VASE TO ZYGOTE

VASE, a vessel, particularly one of ornamental form or decoration; the term is often confined to such vessels which are uncovered and with two handles, and whose height is greater in proportion to their width. (*See* POTTERY AND PORCELAIN.)

VASSAL, the tenant and follower of a feudal lord (see FEUDALISM). The etymology of the word remains obscure. Under the Frankish empire the *vassi dominici,* essentially servants of the royal household. were great officers of state, sent on extraordinary missions into the provinces. to supervise local administration in the interests of the central power. Sometimes they were sent to organize and govern a march; sometimes they were rewarded with benefices; and as these developed into hereditary fiefs. the word *vassus* or *vassallus* ("servant," "retainer") was naturally retained as implying the relation to the king as overlord. and was extended to the holders of all fiefs. In course of time the word came to acquire a military sense, and in medieval French poetry *vasselage* is commonly used in the sense of "prowess in arms." or generally of any knightly qualities. In this sense it became acclimatized in England; in countries not feudally organized —*i.e.,* Castile — vassal meant simply subject. and during the revolutionary period acquired an offensive significance as being equivalent to slave. For usage in international law *see* also SUZERAINTY.

VASSAR COLLEGE, a privately endowed. nonsectarian institution of higher learning for women, was founded by Matthew Vassar at Poughkeepsie. N.Y., in 1861. First called Vassar Female college, it took its present name in 1567. See POUGHKEEPSIE.

VÄSTERÅS (VESTERÅS or WESTERÅS). a town and bishop's see of Sweden. capital of the district *(län)* of Västmanland. on a northern bay of Lake Mälaren. 60 mi. N.W. by W. of Stockholm by rail. Pop. (1960) 77,778. The original name of the town was Västra Aros ("western mouth"). as distinct from Östra Aros. the former name of Uppsala. Several national diets were held in Västerås. the most notable being those of 1527, when Gustavus Vasa formally introduced the Reformation into Sweden. and 1544. when he had the Swedish throne declared hereditary in his family. Its Gothic cathedral, rebuilt by Birger Jarl on an earlier site and consecrated in 1271. was restored in 1850–60, and again in 1896–98. The episcopal library contains the valuable collection of books which Count Axel Oxenstjerna, the chancellor of Gustavus Xdolphus, brought away from Mainz near the end of the Thirty Years' War. A castle overlooking the town was captured by Gustavus Vasa and rebuilt by him, then was rebuilt in the 17th century, and remains the seat of the provincial government,.

VASTERNORRLAND (VESTERNORRLAND or WESTERNORRLAND). county *(län)* of northeast central Sweden, on the Gulf of Bothnia. Pop. (1960) 285.620. Area. 9.921 sq.mi. The heavily forested highland furnishes timber for the sawmilling, woodworking and wood-processing industries throughout the county. Härnösand is the capital and a seaport for shipping timber products.

VATICAN, THE, official residence of the pope. the nucleus of the Vatican City State which forms an enclave in the city of Rome, the geographical centre of the Roman Catholic Church.

GOVERNMENT AND FAMIGLIA

Government. — The hierarchical power of the Roman Catholic Church culminates in the person of the pope *(q.v.)*, whose residence is in the Vatican palace; and the basilica of St. Peter (the Vatican basilica) is the church that occupies the first place in the minds of Catholics. In ancient times. however. the popes habitually resided in the Lateran palace and only at a later date in the Vatican. St. Peter's is the only basilica within the confines of the Vatican City State: but the pope exercises sovereign rights over all the patriarchal basilicas in Rome.

By the Lateran treaty of June 7, 1929. the Italian government recognized the Vatican City State as independent and sovereign, thus restoring the temporal power of the pope, which had been liquidated when Italian forces occupied Rome in 1870.

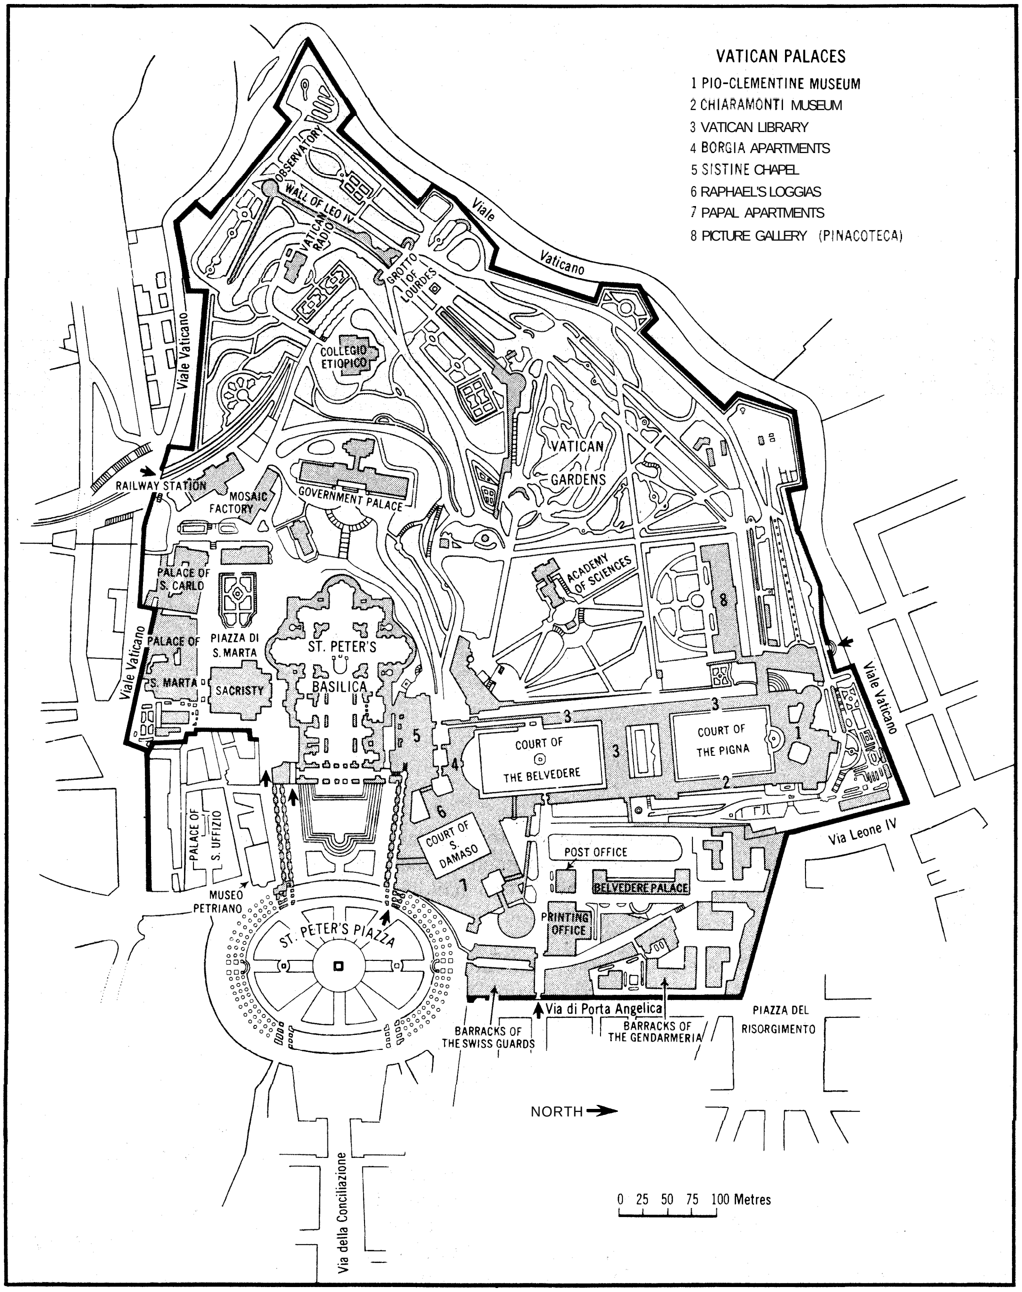
Being the seat of the pope, the Vatican is also the seat of the Sacred College of Cardinals (see CARDINAL), whose members are his closest advisers. The business of ecclesiastical government is administered by the Roman curia (see Ct-RIAROMANA).

All Catholic bishops are obliged to present a report on the state of their dioceses and at the same time to pay periodic visits to the basilica of St. Peter. European bishops have to make this visit every five years, bishops in other parts of the world every ten years.

The permanent representatives of the Holy See with the Catholic hierarchy of other countries are called apostolic delegates. These are prelates, usually with the titular rank of archbishop. According to the country in which they serve. their delegation is subordinate to the Consistorial congregation. to the Congregation for the Eastern Church or to the Congregation de *Propaganda Fide* ("for the propagation of the faith").

Prelates sent abroad by the Holy See on temporary missions for ecclesiastical purposes are called apostolic visitors. On certain important religious occasions a cardinal may be sent by the pope with the title of legate.

The diplomatic representatives of the Holy See with foreign governments are either nuncios or internuncios. the distinction corresponding to that between ambassadors and ministers plenipotentiary. Tuncios. who generally have the titular rank of archbishop, may be of the first or of the second degree. according to the actual or historical rank of their particular post; the diplomatic career of a nuncio of the first degree usually is completed by elevation to the cardinalate. (See NUNCIO.)



THE VATICAN. SHOWING LOCATION OF PRINCIPAL BUILDINGS. DARK ARROWS INDICATE ENTRANCES

Famiglia.—The personal entourage of the pope. as distinct from the government of the church. is known as the *famiglia pontificia*. A great part of this *famiglia* consists of the members of the *cappella pontificia*, the collective name for those participating in the *cappella papale*, that is. in ritrs performed or attended by the pope himself or specifically requiring his presence.

The *cappella* includes all cardinals, patriarchs. bishops assistant at the papal throne and other bishops who happen to be present at the time in the curia: other high officials of the curia: the princes assistant at the throne: the secretaries and assessors of the Sacred Congregations: the apostolic protonotaries: the generals and procurators of the religious orders; the consistorial advocates: the ecclesiastical privy chamberlains: etc. Within the *famiglia*, the cardinals most closely associated with the pope are the palatine cardinals. The privy chamber includes the palatine prelates (the prefect of the Apostolic Palace; the prefect of the bedchamber: the auditor; and the master of the Apostolic Palace) and several groups of privy chamberlains. both ecclesinstical and lay. Certain posts in the *famiglia* are always entrusted to members of certain religious orders. Thus the master of the palace. the theologian of the *famiglia*, is always a Dominican; the sacristan, an Augustinian friar; the apostolic preacher. who delivers the Advent and Lent sermons in the pope's presence, a Capuchin: and the confessor. a Servite.

The principal laymen of the *famiglia* are the heads of the great families of the old Roman nobility. Thus the prince Colonna and the prince Orsini may have the title princes assistant at the pontifical throne and take it in turn to attend upon the pope: the prince Massimo is grand master of the pontifical posts (in the sense of stages in the journeys of the pope. should he have to travel); the prince Ruspoli is grand master of the Sacred Hospice (responsible for hospitality to visiting heads of state and princes); the marchese Sacchetti is *foriere maggiore* (superintendent of buildings, water supply and furnishings) of the Sacred Palaces: the marchese Patrizi is standard bearer of the Holy Roman Church; and the mnrchese Serlupi is master of the horse. The lay privy chamberlains are called "chamberlains of s\\-ord and cloak" (*camerieri* di *spada e cappa*) because of their distinctive ceremonial dress—in the fashion of the 16th-century Spanish nobility. The protection of the pope's person is ensured by the *guardia nobile* which consists of officers drawn from noble families; and by the s\\-iss guard. a corps instituted by Julius II and consisting of Swiss citizens recruited at first from the original cantons of the Swiss confederacy and in modern times from nearly all the others as well. There is also a guard of honour recruited from among the citizens of Rome (*guardia palatina d'onore*). A corps of police known as the *gendarmeria pontificia* is responsible for maintaining order in the Vatican City State and in the palaces that belong to it.

Papal ceremonies are attended by the diplomatic corps accredited

ST. PETER'S BASILICA

The interior of St. Peter's showing the bronze baldachino (canopy) by Bernini (1598–1680) over the papal altar. At the far end of the apse is a bronze throne, also by Bernini, containing the wooden chair of St. Peter, and above it is an aureole of gilded stucco to the Holy See; by the Roman patriciate and nobility; by the knights of Malta and of the Order of the Holy Sepulchre. When the papal entourage appears as a whole, in procession, it provides a spectacle of dazzling splendour. It includes cardinals and bishops wearing *cappae magnae* trimmed with ermine or gold-embroidered vestments; Roman princes with cloaks edged with lace: chamberlains "of sword and cloak"; prelates in violet soutanes: representatives of the religious orders: knights of Malta in scarlet tunics; officers in armour of steel damascened with gold; and the Swiss guards in the blue. red and yellow uniform allegedly designed by Michelangelo or by Raphael. Last in the procession comes the pope on the *sedia gestatoria,* a sort of throne on a platform carried on the shoulders of 12 servants wearing liveries of crimson damask. Above the *sedia* is a canopy of cloth of silver. the golden supports of which are borne by eight prelates. Two privy chamberlains. one on either side of the throne. carry *flabelli* or immense fans adorned with ostrich feathers.

CEREMONIES AND RITES

The Vatican basilica is served by a chapter of canons (who in virtue of their office. like the canons of the chapters in the patriarchal basilicas of St. John Lateran and Sta. Maria Maggiore, rank as supernumerary apostolic protonotaries) and by a large body of clergy under the episcopal jurisdiction of a cardinal. who has the title of archpriest. Some of the ceremonies and rites peculiar to the basilica or to the chapels of the Vatican palace may be mentioned here.

The coronation of a new pope, which takes place within a few days of the preceding conclave. is, in itself. not quite a religious ceremony (see PAPACY). On his way to the place oi coronation. the pope is met by a master of ceremonies holding a silver-plated staff at one end of which a piece of tow has been fixed and by a cleric holding a lighted candle; three times the flame is applied to the tow and the staff raised, each time with the words *Sic transit gloria mundi* ("Thus passes an-ay the glory of the world"). The tiara (*q.v.*) is set on the pope's head by the senior cardinal deacon. who says, in Latin: "Receive the tiara with the three crowns, and know that thou art the Father of kings and princes, the pastor of the universe. and the vicar on earth of our Lord Jesus Christ. to whom belongs honour and glory. world without end.!' Pius XII and John XXIII were crowned on the balcony of the basilica.

The rite of beatification (see CANONIZATION) begins with the reading of a papal brief proclaiming the new blessed in the presence of the cardinal archpriest, of the Vatican chapter and of the members of the Congregation of Rites, and is concluded in the afternoon of the same day, when the pope goes in procession to the basilica: prays before an image of the new blessed and receives the Benediction of the Holy Sacrament. The rite of canonization is of a much more solemn character: after a "postulation" made by the "consistorial advocate" and special prayers for the help of the other saints and for light from the Holy Ghost. the pope himself proclaims the new saint and then celebrates the pontifical mass.

At the beginning of a holy year or jubilee *(see* JUBILEE YEAR) the pope opens a special door, the holy door, in the Vatican basilica. so that the faithful may accomplish the rite of passing through it; and at the end of the year he closes it, after which it remains sealed until the next jubilee. (There are also such doors in the patriarchal basilica.: of the Lateran. of S. Paolo-fuori-le-Mura and of Sta. Maria Maggiore.)

On the eve of the feast of St. Peter every year the pope blesses the pallia in the Vatican basilica; they are then stored in a coffer near the tomb of St. Peter until they are required ior new archbishops.

Another unique ceremony is the washing (*lavanda*) of the principal altar of the basilica with wine and balm. done on the evening of Holy Thursday after the singing of the Tenebrae by the cardinal archpriest and the chapter. A further custom. performed at the great festivals of the church, is the showing (*ostensio*) of certain relics from the balcony of a small chapel in one of the piers supporting the dome of the basilica. These relics are (1) Veronica. the veil n-ith n-hich, according to tradition, a pious woman named Veronica wiped our Lord's face as He was going up to Calvary and on which His features are believed to have remained imprinted; and (2) what is believed to be the point of the lance that pierced the side of Jesus on the cross, discovered at Antioch during the first crusade, later captured by the Moslems and eventually presented to Pope Innocent VIII by the Turkish sultan Bayezid II in 1492.

The blessing of the golden rose (*q.v.*), on the fourth Sunday in Lent (annually in former times. but less frequently in the 20th century), takes place in the pope's private chapel in his official apartments. In the same chapel, which is to be distinguished from the private chapel in his private apartments. important visitors are sometimes allowed to hear mass and to receive the sacrament from the pope himself. For the blessing of the Agnus Dei medallions *see* AGNUS DEI.

The Sistine chapel in the Vatican palace is reserved for papal ceremonies (*i.e.,* for ceremonies performed or attended by the pope accompanied by the *cappella*) and for the conclave (*q.v.*). The Pauline chapel is convenient for the spiritual needs of the inhabitants of the Vatican. The parish church. however, is that of St. Anne, by the Porta di Sant' Anna. (X.)

HISTORY

The Vatican Hill and Necropolis. — Before the erection of the basilica of Constantine, the area of the Vatican had an altogether different appearance from what it has today. The Vatican valley. occupied in part by the circus of Gaius (roughly n-here the palace of the Holy Office is now). was about 59 ft. above sea level. The elevation of the square in front of the present-day sacristy rises from 82 ft. at its eastern corner to about 92 ft. at its western one. The new basilica covers an area nearly 99 ft. above sea. level. while the base of the obelisk in St. Peter's square is at less than 63 ft.; advancing northward up the Vatican hill one encounters a level of 127 ft. for the courtyard of S. Damaso. while the highest point of the entire complex is found in the gardens. 264 ft. above sea level. To the casual observer. however, the diiference of more than 205 ft. between valley and summit is not immediately apparent because of the maze of buildings.

The valley was in antiquity somewhat boggy and consequently considered by the Romans to be unhealthful. This situation was remedied in part by the elder Agrippina (d. A.D. 33), who drained the valley and erected terraces for gardens on the hillside; and it was there that her son. the emperor Gaius (Caligula), constructed the circus. which was joined to the Tiber by a portico. The emperor Nero in A.D. 59 took over other gardens there (Tacitus, *Annals,* xiv, 14) that had belonged to his aunt Doniitia Lepida.

The Vatican zone was reached by three main highways: the Via Triumphalis, which left Rome in a northwesterly direction toward the present-day Monte Mario; the Via Cornelia, perhaps the oldest. which passed near the spot where the emperor Hadrian erected his remarkable tomb; and the Via Aurelia Nova. which must have passed between the circus and the necropolis discovered in the 1940s. The numerous clay deposits in the vicinity were used by the Romans in manufacturing wine jugs. cooking utensils and, especially. bricks and tile.

The Vatican area, from the right bank oi the Tiber up to the top of the hill. lying as it did outside the city walls. was, extensively used by the ancient Romans as a burial ground. Many of their large tombs were given strange names by medieval Romans; for instance the "Pyramid of Romulus." a large mausoleum demolished in 1499 by Alexander VI. and the "Terebintus" or "Obelisk of Nero," a large circular tomb likewise demolished in the 15th century. Many of these tombs belonged to the charioteers of the nearby circus. and some were even used to bury famous race horses in the reigns of the emperors Domitian. Trajan and Antoninus Pius. Roman tombs were found in the time of Pope Nicholas V, when in 1452 work n-as begun on the apse for the new basilica; and others were uncovered as the construction progressed into the 16th and 17th centuries in the area today occupied by the façade of the basilica and St. Peter's square. An immense Roman necropolis was discovered between 1887 and 1908 in the zone between the modern Via di Porta Angelica and the edge of Monte Mario. containing some very ancient tombs. among them those of freedmen of the emperor Claudius. Other Roman tombs were found while foundations for the Vatican governor's palace were being laid. and still others were uncovered in the Vatican gardens and under the Annona Vaticana. Even in 1956, during the construction of an edifice north of the Vatican post office. tombs were discovered bearing inscriptions dating from the 1st century A.D., two of them mentioning a male and a female slave of Nero.

The most interesting necropolis, however, came to light during the excavations carried out by personal initiative of Pius XII during the years 1941–49 under the central nave of St. Peter's basilica. In the zone south and east from the basilica's high altar were discovered two rows of mausoleums belonging for the most part to freed slaves of aristocratic and imperial families. Arranged in two parallel rows. the more ancient mausoleums occupied the north row. the one nearest the hillside; but all had their entrances on the south side, that is. facing the Roman road separating the necropolis from the circus. In fact, above the door of the easternmost mausoleum an inscription was found, in which the heirs of Gaius Popilius Heracla transcribed that section of his will stipulating the erection of this mausoleum for himself. his wife and descendants *in Vaticano* ad *circum* ("on the Vatican near the circus").

The mausoleums. embellished with stucco work and frescoes, were almost all employed for cremation as well as for inhumation; in the case of cremation the ashes were deposited in urns of terra cotta. of marble or even of alabaster; for inhumation the bodies were interred in sarcophagi of terra cotta or of marble richly decorated with scenes from Dionysian mythology or at times even with portraits of the defunct.

Inscriptions on the sarcophagi furnish some idea of the social class of the Romans buried there; they include freedmen of many of the aristocratic families, as well as freedmen of the emperors Antoninus Pius. Diocletian and Maximian. In some of these mausoleums Christian tombs were found; in one inscription can be read the date of the burial; in another a husband wishes for his wife Aemilia Gorgonia eternal rest, the inscription being framed between two doves with olive branches and the carved portrait of Gorgonia. A small mausoleum. first employed for cremation burial and later converted to inhumation. was decorated with a beautiful mosaic depicting on the ceiling Helias (the sun) in a chariot drawn by four white horses, the entire figure a symbol of Christ, the sun of salvation: on the side walls of the mausoleum were represented the Good Shepherd, the Fisher of Souls and Jonah swallowed by the whale. Since these mosaics are patently from a period before Constantine, they are the oldest known Christian examples of such art. Those mausoleums near and under the south side of the high altar of the basilica were partially destroyed by the construction of the *confessio* at the end of the 6th century and partially by the insertion of the foundations for the two south columns of G. L. Bernini's canopy in 1626.

On the ground level south of Constantine's basilica were two massive circular mausoleums, considered for a long time to have been constructed after the basilica itself. When. however, in 1776, the easternmost one was demolished. Gaetano Marini stated that its masonry was from the and century; and later G. B. de Rossi expressed a similar opinion about the other mausoleum. In this latter, Maria, wife of the emperor Honorius. and others were buried. Pope Stephen II (III; 752–57) transformed it into a chapel dedicated to St. Petronilla. whose relics were transferred there by his successor Paul I in 757. Restored by Louis XI of France. it became then the chapel for the French kings. It was chosen by the French cardinal Jean de Villiers de la Groslaie for his tomb, and it was for him that Michelangelo carved his famous "Pietà," seen today in the first chapel on the right in the basilica. After the sarcophagus of St. Petronilla was moved to the new basilica. this mausoleum was demolished during the construction of the south transept (1544). The other mausoleum. the one to the east, was transformed by Pope Symmachus (498–514) into the oratory of St. Andrew, with many altars dedicated to various martyrs; it was demolished in 1776, when Pius VI erected the new sacristy.

The Tomb of **St.** Peter.—If one descends today into the open *confessio* of Paul *V*, one finds immediately under the high altar a gilded bronze grille, behind which is another of smaller dimensions with a metrical inscription of Innocent III (1198–1216); this latter opens on an oaken slab decorated with a representation of Christ among the apostles in Limoges enamel. part of which is today preserved in the Museo Sacro of the Vatican library. Loner down is the niche of the pallia. with a 9th-century mosaic of Christ flanked by other mosaics of St. Peter and St. Paul. On the floor of this niche rests a silver chest containing the pallia and emblazoned with the coat of arms of Benedict XIV.

This chest stands on a bronze plate, placed there by Innocent X (1644–55), engraved with a cross in the right arm of which is a small lid. In 1892 this lid was opened by H. Grisar, who found that it covered a rectangular shaft, the aperture measuring $8\frac{3}{4}$ in. by 63 in. The excavations carried out under Pius XII showed that this shaft. once encased in marble. is more than 14 in. deep and opens on a hollow trenchlike tomb in the earth, where the bones, with the exception of the head, of a robust elderly person were subsequently found This tomb is not at the level of the Roman necropolis. but rather farther north and somewhat higher up the hillside in another inhumation area; some of the surrounding tombs are older than it (for example, a terra-cotta sarcophagus furnished with a libation tube).

Tno stairways gave access to this zone from the south, one flanking the west wall of the early 2nd-century mausoleum of the Matucci, the other farther west between two other mausoleums; this latter led through a door to a small open space provided with a brick bench on the east wall. Beneath this stairway, to carry off rain water and to prevent flooding the tombs, was a drain. some of the tiles from which, dating from the years 147–161, bear the factory stamp of Aurelius Caesar and Faustina. To protect the area on its west side, a wall was erected, running north and south. Covered with red plaster, it is called "the red wall"; a portion of it about 2j ft. long was uncovered during the excavations. In this wall, which passes over the west end of the tomb, was an irregular niche. covered by a marble slab. Higher up on the same wall was a second niche. with marble sheathing topped by a Travertine slab: this slab was once supported by two white marble colonnettes 4 ft. 7 in. high, standing in front (that is, east) of the niche and, as is shown by a cut in the bases of the colonnettes, accommodating a marble grille. Finally. above the second niche, was yet a third one. 3 ft. high and 3 ft. 8 in. wide. This decoration above the tomb is an indication that the monument was visited, and it is evidently to it that the priest Gaius referred when. writing in the time of Pope Zephyrinus (*c.* 199–217), he stated that he could point out the "trophies" of St. Peter and of St. Paul on the Vatican hill and beside the Via Ostiensis, respectively (Eusebius, *Historia Ecclesiastica,* ii, *a* j).

As a further protective measure, another wall was erected on the north side of this area, which was covered with the graffiti of pilgrims. Soon the zone became filled with other tombs arranged around that under the three niches. But this tomb was the only one among all others that was at the same time an object of veneration and of depredation. From this open tomb were collected more than 1,800 coins from all countries from the time of Xugustus to the early part of the reign of Pope Paul V (1605–21); among others. there were 26 from England. dated from the Anglo-Saxon kings of the 7th and 8th centuries to Edward III (1327–77). Among the ex *voto* objects was found a 7th-century gold tablet with a gemmed cross between two eyes. From the tomb the excavations also brought forth traces of fine silver sheeting as well as three thin sheets of lead. undoubtedly used as protection.

This burial monument was encased by Constantine in slabs of precious marbles and was chosen by him as the focal point of his grandiose basilica of five aisles. At the end of the 6th century Gregory the Great raised the sanctuary floor and erected an altar immediately above the tomb monument. This altar. in turn, was enclosed in another constructed by Calixtus II in 1123. Immediately above these two is to be found today the papal altar of Clement VIII. These three altars, one above the other. document in a very special manner the localized veneration paid this tomb throughout the centuries.

Constantine's Basilica.—Scholars are not unanimous in assigning a date for the beginning of the construction of Constantine's basilica, opinions varying from the year 326 to the year 333. Because of the difficulties to be overcome in erecting a five-aisle basilica over the tomb of St. Peter, the enterprise must have lasted about 30 years. Besides having to build on a hill that sloped steeply in two directions, from south to north and from east to west, it was also necessary to demolish the Roman necropolis still in use, cutting off the roofs of the mausoleums and the other protruding structures blocking the construction. First. three massive foundation walls were laid on the south side of the hill; one to support the outside wall of the basilica, one to support the columns separating the two left-side aisles and the third to support the left row of columns of the central nave. Then. after smaller walls had been erected. joining many of the mausoleums together for further support, the Roman necropolis was covered up. On the north or higher side, the foundation walls were naturally less extensive and less massive. The excavations of the 1940s brought to light many new characteristics of Constantinian construction work and furthermore showed the error in the supposition. held from the time of Paul V, that the south aisles of the basilica rested on the north walls of the circus of Gaius and Nero. Furthermore, the excavations brought forth no trace of the Via Cornelia, long considered by Roman topographers to have been on the same line as the axis of the basilica.

Constantine's architects were forced also to carry out extensive fillings and levelings in the area around the basilica. From the street level 35 steps led up to a large portico measuring 203 ft. by 184 ft, and supported by 46 columns; entrance to this was provided by three bronze doors. This portico enclosed a garden, called Paradise. with fountains (one of these fountains can be seen today in the courtyard of the Pigna, so called because the fountain is in the shape of a pine cone). In the course of time three small chapels were erected within the area of the portico. That of Sant' Apollinare. constructed by Honorius I (625–638), was demolished during the erection of the new façade early in the 17th century; that of Sta. Maria in Turri was destroyed by fire in 1167; that of Sta. Maria in Febbre was located near the ancient tomb of St. Gregory the Great.

Entrance from the portico into the basilica proper was provided by five portals, called, from left to right, Porta Judicii. Porta Ravenniana, Porta Mediana or Regia or Xrgentea. Porta Romana and Porta Guidonea. The interior of the basilica formed a rectangular area divided into aisles by four rows of 22 columns each; the central nave measured nearly 79 ft. across and was 131 ft. high, with marble columns 29 ft. high. Its clerestory, pierced by 11 windows. was richly decorated with frescoes; and Pope Liberius (352–366) added a series of portraits of the popes, to which others were added later under Nicholas III (1277–80). Above this zone were three registers, the highest containing the representations of the patriarchs, of the prophets and of the apostles, the two lower ones containing, on either side of the nave, 46 scenes of the Old and New Testaments. Restored by Gregory IV (827–844) and by Formosus (891–896), these frescoes were repainted by P. Cavallini and by Giotto. The flanking aisles were about 29 ft. wide with columns nearly 20 ft. high; the two inner aisles were 62 ft. in height. while the outer two were 46 ft.

At the head of the central nave was the triumphal arch decorated in mosaic and inscribed in golden letters commemorating Constantine, who was also represented in the mosaics in the act of presenting a model of the basilica to the Saviour; this arch was destroyed in 1525. On the axis of the basilica in the centre of the transept. which was 59 ft. wide. stood the tomb of the apostle Peter, vested in porphyry and in blue-veined marble and with four porphyry columns, and surmounted by a gold cross inscribed with niello letters, the donation of Constantine and his mother Helena. The monument was enclosed in a pergola supported by six white spiral columns from the top of which hung a golden votive crown with 50 lamps in the form of dolphins. The entire monument is depicted on a carved ivory box discovered at Samagher near Pola.

The constructions carried out by Constantine interfered with the natural drainage from the springs on the slope of the Vatican hill, with the result that water seeped into the tombs located there. Pope Damasus (366–384) tapped these springs to provide water for the baptistery that he erected in the north transept of the basilica. Later Symmachus added there three small chapels dedicated to the Holy Cross, to St. John the Baptist and to St. John the Evangelist.

Under Sixtus III (432–440) the emperor Valentinian added to the embellishment of the apostle's tomb by donating a representation in gold and precious gems of the Saviour in the midst of the 12 apostles arranged in front of the 12 gates of the heavenly Jerusalem. Leo I (440–461), with the help of the senator Rufus Viventius Gallus. repaired the damage done to the monument by the earthquake of 443 and, with the help of the former prefect and consul Marinianus and his wife Anastasia, restored the facade, where in mosaic were depicted the figures of Christ. the Virgin Mary and St. Peter as well as the symbols of the evangelists and below, between the windows. the 24 elders of the Apocalypse. The mosaic was again restored under Sergius I (687–701), who substituted the figure of the Lamb of God for that of Christ, and yet again, much later. under Gregory IX (1227–41). A reproduction of this mosaic is found in an 11th-century manuscript from the abbey of Farfa. preserved today at Eton college, Windsor.

Pelagius II (579–590) was responsible for the construction of the pulpit in the sanctuary. Gregory the Great (590–604). after raising the level of the sanctuary. erected an altar above the tomb leaving visible, through a small window. only the eastern face of the ancient tomb monument. Further, having changed the pergola with its six Constantinian spiral columns for a screen in front of the apse of the basilica, he then excavated and added the semicircular crypt with its block altar. John VII (705–707) added to the basilica the chapel of the Virgin Mary (often called the Praesepe), richly decorated with mosaics; this was demolished in 1606. Gregory III (731–741) added six spiral columns to the existing six in front of the main altar. Stephen II (III) erected the bell tower and remodeled one of the fountains of the atrium, adding eight porphyry columns and a gilded bronze cupola. Leo III (795–816) enlarged the baptistery and donated three porphyry columns. Paschal I (817–824) constructed the chapel dedicated to the martyrs Processus and Martinianus.

The basilica was sacked and pillaged by the Saracens in 846. and Leo IV (847–855) had to repair the damage. Calixtus II (1119–24) erected a new high altar that enclosed the previous one of Gregory the Great. both of them directly above the tomb housed in the Constantinian monument. The basilica underwent further damage in the time of Innocent II (1130–43).

In 1298 the cardinal Giacomo Stefaneschi commissioned Giotto to execute a mosaic for the portico. Often called the "Navicella" ("little boat") of Giotto, it depicted Christ walking on the waters and stilling the storm that was terrifying the apostles in the boat (Matt. xiv, 22–33); today it is to be seen, considerably altered. in the ceiling of the atrium. During the Avignonese period of the papacy, the basilica was neglected! only Benedict XII (1334–42) repairing the roof. Eugenius IV (1431–47) added a new central door in bronze. designed and executed by Filarete (Antonio Averulino); this same door was used for the central portal of the new basilica in 1619.

Although the construction of the new basilica had already begun. Sixtus IV (1471–84) erected a new altar canopy in 1479 embellished with bas-reliefs depicting episodes from the lives of the apostles Peter and Paul; these today can be seen in the *confessio* of Clement VIII.

The Tombs of the **Popes.**—According to the available written sources. the tombs of all the popes down to Victor I (d. 199), with the exception of that of Clement I. were near that of St. Peter. After Victor, the popes were buried in the various cemeteries around the city, burial on the Vatican being resumed only with Leo I. Today, in the corridor leading to the basilica's sacristy, there is a marble inscription naming more than 140 popes buried there, including some who reigned in the 20th century. There are. however, few the remains of whose monuments or tombs have been preserved; many were destroyed by Saracens in 846, while still more mere lost in the sack of Rome in 1527. For some, only the text of the burial inscription has been .recorded in the later epigraphic collections. Many such monuments were demolished by Bramante (called by some "the ruinous builder") in the construction of the new basilica; those surviving are preserved in the Grotte Vaticane. where Paul y. from 1606 onward, assembled the material left over from the old basilica. In the Grotte are also the tombs or the monuments of Gregory V (996–999), Adrian IV. Nicholas III. Boniface VIII. Urban VI. Innocent VII. Nicholas V. Julius III. Marcellus II and Innocent IS, as n-ell as the tombs of some later popes. for instance Innocent XIII. Benedict XV and Pius XI. After the excavations of the 1940s the remains of the monument of Paul II and Antonio Pollaiuolo's grandiose bronze monument of Sixtus IV were transferred there. together with certain remains from the old basilica previously preserved in Benedict XV's Museo Petriano (no longer existing). In the Grotte are also the monuments of the emperor Otto II. who was interred in the atrium in 983: of Charlotte de Lusignan. queen of Cyprus (d. 1487); of Christina of Sweden (d. 1689); and of "Henry IX," the last of the Stuarts (the cardinal duke of York).

In the old basilica, moreover. were buried certain kings and princes who died while on pilgrimage at Rome: for example. Ceadwalla of Wessex (d. 689); Coenred of Mercia and Offa the son of Sigehere of Essex, who together entered one of the monasteries nearby (*c.* 709); and Ine of Wessex.

During the construction of the new basilica, many inscriptions and sarcophagi were removed from the area under the old Constantinian one: and the excavations of the years 1941–49 showed that the area under the ancient basilica was occupied not only by sarcophagi but also by other tombs in masonry covered with tiles or with marble. The more important sarcophagi and inscriptions from this area were all removed to the Grotte Yaticane. It may be remarked that the floor level cf the Grotte is the same as that of the ancient Constantinian basilica, that of the new basilica being more than ten feet higher up.

The Monasteries. — To provide choir service at St. Peter's four monasteries were founded in the course of time around the basilica. The oldest. dedicated to SS. John and Paul and first mentioned during the time of Leo I. was located on the north side of the basilica; its remains were seen during the construction of the north side of the transept of the new basilica. The second. dedicated to St. Martin. was situated under the southwest pilaster of the cupola. where today is the statue of Veronica. The third monastery, that of St. Stephen Major, called also *cata Galla Patricia*, is found today behind the apse of the new basilica; its church. restored on various occasions from the time of Leo III. was called also St. Stephen of the Moors or Xbyssinians. The fourth was that of St. Stephen Minor, founded by Stephen II (III); it later became the hospice for Hungarians, but it was demolished in 1776 during the construction of the new sacristy. After the 11th century these monasteries became residences for the canons of the basilica; finally Nicholas III erected a residence for the canons on the south side of the basilica on the site of the present one. The site of a fifth monastery. the Jerusalem. probably housing a convent of nuns, may be supposed to have been near the oratory of the same name founded by Symmachus.

The **Diaconiae.**—From the time of Symmachus small edifices for the care of the poor were constructed on the south side of the basilica; they were subsequently restored by Sergius I. by Gregory III and by Leo III. Bathing facilities were also provided nearby. Continuing the care of the poor, the diaconiae (deaconries) were established. The first was that of SS. Sergius and Bacchus. situated on the north side of the basilica and located in the Palatium Caroli. Another diaconia was that of St. Mary. called *in caput Portici* (being at the head of the portico that led from the Tiber to the basilica). Stephen II (III) also erected a hospice there (where today the obelisk stands); but under Pius IV this hospice was demolished. as also n-as the third diaconia. called St. Silvester and recorded from the 8th century. The fourth diaconia was first called *in Hadrianum* because of its nearness to the mausoleum of Hadrian (Castel Sant' Angelo) and later Sta. Maria in Traspontina; it occupied a site somewhat east of that of the existing church of Sta. Maria in Traspontina and lasted till the 15th century. The fifth diaconia, that of St. Martin de *Curtina* or *juxta Porticum,* was located near the second and third ones; it disappeared in the 17th century.

The **Scholae** for Pilgrims. — Around the basilica were erected *scholae* or hospices for pilgrims. who could find lodging and clergy from their native lands there. The oldest hospice was the *schola Saxonum* for the English. which was founded, according to Matthew of Paris. by King Ine of Wessex c. 727–730 or, according to William of Malmesbury, by King Offa of Mercia at the end of the 8th century: and the entire vicinity of the present church of San Spirito in Sassia was called *burgus Saxonum.* This hospice was destroyed by fire under Paschal I and again under Leo IV; both incidents were depicted by Raphael in the *stanze* of the Vatican palace. The *schola Francorum* or hospice for the Franks was on the site now occupied by the oratory of St. Peter and by the palsce of the Holy Office; its chapel was called S. Salvatore de Ferrione. Later,' for German and Flemish pilgrims. Sta. Maria in Campo Santo and the *schola Teutonum* were erected. The *schola Longobardorum,* for the Lombarda, is said to have been founded c. 770 by Xnsa. the wife of King Desiderius; attached to it was the church of St. Justin. The present chapel of SS. Michele e Magno is all that remains of the *schola Frisonum,* for the Frisians, at the upper left part of Bernini's colonnade. Near the present entrance to the sacristy was the hospice for the Hungarians, founded at the beginning of the 11th century in the buildings of the older monastery of St. Stephen Minor. called also *de Agulia* (with reference to the Vatican obelisk nearby).

The Leonine City. — The emperor Lothair I, immediately after the Saracen invasion of 846, wanted to construct a fortified mall around the basilica of St. Peter; but work on it actually began under Pope Leo IV. Lasting through his reign, much of the work was done by Saracen prisoners. Extending for 2½ Roman miles, this wall numbered 48 towers and 3 gates. inscriptions from which are preserved in fragments and in epigraphic collections. Later, Innocent III constructed another fortified wall within the perimeter of the older one. One of the defensive ton-ers from this wall was identified in 1947; about 8; ft. high. this tower had been incorporated in the construction of Nicholas 111's palace.

The New Basilica. — The idea of a new basilica was first conceived by Pope Nicholas V (1447–55), prompted by the state in which he found the old one. The architect Leon Battista Alberti observed that its south wall was leaning 5 ft. 9 in. out of the perpendicular: and the frescoes on the south side of the central nave. leaning by 3 ft. 7 in., were covered with dust. In 1452, then. Nicholas V ordered Bernardo Rossellino to begin the construction of a new apse west of the old one, but the work stopped with the pope's death. Paul II, however. entrusted the project to Giuliano da Sangallo in 1470. Sixtus IV ordered the erection of a new baldachin (canopy) over the high altar, the bas-reliefs of which are preserved today in the Grotte.

On April 18. 1jo6. Julius II laid the first stone for the new basilica. It was to be erected in the form of a Greek cross according to the plan of Donato Bramante, who began the demolition of the old basilica, laying the foundations for the four pilasters of the cupola. saving, however, the apse and main altar. On Bramante's death (1514), Leo X commissioned as his successors Raphael, Fra Giovanni Giocondo and Giuliano da Sangallo. n-ho modified the original Greek-cross plan to a Latin one with three aisles separated by pilasters. Also active at this stage were the architects Antonio da Sangallo (the elder). Baldassare Peruzzi and Andrea Sansovino. After the sack of Rome in 1527 Paul III (1534–49) entrusted the undertaking to Antonio da Sangallo (the younger). who returned to Bramante's plan and erected a dividing wall between the area for the new basilica and the eastern part of the old one. which was still in use.

