive culture of turnips as a forage crop for sheep and cattle began in Great Britain about 1724 and increased rapidly because it fitted so well into the system of crop rotation and stock feeding that was developing in the 18th century. Turnips afforded large quantities of winter feed, thus increasing the conversion of straw into barnyard manure for the improvement of the lighter soils. They are generally grown in rotation with grain crops and are well adapted to clean row culture designed to free the land of weeds that interfere with grain production. Animal manures are generally applied, although chemical fertilizers alone may be used.

White turnips are often sown broadcast, in both Europe and America, and neither cultivated nor thinned. Rutabagas and yellow turnips are usually sown in rows about 2 ft. apart. When large stock-feeding varieties are grown, they are thinned to about 10 in. apart in the row; but when rutabagas or turnips are grown for human food they are thinned to only 3-6 in. apart in the rows.

Although considerable quantities of these species are grown in home and market gardens: and are even shipped long distances in the United States, the total volume of trade in them remains comparatively small. (V. R. B.)

TURNSTONE (*Arenaria interpres*), a shore bird found on the coasts of every part of the world, but breeding only in the high arctic. About nine inches long, it is allied to the plovers (*q.v.*). The turnstone has short legs and a heavy build. The white face. striped with black, the black gorget and white band on the wings are characteristic features. The sexes are alike in appearance. The bird feeds on small crustacea, worms, etc., which it seeks under stones. The nest contains four olive-green eggs, closely blotched with brown. Both male and female incubate.

TURNU SEVERIN, a town of Rumania. in the region of Craiova, on the main Walachian railway, and on the left bank of the Danube river! below the Iron Gates cataracts. Pop. (1956) 31,559. It is a modern commercial town, having a school of arts and crafts, several churches, and large government yards for the building of river steamers, lighters and tugboats. There is a considerable trade in livestock, preserved meat, petroleum and cereals. The town! which was originally called Drobetae by the Romans, took its later name of Turris Severi, or the "Tower of Severus," from a tower built to commemorate a victory over the Quadi and Marcomanni by the Roman emperor Severus (A.D. 222–235). Near Turnu Severin are the remains of the celebrated Trajan's bridge. the largest in the Roman empire, built in A.D. 103 by Apollodorus of Damascus.

TURNVEREIN, an institution founded as a German unifying force by Friedrich Ludwig Jahn (*q.v.*), who set up the first public outdoor gymnasium in Berlin in 1811. In the German revolution of 1848, the turners sided with the political factions which revolted against monarchistic rule. Many turners came to the United States where *Turnverein* took root. The Cincinnati Turngemeinde, established in 1848, is the oldest in the U.S. The U.S. turners have sponsored an educational program combining physical and mental development to strengthen deniocracy and citizenship and to improve cultural opportunities. (J. E. Br.)

TURPENTINE, the oleoresins which exude from some conifers — such as *Pinus* sylvestris — and from the terebinth tree, Pistacia terebinthus. It was to the product of the latter, now known as Chian turpentine, that the term was first applied. The tree is a native of the islands and shores of the Mediterranean, passing eastward into central Asia; but the resinous exudation found in commerce is collected in the island of Chios. Chian turpentine is a tenacious semifluid transparent body, yellow to dull brown in colour, with an agreeable resinous odour and little taste. On exposure to air it becomes dry, hard and brittle. Turpentines are semifluid bodies, consisting of resins dissolved in turpentine oil, the chief constituent of which is pinene. They are largely used in the arts, being separated by distillation into rosin or colophony (see ROSIN) and oil or spirit of turpentine.

Crude or common turpentine is the commercial name for the oleoresin yielded by several coniferous trees. both European and American. The principal European product (Bordeaux turpentine) is obtained from the cluster pine, *Pinus* pinaster, in the Landes *département* of France. Crude turpentine is further yielded by the Scotch fir, P. *sylvestris,* and by the Corsican pine, P. laricio. In the United States the turpentine-yielding pines are the long-leaf pine, P. palustris, and slash pine, P. caribaea, both inhabiting North and South Carolina, Georgia, Florida, and Alabama. Venice turpentine is yielded by the larch, Larix *europaea;* Strassburg turpentine is obtained from the bark of the silver fir. Less known turpentines are obtained from the mountain pine, P. *pumilio,* the stone pine, *P.* Cembra, the Aleppo pine, P. *halepensis,* etc. The so-called Canada balsam, from Abies balsamea, is also a true turpentine.

Turps. — Oil of Turpentine, or Turps, as a commercial product is obtained from all or any of these oleoresins, but on a large scale only from crude turpentine. The essential oil is rectified by redistillation with water and alkaline carbonates, and the water which the oil carries over with it is removed by a further distillation over calcium chloride. Oil of turpentine is a colourless, oily liquid, with a strong odour and a hot disagreeable taste. It begins to boil at about 155° C., and its specific gravity is between 0.860 and 0.880. It rotates the plane of polarized light either to right or left in varying degrees according to the species of tree, the American product from P. palustris being dextrorotatory and P. caribaea levorotatory and the French levorotatory. It is almost insoluble in water, is miscible with absolute alcohol and ether, and dissolves sulfur, phosphorus, resins and caoutchouc. On exposure to the air it dries to a solid resin, and absorbing oxygen gives off ozone. Agitated with successive quantities of sulfuric acid and distilled in a current of steam, it yields terebene, a mixture of dipentene and terpinene mainly, which is used in medicine. Chemically, oil of turpentine is a mixture of terpenes (*q.v.*). It is largely used in the preparation of varnishes and as a medium by painters in their flat colours.

Pharmacology and Therapeutics. — Oil of turpentine (*Oleum* terebinthinae) is used internally as an anthelmintic to kill tapeworm. Externally it acts as a rubefacient, an irritant and a counterirritant. It is an antiseptic and, in small quantities, a feeble anesthetic. It is absorbed by the unbroken skin. It is largely employed as a counterirritant, the pharmacopoeia1 liniments being useful in myalgia, bronchitis, "chronic fheumatism" and pleurisy. In large doses oil of turpentine causes purging and may induce hemorrhage from the bowel or kidneys. It is absorbed unchanged and has a marked contractile action upon the blood vessels. It is a nervous depressant leading even to coma and total abolition of reflex action. The drug is excreted partly by the bronchi and partly in the urine. Glycuronic acid also appears in the urine. It may give rise to an erythematous rash. It must not be given to the subjects of Bright's disease, Its chief uses are as constituents of fomentations and enemata and as a local disinfectant in bronchiectasis (*q.v.*). Old turpentine and French oil of turpentine are antidotes to phosphorus, forming turpentine-phosphoric acid, which is inert. (A. D. J.)

TURPIN, archbishop of Reims. long regarded as the author of the legendary *Turpini Historia* Karoli *Magni* et Rotholandi, and one of the 12 peers in the entourage of Charlemagne in some chansons de geste (*q.v.*), is undoubtedly to be identified with the historical Tilpin, monk of Saint-Denis and archbishop of Reims (c. 751–794 or 800), successor to Milo, who had been intruded into the see by Charles Martel. Sources for his career are his third successor. Hincmar, and Flodoard, 10th-century monk of Reims.

The *Historia* Karoli *Magni* et Rotholandi was composed toward the middle of the 12th century by an ecclesiastic to assist the church's battle to Christianize society. to stimulate national pride by glorifying Charlemagne and to entertain and edify. To win acceptance of his work, the author fraudulently invested it with the authority of Pope Calixtus II (d. 1124). The *Historia* became part of the Codex *Calixtinus* (or Liber Sancti Jacobi), itself compiled to propagandize St James's shrine at Santiago de Compostela. Manuscripts that preserve it in Latin, Old French and Provencal number in the hundreds. Within the first 20, perhaps the first 10, years of the 13th century, six distinct translations of it into Old French appeared. It became a source for some historians writing on Charlemagne (but was rejected by others) and for epics and romances. See also CHARLEMAGNE LEGENDS; ROLAND. LEGEND OF.

See A. Hämel's review of C. Meredith-Jones's 1936 edition in *Speculum,* 13:248–252 (1938); *R.* N. Walpole, ***Philip*** *Mouskés and the Pseudo-Tuupin Chronicle* (1947). (J. N. G.)

TURPIN, RICHARD (DICK) (1706–1739), English robber, was born in 1706 at Hempstead, near Saffron Walden. Essex, where his father kept an alehouse. He was apprenticed to a butcher, but, having been detected at cattle stealing, joined a notorious gang of deerstealers and smugglers in Essex. When the gang was broken up Turpin went into partnership with Tom King, a well-known highwayman. To avoid arrest he finally left Essex for Lincolnshire and Yorkshire, where he set up under an assumed name as a horse dealer. He was convicted at York assizes of horse stealing and hanged on April 7, 1739. Harrison Ainsworth, in his romance Rookwood, gives a spirited account of a wonderful ride by Dick Turpin on his mare, Black Bess, from London to York. But as far as Turpin is concerned the incident is pure fiction. A somewhat similar story was told about a certain John Nevison, known as Nicks, a well-known highwayman in the time of Charles II, who to establish an alibi rode from Gad's Hill to York (some 190 mi.) in about 15 hours.

TURQUOISE, a mineral extensively used as a gem and ornamental stone for more than 80 centuries. As early as 3400 B.C. it was obtained from the Sinai peninsula, Egypt, in what probably was the world's first important hard-rock mining operation. Material of excellent colour later was mined in Persia and brought into Europe through Turkey; this probably accounts for the mineral name (turquoise means Turkish).

Turquoise is a complex phosphate of aluminum and copper with the general formula $CuAl_6(PO_4)_4(OH)_8.4H_2O$. Iron commonly substitutes for a little of the aluminum, and an excess of water is present in some varieties. The mineral ordinarily occurs as dense, cryptocrystalline to finely granular nodules, seams and encrustations. Its hardness is 5 to 6, its specific gravity 2.6 to 2.8.

The colour of turquoise ranges from blue through various shades of green to greenish- and yellowish-gray. A delicate sky-blue, which provides an attractive contrast with precious metals, is most valued for gem purposes. The mineral is opaque except in the thinnest splinters, takes a fair to good polish, and has a feeble, faintly waxy lustre. The lustre tends to become greasy and the colour more greenish and grayish in the presence of perspiration and various acids, also with long-term exposure to sunlight, heat or dry air. Such deterioration is most pronounced in porous varieties.

A secondary mineral deposited from circulating waters, turquoise is found chiefly in arid regions, generally in fractured volcanic and sedimentary rocks. Most of the world production has come from Iran? Egypt, Turkestan, Abyssinia, Australia, Siberia, Germany, France, Mexico and the United States. Iran has yielded material of finest quality, principally from the Ali-Mirsai-Kuh mountains near Nishapur, in the province of Khurasan. Numerous deposits in Arizona, California, Colorado, Nevada, New

Mexico and Utah were opened centuries ago by the American Indians, and some are still being worked. Best known are mines in the Cerrillos hills, near Santa Fe. N.M.

For most gem uses. turquoise is cut *en cabochon,* with a low convex upper surface. Irregular pieces also are set in mosaics. with or without jasper, malachite, obsidian. pyrite and other gem materials. "Turquoise matrix." any natural aggregate of turquoise with limonite or other substances. also is extensively used.

A little turquoise occurs as a replacement of bones and other fossil matter. However, most "bone turquoise." also known as odontolite and "fossil turquoise." is merely hone, teeth or ivory stained by vivianite (iron phosphate) or copper compounds. *See* also GEM. *(R.*H. J.)

TURRETINI (TURRETIN), the name of three Swiss Reformed churchmen and theologians.

BENOIT TURRETINI (1588–1631), was born at Zürich Nov. 9, 1588, was ordained a pastor in Geneva in 1612 and became a professor of theology in 1618. In 1620 he represented the Genevan church at the national synod of Alais. when the decrees of the synod of Dort were introduced into France; in 1621 he was sent on a successful mission to the states-general of Holland and to the authorities of the Hanseatic towns, with reference to the defense of Geneva against threatened attacks of the duke of Savoy. Be published in 1618–20 a two-volume defense of the Genevan translation of the Bible, *Eine Verteidigung der genfer Bibelübersetzung.* He died March 4. 1631.

FRANÇOIS TURRETINI (1623–1687), son of the preceding. was born at Geneva Oct. 17, 1623. He became pastor of the Italian congregation in Geneva in 1647; aiter a brief pastorate at Lyons he again returned to Geneva as professor of theology in 1653. He was one of the most influential supporters of the *Formula Consensus Helvetica* and of the particular type of Calvinistic theology which that symbol embodied. His *Institutio theologicae elencticae,* 3 vol. (1680–83) passed through frequent editions. He died Sept. 28. 1687.