On Sangallo's death (1546) Paul 111 commissioned Michelangelo Buonarroti as chief architect for the task. Although criticized by many for a lack of flexibility in the execution of his plans. Michelangelo was confirmed in his position by Julius 111 (1552) and by Pius IV (1561). At the time of his death in 1564 the drum for the massive cupola was practically complete. He was succeeded by Pirro Ligorio and by Giacomo Barozzi. called Vignola. Gregory XIII (1572–85) placed Giacomo della Porta in charge of the work. The dome was finally completed at the insistence of Sixtus V (1585–90), who was also responsible for moving the Egyptian obelisk to the centre of the piazza in front of the basilica in 1586, a task directed by Domenico Fontana. Gregory XIV (1590–91) ordered the erection of the lantern above the cupola.

The pavement of the new basilica was laid at a level more than ten feet above the old one. Clement VIII (1592–1605) demolished the old apse and erected the new high altar over the altar of Calixtus II. Paul V (1605–21) adopted Carlo Maderno's plan of giving the basilica the form of a Latin cross by extending the eastern arm. With the completion of the work in 1613, the new edifice measured 613 ft. in length; the atrium, 233 ft. long. 42 ft. wide and 65 ft. high. contained Giotto's "Navicella." The façade is 377 ft. long and 151 ft. high. In front of the high altar, the work of Maderno and Martino Ferrabosco, Paul V opened a large *confessio* covered with coloured marble and decorated with bronze statues of the apostle? Peter and Paul. Urban VIII (1623–44) entrusted Giovanni Lorenzo Bernini, the successor of Maderno, with the execution of the new canopy; in gilded bronze. it is 92 ft. high and 136.392 Ib. in weight, with columns modeled after the earlier Constantinian ones (much of the bronze was taken from the beams in the atrium of the Pantheon). Bernini was also responsible for the embellishment of the four huge pilasters on the sides toward the high altar: the lower registers contain four niches with statues of St. Longinus (by Bernini). St. Helena (by A. Bolgi), St. Veronica (by F. hfocchi) and St. Andrew (by F. Duquesnoy). Above are four loggias containing eight of the ancient spiral columns from the sanctuary of the old basilica. In 1637 the bell tower was begun, but the resulting construction was demolished in 1641 for technical reasons.

The marble decoration of the interior. as well as the medallions representing the first 40 popes and 28 allegories of virtues. were ordered by Innocent X (1644–55) and executed by Bernini. The same architect, commissioned by Alexander VII (1655–67), designed and erected the two semicircular cplonnades: they consist of 284 columns of Travertine placed in four rows and surmounted by a balustrade on which are 140 statues of martyrs and confessors. At the same time Bernini also executed the bronze throne (chair) in the apse resting on statues of two Latin doctors of the church, St. Xugustine and St. Xmbrose. and two Greek doctors. St. Athanasius and St. John Chrysostom. He also erected the fountain to the left of the obelisk, substituting it for the one placed there by Innocent VIII; the other fountain was the work of Carlo Fontana. commissioned by Clement X in 1670.

In the pavement of the central nave are indicated the comparative lengths of the world's largest churches, all less than that of St. Peter's.

The Papal Palaces.— From the 4th century until the Avignonese period (1309–76) the customary residence of the popes was at the Lateran. On the Vatican. Pope Symmachus erected two episcopal residences. one on either side of the basilica. to be used for brief stays and certain functions in the church. On the north side of the basilica Chnrlemagne constructed the Palatium Caroli to house his subjects during their visits to Rome. Other edifices were added by Leo III and later by Eugenius III (1153); modernized by Innocent III, they received added protection in the form of a second fortified wall within that of Leo IV. Remains of the towers of this wall have been found in the Vatican gardens. in the large hall of the palace (chapel of Nicholas V). in the rooms flanking the courtyard of the Pappagallo and beneath the Sala Ducale.

Nicholas III, who began the first of the many edifices known today under the name of papal palaces, built a palace decorated remains of which have been discovered on two levels: in the Sala dei Paramenti, in the Sala della Falda, in the Sala dei Pontefici and in the Cubicolo di Niccolo V for the first floor and in the halls of the Chiaroscuri and of Constantine for the second. Rectangular in form, its chapel occupied the same position as the present Sistine chapel, and its gardens covered the area where today is the courtyard of the Belvedere. Nicholas V rebuilt the north and west walls of the palace of Nicholas III, adding also the fortified bastion called after him. He also founded the Vatican library, making use of the services of the architects Leon Battista Alberti, Bernardo Rossellino, Aristotele di Fioravante, Giacomo da Pietrasanta and Antonio di Francesco. For the same pope Giovanni da Fiesole, better known as Fra Angelico, painted the stories of St. Stephen and St. Lawrence in the chapel of Nicholas V. Paul II constructed the stairway to the right of the archway from the courtyard of the Pappagallo to that of S. Damaso.

Cnder commission from Sixtus IV, Giovanni dei Dolci carried out the construction of the Sistine chapel, embellished with the paintings of Perugino. Pinturicchio. Ghirlandaio. Botticelli. Signorelli and others. He also remodeled and decorated the Vatican library. Innocent VIII (1484–92) rebuilt the lower palace betn·een the basilica and the courtyard of the Maresciallo and also erected the small palace of the Belvedere on the north edge of the hill (its chapel of St. John the Baptist. decorated by Mantegna, was later demolished to make room lor the gallery of statues put up under Clement XIV and Pius VI). Alexander VI (1492–1503) constructed the Korgia tower on the northwest side of the palace and remodeled the rooms on the north flank. called the Borgia apartments. Under Julius II (1503–13), Bramante completed the north façade, two of the so-called *logge* (to which Raphael added a third) and the extensive corridor occupied today by the Chiaramonti and inscription galleries. Julius also commissioned Michelangelo to paint the ceiling of the Sistine chapel (1508–12) and Raphael to decorate the rooms of the Signatura and of Heliodorus. Under Leo X (1513–21), Raphael painted the loggia overlooking the courtyard of the Maresciallo, restored in 1943, as well as the bath of Cardinal Bibbiena. At the same time the small palace flanking the north side of the *logge,* considerably altered under Paul V, was erected.

To the period of Clement VII (1523–34) belongs the bath in the edifice next to the papal stairs. Under Paul III, Antonio da Sangallo (the younger) erected the Sala Regia. the Pauline chapel, the *logge* in the courtyard of the Maresciallo and the bastion on the northwest corner. The painters Giorgio Vasari. Taddeo Zuccaro, the two Della Portas arid Daniele da Volterra decorated the Sala Regia: Michelangelo painted his "Last Judgment" (1535–41) in the Sistine chapel, as well as episodes from the lives of St. Peter and St. Paul in the Pauline chapel (1542–50). Pius IV (1559–65) completed the west side of the corridor of the Belvedere and erected the Casino of Pius IV in the gardens. his architects being Pirro Ligorio and Giovanni Salustio I'eruzzi: today this edifice is the seat of the Pontifical Academy of Sciences. From the time of Pius V (1566–72) are the three chapels of St. Stephen, of St. Peter and of St. Michael, embellished with paintings by Vasari and with stuccoes by Giacomo della Porta. and also the chapel of the Swiss guards painted by Giulio Mazzoni and Daniele da Volterra. Gregory XIII (1572–85) was responsible for the wing closing the north side of the present courtyard of S. Damaso, containing rooms decorated by Antonio Tempesta and Mathys Bril; for the famous Gallery of Maps, designed by Ottaviano Mascherino, with maps of the regions of Italy proposed by the Dominican friar Ignazio Danti: and for the observatory in the Tower of the Winds, with pictures by Niccolo dalle Pomarancie and by M. Bril.

The present papal residence along the eastern side of the courtyard of S. Damaso was erected in the time of Sixtus V (1585–90) by Domenico Fontana. who also constructed a new wing for the Vatican library with the Sala Sistina. thereby cutting in half the Belvedere courtyard. Under Clement VIII (1592–1605) Giovanni and Cherubino Alberti decorated the Clementine hall, while Paul Bril undertook the painting of the Hall of the Consistory; the main entrance to the palaces mas rebuilt with the addition of the bronze doors, executed by Martino Ferrabosco and Giacomo Vasanzio; and the building that flanks the Street of the Lluseums, the halls of the Museo Profano and the fountains of the Specchi, the Torri and the Scoglio (all three in the gardens) also date from this pontificate. Urban VIII (1623–44) constructed the Hall of Countess hlatilda, today called the Matilda chapel, decorated by Pietro da Cortona. Under Alexander VII (1655–67), Bernini constructed the Sala Regia, uniting it with the Sala Ducale. Clement XII (1730–40) added a new wing to the Vatican library, and his successor Benedict XIV joined the Museo Sacro or Christian museum to the library. Clement XIII (1758–69) erected the Gallery of the Candelabra.

Clement XIV (1769–74) and Pius VI (1775–99) were responsible for the construction of the Pio-Clementine museum; this complex includes the Porch of the Four Doors, the Simonetti stairway (named after the architect Michelangelo Simonetti), the Hall of the Greek Cross, the Rotonda, the Hall of the Muses, the Hall of the Animals, the Octagonal courtyard, the Room of the Busts, the Cabinet of Masks and the uncovered loggia. Pius VII (1800–23) founded the Chiaramonti museum and the new wing that intersected the Belvedere courtyard. Under Gregory XVI the Gregorian, Etruscan and Egyptian museums were erected at the north end of the courtyard of the Pigna. Pius IX (1846–78) constructed the magnificent stairway leading up from the bronze doors to the courtyard of S. Damaso and opened. in the Borgia tower, the Hall of the Immaculate Conception, decorated by Francesco Podesti. Leo XIII (1878–1903) added the Gallery of the Chandeliers, painted by Ludwig Seitz and others: he also founded the Vatican observatory in one of the towers of the Vatican gardens. Pius X (1903–14) constructed the underground passage between the corridor of Bramante and the gardens, as well as the stairway between the Viale del Belvedere and the courtyard of the Holy Office. He also located the Pinacoteca in the west wing of the Belvedere corridor.

The activities of Pius XI (1922–39) were many and varied. He erected the radio station in the gardens and the new seat of the Pinacoteca with its entrance formed of a double spiral ramp; added a hall to the Casino of Pius IV; renovated the Vatican library; rearranged the gardens; constructed the governor's palace; and erected the edifices housing the post office, the tribunals, the railroad station, the mechanical centre and the studio for the restoration of art works. After the signing of the Lateran treaty, he remodeled Castel Gandolfo and moved the observatory there. Pius XII (1876–1958) renovated the offices of the secretariat of state, founded the television station and restored the Vatican palaces. A new and more powerful radio station. near Sta. Maria di Galeria, was dedicated by Pius XII at the end of 1957.

The Vatican Library.— From the ancient library of the popes at the Lateran nothing remains except the registers of Innocent III, some inventories for the years 1295, 1327 and 1339, others for the Avignonese period and the *Borghesiana* codices. Xlthough a new library had been developing since the time of Eugenius IV, the true founder of the Vatican library was Nicholas V. Its first permanent seat was in the palace of Nicholas V, located there by Sixtus IV according to a plan made by Bartolomeo Platina. Sixtus V erected the present seat of the library in the courtyard of the Belvedere between 1587 and 1589. Considerably enriched during the 17th and 18th centuries, the library suffered severely when numerous manuscripts and incunabula mere transported to France at the end of the 18th. Leo XIII gave the library its famous consultation hall. and Pius XI was responsible for its modernization. The library contains about 60.000 manuscripts, 7,000 incunabula. 100.000 engravings and maps and more than 700,000 printed books. In 1952 it received through the generosity of Francis Cardinal Spellman the only copy in Europe of the Princeton *Index of Christian Art*, begun by Charles Rufus Morey in 1917.

The Vatican Archives.— Founded in 1612 by Paul V, the Vatican archives contain the acts and documents relative to the government of the church. Leo XIII made these documents available to interested scholars. With it is connected the school of paleography. diplomatic and related sciences, founded by Leo XIII in 1884.

The Medal and Coin Collection.— After the loss in 1798 of the collection of coins and medals from the museums of Benedict XIV and Clement XII. a new collection was begun and enlarged by the acquisition of other collections. Pius XII enriched this with the coins found during the excavations of the 1940s.

VATICAN CITY STATE, the name created for the territory in Rome (area .17 sq.mi., pop. [1959 est.] 1,000) belonging to the Holy See by the Lateran treaty, signed by Cardinal Gasparri, on behalf of the pope, and by Benito Mussolini on behalf of the king of Italy. on Feb. 11, 1929. *See* PAPACY: *The Pupacy in the International Crisis, From 1914;* ITALY; VATICAN, THE.

VATICAN COUNCIL, the most recent ecumenical council of the Roman Catholic Church. It was convened in 1869 and prorogued in 1870; it was never formally dissolved. The principal achievement of the council was the decree *Pastor Aeternus,* asserting the infallible authority of the pope in matters of faith and morals.

Since the Council of Trent (1545–63), no general council' had assembled. In the meantime the rise of rationalism, liberalism and materialism had brought forth systems of thought that denied such fundamental Christian dogmas as the possibility of divine revelation: the existence of God and the immortality of the soul. The desire for a condemnation of these errors and the need for a reform of church law were the principal motives that led Pope Pius IX to begin in 1864 to prepare for a general council. The critical political situation in Europe, and particularly in Italy, seemed to offer but little hope for a successful council. but thanks to the presence of French troops in Rome and to the indifference of the powers. Pius IX was able not only to prepare and assemble the council but also to carry through some important actions between the close of the Seven Weeks' War (*q.v.*) between Prussia and Austria (1866) and the occupation of Rome by the forces of Victor Emmanuel II (1870).

The formal summons to the council was issued on June 29, 1868. At the outset the prospect of a council was greeted with joy by Catholics and benevolent neutrality by Protestants. But not long after the official convocation a storm arose that had repercussions within and without the church. Of little importance was a council of freethinkers assembled at Naples in opposition to the council by Italian Freemasons. The oriental churches, not in union with Rome. rejected an invitation to appear at the council, as did the Protestant churches. Far more important were the reactions within the church itself. Manifestations of discontent soon were observed, particularly in Germany, France and England. In those countries a statement of the papal prerogatives was foreseen and feared. Although the Catholic teaching on this subject had formerly provoked opposition in Gallican and Febronian circles, papal infallibility was looked upon by a majority even of the French episcopate as a truth revealed by God, but the opportuneness of defining it (stating it precisely and making it obligatory doctrine for the whole church) was an open question. It soon became obvious that the question of papal infallibility was destined to dominate the council.

The occasion of the controversy was a communication from France that appeared in the Feb. 1869 issue (series vii. vol. v. p. 34j ff.) of the *Civiltà Cattolica*, organ of the Italian Jesuits. The writer divided the French Catholics into those who were simply Catholics (*Cattolici semplicemente*) and those who were liberal

Catholics *(Cattolici liberali)*. He stated that the former formed the great majority of the Catholics of France and would welcome the proclamation'of papal infallibility.

Thereupon a series of articles (afterward published in book form as *Der Papst und das Konzil* ["The Pope and the Council"]), angrily attacking the doctrine of papal infallibility. appeared in the Augsburg *Allgemeine Zeitung*. The author disguised his identity under the pen name of Janus but was apparently Ignnz von Dollinger (*q.v.*), one of the leading Roman Catholic historians of Germany. Certainly Prince Hohenlohe, foreign minister of Bavaria. acting under Döllinger's influence, tried to induce the powers to take concerted action to prevent the definition. but his efforts were futile. In France Bishops H. L. C. Maret and Félix Dupanloup wrote against the definition of papal infallibility. and answers appeared from the pens of Archbishop Henry Edward Manning (*q.v.*) in England, of Xrchbishop Xdolphe Dechamps in Belgium and of Joseph Hergenrother of Würzburg (*Anti-Janus*, Freiburg, 1870). German opinion was particularly agitated, and 14 of the 22 German bishops thought it advisable to warn Pius IX that a definition of papal infallibility was inopportune. The consequence of this controversy was that before the council began, the Fathers (cardinals. archbishops, bishops, abbots and generals of orders) were already divided into two groups: those for the definition and those against it. Archbishop Manning was the leader of the former group. Bishop Dupanloup of the latter.

Organization. — In186j Pius IX named a commission of cardinals, known as the central commission. to direct the preparations for the council. The central commission named subsidiary commissions on faith and dogma. on ecclesiastical discipline and church law. on religious orders, on oriental churches and ioreign missions. on politico-ecclesiastical affairs and relations of church and state. and on rites. In all, these subcommissions comprised 102 members, of whom 10 were bishops. 69 secular priests and 23 religious priests. The labours of the commissions were conducted in the greatest secrecy. They resulted in 51 schemata (proposed decrees), carefully prepared for the consideration of the Fathers of the council.

The Vatican council was formally opened by Pius IX on Dec. 8, 1869. Of the 1,055 Fathers who had a right to vote. 774 eventually appeared. Principally because of the differences with the Italian king, the pope had judged it opportune to break with a custom that went back to Constantine the Great and not invite the Catholic princes to attend.

The schemata were discussed in general congregations of the Fathers. Such alterations as were considered necessary could be introduced. In order to facilitate the work of the congregations, four permanent committees were established. the most important of which was the Committee on Faith. The leaders of the majority endeavoured to exclude from this committee any member of the minority opposed to a pronouncement on papal infallibility. In so doing they were acting against the wishes of Pius IX. who would have welcomed the choice of Bishop Dupanloup. Xrchbishop Manning. who said. "Heretics come to a council to be heard and condemned. not to take part in formulating doctrine." was chiefly responsible. The bishops of the minority could of course defend their position in the general congregations: but it was strange that a group comprising so many learned and distinguished men should have little or no representation (a member of the minority had been included by mistake) on the most important committee.

Decree **"Dei Filius."**—The debates on the first schema. "On Catholic doctrine against the errors stemming from rationalism," opened on Dec. 28, 1869. After lively and sometimes violent discussions, occupying 23 general congregations, the decree ***Dei** Filius* was unanimously voted on April 24. 1870. The first chapter treats of God. Who has of His goodness and by His almighty power created all things. Who foresees all things and Who by His providence protects and governs all things. The second chapter declares that God. the beginning and end of all things, can. from created things. be known with certainty by the natural light of reason; it then treats of the necessity and existence of supernatural revelation. The third chapter treats of faith! its reasonableness, supernaturalness and necessity. The fourth chapter treats of the relations of faith and reason: although faith is above reason. there can never be any real discrepancy between them since God. who reveals mysteries. is also author of reason.

Infallibility. — From the beginning of the council the question of papal infallibility had been an issue. No provision had been made for a discussion of this thorny question, but since the majority of the bishops desired the definition the matter could not he excluded from the agenda.

On Dec. 23. 1869. Archbishop Dechamps. Archbishop Manning and others launched a campaign to define papal infallibility. This initiative was successful, and soon more than joo of the Father? had subscribed to the plea. The petitions of the minority opposed could muster only 136 names. As a result a chapter on papal infallibility was added to the schema "The Church of Christ." On April 27, 1870, it was decided to take up immediately the discussion of this additional chapter, which was transformed into a separate decree. Under threat of interference from the powers. the council worked feverishly, holding betn-een May 13 and July 16. 1870, no fewer than 37 general congregations.

The minority alleged many arguments against the opportuneness of the definition and also against the doctrine itself. The majority defended papal infallibility n-ith great vigour, maintaining that the doctrine was clearly contained in both Scripture and tradition, that the historical difficulties alleged were not decisive and that the power of bishops and general councils would not be destroyed by the definition. After various alterations in the text oi the schema. the definitive ballot was taken in the 85th general congregation on July 13. 1870. Of 601 \\-ho were present, 451 voted in favour of the decree. which is known as *Pastor Aeternus*. Of the other 150. 62 accepted it on condition that certain alterations be made. and 88 rejected it. Of the 88. only 15 were opposed to the doctrine itself. On Monday, July 18. 1870. one day before the outbreak of the Franco-German War. 535 Fathers assembled in St. Peter's under the presidency of Pius IX and the last vote n-as taken: j33 Fathers voted *placet*, and only two, Bishop Aloisio Riccio of Cajazzo in Italy and Bishop Edward Fitzgerald of Little Rock. Ark., voted *non placct*. The pope immediately promulgated the dogma.

The decree *Pastor Aeternus* teaches that St. Peter had a true primacy of jurisdiction over the universal church and that this primacy passed to his successors. the bishops of the see of Rome; that accordingly the Roman pontiff enjoys full and supreme power of jurisdiction over the whole church; that he has the right of free communication with the pastors of the whole church and with their flocks; and that the primacy of the Roman pontifi includes the supreme teaching power to which Jesus Christ added the prerogative of infallibility:

> When, in the exercise of the office of pastor and teacher of all Christians, the Roman pontiff by virtue of his supreme apostolic authority teaches definitively that a doctrine concerning faith or morals is to be held by the universal church, he is, through the divine assistance promised to him in St. Peter. possessed of that infallibility with which the divine Redeemer willed his church to be endowed.

After the discussion on infallibility the Fathers n-ere permitted to Ieave Rome for a few months. Before they could return the Piedmontese troops occupied Rome. On Oct. 20. 1870. Pius IS prorogued the council indefinitely. It had completed only a small fraction of the work planned.

Results of the Decree "Pastor **Aeternus."**—Within a few years all the members of the episcopate who had opposed the definition signified their acceptance of the conciliar decision. In Germany.however, a number of priests and professors decided to resist the Vatican decrees.and their move was imitated in other countries. This led to the formation of the Old Catholic Church. which at one time numbered over 150,000 members in Germany, Switzerland. Austria. the Setherlands and other countries. These losses to the church were offset, however. by its gain in the council's clear and unequivocal statement on the nature of the papacy. The controversy that had arisen at the Council of Constance (1414–18) regarding the superiority of the council over the pope was now definitely settled. Gallicanism and Febronianism were finally banned, and the union of all Catholics with the Roman pontiff was greatly strengthened. Apart from the defection of the Old Catholics, the fear of losses to the church expressed at the council was not realized. Later popes have made little use of the defining power, the one certain instance being the definition by Pope Pius XII (1876–1958) on Nov. 1, 1950, of the dogma of the Assumption of the Blessed Virgin Mary into heaven. Furthermore, there is no indication that the power of the bishops has been diminished. Some, indeed, hold that practically it has increased.

VATICAN STATE: *see* VATICAN CITY STATE.

VATTEL, EMERICH DE (1714–1767), Swiss jurist whose reputation rests chiefly upon his treatise on international law, was born at Couvet, in the principality of Neuchâtel. April 25, 1714. The treatise he frankly confessed was not an original work but a popularization of a volume published in 1749 by the German philosopher Christian Wolff and entitled *Jus gentium.* Vattel's own work. published in 1758. bears the title *Le Droit des gens* ("Law of Nations"). with the subtitle "Principles of Natural Law Applied to the Conduct and Affairs of Nations and Sovereigns." Vattel died at Neuchâtel on Dec. 28, 1767.

Vattel's analysis of international law is elaborate and complex. He explicitly rejects Wolff's conception of a commonwealth of nations. a world state having authority over its component members; in its place he substitutes rights and obligations derived from the law of nature. which he holds to be binding upon nations as upon their individual citizens. Where the inference from the law of nature is clear, the rights and duties are absolute; where the inference is not clear, each state must be allowed to judge for itself the extent of its obligations, nith the result that many of Vattel's conclusions are no more than his personal interpretations of the proper conduct of sovereigns.

In spite of its logical weaknesses. Vattel's treatise exercised great influence over the development of' international law, especially in the United States. where it was quoted not only by secretaries of state but also by federal judges in cases involving international law. His wealth of illustrations came to serve as precedents, and his liberal and humanitarian principles were readily adaptable to the policy of a democratic state. The principles of liberty and equality that he had absorbed in his native country fitted well into the ideals of the Declaration of Independence. Particularly his defense of neutrality and his detailed rules upon commerce between neutrals and belligerents proved to be of service to U.S. statesmen.

Translations of Vattel's work appeared almost immediately after its publication, the translation by Joseph Chitty being perhaps the best known. In 1916 the Carnegie Endowment for International Peace published a photographic copy of the original text of 1758, with an introduction by Albert de Lapradelle and a new translation by C. G. Fenwick.

See Charles G. Fenwick, "The Authority of Vattel," *American Political Science Review,* 7:395 (1913), 8:375 (1914); Arthur Nussbaum, *Concise History of the Law of Nations,* rev. ed. (1956). (C. G. Fx.)

VAUBAN, SEBASTIEN LE PRESTRE DE (1633–1707), marshal of France, was born at Saint-Léger-Vauban (Yonne). At the age of ten he was left an orphan in poor circumstances, and his youth was spent amongst the peasantry of his native place. At the age of seventeen Vauban joined the regiment of Condé in the war of the Fronde. He was soon offered a commission which he declined. Condé then employed him in the fortification of Clermont-en-Argonne.

Soon afterwards he was taken prisoner by the royal troops, and was converted into a devoted servant of the king. He besieged and took his own.first fortress, Clermont; in May 16jj he became an *ingénieur du roi.*

After the peace of Aix-la-Chapelle Vauban improved or rebuilt various fortresses. Hitherto the characteristic features of his method of fortification had not been developed, and he followed the systems of preceding engineers. Colbert and Louvois were profoundly intcrcstcd in the work, and it was at the request of the latter that the engineer drew up in 1669 his *Mémoire pour servir à l'instruction dans la conduite des sikges* (this, with a memorandum on the defence of fortresses by another hand was published at Leiden, 1740).

On the renewal of war Vauban conducted the sieges of Rheinbergen and Nijmwegen 1672, Maestricht and Trier 1673, Besançon 1674.

Vauban's introduction of a systematic approach to strong places by parallels dates from the siege of Maestricht, and in principle remains to this day the standard method of attacking a fortress. Vauban became *commissaire-général des fortifications* on the death of De Clerville, and in 1681 rebuilt the fortress of Strasbourg.

At Saarlouis for the first time appeared Vauban's "first system" of fortification. He always retained what was of advantage in the methods of his predecessors. In 1682 his "second system," which introduced modifications designed to prolong the resistance of the iortress, began to appear.

In 1687 Vauban chose Landau as the chief place of arms in lower Alsace. But side by side with this development grew up the far more important scheme of attack. He instituted a company of miners, and the elaborate experiments carried out under his supervision resulted in the establishment of all the necessary formulas for military mining *(Trait6 des mines* [Paris, 1740, 1799; The Hague. 1744]); at the siege of Ath in 1697 he employed ricochet fire for the first time to break donn the defense. He had indeed already used it with effect at Philipsburg in 1688 and at Namur, but was hindered by the jealousy of the artillery. After the peace of Ryswick Vauban rebuilt or improved other fortresses, and finally New Breisach, fortified on his "third system," which he called *système de Landau perfectionné.* His last siege was that of Old Breisach in 1703, which he reduced in a fortnight. On Jan. 14 Vauban had been made a marshal of France, a rank too exalted for the technical direction of sieges, and his active career came to an end with his promotion. Soon afterward appeared his *Traite' de l'attaque des places.*

But Louis XIV was now on the defensive, and the War of the Spanish Succession saw the gradual wane of Vauban's influence, as his fortresses were taken and retaken. The various captures of Landau, his *chef-d'oeuvre,* caused him to be regarded with disfavour; he then turned his attention to the defense; but his work *De la défense des places* (ed. by General Valazé, Paris. 1829) is of far less worth than the *Attaque,* and his ideas on entrenched camps (*Traité des fortifications de campagne*) were coldly received. though they contained the elements of the "detached forts" system that came to be universal in Europe. He now devoted himself to the arrangement of the manuscripts (*Mes oisivetés*) which contained his reflections on war, administration, finance, agriculture and the like. In 1689 he made a representation to the king in favour of the republication of the Edict of Nantes, and in 1698 he wrote his *Projet d'une dixme royale* (see *Economistes financières du XVIII^e sikcle* [Paris, 1851]), a remarkable work foreshadowing the principles of the French Revolution.

Vauban was impressed with the deplorable condition of the peasantry, nhose labour he regarded as the main foundation of all wealth, and protested against unequal taxation and the exemptions of the upper classes. His *dixme royale,* a tax to be impartially applied to all classes, was a tenth of all agricultural produce payable in kind. and a tenth of money chargeable on manufacturers and merchants. This work was published in 1707 and instantly suppressed by order of the king. The marshal died heartbroken at the failure of his efforts a few days after the publication of the order (March 30. 1707). At the Revolution his remains were scattered, but in 1808 his heart was found and deposited by order of Napoleon in the church of the Invalides.

VAUCLUSE, a *de'partement* of France, formed in 1793 out of the countship of Venaissin, the principality of Orange and a part of Provence. and bounded by Drôme on the north. Basses-Alpes on the east, Bouches-du-RhBne (from which it is separated by the Durance) on the south and Gard and Ardkche (from which it is separated by the RhBne) on the west. It has also an enclave, the canton of Valréas, in the *département* of Drôme. Pop. (1954) 268,318. Area, 1,382 sq.mi. In the *de'partement* east to west chains of the French Alps die down westward toward the RhBne; the northernmost includes the Montagne de Lure (5,994 ft.) and Mont Yentoux (6,273 ft.) and is separated from the next, the Plateau de St. Christol (4,075 ft.), by the Nesque river; the river Coulon separates this plateau from the Chaine du Léberon (3.691 ft.), which in turn is bounded on the south by the Durance. The very numerous streams feed irrigation canals. The climate is that of the Mediterranean region. The valley of the RhBne suffers from the mistral, a cold and violent wind from north-northwest. but the other valleys are sheltered by the mountains, and produce oleander, pomegranate, olive, jujube, fig and other southern trees and shrubs. The winter average temperature is about 41° and the summer average temperature 73°. Wheat and potatoes are the most important crops; sugar beets, sorghum, millet, ramie! early vegetables and fruits: notably the melons of Cavaillon, are cultivated, and also the vine, olive. mulberry and tobacco. The truffles of the regions of Apt and Carpentras and the fragrant herbs of the Ventoux range are renowned. Sheep are the principal livestock, and mules are also numerous. Lignite and sulphur are mined; rich deposits of gypsum, fire clay, ochre, etc., are worked. Beaumes-de-Venise and Montmirail have mineral springs. The industries include the spinning and weaving of silk, wool and hemp, metalworking, printing (Avignon), tanning and the making of paper, bricks, tiles, pottery, glassware and tobacco. The department is served by the P.L.M. railway, and the Rhône is navigable for 40 mi. within it. It is divided into three *arrondissements* (Avignon, Carpentras and Apt), 22 cantons and 151 communes. Avignon, the capital, is the seat of an archbishop. The department belongs to the region of the 15th army corps and to the *académie* (educational division) of Aix, and has its appeal court at Nimes.

The chief towns are Avignon, Apt, Carpentras, Cavaillon, Orange and Vaison-la-Romaine.

VAUD (Ger. WAADT), a canton of southwestern Switzerland, lying mainly between the Lake of Neuchâtel and the Lake of Geneva. It occupies 1,240 sq.mi., of which 85% is productive. Vaud. with 119.8 sq.mi. of water surface of the larger lakes, has more than one-quarter of the total for Switzerland. The largest lake in Yaud is de Joux (3.7 sq.mi.). There are more than 4 sq.mi. of glaciers; these and the loftiest summit in the canton (Diablerets, 10.528 ft.) occur in the western Bernese Oberland (S. Vaud). The canton includes most of the northern shore of the Lake of Geneva and stretches from slightly beyond Bex in the southeast to the Juras on the northwest. A long, narrow eastern tongue extends past Payerne to the Lake of Neuchâtel. Beyond its tip is the Avenches region, forming an enclave in Fribourg. Parts of Fribourg, in turn. form enclaves within Vaud along the shore of Neuchâtel. A strip of the right bank drainage of the RhBne (from above Bex to the Lake of Geneva) lies within the canton, but north and northeast of Lausanne the land is drained by the Broye and Thikle, of the Aar-Rhine basin.

Vaud, with plains near the lakes, is hilly rather than mountainous. Lausanne is a railway centre. and the canton has numerous small-gauge railways and mountain lines. In 1950 the population was 377.585. of whom 319.287 were French-speaking, 41.818 German-speaking, 10,925 talia an-speaking; 294.823 were Protestants, 75.142 Catholics, 1,814 Jews. In 1960 the population was 429.512.

The vineyards (15.4 sq.mi.), though showing a considerable decrease during the 20th century, are still the most extensive in Switzerland. White wines predominate; the best come from Yvorne (near Aigle), while the slopes of La Vaux (east of Lausanne) produce both red and white wine. Tobacco is grown in northeast Vaud, particularly near Payerne, and cigars are made at Grandson. Ste. Croix, in the Jura, is world-famed for watches, gramophones, musical boxes and jewelry. The Juras produce limestones and sandstones, and the canton-owned salt beds at Bex provide raw materials for a thriving chemical industry. Vaud is famed for its health resorts and for its educational establishments; visitors chiefly frequent Lausanne, Vevey, Montreux and Château d'Oex in the upper Saane valley. Lausanne academy (founded 1537) was raised to university rank in 1890; the 12th-century castle in Yverdon was the residence and school of Pestalozzi from 1806 to 1825. Lausanne (*q.v.*) is the political capital. The "agglomeration" known as Montreux in 1960 had 12,222, while Vevey had 16.269 and Yverdon 16,338. Other important small towns in 1960 were Ste. Croix (6,925), Payerne (6,024), Nyon (7,643), Morges (8,420), Aigle (4,381) and Château d'Oex (3.378). Among the historical spots are Avenches (the largest Roman colony in Helvetia), Grandson (scene of the first great victory of the Swiss against Charles the Bold in 1476), and the castle of Chillon (where Bonivard, lay prior of St. Victor, near Geneva, was imprisoned 1530–36 for defending the freedom of Geneva against the duke of Savoy).

The canton is divided into 19 administrative districts and contains 388 communes. Its constitution dates from 1885. The legislature consists of a *grand conseil* of 219 deputies (one member to every 450 electors) with an executive *conseil d'état* of seven members; both bodies hold office for four years. Six thousand citizens can compel the government to consider any project, whether legislative or constitutional; this initiative dates back to 1845. Since 1885 the referendum has existed in its "facultative" form for certain measures, and in its obligatory form for financial matters. The two members of the federal *standerat* are named by the *grand conseil,* while the 15 members of the federal *nationalrat* are chosen by a popular vote.

History. — The early history of the canton is that of southwest Switzerland. The Romans conquered (58 B.C.) the Celtic Helvetii and so thoroughly colonized the land that it has remained a Romance-speaking district. It formed part of the empire of Charlemagne, and of the kingdom of Transjurane Burgundy (888–1032). After the extinction of the house of Zahringen (1218) the counts of Savoy gradually won the larger part of it, especially in the days of Peter II, "le petit Charlemagne" (d. 1268). The bishop of Lausanne, however, still maintained the temporal power given to him by the king of Burgundy, and in 1125 had become a prince of the empire. (There is a distinction between the canton of Vaud and the old medieval Pays de Vaud: the districts forming the canton very nearly correspond to the Pays Romand.) In 1536, both Savoyard Vaud and the bishopric of Lausanne were annexed by Berne. Berne in 1526 sent Guillaume Farel, a preacher from Dauphiné, to carry out the Reformation at Aigle, and after 1536 the new religion was imposed by force of arms and the bishop's residence moved to Fribourg (permanently from 1663). Thus the whole land became Protestant, save the district of Échallens. Vaud was ruled harshly by bailiffs from Berne. Political feeling was therefore much excited by the outbreak of the

French Revolution. and a Vaudois, F. C. de La Harpe, an exile and a patriot, persuaded the Directory in Paris to march on Vaud in virtue of alleged rights conferred by a treaty of 1565. The French troops were received enthusiastically, and the "Lemanic republic" was proclaimed (Jan. 1798), succeeded by the short-lived Rhodanic republic, till in March 1798 the canton of Léman was formed as a district of the Helvetic republic. This corresponded precisely with the present canton minus Avenches and Payerne, which were given to the canton of Vaud (set up in 1803). The new canton was thus made up of the Bernese conquests of 1475, 1475–76, 1536 and 1555. The constitutions of 1803 and 1814 favoured the tonns and wealthy men, so that an agitation went on for a radical change, which nas effected in the constitution of 1831. Originally acting as a mediator, Vaud finally joined the anti-Jesuit movement (especially after the Radicals came into power in 1845). opposed the Sonderbund and accepted the new federal constitution of 1848, of which Druey of Vaud mas one of the two drafters. From 1539 to 1846 the canton was distracted by religious struggles, as a result of the attempt of the Radicals to turn the church into a simple department of state, a struggle which ended in the splitting off (1847) of the "free church." In 1882 the Radicals obtained a majority, and in 1885 the constitution of 1861 was revised. See SWITZERLAND: *History*.

VAUDEVILLE. The term vaudeville. which in modern popular usage in the United States and, to a lesser extent. in England, is synonymous with music hall and variety shows (see MUSIC HALL AND VARIETY), is of French origin. According to one derivation, it is a corruption of *vaux-de-vire,* satirical songs sung to popular airs in the 15th century in the Val (*Vau*)-de-Vire, Normandy. It is possible that the author of some of the songs was Olivier Basselin (*q.v.*). This derivation fits in with characteristics which remained constant in French vaudevzlle: the songs were in couplets, were political and satirical, and were sung to popular tunes. The term vaudeville was used to describe ballads of this type by Boileau in 1674.

The term passed into theatrical usage in the early 18th century as a device employed by professional actors and strolling players to circumvent the dramatic monopoly held by the state theatre. the Comédie Française. Forbidden to perform legitimate drama, they were forced to present their plays in pantomime, interpreting the action with lyrics and choruses set to popular tunes. The *comédie-en-vaudevilles* thus became an established part of the repertory of the theatres in street fairs (*théâtres* de la *foire*), and its success emboldened playwrights and producers to create a form of light musical drama, with spoken dialogue interspersed with songs. These *pièces* en vaudeville, as they were called, corresponded in kind to the English ballad opera (*q* v.) and developed into the specifically French *opéra comique;* their history also forms part of the development of opera.

Vaudeville continued to have its influence in the French theatre, and from the musical vaudevilles of C. S. Favart and M. J. Sedaine (*qq.v.*) developed the more literary comedies of Eugène Scribe and Eugène Labiche (*qq.v.*). It also spread to Austria. where vaudevilles were popular in Vienna in the 18th and 19th centuries, and to Denmark where it was introduced by J. L. Heiberg and imitated by Henrik Hertz (*qq.v.*).

In the United States the development of variety entertainment was encouraged from the beginning, although the word vaudeville was not used to describe it until late in the 19th century. The companies that toured between the widely separated urban centres of the colonies and the early states founded their popularity as much on the entr'acte specialties of the individual performers as upon their legitimate offerings. The scattered frontier settlements eagerly nelcomed strolling acrobats, singers and storytellers nhere formal companies could not afford to travel. In the larger cities so-called museums added freaks, trained animals and skits to their inanimate exhibits. Perhaps the best known of these uas Phineas T. Barnum's American museum in New York, established in 1841. In 1842 the Franklin theatre in New York advertised itself as the first variety theatre in that city; it nas at least the first New York theatre to maintain for a dozen years a program of what was later called vaudeville. It opened with J. Morris' Concert and Olio company of 20 persons. offering living models, magic lantern slides, comic lecturers and so on.

The olio seems to have originated as a feature of the minstrel show, a variety entertainment that came into popularity in the decades before the Civil War. The minstrel show. performed by a troupe of white men in blackface, consisted of a first part of songs and jokes, a second part or olio of skits and specialties, and a finale that usually was a legitimate play digested or parodied.

In the 1850s and '60s straight variety began to grow in popular favour until the "concert saloons" in which it was played outnumbered the regular theatres and spelled the death of the resident minstrel troupe. Many of these saloons were described as "dumps and slabs," the equivalent of the British "free and easies," beer parlours whose patrons were generally masculine and loner class and whose programs were always vulgar and sometimes downright obscene. But with the debut of Tony Pastor at the American theatre in the 1860s vaudeville became increasingly domesticated and respectable, with performance standards of narrow but incredible perfectionism. After a brief career as a singer of sentimental ballads. Pastor established on 14th street a small theatre dedicated in 1881 to the "straight. clean, variety show." His unexpected success encouraged other managers to elaborate on his code of prohibitions, until vaudeville achieved the innocuousness of a Sunday school picnic.