JEAN ALPHONSE TURRETINI (1671–1737). son of the preceding, was born at Geneva Xug. 13, 1671. After travel in Holland, England and France he was received into the Vénérable Compagnie des Fasteurs of Geneva in 1693. Here he became pastor of the Italian congregation, and in 1697 professor of church history and later (1705) of theology. During the next 40 years he advocated a more liberal theoiogy. and it was largely through him that the rule obliging ministers to subscribe to the *Formula Consensus Helvetica* was abolished. He died Slay 1. 1737.

TURRIFF, a small burgh of Aberdeenshire, Scot.. 34 mi. N.N.W. of Aberdeen by road. I'op. (1951) 2.994. The old town dates from the 6th century. The Wars of the Covenanters began with the skirmish known as the Trot of Turriff (1639). A prosperous market town and a centre of the Aberdeen-Angus cattle trade. Turriff has extensive agricultural engineering works.

TURTLE, common name for members of an ancient order of reptiles chiefly characterized by a shell that encloses the vital organs of the body and more or less protects the head and limbs. Although there has been much confusion over the scientific as well as the common name of the group, most scientists now accept the earlier term Chelonia rather than the later ones Testudines and Testudinata. Two common names are in wide use, tortoise and turtle. "Tortoise" is applied in the British isles to all members of the group except the few marine species. all of which have paddle-shaped limbs. '"Turtle" has long been much more broadly applied in the United States. with the addition of "terrapin" for some edible species. Usage both in the British isles and in the United States left the group without a general name comparable to "bird" or "mammal." However. the American Society of Ichthyologists and Herpetologists standardized the common nnnies of the reptiles of the United States. assigning "turtle" to all of those with a shell. "tortoise" being reserved as a secondary name for the slow-moving terrestrial species, such as those of the genera *Testudo* and *Gopherus.*

Origin and **Evolution.**—The evolution of the turtle is one of the most remarkable in the history of all vertebrates. Unfortunately, the origin of this highly successful order is obscured; by the middle of the Triassic period (about 175,000,000 years ago) its members were already numerous and in possession of the basic turtle characteristics. The links between turtles and the cotylosaurs (the most primitive reptiles) from which turtles probably sprang are almost entirely lacking. The most likely missing link is a small. toothed reptile (*Eunotosaurus*) of the Permian period of southern .Africa.

While some reptiles flourished and vanished (as the dinosaurs), others persisted. some as once successful groups, and a few as initiators of expanding groups (snakes and lizards). The turtles, however. have plodded a stolid and steady course through evolutionary time, changing very little in basic structure.

Structure. — The protective shell, to which the evolutionary success of turtles is largely attributed, is a case of bone covered by horny shields. Plates of bone are fused with vertebrae, ribs and elements of shoulder and hip girdles. There are many shell modifications from family to family?some of them extreme.

At its highest development, the shell is not only surprisingly strong but also completely protective. For example. a box turtle (*Terrapene*) of North America can readily support a weight 200 times greater than its own; a man with proportionate supporting power could bear up two large African elephants. In a closed position the lower shell (plastron) can fit so snugly against the upper (carapace) that a knife blade cannot be inserted between them.

This protection was acquired by the development of structural peculiarities. two of which are especially worthy of mention. As a rule. the limb girdles of vertebrates lie outside the rib box; in turtles, however, they are partly within it. This is accomplished by a fusion of the developing ribs with the growing shell, which carries the ribs to a position partially within the rib box.

In man the ribs play an important part in the chest expansion that enables him to breathe. The turtle's ribs are immovable. and so the task of chest expansion has been transferred to abdominal muscles; two muscles enlarge the chest cavity for inspiration, and the others press the organs against the lungs to force the air out. Some aquatic species have additional methods of breathing: the vascularized mucous membrane of the cloacal region or of the throat can function like the gill of a fish. Such accessories to ordinary respiration enable turtles to lie quietly submerged for hours or even days.

The vertebral column, with very little to support, underwent drastic modification. The trend in turtles. in contrast to that in most other reptiles, has been to reduce the number of vertebrae. The ability to retract the head into the shell is related to the retention of eight specialized vertebrae. The result is that the neck has almost as many vertebrae as does the central part of the column (between neck and tail). The manner in which the neck bends is of importance in classification.

Natural History. — Turtles have been toothless for more than 150,000,000 years; the teeth of even the Triassic turtles were oddly placed, having been as far as is known, confined to the palate. In some modern types the moderately sharp and jagged edges of the horny jaws function as teeth. Food is chewed, the claws of the forelimbs often assisting in manipulation, until it is reduced to fragments that can be swallowed.

Most turtles prefer a varied diet. Fibrous parts of plants are avoided because the jaws are not sharp enough to cut well and are entirely incapable of grinding. Small invertebrates such as worms, snails, slugs. insects, thin-shelled bivalves and crayfishes and other crustaceans make up the bulk of the animal food. Large aquatic turtles are able to catch fishes and occasionally a few birds and small mammals.

Turtles, like other reptiles. can survive long fasts, being able to live on weekly or even monthly feedings; however, when food is readily available, they may eat frequently and grow very fat. The rate of digestion varies with the temperature. In the wild, they probably maintain a relatively constant temperature by retiring to suitable surroundings; this may require constant activity. Turtles drink readily, and some store water in cloacal bladders. an ability that allows them to survive long periods of drought.