The vagabond life of the vaudeville performer (Fred Allen called him part gypsy and part suitcase) forced him to develop the qualities that made the vaudeville stage a training ground for the more serious theatres arts: precision, polish, timing and secure resources for producing gaiety or pathos on demand. The vaudeville actor was rarely allowed more than ten minutes for his turn, which meant that he must be able to establish himself without wasted motion, must display his talents with unvarying skill and move speedily to the climax, or "wow finish," knowing that he had no second chance. Under such conditions were developed the talents of Pat Rooney, the song-and-dance man; W. C. Fields, juggler and comic; and (Jim) MacIntyre and (Tom) Heath, whose "Ham Tree" nas perhaps the most famous of all blackface skits. Out of vaudeville and into the legitimate theatre went such stars as Sam Bernard, Lillian Russell, (Charles) Evans and (Bill) Hoey, May Irwin, Francis Wilson and Nat C. Goodwin. Through vaudeville such European stars as Harry Lauder, Albert Chevalier, Yvette Guilbert and Vesta Victoria first confronted United States audiences A typical bill might open with a song-and-dance team, followed by a singer, a comedy sketch, a monologuist, a character specialty (such as Will Rogers, with trick cowboy-style roping and comic patter), a musical act from the legitimate theatre, a dramatic skit (like the oft-performed *The* Valiant), a "headliner" (such as the singer Eva Tanguay. the "I Don't Care Girl"), concluding with an acrobatic troupe. From about 1895, a short program of motion-picture viens mas used to "clear the house."

In the days of Tony Pastor, vaudeville was an individual operation, the manager booking acts for his theatre alone, and the acts moving from theatre to theatre and town to town as bookings were offered them. By the end of the 19th century. however, the era of the vaudeville chain. a group of houses controlled by a single manager, mas firmly established. Among these managers were Percy C. Williams, who operated a dozen theatres in New York city, Sylvester Z. Poli in New England, Alexander Pantages on the west coast, Charles Kohl and George Castle in the midwest and Gus Sun in Ohio. Dominating all was Benjamin Franklin Keith, who had opened a museum in Boston in 1883. Two years later he joined forces with Edward Franklin Albee to establish the Boston Bijou as the home of "continuous vaudeville," playing from 10 A M. to 11 P M. Success led Keith and Albee to Providence to Philadelphia and finally in 1893 to New York. By 1920 Keith and Albee controlled nearly 400 theatres in the east and midwest, a chain governed by an iron financial and managerial hand and operated on puritanical principles. Through its United Booking office (1900) and its company union, the National Vaudeville Artists (1916), it achieved a near monopoly on both talent and production.

Keith and Albee's chief opposition came from the Orpheum circuit, whose manager, Martin Beck, controlled houses from Chicago to California. Beck built the Palace theatre in New York, from 1913 to 1932 the outstanding vaudeville house in America. Criticism too came from the trade paper *Variety,* founded by Sime Silverman in 1905 to report honestly and frankly on the conditions of the profession and to comment without fear or favour on the performers, performances and the managers. Final defeat for vaudeville came from mechanically reproduced theatre entertainment. Motion pictures, first introduced in 1893 by the former brewers John Koster and Adam Bial at their 31th Street Music hall in New Tork city as an added attraction, gradually consumed more and more of the performing time until. after the advent of the "talkies" about 1927, the customary bill featured a full-length motion picture with "added acts" of vaudeville. Circuits dwindled and playing time grew shorter. Keith-Xlbee absorbed Orpheum. but the combine was in turn absorbed by a film company. A great financial depression and the rapid growth of sponsored radio in the 1930s further restricted vaudeville to a few large population centres. After World War II the rapid development of television was another blow and vaudeville became almost a thing of the past. *See* also THEATRE.

VAUGELAS, CLAUDE FAVRE, SEIGNEUR DE. BARON DE PÉROGES (1595–1650), French grammarian and man of letters. was born at Meximieu (Ain), on Jan. 6, 1595. Vaugelas was among the original Academicians. In his *Remarques sur la langue française* (1647), he maintained that words and expressions were to he judged by the current usage of the best society, of which, as an habitué of the Hôtel de Rambouillet, Vaugelas was a competent judge. He shares with Malherbe the credit of having purified French diction. His book fixed the current usage, and the classical writers of the 17th century regulated their practice by it. He died in Paris in Feb. 1650.

VAUGHAN, HENRY (1622–1695), British poet and mystic remarkable for the range and intensity of his spiritual intuitions, came of an ancient Welsh family and was born on April 17, 1622, at Llansantffraed. Breconshire, where he lived nearly all his life. He and his twin brother Thomas were privately educated by Matthew Herbert, a neighbouring rector, and went on to Jesus college, Oxford. Henry spent two years there from about 1638 and then went to London to study law, but he was summoned home in 1642 on the outbreak of the Great Rebellion, in which he seems to have taken some part on the royalist side. In 1646 he published *Poems, With the Tenth Satyre of Juvenal Englished* ("The Vanity of Human Wishes") and he had another volume of secular verse ready the next year; but between 1646 and 1650 he was profoundly impressed by George Herbert's poetry and, partly as a result of this, underwent a "conversion" which led him to repudiate all "idle verse." His *Silex Scintillans* (1650, enlarged 1655) and the prose *Mount of Olives or Solitary Devotions* (1652) show the depth of his religious convictions and the authenticity of his poetic genius. Of his secular poems, *Olor Iscanus* was puhlished in 1651 and *Thalia Rediviva* in 1678, both ostensibly without his sanction; but it is his religious poetry that has made his name live. He translated a number of short moral and religious works in prose, four included in *Olor Iscanus*, one in *The Mount of Olives* and four in *Flores Solitudinis* (1654). By that time he had become interested in medicine and, probably at his brother's instigation, he translated two medical works by Heinrich Nolle, under the titles *Hermetical Physick* (1655) and *The Chymists Key* (1657). When he began to practise medicine is not known, but he seems to have continued to do so with good results until shortly before he died in Llansantffraed on April 23, 1695. He was twice married. Little is known about his character except for Anthony à Wood's observation that he "was esteemed by scholars an ingenious person, but proud and humorous," and for what can be gathered from his letters (nine are extant) and his published works.

Vaughan learned a great deal from other writers and borrowed many phrases from George Herbert. He was nevertheless one of the most original poets of his day. His chief asset was a gift of spiritual vision or Imagination which enabled him to write of immaterial things more freshly and convincingly than any of his contemporaries except Milton; and this is illustrated not only in the famous lines beginning

> I saw Eternity the other night
> Like a great Ring of pure and endless light,

but when he plays the same light of eternity round things of common experience. He was a great lover of natural beauty and took easily to the old notion of a life in nature, making it his faith that every flower enjoys the air it breathes and that even sticks and stones share in the earnest expectation of the creature:

> I would I were a stone or tree
> Then should I (tied to one sure state)
> All day expect my date,

and

> Each Bush
> And Oak doth know I AM; canst thou not sing?

The often-pointed contrast between unfallen nature and degenerate man gained force with him from the political events of the 1640s; and these may also help to explain Vaughan's retrospection, his idealizations of the past and his readiness to admire all fresh, unspoiled, pristine existences, including childhood, the time of "white Celestial thought" and paradisal memories:

> When on some gilded Cloud, or flower,
> My gazing soul would dwell an hour,
> And in those weaker glories spy
> Some shadows of eternity.

The element of greatness in Vaughan's poetry owed much to his power of seeing all things *sub specie aeternitatis*, nourished in him not only by Christian theology but by Neoplatonist traditions and the sort of theosophical speculations favoured by his brother Thomas. Some features of Vaughan's poetry have analogies in that of Wordsworth (the similarities between "The Retreat" and the ode on "Intimations of Immortality" have often been appreciated); and it is possible that Wordsworth was influenced by Vaughan.

His technical accomplishments were of a higher order than has usually been recognized. He had not Herbert's sense of build and finish, but he knew how to make idiomatic usage serve the purposes of poetry, and he was a master of evocative phrasing and persuasive rhythm. His prose also deserves attention, not only for its molding and fluency but for the further light which it throws on his mind and imagination; for though most of it is translation he often interrupts his originals to insert his own self-revealing comments.

His poetry was largely disregarded in his own time and for over 100 years after his death. In the 19th century several editions appeared, of which those by H. F. Lyte, A. B. Grosart and E. K. Chambers were the chief. His *Works* were edited by L. C. Martin (2nd ed 1958).

See F. E. Hutchinson, *Henry Vaughan: a Life and Interpretation* (1947). (L. C. MN.)

VAUGHAN, HERBERT (1832–1903), cardinal and archbishop of Westminster, was born at Gloucester on April 15, 1832. He spent six years at Stonyhurst, and was then sent to study with the Benedictines at Downside, near Bath, and subsequently at the Jesuit school of Brugelette, Belgium, which was afterward removed to Paris. In 1851 he went to Rome. After two years of study at the Xccademia dei Nobili Ecclesiastici, where he became a friend and disciple of H. E. Manning, he took priest's orders at Lucca in 1854. On his return to England he became for a period vice-president of St. Edmund's college, Ware, at that time the chief seminary for candidates for the priesthood in the south of England. Since childhood he had been filled with zeal for foreign missions, and he conceived the determination to found a great English missionary college to fit young priests for the work of evangelizing the heathen. With this object he made a great begging expedition to America in 1863, from which he returned with £11,000. St. Joseph's Foreign Missionary college, Mill Hill Park, London, was opened in 1869. Vaughan also became proprietor of the *Tablet*, and used its columns vigorously for propagandist purposes. In 1872 he was consecrated bishop of Salford, and in 1892 succeeded

Manning as archbishop of U'estminster, receiving the cardinal's hat in 1893.

It was his most cherished ambition to see before he died an adequate Roman Catholic cathedral in Westminster, and he laboured untiringly to secure subscriptions. with the result that its foundation stone was laid in 1895, and that when he died, on June 19. 1903, the building was so far complete that a Requiem Mass was said there over his body.

See the *Life of Cardinal Vaughan,* by J. G. Snead Cox (2 vol., 1910).

VAUGHAN, THOMAS (1622–1666), British chemist and mystic whose writings, once notorious for their obscurity, are yet sometimes comparable with those of his elder twin brother Henry, the poet, was born on April 17, 1622, at Llansantffraed, Breconshire. Thomas was educated at Oxford and was ordained, for a time holding the living of his native parish; but he was evicted in 1650 on various charges including that of having borne arms for the king. Under the name of Eugenius Philalethes he published *Anthroposophia Theomagica* (1650), *Anima Magica Abscondita* (1650), *Magia Adamica* (1650), *Lumen de Lumine* (1651) and other works. After 1650 he worked in London as a chemist. He died in Albury, Oxfordshire. on Feb. 27, 1666.

Thomas Vaughan was at once an empirical scientist and a hierophant of theosophical mysteries. Rejecting scholastic science, and despising those who limited investigation to the material world, he hoped by analysis to isolate the "first matter:" a concept which he seems to understand both physically and spiritually, and which would bring the experimenter near to the Creative Spirit itself, and break down the imagined barriers between the material and the spiritual worlds. Much of his speculation was rooted in Neoplatonist and cabbalistic traditions, and seems to have been independent of his chemical researches. except in so far as these might throw light on the wider problems in which he was more deeply interested: the nature of the soul—"a seed or glance of light . . . descending from the first Father of Lights,"—the effects of this separation, the hope and the way of complete reunion with the divine spirit.

His esoteric language and fantastic symbols often baffled his readers and came in for some ridicule; and considering the abstract and elusive nature of his subjects his confident manner may seem less persuasive than he intended. He was nevertheless an honest seeker after truth, wayward and excitable, but intelligent and essentially modest. His works have moments of visionary power and luminous phrasing which recall his brother's writing; but he is likely to be remembered more for his eccentric contributions to mystical philosophy than as a man of letters.

The Works of Thomas Vaughan (1919), edited by E. A. Waite, includes his chief prose and verse in English; Henry Vaughan's *Thalia Rediviva: . . . With . . . Remains of Eugenius Philalethes* (1678) includes his Latin verse; as does *Complete Works* (of Henry Vaughan), edited by A. B. Grosart, 4 vol. (1870–71).

(L. C. Mn.)

VAUGHAN, WILLIAM (1577–1641), English author and colonial pioneer, was born at Golden Grove, Carmarthenshire, in 1577. William was educated at Jesus college, Oxford, and took the degree of LL.D. at Vienna. In 1616 he bought a grant of land in the south coast of Newfoundland, to which he sent two batches of settlers. In 1622 he visited the settlement, which he called Cambriol, and returned to England in 1625. Vaughan apparently paid another visit to his colony, but his plans for its prosperity were foiled by the severe winters. He died at his house of Torcoed, Carmarthenshire. in Aug. 1641.

His chief work is *The Golden Grove* (1600), a general guide to morals, politics and literature, in which the manners of the time are severely criticized, plays being denounced as folly and wickedness. The section in praise of poetry borrows much from earlier writers on the subject. *The Golden Fleece . . . transported from Cambriol Colchis . . . by Orpheus jun., alias Will Vaughan,* which contains information about Newfoundland, is the most interesting of his other works.

VAUGHAN WILLIAMS, RALPH (1872–1958), English composer, whose music derived from folk song and from medieval and Tudor polyphony. is in the great English tradition. He was born at Down Ampney, Gloucestershire. Oct. 12, 1872, and was educated at Charterhouse. Trinity college, Cambridge (D.Mus., 1901) and the Royal College of Music. He also studied with Max Bruch in Berlin. In 1904 he joined the newly founded English Folk Song society and his contacts with folk singers in Norfolk led him to write the three *Norfolk Rhapsodies* (1906). By studying folk music and the work of medieval and Tudor musicians. he evolved a musical language distinguished by vigorous melodic outlines, the free use of modal scales: a strong contrapuntal texture and a highhanded attitude toward harmony. His first two symphonies. *Sea Symphony* (1910) and *A London Synzphony* (1914), his *Fantasia on a Theme by Thomas Tallis* (1910) and his opera. *Hugh the Drover* (1911–14), were outstanding works of his early period. After serving in Macedonia and France during World War I. he became professor of composition at the Royal College of Music and from 1920 to 1928 conductor of the London Bach choir. His presidency of the English Folk Dance and Song society and his support for local music festivals are the signs of his belief expressed in his book *National Music* (1934) that the roots of art should be firmly planted in native soil. Vaughan Williams' principal works, in addition to those mentioned, are: *Toward the Unknown Region* (1907), *The Lark Ascending* (1921), *A Pastoral Symphony* (1922), *Mass in* G *Minor* (1923). the cantata *Flos Campi* (1925). the operas *Sir John in Love* (1929) and *The Pilgrim's Progress* (1951). *Symphony No.* 4 *in F Minor* (1935), *Symphony No.* 5 (1943). *Sixth Synzphony* (1948), *Sinfonia Antartica* (1953), *Eighth Synzphony* (1956) and *Ninth Symphony* (1958).

He has also set or arranged many songs. He was an-arded the Order of Merit in 1935. He died in London on Aug. 26. 1958.

VAULT, any covering for an enclosed room, formed of small pieces of material, generally wedge-shaped and arranged with the undersides forming a generally curved surface, in such a way that each separate unit is held in place by its neighbours on either side; a continuous arch: also, loosely, any curved ceiling or covering of a room, irrespective of its material *(see* ARCH AXD *VAULT)*. The word is also used for a room or series of rooms built for storing valuables and enclosed with heavy walls, doors and ceilings specially constructed to withstand the effect of fire or the attacks of burglars, and entered by a burglar-proof door *(see* SAFES. STRONG-ROOMS AND VAULTS); and, by a somewhat similar extension, to a masonry enclosure in a graveyard, intended either as a permanent tomb or to receive bodies until a final grave is made.

VAULTING: *see* POLE VAULTING.

VAUQUELIN, LOUIS NICOLAS (1763–1829). French chemist who discovered beryllium and chromium. was born at St. André des Berteaux in Normandy on May 16, 1763. A laboratory boy to an apothecary in Rouen (1777–79), after various vicissitudes he obtained an introduction to A. F. Fourcroy, in whose laboratory he was an assistant (1783 to 1791). At first his work appeared as that of his master and patron, then in their joint names; but in 1790 he began to publish on his own authority, and between that year and 1833 his name is associated with 376 papers. Most were simple records of patient and laborious analytical operations, in the course of which he detected two new elements—beryllium (1797) in beryl and chromium (1798) in a red lead ore from Siberia. In organic chemistry he is known as the discoverer of quinic acid, asparagine, camphoric acid and other naturally occurring compounds. He succeeded Fourcroy (1809) as professor of chemistry to the medical faculty in Paris. In 1827 he was elected to the chamber of deputies from Calvados. He died at his birthplace on Nov. 14, 1829. He published *Manuel de l'Essayeur* (1812).

See essay in G. Bugge, *Buck der grossen Chemiker (1955).*

VAUQUELIN *DE* LA FRESNAYE, JEAN (1536–1607), French poet, mas born at the château of La Fresnaye, near Falaise, in 1536. He studied the humanities at Paris and law at Poitiers and Bourges. He fought in the civil wars under Jacques de Matignon and was wounded at the siege of Saint L8 (1574). Most of his life mas spent at Caen, where he was president and where he died. La Fresnaye was a disciple of Pierre de Ronsard but laid stress on the continuity of French literary history. He was a student of the trouvbres and the old chroniclers and desired to see French poetry set on a national basis.

These views he expounded in an *Art poétique,* begun in 1574 and published in 1605.

Les Foresteries appeared in 1555, *Les Diverses Poe'sies* (including the *Aut poe'tique,* the *Satyves françoises* and the *Idylles,* with some epigrams and sonnets) in 1605. *Les Diverses Poe'sies* and *Oeuvres diverses* were edited *by* J. Travers (1869–73); there is also an edition of *Les Foresteries* prefaced by P. Blanchemain (1869) and an edition of the *Art poétique* by G. Pellissier (1884). Among Vauquelin's political writings may be noted *Pour la monarchie de ce royaume contre la division* (1570). *See* further A. P. Lemercier, *Etude littéraire et morale sur les poésies de Jean Vauquelin de La Fresnaye* (1887); C. Des Guerrois, *Études sur quelques-uns de nos vieux poètes* (1923); J. Boullé, *Trois Vauquelin* (1912).

VAUVENARGUES, LUC DE CLAPIERS, Marquis de (1 715-1747), French moralist and miscellaneous writer, was born at Aix in Provence on Aug. 6, 1715. His family was poor though noble; he was educated at the college of Aix, where he learned little — neither Latin nor Greek — but by means of a translation acquired a great admiration for Plutarch. He entered the army as sublieutenant in the king's regiment and served for more than ten years, taking part in the Italian campaign of Marshal Claude de Villars in 1733 and in the disastrous expedition to Bohemia in support of Frederick the Great's designs on Silesia, in which the French were abandoned by their ally (1741-42). In the course of Marshal Charles Belle-Isle's minter retreat from Prague. Vauvenargues' legs were frozen, and though he spent a long time in a hospital at Nancy he never completely recovered. He was present at the battle of Dettingen, and on his return to France was garrisoned at Arras. His military career was then at an end. He had long been urged by the marquis of Mirabeau (author of *L'Ami des hommes* and father of the statesman) to turn to literature, but poverty prevented his going to Paris as his friend wished.

He decided to enter the diplomatic service and made application to the ministers and to the king himself. These efforts were unsuccessful. but Vauvenargues was on the point of securing his appointment through the intervention of Voltaire when an attack of smallpox completed the ruin of his health and rendered diplomatic employment out of the question. Voltaire then asked him to submit to him his ideas of the difference between Jean Racine and Pierre Corneille. The acquaintance thus begun ripened into real and lasting friendship. Vauvenargues moved to Paris in 1745, and lived there in retirement, seeing but few friends, of whom Jean Marmontel and Voltaire were the chief. Among his correspondents was the archaeologist Fauris de Saint-Vincens. Vauvenargues published in 1746 his *Introduction à la connoissance de l'esprit humain, suivie de Réflexions et de Maximes.* He died in Paris on May 28, 1747.

The bulk of Vauvenargues' work is small, but its interest great. His real strength is in a department which the French have always cultivated with greater success than any other modern people — the expression in more or less epigrammatic language of the results of acute observation of human conduct and motives.

An edition of the *Oeuvres* of Vauvenargues, slightly enlarged, appeared in the year of his death. Later editions, containing correspondence, *Dialogues of the Dead* ("characters" in imitation of Thcopbrastus and La Bruyère) and numerous short pieces of criticism and moralizing, are those of D. L. Gilbert, 2 vol. (1857), and of P. Varillon, 3 vol. (1929). For the *Re'flexions et Maximes* see the edition with Eng. trans. by F. G. Stevens (1940). *See* also E. Gosse, *Three French Moralists* (1918). and P. Souchon, *Vauvenargues, philosophe de la gloire* (1947).

VAUXHALL, a district on the south bank of the Thames river. in London. Eng.. included in the metropolitan borough of Lambeth. The manor was held by Falkes de Breauté (whence the name. Falkes hall) in the time of John and Henry III. About 1661 public gardens were laid out. known as the New Spring garden (frequented by Pepys and Evelyn). and later as Spring garden\, but more familiarly as Vauxhall gardens. They soon became the favourite resort of the metropolis. In 1732. under the management of Jonathan Tyers (d. 1767) and his sons, they were greatly developed and became quite fashionable. As such they were described by Thackeray and Fanny Burney. In 1822, pith the approval of George IV. who frequented the gardens before his accession, the epithet Royal was added to their title. By mid-19th century, however, Vauxhall had lost its high reputation, and in 1859 the gardens were closed and the site was quickly built over.

VAUX OF HARROWDEN, THOMAS VAUX, 2nd Baron (1510–1556), one of the group of early Tudor courtier poets which included Sir Thomas Wyatt and the earl of Surrey. Born in 1510, he succeeded his father. Nicholas Vaux, in 1523. He accompanied Cardinal Wolsey on his embassy to France in 1527 and attended Henry VIII to Calais and Boulogne in 1532. Created a knight of the Bath at the coronation of Anne Boleyn (1533), he was captain of the isle of Jersey until 1536. He died in Oct. 1556.

Vaux's two best-known poems, included in Tottel's *Miscellany* (1557), are "The aged lover renounceth love" and "The assault of Cupide upon the fort where the lovers hart lay wounded." They exemplify the underlying melancholy of the early Tudor poets. and also their pleasure in neat antithesis. the development of a conceit and the handling of metre. The *Paradyse of daynty devises* (1576) contains 13 poems signed by him. "The aged lover renounceth love," also called in an early manuscript version "Dittye . . . representing the image of deathe," is misquoted by the gravedigger in *Hamlet*—a testimony to its contemporary popularity.

See A. B. Grosart, *Miscellanies of the Fuller Worthies Library,* vol. iv (1872), for the poems from the *Paradyse of Dainty Devices;* and H. E. Rollin's edition of Tottcl's *Miscellany* (1928–29).

VAVASSOR, in its most general sense a mediate vassal; *i.e.,* one holding a fief under a vassal. The word was. however. applied at various times to the most diverse ranks in the feudal hierarchy, being used practically as the synonym of vassal. Thus tenants-in-chief of the crown are described by the emperor Conrad as *valvassores majores* as distinguished from mediate tenants, *valvassores minores.* Gradually the term without qualification was found convenient for describing subvassals, tenants-in-chief being called *capitanei* or *barones.* Its implication, however, still varied in different places and times. Bracton ranks the *magnates seu valvassores* between barons and knights; for him they are "men of great dignity." and in this order they are found in a charter of Henry II (1166). But in the *regestum* of Philip Augustus one finds that five vavassors are reckoned as the equivalent of one knight. Finally, Du Cange quotes two charters, one of 1187. another of 1349, in which vavassors are clearly distinguished from nobles. The derivation of the word vavassor is obscure. Some would derive it from *vassi* tad *valvas* ("at the folding-doors." *valvae*), *i.e.,* servants of the royal antechamber. Du Cange, with more justice. regards it merely as an obscure variant of *vassus.*

VAVILOV, NIKOLAI IVANOVICH (1887–1943), Russian plant geneticist. was born in Moscow (?) on Dec. 6. 1887. He graduated at the Agricultural academy at Petrovsko-Razumovskoe near Moscow, and later studied under W. Bateson at Cambridge university and the John Innes Horticulture institution. London, in 1913–14. Returning to Russia. he became professor of botany at the University of Saratov (1917–21). and then head of what was finally called the Lenin -ill-Union Academy of Agricultural Sciences.

Vavilov made a comprehensive study of the origin of cultivated plants and proposed that there were several world centres of origin at which the greatest concentration of diversity in cultivated plant species occurred. He made expeditions to many parts of the world, including Persia, Afghanistan. Abyssinia. China. Central and South America. and amassed an immense collection of varieties of cultivated plants which was intended to be used for further study and the breeding of new varieties. However. in 1940 he was ousted from his positions by T. D. Lysenko, and is thought to have spent the years 1940–42 in prison, dying in Magadan, Sib.! in 1943. He was elected a member of the Academy of Sciences of the U.S.S.R. in 1929, and a foreign member of the Royal society of London in 1942.

Vavilov's The *Origin, Variation, Immunity and Breeding of Cultivated Plants,* selected and translated by K. S. Chester was published in an English edition in 1951.

See T. G. Dobzhansky, "N. I. Vavilov, a Martyr of Genetics," *J. Hered,* 38:227–232 (1947). (G. H. Be.)

VAZOV, IVAN MINCHEV (1850–1921), Bulgarian writer of poems, short stories, novels and plays inspired by patriotism and love of the Bulgarian countryside and reflecting all the main events in his country's history. He was born on June 27, 1850, at Sopot, and educated there and in Plovdiv. He then taught for a time in the provinces. His father sent him to Rumania to study commerce, but contact with the *émigré* leaders of the Bulgarian revolutionary, movement hastened his resolve to devote his life to literature and the national cause. After the Liberation, he was a civil servant and a district judge. In 1880 he settled in Plovdiv, where he edited several newspapers and periodicals. During the anti-Russian regime of Stefan Stambulov he went into exile in Odessa (1886–89), where he began his greatest novel, *Pod Igoto,* a chronicle of the trials of the Bulgarians under Ottoman rule (Eng. trans., *Under the Yoke,* 1894). After Stambulov's fall (1894) he was elected to the assembly and during 1898–99 served as minister of education. His works include the epic cycle of poems *Epopeya na zabravenite* ("Epic to the Forgotten." published in two collections of verse. 1881. 1884): the novella *Nemili-Nedragi* ("Unloved and Unwanted," 1883) ; the novels *Nova Zemya* ("New Land," 1896), *Kazalarskata Tsaritsa* (1903) and *Svetoslnv Terter* (1907); and the plays *Hashove* (1894); *Kam Propast* ("Towards the Abyss") and *Borislav* (both 1910). He died at Sofia on Sept. 22, 1921. Vazov's *Short Stories* were translated by Zhana Molkhova and Peter Tempest (1950). (L. By.)

VEBLEN, OSWALD (1880–1960), leading U.S. mathematician, was born in Decorah. Ia., June 24. 1880, and studied at the universities of Iowa, Harvard and Chicago. From 1905 to 1932 he taught mathematics at Princeton university: in 1932 he was appointed professor at the Institute of Advanced Study in Princeton. where he became professor emeritus in 1950. Veblen's first important research was in the field of topology and, in addition to his own work, he laid the foundations of the Princeton school of research in that subject. Soon after the discovery of general relativity he turned to differential geometry and took a leading part in the development of generalized affine and projective geometry. He also contributed to the mathematical theory of spinors, so-called because of their application to Paul Dirac's treatment of electron spin. He died in Brooklyn. Me., Aug. 10, 1960.

Veblen wrote the following: *Infinitesimal Analysis,* with N. J. Lennes (1907); *Projective Geometry,* vol. i, with J. W. Young (1910) and vol. ii (1918): *Analysis Situs* (1922); *Invariants of Quadratic Differential Forms* (1927): *Foundations of Differential Geometry,* with J. H. C. Whitehead (1932); *Projektive Relativitätstheorie* (1933); *Geometry of Complex Domains,* with W. Givens (1936). (J. H. C. W.)

VEBLEN, THORSTEIN BUNDE (1857–1929). U.S. economist. who was a leader in the development of modern dynamic analysis broadly conceived as concerned with growth and change. Born on a farm in Manitowoc county. Wis., on July 30. 1857, he received his B.A. from Carleton college in 1880. He pursued graduate studies at Johns Hopkins university for a semester (1881), then went to Yale (Ph.D. 1884) and Cornell (1891–92) universities. He taught at The University of Chicago (1892–1906), Stanford university (1906–1909), the University of Missouri (1911–1918) and the New School for Social' Research (1919–1926). He helped to launch *The Journal of Political Economy* in 1892, of which he served as managing editor until 1905; in 1918–19. he served as an editor along with John Dewey and Helen Marot of the section on postwar reconstruction of *The Dial.* He retired in 1927 and died near Rlenlo Park, Calif., on Aug. 3, 1929. Veblen was trained in philosophy and all branches of the social sciences in the period that witnessed the triumph of the Darwinian theory of evolution in the 1870s and 1880s. He played a decisive role in extending the impact of that movement in economics at the turn of the century. He attacked the Benthamite psychology and the narrow bounds of the neoclassical school of economics of his day. He thus became a powerful catalytic agent in the modernization of economic thought and policy.

His most important works are *The Theory of the Leisure Class* (1899), *Tlze Theory of Business Enterprise* (1901). *Tlze Instinct of Workmanship and the State of the Industrial Arts* (1914). *Imperial Germany and the Industrial Revolution* (1915), *An Inquiry info the Nature of Peace and the Terms of Its Perpetuation* (1917) and *The Place of Science in Modern Civilisation and Other Essays* (1919). These studies are analyses from different vantage points of the development and functioning of the modern economic order. Veblen's evolutionary approach focuses on two economic institutions: technology and business. In modern society, technology takes the form of the machine process, of which modern science is the purest embodiment; business takes the form of the massive corporation, which dominates the economic scene. To Veblen the modern corporation was a complex organism which if unrestrained would breed unmitigated pecuniary habits of thinking that might run counter to its proper function in the economy and lead to such phenomena as severe business cycles. Modern technology embodied imagination, playfulness, economical effort and taste. Veblen recognized that like all institutions it lent itself to passivity, habit and ugliness. Man's story, for Veblen, is one of constant attempts at a harmony between his interests and aspirations and the institutions he creates to give them expression. Veblen's influence extended beyond his own discipline of economics; his works interested, for example, such leaders in the biological and physical sciences as Jacques Loeb and .Alfred Einstein.

VECTOR ANALYSIS. Some physical and geometrical entities, called scalars, can be fully described by specifying their magnitude in suitable units of measure. Thus, mass of a body can be described by the number of grams, temperature by degrees on some scale, volume by the number of cubic feet and time by hours. Scalars can be represented graphically by points on some kind of numerical scale as, for instance, on a clock or thermometer. There are also entities, called vectors, that require the specification of direction as well as magnitude. Velocity, force and displacement are examples of vectors. A vector quantity can be represented graphically by a directed line segment. symbolized by an arrow pointing in the direction of the vector quantity. with the length of the segment representing the magnitude of the vector. The study of operations on directed segments and generalizations resulting from such a study is the subject of vector analysis.

The origin of vector analysis was in the formulation. by Simon Stevin in 1586, of the "parallelogram law" of addition of forces. Vector analysis specifically adapted to the needs of mathematical physics was developed largely by Josiah Willard Gibbs and Oliver Heaviside in the last quarter of the 19th century, but it was antedated by the algebra of quaternions of Sir William Rowan Hamilton in 1843 (*see* NUMBER) and by *Die Ausdehnungslehre* ("theory of extended magnitudes") of Hermann Günther Grassmann in 1844. The needs of geometry and physics led to the generalization of the vector concept to spaces of higher dimensions by Georg Friedrich Bernhard Riemann and Elwin Bruno Christoffel in the second half of the 19th century. Their work culminated in the invention of tensor analysis (*q.v.*) which deals with a study of generalized vectors called tensors. Tensor analysis induced rapid developments in differential geometry and mathematical physics and made possible the creation of the general theory of relativity.

Vector Algebra.—A prototype of a vector is a directed line segment $\overrightarrow{AB}$ (*see* fig. 1) which can be thought to represent the displacement of a particle from its initial position *A* to a new position *B*. To distinguish vectors from scalars it is customary to denote vectors by single boldface letters. Thus the vector

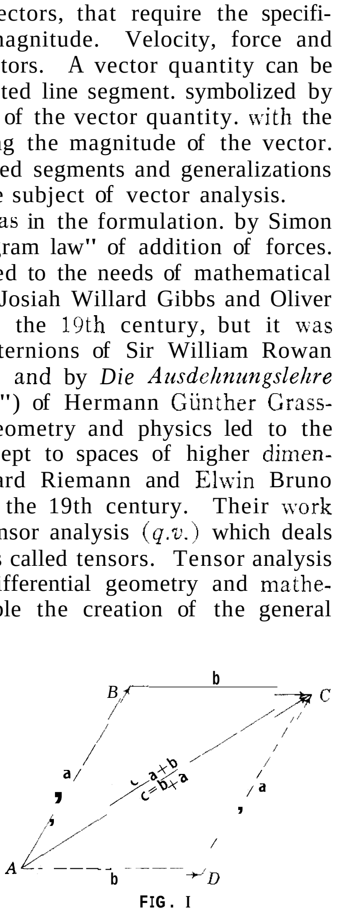

FIG. I

$\overrightarrow{AB}$ in fig 1 can be denoted by **a** and its length (or magnitude) AB by |**a**|. In many problems the location of the initial point *A* of a vector **a** is immaterial, so that two vectors are regarded as equai if they have the same length and the same direction.

The equality of two vectors $\boldsymbol{a}$ and $\mathbf{b}$ is denoted by the usual symbolic notation $\boldsymbol{a} = \boldsymbol{b}$, and useful definitions of the elementary algebraic operations on vectors are suggested by geometry. Thus, if $\overrightarrow{AB} = \boldsymbol{a}$ in fig. 1 represents a displacement of a particle from A to B and subsequently the particle is moved to a position C, so that $\overrightarrow{BC} = \mathbf{b}$, it is clear that the displacement from A to C can be accomplished by a single displacement $\overrightarrow{AC} = \mathbf{c}$. Thus, it is logical to write $\boldsymbol{a} + \mathbf{b} = \mathbf{c}$. This construction of the sum $\mathbf{c}$ of $\boldsymbol{a}$ and $\boldsymbol{b}$ yields the same result as the "parallelogram law" in which the resultant $\mathbf{c}$ is given by the diagonal $\overrightarrow{AC}$ of the parallelogram constructed on vectors $\overrightarrow{AB}$ and $\overrightarrow{AD}$ as sides. Since the location of the initial point B of the vector $\overrightarrow{BC} = \boldsymbol{b}$ is immaterial, it follows that $\overrightarrow{BC} = \overrightarrow{AD}$. Also, fig. 1 shows that $\overrightarrow{AD} + \overrightarrow{DC} = \overrightarrow{AC}$, so that the commutative law

$$\mathbf{a} + \mathbf{b} = \mathbf{b} + \mathbf{a} \tag{1}$$

holds true for vector addition. The extension of this commutative law to a larger number of vectors is immediate. Also, it is easy to show that the associative law

$$(\mathbf{a} + \mathbf{b}) + \mathbf{c} = \mathbf{a} + (\mathbf{b} + \mathbf{c}) \tag{2}$$

is valid. and hence the parentheses in *(2)* can be omitted without any ambiguities.

If s is a scalar, $s\boldsymbol{a}$ or $\boldsymbol{a}s$ is defined to be a vector whose length is $|s|$ $\boldsymbol{a}$ and whose direction is that of $\boldsymbol{a}$ when s is positive and opposite to that of a if s is negative. Thus, $\boldsymbol{a}$ and $-\boldsymbol{a}$ are vectors equal in magnitude and opposite in direction. This suggests defining $\boldsymbol{a} - \boldsymbol{b}$ by the formula $\boldsymbol{a} - \boldsymbol{b} = \boldsymbol{a} + (-\mathbf{b})$, and to define the zero vector. written $\mathbf{0}$, as a vector of zero length such that $\boldsymbol{a} + \mathbf{0} = \boldsymbol{a}$. The foregoing definitions and the well-known properties of scalar numbers show that

$$\begin{aligned} s(t\mathbf{a}) &= (st)\mathbf{a} \\ (s+t)\mathbf{a} &= s\mathbf{a} + t\mathbf{a} \\ s(\mathbf{a} + \mathbf{b}) &= s\mathbf{a} + s\mathbf{b} \end{aligned} \tag{3}$$

Inasmuch as the laws (1), (2) and *(3)* are identical with those encountered in ordinary algebra, it is quite proper to use familiar algebraic rules to solve systems of linear equations containing vectors This fact makes it possible to deduce by purely algebraic means many theorems of synthetic Euclidean geometry that require complicated geometrical constructions

Products of Vectors.—The algebraic operations introduced so far provide no means for dealing with metric properties of geometric configurations; that is, with the calculations of lengths and angles betneen vectors These are provided by two types of products of vectors. the dot product and the cross product

The dot or scalar product of two vectors $\boldsymbol{a}$ and $\boldsymbol{b}$, written $\boldsymbol{a} \cdot \boldsymbol{b}$, is a real number $|\mathbf{a}|\ |\mathbf{b}| \cos(\mathbf{a},\mathbf{b})$, where $(\mathbf{a},\mathbf{b})$ denotes the angle between the directions of $\boldsymbol{a}$ and $\boldsymbol{b}$. Geometrically,

$$\begin{aligned} \mathbf{a} \cdot \mathbf{b} &= |\mathbf{a}|\ |\mathbf{b}| \cos(\mathbf{a},\mathbf{b}) \\ &= |\mathbf{a}| \times \text{projection of } \boldsymbol{b} \text{ on a} \end{aligned} \tag{4}$$

If $\boldsymbol{a}$ and $\boldsymbol{b}$ are at right angles then $\boldsymbol{a} \cdot \boldsymbol{b} = 0$. and if neither $\boldsymbol{a}$ nor $\boldsymbol{b}$ is a zero vector then the vanishing of the dot product shows the vectors to be perpendicular. If $\boldsymbol{a} = \mathbf{b}$ then $\cos(\mathbf{a},\mathbf{b}) = 1$. and $\boldsymbol{a} \cdot \boldsymbol{a} = |\mathbf{a}|^2$ gives the square of the length of $\boldsymbol{a}$.

It is not difficult to show that the associative, commutative and distributive laws of elementary algebra remain valid for the dot multiplication of vectors. Thus

$$\begin{aligned} (s\mathbf{a}) \cdot (\boldsymbol{b}) &= s(\mathbf{a} \cdot \mathbf{b}) \\ \mathbf{a} \cdot \mathbf{b} &= \mathbf{b} \cdot \mathbf{a} \\ \mathbf{a} \cdot (\mathbf{b} + \mathbf{c}) &= \mathbf{a} \cdot \mathbf{b} + \mathbf{a} \cdot \mathbf{c} \end{aligned} \tag{5}$$

and hence it is permissible to employ the familiar rules of scalar algebra in calculations involving addition and scalar multiplication of vectors.

The cross or vector product of two vectors $\boldsymbol{a}$ and $\mathbf{b}$, written $\boldsymbol{a} \times \boldsymbol{b}$, is the vector

$$\mathbf{a} \times \boldsymbol{b} = \mathbf{n}|\mathbf{a}|\ |\mathbf{b}| \sin(\mathbf{a},\mathbf{b}) \tag{6}$$

where n is a vector of unit length perpendicular to the plane of $\boldsymbol{a}$ and $\boldsymbol{b}$ and so directed that a right-handed screw rotated from $\boldsymbol{a}$ toward $\boldsymbol{b}$ will advance in the direction of n (*see* fig. 2) If $\boldsymbol{a}$ and $\boldsymbol{b}$ are parallel, $\boldsymbol{a} \times \boldsymbol{b} = \mathbf{0}$. It follows from the definition (6) that the magnitude of $\boldsymbol{a} \times \boldsymbol{b}$ can be represented by the area of the parallelogram having $\boldsymbol{a}$ and $\boldsymbol{b}$ as adjacent sides. Also. since rotation from $\boldsymbol{b}$ to $\boldsymbol{a}$ is opposite to that from $\boldsymbol{a}$ to $\boldsymbol{b}$,

$$\mathbf{a} \times \mathbf{b} = -\mathbf{b} \times \mathbf{a}$$

This shows that the cross product is not commutative; but, it is true that the associative law $(s\mathbf{a}) \times \boldsymbol{b} = s(\mathbf{a} \times \boldsymbol{b})$ and the distributive law

$$\mathbf{a} \times (\mathbf{b} + \mathbf{c}) = \mathbf{a} \times \mathbf{b} + \mathbf{a} \times \mathbf{c} \tag{7}$$

are valid for cross products.

From definitions (4) and (6) it follows that when the scalar and vector products of $\boldsymbol{a}$ and $\mathbf{b}$ are known. then the angle between $\boldsymbol{a}$ and $\boldsymbol{b}$ is determined uniquely, since both $\cos(\mathbf{a},\mathbf{b})$ and $\sin(\mathbf{a},\mathbf{b})$ are determined by (4) and (6).

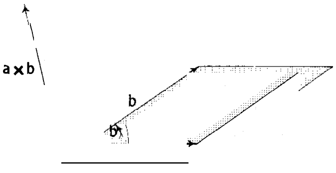

FIG 2

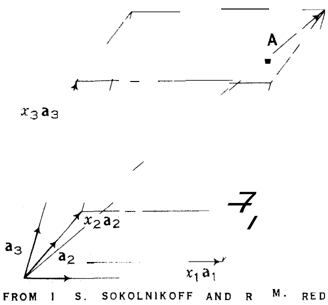
As an indication of the fundamental nature of the dot and cross products in mechanics. it should be noted that if $\boldsymbol{a}$ represents the force producing the displacement $\boldsymbol{b}$, then, as is clear from (4), $\mathbf{a} \cdot \boldsymbol{b}$ gives the work done by the force. If $\boldsymbol{b}$ is a position vector of some point P in a body and $\boldsymbol{a}$ is the force applied at P, then *(6)* shows that $\boldsymbol{a} \times \boldsymbol{b}$ is the torque or moment of force $\boldsymbol{a}$ about the initial point of $\mathbf{b}$.

Co-ordinate Systems.—The foregoing summary of operations on vectors makes no reference to any particular frame relative to which the vectors may be located Since natural laws of physics do not depend on special or accidental choices of reference frames selected to represent physical relations and geometric configurations, vector analysis forms an ideal tool for the study of the physical universe The introduction of a special reference frame or co-ordinate system establishes a correspondence between vectors and sets of numbers representing the components of vectors in that frame. and it induces definite rules of operation on these sets of numbers that follow from the rules for operations on the line segments.

If some particular set of three noncollinear vectors. $\boldsymbol{a}$,, $\boldsymbol{a}$,. $\mathbf{a}_3$, termed base vectors, is selected. then every vector $\boldsymbol{A}$ can be expressed uniquely in the form

$$\boldsymbol{A} = x_1\mathbf{a}_1 + x_2\mathbf{a}_2 + x_3\mathbf{a}_3 \tag{8}$$

where $\mathbf{A}$ is the diagonal of the parallelepiped (*see* fig. 3) nhose edges $x_1\mathbf{a}_1$, $x_2\mathbf{a}_2$, $x_3\mathbf{a}_3$ are the components of $\mathbf{A}$ in the directions of the base vectors. Since the base vectors are given. the triplet of numbers $(x_1\ x_2,x_3)$ completely determines $\boldsymbol{A}$, and hence the specification of three numbers x_1,x_2,x_3 is equivalent to specifying $\mathbf{A}$. The operations of addition of vectors, dot multiplication. etc can therefore be rephrased to yield the corresponding operations on the triplets of numbers determining vectors This is the procedure followed in a purely algebraic treatment of vector analysis



FROM I S. SOKOLNIKOFF AND R M. REDHEFFER MATHEMATICS OF PHYSICS AND MODERN ENGINEERING BY PERMISSION OF MCGRAW HILL BOOK CO

FIG 3

A useful special set of base vectors in common use is a set of three mutually orthogonal unit vectors (*i.e.*, vectors of length 1) $\mathbf{i},\mathbf{j},\mathbf{k}$ directed along the axes of the familiar Cartesian reference frame (*see* fig. 4). In this system the representation (8) takes the form

$$\mathbf{A} = x\mathbf{i} + y\mathbf{j} + z\mathbf{k}$$

where (x,y,z) are the projections of **A** in the directions of the co-ordinate axes. When two vectors **A**, and **A**, are represented as

$$\mathbf{A}_1 = x_1\mathbf{i} + x_2\mathbf{j} + x_3\mathbf{k}$$
$$\mathbf{A}_2 = y_1\mathbf{i} + y_2\mathbf{j} + y_3\mathbf{k}$$

then the use of laws (3) yields for their sum

$$\mathbf{A}_1 + \mathbf{A}_2 = (x_1 + y_1)\mathbf{i} + (x_2 + y_2)\mathbf{j} + (x_3 + y_3)\mathbf{k} \qquad (9)$$

Thus in a Cartesian frame, the sum of **A**, and **A**, is the vector determined by $(x_1 + y_1, x_2 + y_2, x_3 + y_3)$. Also, the use of laws (5) yields for the dot product

$$\mathbf{A}_1 \cdot \mathbf{A}_2 = x_1y_1 + x_2y_2 + x_3y_3 \qquad (10)$$

since

$$\mathbf{i}\cdot\mathbf{i} = \mathbf{j}\cdot\mathbf{j} = \mathbf{k}\cdot\mathbf{k} = 1, \mathbf{i}\cdot\mathbf{j} = \mathbf{j}\cdot\mathbf{k} = \mathbf{k}\cdot\mathbf{i} = 0$$

For

$$\mathbf{A}_1 = \mathbf{A}_2 = x\mathbf{i} + y\mathbf{j} + z\mathbf{k}$$

eq. (10) reduces to

$$\mathbf{A}\cdot\mathbf{A} = x^2 + y^2 + z^2 \qquad (11)$$

which is the square of the length of **A**. As is clear from fig. 4, the same result follows from the use of the Pythagorean theorem.

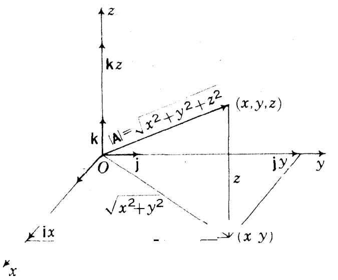
The use of the law (7) yields for

$$\mathbf{A}_1 \times \mathbf{A}_2 = (x_2y_3 - x_3y_2)\mathbf{i} + (x_3y_1 - x_1y_3)\mathbf{j} + (x_1y_2 - x_2y_1)\mathbf{k} \quad (12)$$

so that the cross product is the vector determined by the triplet of numbers appearing as the coefficients of **i**, **j** and **k** in (12).

The co-ordinates of the terminal points of the base vectors **i**, **j**, **k** in fig. 4 are those appearing in the rows of the 3×3 matrix

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix} \qquad (13)$$



FROM I. S. SOKOLNIKOFF AND R. M. REDHEFFER "MATHEMATICS OF PHYSICS AND MODERN ENGINEERING", REPRODUCED BY PERMISSION OF MCGRAW HILL BOOK CO., INC.

FIG. 4

and if vectors are represented by 1×3 (or 3×1) matrices consisting of the components (x_1,x_2,x_3) of the vectors. it is possible to rephrase formulas (9) through (12) in the language of matrices. Such rephrasing suggests a generalization of the concept of a vector to spaces of dimensions higher than three. There is nothing mysterious about the notion of higher-dimensional spaces. In physics there are quantities that require more than three variables (or co-ordinates') for their representation. For example. the state of gas generally depends on the pressure p, volume v, temperature T and time t. A quadruplet of numbers (p,v,T,t) cannot be represented by a point in the three-dimensional reference frame. But since geometric visualization plays no role in algebraic calculations. the figurative language of geometry can still be used by introducing a four-dimensional reference frame determined by the set of base vectors $\mathbf{a}_1,\mathbf{a}_2,\mathbf{a}_3,\mathbf{a}_4$ with components determined by the rows of the matrix

$$\begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}$$

as in (13). A vector **x** is then represented in the form

$$\mathbf{x} = x_1\mathbf{a}_1 + x_2\mathbf{a}_2 + x_3\mathbf{a}_3 + x_4\mathbf{a}_4$$

so that in a four-dimensional space, every vector is determined by the quadruple of the components (x_1,x_2,x_3,x_4). The sum of **x** and

$$\mathbf{y} = y_1\mathbf{a}_1 + y_2\mathbf{a}_2 + y_3\mathbf{a}_3 + y_4\mathbf{a}_4$$

is the vector determined by the quadruple $(x_1 + y_1, x_2 + y_2, x_3 + y_3, x_4 + y_4)$, the scalar product is

$$\mathbf{x} \cdot \mathbf{y} = x_1y_1 + x_2y_2 + x_3y_3 + x_4y_4$$

and the square of the "length" is

$$\mathbf{x}\cdot\mathbf{x} = x_1^2 + x_2^2 + x_3^2 + x_4^2$$

These are obvious extensions of formulas 19) through (11).

The extension of these ideas to spaces of arbitrary finite dimensionality is obvious. Such spaces occur in the study of dynamical systems with n degrees of freedom such as appear in the study of vibration of a flexible string carrying n beads. The needs of modern physics require the construction of vector theory in infinitely many dimensional spaces which arise. among other places. in the study of systems with infinitely many degrees of freedom, such as a vibrating piano string.

Calculus of Vectors.—A particle moving in three-dimensional space can be located at each instant of time t by a position vector **r** drawn from some fixed reference point O. Since the position of the terminal point of r depends on time, **r** is a vector function of t. Its components in the directions of Cartesian axes. introduced at O, are the coefficients of **i**, **j** and **k** in the representation

$$\mathbf{r} = x(t)\mathbf{i} + y(t)\mathbf{j} + z(t)\mathbf{k}$$

If these components are differentiable functions, the derivative of **r** with respect to t is defined by the formula

$$\frac{d\mathbf{r}}{dt} = \frac{dx}{dt}\mathbf{i} + \frac{dy}{dt}\mathbf{j} + \frac{dz}{dt}\mathbf{k} = \mathbf{v} \qquad (14)$$

which represents the velocity v of the particle. The Cartesian components of **v** appear as coefficients of **i**, **j** and **k** in (14). If these components are also differentiable, the acceleration $\mathbf{a} = d\mathbf{v}/dt$ is obtained by differentiating (14):

$$\frac{d^2\mathbf{r}}{dt^2} = \frac{d^2x}{dt^2}\mathbf{i} + \frac{d^2y}{dt^2}\mathbf{j} + \frac{d^2z}{dt^2}\mathbf{k} = \mathbf{a} \qquad (15)$$

It is easy to verify that the rules for differentiating products of scalar functions remain valid lor derivatives of the dot and cross products of vector functions. and suitable definitions of integrals of vector functions allow the construction of the calculus of vectors. Such calculus has become a basic analytic tool in physical sciences and technology.

Field Theory.—Applications of vector calculus to problems of continuum mechanics (fluid mechanics. elasticity, aerodynamics, heat conduction. electrodynamics, etc.) call for a consideration of scalar and vector functions specified at each point of some region. A region of space with each point of which a scalar function is associated is called a scalar field. while a region in which a vector function is determined is a vector field. Examples of scalar fields are regions at each point of which the temperature or density of a body can be determined. A region in the vicinity of a charged body in which the electric-intensity vector is determined is an example of a vector field. A scalar function $u(P)$ determined at each point P of a scalar field is called a scalar point-function, while a vector function $\mathbf{v}(P)$ specified in a vector field is a vector point-function.

Gradient of a Scalar Field.—If there is a scalar point-function $u(P)$ at a point P, and another scalar point-function $u(P')$ at a nearby point P', where

$$\overrightarrow{PP'} = \Delta\mathbf{r}$$

then

$$\frac{u(P') - u(P)}{|\Delta\mathbf{r}|}$$

represents the average space rate of change of $u(P)$ in the direction of $\Delta\mathbf{r}$. The limit of this ratio as $|\Delta\mathbf{r}| \to 0$, when this limit exists. represents the space rate of change of $u(P)$ in the direction of $\Delta\mathbf{r}$. The vector in that direction for which the space rate of change of $u(P)$ is a maximum is called the gradient of $u(P)$

and is denoted by grad u or ∇u. It can be shown that in Cartesian co-ordinates

$$\nabla u = \mathbf{i}\frac{\partial u}{\partial x} + \mathbf{j}\frac{\partial u}{\partial y} + \mathbf{k}\frac{\partial u}{\partial z}$$

Thus with each point of a scalar field, where ∇u exists, there can be associated a vector field. If $u(P)$ is the temperature, then ∇u gives the direction of the heat-flow vector in the field.

Divergence of a Vector Field.—On the other hand. two important fields can be associated with each continuously differentiable vector point-function $\mathbf{v}(P)$: one is a scalar field and the other a vector field. Let $\mathbf{v}(P)$ be defined in some region τ about the point P and let σ be the surface of τ. The component of $\mathbf{v}(P)$ (which for the sake of concreteness can be thought to represent velocity $\mathbf{v}$ of fluid particles moving in τ) in the direction of the exterior unit normal $\mathbf{n}$ to σ is $\mathbf{v}\cdot\mathbf{n}$. The amount of fluid issuing from a then is given by $\int \mathbf{v}\cdot\mathbf{n}\,d\sigma$, where the integration symbol represents the summation of $\mathbf{v}\cdot\mathbf{n}$ over the elements $d\sigma$ of the surface σ. The flux of fluid per unit volume τ is thus equal to

$$\frac{\int_\sigma \mathbf{v}\cdot\mathbf{n}\,d\sigma}{\tau}$$

and the limit of this ratio as $\tau \longrightarrow 0$, so that a shrinks toward P, is an important scalar called the divergence of $\mathbf{v}(P)$. Thus, the divergence of $\mathbf{v}(P)$, written div $\mathbf{v}(P)$, represents the rate of fluid flow from P. If div $\mathbf{v}(P)$ is positive at P, then P is a source of fluid: if it is negative. then P is a sink. If div $\mathbf{v}(P) = 0$, then no fluid issues from P.

In Cartesian co-ordinates div $\mathbf{v}(P)$ turns out to be given by the simple formula

$$\text{div } \mathbf{v} = \frac{\partial v_1}{\partial x} + \frac{\partial v_2}{\partial y} + \frac{\partial v_3}{\partial z}$$

where

$$\mathbf{v} = \mathbf{i}v_1 + \mathbf{j}v_2 + \mathbf{k}v_3$$

Curl of a *Vector* Field.—Also associated with $\mathbf{v}(P)$ is an important vector field in which the vector called curl of $\mathbf{v}(P)$ is defined by the formula

$$\text{curl } \mathbf{v}(P) = \lim_{\tau \longrightarrow 0} \frac{\int_\sigma \mathbf{n} \times \mathbf{v}\,d\sigma}{\tau}$$

This vector provides a measure of the angular velocity of the fluid at any point P in the field. In Cartesian co-ordinates curl $\mathbf{v}$ is given by the formula

$$\text{curl } \mathbf{v} = \mathbf{i}\left(\frac{\partial v_3}{\partial y} - \frac{\partial v_2}{\partial z}\right) + \mathbf{j}\left(\frac{\partial v_1}{\partial z} - \frac{dm)}{\text{ax}}\right) + \mathbf{k}\left(\frac{\partial v_2}{\partial x} - \frac{\partial v_1}{\partial x}\right)$$

When curl $\mathbf{v} = 0$ at every point of the region, the field is said to be irrotational, and when $\mathbf{v}(P)$ is such that div $\mathbf{v} = 0$, the field is solenoidal. The importance of these two special fields stems from the fact that every continuously differentiable vector function $\mathbf{v}(P)$ defined in a region τ (subject to mild restrictions) can be expressed as a sum of two vector functions $\mathbf{f}(P)$ and $\mathbf{g}(P)$ such that $f(P)$ is solenoidal and $\mathbf{g}(P)$ is irrotational. The possibility of such decomposition greatly simplifies the study of many velocity and force fields occurring in physics.

VECTOR SPACES. Consider the totalitv of all forces in a plane acting on a particle. Such forces, *e.g.*, $\mathbf{F}_1$ and $\mathbf{F}_2$ of fig. 1, combine to make a resultant force $\mathbf{F}_3$ according to the "parallelogram of forces" law of mechanics. The resultant force $\mathbf{F}_3$ may be termed the sum of $\mathbf{F}_1$ and $\mathbf{F}_2$. The forces $\mathbf{F}_1$, $\mathbf{F}_2$ and $\mathbf{F}_3$ may be represented in a diagram by pointed arrows, which indicate simultaneouslp direction and magnitude. Furthermore, each force $\mathbf{F}$ can be multiplied by a real constant c so as to yield a new force $c\mathbf{F}$ that is c times as large as F; $c\mathbf{F}$ points in the same direction as $\mathbf{F}$ if c is positive and in the opposite direction if c is negative. For each force $\mathbf{F}$ there is an opposite force, $-F$, such that their sum $\mathbf{F} + (-\mathbf{F})$ does not move the particle; that is, their resultant is the zero force, 0.

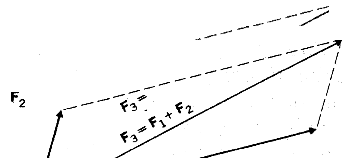

FIG. 1.—VECTOR ADDITION OF FORCES: $\mathbf{F}_3 = \mathbf{F}_1 + \mathbf{F}_2$

If the action of a planar force F is related to a Cartesian co-ordinate system located at the particle, then the force $\mathbf{F}$ is uniquely determined by a pair of real numbers x_1, x_2 (fig. 2). Thus $\mathbf{F}$ is the sum of the directed component forces x_1 and x_2 along the given axes of the Cartesian co-ordinate system. Note that x_1 and x_2 are the (perpendicular) projections of $\mathbf{F}$ on the co-ordinate system. Thus $\mathbf{F}$ can be identified with this fixed ordered pair of numbers (x_1, x_2). Then, if another force G is represented by the pair (y_1, y_2), their sum $F + G$ is represented by the pair $(x_1 + y_1, x_2 + y_2)$, while $c\mathbf{F}$ is represented by (cx_1, cx_2).

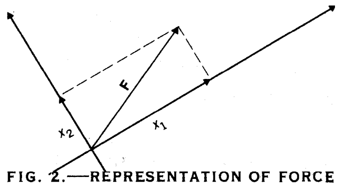

FIG. 2.—REPRESENTATION OF FORCE VECTOR IN CARTESIAN CO-ORDINATES

These elementary properties of forces can be summarized as follows: given any two forces F and G, there is a unique third force H, called their sum. The summation operation satisfies the following lams:

1. $(F + G) + \mathbf{H} = \mathbf{F} + (\mathbf{G} + H)$	"associativity"
2. $\mathbf{F} + \mathbf{G} = \mathbf{G} + \mathbf{F}$	"commutativity"
3. There is a iorce 0 such that $F + 0 = 0 + \mathbf{F} = \mathbf{F}$ for all $\mathbf{F}$	"existence of an additive identity force"
4. For each force $\mathbf{F}$ there is a iorce $-\mathbf{F}$ such that $\mathbf{F} + (-F) = 0$	"existence of an additive inverse"

Furthermore, for each force $\mathbf{F}$ and for each real number c there is a unique force $c\mathbf{F}$, such that

5. $c(\mathbf{F}_1 + \mathbf{F}_2) = c\mathbf{F}_1 + c\mathbf{F}_2$	"distributivity"
6. $(a + b)\mathbf{F} = aF + b\mathbf{F}$	
7. $(ab)\mathbf{F} = a(b\mathbf{F})$	
8. $1\,\mathbf{F} = \mathbf{F}$	

where a, b denote real numbers.

This summary would be an idle exercise if there were not other systems apart from the forces of mechanics that obey the same algebraic laws (1) to (8). Here are some examples:

A. All 12-tuples, *i.e.*, ordered systems of real numbers $x_1, \ldots,$ xi, $\ldots, x_n$ arranged as "rows": X = (xi, $\ldots, x_i, \ldots, x_n$). Here $X + Y$, where $Y = (y_1, \ldots, y_i, \ldots, y_n)$ is another ordered system of real numbers yi, is defined to be $(x_1 + y_1, \ldots, x_i + y_i, \ldots, x_n +$ y,). The scalar product cX, where c is a given real number, is defined as the n-tuple $(cx_1, \ldots, cx_i, \ldots, cx_n)$. The laws (1) to (8) are verified as consequences of appropriate properties of the component (real) numbers x_i and y_i. Note that $n = 2$ is the case of the pairs of component forces in the earlier discussion. If $n = 3$, then forces in three-dimensional space are described.

B. All polynomials $f(t) = x_1 + x_2t + \ldots + x_nt^{n-1}$ in an indeterminate (or variable) t which are of degree at most equal to $n - 1$, where n is a given positive integer. The sum and scalar product, $f(t) + g(t)$ and $cf(t)$, are defined in the customary fashion.

C. All sequences of real numbers $x_1, \ldots,$ xi, $\ldots$, for which $\sum_{i=1}^{\infty}$ xi is finite (convergent).

D. All sequences of complex numbers $x_1, \ldots, x_i, \ldots$, for which $\sum_{i=1}^{\infty} |x_i|^2$ is finite—a "Hilbert space."

E. All continuous functions $f(x)$ on the real line segment $-1 \leq x \leq 1$.

Note that verification of the laws (1) to (8) for the examples (C) to (E) requires recourse to basic facts of analysis; for example, why is $\sum_{i=1}^{\infty}(x_i + y_i)$ finite if both $\sum_{i=1}^{\infty} x_i$ and $\sum_{i=1}^{\infty} y_i$ are finite?

Many of the consequences which follow from laws (1) to (8), using in addition new definitions and concepts, do not depend on the nature of the scalars as real numbers. To illustrate this, call a mathematical system $K = \{a, b, c, \cdots, 0, 1\}$ a field if it has all those properties of addition, subtraction, multiplication and division of the real numbers, which do not involve the concept of order or magnitude. Such systems can be easily constructed. For example, take two symbols z and e and postulate for them $z + z = z$, $e + z = z + e = e$, $e + e = z$ and $zz = z$, $ez = ze = z$, $ee = e$. Note that z acts like the real number "zero" and that e acts like the real number "one" as far as the fundamental laws of algebra for addition and multiplication are concerned. Now replace the real numbers x_i in example (A) by the symbols e or z. It is easily verified that the new system has all the properties (1) to (8). Similarly, in place of the real numbers x_i the elements of any field K (for example, all rational numbers) may be used to obtain a system $V_n(K)$ which again satisfies (1) to (8) if the sum and scalar product are defined as in (A). In a similar fashion the "columns" $\begin{pmatrix} x_1 \\ \vdots \\ x_n \end{pmatrix}$ of n elements $x_1, \cdots, x_n$ taken from a field K form a system $V_n(K)'$ in which sum and scalar product are defined by replacing the horizontal arrangements by a vertical arrangement (F). (See FIELDS.)

Basic Properties; Subspaces.—The general definition of a linear vector space is obtained by abstracting from the examples (A) to (E) the specific nature of the elements and scalars. Thus a linear vector space (for short, vector space) $V = (\mathbf{F}, \mathbf{G}, \mathbf{K}, \ldots)$ over a field $K = (c, \ldots)$ is a system in which are given (i) a concept of identity $\mathbf{F} = \mathbf{G}$ subject to the laws of reflexivity ($\mathbf{F} = \mathbf{F}$), symmetry ($\mathbf{F} = \mathbf{G}$ implies $\mathbf{G} = \mathbf{F}$) and transitivity (if $\mathbf{F} = \mathbf{G}$, $\mathbf{G} = \mathbf{K}$, then $\mathbf{F} = \mathbf{K}$); (ii) a concept of sum $\mathbf{F} + \mathbf{G}$; and (iii) a concept of scalar product $c\mathbf{F}$ such that the laws (1) to (8) hold as postulated axioms. The elements of V are called vectors and the elements of K are called scalars (*see* VECTOR ANALYSIS). Note that scalars are always given when vector spaces are considered.

If $\mathbf{F}_1, \ldots, \mathbf{F}_k$ are vectors and $c_1, \ldots, c_k$ are scalars, then the sum, which is defined inductively, $c_1\mathbf{F}_1 + \ldots + c_k\mathbf{F}_k = \sum_{i=1}^{k} c_i\mathbf{F}_i$ is called the linear combination of the k vectors $\mathbf{F}_i$ with the k scalars c_i. A subspace S of a vector space V/K is a collection of elements in V which contains all linear combinations of any finite set of its elements. In example (A), for $n = 3$ all triples of real numbers $x_1 = u + v$, $x_2 = u - 2v$, $x_3 = 2u - v$, where u and v denote arbitrary real numbers, form a subspace (example [G]). Note that $(x_1, x_2, x_3) = u(1, 1, 2) + v(1, -2, -1) = u\mathbf{G}_1 + v\mathbf{G}_2$ for every vector of this subspace. Similarly, all triples of real numbers with the restriction $x_2 = 0$ form a subspace. However, the triples $(x_1, 1, x_3)$, with arbitrary real numbers x_1 and x_3, do not form a subspace.

Let $S_1, \ldots, S_i, \ldots, S_k$ denote subspaces of $V = V/K$. Then all linear combinations $\sum_{i=1}^{K} c_i\mathbf{F}_i$ of vectors $\mathbf{F}_i$ in the subspaces S_i and coefficients c_i in the common field of scalars K determine a subspace $S = \cup_i S_i$, called the sum (union) of the given subspaces. The space S is the "smallest" subspace of V which contains $S_1, \ldots, S_k$; *i.e.*, if S_o is another subspace containing these subspaces, then S_o contains S. Furthermore, all vectors common to $S_1, \ldots, S_k$ form a subspace $\mathbf{I} = \cap_i S_i$, called the intersection (mean) of the given subspaces. The space $\mathbf{I}$ is the "largest" subspace which is contained in $S_1, \ldots, S_k$; *i.e.*, if S_{oo} is a subspace of these k spaces then S_{oo} is contained in $\mathbf{I}$.

If there are k vectors $\mathbf{F}_1, \ldots, \mathbf{F}_k$ in a linear space V such that V is the totality of all linear combinations $\sum_{i=1}^{K} c_i\mathbf{F}_i$, the elements c_i being arbitrarily selected in the field of scalars K, then V is said to be spanned by $\mathbf{F}_1, \cdots, \mathbf{F}_k$. If V can be spanned by a finite number of its vectors, it is called finite-dimensional. In example (A) the vectors $\mathbf{U}_i$ which have all components equal to 0 except the ith, $i = 1, \ldots, n$, span the space; similarly in example (B) $1, t, \ldots, t^{n-1}$ span the space; but in example (C) no finite collection of vectors spans the whole space. Therefore (C) is called an infinite-dimensional space.

A sum $c_1\mathbf{F}_1 + \ldots + c_k\mathbf{F}_k = 0$ is called a linear-dependence relation of the vectors $\mathbf{F}_1, \ldots, \mathbf{F}_k$. If $c_1 = \ldots = c_k = 0$ are the only constants for which the given vectors $\mathbf{F}_1, \ldots, \mathbf{F}_k$ are linearly dependent, then these constants are called linearly independent. Thus, the vectors $\mathbf{U}_1, \ldots, \mathbf{U}_n$ mentioned earlier are linearly independent. In the subspace S of example (G) the vectors $\mathbf{G}_1$ and $\mathbf{G}_2$ which are obtained by letting $u = 0$, $v = 1$ and $u = 1$, $v = 0$, respectively, are linearly independent. On the other hand, for vectors $\mathbf{F}_1, \ldots, \mathbf{F}_k$ to be linearly dependent there must be at least one set of scalars $c_1, \ldots, c_k$ all of which are not 0, such that $\sum_{i=1}^{k} c_i\mathbf{F}_i = 0$. Thus, in example (A) the vectors $\mathbf{U}_1 = (1, 0, 0)$, $\mathbf{U}_2 = (0, 1, 0)$, $\mathbf{U}_3 = (0, 0, 1)$ and $\mathbf{F}_4 = (1, 0, 3)$ are linearly dependent, because $(-1)\cdot\mathbf{U}_1 + 0\cdot\mathbf{U}_2 + (-3)\cdot\mathbf{U}_3 + 1\cdot\mathbf{F}_4 = (0, 0, 0) = 0$. Note also that in example (G) the vectors $\mathbf{G}_1$, $\mathbf{G}_2$ and $\mathbf{G}_3 = (-1, -6, -7)$ are linearly dependent; that is, $\mathbf{G}_3$ lies in the subspace S. However, the vectors $\mathbf{G}_1$, $\mathbf{G}_2$ and $(-1, -7, -7)$ of the linear space of all triples are linearly independent. The latter is true because there are no numbers a, b, c except 0 for which $a\mathbf{G}_1 + b\mathbf{G}_2 + c(1, -7, -7) = (0, 0, 0)$; that is, the system of linear equations $a + b + c = a - 2b - 7c = 2a - b - 7c = 0$ has no other solution except $a = b = c = 0$.

The elements $\mathbf{F}_1, \ldots, \mathbf{F}_n$ of a linear space $V = V/K$ are said to form a basis of V if they span V and are also linearly independent. Thus, in example (A) the vectors $\mathbf{U}_1 = (1, 0, 0)$, $\mathbf{U}_2 = (0, 1, 0)$, $\mathbf{U}_3 = (0, 0, 1)$ or $\mathbf{F}_1 = (1, 1, 1)$, $\mathbf{F}_2 = (3, -1, 4)$, $\mathbf{F}_3 = (5, 6, 9)$ form distinct bases for the space of triples of real numbers.

If a space is finite-dimensional and is spanned by k elements, then it has a basis of at most k elements. Actually, all bases of a linear space contain the same number of elements. This common number is called the dimension $m = \dim V$ of V, and V is called m-dimensional. (A) and (B) are examples of n-dimensional space, and the subspace S in example (G) is two-dimensional. This important fact of the uniqueness of the dimension of a linear space is a consequence of the so-called Steinitz exchange theorem. This theorem states that, given r linearly independent vectors $\mathbf{L}_1, \cdots, \mathbf{L}_r$ of a space V and k vectors $\mathbf{F}_1, \cdots, \mathbf{F}_k$ spanning V, then certain r vectors $\mathbf{F}_i$ can be replaced by the vectors $\mathbf{L}_j$, $j = 1, \cdots, r$, such that the resulting collection of vectors $\mathbf{L}_j$ and the remaining $k - r$ vectors $\mathbf{F}_i$ still span the space V. The theorem has important consequences. If S is a proper subspace of the n-dimensional space V, *i.e.*, if V contains vectors which do not lie in S, then $\dim S < n$. A basis of a subspace S can always be augmented by $n - \dim S$ vectors of V so as to obtain a basis of the whole space V. Starting with a nonzero vector of V whose multiples by all scalars from the field K form a one-dimensional space, the preceding statement implies that V has proper subspaces of dimensions $1, 2, \ldots, n-1$. Furthermore, $\dim S + \dim T = \dim (S \cup T) + \dim (S \cap T)$ for two subspaces S and T of V. This equation is of significance in the analytic treatment of projective geometry.

If $S \cap T = 0$, *i.e.*, if the subspaces have only the zero vector in common, the union $S \cup T$ is called the direct sum of S and T, frequently denoted by $S \dotplus T$. Every vector $\mathbf{F}$ of $S \dotplus T$ is the sum $\mathbf{F}_S + \mathbf{F}_T$ of uniquely determined vectors $\mathbf{F}_S$ and $\mathbf{F}_T$ in S and T, respectively. The vector $\mathbf{F}_S$ is called the component of $\mathbf{F}$ in the subspace S, or the projection of $\mathbf{F}$ on S along T. If $\mathbf{F}_1, \ldots, \mathbf{F}_n$ constitute a basis of V and $S_1, \ldots, S_n$ denote the one-dimensional subspaces spanned by them individually, then $V = S_1 \dotplus \ldots \dotplus S_k$. Given a subspace S of V, there is always at least one subspace T such that $V = S \dotplus T$. The space T is not uniquely determined by S; note, for example, that $V_2(K) = S \dotplus T = S \dotplus T_1$, where S, T and T_1, respectively, consist of all the multiples of (1, 0), (0, 1) and (1, 1).

Homomorphism. — An important concept in the discussion of linear spaces is that of homomorphism, or linear transformation, or linear mapping. There are given tn-o linear spaces V and W with the same field of scalars K. A one-valued function ϕ with argument in I' and value in W is called a homomorphism of V into W if $(a_1\mathbf{F}_1 + a_2\mathbf{F}_2)\phi = a_1(\mathbf{F}_1\phi) + a_2(\mathbf{F}_2\phi)$ for every pair of vectors $\mathbf{F}_1$, $\mathbf{F}_2$ in V and arbitrary scalars a_1, a_2 in K. For $\mathbf{F}$ in V the vector $\mathbf{F}\phi$ of W is called the value of ϕ at F, or the image (map) of F by ϕ. The defining equation above may be stated in words thus: the map of a linear combination $a_1\mathbf{F}_1 + a_2\mathbf{F}_2$ is the linear combination of the maps $\mathbf{F}_1\phi$ and $\mathbf{F}_2\phi$ with the same coefficients a_1 and a_2. The collection of all maps $\mathbf{F}\phi$ is a subspace $V\phi$ of W; $V\phi$ can be a proper subspace of W. In example (G) consider (u,v) to be a vector G in the two-dimensional space $V = V_2(K)$ and let $\mathbf{G}\phi = (u + v,\ u - 2v,\ 2u - a)$ in $W = V_3(K)$ (example [H]). Then $V\phi$ is a proper subspace of W. On the other hand, letting $V = V_2(K)$, $W = V_2(K)$ and setting (I) $(x_1, x_2)\phi = \mathbf{F}\phi = (x_1 + 3x_2,\ 2x_1 - x_2)$, the image space $V\phi$ coincides with W; or letting $V = V_3(K)$, $W = V_2(K)$ and setting (J) $(x_1, x_2, x_3)\phi = \mathbf{F}\phi = (x_1 + x_3,\ x_1 - 2x_2 + 4x_3)$, there is obtained a homomorphism of V on 14'—the image space of V equals W. Note that a homomorphism ϕ is completely determined if its effect on a set of basis vectors is known.

To each homomorphism ϕ there is associated its "kernel" N_ϕ, also called the inverse image $0\phi^{-1}$ of the zero vector in W. It is the set of all vectors $\mathbf{F}$ in V for which $\mathbf{F}\phi = 0$; N_ϕ is a subspace of V. If elements F and G in V have the same image in W, then their difference $\mathbf{F} - G$ lies in N_ϕ, and conversely. In examples (H), (I) and (J) the kernels are, respectively, the zero-dimensional subspaces (0, 0), (0, 0) and the subspace of all vectors $a(1, -\frac{3}{2}, -1)$, where a denotes an arbitrary element of K, taken here as the field of all rational numbers, Note that the problem of determining the kernel of a homomorphism is equivalent to that of solving a system of linear homogeneous equations. For example, in (J) it is $x_1 + x_3 = x_1 - 2x2 + 4x_3 = 0$.

Special homomorphisms ϕ_S are determined as follows: suppose that S is a subspace of V. and let $\mathbf{F}$ denote a typical vector of V. Then consider the totality $\underline{\mathbf{F}} = \mathbf{F}\phi_S$ of all sums $\mathbf{F} + G$ where, for fixed $\mathbf{F}$, the vector $\mathbf{G}$ varies over all vectors of S. The set $\underline{\mathbf{F}}$ is called the "coset of $\mathbf{F}$ modulo S," and an element H in $\underline{\mathbf{F}}$ is called a representative of $\underline{\mathbf{F}}$. Then $\mathbf{H}\phi_S = \underline{\mathbf{H}} = \underline{\mathbf{F}}$, and two cosets, when considered as collections of elements in V, are either coincident or they have no element in common. Now denote by $V/S = \underline{\mathbf{V}}$, "$V$ modulo S," the collection of all distinct cosets $\underline{\mathbf{F}}$ for vectors $\mathbf{F}$ in V. This collection can in turn be made into a vector space over K called the "factor" ("quotient" or "difference") space of V modulo S.. A nen- sum $\underline{\mathbf{F}} + \underline{H}$ is defined as the coset which is determined by the sum $\mathbf{F}_1 + \mathbf{H}_1$ of any two representatives $\mathbf{F}_1$, $\mathbf{H}_1$ of $\underline{\mathbf{F}}$, H, respectively: similarly, the scalar product $a\underline{\mathbf{F}}$ for a in the field of scalars K is defined as the coset modulo S of the vector $a\mathbf{F}_1$, where $\mathbf{F}_1$ is a representative of $\underline{\mathbf{F}}$. Then the mapping ϕ_S which associates to each vector $\mathbf{F}$ of V its coset $\underline{\mathbf{F}} = \mathbf{F}\phi_S$ in V/S is a homomorphism of V on V/S.

The isomorphisms, whose kernels N_ϕ consist of the zero vector, are special homomorphisms. For an isomorphism, distinct elements have distinct images. For example, if $(x_1, x_2)\phi = (x_1 + 3x2, 2x1 - x_2)$ for $V = W = V_2(K)$, where K is the field of all real numbers, then ϕ is an isomorphism of I onto itself. Note that the equations $x_1 + 3x_2 = 2x_1 - x_2 = 0$ have the solution $x_1 = x_2 = 0$ and no other; that is, the kernel N_ϕ is given by (0, 0).

The connection between homomorphisms and factor spaces is established by the important "isomorphism theorem," which states that, given a homomorphism ϕ of a vector space V/K into a vector space W/K with the kernel $N_\phi = S$, there is an isomorphism ψ between $V\phi$ and V/S. The mapping ψ may be constructed by picking in V any element G which maps on the given image vector $\mathbf{F}\phi$ and then taking its coset $\mathbf{G}\phi_S$, set $(\mathbf{F}\phi)\psi = \mathbf{G}\phi_S$.

This theorem has significant corollaries, such as the following ones:

a. There are bases $\mathbf{F}_1, \ldots, \mathbf{F}_m$ and $\mathbf{H}_1, \ldots, \mathbf{H}_n$ in the vector spaces V/K and W/K of respective dimensions m and n such that $\mathbf{F}_1\phi = \mathbf{H}_1, \ldots, \mathbf{F}_r\phi = \mathrm{H}_r$, $\mathbf{F}_{r+1}\phi = 0, \ldots, \mathbf{F}_m\phi = 0$ for a homomorphism ϕ on V into TY. The integer r, which is at most equal to the smalier of the integers m and n, is called the rank of ϕ.

b. $\dim V = \dim V\phi + \dim N_\phi$.

c. $\dim V\phi \leq \dim V$. If $\dim V\phi = \dim V$, then ϕ is an isomorphism of V into W. (All dimensions are assumed to be finite.)

An interesting isomorphism of an n-dimensional space V/K with $V_n(K)$ is obtained as follows: Suppose that $\mathbf{F}_1, \ldots, \mathrm{F}_n$ is a basis of V/K, let $\mathrm{F} = x_1\mathbf{F}_1 + \ldots + x_n\mathbf{F}_n$, and set $\mathbf{F}\phi = (x_1, \ldots, x_n)$. Then $V\phi = V_n(K)$. This means that all n-dimensional spaces over K are isomorphic. Note, however, that this does not mean that the spaces coincide. For example, the two-dimensional space of all pairs (u, v) is isomorphic to the set of all triples $(u + v,\ u - 2v,\ 2u - v)$ in V_3 (see example [H]). Also, the subspace in V_3 of all linear combinations of $\mathbf{F}_1 = (1, 2, 3)$ and $\mathbf{F}_2 = (0, 1, 6)$ has dimension 2, and in V_3 it is isomorphic to the subspace spanned by $\mathbf{M}_1 = (0, 6, 0)$ and $\mathbf{M}_2 = (1, 1, 1)$; however, the two subspaces do not coincide. Given two linear spaces V and W of respective dimensions m and n over the same field of scalars K, all homomorphisms ϕ, ψ, ... of I.' into W can be considered as vectors of a linear space $\mathrm{Hom}\,(V, W) = \mathrm{H}$ over K. Properties and laws of H are set up as follows: (iv) the mappings ϕ and ψ are called equal, $\phi = \psi$, provided $\mathbf{F}\phi = \mathbf{F}\psi$ for all'vectors $\mathbf{F}$ in V; (v) the mapping of F on the vector $\mathbf{F}\phi + \mathbf{F}\psi$ in W, which turns out to be a homomorphism of V into W, is termed the sum $\sigma = \phi + \psi$, and thus $\mathbf{F}\sigma = \mathbf{F}\phi + \mathbf{F}\psi$ for all F in V; and (vi) if a is a scalar then the mapping of F on $(a\mathbf{F})\phi$, being a homomorphism of V into W, is called the scalar product $a\phi$, $\mathbf{F}(a\phi) = a[\mathbf{F}\phi]$. It is easy to verify that this new sum σ and scalar product in H turn it into a linear space over K. It is found that $\dim \mathrm{H} = mn$. Thus, if $V = V_m(K)'$ and $W = V_n(K)'$ (see example [F]) a system of linear equations (vii)

$$\sum_{j=1}^{m} a_{ij}x_j = y_i,\ i = 1, \ldots, n,$$ with given constants a_{ij} in the field K, determines a homomorphism of the column vectors X $= (x_1, \ldots, x_m)'$ into the space of column vectors Y' $= (y_1 \ldots, y_n)'$.

An Important special case arises if W is assumed to be a one-dimensional space over K; *i.e.*, essentially the same as K. Then $\mathrm{Hom}\,(V, K)$ is the set of all "linear functionals" of V/K, or the so-called dual space V^*/K. The theorems on $\mathrm{Hom}\,(V, W)$ imply that V^* is a linear space over F and $\dim V^* = \dim V$ for finite-dimensional spaces; definitions (iv) to (vi) are carried over.

Annihilators. — To each linear subspace S of V there is associated its annihilator an (S);that is, the linear subspace of all linear functionals χ in V^* such that $\mathbf{F}\chi = 0$ for all vectors F of S. The dimension of an (S) equals n-dim S; it is called the codimension of S. The operations of union and intersection of linear subspaces S, T of V and the rule of associating to them their respective annihilators are connected by the following laws: (viii) if $S \subseteq T$ (*i.e.*, if all elements of S lie in T), then an $(T) \subseteq$ an (S); (ix) an $(S \cup T)$ = an (S) $\cap$ an (T): (x) an $(S \cap T)$ = an (S) $\cup$ an (T). Furthermore, an (an S) is essentially the same as S, which means in effect that the vectors $\mathbf{F}$ of S can be viewed as linear functionals $\kappa_{\mathbf{F}}$ on the subspace $\{\phi\}$ = an (S) of V^* for which $\phi\kappa_{\mathbf{F}} = 0$. (To achieve the latter relation, let $\phi\kappa_{\mathbf{F}} = F\phi$ and vary ϕ.) These results are the equivalent in algebra to the basic rules on duality in projective geometry.