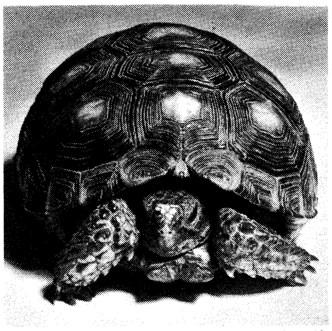
COMMON TURTLES OF TEMPERATE NORTH AMERICA

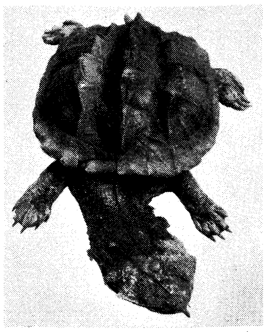
Top two rows: Baby turtles, of three **types** commonly sold as pets, showing (top) plastron and (second row) shell **of** (left to right) map turtle (***Graptemys*** geographica), **Mississippi** map turtle (G. ***kohni***) and red-eared turtle (***Pseudemys scripta elegans***)

Third row: (Left) box turtle (Terrapene ***carolina***); **(right)** ornate box turtle (T. ornata ***ornata***)

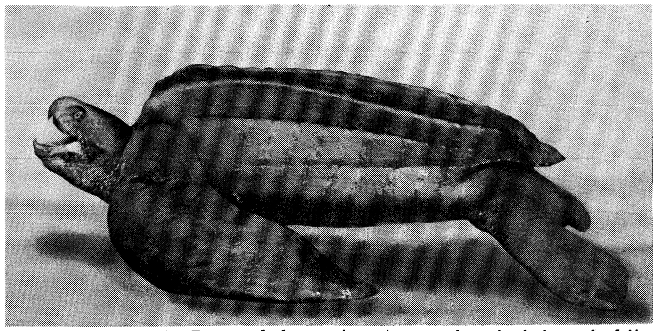
Bottom row: (Left) common snapping turtle (***Chelydra serpentina serpentina***); (right) painted turtle (***Chrysemys*** picta)



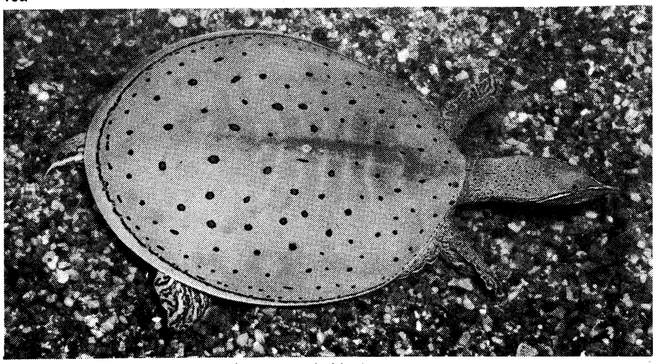
Texas tortoise (*Gopherus berlandieri*), a gopher tortoise of North America



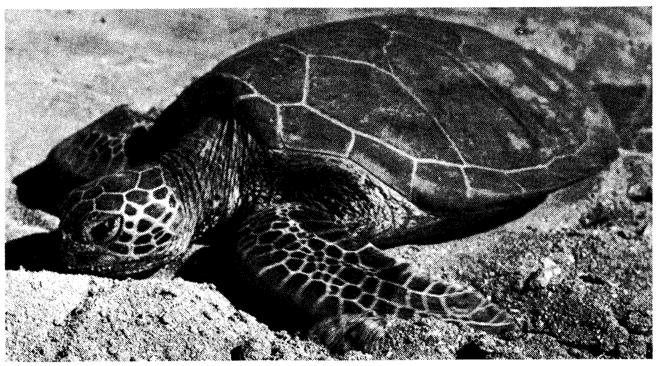
Matamata (*Chelys fimbriata*), a South American fresh-water turtle



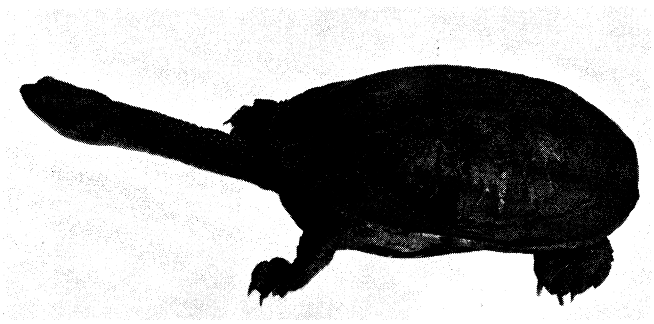
Atlantic leatherback (*Dermochelys coriacea*), **a marine giant, largest of the** living turtles



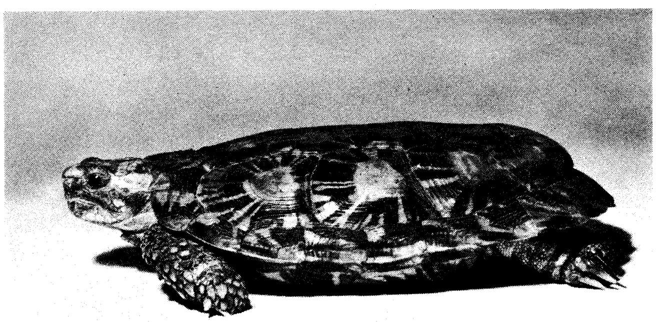
Spiny softshell turtle (*Trionyx spinifer*), widely distributed in U.S. and adjacent parts of Mexico



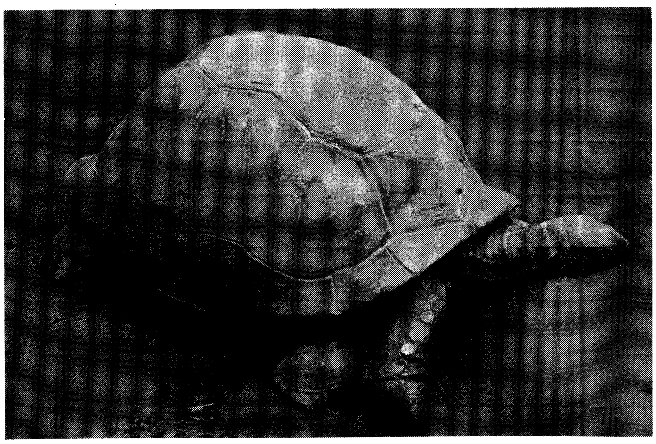
Green turtle (*Chelonia mydas*), large marine turtle of both the Atlantic and Pacific oceans



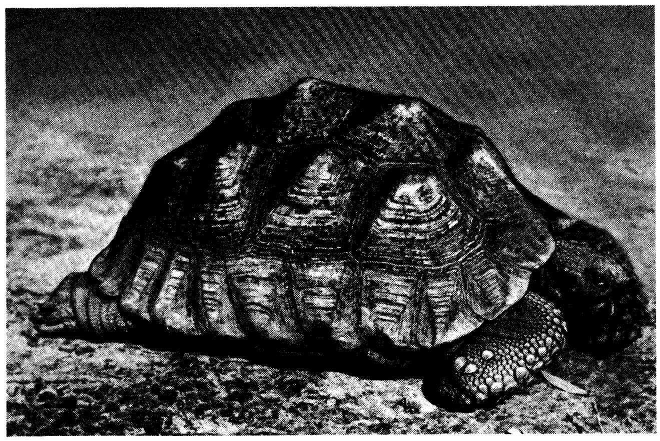
Australian snake-necked turtle, *Chelodina longicollis*