An important concept used for the proofs of these facts is that of the dual basis $\phi_1, \ldots, \phi_n$ in V^* belonging uniquely to a basis $\mathbf{F}_1, \ldots, \mathbf{F}_n$ of V. The functionals ϕ_j and the vectors $\mathbf{F}_j$ are paired by the n^2 conditions $F_i\phi_j = 0$ for $i \neq j$ and $\mathbf{F}_i\phi_i = 1$, $1 \leq i,$

$j \leq n$. If the general vectors $F = \sum_{i=1}^{n} x_i\mathbf{F}_i$ and the general functional $\phi = \sum_{j=1}^{n} y_j\phi_j$ with co-ordinates x_i and y_j in the field of scalars K are given, then (xi) $\mathbf{F}\phi = \sum_{h=1}^{n} x_h y_h$. This means that the "row" vector $X = (x_1, \ldots, x_h, \ldots, x_n)$ of $V_n(K)$ is multiplied by the "column" vector $Y' = (y_1, \ldots, y_h, \ldots, y_n)'$ of $V_n(K)'$ (see example [F] according to the rules of matrix multiplication [see MATRIX]).

There is a close connection between the theory of linear functionals and that of linear equations. Take a system of m linear equations in n unknowns $x_1, \ldots, x_n$, *e.g.*, (xii) $a_{h1}x_1 + \ldots + a_{hi}x_i + \ldots + a_{hn}x_n = b_h$, with $1 \leq h \leq m$ and given numbers a_h, and b_h in the field K. If the row of elements $(a_{h1}, \ldots, a_{hn})$ is denoted by A_h and the column of unknowns $x_1, \ldots, x_n$ by X', then the equations (xii) take the form $A_h\mathbf{X}' = b_h$, $1 \leq h \leq m$. Therefore, recalling (xi), the problem of solving (xii) is the same as that of finding all linear functionals $\mathbf{X}'$ with $A_h X' = b_h$. Similarly, the annihilator an (A) of the subspace A of $V_n(K)$ which is spanned by the row vectors $\mathbf{A}_1, \ldots, \mathbf{A}_m$ is precisely the collection of all column vectors X' of the solutions of the system (xii) after all b_h have been set equal to 0. From the general results on annihilators, this is a linear space over K. Direct verification is easy; for, if $Y' = (y_1, \ldots, y_n)'$ is another solution, then $\sum_{i=1}^{n} a_{hi}(x_i + y_i) = \sum_{i=1}^{n} a_{hi}x_i + \sum_{i=1}^{n} a_{hi}y_i = 0 + 0$ and $\sum_{i=1}^{n} a_{hi}(cx_i) = c\sum_{i=1}^{n} a_{hi}x_i$ for the hth equation, thus $X' + Y'$ and $c\mathbf{X}'$ are also solutions.

Upon combining the properties of homomorphisms and annihilators, the useful result is found that the dimension of the annihilator of A equals the dimension of the kernel of the mapping given in (vii). The formula (xi) is "bilinear" in the two variables F and ϕ; $(a_1\mathbf{F}_1 + a_2\mathbf{F}_2)\phi = a_1(\mathbf{F}_1\phi) + a_2(\mathbf{F}_2\phi)$ and $\mathbf{F}(b_1\phi_1 + b_2\phi_2) = b_1(\mathbf{F}\phi_1) + b_2(\mathbf{F}\phi_2)$, where a_1, a_2, b_1, b_2 are constants, $\mathbf{F}_1$ and $\mathbf{F}_2$ are vectors, and ϕ_1 and ϕ_2 are linear functionals.

Euclidean Spaces.—A similar formula occurs in analytic geometry; it is obtained by expressing the angle α between two nonzero vectors $\mathbf{F} = (x_1, x_2)$ and $\mathbf{G} = (y_1, y_2)$ in terms of their co-ordinates relative to a Cartesian co-ordinate system (fig. 3). The law of cosines implies $\cos\alpha = \dfrac{x_1y_1 \quad x_2y_2}{\sqrt{x_1^2 + x_2^2}\sqrt{y_1^2 + y_2^2}}$, where the square roots are positive real numbers. This formula is a special case of an important result valid in Euclidean linear spaces.

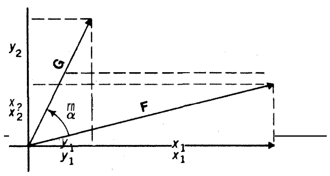

FIG. 3.— REPRESENTATION OF ANGLE α BETWEEN TWO VECTORS

Such a space E has the real numbers for scalars. Moreover, there is given a rule which associates to every pair of vectors F and G of E a real number (F, G) called their inner product such that (xiii) $(a_1\mathbf{F}_1 + a_2\mathbf{F}_2,\ b_1\mathbf{G}_1 + b_2\mathbf{G}_2) = a_1(\mathbf{F}_1, \mathbf{G}_1)b_1 + a_2(\mathbf{F}_2, \mathbf{G}_1)b_1 + a_1(\mathbf{F}_1, \mathbf{G}_2)b_2 + a_2(\mathbf{F}_2, \mathbf{G}_2)b_2$ ("bilinearity"); (xiv) (F, G) = (G, F) ("symmetry"); and (xv) (F, F) is always positive for a nonzero vector F, (0, 0) = 0 ("positiveness"). If, for example, the vectors $F = (x_1, \ldots, x_n)$ and $G = (y_1, \ldots, y_n)$ are given with real components, and (F, G) is defined as $\sum_{i=1}^{n} x_iy_i$, then $(\mathbf{F}, G)$ is an inner product defined on the linear space E_n of all n-tuples of real numbers. Properties (xiii) and (xiv) are implied by the algebra of real numbers, whereas property (xv) means that a sum of squares $\sum_{i=1}^{n} x_i^2$ of real numbers x_i can be zero if and only if $x_1 = \ldots = x_n = 0$.

General Euclidean spaces are important in geometry and analysis. For example, all continuous real-valued functions (or to be more restrictive, all polynomials) $f(x)$, $g(x)$ on the closed segment from -1 to $+1$ form a Euclidean space of infinite dimension, if the inner product $(f(x), g(x))$ is defined as the definite integral $\int_{-1}^{+1} f(x)g(x)dx$. Note that significant results of analysis are needed to verify the rules (xiii) to (xv). In every Euclidean space the important Schwarz inequality (xvi) $|(\mathbf{F}, G)| \leq |\mathbf{F}|\,|\mathbf{G}|$ is valid, where $|\mathbf{F}|$ denotes the positive square root of (F, F). This inequality expresses the simple geometric fact that the law of cosines is true in analytic geometry. Furthermore, (xvii) $|\mathbf{F} + \mathbf{G}| \leq |\mathbf{F}| + |\mathbf{G}|$. This inequality, the triangle inequality, describes in plane geometry the fundamental fact that in a triangle the length of a side never can exceed the sum of the lengths of the other two sides. Suppose that P and Q are the end points of the vectors $\mathbf{F}$ and G, and call $|\mathbf{F} - \mathbf{G}|$ the distance $d(P, Q)$ between P and Q (fig. 4). The properties of a Euclidean space simply imply that (xviii) $d(P, P) = 0$; (xix) $d(P, Q) = d(Q, P)$; and (xx) $d(Q, R) \leq d(P, Q) + d(P, R)$ as a consequence of (xvii). The inner product (F, G) with its defining properties (xiii) to (xv) can be recaptured from $|\mathbf{F}|$ and $|\mathbf{G}|$ by means of the formula $(\mathbf{F}, \mathbf{G}) = \frac{1}{2}[|\mathbf{F} + \mathbf{G}|^2 - |\mathbf{F}|^2 - |\mathbf{G}|^2]$, if the "length" $|\mathbf{F}|$ satisfies $|\mathbf{F}| > 0$ if $F \neq 0$, if $|a\mathbf{F}| = |a|\,|\mathbf{F}|$ for any real number a and if (xvii) holds; the space is called a metric linear space over the real field.

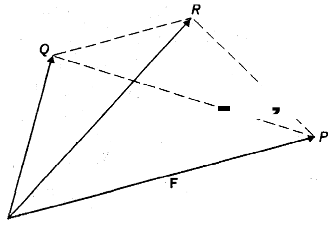

FIG. 4.— TRIANGLE INEQUALITY (*see* TEXT)

For a Euclidean space of dimension n, there is always a basis $\mathbf{H}_1, \ldots, \mathbf{H}_n$ such that $|\mathbf{H}_i| = 1$, $(H_i, H_j) = 0$ for $i \neq j$, $1 \leq i$, $j \leq n$ ("orthonormal basis"). If such a basis has been determined by the so-called Gram-Schmidt orthogonalization process (which involves nothing else but solving linear equations), then $(\mathbf{F}, \mathbf{G}) = \sum_{i=1}^{n} x_iy_i$, where $\mathbf{F} = \sum_{i=1}^{n} x_i\mathbf{H}_i$ and $G = \sum_{i=1}^{n} y_i\mathbf{H}_i$. Furthermore, the Bessel inequality $\sum_{i=1}^{k} (F, \mathbf{H}_i)^2 \leq |\mathbf{F}|^2$, $k \leq n$, holds. Many of the properties of finite-dimensional Euclidean spaces can be suitably extended to spaces of infinitely many dimensions.

Unitary Spaces.—Other linear spaces, this time over the field of all complex numbers, with a concept of length $|\mathbf{F}|$ and inner product (F, G), are the unitary spaces. For these, there are usually the postulates (xxi) $(a_1\mathbf{F}_1 + a_2\mathbf{F}_2, G) = a_1(\mathbf{F}_1, G) + a_2(\mathbf{F}_2, G)$ ("linearity in the first argument"); (xxii) $(F, G) = \overline{(G, F)}$, the bar denoting the conjugate complex number; and (xxiii) (F, F) > 0, except for the zero vector. Many of the results found for Euclidean spaces carry over to these unitary spaces; however, formal generalizations are not always true. Noteworthy instances of unitary spaces (and metric spaces) over the complex numbers are complex Hilbert spaces and Banach spaces. They are of extreme importance in analysis (Fourier analysis, differential equations, etc.) and in physics (quantum mechanics and relativity). See ANALYSIS, ABSTRACT; TOPOLOGY, GENERAL.

VEDANTA, one of the six schools of thought to which Indian philosophers adhered in the centuries following the Epic period. Its metaphysics attracted a number of western thinkers in the 20th century.

See INDIAN PHILOSOPHY: The Six *Systems*.

VEDDA, a primitive people of Ceylon, the original inhabitants prior to the Hindu invasion in the 6th century B.C. During the Dutch occupation (1644–1796) they were found as far north as Jaffna. but are now confined to the southeastern district. They have adopted Sinhalese and no longer use their own language.

Physically, they are allied to the Dravidian jungle peoples of southern India and to early populations in Southeast Asia and Indonesia; the term "Veddoid" is often applied to this assumed early physical type. The Vedda average a little over 5 ft. in stature, are dark-skinned and dolichocephalic, and have long wavy hair.

The aboriginal material culture and subsistence patterns were extremely simple. The Vedda lived in caves and rock shelters. wore barkcloth clothing. hunted game with bow and arrow and gathered wild plants and honey. Pottery vessels of a crude type were made, and a fire drill twirled by hand was used to make fire.

The Vedda are divided into maternal exogamous clans which probably were formerly territorial units. Marriage is strictly monogamous; cross-cousin marriage is common and divorce rare. The dead are abandoned in rock shelters and the location temporarily deserted.

Vedda religion is essentially a cult of the dead. Ancestral spirits enter the body of the shamans, or religious practitioners, and communicate with their descendants. Otherwise there seems to be no trace of supernatural beings or deities associated with natural phenomena. The arrow occupies an important role in the ceremonials, the ancestral spirits using it as a means of passing into the shaman. Most rituals are performed to achieve success in hunting or to divine the proper direction to hunt. Little trace of mythology has survived.

The Vedda have been largely absorbed into the modern Sinhalese population at present. both physically and in terms of culture and language.

See C. G. and B. Z. Seligmann, *The Veddas* (1911). (F. R. E.)

VEDDER, ELIHU (1836–1923). U.S. painter. whose work was typical of its period in its academic and literary character but at its best also possessed a unique imaginative quality, was born in New York city. Feb. 26. 1836. He studied under the genre and historical painter Tompkins H. Matteson (1813–84), at Sherburne, N.Y., later under François Édouard Picot, in Paris. and then. in 1857–61. in Florence. Italy. After 1867 he lived in Rome. making occasional visits to the U.S. He mas elected to full membership in the National Academy of Design. New Tork, in 1865. He devoted himself to the painting of genre pictures. which, however. attracted only modest attention until the publication, in 1884, of his illustrations to the *Rubaiyat* of Omar Khayyam; these immediately gave him a distinguished place in the art world. Important decorative work came at a later date. more particularly the painting symbolizing the art of the city of Rome. in the Walker art gallery of Bowdoin college at Brunswick, Me., and the five lunettes (1896: in the entrance hall) symbolical of government and the mosaic "Minerva" (1897) in the Library of Congress at Washington. D.C.

Vedder died in Rome on Jan. 29, 1923.

Shortly before his death, his book, *Doubt and Other Things*, was published.

VEDIC RELIGION, or the religion of the Veda, is the oldest stratum of religious activity known to have existed in India. It is the starting point of the religion variously called Brahmanism or Hinduism (*q.v.*), the first of these terms denoting chiefly the older aspects and learned forms of this religion. the second embracing all its manifestations. Most of the beliefs, practices and speculations born in India are derived more or less directly from Vedism.

The Vedic religion was brought to India by the Aryan invaders when they invaded the upper Indus basin sometime around 1500 B.C. Its basic beliefs go back to the period when the Aryans lived in Iran. and Iranian religion before the reforms of Zoroaster so closely resembles that of Vedic India that we can. with some reservation. talk about an Indo-Iranian religion. There is, on the one hand. a common belief in certain fundamental ideas—for example, that of a twofold divine hierarchy. the *daivas* (the Indo-Iranian form of *devas*) and the *asuras*—and. on the other, the same cults of fire, animal sacrifice and the sacrifice of Soma (see *Ritual,* below).

It seems likely that in yet more ancient times there was an Indo-European religion. though the basic elements that would permit its reconstruction are lacking. It is also probable that from the time of Indo-European unity onward, there was a network of fairly complex beliefs, notably at the mythological level, and that this mythology contained features that were at one and the same time naturalistic, ritualistic and social. Certain modern writers believe that Indo-European religious activity had a framework of three different types of functions: the religious function proper, with magical and juridical aspects; a warlike function, or one concerning itself with the temporal power; and an "economic" function. concerned with agriculture and, later, commerce and the activities of craftsmen.

However, this twin Indo-Iranian and Indo-European heritage offers only an inadequate explanation of Vedic religion. Either through contact with indigenous elements, or else as the result of internal evolution the ancient forms mere swamped by new accretions. It is impossible to say when Vedism gave way to Hinduism, but there was less literary activity among the Vedic schools from the 5th century B.C. onward, and about this time texts of Hindu character began to appear.

Vedic Texts.—The only extant Vedic material is the texts, great in length and very varied in content. They were written down over a period of about ten centuries, from approximately the 15th to the 5th century B.C., this being the period when Vedism was a living force. Out of the vast literary production of Vedism, only a part has survived, but this part is sufficient for understanding of the nature of the whole.

Religious activity tended to be concentrated within certain groups. or schools, stemming from subdivisions that had early occurred in the four main branches of Vedic literature—branches themselves determined by the adhesion of devotees to one or another of the four Vedas. and by the fourfold function of the chief officiants of the cult. The rise and duration of the schools cannot be dated precisely; tradition furnishes the names of several hundred. but nothing is known of them beyond those few whose supposed texts survive, for example the Xitareya and Shankhayana schools of the Rigveda and the Apastamba and the Baudhayana of the Yajurveda.

The most important texts are also the oldest. They are the four collections (Samhita) which, taking the word in its most restricted sense, we call the Veda or Vedas (*i.e.*, "Book[s] of Knowledge"). In a broader sense the term Veda(s) also includes all or part of the later literature! insofar as this is based on one or another of the four Samhitas.

The Rigveda. or "Veda of Verses." earliest of the Samhitas. is composed of about 1,000 hymns addressed to the deities. arranged for the most part to serve the needs of the priestly families who mere the custodians of this sacred literature. Most of the hymns refer directly or indirectly to the Soma cult. but in general they have only a distant connection with the ritual. The Yajurveda or "Veda of Sacrificial Formulas" contains prose formulas applicable to the different rites (*see* below), verses intended for a similar purpose and, finally, commentaries. or Brahmanas. The Samaveda or "Veda of Chants" is made up of a selection of verses (drawn almost wholly from the Rigveda), with musical notation, intended as an aid to the performance of sacred song. Finally. the Xtharvaveda is considered to be either of less worth than, or of similar content to, the three earlier collections.

Next in probable chronological order come the Brahmanas, or commentaries. These are prose texts. compiled separately for the various Vedas and serving to interpret either their formulas or their ritual. The Aranyakas. or "Forest Texts." composed c. 600 B.C., were intended to be studied in the iorest. away from the community, because of their esoteric or magical character. They contain mostly symbolic interpretations of ritual or of the *mantras* (sacred formulas). Finally, and most important, are the Upanishads (*c.* 600–300 B.C.), which touch the very quick of specula-. tion. These texts are generally very short and summarize a speculative teaching, often through parables or passages of dialogue. The so-called "Vedic" Cpanishads are 13 in number; the remainder (about 100) are probably post-Vedic, though many of them are influenced by the Vedas.

The Samhitas, Brahmanas, Aranyakas and Upanishads form what is known as the *shruti,* the "heard" or divinely revealed section of the literature. The remaining Vedic documents belong to the *smriti,* "traditional texts based on human memory," a term which also includes a whole assemblage of post-Vedic texts including the juridical *smritis* and the Bhagavad Gita (*q.v.*). They are essentially collections in the form of sutras, or aphorisms, which give a detailed description of the ceremonies or else condense certain teachings complementary to religion. for instance jurisprudence, astronomy, phonetics and metrics. Others among these ancillary texts are written either in a running prose or in didactic verse.

The Vedic corpus is written in an archaic Sanskrit whose morphological and syntactical singularities decrease with the age of the texts. The whole of this literature seems to have been preserved orally (although there must early have been manuscripts to assist memory); even today several of these works, notably the three oldest Vedas, are recited throughout India with subtleties of intonation that must have been handed down from their earliest days.

Mythology.—Although the earliest-known features of Vedic religion is its mythology, found in the Rigveda, this in no way means that there was a period when myths were recited to the exclusion of all other religious activity. The mythology in any case shows certain correlations with the ritual. Two of the greatest deities are at the same time material elements of the offering: on the one hand. Agni (*q.v.;* fire) is equally the fire of the sun. lightning the fire that is hidden in wood and in plants. and that which men light for the purposes of worship: on the other hand, Soma (*q.v.*) is simply the deified aspect of the liquid poured in oblation.

Important as Agni and Soma are, the highest rank is held by Indra (*q.v.*), a warlike god—one might say a typically Aryan god—who conquered innumerable human and demon enemies, vanquished the sun, killed the dragon Vritra who held up the flow of the waters and delivered the cows Vritra held captive (which partly represent the Dawns). Although there is no systematic mythological explanation of the creation of the universe in the Vedas, Indra is sometimes designated creator of parts of it; for instance, in the hymns to Indra he is addressed as the creator of light and of the oceans. Among his allies are the Maruts (q *v.*), young men who ride the clouds and who make rain; the Ashvins or Nasatyas, twin brothers famed for their powers of healing and analogous to the Dioscuri of Greek legend; and Vishnu. the giant who is said to cover the world in three strides and who later evolves into one of the three principal gods of Hinduism.

Among the other great deities, the chief is Varuna, the god-"sovereign." to be distinguished from Indra. the god-"king" and prototype of the warrior chief. Varuna is upholder of the cosmic and moral laws; he is associated with Mitra. who represents the more juridical side of sovereignty, while Varuna represents the magical and speculative aspects. Both are members of the Adityas. a group of gods who are supposed to have descended from Aditi. a somewhat shadowy mother-goddess. There are indications that Varuna was once the highest god but was deposed to the advantage of Indra; this event seems to coincide with the victory of the devas, or gods, over the asuras, who may be equated roughly with the Titans.

In the background is the Father of the Heavens, Dyaus or Dyauh Pitar, the equivalent (as his name alone shows) of the Roman Jupiter but generally coupled with the Earth goddess and forming with her a pair in which the feminine side dominates. The female deities are numerous but not clearly differentiated; the most distinctive is Ushas, or Dawn. Rudra stands somewhat apart: he is an ambivalent god, in part beneficent, in part a source of fear, and as such is a forerunner of the post-Vedic deity Shiva.

The cosmos is filled with living beings; apart from the individual gods there are the demigods or spirits of uncertain status (such as the Gandharvas and their female companions, the Apsarases), and there are the divine groups, the most extensive of which is the one that goes under the name of the Vishve Devas. "All-gods." There exist also demons or groups of demons (most numerous in the Atharvaveda), whose leader is Vritra, the warrior demon. But there is no dominant figure: Vedic India elaborated no principle of evil comparable to the principle of good embodied by the gods (who are often called vasu, an Indo-Iranian term meaning "good"). Evil is within, and numerous divine and normally favourable entities have another side which inspires fear and brings misfortune.

Finally, few roles are strictly defined. The qualities and exploits attributed to one god pass very easily to another, showing that in the midst of so many and varied images there was a tendency to blend the different elements. This indicates a move in the direction of monotheism and prepares the way for that weakening of mythology that takes place in the Vedic texts written after the Samhitas; Prajapati, the lord of living creatures, takes on the rank of supreme god, and, still later, the concept *brahman* replaces any specific personification.

Cosmology and Cosmogony.—Just as there is no stable principle of evil, there is no precise picture of an infernal region. Paradise. or the world of "the pious act," is scarcely more clearly described: it is situated in the third heaven and represented as a place of material felicity. Vedic man asks. in general, for nothing more than the life of the moment—riches. good fortune, male, progeny—and has no clear vision of a rebirth. Yama, who was the first of human beings and so the first of the dead, became king of the dead, sovereign sometimes of a subterranean world. sometimes of paradise. As for the creation of the world. it is at times conceived in nonfigurative terms; starting from abstract ideas, but the dominant image is that of a cosmic giant who initiates a primordial sacrifice in which he himself is the willing victim and from whose limbs are born the structural elements of the universe (see also HINDUISM: *Cosmology*).

Metaphysical Speculation.—Vedic thought became increasingly refined and subtle, but its foundations are all to be found in the Rigveda. All speculation was directed toward the search for harmony, equivalences and correspondences between macrocosm and microcosm: and its ultimate goal was a reduction to unity by way of successive equations. There was already a hint of this tendency in the mythico-religious complex of the earliest ages and in the setting in an order of human, atmospheric and celestial phenomena, designated by the old term *rita* (now sometimes translated by "truth"). Elements of natural philosophy. culled from a theory of fire, a theory of breath and a theory of the cycle of the waters, provided a concrete illustration of the Upanishadic *gnosis,* in which all images came together and where ancient myth was reduced to parable.

The crucial idea was that of *brahman;* this word, which is neuter in gender and originally denoted the sacred formula (or, to be more exact, the particular energy expended either in repeating the formula or in maintaining silence) tends to become a guiding principle, a sort of universal soul, in which is merged the individual soul: Atman. This is the central thesis of the Upanishads. but was already partially developed in the Brahmanas and even in the Atharvaveda.

Ritual.—There were three phases in the development of Vedic ritual. In the Rigveda the ritual seems to have been relatively simple; the hymns served as introductions to the most solemn ceremonies, which were also accompanied by chants and various activities, such as horse races, real or imagined raids and perhaps verse competitions. In the last stage, that of the Aranyakas and Upanishads. the ritual is smothered either by mental or symbolic forms or by pure speculation. Between the two is the whole range of the Vedic liturgy, which culminated in sacrifice. Homage to the divinity consists essentially of offerings to Fire, the aim being to enter into communication with the divine world and by so doing to obtain certain benefits, general or particular, collective or personal. There are fixed ceremonies, corresponding to' precise dates in the lunar calendar, and others, votive in intention, which accompany some particular occasion, sometimes of a national, sometimes of an individual character.

The shortest solemn rite is the Agnihotra or Oblation to Fire, which is simply an offering of milk, morning and evening, and calls for only one officiant. More complex is the Sacrifice of the Full and New Moons, which serves as the norm for a series of other liturgies and consists of offerings of plants. Animal sacrifice — the killing of a ram — existed either independently or as an integral part of the Sacrifice of Soma. a plant whose juice acts as a stimulant. In the basic form of this ritual the lay sacrificer is first consecrated and then the juice is three times pressed from the plant, part being offered to the fire and part consumed by the priests. Each of the three occasions is preceded and followed by recitations and chants. The longest rituals are the "sessions." for example the "way of the cows" *(gavam ayana)*, the crucial point of which is a festival of the winter solstice known as the "great observance." The *rajaszrya*, or sprinkling of the (newly elected) king, the *Vajapeya*, or "drink of victory" destined for the victorious prince, the *ashvamedha*, or horse sacrifice, are elaborate variants of the Soma sacrifice.

The patron who ordered the sacrifice took part in it with his spouse; he pronounced certain formulas and distributed the fees due to the professional priests. who numbered from 4 to 16 or 17 and mere theoretically under the orders of the *brahman*, who supervised in silence. The *hotar* poured the oblation and recited stanzas drawn from the Rigveda: the *udgatar*, or cantor. chanted the stanzas taken from the Samaveda; the *adhvaryu* performed numerous ritual gestures and recited the formulas emanating from the Yajurveda. There were no temples or images; the ceremony took place in an open space, consecrated afresh for every important ceremony, whose altar *(zedi)* was a quadrangle marked out by hollowing or slightly raising the ground. No prayer existed independent of the formulas used for sacrifice. At first the sacred formulas must have consisted principally of invitations to the gods to come to the earth and participate in human worship; later they became learned elaborations of this elementary pattern.

Private Rites. — All the rituals mentioned above were public, necessitating the participation of priests, and these are the true Vedic rituals. Mention must also be made. however, of the private or domestic rites, even though it is not clear whether they are really Hindu (or the precursors of Hindu) rites that have incorporated certain genuine Vedic patterns. They are carried out by the head of the household at the family hearth, and are brief ceremonies in which milk, butter or grain are offered either to the fire or to the winds. Some occur daily or monthly. others accompany a particular event and have votive or expiatory significance. The *sanzskaras* (sacraments) are consecration rites of various kinds marking the life of the Indian (of the first three castes) from the period as an unborn child up to time of death and nhat lies beyond it. The most elaborate ceremonies are those relating to marriage and death. Marriage rites. which include oblations to the gods, recited formularies and symbolic acts, are followed by a three-day period of abstinence from sexual intercourse.

The normal way of disposing of the dead is cremation. There too the rites include symbolic acts, particularly the custom, already attested in the Rigveda, of inviting the widow to lie down for a moment beside the dead body of her husband, then to get up and join her brother-in-law as a substitute for the dead man. Cremation is followed by purificatory rites; later a mound is set up. and commemorative rites *(shraddhas)* are performed on a fixed date. These rites have some social importance. for they confirm the authenticity and the limits of the family line and determine who is later to have the right of inheritance. On the religious plane they help to transform the dead man into a *pitr*, that is, a powerful and friendly ancestor.

The most important sacrament socially is *upanayana* or initiation, which confirms the admission of the child into the brahmanical community. The master of ceremonies gives a staff to the candidate. girds him and grasps him by the hand: after a short interchange of request and acceptance the child receives instructions and is commended to the gods. Thus he becomes "twice born " He is then eligible to consume the remains of the offerings and takes his place in the male brahmanical line.

Finally. there are the magical and ascetic practices. Magic was highly developed and even found a place in religious observances and the ancient hymnary. The magician made use of an extensive range of symbols, he was familiar with the mysteries of divination, and in the role of chaplain he put himself at the service of the king. It also seems that there already existed certain ascetic practices of the type which in later times was especially associated with the Yoga of Patanjali.

Conclusion. — The literature gives a relatively full account of certain aspects of religious life but leaves others unexplained. Very little is known about Vedic man: he is seen beseeching the gods with his petitions — what one is tempted to call faith *(shraddha)* is plainly rather the confidence that is felt in the efficacy of the ritual — and troubled by the fear of sinning. However. it is not known how this religion fitted into a precise political system nor how it manifested itself at the social level.

In spite of the fact that the religion seems to have had a very fixed and decisive nature, various aspects nevertheless managed to survive in later periods down to the present time. Hindu mythology inherits much from the mythology of the Rigveda; the ancient speculation gave birth to a number of systems of thought in classical India *(see* IXDIAX PHILOSOPHY). As for the ritual, if most of the spectacular ceremonies have been practised only on rare occasions. and perhaps inspired by antiquarian sentiment rather than religious feeling; the private rites on the other hand continued in use alongside the later developments of Hinduism in the Puranas and Tantras, and many of them have remained alive.

VEERY *(Hylocichla fuscescens)*, also called Wilson's thrush, a North American songbird of the thrush *(q.v.)* family (Turdidae). It breeds from Newfoundland to New Jersey (in the mountains as far south as Georgia) and ranges west to central Oregon and northern New Mexico, migrating to South America in the winter. About 7 in. long, the veery is an even tawny brown above and white below, the throat and upper breast being buff-marked with a few indistinct brownish spots. The young have upper parts spotted tawny olive. The veery is often seen in young hardwood thickets of willow or alder where it feeds on insects, berries and seeds. Its characteristic song is a vibrant series of downward-slurred notes having a ventriloquistic, faraway quality.

VEGA, GARCILASO DE LA (1503–1536), Spanish soldier and poet. was born at Toledo. At the age of 17 he was attached to the bodyguard of Charles V. fought against the insurgent *communeros* and afterward gained great distinction by his bravery at the battle of Pavia (1525). In 1526 he married a lady-in-waiting to Queen Eleanor. He took part in the repulse of the Turks from Vienna in 1529, was present at the coronation of the emperor at Bologna in 1530 and was charged with a secret mission to Paris in the autumn of the same year. In 1531 he accompanied the duke of Alva to Vienna, where, for conniving at the clandestine marriage of his nephew to a maid-of-honour, he nas imprisoned on an island in the Danube. During this captivity he composed the fine cancion. "Con un manso ruido de agua corriente y clara." Released and restored to favour in June 1532, he nent to Naples on the staff of Don Pedro de Toledo, the newly appointed viceroy, by whom he was twice sent on public business of importance to Barcelona, in 1533 and 1534. After having accompanied the emperor on the expedition to Tunis (1535), he took part with him in the invasion of Provence and was mortally wounded while storming a fort at Muy, near Fréjus. His poems, which are among the finest in their language, include three pastorals, which rank among the finest in the Spanish language, 37 sonnets, five canciones, two elegies, and a blank verse epistle, all influenced by Italian models. An English translation was published by J. H. Wiffen in 1823. Garcilaso's delicate charm has survived all changes of taste, and by universal consent he ranks among the most accomplished and artistic of Spanish poets.

See H. Keniston, *Garcilaso* de la *Vega* (1922–25).

VEGA, GARCILASO DE LA, called "Inca" 150–1616), historian of Peru, was born at Cuzco. His father, Sebastiano Garcilaso (d. 1559), was a cadet of the illustrious family of La Vega, who had gone to Peru in the suite of Pedro de Alvarado, and his mother was of the Peruvian blood-royal, a circumstance of which he was very proud as giving him a right to the title which he claimed by invariably subscribing himself "Inca." About 1560 he removed to Spain, but failed to win the preferment for which he hoped. After long service in the army, he turned to literature, solacing himself in his rather meagre circumstances by depicting the riches of the new world. He died in Spain in 1616. He published in 1590 a translation of *Dialoghi* di *Amore* of Léon Hebro, but his fame depends upon La Florida del Ynca (1605) and his history of Peru (Pt. 1, *Commentarios Reales que tratan del origen* de *los Yncas,* Lisbon, 1608 or 1609; Pt. 2, Cordova, 1617). This latter work has been translated into English, French, German and Italian and has been utilized by Robertson, Prescott, Marmontel and Sheridan. The former work, a history of the De Soto expedition, was long regarded primarily as fiction. In spite of its exaggerations as to the numbers and wealth of the Indians, recent investigations have shown it to possess more ethnological value than had been hitherto supposed. Garcilaso de la Vega wrote before history was regarded as a science; by temperament and circumstances he was inclined to the romantic; nevertheless his work possesses permanent intrinsic interest and he will be remembered as the first South American in Spanish literature.

See monograph by J. Fitzmaurice-Kelly (1921) in Hispanic series, and Lima edition of the Peruvian history (1918–21) prepared by H. H. Urteaga with introduction by Don José de la Riva Agüero.

VEGA, the bright star in the constellation Lyra (*q.v.*), hence its Bayer equivalent, α Lyrae; it is one of the brightest stars in the sky. It is also one of the sun's nearer neighbours in space, being located at a distance of about 26 light years.

VEGA CARPIO, LOPE FELIX DE (1562–1635), Spanish dramatist and poet, was born in Madrid. His father and mother, Felices de Vega and Francisca Hernandez Flores, originally came from the valley of Carriedo in Asturias. Lope began his studies at the Theatine college in Madrid, and afterwards entered the service of Don Jerónimo Manrique, bishop of Avila, who sent him to the University of Alcalá de Henares, perhaps from 1577–81. He took part in the expedition to the Azores in 1582, and from 1583–87 was secretary to the marqués de las Navas. In Feb. 1588 he was banished for circulating criminal libels against his mistress. Elena Osorio, whom he has celebrated under the name of Fills. He defied the law by returning to Madrid soon afterwards and eloping with Isabel de Urbina, sister of Philip II.'s herald; he married her by proxy on May 10, 1588, and joined the Invincible Armada, losing his brother in one of the encounters in the Channel. He settled for a short while at Valencia, where he made acquaintance with a circle of young poets who were afterwards to be his ardent supporters in founding the new comedy. He joined the household of the duke of Alva, with whom he remained till 1595. Soon afterwards he lost his wife. He was prosecuted for criminal conversation in 1596, became secretary to the marquis de Malpica (afterwards count of Lemos), and in 1598 married a second wife, Juana de Guardo, by whom he had two children (Carlos, who died in 1612, and Feliciana Felix); but she died, shortly after giving birth to the latter, in 1613. Lope then sought a refuge in the church. After having been affiliated to a tertiary order, he took priest's orders.

At this juncture, about 1614, he was in the very zenith of his glory. A veritable dictator in the Spanish world of letters, he wielded over all the authors of his nation a power similar to that which was afterwards exercised in France by Voltaire. At this distance of time Lope is to us simply a great dramatic poet, the founder of the Spanish theatre; but to his contemporaries he was much more. His epics, his pastorals, his odes, his sonnets, now forgotten, all placed him in the front rank of authorship. Such was his prestige that he dealt with his noble patrons almost on a footing of equality. The duke of Sessa in particular, his Maecenas from 1605 onwards, was also his personal friend, and the tone of Lope's letters to him is one of frank familiarity, modified only by some forms of deference. Lope's fame, too, had travelled abroad; foreigners of distinction passing through Madrid made a point of visiting him; papal legates brought him the compliments of their master; in 1627 Urban VIII., a Barberini, sent him the diploma of doctor of theology in the Collegium Sapientiae and the cross of the order of St. John of Jerusalem (whence the poet's titles of "Doctor" and "Frey"). His last days were full of sadness; the death of his son Lope, the elopement of his daughter, Antonia Clara, wounded him to the soul. Montalban tells us that every Friday the poet scourged himself, so severely that the walls of his room were sprinkled with his blood. His death, on Aug. 27, 1635, was followed by national mourning.

For a rapid survey of the works of Lope, it is convenient to begin with those which the Spaniards include under the name of *Obras* Sueltas, the title of the large collection of the poet's non-dramatic works (1776–79). We shall enumerate the most important of these, as far as possible in the order of publication. The Arcadia (1598), a pastoral romance, inspired by Sannazaro, is one of the poet's most wearisome productions. La *Dragontea* (1598), is a fantastic history in verse of Sir Francis Drake's last expedition and death. *Isidro* (1599), a narrative of the life of Isidore, patron of Madrid, is called a Castilian poem on account of the rhythm in which it is composed—quintillas of octosyllabic verse. The *Hermosura* de *Angélica* (1602), in three books, is a sort of continuation of the Orlando *Furioso,* in octaves after the fashion of the original poem. Finally, the *Rimas* are a miscellany of short pieces. In 1604 was published the *Peregrino* en *su Patria,* a romance similar in kind to the Aethiopica of Heliodorus. Having imitated Ariosto, he proceeded to imitate Tasso; but his Jerusalem conquistada (1609) has preserved nothing of the art shown in its model and is an insipid performance. Next follows the *Pastores* de *Belen* (1612) a pious pastoral, dedicated to his son Carlos, which forms a pendant to his secular Arcadia; and incidental pieces published in connection with the solemnities of the beatification and canonization of St. Isidore in 1620 and 1622. It is enough to mention La *Filomena* (1621), La *Circe* (1624) and other poems published about the same date, as also the four prose novels, Las *Fortunas* de Diana, El Desdichado *por* la *Honra,* La *Más Prudente Venganza* and *Guzmán* el Bravo. The great success of the *Novelas exemplares* (1613) of Cervantes had stimulated Lope, but his novels have none of the grace, naturalness, or interest which characterize those of his rival. The last important work which has to be mentioned before we leave the narrative poetry of Lope is the Laurel de Apolo (1630). This piece describes the coronation of the poets of Spain on Helicon by Apollo, and it is more meritorious as a bibliographical manual of Spanish poetry at that time than as genuine poetry. One other obra *suelta,* closely akin to Lope's dramatic works, though not, properly speaking, a drama, is La Dorotea (1632). Lope describes it as an "action in prose," but it is rather a "romance in dialogue"; for, although divided into acts, the narrative is dramatic in form only. Of all Lope's productions Dorotea shows most observation and study; the style also is unusually simple and easy. Of all this mass of obras *sueltas,* filling more than 20 volumes, very little (leaving *Dorotea* out of account) holds its own in the judgment of posterity. The lyrical element alone retains some vitality. From the *Rimas* and other collections of detached pieces one could compile a pleasing anthology of sonnets, epistles, elegies and romances, to which it would be proper to add the *Gatomaquia,* a burlesque poem published along with other metrical pieces in 1634 by Lope under the pseudonym of Tomé de Burguillos.

It is, however, to his dramatic writings that Lope owes his eminent place in literary history. It is very curious to notice how he himself always treats the art of comedy-writing as one of the humblest of trades (*de pane lucrando*), and protests against the supposition that in writing for the stage his aim is glory and not money. The reason is not far to seek. The Spanish drama, which, if not literally the creation of Lope, at least owes to him its definitive form — the three-act comedy — was totally regardless of the precepts of the schooi, the pseudo-Aristotelianism of the doctors of the period. Lope accordingly, who stood in awe of the criticism of the *científicos,* felt bound to prove that, from the point of view of literary art, he attached no value to the "rustic fruits of his humble *vega.*" In his *Arte Nuevo de hacer comedias en este tiempo* (1609), Lope begins by showing that he knows as well as any one the established rules of poetry, and then excuses himself for his inability to follow them on the ground that the "vulgar" Spaniard cares nothing about them. "Let us then speak to him in the language of fools, since it is he who pays us." Another reason which made it necessary for him to speak deprecatingly of his dramatic works is the circumstance that the vast majority of them were written in haste and to order. The poet does not hestitate to confess that "more than a hundred of my comedies have taken only 24 hours to pass from my brain to the boards of the theatre." Nevertheless, Lope did write dramas in which the plan is more fully matured and the execution more carefully carried out; still, hurried composition and reckless production are after all among the distinctive marks of his theatrical works. Towards the close of his career Lope somewhat modified the severe and disdainful judgments he had formerly passed upon his dramatic performances; he seems to have had a presentiment that posterity, in spite of the grave defects of his work in that department, would nevertheless place it much higher than *La Dragontea* and *Jerusalem conquistada,* and other works of which he himself thought so much. We may certainly credit Lope with creative power, with the instinct which enabled him to reproduce the facts of history or those supplied by the imagination in a multitude of dramatic situations with an astonishing cleverness and flexibility of expression; but unfortunately, instead of concentrating his talent upon the production of a limited number of works which he might have brought to perfection, he dissipated it, so to say, and scattered it to the winds.