Pancake, or Tornier's, tortoise (*Malacochersus tornieri*) of central Africa, remarkable among land tortoises for the plasticity of its shell



Elephant tortoise (Testudo gigantea), a giant land turtle of the Seychelles and Aldabra Islands



Leopard tortoise (Testudo *pardalis*), one of the two largest mainland tortoises of Africa

MARINE, FRESH-WATER AND TERRESTRIAL TURTLES

BY COURTESY OF (TOP CENTRE. THIRD ROW LEFT, BOTTOM LEFT) RAYMOND L. DITMARS AND THE AMERICAN MUSEUM OF NATURAL HISTORY, (TOP RIGHT) THE AMERICAN MUSEUM OF NATURAL HISTORY. PHOTOGRAPHS. (TOP LEFT THIRD ROW RIGHT) ISABELLE HUNT CONANT, (SECOND ROW LEFT, SECOND ROW RIGHT) JOHN H. GERARD, (BOTTOM RIGHT) ROGER CONANT

Copulation is usually preceded by an elaborate courtship highly characteristic for a species or related group of species. The male's courtship performance may include such antics as lunging at the female while roaring. or. in some aquatic kinds, gracefully swimming backward in front of her while stroking her lores (cheeks) with the excessively long nails of his forelimbs. The penis, paired in snakes and lizards, is single in turtles. The most unusual aspect of turtle reproduction is the ability of females to lay fertile eggs for years after a single mating.

Both terrestrial and aquatic turtles lay their eggs on land. For the nest the female usually selects a sunny place; she then digs a hole, about as deep as her hindlimbs are long, into which she deposits round or elliptical whitish eggs (they are never pigmented like birds' eggs), the shells of which may be either flexible or brittle. Several clutches may be laid in a season, though this is by no means the rule. A clutch may have more than 200 eggs (as in some sea turtlesj or as few as one. The sea turtles and the largest tortoises lay eggs about two inches in diameter. whereas nearly all of the other turtles lay much smaller ones.

Most nests are carefully constructed and hidden; a fen- are crudely made. The period of incubation depends to an appreciable extent on the temperature. After the nest is completed: the mother appears to take no further interest in it. or, for that matter, in the hatchlings. As a result, the nest is often robbed of eggs, and freshly hatched turtlets, whose shells are still soft, are frequently preyed upon by large birds and small mammals.

These shelled reptiles outlive all other vertebrates. including man, the longest-lived mammal. An eastern box turtle (*Terrapene carolina*) survived 138 years in the wild. There is good evidence of a turtle of another species having lived more than a century and a half. In spite of widespread belief, turtles do not grow unusually slowly; maturity is reached in less than ten years. and gronth in a large species may be more rapid than that in man himself.

Age estimates are sometimes made for some cpecies by counting the growth rings on the horny shields of the shells: this method is of little practical value. however. because the rings become indistinct with maturity. Size is equally untrustworthy as an indication of age.

Turtles run the gamut in size. The .Atlantic lestherhack (*Dermochelys coriacea*). largest of living kinds, may weigh more than $\frac{3}{4}$ ton and measure 12 ft. from the tip of one flipper to that of the other. An extinct marine giant. *Archelon,* of North America was probably noticeably larger. and an extinct tortoise of Asia (*Colossochelys* atlas) had a shell 7 ft. long. The largest living tortoises may weigh more than 500 lb.

At the opposite extreme the adults of some species weigh less than a pound and have a shell less than five inches long. The length of the shell of most adult turtles would fall between 5 and 15 in.

Although scientific evidence is lacking, turtles appear to depend heavily on their sense of smell. Their sight is reasonably good and they are able to distinguish colours: they are especially responsive to reds. colours that most often figure in the adornment of the turtles themselves. Turtles do not hear in the ordinary sense of the word; they are indifferent to sounds carried by the air hut are sensitive to vibrations transmitted through solids. Turtles seldom emit sounds: except when courting and mating; even then they do little more than grunt or bark. Exceptions are a few sea turtles that can give a loud cry of anger or a "plea for mercy."

Experiments on the intelligence of turtles indicate that they learn readily: in some ways they are comparable to the laboratory rat. Persons who have had extensive experience n-ith pets sometimes elicit from turtles a degree of intelligence usually credited only to mammals. To the casual observer. however. a turtle oiten appears to be very stupid, especially when it repeatedly climbs over an obstacle it could easily go around.

The turtle is proverbially one of the slon-est animals. and there is some justification for this reputation. at least for some land forms. It is an odd fact that aquatic species in general move faster, even on land. The tortoises of the genus *Gopherus* have been clocked at rates of 0.13 to 0.30 m.p.h., whereas the rate on land of a normally aquatic cooter (*Pseudemys floridana*) has been recorded at 1.07 m.p.h. in spite of the fact that it was out of its element.

A green turtle (*Chelonia mydas*) has been known to swim 300 mi. in 10 days; it must have traveled at an appreciable rate, since it scarcely could have swum steadily ahead without taking time to eat. sleep or rest. Softshell turtles (Trionychidae) are able to move their limbs at a rate comparable to that in birds and mammals.

The sense of location is well developed; turtles released in an enclosure will usually pick out a resting place and spend much time in it. Some species have a "home area" to which they will return if they are taken a short distance away. The sea turtles are probably exceptions to the general rule of living in a restricted area. There is some evidence to indicate that sea turtles are able to make long migratory journeys and that mass migrations from breeding beach to feeding ground and back take place annually.

Economic **Value.**—Man has always relished turtles, and it is likely that almost every species has at one time or another satisfied the broad human appetite. The green turtle! with its distribution extencling around the world. no doubt has supplemented the diet of peoples of more cultures than has any other wild vertebrate. Tortoise populations of many oceanic islands have been decimated; it has been estimated that 10,000,000 land giants were taken from the Galápagos Islands as food supply for the early whaling ships. Turtle eggs are also prized as food. These are deposited in such abundance on certain beaches that harvesting them has become a national industry in one country.