The classification of the enormous mass of Lope's plays (about 470 *comedias* and 50 *autos* are known to us) is a task of great difficulty, inasmuch as the terms usually employed, such as comedy, tragedy, and the like, do not apply here. There is not explicitness enough in the division current in Spain, which recognizes three categories: — (I) *comedias de capa y espada,* the subjects of which are drawn from everyday life and in which the persons appear as simple *caballeros;* (2) *comedias de ruido* or *de teatro,* in which kings and princes are the leading characters and the action is accompanied with a greater display of dramatic machinery; (3) *comedias divinas* or *de sarztos.* Some other arrangement must be attempted. In the first place, Lope's work belongs essentially to the drama of intrigue; be the subject what it may, it is always the plot that determines everything else. Lope in the whole range of his dramatic works has no piece comparable to *La Verdad Sospechosa* of Kuiz de Alarcon, the most finished example in Spanish literature of the comedy of character: and the comedy of manners is represented only by *El Galan Castrucho, El Anzuelo de Fenisa* and one or two others. It is from history. and particularly Spanish history. that Lope has borrowed more than from any other source. But it is to the class of *capa y espada* — also called *novelesco,* because the subjects are almost always love intrigues complicated with aifairs of honour — that Lope's most celebrated plays belong. In these he has most fully displayed his powers of imagination (the subjects being all invented) and his skill in elaborating a plot. Among the plays of this class which are those best known in Europe, and most frequently imitated and translated. may be specially mentioned *Los Ramilletes dr Madrid, Lrr Boba para los Otros y Discreta para si, El Perro del Hortelano, La Viuda de Valencia* and *El Maestro de Danzar.* In some of them Lope has sought to set forth some moral maxim. and illustrate its abuse by a living example. as in *Las Flores de Don Juan.* Such pieces are, however. rare in Lope's repertory; in common with all other writers of his order in Spain. with the occasional exception of Ruiz de Alarcon, his sole aim is to amuse and stir his public; not troubling himself about its instruction. The strong point of such writers is and always will be their management of the plot.

To sum up. Lope found a poorly organized drama, plays being composed sometimes in four acts. sometimes in three: and. though they were written in verse. the structure of the versification was leit far too much to the caprice of the individual writer. The style of drama then in vogue he adopted. because the Spanish public liked it. The narrow framework it afforded he enlarged to an extraordinary degree. introducing everything that could possibly furnish material for dramatic situations — the Bible. ancient mythology. the lives of the saints. ancient history. Spanish history, the legends of the middle ages. the writings of the Italian novelists, current events. Spanish life in the 17th century. Before him manners and the conditions of persons and characters had been barely sketched; with fuller observation and more careful description he created real types. and gave to each social order the language and drapery appropriate to it. The old comedy was awkward and poor in its versification; he introduced order into the use of all the forms of national poetry. from the old romance couplets to the rarest lyrical combinations borrowed from Italy. Hence he was justified in saying that those who should come after him had only to go on along the path which he had traced.

Renncrt and A. Castro (1919); M. Menéndez y Pelayo, *Historia de las Ideas Estéticas en España;* A Morel Fatio, *La Comédie espagnole du XVII^me siècle* (1885). (X.; J. F.-K.)

VEGETABLE, in its broadest sense, refers to any kind of plant life or plant product; viz., "vegetable matter." However, in common. narrow usage "vegetable" usually refers to the fresh, edible portion of a herbaceous plant — roots. stems. leaves. flowers or fruit. These plant parts are either eaten fresh or prepared in a number of ways. (*See* VEGETABLE COOKERY.)

The edible portion may be a root — rutabaga,beet. turnip. radish. carrot. parsnip. celeriac, sweet potato. salsify, horse-radish; tuber (storage stem)—white (Irish) potato. yam. taro; stem—asparagus. kohlrabi: bud — Brussels sprouts: bulb — onion, garlic, shallot; petiole — celery. rhubarb. fennel, cardoon; leaf — cabbage, lettuce: kale, mustard. turnip (leaves). endive, chard, collard. parsley, spinach, chive; immature flower—cauliflower. sprouting broccoli, artichoke; seed — pea. southern (cow) pea. Lima bean; fruit (immature) — snap bean. chayote, okra. eggplant. summer squash (vegetable marrow). cucumber. sweet corn (maize); fruit (mature) — muskmelon, watermelon. squash (winter), pumpkin. tomato. pepper. The fruit-producing vegetables are all herbaceous annuals or, rarely, in temperate climates. perennials. The "fruit" crops, except strawberries. are produced on woody perennial vines or trees. A decision of the U.S. supreme court in 1893 held, in effect, that a plant or plant part is a vegetable if generally eaten as a part of the main course of a meal, but is a fruit if eaten as an appetizer, or as a dessert. or out of hand. Muskmelons and watermelons are, broadly speaking, vegetables, but they. and tomatoes also. are frequently commonly and botanically classed as fruits. (*See* FRUIT.)

The importance of vegetables in the human diet lies primarily in quantities of usable iron and calcium. the high vitamin C (ascorbic acid) content and. in the yellow or leniy vegetables, the large amount of vitamin A. Many vegetables contain appreciable quantities of the B-complex vitamins. niacin. riboflavin and thiamin, The iron and calcium in spinach and rhubarb are practically unavailable, because of their oxalic acid content. Most vegetables are low in protein and carbohydrate. Lima beans and peas are relatively high in protein, and Lima beans. sweet corn. peas, white potatoes and sweet potatoes have moderate amounts of carbohydrate (*see* DIET AND DIETETICS).

About 80 plant species and 18 families are represented in crops cultivated as food by Europeans alone. Nearly one-third of these are of economic value. Of the more important vegetahles. all except the rutabaga have been cultivated since ancient times and are contributions from early civilizations of both the new and old worlds. Some have been so changed by man that their wild ancestors can no longer be identified with certainty. Examples are the cucumber. muskmelon. white potato. sweet potato. pumpkin, squash, sweet corn and onion.

The diversity of origin and of the plant part utilized. aided by human selection through the centuries. has resulted in a variety of vegetables adapted to each climate. from the short summers of the arctic to the year-around gron·ing season of the tropics. The primary factor influencing vegetable growth is temperature. With a few exceptions, crops grown for vegetative parts require cool temperatures, and fruit-producing vegetables require warmer temperatures. A general classification based on average temperatures for satisfactory growth is:

1. Cool-season crops—adapted to 55°–70° F.:
   - (a) Tolerant of some frost: cabbage. Brussels sprouts. kale, sprouting broccoli, collards, kohlrabi, turnips, spinach, beets, parsnips. onions, asparagus.
   - (*b*) Intolerant of frost at maturity: lettuce, peas. cauliflower, celery, carrots, artichoke, white potatoes, endive.
2. Warm-season crops—readily damaged by frost:
   - (a) Adapted to 6;"–So° F.: muskmelon. cucumber, squash, pumpkin, beans (all), tomatoes. peppers, sweet corn.
   - (*h*) Require temperatures above 70° F. and long growing season : sweet potatoes, watermelon. eggplant, okra.

The time from planting to maturity also may vary—irom 26 to 28 days for radishes to five months for sweet potatoes. (*See* HORTICULTURE; CABBAGE: CORN; ONION; TOMATO; POTATO; etc.)

The photoperiod (length of light) interacts with temperature to influence bulb formation in onions. tuber development in potatoes and seed-stalk production in spinach. lettuce and endive. With cucunibers in the greenhouse. photoperiod may alter the ratio of male to female flowers (*see* PHOTOPERIODISM).

Some crops (white potatoes. sweet potatoes. onions. cabbage. carrots. beets, garlic. turnips. winter squash. pumpkin. winter radish, salsify. parsnip and horse-radish) may he stored for considerable periods under proper humidity and temperature. Others may not be stored longer than a few weeks.

Controlled storage temperatures permit long-term holding of storage crops and large-scale shipment of perishable crops to distant markets. The storage liie of cool-seasoit crops and sweet corn is maximum near 32° F.. except that potatoes below 38° F. develop undesirable sweetness. Warm-season crops may be damaged at temperatures below 45°–55° F., depending on the crop. A chemical. maleic hydrazide. is widely used to prevent sprouting of potatoes in storage. (*See* also FOOD PRESERVATION.)

There are no reliable estimates on world-wide acreage and production of most vegetables. However. it is known that locally grown vegetables provide a substantial. though unmeasured, part of the diet of the agricultural three-fifths of the world's population. as well as a portion of the food for nearby village and city dwellers. Among many peoples in underdeveloped areas of the world. native plants are often utilized. mostly in the form of tender young shoots and leaves. for cooked greens. Cooking not only renders the plants palatable but also, unintentionally, safe from serious soil- and water-borne disease organisms.

Vegetable Culture in the United **States.**—Many kinds of vegetables are grown throughout the U.S. in home and market gardens. Twenty-nine vegetahles are listed by the U.S. department of agriculture as having farm value in excess of $1,000,000. Total annual acreage for all vegetables approximates 6,250,000, with a value near $1,400,000,000. White potatoes alone equal nearly 40% of all other vegetables in value and acreage. Following white potatoes in descending order of production are: tomatoes, sweet corn, watermelons. lettuce, cabbage, sweet potatoes, onions, celery, muskmelons and carrots.

Commercial vegetable-growing has developed into two quite distinct types of enterprises: production for storage or processing, and production for immediate fresh-market sale.

Storage crops and processing crops (for canning or freezing) are grown mainly where good quality. high yield and low costs prevail. and where time of harvest is relatively unimportant. The major areas of such production are the Pacific coast states; a belt along the northern third of the country, from Minnesota eastward; southward along the Atlantic seaboard; and the Texas-Arkansas area.

Before World War I most fresh-market vegetables were grown near the areas of consumption. Since that time, however. development of modern refrigerated trucks and railroad cars has permitted a steady, orderly and large-scale expansion of off-season perishable fresh-vegetable production in the south and on the irrigated lands of the southwest and west. far from centres of population. Vegetables can now be produced in the areas best suited to their growth and shipped in great quantities over long distances to large urban centres. This. together with local greenhouse production and imports from Cuba and, in rapidly increasing volume, from Mexico, makes fresh vegetables of all kinds available to consumers throughout the year.

The primary areas for production of fresh-market vegetables lie near large temperature-moderating bodies of water (Great Lakes. Atlantic and Pacific oceans. Gulf of Mexico) and certain intermountain valleys of the western states. Nearly one-third of all vegetables produced in the United States are grown in California.

Consumption of fresh vegetables approximates 144 lb. per capita annually. From the beginning of World War II until the late 1950s consumption declined slightly while annual per-capita use of processed vegetahles rose substantially—canned vegetables by 30% to 72 lb. annually and frozen vegetables by more than 800% to 14 lb. (fresh equivalent') annually. During the same period. per-capita consumption of white potatoes declined 20% to 100 lb. annually and sweet potatoes declined 60% to 9 lb.

Modern developments include a marked increase in mechanization of cultural, harvesting and packing operations; greater use of chemical fertilizer; new herbicides, insecticides and pesticides; and the introduction of irrigation to supplement rainfall in the eastern Cnited States. Farm and marketing units have steadily increased in size. and farm management is increasingly conducted on a business basis, requiring large capital outlays for land: equipment and operation. The small market garden is steadily disappearing.

Vegetable Culture in Western Europe.—In the northern countries of western Europe only cool-season crops can be produced in quantity. Special methods of production. in the form of sashes, cloches and greenhouses, are extensively employed for warm-weather and off-season crops. More than 16.000 ac. of vegetables are grown under glass. mainly in the Netherlands and England. Western Germany, the United Kingdom and France import quantities of vegetables from the Netherlands. Italy, Spain, north Africa and the Canary Islands. Moderate climates around the Mediterranean permit the culture of most vegetables during much of the year and the production of warm-season crops for shipment to northern areas.

Throughout Europe the pattern of farming remains a family-sized unit. too small for extensive mechanization or volume merchandising. More economic farming units can develop only gradually if existing social and economic systems are not to be seriously disrupted. Agreements designed to remove trade barriers between certain western European countries. and improved refrigerated transport, may result in greater movement of perishable foods, as well as the development of areas for more specialized production of specific crops. particularly in the Mediterranean basin. About 14,500,000 ac. are used for vegetable production in western Europe, of which nearly 11.000,000 ac. are devoted to white potatoes.

In Great Britain the family-sized market-garden unit remains essentially unchanged. and the land is intensively cultivated. The use of machinery and other improved methods of production is increasing. as is irrigation to supplement rainfall. The present trend is to combine frame, cloche or greenhouse crop culture with market-garden production.

In the past vegetable-growing areas were located near large cities. which provided a ready market and a convenient source of needed animal manure. Although some market gardening remains near the cities, rail and truck transport and the disappearance of the horse from urban areas have permitted the movement of the vegetable industry into districts with climate and soil better suited to these crops. Primary production areas for vegetables other than potatoes. in the Midlands and south England, are: (1) the Fens (peat-soil areas) in parts of Norfolk, Isle of Ely and Holland district of Lincolnshire; (2) Vale of Evesham, Worcestershire; (3) Sandy district. Bedfordshire; (4) northwest Kent; (5) south Essex; (6) Middlesex plain; and (7) southeast Cornwall. In Scotland, vegetable-growing areas are close to Glasgow and the Lothian coastal plain, near Edinburgh. White-potato production is more widespread, with the Fens in England and the Angus-Perth-Fife area in Scotland being most important. Of the more than 3,000 ac. of greenhouses used for vegetables, more than two-thirds are devoted to tomato growing.

Crops of Great Britain, in descending order of importance, based on production, are: potatoes, cabbage, carrots, cauliflow-er and broccoli, peas, tomatoes, lettuce and beets. About 1,400,000 ac. are cultivated for vegetables. nearly three-fourths of which are used for white potatoes. Although nearly all tillable land is utilized. Great Britain must import large quantities of food. With the exception of white potatoes, about one-fifth of the vegetables (mainly onions and tomatoes) are imported. (P. G. S.)

VEGETABLE COOKERY. The term vegetables other than pulses and cereals (*q.v.*) covers those plants which have edible flowers, fruit or seed, stalks, roots or leaves. Green vegetables are valuable in the diet chiefly on account of their potassium salts and vitamins; cellulose, which supplies the body with bulk or "roughage," thus assisting digestion; and for their water content (average 90%–95%). Roots and tubers are heat- and energy-giving foods. The cellulose of vegetables is valuable as roughage in the intestinal tract.

Green Vegetables. — There are three distinct methods of cooking green vegetables. Steaming is one. In the second, only enough water is used to preven. the vegetables from sticking to the pan and getting burned, and the aim is to conserve the natural salts and flavours of the vegetables. The third and most common method of cooking ordinary "greens" is to boil the vegetable in a pan of fast-boiling salted water with the lid off. Soda is frequently added to soften the water and preserve the colour but it destroys the vitamins and is not recommended.

All these methods can be used for most green vegetables with the exception of sorrel and spinach, which have a very high water content and require very little water in cooking.

To cook cabbage first wash well in salt and water to get rid of any insects, trim off outside discoloured leaves and put into a kettle full of boiling water, with at least 1 teaspoon salt to each quart. To lessen odour of cooking, do not cover. Whole young cabbage, 25–30 min., old. 30 min.–1 hr. Quartered. 10–15 min. Leaves, 5–10 min. Drain, add 1 tablespoon butter ior each lh.

Cabbage may be stuffed with forcemeat or savoury rice (cooked rice and grated cheese, chopped onion and seasoning) by separating the leaves from a parboiled cabbage and rolling each leaf round the forcemeat, or the stuffing may be placed in the centre of the cabbage. If the cabbage is rolled, stem in a thickened gravy.

Brussels sprouts may be dipped in batter and fried. Single leaf vegetables, *e.g.*, spinach, beet tops, etc., may be cooked until tender, drained and passed through a sieve, then mixed with butter, cream, seasoning, and formed into a purée which can be garnished with hard-boiled eggs or served on toast. Green purée soups are made from green vegetables. It is, of course, of essential importance in the cooking of vegetables to avoid any overcooking.

White Vegetables. — To prepare white vegetables for cooking, wash, scrub or scrape. Celery should be cut up in thin strips lengthwise to facilitate cooking. Have ready a pan of salted boiling water, squeeze into it a little lemon juice to keep the vegetables a good colour. In cooking certain blanched vegetables, *e.g.*, asparagus, leeks, etc., it is best to tie the vegetables in bundles. Overcooking of all white vegetables should be avoided. As a rule, 15–30 min. (according to the age and type of vegetable being boiled) is sufficient time to allow.

Jerusalem artichokes, salsify (oyster plant), etc., may be passed through a sieve and creamed, sprinkled with grated cheese and sauce and then baked au gratin. They may also be fried in batter as fritters. Celery can be stewed in milk or brown sauce, or served au gratin. Sea kale and asparagus are usually served with melted butter but may be served with sauces, mayonnaise, etc. All white vegetables may be made into soup by passing through a sieve, thickening and mixing with milk.

Potatoes. — There are innumerable ways of cooking potatoes but for most potato dishes they must be first plain boiled. To boil in their skins, clean thoroughly and place in boiling salted water. Simmer until tender (about 30–40 min.; but see note in FOOD PREPARATION on boiling at high altitudes) ; drain off the water and allow them to steam in the pan for five minutes with the lid on. Remove the lid, allow the steam to escape for a few seconds and use as required.

To bake potatoes bake them in their skins or peel and put in a baking dish with sufficient fat to keep them from burning and place under a piece of roasting meat so that the fat from the meat can drip onto them and so keep them moist while cooking.

Mashed potatoes are plain boiled or steamed, mashed with butter and milk, and then beaten with a wooden spoon until creamy. Potatoes may be fried either in a frying pan or in a pan of deep fat. Before frying thoroughly dry; then after slicing cut into strips or fancy shapes. To cream potatoes for vegetarian dishes add eggs, cream or sauce to mashed potatoes and bake or steam as a soufflé.

VEGETABLE MARROW, a form of Cucurbita *pepo*, the fruit of which is popular, in the immature state, as a vegetable in Europe and the United States. Related to the pumpkin, this form of C. *pepo* is called summer squash in the U.S. *See* SQUASH. (V. R. B.)

VEGETARIANISM. The word vegetarian comes from the Latin *vegetus*, meaning "whole. sound, fresh, lively" and was formed in 1842 with the meaning: "one who abstains frorn the use as food of flesh, fish and fowl. with or without the addition of eggs and dairy produce."

The practice of vegetarianism is old and has been a religious precept in the east for thousands of years among Jains, some Hindu sects. Zoroastrians. Buddhists and others. Among those who in the past have advocated a fleshless diet were Buddha. Asoka. Pythagoras. Plato, Plutarch, Ovid, Seneca. Diogenes. Origen. Tertullian. John Chrysostom, Clement of Alexandria, Milton, Pope, Shelley, Voltaire, Rousseau, Thoreau. Tolstoy, Wesley. Swedenborg, Isaac Newton. William Booth. F. B. Kellogg. Gandhi and G. B. Shaw. Some religious and philosophical groups still advocate vegetarianism. They include the Order of the Cross. Mazdaznans, Seventh-day Adventists and some Catholic orders (*e.g.*, Trappists).

The vegetarian movement in Britain started in 1809, near Manchester. when members of the Bible Christian Church, Salford, pledged themselves to abstain from flesh-foods. In 1871 41 members emigrated to the United States and founded a similar religious group at Philadelphia, Pa. The first secular organization was established at Manchester in 1847 (mainly bv members of the Bible Christian Church) and was named the Vegetarian society, and it is irom this parent society that all others owe their inception. The London Vegetarian society assumed independence in 1888 and operates as a second national society with the Vegetarian society, which in 1956 had 4j affiliated societies in Britain. During World War II 120,000 persons in Great Britain registered with the ministry of food as vegetarians. The International Vegetarian union was founded in 1908 and. with its 30 affiliated national societies, holds biannual congresses in different countries. The Vegan society was formed in 1944 by a small minority of vegetarian purists, known as Vegans, who believed that no animal products should be included in the diet, but that it should consist solely of fruit. nuts, grains and vegetables.

The early pioneers of vegetarianism based their way of life on ethical principles, though the accumulation of supporting medical and scientific data concerning nutrition. metabolism, vitamins. etc., has tentlrd to shift the emphasis toward the attainment and maintenance of health. The main arguments used in favour of vegetarianism are:

1. Ethical. — It is held that life is sacred, not necessarily in a religious sense? hut that all living creatures should have the right to enjoy life without exploitation and unnecessary pain and fear. If it is accepted that the purpose of human life is spiritual development, then, it is argued, the same should apply to all living creatures and their life span should not be deliberately cut short.

2. Physiological. — Certain characteristics common to all carnivores are absent in man, such as a short bowel for rapid expulsion of highly toxic substances, the lack of sweat pores, specially developed teeth and claws for bringing down living prey.

3. Aesthetic. — The processes of slaughter and of eating flesh on the way to decomposition are considered revolting and barbaric. The eating of flesh causes certain individuals to follow degrading trades in the slaughterhouse and butcher's shop since, it is claimed, the killing of animals and handling of meat can only breed callousness and irreverence for life.

4. Nutrition. — Protein obtained from dead animals has certain disadvantages. Toxic wastes, including uric acid, are present from blood and tissue, as also are dead and virulent bacteria, not only from putreiactory processes, but from animal diseases such as tuberculosis, foot and mouth, contagious abortion, swine fever, cancer tumours, etc. Similarly, meat contains serums and vaccines injected into cattle and meat animals against prevalent diseases. Protein obtained from nuts, pulses, grains and dairy produce is claimed to be relatively pure as compared with beef with a 56% impure water content. It is pointed out that the vegetable kingdom is the richest source of all necessary elements, minerals, carbohydrates and vitamins; and is the source from which herbivorous animals of immense strength and endurance obtain their food.

5. Health. — Vegetarians believe that a meatless diet is more health-

giving than one which includes deleterious substances. Flesh, an end product, breaks down by putrefaction whereas vegetarian food is digested by processes of fermentation involving quite different types of intestinal flora. Failure of eliminatory organs to deal with excess toxic material leads to ill-health and disease; irritants may cause cancer, which is unknown in, for example, the vegetarian Hunza tribe. Vegetarian athletes have achieved distinction out of all proportion to their numbers. "Nature cure" treatments are based on the remedial qualities of a raw food diet preceded by a short fast.

6. Economics.—There is in the world about one acre to each person of land that is capable of producing food, and a meat eater requires two acres Therefore, it is alleged, he takes more than his fair share A vegetarian requires only three-quarters of an acre for his food; thus vegetarianism is put forward as a solution to food problems caused by rapidly increasing populations

Vegetarians have led the demand for wholesome food. This includes the growing of fruit and vegetables by organic methods (composting) and not by havina recourse to chemical fertilizers and poisonous sprays and systemic insecticides. Whole-grain bread without toxic "improvers" and unprocessed foods are preferred to those demineralized and devitalized by milling, refining, canning, preserving and colouring with chemicals.

VEGETATIVE REPRODUCTION: see Plant Propagation.

VEGETIUS (Flavius Vegetius Renatus) (4th century A.D.), military writer. His treatise. commonly called De re *Militari* or *The Military Institutions of the Romans*, was a compilation from ancient sources. Vegetius was not a practical soldier and did not realize that the military reform and revival of the ancient organization of the legion he proposed had become impossible because of the evolution of warfare. By one of the strange mutations of history, when later the crossbow and gunpowder deprived cavalry of its shock power, the tactics of Vegetius became ideal for armies, and his work became a military bible for European soldiers for hundreds of years.

In manuscript. Vegetius' work had a great vogue. In the middle ages his rules of siegecraft were much studied. and during and after the Renaissance the sections dealing with training and tactics were indispensable. His work was translated into English, French and Bulgarian before the invention of printing. An English version was published by Caxton in 1489, and *The Military Institutions of the Romans* was included in T. R. Phillips' Roots of Strategy (1940), with brief critical introduction.

VEII, an ancient town of Etruria. Italy, situated about 10 mi. N. by W. of Rome by road. It is mentioned in the earliest history of Rome as a constant enemy, being the nearest Etruscan city to Rome, but the site was occupied in the Villanovan period, remains of huts having been found on the acropolis as well as numerous tombs. The story of the slaughter of the Fabii. who had encamped in the territory of Veii (perhaps in an effort to cut the communications of Veii with Fidenaej and of whom but one boy escaped, is well known (Livy, ii, 50). After constant warfare, the last war (the 14th, according to the annalists) broke out in 406 B.C. The Romans laid siege to the city, and after a ten years' siege, M. Furius Camillus took it by storm in 396, by means, so we are told, of a tunnel leading into the citadel. According to the legend, the emissarium of the Alban lake was constructed in obedience to the Delphic oracle, which declared that, until it was drained, Veii could not be taken. The captured territory was made into four new rustic tribes. Tradition says that after the defeat of the Romans at the Allia in 390 B.C., a project was broached for abandoning Rome for Veii, which was successfully opposed by Camillus. Veii is spoken of by Propertius as almost deserted, but Augustus founded a municipality there, inscriptions of which have been found down to the time of Constantius.

Veii was reached by branch roads from the Via Clodia. The site is characteristic — a plateau, the highest point of which is 407 ft. above sea level, divided from the surrounding country by deep ravines and accessible only on the west, where it was defended by a wall and fosse. Remains of the city walls, built of blocks of tufa 2 ft. high, may be traced at various points in the circuit. The area covered measures about 1 sq.mi. and it was thus only second to Rome in size among the cities in the neighbourhood.

Etruscan houses and temples (one dating from the 6th century B.C., with three cellae) have been discovered at Veii. The most famous of the Etruscan tombs is the Grotta Campana, which contains paintings on the walls with representations of animals, among the earliest in Etruria. One of the numerous Etruscan inscriptions confirms the existence in Veii of the gens Tolumnia, which gave a king to the city *c.* 430 B.C. Toward the end of the 6th century B.C. a sculptor from Veii, Vulca, provided statues for the temple of Jupiter Capitolinus in Rome; a terra-cotta statuette of Apollo discovered at Veii in 1916 and other important fragments of archaic sculpture may have come from his atelier. The forum of the Roman municipium stood on the west side of the plateau; a statue of Tiberius (now in the Vatican) and the 12 Ionic columns now decorating the western side of the Piazza Colonna in Rome were found there. (T. A.; X.)

VEIN. A vein (geological) is a deposit of mineral matter sheetlike in form and usually following a zone of fracturing in the rocks. It may consist of one or of many minerals, either valuable or worthless. Veins carrying the metals or their 'compounds are of great industrial importance.

Veins were deposited from underground solutions that easily circulated along the fractures and penetrated the pores of the rocks. Deposition of the vein minerals was often accompanied by a dissolving of rock minerals. Valuable mineral veins are commonly several thousand feet in length and a few feet to a few yards in width. (E. S. Ba.)

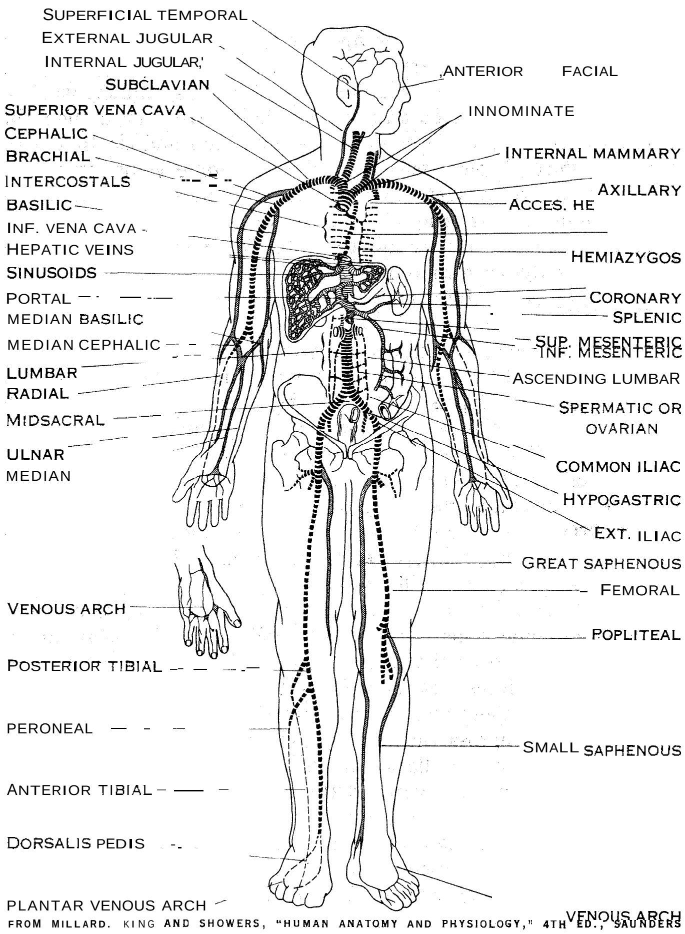
VEINS, in the anatomy of animals, are blood vessels that return the blood from the capillaries toward the heart. They begin as tiny venules, which join together to form larger and larger trunks as they approach the heart. In man and other mammals three venous systems are recognized: (1) the general venous system; (2) the pulmonary system; and (3) the hepatic portal system.

Apart from vessels related to specific internal organs, there are superficial and deep veins. The former lie in the superficial fascia and are often visible through the skin. They are usually accompanied by lymphatic vessels though not as a rule by arteries, and, sooner or later, they empty their blood into the deep veins, often passing through special openings in the deep fascia to do so. The deep veins usually accompany arteries, and are often enclosed in a common sheath; they are therefore known as companion veins (venae comites). With small and medium-sized arteries there are two of these companion veins, one on each side: connected by occasional cross communications; large arteries have only one companion vein.

The following account refers to the vessels as they occur in man (fig. 1).

Veins of the Head and Neck.—In the scalp and face the superficial veins follow the very tortuous route of their corresponding arteries more or less closely in order to drain effectively the areas served by the arteries. The deep veins run a comparatively straight course. Frontal, superficial temporal, posterior auricular and occipital veins are found in the scalp, their names indicating the areas they drain. Like all other superficial veins, they anastomose freely and also at certain places communicate, through foramina (openings) in the skull! with the intracranial blood sinuses; these communications are known as emissary veins, and act as safety valves to the sinuses. The frontal vein on the forehead passes down on the inner side of the eyelids, where it is known as the angular, and then becomes the facial vein, which runs down to an inch in front of the angle of the jaw, whence it passes into the neck to join the common facial. In the greater part of its course it lies some distance behind the facial artery itself.

The superficial temporal vein runs down in front of the ear, where it joins the maxillary vein from the pterygoid plexus and so forms a common trunk that passes down, embedded in the parotid gland, to about the angle of the jaw. Here it divides into



FROM MILLARD. KING AND SHOWERS, "HUMAN ANATOMY AND PHYSIOLOGY," 4TH ED., SAUNDERS (1956)

FIG. I. — DIAGRAM OF THE HUMAN VENOUS SYSTEM
(Solid lines indicate superficial veins)

an anterior branch. which joins the facial vein to form a common stem. and a posterior branch. which receives the posterior auricular vein and becomes the external jugular.

The external jugular vein is easily recognized through the skin on the side of the neck; it eventually pierces the deep fascia above the middle of the clavicle to join the subclavian vein. The occipital vein sinks deeply into the back of the neck and so forms the beginning of the vertebral vein.

The intracranial venous sinuses lie betneen two layers of the dura mater (see MENINGES AND CEREBROSPINAL FLUID) and differ from the veins in having fibrous walls that do not contract or expand. The superior sagittal sinus runs along the upper margin of the falx cerebri (*see* BRAIN), nhile the inferior sagittal sinus runs along the loner margin; these drain the surface of the brain. and the blood passes backward in both. Where the falx meets the tentorium cerebelli. the inferior sagittal sinus receives the great cerebral veins from the interior of the brain and then passes backward as the straight sinus to join the superior sagittal sinus at the internal occipital protuberance.

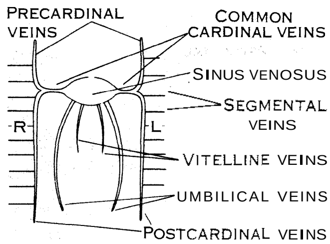


FIG. 2.—DIAGRAM OF THE FORMATION OF THE VENOUS SYSTEM IN THE FIRST STAGE

The meeting place here is known as the confluence of the sinuses, and from it the blood passes outward and downward through the right and left transverse sinuses, nhich groove the cranium, until they reach the posterior lacerated foramina, through which they pass to form the beginning of the internal jugular veins.

Most of the blood from the base of the brain passes into the cavernous sinuses, which lie in the middle cranial fossa. one on each side of the hypophyseal fossa. These receive the ophthalmic veins from the orbit in front and, after running backward for about an inch, divide into the superior and inferior petrosal sinuses, the former of which joins the transverse sinus within the cranium; the latter runs to the posterior lacerated foramen, after passing through which it joins the transverse sinus, which is now becoming the internal jugular vein.

The internal jugular vein thus formed runs down at first behind and then to the outer side of the internal and common carotid arteries and at the root of the neck joins the subclavian vein of its own side to form the innominate (or brachiocephalic j vein. In its course down the neck it receives the common vein from the face and tributaries from the tongue, pharynx, larynx and thyroid body. The deep veins of the head and face tend to form plexuses rather than venae comites; among these. pterygoid, pharyngeal and basilar plexuses are recognized.

Veins of the **Upper** Extremity. — On the back of the hand and in front of the wrist, superficial venous plexuses are easily seen through the skin. From these and others on the palmar surface the blood passes up the forearm chiefly on its flexor surface by the basilic and cephalic veins and their tributaries. Just below the bend of the elbow the cephalic vein communicates with the deep veins and then gives off the median cubital vein, which passes across and joins the basilic; it is the vein from which patients are usually bled. After this junction the common vessel is continued up the inner side of the arm as the basilic, which pierces the deep fascia about the middle of the arm and in the axilla becomes the axillary vein. which lies on the inner side of its artery. Continuing above the level of the elbow. the cephalic vein runs up the outer side of the arm and, a little below the clavicle. passes through the clavipectoral fascia to enter the upper part of the axillary vein. At the outer border of the first rib the axillary vein becomes the subclavian. which lies in front of and below its artery and is separated from it by the anterior scalene muscle. The arrangement of the superficial veins, especially in front of the elbow, is liable to great variation.

Veins of the Lower Extremity. — The superficial veins of the lower extremity begin in a venous arch on the dorsum (the word dorsum means "back." and hence any part corresponding to the back or upper side) of the foot.

From the inner extremity of this the great saphenous vein runs up, in front of the inner ankle, along the inner side of the leg, and. passing behind the inner side of the knee. continues up the thigh. gradually working forward until it reaches the saphenous opening in the deep fascia of the thigh a little below the spine of the pubis. Here it pierces the deep fascia (fascia lata) to enter the femoral vein. In this long course it has many valves and receives numerous tributaries. From the inner end of the dorsal arch of the foot the small saphenous vein runs up behind the outer ankle along the midline of the calf to pierce the deep fascia in the popliteal space behind the knee and open into the popliteal vein. Among the deep veins, venae comites occur as tibial vessels; they unite to produce the popliteal in the region of the knee and then the femoral of the rest of the thigh and groin.

Veins of the Abdomen. — The femoral vein. after passing deep to the inguinal ligament, becomes the external iliac. which runs along the brim of the true pelvis and, after a course of some three inches, joins the internal iliac (or hypogastric). which drains the pelvis, and so forms the common iliac vein. In front of the body of the fifth lumbar vertebra the common iliac veins of the two sides unite to form the inferior vena cava, a very large trunk which runs up on the right of the abdominal aorta to an opening in the diaphragm (*q.v.*). On its way it receives lumbar veins from the body wall. testicular or ovarian veins from the genital glands. renal veins from the kidneys and vessels from the right adrenal gland and the diaphragm. Before reaching the diaphragm it lies in a groove in the back of the liver and receives the hepatic veins from that organ. The hepatic portal system which lies in the abdomen is discussed below,

Veins of the Thorax. — The inferior vena cava. after piercing the diaphragm. has a very short thoracic course and opens into the lower and back part of the right atrium of the heart. The right and left innominate veins are formed behind the sternal end of the clavicle by the union of the subclavian and internal jugulars of their own side. The left vein is much longer than the right. and runs nearly horizontally behind the upper half of the manubrium sterni to join its fellow on the right side of that bone just below the first rib. By the junction of these the superior vena cava is formed, which runs down to the right atrium of the heart. The chief tributaries of the innominate veins are the vertebral, the internal thoracic (or internal mammary) and the inferior thyroid.

The intercostal veins open into the azygos system of veins, which begins in the abdomen by (1) a continuation of the ascending lumbar, a vertical trunk which joins together the lumbar veins, or (2) sometimes on the right side by a communication with the inferior vena cava. The right azygos vessel is known as the vena azygos and passes through the aortic opening of the diaphragm. Entering the thorax, it runs up in front of the thoracic vertebrae, and to the right of the aorta and thoracic duct, and receives the intercostal veins of the right side. At the level of the fourth thoracic vertebra it arches forward to open into the posterior surface of the superior vena cava.

On the left side, the upper intercostal veins join to form the left highest intercostal vein, which commonly opens into the left innominate. Lower down the intercostal veins, from the fourth to the seventh spaces, form the accessory hemiazygos vein, which runs down on the left of the spinal column and, crossing it about the level of the eighth or ninth thoracic vertebra, opens into the vena azygos. The lower intercostal veins on the left side join the hemiazygos vein, which runs up and opens either into the accessory hemiazygos or into the azygos proper, below the opening of that vein.

Pulmonary Venous System.—The pulmonary veins emerging from the lungs bring back the oxygenated blood from those organs to the left atrium and ventricle of the heart, and also the greater part of the blood carried by the bronchial arteries to nourish the lungs. Bronchial veins return blood from the larger bronchi and drain it into the azygos system. There are three pulmonary veins coming out of the right lung, while on the left there are only two. On the right side, however, two of the three veins usually unite in the root of the lung, so that there are, as a rule, two pulmonary veins entering the left atrium of the heart on each side, but it is not uncommon to find three on the right side or one on the left. The pulmonary veins have no valves.

Hepatic Portal System.—The veins that drain the blood from the stomach, intestines, spleen and pancreas unite to form a large vein that begins behind the head of the pancreas and ends by dividing into right and left branches in the porta of the liver. This is the portal vein. which lies in front of the inferior vena cava and is about three inches long. Its chief iormative tributaries- are the superior and inferior mesenteric and the splenic veins. There are two marked characteristics of the portal system; one is that it has no valves and the other that it begins and ends in capillaries, since the two terminal branches of the portal vein branch and rebranch in a complex manner as described in the article LIVER. In the lower part of the rectum the veins discharge partly into the portal and partly into the general system, and in this dependent position they are liable to become varicose and to form hemorrhoids.

Structure of Veins.—The histology of veins follows the same general plan as that for arteries (see ARTERIES). The wall of the tube is composed of three similar coats. but it is thinner, weaker, more loosely constructed and more variable from type than the corresponding artery. It contains less muscular and elastic tissue, whereas white fibrous tissue is in excess. Some veins. especially those of the appendages, bear valves, and these are commonest where tributaries come in. The lining of a vein is folded to produce such pockets, usually in pairs. Their cavity, so formed, fills with blood only when there is backflom.

Embryology.— Human embryos three millimetres long possess three sets of paired veins (fig. 2). These are: (1) umbilical veins, from the chorionic sac (future placenta); (2) vitelline veins, from the yolk sac; and (3) cardinal veins, from the body of the embryo itself. The last comprise two sets. the precardinals, which drain blood from the head region, and the postcardinals, which return blood from levels caudal (the word cauda means "tail"; hence caudal, "tailward") to the heart; both pairs unite into short, common stems, known as the common cardinals (or ducts of Cuvier). Hence three pairs of vessels open into the sinus venosus, or caudalmost portion of the primitive heart. As the heart is at first situated in the region that later will be the neck of the embryo, the precardinals receive few segmental veins and the postcardinals many.

As the vitelline veins run from the yolk sac to the heart along each side of the primitive foregut, they pick up the mesenteric veins from the intestines as well as the splenic and pancreatic veins as soon as these viscera are formed. The liver, however, is developed right across their path, and the vitelline veins break up into a mass of capillaries in it, leaving that part of them which lies between the liver and the heart to form the primitive hepatic veins (fig. 3). While the vitelline veins are still lying on each side of the foregut (future duodenum) they are connected by three transverse channels. the anterior and posterior of which appear on the ventral side of the gut, the middle on the dorsal side (fig. 3 [A], [B]). This figure of eight does not persist. however, because the cephalic part of it on the left and the caudal part on the right become obliterated, and what is left forms the portal vein (fig. 3 [C]).