Just as turtle meat has long satisfied our appetite, so has "tortoise shell" gratified our sense of beauty. In recent years, plastics have come to the rescue of the hawksbill turtle (*Eretmochelys*), chief source of the horny shields from which tortoise-shell ornaments are made.

Care in Captivity. — Turtles are among the most popular reptile pets. The vast majority of those kept in captivity are baby turtles: these demanding charges are unfortunately often given over to children who are too young to properly care for them. Countless numbers of tiny cooters (*Pseudemys*) and their relatives are shipped from the southern U.S. where they are adapted to a warm climate. Cooters. aquatic and normally capable of attaining a large size. when placed in the home aquarium. nearly always suffer from malnutrition and slowly die. Their lamentable condition may persist for months without being noticed, Imperceptible growth, failure of the shell to harden and sore eyes are danger signs. Turtles suffering these disorders can seldom be restored to health.

The diet must include raw fish or lean raw beef finely chopped and mixed with generous amounts of bonemeal and cod liver oil. This mixture should be given daily until the shell is several inches long (often attained in two or three years:), when two feedings a week will suffice. As few owners want such big pets the older turtles are discarded for the more popular turtlets.

However. adult turtles of many species make good pets. and they do not suffer readily from malnutrition. It is only necessary to identify the species and learn about its particular habits from a good handbook. Hatchling cooters will of course thrive on a diet of the animals which they normally eat in nature. but the collecting of such food requires special knowledge and techniques. The adults can live on artificial foods. but they fare better when their diet is supplemented by natural foods such as aquatic greens. lettuce. carrot tops, worms, insects. fish. etc. Vegetarian species usually present fen-er problems than do the carnivorous ones; however. most turtles are omnivorous, preferring a varied diet (see *Natural History,* above).

Classification and Distribution. — The hackboned animals (subphylum Vertebrata) are divided into eight classes: bony fishes and their relatives (four classesi. Amphibia, Reptilia. Aves and Mammalia. The turtles (Chelonia) constitute one of the 15 or 16 orders of living and extinct reptiles. Together with the cotylosaurs the turtles are known as anapsid reptiles (subclass Anapsida), characterized by a skull with a solid roof.

Turtles fall into three suborders: Amphichelydia, extinct primitive turtles; Pleurodira, side-necked turtles; and Cryptodira. all remaining kinds. The last two suborders, which evolved from the first during the late Mesozoic, are thriving today. The pleurodires are now restricted to South America, Africa, Madagascar, Australia and New Guinea and adiacent islands. The cryptodires. in contrast. are found on all the continents except Australia and include about $\frac{4}{5}$ of all living species. When reckoned by families. about half of the 21 or 22 families known to science are now extinct.

The living species of turtles number approximately 225 and new species are continually being discovered. The two suborders and the important families may be characterized as follows (the English names of these families are not well fixed):

Suborder Cryptodira (Vertical-necked *Turtles*).—Among these turtles the neck is drawn into the shell by vertical flexure, an ability that calls for highly specialized cervical vertebrae. The largest family, the common fresh-water turtles, Emydidae, includes a third of all living species and has a geographical range about as extensive as that of the entire suborder. The species, many of which occur in the eastern half of the U.S., are predominantly occupants of aquatic and semi-aquatic habitats. Next in number of kinds are the true tortoises, family Testudinidae, with a little more than half as many species as are found in Emydidae.

The slow, plodding tortoises of fable belong to this widely distributed terrestrial group, the gigantic species of which are confined to oceanic islands.

There are only two other groups of cryptodires having an appreciable number of species. One of these, family Kinosternidae. the musk turtles and mud turtles, is confined to the new world and includes only about twenty species, several of which are found in the United States, many in Mexico. The group is sometimes divided into two families.

Members of the remaining large lot of cryptodires, family Trionycidae, are readily recognized by their skin-covered flexible shells. These are the softshells, aquatic creatures that have been described as animated pancakes. Their range, wide on both sides of the world, excludes, however, both Australia and South America.

The six species of marine turtles live in warm seas; they are divided into two groups: Dermochelyidae, comprising only one form, the leatherback, largest of living turtles; and Cheloniidae, the sea turtles. All marine turtles are large and can be easily recognized by their paddlelike limbs.

Chelydridae, the snapping turtle family, though it has only two species, is, nevertheless, well known in North America because its members, large and bad-tempered, have a disputed economic status. One species ranges into northwestern South America. Three other famílies of cryptodires, each consisting of a single species, are less well-known groups having narrow geographical distribution.

Suborder *Pleurodira* (Side-necked Turtles). — This suborder, once world-wide in distribution and now restricted to the southern continents, includes about 20% of living turtles. The habit of bending the neck sideways to retract the head makes recognition of these primarily aquatic reptiles sure and easy. The neck of some species is responsible for one common name of the larger of the two families, Chelidae, the 28 species of snake-necked turtles.

The queerest of all turtles, the matamata (Chelus *fimbriata*) of South America, belongs here. The other family, Pelomedusidae, with only half as many species, comprises the side-necked turtles from which the common name of the suborder is derived.

ROCHE

TURYLEHEAD (CHELONE GLABRA)

TURTLEHEAD (Chelone). a small genus of North American herbs of the figwort family (Scrophulariaceae; *q.v.*), all smooth perennials that bear clusters of showy flowers. the corolla resembling a turtle's head. The common turtlehead (C. *glabra*), with ahite flowers, occurs from Newfoundland to Manitoba and southward.

Other species, having yellowish, pink and purple flowers, are found in damp, woodsy soil in the southeastern and central states.

TUSCALOOSA, a city of western Alabama, U.S., on the Warrior river 58 mi. S.W. of Birmingham; the seat of Tuscaloosa county. The city lies at the edge of the great coal and mineral deposits of Alabama in a rich agricultural region. In the county are many important industries, including chemicals, kraft paper, lumber, cottonseed products, fertilizer and auto and truck tires and tubes.

There are many old residences and gardens, dating from the time Tuscaloosa was the capital of the state (1826–46). The streets are wide and lined with magnificent oaks, planted in the early days of settlement. In the city are the Bryce hospital and Partlow state school (major units of the Alabama state hospitals) ; a Gnited States veterans' hospital; Hale Memorial Tuberculosis hospital; Stillman college (Presbyterian, founded 1876) ; and the University of Alabama (see ALABAMA : Education).