The two umbilical veins unite between the placenta and the umbilicus, and soon all the blood from the placenta passes through the left one aithin the body, the right becoming rudimentary. The left umbilical vein on reaching the liver now joins the left branch of the portal vein and establishes a new communication

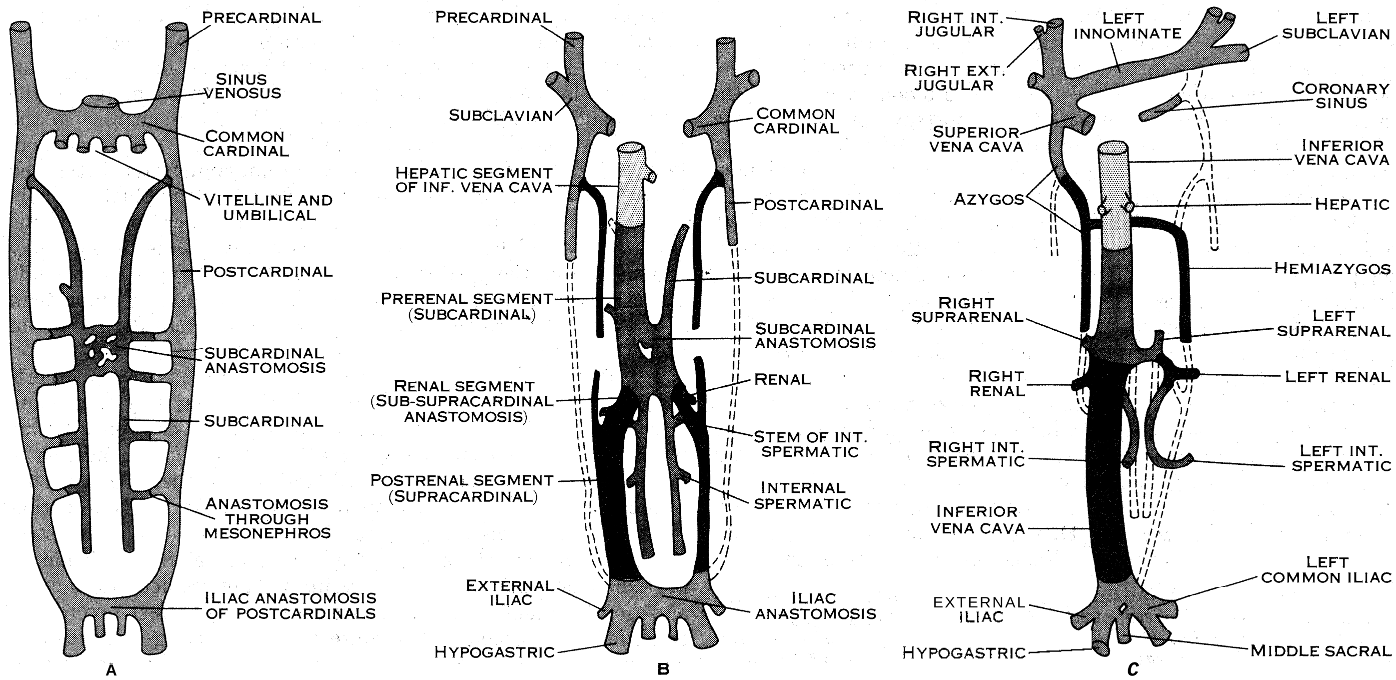
FIG. 3.—TRANSFORMATION OF THE HUMAN VITELLINE AND UMBILICAL VEINS IN THE REGION OF THE LIVER. SEEN IN VENTRAL VIEW (A, B AND C AT ABOUT FOUR WEEKS: D AT FIVE WEEKS)



FROM AREY, 'DEVELOPMENTAL ANATOMY," SAUNDERS (1954)

FIG. 4.— DIAGRAMS OF THE TRANSFORMATION OF THE PRINCIPAL HUMAN VEINS FROM THE EARLY EMBRYONIC CONDITION (A AT SIX WEEKS; B AT EIGHT WEEKS; C, ADULT)

with the left hepatic vein. This is the ductus venosus (fig. 3 [B], [C]), and, as soon as it is formed, most of the blood returning from the placenta bypasses the liver capillaries. After birth the pulmonary circulation becomes established and the ductus venosus and umbilical vein convert into ligamentous cords (ligamentum venosum; ligamentum teres).

As the heart moves from the neck into the thorax the precardinal veins elongate and become the internal jugulars in the greater part of their extent. When the arms begin to bud out, subclavian veins are developed (fig. 4 [B]) and an oblique connecting vein (fig. 4 [C]) is established between the point of junction of the left subclavian with the left precardinal and the caudal part of the precardinal of the right side. This connection becomes the left innominate vein. while the caudal part of the left precardinal persists as the highest intercostal vein (fig. 4 [B]). On the right side that part of the precardinal between the subclavian and the junction with the left innominate becomes the right innominate, while the caudal part of the right precardinal and the right common cardinal become the superior vena cava (fig. 4 [B]). The external jugulars are later, secondary formations.

The right and left postcardinal veins receive the intercostal and lumbar segmental veins and are continued into the lower limbs as the common iliac veins (fig. 4), the primitive blood path from the thighs. The veins from the primitive kidneys open into the segmental veins. and when the permanent kidney (metanephros) is formed a large renal vein on each side is established (fig. 4 [B, C]).

Little of this postcardinal set of veins is retained when the unpaired inferior vena cava becomes dominant. The origin of the inferior vena cava is multiple (fig. 4 [B. C]). Its components are as follows: (1) a hepatic segment, derived from the hepatic vein and a caudal extension from it; (2) a prerenal segment, derived from the right member of a pair of secondary (subcardinal) vessels; (3) a postrenal segment, derived from the right member of a still different pair of vessels (supracardinals) that replace the postcardinals. The inferior vena cava, when formed, receives from both sides of the body most of the blood that previously drained into the postcardinals and subcardinals. Above the level of the kidneys, the supracardinal vessels become the azygos system of drainage.

Comparative Anatomy. — The venous system of vertebrates is much less standardized than is the arterial system, and variations are marked even among placental mammals. Vessels that become functionless. through elimination of the structures they originally supplied, either modify and adapt to the new conditions or disappear. The venous system of fishes is a primitive arrangement, with paired and symmetrical sets of veins. In the higher groups there is a progressive shift toward the right side, and hence an asymmetrical plan. The veins can be considered in four regional sets: (1) systemic veins. returning blood from most parts of the body directly to the heart; (2) a hepatic portal system, conveying blood from the digestive tract to the liver; (3) a renal portal system. carrying blood from the tail and caudal trunk to the kidneys; and (4) pulmonary veins, returning blood from the lungs to the heart. The two portal systems arose when the liver and kidneys interrupted a portion of the primitive venous return; they are characterized by vessels that arise from a capillary bed and again break down into capillaries in the liver or kidneys.

Systemic *Veins*.—In fishes, paired precardinal and postcardinal veins, respectively, serve regions headward and tailward of the heart; they reach the sinus venosus of that organ by common cardinal veins (or ducts of Cuvier). Subclavian and iliac veins return blood from the pectoral and pelvic fins, respectively. The Dipnoi (lungfishes) add a postcava (or inferior vena cava), a hich carries most of the blood directly from the caudal body and kidneys to the heart; also the vein of each lateral line in lower fishes is represented by a single, median abdominal vein. The plan in amphibians is little changed, yet subcardinal veins, beneath the kidneys, have united to produce the lower portion of a prominent postcava. In amniotes (reptiles. birds and mammals) the postcava becomes an increasingly dominant collecting vein, below the level of the heart, as the postcardinals disappear or give place to other vessels such as the azygos set. The abdominal veins of fishes, amphibians and reptiles become important during the development of reptiles birds and mammals. since they bring blood from the allantois or placenta. In placental mammals they receive the name umbilical veins; only the left one persists throughout fetal life, and it makes a short cut through the liver known as the ductus venosus. After birth the outmoded vessel fibroses into a ligamentous cord. The precardinal veins give rise to the internal and external jugular veins. In reptiles, birds and some mammals both common cardinal veins persist as precaval stems, but in other mammals, including man, all the blood for the head and forelimbs passes into the right precava, the common vessel then being known as the superior vena cava.

Hepatic *Portal System* —All vertebrates possess a hepatic portal system of veins. Vessels from the stomach-intestine and associated organs converge into a hepatic portal vein. which discharges blood into the sinusoids of the liver. The blood then leaves the liver in hepatic veins. which pass to the postcava or to the heart.

Renal Portal System. — Blood from the tail of fishes and from the tail and caudal trunk of amphibians is shunted to the kidneys (mesonephroi) by paired vessels, formed by the forking of the caudal vein and then knonn as renal portal veins. The capillary bed of the kidneys, in turn, connects with the postcardinals or the postcava, as the case may be, so that the detoured blood eventually reaches the heart. This system is incompletely represented in reptiles. whereas in birds and mammals it is wholly lacking: this abandonment is correlated nith the development of a different kind of kidney (metanephros).

Pulmonary Veins — Lungs and pulmonary veins occur first in dipnoid fishes and are constant features of all higher groups. In every instance the blood reaches either the left atrium or the left side of a single or partly partitioned atrium. See ARTERIES; BLOOD VESSELS. SURGERY OF: CIRCULATION OF BLOOD; CIRCULATORY SYSTEM; HEART, ANATOMY OF; HEART, COMPARATIVE PHYSIOLOGY OF. See also references under "Veins" in the Index volume.

VEINS, DISEASES OF. The veins of the body can be affected by a number of different conditions, including inflammatory, obstructive and degenerative abnormalities. The clinical manifestations of these disorders depend upon the location of the involved vessel and its role in returning blood to the heart.

In inflammation of a vein, called phlebitis (*q.v.*), the process affects all layers of the mall of the vessel. If it continues for some time, there mill usually be enough irritation of the inner lining (intima) of the vein to result in the deposition of various elements in the blood and subsequently the production of a clot locally (thrombus). The condition is then called a thrombophlebitis. If the initial change is a clot, there generally follows an inflammatory response in the vessel wall at the point of contact.

Thrombophlebitis in the extremities is a relatively common occurrence. If the process is located in a vessel under the skin (superficial vein), the condition is relatively innocuous and the clinical course and complications are of minor consequence. The reason for this is that there are many superficial veins, and obstruction of one or even several does not interfere with drainage of blood from the limb and into the main veins emptying into the right side of the heart. Therefore, the only untoward effects in such a condition are noted locally in the site of involvement.

The patient first notices a tender, red and warm area on the limb, which becomes painful on walking or on stretching the inflamed tissues. Examination reveals an elevated temperature in the site and a tender cordlike mass under the skin. As the condition subsides, the signs of inflammation disappear and the hard mass generally becomes smaller. At times, however, it may remain for months and even years in an unchanged state.

When the clot is situated in the small veins in the muscles of the calf and foot or in the main deep venous channels through which the blood from the extremity must pass in order to reach the heart, the outlook may be entirely different. In the case of involvement of the small deep venous channels in the muscles, the clot may be poorly attached to the interior of the vessel; as a result. portions of it may break off and become liberated in the blood stream, eventually reaching the blood vessels in the lungs and obstructing them. This complication (pulmonary embolism) may be very serious since it can produce death of lung tissues (pulmonary infarction), a condition typified by cough, expectoration of bloody sputum and pain in the chest, exaggerated on taking a deep breath (pleuritic type). Since the veins involved in this type of process are not particularly important in the removal of blood. the local findings in the limb are minimal and the diagnosis frequently is not made until after the changes in the lungs appear.

If the clot continues to grow upward and then enlarge to the point that it completely obstructs a main venous channel in the thigh, obvious clinical changes will be noted. This condition, known as milk-leg (deep iliofemoral thrombophlebitis). is typified by the appearance of smelling of the foot, leg and thigh. pain in the groin on the involved side and along the inner portion of the thigh, fever and loss of appetite. Although pieces of clot may break off from the portion obstructing the main vein (to occlude vessels in the lungs), this complication is much less common than in the case in which the clot originates in the small deep veins in the leg and foot.

In the early stage of thromboangiitis obliterans, or Buerger's disease (*q.v.*), primarily a disorder of the arterial system. clots may be noted in small portions of superficial veins on all four limbs, more marked on the lower extremities. This condition is typified by the presence of small, red and tender masses, surrounded by an area of inflammation of the skin Examination over the site reveals the presence of short, firm, cordlike masses.

The inflammatory condition appears to travel from portion to portion of the same and different veins in an unpredictable manner. and from one limb to another. At times it may affect several extremities simultaneously. Because of these fleeting qualities and because the disorder is noted only in those veins on the surface oi the extremity, it has been called superficial migratory thrombophlebitis.

Relatively rarely veins show degenerative changes. Among these is deposition of calcium, usually in the middle or muscle coat of the vein. The process may be present throughout the length of the vessel or may be localized in the form of small beady masses (phleboliths). This type of change can be seen on X-ray examination. It has no clinical significance with regard to the efficiency of the venous circulation. Veins may also show signs of increased deposition of fibrous tissue in the muscle coat. As a result, the vessels become much firmer to touch but are not dilated. See also ARTERIES, DISEASES OF; THROMBOSIS AND EMBOLISM. (D. I. A.)

VEIOVIS, a Roman god of uncertain attributes. His name is connected with that of Jupiter (Iovis), but there is little agreement as to its meaning: he may be a "little Jupiter" or a "sinister Jupiter" or "the opposite of Jupiter", *i.e.,* a chthonian god. The last seems most likely from the offering of a goat *humano* ritu (*i.e.,* either on behalf of the dead or in place of a human sacrifice). (R. B. LD.)

VELÁZQUEZ (VELÁSQUEZ), **DIEGO RODRÍGUEZ DE SILVA** (1599–1660), the most important of Spanish painters and one of the world's greatest artists. was born in Seville and baptized on June 6, 1599.

The principal source of information about Velázquez' early career is a treatise by his master and father-in-law Francisco Pacheco (Arte de la *pintura*, 1647). The first complete biography of Velázquez appeared in El Parnaso *español* by Antonio Palomino (*Museo pictórico*, vol. iii, 1724), based on notes by the artist's pupil Juan de Alfaro. The number of personal documents is very small; the official ones relating to his paintings are relatively few and as he seldom signed or dated his works their identification and chronology has often to be based on stylistic evidence alone. Though many copies of his portraits were evidently made in his studio by assistants, his own production was not large and his surviving autograph paintings probably number less than 1jo. He is knonn to have norked slowly, and during his later years much of his time was occupied by his duties as court official in Madrid.

Velazquez' European fame dates from the beginning of the 19th century. when many of his early Sevillian paintings were acquired by foreign (chiefly English) collectors and most of his later official works, which had remained in the royal collection, were incorporated in the Prado museum, Madrid.

Seville: Training and Early Production. — According to Palomino. Velizquez' first master was for a short time Francisco de Herrera the Elder. In 1611 he was formally apprenticed to

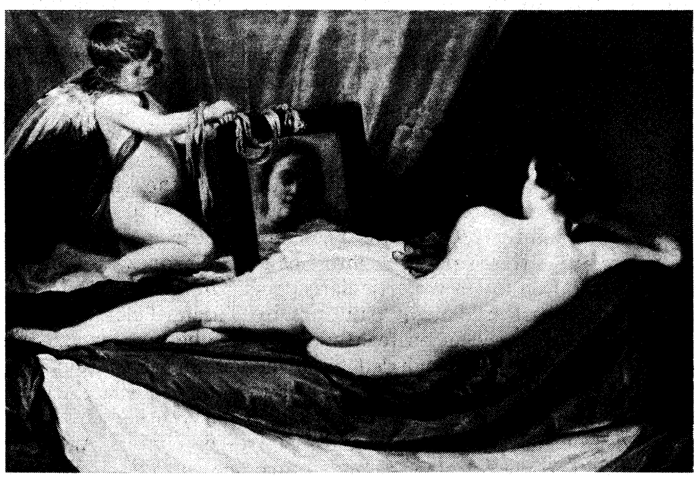
Francisco Pacheco, whose daughter he married in 1618. "After five years of education and training." Pacheco writes, "I married him to my daughter, moved by his virtue. integrity and good parts and by the expectations of his disposition and great talent." Although Pacheco was himself a mediocre mannerist painter, it was through his teaching that Velázquez developed his early naturalistic style. "He worked from life." writes Pacheco. "making numerous studies of his model in various poses and thereby he gained certainty in his portraiture." The strong modeling and sharp contrasts of light and shade of Velázquez' early illusionistic style closely resemble those of Caravaggio, and it is reasonable to assume that he had seen paintings by Caravaggio or his followers. Velázquez' early subjects were mostly religious or genre and he popularized a new type of composition in Spanish painting, the *bodegón* (a kitchen scene with prominent still life). based on northern prototypes, sometimes with religious scenes in the background, as in "Christ in the House of Martha" (National gallery, London) and "Christ at Emmaus" (Sir Alfred Beit collection, Russborough, Ire.). The "Adoration of the Magi" (Prado), dated 1617 or 1619, is one of the few Sevillian paintings of Velázquez that have remained in Spain.

Madrid: **Appointment** as Court Painter. — In 1622, a year after Philip IV came to the throne, Velizquez visited Madrid for the first time, "desirous of seeing the Escorial," according to Pacheco. and also in the hope of obtaining royal patronage. He painted a portrait of the poet Luis de Góngora (Museum of Fine Arts, Boston), but there was no opportunity of portraying the king or queen. In the following year he was recalled to Madrid by the prime minister Count Olivares. a fellow townsman of Velázquez and a future patron, and soon after his arrival he painted a portrait of Philip IV which won him immediate success. He was appointed court painter with a promise that no one else should portray the king. Pacheco describes an equestrian portrait of Philip (lost) painted soon afterward. "all taken from life, even the landscape"; the portrait was exhibited publicly "to the admiration of all the Court and the envy of members of the profession." The envy of fellow artists who accused Velázquez of only being able to paint heads is said by his friend Jusepe Martinez to have been the occasion of the king ordering him to paint a historical subject, the "Expulsion of the Moriscos" (lost), in competition with other court painters. Velázquez was awarded the prize and the appointment of gentleman usher (1627). Though he continued to paint other subjects, as court painter he was chiefly occupied in portraying members of the royal family and their entourage, and he painted numerous portraits of Philip IV during the course of his life. "The liberality and affability with which he is treated by such a great monarch is unbelievable!" writes Pacheco; "he has a workshop in his gallery and His Majesty has a key to it and a chair in order to watch him painting at leisure, nearly every day."

Velázquez' position at the court gave him access to the royal collections, rich in paintings by Titian. who was to have more influence than any other artist on the development of his style. The full-length portraits of Philip and his brother the Infante Don Carlos (Prado) are in the tradition of Spanish royal portraits established by Titian and are to some extent influenced by his style. The detailed description and dramatic tenebrism of Velázquez' Sevillian paintings has become modified; only the faces and hands are accentuated and the dark figures stand out against a light background. In his later court portraits Velázquez was to adopt something of the more elaborate décor and richer colouring of Rubens, whom he met during the latter's second visit to the Spanish court in 1628. Pacheco tells how Rubens praised Velázquez' works very highly because of their simplicity. Velázquez' painting of Bacchus, known as "Los Borrachos" ("the Topers"; Prado), seems to have been inspired by Titian and Rubens, but his realistic approach to the subject is characteristically Spanish and one that Velázquez was to preserve throughout his life.

Italy: First **Journey.**—Velázquez' visit with Rubens to the Escorial is said by Palomino to have aroused his desire to go to Italy. Having obtained leave and two years' salary from the king, and money and letters of recommendation from Olivares, he sailed from Barcelona to Genoa in Aug. 1629. In letters from Italian ambassadors in Madrid he is referred to as a young portrait painter, favourite of the king and Olivares. who was going to Italy to study and to improve his painting, and the visit was in fact to have an important effect on his artistic evolution. He stopped in Venice. where Palomino says he made drawings after Tintoretto and then hurried on to Rome Pacheco relates that he was given rooms in the Vatican palace, nhich he found very isolated. Having obtained facilities to return to the Vatican to make drawings after Michelangelo's "Last Judgment" and the paintings of Raphael, he therefore moved to the Villa Medici, which was "high and airy" and had "antique sculptures to copy." An attack of fever obliged him later to move nearer to the Spanish ambassador and after a year in Rome he returned to Spain, stopping on the nay in Naples. He arrived back in Madrid at the beginning of 1631

None of Velázquez' Italian drawings appear to have survived. Of the few paintings that he made in Italy, a "famous portrait of himself" made in Rome. mentioned by Pacheco, has probably survived only in replicas (Uffizi, Florence; Valencia museum; etc.); the portrait of Philip's sister Mary of Hungary painted in Naples is identified with an unfinished bust (Prado). The chief fruits of his Italian visit are the two "celebrated pictures" painted in Rome. which he took back to Spain and offered to the king (recorded by Palomino): "Joseph's Coat" (Chapter house. Escorial) and the "Forge of Vulcan" (Prado). These two monumental figure compositions are far removed from the limited realism in which he had been trained. As a result of his Italian studies, particularly of Venetian painting, his development in the treatment of space. perspective, light and colour and the freer technique mark the beginning of a new phase in his life-long pursuance of the truthful rendering of visual appearance.



BY COURTESY OF NATIONAL GALLERY, LONDON

"ROKEBY VENUS" BY DIEGO VELAZQUEZ. IN THE NATIONAL GALLERY, LONDON

Middle Years. — After his return to Madrid Velizquez entered upon the most productive period of his artistic career. He took up again his chief official task of portraiture, and was occasionally called upon to paint historical, religious and mythological subjects. For the decoration of the throne room of the new Buen Retiro palace. completed in 1635, Velazquez painted a series of royal equestrian portraits (now in the Prado), following a tradition that goes back in Spain to Titian's "Charles V at Mühlberg" and was continued by Rubens. Velizquez' equestrian groups have a balance and poise closer to Titian's than to Rubens' baroque compositions. and after his return from Italy he achieved a three-dimensional effect without detailed drawing or strong contrasts of light and shade. but with a broad technique and natural outdoor lighting. The "Surrender of Breda." Velázquez' famous contribution to the series of military triumphs painted for the same throne room, is his only surviving historical subject. Though the elaborate composition was based on a pictorial formula of Rubens, he creates a vivid impression of actuality and of human drama by means of accurate topographical details and the lifelike portraiture of the principal figures.

Though Velázquez frequently followed traditional compositions, particularly for his royal portraits. it was from no lack of ability to compose or invent. With his portraits of Philip IV, the Infante Ferdinand and Prince Baltasar Carlos as huntsmen (Prado), painted for the king's new hunting lodge, he created a new type of royal portrait. For the same place he painted hunting scenes of which "Philip IV Hunting Wild Boar" (National gallery, London) is possibly an example, and some mythological subjects, including probably the portraitlike figures of "Aesop" and "Menippus" (Prado). The "Coronation of the Virgin" (Prado), one of his rare religious subjects after he became court painter, was painted for the queen's oratory, about 1641–42. The series of "Court Dwarfs" (Prado), painted during the next few years, are seen with the same impartial and discerning eye as are his royal and noble sitters. while the character of their deformities is revealed through their awkward, unconventional poses, their individual expressions and by the exceptionally free and bold technique. The "Lady With a Fan" (Wallace collection, London), one of the few informal portraits of women, is, on the other hand, remarkable for the subtle and delicate painting and for the sensitive portrayal of personal charm.

Italy: Second Journey.— At the beginning of 1649 Velázquez left Spain on a second visit to Italy, this time on official business as gentleman of the bedchamber, and was given a carriage for pictures, possibly gifts from Philip to Pope Innocent X, who was to celebrate a jubilee in the following year. The chief purpose of the journey was to buy paintings and antiques for the king for the decoration of new apartments in the royal palace and also to engage fresco painters to decorate the ceilings of the apartments and to reintroduce fresco painting into Spain. Velázquez also found fresh inspiration in Italy. particularly from Titian. First he went to Venice, where he bought paintings by Titian, Tintoretto and Veronese; then he went on to Modena, where he saw the famous ducal collection which included his own portrait of the duke of Modena. painted in Madrid in 1638 (now in the Modena gallery). According to Palomino he also stopped in many other cities, including Bologna. where he visited the fresco painters Agostino Mitelli and Michelangelo Colonna to arrange to take them back to Spain, though they did not go there until 1658. Palomino recounts that on reaching Rome Velizquez was befriended by eminent prelates and artists, including Nicolas Poussin and G. L. Bernini. He gives a list of the antiques selected by Velázquez, from which it seems that he followed the tradition of great collectors since the 16th century and rather than inferior originals chose casts of the most famous statues in Rome. "Without neglecting his other business he also did many paintings" in addition to the portrait of Innocent X. Palomino relates that before portraying the pope, as an exercise in painting a head from life, Velázquez made the portrait of his mulatto assistant Juan de Pareja (earl of Radnor's collection. Longford castle, Wiltshire), an exceptional unofficial portrait, unusually boldly painted, which creates a powerful effect of familiar and living likeness.

For the portrait of Innocent X (Doria gallery, Rome), one of his most important official works. Velázquez followed a tradition for papal portraits created by Raphael and used by Titian. The powerful head: the brilliant combinations of curtain. chair and cope. the dazzling white surplice. are painted with a fluent technique and almost imperceptible brush strokes that go far beyond the late manner of Titian and announce the last stage in Velázquez' development in the direction of Impressionism. This portrait, which has always been Velázquez' most famous painting outside Spain, was copied innumerable times and won him immediate and lasting renown in Italy. In 1650 he was made a member of the Accademia di San Luca and of the Congregazione dei Virtuosi in Rome. The portrait earned for him the pope's support for his application for membership of a Spanish military order, though the difficulties arising from the fact that he was not of noble birth were so great that it was not until 1659 that he received the habit of the Order of Santiago. *(See* also PORTRAIT PAINTING: *Baroque* and *Ro-*

The two small "Views of the Villa Medici" (Prado), where Velázquez stayed during his first visit to Rome, must, for stylistic reasons, have been painted during his second visit. They are unique examples of pure landscape in his surviving work and among those of his achievements which foreshadow 19th-century Impressionist landscapes. The "Rokeby Venus" (National gallery, London) was also probably painted in Italy and is one of the few representations of the female nude in Spanish painting. The theme of the Toilet of Venus, the rich colouring and warm flesh tones are inspired mainly by Titian and other Venetian painters, though Velázquez has characteristically made no attempt to disguise or idealize his model and his Venus is exceptional for his time as a portrayal of a living nude model.

Last **Years.**—Velázquez arrived back in Madrid in the summer of 1651 with some of his purchases and was warmly welcomed by the king who, in the following year, appointed him chamberlain of the palace, an office that entailed the arrangement of the royal apartments and of the king's journeys. During his absence Philip had remarried, and the young Queen Mariana of Austria with her children provided new subjects for him to portray. For his portraits of the queen (Prado) and of the king's oldest daughter, the Infanta Maria Teresa (Kunsthistorisches Museum, Vienna), who had reached marriageable age, he used identical formulas; and numerous studio replicas of them were made. The royal ladies appear as doll-like figures with their enormous coiffures and farthingales, and the effect of form. texture and ornament is achieved in Velázquez' late manner without any definition of detail, in a free, "sketchy" technique. The portraits of the young Infanta Margarita and Prince Philip Prosper (Kunsthistorisches Museum. Vienna). similar in composition and manner, are among the most colourful of his works, and he most sensitively reveals the childlike character of his sitters behind the façade of royal dignity. Velázquez' late bust portraits of Philip IV (Prado and National gallery, London), of which many studio versions exist, are very different in character and are exceptional as royal portraits for their informal appearance. These last close-up views of the sad and aging monarch are among the most intimate of all Velázquez' characterizations.

In addition to his many royal portraits, Velázquez painted during his last years two of his most original figure compositions and greatest masterpieces, which epitomize his whole artistic achievement. The "Spinners" (Prado), a genre scene in a tapestry factory. is at the same time an illustration of the fable of Pallas and Arachne. the mythological subject—like the religious scenes in his early *bodegones*—being represented in the background. But in his late work there is no barrier between the world of myth and reality; they are united in an ingenious composition by formal and aerial perspective. In the "Meninas" ("Maids of Honour"; Prado) (1656), a more natural subject, he has created the effect of a momentary glance at a casual scene in the artist's studio while he is painting the king and queen, whose reflection only is seen in the mirror in the background, accompanied by the Infanta Margarita with her ladies-in-waiting and other attendants. In this complex composition, the nearly life-size figures are painted in more or less detail according to their relation to the central figure of the Infanta and to the source of light. creating a remarkable illusion of reality never surpassed by Velázquez or any other artist of his age.

Velázquez' last activity was to accompany the king and court to the Isle of Pheasants in the summer of 1660 to arrange the decoration of the Spanish pavilion for the marriage of the Inianta Maria Teresa with Louis XIV. Shortly after his return to Madrid he fell ill and died on Aug. 6. 1660. Though he must have had many assistants, he left few pupils or immediate followers. The naturalistic tradition in which he was trained was one of the bases of 17th-century Spanish painting, but Velázquez' later achievements go beyond those of any Spanish or other artist of his century and make him a forerunner of modern painting. The first artist in Spain on whom they had a profound influence was Francisco de Goya, and they provided an important stimulus to Edouard Manet and the French Impressionists. *Ser* also PAINTING: *Spain.*

VELÁZQUEZ (DE CUÉLLAR), DIEGO (1465–1524), first lieutenant governor of Cuba, was born at Cuéllar, province of Segovia, Spain, in the year 1465. He arrived in Espafiola with Christopher Columbus in 1493 and became the lieutenant of Gov. Nicolas de Ovando. He was reputed to be the wealthiest man in the island, of graceful presence with fair face and blond hair, amiable in disposition and a close friend of the treasurer, Miguel de Pasamonte. Through him, Velazquez established direct connection with the crown. Under Diego Colón's order, Velizquez headed an expedition to Cuba in 1511, establishing on that island a base at Baracoa. Natives of Espafiola, escaping to Cuba, had already warned of the Spaniards and the Cubeños, bravely resisted the incursion, but the discovery of gold made the Spaniards the more eager and valiant. Early in 1513 Velázquez was married to Doña Maria, the daughter of Cristóbal de Cuéllar, but she died within a week of the nuptials. Upon teceipt of news of Velázquez' activities in Cuba, the crown made him *repartidor*, thus authorizing the encomienda system in the new colony. By Aug. 1515, the *repartidor* had founded seven cities, built warehouses, and had stocked Cuba with cattle in addition to the agricultural plantings. In 1517 he sent Fernandez Chrdova, his nephew Juan de Grijalva, and Cristóbal de Olid to Yucatan in separate expeditions to investigate the possibilities of plundering that area. The reports led him to commission Hernando Cortés, his secretary, to attempt the conquest which was begun in 1519. Velazquez had spent the greater part of his fortune in the equipment of the flotilla but before Cortés had left Cuba had lost confidence in his choice of commander. He tried in vain to halt Cortés and although he importuned the Spanish courts for aid, he lost not only the original investment but also the fleet and equipment under command of Pánfilo de Narváez with which he sought to retrieve his loss. His misfortunes were increased by his temporary removal from office as lieutenant governor of Cuba in 1521. The office of *repartidor* remained to him, however, and through it he was able to recoup his fortune. Shortly after the loss of his title of *adelantado* of Mexico he died and was buried in Santiago de Cuba, June 11, 1524.

The story of Velázquez rests largely on Bartolomé de Las Casas' *Historia de las Indias* (1875–76). In English, *see* I. A. Wright, *The Early History of Cuba 1492–1586* (1916). (R. G. RR.)

VELDE, VAN DE, a family of Dutch artists.

ESAIAS I VAN DE VELDE (*c.* 1590–1630), chiefly a landscape painter, draftsman and etcher, who was born in Amsterdam about 1590 and died at The Hague in 1630. He was among the first who changed from the romantic Flemish style to a colourful realistic vision. Also his genre pieces of elegant garden parties, etc., belong to the most modern of this type in Holland.

WILLEM II VAN DE VELDE (1633–1707), a marine painter who was born in Leiden in 1633. With his father, Willem I, also a marine painter, he settled in England in 1672. He made numerous drawings of sea fights (collection in the National Maritime museum, Greenwich)! first from the Dutch and later from the English side. Some of his paintings are exact renderings of actual sea history; others are freely composed, carefully executed calm and stormy seas. His influence on the development of English sea painting was strong. He died in London in 1707.

ADRIAEN VAN DE VELDE (1636–1672), a brilliant landscape painter, also sought after to paint figures in other artists' landscapes, was born in Amsterdam in 1636 and died there in 1672. He specialized in Italian landscapes (although it is not known whether he really visited Italy), delicately executed in brilliant colours. The figure drawings are sensitive and academic.

See K. Zoege von Manteuffel, *Die Künstlerfamilie van de Velde* (1927); C. Hofstede de Groot, *Catalogue of Dutch Painters*, vol. iv (1912) and vii (1923). (H. K. GN.)

VELDE, HENRY CLEMENS, VAN DE (1863–1957), Belgian architect and teacher, who ranks with his compatriot Victor Horta as an originator of the *art nouveau* (*q.v.*) style, was born at Antwerp on April 3, 1863. By designing furniture and interiors for the Paris art galleries of Samuel Bing in 1896, he was responsible for bringing the *art nouveau* style to Paris. However, he was not interested in the style as such, but rather in the philosophy of William Morris and the arts and crafts movement (*q.v.*) in England; and although he had studied in Paris as a painter under Carolus Duran his most vital contributions to modern design were made as a teacher in Germany, where his name became known through the exhibition of furnished interiors at Dresden in 1897.

In 1902 he went to Weimar as artistic adviser to the grand duke of Saxe-Weimar, reorganized the Kunstgewerbliches (Arts and Crafts) Institut and the Academy of Fine Art, and thus laid the foundations for Walter Gropius' amalgamation of the two bodies into the Bauhaus in 1919. Like all progressive German designers at the time van de Velde was connected with the Deutscher Werkbund, designing the theatre for the Werkbund exhibition in Cologne in 1914, but at the same time he was involved in the disputed designs for the Théâtre des Champs Elysées in Paris, later completed by Auguste Perret. In spite of his long life, and numerous official appointments in Belgium after 1918, he made no further live contributions to the progress of architecture or design, but remained, even in his last years of retirement in Switzerland, an admired and venerated living memorial to the creative vitality of the early years of the 20th century.

The extract from van de Velde's *Memoirs, 1891–1901*, published in the *Architectural Review*, 112:143–148 (Sept. 1952), gives a valuable firsthand account of his ideas and intentions.

See S. Giedion, *Space, Time and Architecture* (1949). (R. BM.)

VELEZ DE GUEVARA, LUIS (1579–1644), Spanish dramatist and novelist, was the author of more than 400 plays, of which the best known are *Reinar despues de morir* and *Más pesa el rey que la sangre*. He won considerable fame as the author of *El Diablo cojuelo* (1641), a fantastic novel which suggested to Alain Rene Le Sage the idea of his *Diable boiteux*.

VÉLEZ-MÁLAGA, a town of southern Spain, in the province of Malaga, finely situated in a fertile valley at the southern base of the lofty Sierra de Alhama, and on the left bank of the small river Vélez, 1 mi. from its mouth and 27 mi. E.N.E. by road of Málaga. Pop. (1950) 31,948 (mun). Vélez-Málaga was taken from the Moors in-1487 by Ferdinand of Castile. Under Moorish rule the citadel was built and the town became an important trading station and fortress.

VELIA, an ancient town of Lucania (Gr. *Yele*, later *Elea*), Italy, on the hill now crowned by the medieval castle of Castellammare della Bruca, 440 ft. above sea level, on the southwest coast, $1\frac{3}{4}$ mi. N.W. of the modern railway station of Ascéa, 25 mi. S.E. of Paestum. Remains of the city walls, with traces of one gate and several towers, of a total length of more than 3 mi. still exist. It is celebrated for the philosophers who bore its name. (*See* ELEATIC SCHOOL.) About 530 B.C. the Phocaeans, driven from Corsica, seized it from the Oenotrians. Its coins were widely diffused in southern Italy, and it kept its independence till 78 B.C.

VELIKA KIKINDA, a town in the Vojvodina, Serbia, Yugos. Pop. (1953) 29,570. It is one of the centres of production of the famous wheat of the Banat.

VELLEIUS PATERCULUS, GAIUS (*c.* 19 B.C.–after A.D. 30), Roman historian whose work is an important source for the principates of Augustus and Tiberius. His father was of equestrian status and his mother belonged to a distinguished Campanian family. He served as military tribune in Thrace, Macedonia, Greece and the east, and in A.D. 2 was present at the interview on the Euphrates between Gaius Caesar. grandson of Augustus, and the Parthian king, Phraataces (Phraates V). Later, as prefect of cavalry and legatus, he served for eight years (from A.D. 4) in Germany and Pannonia under Tiberius. He was quaestor in A.D. 7, praetor in 15, and was still alive in 30, for he dedicated his work to M. Vinicius as consul of that year. He wrote a compendium of Roman history from the origins to A.D. 29. The period from the death of Caesar to that of Augustus is treated most fully, and the achievements of Tiberius are described in eulogistic terms. He enlarges on Roman colonization, the Roman provinces and literary topics. He applies biographical methods in his account of historical figures. His style shows distinct characteristics of the Silver Age: antithesis, epigram and rhetorical embellishment.

There are editions of his history by C. Halm in the "Teubner Series" (1876), R. Ellis in Oxford classical texts (1928) and. with English translation by F. W. Shipley, "Loeb Series" (1924).

(A. H. McD.)

VELLETRI (anc. Velitrae), a town and episcopal see of the province of Roma, Lazio, Italy, at the southeast foot of the outer ring wall of the Alban crater. 26 mi. S.E. of Rome by rail and 24 by electric streetcar line, 1,155 ft. above sea level. Pop. (1951) 15,329. It is the seat of the bishop of Ostia. Good wine is made in the vineyards and there is a government experimental station for viticulture. Velletri is the junction of the Terracina line and a branch to Segni. on the main line to .Naples. At the highest point is the municipal palace. The internal façade of the Palazzo Ginetti is finely decorated with stucco, and has a curious detached baroque staircase by Martino Lunghi the younger. The lofty campanile of S. Maria del Trivio. erected in 1353, is in the style of contemporary brick campaniles in Rome. but built mainly of black selce (lava), with white marble columns at the windows. The cathedral, reconstructed in 1660, contains traces of the 13th century structure.

The ancient city of Velitrae was Volscian in Republican times, and it is the only Volscian town of which an inscription in that language is preserved (4th century B.C.). It mentions the two principal magistrates as *medix*. Velitrae was important as commanding the approach to the valley between the Alban and Volscian mountains. Interesting terra-cotta reliefs from a Volscian temple have been found (especially 5th century B.C.) belonging to the period when it had regained its freedom after its first capture by Rome. It was only reduced in 338 and was punished by the destruction of its walls and the banishment of its town councilors to Etruria, while their lands were handed over, to Roman colonists. It was the home of the gens Octavia, to which the emperor Augustus belonged. (T. A.)

VELLORE, headquarters city of North Arcot district, Madras state, India, on the Palar river and 5 mi. from a station on the Southern railway, 80 mi. W. of Madras city. Pop. (1951) 106,024. It has a fortress, famous in the wars of the Carnatic, dating probably from the 17th century. It is a good example of Indian military architecture, and contains a finely sculptured temple of Siva. In 1780 it withstood a siege for two years by Hyder Ali. After the fall of Seringapatam (1799) Vellore was the residence of the sons of Tipu Sahib, and to them has been attributed the mutiny of the sepoys there in 1806. The town contains an arts college and a medical school connected with Madras university.

VELLUM: see **PARCHMENT.**

VELOCITY OF LIGHT. The history of the measurement of the velocity of light, perhaps the most important of all the constants fixed by nature, may be said to have started in 1676 when Ole Roemer observed certain significant fluctuations in the time of arrival of the eclipses of Io, Jupiter's first satellite. A series of earlier observations of eclipse periods, T, by the Italian astronomer Giovanni Domenico Cassini had yielded an accurate evaluation of the average eclipse period, T_0, for this satellite. (A modern determination gives this average period as 42 hr., 28 min., 16 sec.) The distance between Jupiter and the earth varies because of the different orbital periods of these two bodies, the difference between the maximum and minimum distances being the diameter of the earth's orbit. Roemer found a slow variation in the period with an amplitude of approximately 20 sec. and a period of 13 mo.; the latter is just the time required for the earth to move in its orbit from one closest approach to Jupiter to the next. Starting at a time when the earth was closest to Jupiter, and trying to predict on the basis of the mean eclipse period the time of occurrence of an eclipse six and one-half months later (when the earth was its full orbital diameter more distant), Roemer found that the actual eclipse occurred with a delay, relative to this prediction, which he estimated to be of the order of 22 min. He drew the correct inference from this that light travels with a finite velocity, the delay of 22 min. representing its transit time across the diameter of the earth's orbit. More recent measurement shows this delay to be nearer 16 min. This interpretation did not receive acceptance, however, until the English astronomer James Bradley in 1727 found entirely independent evidence for the finite propagation velocity of light. He found it in his observation of the phenomenon known as the aberration of light, a displacement of the apparent position of the stars in the direction of the earth's orbital velocity.

An elementary explanation of this effect is usually offered by likening the situation of the astronomer with his telescope to a man walking through a shower of vertically falling raindrops and carrying a straight vertical pipe. If the man were stationary he would have to hold the pipe vertically in order that the raindrops fall straight down the pipe without striking its walls, but if he were walking with horizontal speed, v, then he would have to incline the tube forward at an angle whose tangent is v/c to the vertical (where c is the velocity of the falling raindrops) in order that each raindrop traverse the length of the pipe in a direction parallel to its axis. The analogy to the aberration of light is only valid when v/c is an extremely small ratio.

In 1849 the French physicist A. H. L. Fizeau was the first to succeed in measuring c, the velocity of light, by a method not involving astronomical observations. He measured the time of transit of light flashes between two hills about 8.6 kilometres (km.) apart, near Paris. The beam of light was chopped into flashes by means of a rotating wheel aith 720 teeth, and Fizeau measured the successive critical speeds of rotation at which the returning flash of light (from a mirror on one of the hills) was just eclipsed by rotation of succeeding teeth into the path. The experimental conditions were later improved upon by M. A. Cornu and by T. Young and G. Forbes with more accurate results. A drawback to this method is that the exact speed at which complete eclipse occurs is ill-defined.