The town was named for the Choctaw chief Tuskalusa, who is commemorated by a granite monolith on the courthouse lawn. The first white settlers arrived in 1816. The county of Tuscaloosa was created in 1818; the town was incorporated Dec. 13, 1819, one day before the state of Alabama was admitted to the union. The population in 1960 was 63,370 in the city and 109,047 in the standard metropolitan statistical area (Tuscaloosa county). (B. CR.)

TUSCANIA, a town of the province of Viterbo, Italy, 15 mi. N.E. of Corneto by road, 545 ft. above sea level. Pop. (1951) 5,987. The ancient town lay on the Via Clodia; its Etruscan tombs have yielded valuable antiquities, and remains of a large thermal establishment of the Roman period have also been found. The medieval walls with their towers are still preserved. On the ancient citadel hill is the Romanesque church of S. Pietro, belonging to four different periods — 739, 1093 (the date of the reconstruction of the crypt), the middle of the 12th and the end of the 12th century. It has the shape of a Roman basilica, with a nave and two aisles and one apse. The elaborate façade with its rose window also belongs to the 12th century. Sta. Maria in the valley below dates from 1050 to 1206, and has a similar façade and a massive square campanile. In the town are two other Romanesque churches.

The town was called Toscanella until 1912, when it resumed the name which it bore in ancient Latin times.

TUSCANY (Italian TOSCANA), a region of central Italy, consists of the provinces of Arezzo, Grosseto, Florence (Firenze), Leghorn (Livorno), Lucca, Massa-Carrara, Pisa, Pistoia and Siena (*qq.v.*), with a total area of 22,989 sq.km. (8.876 sq.mi.) and a population (1951) of 3,158,811. In the north and northeast the region is bounded by the Tuscan-Emilian Apennines (Appennino Tosco-Emiliano), these being separated by a series of long valleys (Mugello. Casentino) from the sub-Apennine uplands of Monte Albano, Pratomagno and others. Quite separate from the Apennine and sub-Apennine systems are the so-called anti-Apennines of Tuscany, consisting of low mountains (*e.g.,* the Apuane alps and the Colline Metallifera) and plateaus extending as far south as the volcanic uplands of the Lazio region. Farthest west are several isolated massifs along or near the coast (Monte Argentario, Monte Amiata). The lowlands of Tuscany are either interior valleys (*e.g.,* Val di Chiana and Valdarno) or littoral plains, the most important coastal plain being the Maremma. Watered chiefly by the Arno (*q.v.*) and the Ombrone, Tuscany has few rivers capable of supporting major hydroelectric projects, but the borax deposits at Larderello produce enough underground steam to power a major generating station. Among the mineral resources, easily worked iron ore from Elba (*q.v.*) is nearing exhaustion but lead, zinc, antimony, mercury, copper and iron pyrites are still produced in the region. Lignite is mined around San Giovanni Valdarno and the marble of Carrara is world famous. Steel and iron are manufactured at Piombino (*q.v.*), chemicals at Leghorn and near Pisa, ships at Leghorn and textiles and ceramics in many cities. Besides larger manufacturing establishments Tuscany is famous for its artisan industries, especially in Florence (leather, lace, silver).

Agriculture in Tuscany is among the most prosperous in Italy, characterized by specific forms of land ownership and a variety of crops. The classic form of land ownership and utilization is share growing, the *mezzadria* system, with the landlord (who provides capital and current expenses) sharing the harvest with the tenant, who supplies the labour. (See MÉTAYAGE SYSTEM.) Shares are fixed by law, and many tenancy contracts have been carried on for generations between landowner and tenants. Besides cereals. Tuscan agriculture is noted for wines (the wines of the Chianti district, near Siena, are the best known and most widely exported of all Italian wines), olives and olive oil (around Lucca), vegetables and fruit. Cattle, horses, pigs and poultry are raised in large numbers. The railway system is characterized by two trunk lines, the coast line, running from Rome through Grosseto, Leghorn and Pisa to Genoa; and the interior line, from Rome through Arezzo to Florence, Bologna and Milan. There are numerous secondary railways and a good network of highways and of bus services. Florence is the largest city and Leghorn the leading port; Florence, Pisa and Siena are important tourist resorts. (G. KH.)

HISTORY

The name Tuscany is derived from that of the Tusci, Tuscans or Etruscans (*q.v.*). Their country, Etruria (*q.v.*), which was finally annexed by the Romans in 351 B.C., comprised not only Tuscany but also the northern part of what is now Lazio. In the 8th century A.D., however, after Charlemagne occupied the Lombard kingdom in northern Italy, the name of Tuscia or Toscana became restricted to the area north of Viterbo and Eolsena. Tuscany then became a march or frontier district of the Frankish dominions, the principal authority in the march being, from 774, in the hands of the counts of Lucca (*q.v.*). Boniface I, the first known count of Lucca, died in 823 and was succeeded by his son Boniface II, whose victories over the Arabs in the Mediterranean served to bring both Corsica and Sardinia into the Tuscan sphere of influence. With the decline of the Carolingian power in Italy the counts began to assume occasionally the style of duke or margrave of Tuscany. The 10th century, however, saw the rise of the house of the Attoni of Canossa (*q.v.*), and a member of this house, Boniface, *c.* 1027 was invested with the margraviate of Tuscany by the emperor Conrad II. On the assassination of Boniface (1052). his widow Beatrice governed till 1076, when her daughter, the great Matilda (*q.v.*) of Tuscany, took her place.

The quarrel about investiture between the empire and the papacy coincided with the rise of the communes in northern Italy (see ITALY: History), whereby a number of the more prosperous towns asserted their independence of their overlords. In Tuscany the first communes to emerge were Pisa, Lucca and Pistoia, which, having obtained concessions from the emperor Henry IV, joined the Ghibelline faction. Subsequently Siena, Florence and Arezzo also established communes. Florence, influenced to some extent by Matilda's benevolent attitude toward its commune, inclined, as she did, to the Guelph or papal side. As Matilda bequeathed all her extensive possessions to the church, her death (1115) was followed by a struggle over her inheritance between the popes and the emperors. This enabled the Tuscan cities gradually to confirm their independence till the old unity of the march was lost altogether. Widespread inundations in the Arno valley and in the Lucca area led to destitution which helped to bring about the politico-economic upheaval.

Pisan supremacy in the 12th and 13th centuries was contested by Florence and by Lucca (which eventually left the Ghibelline camp), and Pisa. though supported by Siena and Pistoia, had also Genoa for an enemy. After the defeat of the Pisan navy by the Genoese in the battle of Meloria (1284), Florence grew to be the leading city of Tuscany. The Tuscan dialect as spoken in Florence and written by Dante (q v.) came to be a standard iorm for Italian.

The Medici Grand Duchy.—The later medieval history of Tuscany is chiefly that of the consolidation of Florentine supremacy (see FLORENCE) and of the establishment in Florence of the dynasty of the Medici (*q.v.*). Twice between 1430 and 1530 (1495–1512 and 1527–30) the Medici were expelled, but after the surrender of Florence to the emperor Charles V's forces in Aug. 1530 they were restored, and Alessandro de' Medici became gonfaloniere for life, a dignity that was made hereditary in the family. As he held the title of duke of Città di Penna, he is generally called duke of Florence. Under his successor Cosimo de' Medici. Siena, the one remaining outpost of republicanism in Tuscany, was annexed (1559), and Cosimo mas created grand duke of Tuscany (Cosimo I) by Pope Pius V in 1567. His son Francesco I was recognized as grand duke by the emperor Maximilian II in 1576. Under his descendants, Ferdinand I, Cosimo II, Ferdinand II, Cosimo III and Gian (Giovanni) Gastone, Tuscany played but a small part in European history.

The House of Habsburg-Lorraine.—Gian Gastone being childless, it was agreed in the preliminaries (1715) of the treaty of Vienna during the War of the Polish Succession that Francis of Lorraine, future husband of the Austrian archduchess Maria Theresa of Habsburg, should succeed eventually to Tuscany in compensation for Lorraine, of which he was dispossessed. In 1737 Gian Gastone died, and Tuscany was governed for Francis, who resided in Austria, by a series of foreign regents.

Francis, who had been elected emperor in 1745, died in 1765 and was succeeded on the throne of the grand duchy by his younger son, Leopold I (see LEOPOLD II, Holy Roman emperor). Leopold resided in Tuscany and proved one of the most capable and remarkable of the reforming princes of the 18th century. He substituted Tuscans for foreigners in government offices. introduced a system of free trade in foodstuffs (at the suggestion of the Sienese Sallustio Bandini) and promoted agriculture. He reorganized taxation on a basis of equality for all citizens. reformed the administration of justice and local government and suppressed torture and capital punishment. He also curbed the power of the clergy, suppressed some religious houses, reduced the mortmain and rejected papal interference With the aid of Scipione de' Ricci. bishop of Pistoia, he even attempted to reform church discipline, but Ricci's action was condemned by Rome and he was forced to resign. At the death of his brother Joseph II in 1790, Leopold became emperor and moved to Vienna. After a brief regency he appointed his second son, Ferdinand III (q *v.*), grand duke.

The French Occupation.—During the French Revolutionary Wars a French force entered Florence in 1799 and mas welcomed by a small number of republicans. The grand duke nas forced to flee. and a provisional government on French lines was established. But the mass of the people were horrified at the irreligious character of the nen regime, and a counterrevolution broke out at Arezzo. Bands of armed peasants expelled the French from the countryside, with many atrocities. With Austrian help Florence was occupied and a government established in Ferdinand's name, but after Bonaparte's victory at Marengo the French returned in force, dispersed the bands and re-entered Florence (Oct. 1800). They too committed atrocities, but they were more warmly welcomed than before by the people, after the experience of Austro-Aretine rule. Joachim Murat set up a provisional government.

By the treaty of Lunéville (1801), Tuscany was renounced by the Austrians. It was then erected into the kingdom of Etruria for the Bourbon prince Louis, son of Ferdinand, duke of Parma. When Louis died (1803), his widow, the Spanish infanta Maria Luisa, ruled as regent for her son Charles Louis until 1807. Then the emperor Napoleon obliged her father, Charles IV of Spain. to agree to the cession of Tuscany-Etruria to France, compensating Charles Louis with a Portuguese principality.

From 1808 to 1809 Tuscany was a French *département*. Then in 1809 the grand duchy was revived for Napoleon's sister Elisa Bonaparte and her husband Felix Baciocchi. French progressive ideas gained some adherents, but to most Tuscans the new institutions were distasteful as subversive of cherished traditions. The heavy taxes and conscription were especially resented.

The **Habsburg** Restoration.—After Napoleon's defeats in 1814, Ferdinand III returned to Tuscany, where he was received with some enthusiasm. The congress of Vienna added some further territory to the grand duchy and guaranteed, moreover, that Lucca should in due course revert to it (as it did in 1847). The restoration in Tuscany was unaccompanied by the excesses which characterized it elsewhere: and much of the French legislation was retained. Ferdinand was succeeded in 1824 by his son Leopold II (*q.v.*), who continued his iather's policy of benevolent but enervating despotism. When the political excitement consequent on the election of Pius IX spread to Tuscany, Leopold, in Feb. 1848, granted a constitution. For some months Gino Capponi (*q.v.*) was prime minister. A Tuscan contingent took part in the Sardinian (Piedmontese) campaign against Austria, but the increase of revolutionary agitation in Tuscany, culminating in the proclamation of the republic (Feb. 9, 1849), led to Leopold's departure for Gaeta. Under the republican triumvirate of F. D. Guerrazzi, Giuseppe Mazzini and G. Montanelli disorders continued, and Leopold was invited to return and did so, but forfeited his popularity by according the protection of an Austrian army (July 1849). In 1852 he formally abrogated the constitution, and three years later the Austrians departed. When in 1859 a second war between Sardinia and Austria became imminent, revolutionary agitation broke out once more. There mas a division of opinion between the moderates, who favoured a constitutional Tuscany under Leopold as part of an Italian federation, and the popular party, led by Ferdinando Bartolommei, who aimed at the unity of Italy under Victor Emmanuel. At last a compromise was reached and the grand duke was requested to grant a constitution and to take part in the war against Austria. Leopold having rejected these demands, the Florentines rose and expelled him (April 27, 1859).