Rotating-Mirror Method.—The French astronomer D. F. J. Arago was the first to suggest the famous rotating-mirror method which permits considerably higher accuracy than the toothed wheel. It was first successfully applied by Fizeau and by J. L. Foucault working independently in 1850. In these experiments a pencil of light from a point source was reflected from a rapidly rotating plane mirror and, after traversing a path to a stationary mirror about 20 m. distant, returned to the rotating mirror. During the time of transit this mirror was found to have rotated sufficiently to displace the focused image of the light source by a distance of 0.7 mm. Foucault's result for the velocity of light was roughly 298,000 km. per second. This method was greatly improved by Cornu, by Simon Newcomb and by A. A. Michelson. They increased the path distance and utilized rotating polygonal mirrors of glass and steel with very accurately polished optically plane faces and with optically accurate mutual orientations between faces. The dihedral angles between adjacent faces were equalized by interferometry to better than $\frac{1}{20}$ sec. of arc. In a series of experiments performed in California and published in 1927, Michelson used a light path of 44 mi., from Mt. Wilson to Mt. San Antonio and return. His zoo determinations varied between extremes of 299,756 and 299,803 km. per second. The average value, after correction for the group velocity refractive index of air to obtain the vacuum value, yielded

$$c = 299{,}798 \pm 4 \text{ km. per second} \qquad (1)$$

The length of the light path for Michelson's Mt. Wilson determinations was measured by the U.S. coast and geodetic survey in a remarkably accurate triangulation from a 40-km. base line. The length of this base was determined to an estimated error of 1 part in 11,000,000. The result (1), within its estimated error range, is in accord with the results of the best modern measurements.

Group Velocity and Phase Velocity.—All methods in which a light beam is modulated or chopped into signals whose transit times are then measured, such as the toothed-wheel, rotating-mirror or Kerr-cell modulation methods, yield values of the group velocity

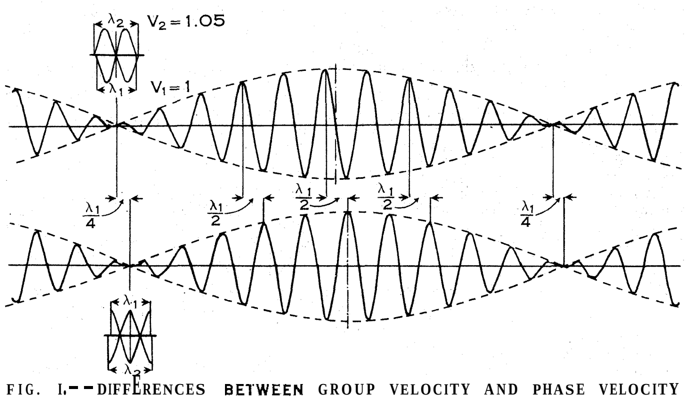

FIG. 1.—DIFFERENCES BETWEEN GROUP VELOCITY AND PHASE VELOCITY IN A DISPERSIVE MEDIUM

The velocity with which the nodes and loops propagate is called the group velocity. The figure illustrates an exaggerated case in which $\Delta\lambda/\lambda = 0.1$ and the corresponding $\Delta V/V = 0.05$, so that the group velocity is only half the phase velocity

of light in the medium employed. The group velocity is to be distinguished from the phase velocity; the latter is the velocity of propagation of each wave crest of an infinitely long, pure, sinusoidal plane wave train. In a dispersive medium (one in which different wave lengths propagate at different phase velocities), the group velocity and phase velocity are, however, not identical and therefore the group refractive index of air is the one which must be used in correcting the results (of a measurement in air) to find the vacuum value of c, the fundamental natural constant. Fourier analysis shows that the effect of modulating or chopping an infinite wave train originally consisting of a pure sine wave into identifiable groups always introduces other frequencies in addition to the original one. The simplest way to illustrate the difference between phase velocity and group velocity is, therefore, to consider two superposed pure wave trains of equal amplitude and nearly equal wave length, λ and $\lambda +$ AX, propagating in the same direction, say from left to right. Because of the slight difference in the two wave lengths the train will be modulated with nodes and loops as shown in fig. 1, the nodes being separated by a number, $\lambda/\Delta\lambda$, of the original wave lengths, λ. If the longer of the two wave lengths propagates at slightly higher phase velocity it will be noted that the crests of the wavelets in each group will be moving forward slightly faster than the group as a whole, the wavelets continually dying at the front of the group and new wavelets apparently being born at the rear. The relationship of group velocity, V', to wave velocity, V, is then given by the equation

$$V' = V[1 - (\lambda/V)dV/d\lambda] \tag{2}$$

Actually Michelson had incorrectly used the phase velocity refractive index in reducing his 1926 results from air to vacuum. R. T. Birge detected this error, and for this reason made a correction upward of 2 km. per second in Michelson's value, obtaining the result (1) above. As Table I below shows, this point was overlooked by several other workers also. Birge refers to this oversight on Michelson's part as "one of the most inexplicable errors" he ever encountered since Michelson had: in earlier work, shown himself to be completely familiar with the distinction between group and phase velocity indices.

Irvine Ranch Experiment.—A rotating-mirror experiment, begun in 1929 by Michelson, F. G. Pease and F. Pearson but not completed until after Michelson's death in 1931, was conducted over a light path in an evacuated pipe one mile long on the Irvine ranch near Laguna beach in California. Successive to-and-fro reflections between plane mirrors were employed to yield a total light path of some 10 mi. A plot of the statistical frequency distribution of the results of nearly 3,000 measurements with this equipment showed a distribution with a strong symmetrical peak centred at the mean value

$$c = 299{,}774 \text{ km. per second} \tag{3}$$

The distribution exhibited, however, rather widely spreading and more or less symmetrical wings or plateaus on either side of the central peak which were decidedly of non-Gaussian character and which, in the late 1950s, were still, unexplained. The computed "probable error" of this array of results was ± 0.2 km. per second, but this apparently overestimates the true accuracy considerably, and in the light of knowledge available by the late 1950s the mean result (3) is almost certainly 18 or 19 km. per second too low. It may be significant that the value strongly indicated as correct by modern and very accurate methods, namely 299,793 km. per second, or even Michelson's slightly higher value (1), falls well inside the above-mentioned non-Gaussian plateau on the Irvine ranch statistical distribution curve. A posteriori reasons to account for the systematic errors in the Irvine ranch work are not hard to find. The base line was on very unstable alluvial soil. A correlation between fluctuations in the results and the tides on the sea coast was reported by Pease and Pearson. A far greater number of time-of-transit measurements with the rotating mirror than with length measurements of the admittedly fluctuating base length were made. Base-length measurements, it appears, were all made in the daytime. whereas a great majority of the rotating-mirror measurements were made at night.

The Kerr-Cell Method.—The Kerr cell or electrooptical shutter furnishes a method of modulating a light beam much more rapidly than the mechanical methods just described. In 1875 the Scottish physicist John Kerr discovered that when a plate of glass is subjected to a strong electric field it becomes doubly refracting, a phenomenon which appears also in liquids. In the electrooptical-shutter method the Kerr cell, consisting usually of two electrical condenser plates immersed in a liquid such as nitrobenzene, is placed between a polarizer and an analyzer "crossed" so as to give complete extinction when the cell is not active. The light beam passes through the cell in a direction parallel to the condenser plates. When a considerable difference of potential is established between the condenser plates. the electric field causes the liquid to behave optically like a uniaxial crystal with its optical axis parallel to the field direction. With the cell oriented at 45° to the plane of polarization of the polarizer, the incident plane vibrations from the polarizer are broken up into two equal components that are parallel and perpendicular to the electric field. These travel through the cell with different speeds so that a phase difference is introduced and the light emerges from the cell as elliptically polarized light. The horizontal component of this light is then transmitted by the analyzer. Thus in the absence of the electrical field no light is transmitted, but with application of the field the light is able to pass.

A. Karolus and O. Mittelstaedt in 1925 were the first to develop this Kerr-cell method, and W. C. Anderson in 1937 and in 1941 improved upon it. Nearly 3,000 observations in 1941 by Anderson yielded the mean value

$$299{,}776 \pm \text{g km. per second} \tag{4}$$

which agrees very well with the Michelson, Pease and Pearson value, but is the one which is regarded as almost certainly 19 km. per second too low. The different transit times of the electrons in the tube used for detecting the modulated light pulses in Anderson's work constituted a possible source of systematic error which he recognized clearly himself. This latter objection is avoided in the Kerr-cell method of E. Bergstrand described below.

The two measurements (3) and (4), with their impressively large number of replicated observations and their excellent (but apparently fortuitous) agreement, misled physicists, including Birge, for about a decade. Not until 1949 was suspicion cast on the value $c = 299{,}776$ km. per second. In that year C. I. Aslakson, using Shoran, a radar method of measuring the distance of an airplane from a ground station by the time of flight of a radio signal, reported a higher value of c. When signals were measured using Shoran, as the airplane approached a position of exact alignment between ground stations separated by a known distance, Aslakson obtained limiting results indicating a value, $c = 299{,}792 \pm 3.5$ km. per second. Since then all other measurements of the constant c for electromagnetic radiation made by many observers and by much more accurate methods support the higher value $c = 299{,}793$ km. per second.

The Bergstrand Geodimeter.—E. Bergstrand developed equipment for an improved Kerr-cell modulation method of measuring the transit time of light over long outdoor light paths of several kilometres. He gave the equipment the name "geodimeter" because it was developed with the idea of using the method in high-precision geodetic surveying. A frequency of 8.33 megacycles (mc.) per second with amplitude of 2.000 v. is used to modulate the light source by means of a Kerr cell, and the same high-frequency oscillator also modulates the detecting photomultiplier tube which receives the returning light from the distant mirror. A jo-cycle-per-second (c.p.s.) alternating bias voltage of 5,000 v. with a square wave form is also applied to the Kerr cell so that the 8.33-mc.-per-second oscillations swing to and fro over the steepest and most linear region of the Kerr cell's characteristic curve of light intensity v. applied voltage. Thus one set of alternate half waves of the 8.33-mc.-per-second oscillator give high light transmission during one entire half cycle of the 50-c.p.s. square-wave bias voltage. while the other half cycles of the high frequency give low light transmission so as to yield a nearly pure sinusoidal variation of light intensity at 8.33 mc. per second. During the next half cycle of the 50-c.p.s. square wave the reversed bias causes the oscillations of light intensity to occur with the high light-transmission maxima 180° (of the 8.33-mc.-per-second frequency) out of phase with respect to their phase during the preceding half cycle of the low frequency. If the oscillations of intensity of the returning light are in suitable phase coincidence with the electrical high frequency which modulates the plate voltage of the photomultiplier tube, the latter will supply 50-c.p.s. rectified pulses of a maximum amplitude during one set of alternate half cycles, and these are arranged to furnish a rectified pulsating signal to an amplifier. During the other set of alternate half cycles oi the 50-c.p.s. square-wave biasing voltage practically no rectified signal will be available from the photomultiplier tube because the 8.33-mc.-per-second modulating voltage applied to its plate is in the wrong phase. Clearly. however, a shift in phase of the sinusoidal light intensity can modify this condition of extreme unbalance between the rectified signals from the two sets of alternate jo-cycle half waves. Two vacuum tuhes, controlled from the 50-c.p.s. square-wave supply. serve to switch alternate phases of this amplified signal from the photomultiplier through a D.C. meter of long period. Reversing switches permit the operator to reverse the phases of the 50 c.p.s. which the switching tubes select and also to reverse the phase of the 8.33-mc. voltage applied to the photomultiplier tube plate. There will be *some* distance for the remote mirror such that the phase delay of the returning oscillations of light intensity will just yield a zero reading on the D.C. meter, and for the selected frequency of 8.33 mc. per second there will occur another such zero for every increase or decrease in distance of the remote mirror of about nine metres.

Uergstrand used great care in guarding against all possible sources of systematic error. For example, he explains in his published articles the means provided to correct a systematic error resulting from the fact that different parts of the image of the light source at the distant mirror have different phases, depending on the part from which light is emanating in the space between the Kerr-cell condenser plates.

Summary of Significant Determinations.— In Table I is given a list of all the significant determinations of the velocity of light of optical frequencies. The first 12 are taken from the 1941 review of this subject by Birge. Bergstrand's geodimeter measurements are seen in this table to yield a value of c about 19 km. per second higher than the Michelson, Pease and Pearson or the Anderson values. The geodimeter has also been independently used by I. C. C. Mackenzie in Scotland with results which do not differ significantly from Bergstrand's. This higher value of c also, as will be seen. receives further support from high-precision work with microwaves. For purposes of comparison, an indirect determination of c by E. B. Rosa and N. E. Dorsey, obtained by measuring the ratio of an electrical charge in absolute electrostatic units (e.s.u.) to the same charge in electromagnetic units (e.m.u.), is included in 'Table I. This experiment, carefully carried out at the U.S. national bureau of standards, has been characterized by

TABLE I.— Determinations of the Velocity of Optical Light

Author	Method†	Year	Corrected result (km. per second)	Standard deviation‡ (km. per second)	Corrected by	Corrected for
Cornu-Hélmert	TW	1875	299,990	± 300

Mittelstaedt	KC	1928	299,786	± 15	R. T. Birge, 1941	Group-velocity indices of optical path
Michelson, Pease and Pearson	RM	1933	299,774	± 6		
Anderson	KC	1937	299,771	± 15	R. T. Birge, 1941	Group-velocity indices oi optical path
Hüttel	KC	1937	299,771	± 15	R. T. Birge, 1941	Group-velocity refractive index of air
Anderson	KC	1941	299,776	+ 9		
Bergstrand	KC	1951	299,793.1	± 0.32		
Mackenzie	KC	1953	299,792.4	± 0.5		

*The Rosa-Dorsey determination is listed here for purposes oi comparison. It is not a determination of the velocity oi optical light but of the constant, c, in Maxwell's equations (*see* LIGHT: *Tie Electromagnetic Equations*).There is no reason to believe that the two should differ in value, however.

†TW = toothed wheel; RM = rotating mirror; REU = ratio electrical units: KC = Kerr cell.

‡The root-mean-srjuare or "standard" error is adopted as the index of precision in this article in accord with the best modern error-statistical usage. Wherever "probable errors" were those originally given they have been converted to standard errors by dividing each probable error by o 6745.

Birge as "one of the most beautifully executed pieces of precision research in the entire history of science." (R. T. Birge. "The General Physical Constants as of August 1941 With Details on the Velocity of Light Only." The Physical Society. *Reports on Progress in Physics*, vol. 8 [London, 1941].) The Rosa and Dorsey value, c = 299.784 ± 15 km. per second. is about at the mid-point of the above-mentioned 19-km.-per-second discrepancy interval and its precision is insufficient to discriminate clearly in favour of either the old 299,774 value or the modern 299,793 value, but it is worth noting that this careful piece of work is not inconsistent with the modern high value since the difference, 9 km. per second, has an expected standard deviation of ±1j km. per second. In fact. if the Michelson, Pease and Pearson and the Anderson values are excluded. the remaining data of Table I, including the work of Rosa and Dorsey and the Mt. Wilson work of Michelson, are not at all inconsistent with the newer. much more accurate. high value.

VELOCITY DETERMINATIONS OF RADIO-FREQUENCY WAVES

The question of whether the speed of light in vacuum varies with wave length or frequency seems to have been clearly settled long ago by observationsof variable stars. Some of these are so distant that their light must take many centuries to reach the earth. Were there any difference in the propagation velocity of the light of different colours, even to so small an extent as one part per million, the apparent colour of the star would change as it waxed and waned, and no evidence whatever for such an effect has been observed.

An even more conclusive test of the absence of any dispersion, in the propagation of radiation of very different wave lengths across intergalactic space has been obtained as a by-product of radio-astronomy. In 1951 F. G. Smith of Cambridge university succeeded in locating within an area of less than one square minute of arc an already well-known. exceedingly intense source of extra-galactic radio waves in the constellation Cygnus. Walter Baade thereupon took a picture of the object with the zoo-in. Palomar telescope and discovered that at this point two very distant galaxies gave every evidence of being in close collision. The Doppler shift toward the red of the optical spectral lines emitted from this object show it to be 270,000,000 light years distant from the earth. and the 21-cm. radio line of hydrogen (discovered in the laboratory by Willis Lamb, Jr., and R. C. Retherford in 1950) as emitted from this radio object was found to have exactly the same red shift. One is forced to the conclusion that the radio waves and the light waves have been propagated over this huge distance with exactly the same velocity. Recent experiments measuring the propagation velocities of radio waves on the one hand and of very short wave-length gamma rays on the other give complete support to the hypothesis that all wave lengths propagate with the same speed in vacuum.

The principal high-precision radio-frequency measurements of c up to 1955 may be listed as (1) W. W. Hansen and K. Bol at Stanford university, Stanford, Calif., using microwave cavity resonance with a cavity of fixed length; (2) L. Essen at the National Physical laboratory, Teddington, Eng., using cavity resonance in a cavity of variable length; (3) K. D. Froome, also at the National Physical laboratory, using a free-space microwave interferometer; (4) Aslakson, using the above-mentioned Shoran radar method originally devised for determining the distance of an airplane from a ground station; (5) E. K. Plyler. L. R. Blaine and W. S. Connor, and D. H. Rank et al., using infrared spectroscopic measurements of the molecular constants of carbon monoxide; (6) E. F. Florman, using a large-scale radio interferometer at 172.8 mc. per second. set up on a dry lake bed in Arizona.

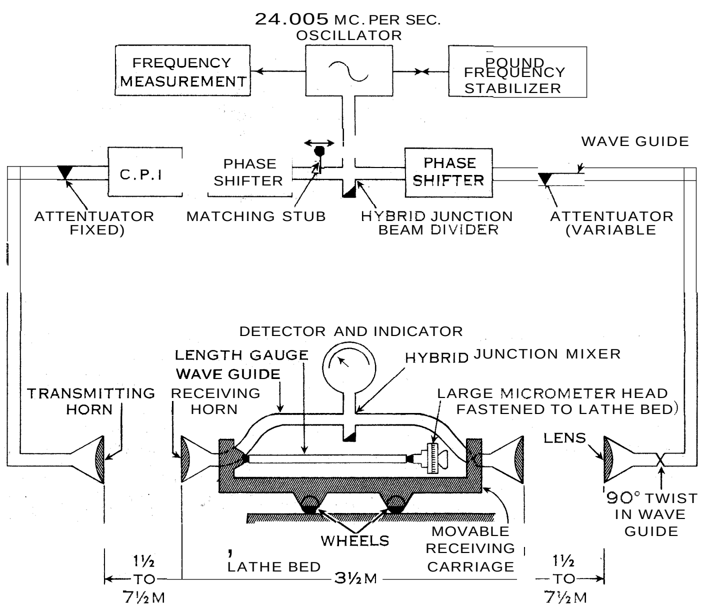
All these radio-frequency methods depend in principle on determining independently a frequency, ν, and a wave length, λ, associated with some electromagnetic wave phenomenon. If ν and λ were the frequency and wave length of a train of infinite plane waves in free space (vacuum), then the velocity of light, c, would be simply given by the product, $\nu\lambda = c$. If the waves are confined in cavities or interact with material objects, or if they are neither plane nor infinite (as is usually the case), then complicated corrections are required.

The results of all these methods (see Table II) indicate clearly that the earlier-weighted average value arrived at by R. T. Birge, based chiefly on the Michelson, Pease and Pearson rotating-mirror and evacuated-tube determination and on the Anderson Kerr-cell determination, *i.e.,* 299,776 km. per second, was too low by about 16 or 17 km. per second. The values after 1948 are far from being of equal reliability or accuracy, nor are they all completely in agreement to within the accuracy estimated by their authors. The Hansen and Bol result in particular disagrees with the others by being about 3 km. per second lower—a disagreement which, though small judged by earlier standards, is uncomfortably large relative to the claimed precision measures.

The Hansen and Bol Method (Fixed-Length Cavity Resonance).—In the Hansen and Bol measurement a cavity resonator was employed which was an accurately machined right circular metal cylinder with optically flat removable metal ends. To reduce losses and to insure a "high-Q" resonance, the machined cast-iron cavity surfaces were plated with silver. Three spacer rods, located in longitudinal holes in the cylinder wall, were used to space the silver-plated surfaces of the cast-iron optical flats which formed the end faces of the microwave cavity. These spacer rods had convex spherical ends which on each rod were zones of a common sphere. All three rods were carefully equalized so that as long as contact was with the ends, the distance between two parallel planes (one contacting each convex surface) was independent of the orientation of the rod axis. The three rods were intercompared in a temperature-controlled oil bath by an ingenious spring-feeler multiplying gauge and were lapped to uniform length. The distance between plane end faces of the cavity was determined interferometrically by replacing the silver-plated cast-iron flats with glass flats. A source of some uncertainty entered here because of the possible difference in elastic or plastic yield at the points of contact between spacer rods and the two different kinds of flats. A study of this effect was made by varying the loading. The diameter of the cylindrical cavity could not be measured accurately by direct means, but the ratio of length to diameter could be determined by a calculation from the ratio of the observed resonant frequencies for two modes of electrical vibration (the TE_{012} and TE_{021} modes) since one of these depends primarily on the length of the cylinder and the other primarily on its diameter. The ratio of length to diameter had been chosen purposely so as to put the frequencies of the two modes only a few megacycles apart out of 3,000 mc. A correction to the resonant frequencies was required because of the perturbation produced by the probe hole through which the electromagnetic energy is introduced into the cavity. The shift in resonant frequency produced by this hole was theoretically predicted to vary as the cube of the diameter, and this was experimentally verified. This finding permitted extrapolation to find the frequency for a vanishingly small hole. An insulating gap was purposely allowed between the plane ends and the cylindrical walls to suppress those certain unwanted modes of electrical vibration for which currents would otherwise be required to flow across this gap. Correction for the gap was small and easily made.

The high-frequency currents in the conducting walls of the cavity, which must necessarily accompany the electromagnetic waves, only penetrate into the conductor to a certain very shallow depth (the shallower the higher the frequency of the particular mode of oscillation), known as the "skin depth." The skin depth and current distribution depend also on the resistivity and dielectric constant in this shallow region. In this experiment the true electrical dimensions of the cavity are greater than the mechanical dimensions by an amount of the order of magnitude of the skin depth. The possible presence of a thin film of silver sulfides of unknown thickness with a resistivity and a dielectric constant differing from the values for bulk silver will affect the observed resonant frequency of the cavity. Correction for this should increase the Hansen and Bol value of the velocity slightly. It has been also suggested by E. S. Dayhoff that the mechanical effect of polishing the silver-plated surface may cold-work the metal and thus greatly decrease its conductivity in an extremely shallow layer. It is unfortunate that Hansen and Bol only made measurements at just enough frequencies to determine *c* in the absence of such anomalous skin effects. In any precision measurement it is always a better policy to overdetermine the measurements in an effort to uncover unsuspected systematic errors.

The Froome Method (Free-Space Microwave Interferometer). — The four-horn Fraunhofer diffraction microwave interferometer of Froome is shown schematically in fig. 2. A Pound stabilized reflex klystron oscillator is used as the source of 24,005-mc.-per-second microwaves corresponding to a wave length of about 1.25 cm. The accuracy of the frequency measurement is about 1 part in 100,000,000. The microwave energy from the oscillator passes to a hybrid junction ("magic T") which serves as a beam divider, from which it passes through two long wave-guide arms to the pair of transmitting horns. The matching stub and phase shifter (see fig. 2) to the left of the beam divider, together with a "constant phase auxiliary interferometer" (c.p.i.), constitute a device for altering the amplitude of the waves transmitted



ADAPTED FROM FROOME, OF THE NATIONAL PHYSICAL LABORATORY, "PROCEEDINGS OF THE ROYAL SOCIETY," LONDON (1952)

FIG 2 — THE FREE-SPACE MICROWAVE INTERFEROMETER OF K. D. FROOME AT THE NATIONAL PHYSICAL LABORATORY, TEDDINGTON. ENG.

down this arm without introducing any change of phase. In this c.p.i. the input wave is split into two components of equal amplitude in two different paths. These components are subsequently recombined after a change in their relative phases brought about by an increase in path length for one path and an exactly corresponding decrease in path length for the other. The two equal vectors representing the phases of the two components are thus rotated in opposite directions through the same angle so that the direction (phase) of their resultant is unchanged while its amplitude is reduced. The phase shifter to the right of the beam divider, together with the variable attenuator, is required in order to adjust and balance the position of the first interference minimum.

A pair of receiving horns mounted on a movable carriage constructed almost entirely of silica tubes (for thermal stability) is arranged to travel on ways through a path of about one metre length. The pair of receiving horns is centred on a straight line, the central axis running betueen the two stationary transmitting horns. The tuo received signals are "mixed" to produce interference, and are detected by means of a simple superheterodyne arrangement; the output is rectified and indicated on a milliammeter. An interference minimum is then indicated by minimum current through the meter and the carriage can be set on a minimum to better than one micron. Lenses were introduced into the horns to render the waves more nearly plane-parallel. Of course diffraction effects coming from the finite dimensions of the horns relative to the wave length tend to distort the wave fronts so that the simple relationship $\lambda\nu = c$ is invalidated and requires a correction. The seriousness of errors of this sort diminishes the farther. in terms of wave lengths, the two transmitting horns are placed from the receiving horns, and by varying this distance it was possible therefore for Froome to arrive at an estimate for the correction to be applied.

A wave-length measurement then consists of determining the exact displacement of the carriage corresponding to 81 wave lengths (162 minima) measured to $\frac{1}{4}$ micron by means of end-contact gauges. Froome states that this 24,005-mc.-per-second equipment is merely a. prototype constructed for the investigation of sources of inherent error. The conditions were, therefore, deliberately chosen to cause errors. as. for example, the random effects arising from reflections in the rather small room. Nevertheless the apparatus was found to yield an accuracy of 1 part in 10^6 for the velocity measurements. Much better results are anticipated from the final equipment which is to operate at 70,000 mc. per second ($\lambda = 4$ mm.) over a path difference of 1,000 minima in a much larger room. Ten observations with the present prototype have been reduced to yield a preliminary value for the free-space velocity of electromagnetic waves in *vacuo* of

$$c = 299{,}793.0 - 0.3 \text{ km. per second} \qquad (5)$$

The original papers of Essen and of Froome give many details and refinements which are omitted here, and contain a particularly careful study of correctioris for the refractive index of air and water vapour.

Table II lists the experimental values of c obtained for radio, microwaves and infrared radiation since 1949 and, for comparison with these, the results of Bergstrand's, Mackenzie's and Schöldstrom's determinations with optical light by means of the geodimeter. Although the other methods are somewhat less precise than those of Froome and of Bergstrand, it will be noted that all of the modern determinations strongly support the higher value. $c = 299{,}793.0 \pm 0.3$ km. per second. upon which the quite independent methods of Froome and of Bergstrand are in excellent agreement as contrasted with the value some 17 km. per second lower which was thought in 1941 to be correct. The reader will find cited in the bibliography an excellent review by J. F. Mulligan and D. F. McDonald in which all methods listed in Table II are described and discussed. See also ELECTRICITY; LIGHT.

TABLE II.—*Experimental Values of the Velocity of Electromagnetic Radiation in Vacuum*

Author	Date of publication	Method†	velocity	(Km. per second)
Aslakson	1949	Shoran	299,792	± 3.5
Hansen and Bol	1950	FLCR	299,789.3	± 1.2
Essen	1950	VLCR	299,792.5	± 1.0
Bergstrand*	1951	Geodimeter	299,793.1	± 0.32
Aslakson	1951	Shoran	299,794.2	± 1.9
Froome	1952	FSMWI	299,792.6	± 0.7
Mackenzie*	1953	Geodimeter	299,792.4	± 0.5
Froome	1954	FSMWI	299,793.0	± 0.3
Plyler, Blaine and Connor	1955	Infrared Spectroscopy	299,792	± 6.0
Florman	1955	FSMWI	299,795.1	± 1.9
Rank, Bennett and Bennett	1956	Infrared Spectroscopy	299,791.9	± 2.2
Schöldström*	1956	Geodimeter	299,792.4	± 0.4

*The measurements of Bergstrand. Mackenzie and Schöldström are at optical frequencies; all the others are for radio waves.

†FLCR = fixed-length cavity resonance; VLCR = variable-length cavity resonance; FSMWI = free-space microwave inlerferometer.

Birge, "The General Physical Constants as of August 1941 With Details on the Velocity of Light Only," The Physical Society, *Reports on Progress in Physics*, 8:90 (1941). (J. W. M. D.)

VELOUR. The term velour (French for velvet) refers in particular to a large variety of woolen textures, and in general to several varieties both of woolen and cotton textures, and also to union fabrics, that are formed with a short furry nap or fur on either one side only or on both sides of the fabric, and developed. subsequent to weaving, by operations of milling and raising. Velour fabrics are characterized by a soft and full "handle" or "feel" and used as dress and costume fabrics, suitings. coatings and dressing gowns according to the texture. Velour is also applied as a general description of many other varieties of fabrics produced from a mixture both of wool and cotton, and to some varieties of all-cotton fabrics on which there is developed the characteristic "velour finish." after weaving.

The nap or pile surface of a velour fabric. produced by milling and raising, is not analogous to the velvet or plush pile of true velvet or plush, nor of velveteen (cotton velvet) in which the pile is produced by a series of tufts, that stand erect from a foundation texture. and are developed by severing the pile warp threads, in velvet and plush (*q.v.*) fabrics, and the pile picks of weft in velveteen or cotton velvet.

VELSEN, a town of the Setherlands, in the province of North Holland, close to Ymuiden. with which it forms a single municipal administration. Pop. (1957 est.) 59.938 (mun.). It is on the North sea canal. and forms the port of entrance for Amsterdam.

VELVET. The term "velvet" applies strictly to the true type of the plain silk velvet of the lighter textures. constructed with a short "velvet!' or plush pile surface, which is developed during weaving by severing certain warp threads of silk, thereby causing the severed threads to stand erect in the form of short tufts from a substantial foundation texture of silk. cotton or other textile material. Velvet has been greatly in the popular favour for many centuries as a dress material. also for garments for use on such occasions as state: social and religious ceremonies and an infinite variety of uses such as curtain drapery. hangings and furniture upholstery and many other purposes. The richest velvet fabrics are those of Dutch (Utrecht) and Genoese manufacture. and that variety known as "collar velvet" for use specially in making the collars of men's overcoats. The velvet pile warp consists of pure silk yarn, though the foundation texture may be woven from a silk warp and cotton weft. or all cotton for both warp and weft.

One of the oldest examples of velvet is that forming part of a 14th-century embroidered cape in the College of Mount St. Mary, Chesterfield, Eng. In the earliest of the inventories relating to church vestments. there is a reference, in St. Paul's. London. A.D. 1295. to the use of "velvet" nith its kindred web "fustian," for "chasubles"; while in that of Exeter cathedral, in 1327, velvet. for the first time is mentioned as being "in two pieces not made up. of which some yards had been then sold for vestment making "

Velvet Weaving.— Velvet fabrics of the lighter textures are woven on hand looms and produced from two distinct series of warp threads and one series of weft threads, viz., "ground" threads to form the foundation texture. and "pile" threads to form the pile, arranged in the fabric in the order of two ground threads and one pile thread, uniformly. Also. each system of warp threads is contained on a separate warp beam or roller in order to permit the tension and rate of delivery of each system to be adjusted and controlled independently. This provision is essential by reason of the two warps contracting at different rates during weaving; that of the pile warp being considerably greater than that of the ground warp, and in the ratio of about six or eight to one, respectively, according to the length or depth of the pile.

During weaving, the pile is developed by raising all the pile warp threads while the ground threads remain down, and then insetting through the warp shed thus formed, a long, thin steel wire, having a narrow groove formed in the upper edge, and extending for its entire length. This wire, termed a "pile wire" is then beaten-up by the reed right up to the "fell" of the cloth, just as an ordinary pick of weft, after which (in one velvet structure), three picks of weft are inserted in succession. These interweave with the ground warp threads on the plain calico principle to produce a firm foundation texture for the tufts of pile. Also, for the first and third of these picks, all pile warp threads are left down, but are raised on the second or intermediate pick, thereby interweaving these threads on the principle known as "fast" or "lashed" pile which binds them very securely to the foundation texture, with less risk of their accidental withdrawal, when the fabric is in use. After these three picks of weft are inserted, another pile wire is inserted in the warp shed, formed, as before, by raising all pile warp threads only and leaving down all ground threads. Then follow the next three ground picks in succession, and so on, in the same regular sequence, uniformly.

Producing the Pile.—From this brief description, it will be apparent that all the pile warp threads simply bend over the grooved pile wires and thus form a horizontal row of loops extending across the entire widrh of the fabric, between the two selvedges, while those wires virtually constitute thick picks of weft which, along with the three fine picks, are all beaten up close together, by the reed, in the usual manner. After the second pile wire has been inserted, and followed by the three ground picks, the weaver releases the first wire by severing, with a knife specially adapted for that purpose, all the pile threads that pass over it. This wire is then removed and inserted in the next pile warp shed to be followed by three more ground picks, after which the second wire is also released, and removed to be again inserted in the next following pile warp shed, and so on, continuously. The severing of the loops formed by the pile warp threads causes these to stand erect as short tufts and thus produce the pile surface.

The instrument employed by a velvet weaver, for cutting the pile warp threads, consists of a special form of knife blade, bent at an angle and fixed adjustably in a frame described as a "trevette." This frame serves both as a handle and guide for the blade, of which the thin and sharp edge is inserted by the weaver into the narrow groove of the pile wires, and drawn quickly, by the right hand, from the left selvedge to the right, with the rear side of the "trevette" bearing against the pile wire last inserted, to serve as a guide, while the knife edge passes along the groove of the pile wire nearest the weaver.

Types of Velvet.—Velvet fabrics also comprise many other varieties ranging from the light, plain textures employed for personal adornment, to the heavier and stronger figured textures for furniture upholstery, curtain drapery, mats, rugs, and similar articles of a more durable character. These comprise such types as Utrecht velvet, "frieze" velvet, "moquette" velvet, and others of a similar kind. Many of these varieties of figured velvets, with the pile produced from mohair and uool, are woven in pouer looms furnished with a special mechanism adapted to insert the "pile wires" into the warp sheds and afterward withdraw them from the cloth, automatically.

Figured velvet fabrics are also sometimes embellished with both a cut or "velvet" pile and an uncut (*i.e.*, looped or "terry") pile, with very pleasing effect owing to the lighter and darker tones of colour resulting from the difference in the reflection of light from the velvet and terry pile surfaces, which appear to be of darker and lighter tones, respectively, although produced from warp threads of exactly the same material, colour and counts of yarn.

Very beautiful varieties of figured, plush pile fabrics are those so-called "embossed" plush or velvet pile fabrics.

(H. N.)

VELVETEEN. One of the most important varieties of the type of fabrics comprised under the general description of "fustian" (*q.v.*). Such fabrics are virtually "cotton velvets" constructed with a short weft pile surface and bear a very close resemblance to the true velvets (*q.v.*) constructed with a warp pile of silk.

Although "velveteen" and "velvet" have a similar general appearance, they are each constructed on distinctly different principles of fabric structure.

Before being submitted to the operation of fustian cutting, all velveteen fabrics have a smooth and even weft surface very similar to that of ordinary cotton weft-face satin textures known as "sateen," and may be made to assume, during that operation, either a plain pile surface uniformly, or else a ribbed or corded surface with the ribs extending lengthwise of the fabric, *i.e.*, in the direction of the warp threads. Although they comprise several different modifications in respect of their structural details, they all embody the same essential features in their construction.

This consists of the development of a series of short tufts of weft pile on a foundation of the plain calico, a simple twill or other elementary weave structure of a suitable character. They consist essentially of one series of warp threads and two series of weft threads, viz., "face" or pile picks and "back" picks, respectively, of the same kind of weft from a single shuttle. The warp threads and back picks are interwoven on some elementary principle to constitute the foundation texture, while the face or pile picks are allowed to "float" somewhat freely on the face, as in a sateen fabric, to be afterward severed by the fustian knife, in order to develop the tufts of pile.

Face and back picks may be employed in any suitable ratio ranging from two to as many as nine pile picks for each ground pick, and with the face picks floating loosely over from 3 to 11 warp threads chiefly according to the character of texture as regards the length (or depth) and density of the pile and the weight and quality of the fabric and its particular use.

Forming the Pile.—During the operation of fustian cutting, all the floating pile weft is severed by the fustian knife, thereby causing that weft to stand erect, and thus form the short tufts of pile which lie in close formation. This operation develops the characteristic velvet or plush pile over the entire surface of the fabric.

The picks are cut by the fustian knife. This knife blade is formed with a very fine and sharp cutting edge at the extreme end of a long, square, steel shank inserted in a wooden haft to be held by the fustian cutter.

After the velveteen fabric has been prepared in a suitable manner for cutting and stretched taut in a frame for that purpose, the fustian cutter, commencing at one selvedge, proceeds to cut that stretch of cloth one "race" or "run" at a time, taking each "race" in succession.

Varieties of Velveteen.—There are three principal varieties of velveteen, distinguished chiefly by the particular weave structure on which the foundation texture is based. Hence, they are described as "plain" or "tabby-back"; "jean" or "jeanette-back"; and "Genoa-back" velveteens.

The tabby-back variety signifies a foundation texture based on the plain calico weave; while jean-back signifies those based on the three-end $(\frac{2}{1})$ regular twill weave; and Genoa-back those based on the four-end two-and-two $(\frac{2}{2})$ regular twill weave; while there are many other weaves employed in their construction. In addition to these variations, some velveteens are also constructed as "fast" or "lashed" pile velveteen, a name derived from the method of interweaving the picks of pile weft with the warp threads in such a manner that the tufts of pile are thereby interlocked or "lashed" more securely in the foundation texture. Thus, instead of each tuft of pile being looped underneath only one warp thread by the usual method, each tuft in a lashed-pile velveteen intersects with three warp threads in succession.

See H. Nisbet, Grammar of Textile Design (1927). (H. N)

VELVETLEAF (*Abutilon theophrasti*), an annual velvety-hairy plant of the mallow family (Malvaceae; *q.v.*), known also as Indian mallow, native to southern Asia and widely naturalized in the warmer parts of the United States, where it grows as a weed.

It grows from two feet to eight feet high, with heart-shaped leaves and clusters of beaked seed pods with very long-lived seeds. In China it is grown for a fine fibre called chingma, derived from the stem.

VENAISSIN, formerly a province of France, bounded on the north and northeast by Dauphiné, on the south by the Durance, on the east by Provence and on the west by the Rhône. It comprises the present de'partement of Vaucluse. Its capital is Carpentras.

Venaissin is a picturesque territory, varying in scenery between the foothills of the Alps and magnificent plains, which are irrigated by canals supplied by the Rhône, the Durance and the Sorgue

The Comtat-Venaissin (*Comitatus Venassinus*), the territory of the Gallic people, the Cavares, belonged first to the counts of Provence and then to the counts of Toulouse. Ceded to the pope in 1218 by Raymond VII, count of Toulouse, and again in 1274 by Philip the Bold, it was only united to France in 1791.

The town of Avignon (*q.v.*), anciently distinct from the Comtat-Venaissin, was incorporated in it by Pope Clement VI at the beginning of the 14th century. Avignon, a bishopric since the 1st century, became an archbishopric in 1475. Carpentras was a bishopric from 483 till 1805.

For history see L. Loubet, Carpentras et *le Comtat-Venaissin* avant *et après l'annexion* (1891).

VENDACE (*Coregonus vandesius*), a small fish of the salmon family, from the lakes of Lochmaben, in Dumfriesshire, Scotland; the name is also given to an allied form (C. *gracilior*), from Derwentwater and Bassenthwaite. These differ from other British species in having the lower jaw prominent; the scales are larger than in related species from the Arctic ocean and the countries round the Baltic. (See WHITEFISH; SALMON AND SALMONIDAE.)

VENDÉE, a maritime de'partement of western France, formed in 1790 out of Bas-Poitou, and taking its name from an unimportant tributary of the Sèvre Niortaise. It is bounded by Loire-Inférieure and Maine-et-Loire on the north, by Deux-Silvres on the east, by Charente-Inférieure on the south and by the Atlantic ocean on the west for 93 mi. Pop. (1954) 395,641. Area, 2,709 square miles. The islands of Yeu (area, 9 sq.mi.) and Noirmoutier are included. The de'partement stretches from the Hauteurs de la Gâtine (935 ft.) in the northeast doun the wooded slopes of the Bocage Vendéen to the plain, bordered toward the sea by the Marais, largely salt marshes reclaimed during the last four centuries. The Gdtine is a southeast to northwest axial line of the Armorican system, and the Bocage on its flank is formed mainly of Palaeozoic rocks, but the plain on the edge of the Marais is of Jurassic limestone. The three chief rivers are the Sèvre Nantaise, draining the Gdtine longitudinally, the Lay, and, in the south, the Silvre Niortaise. The climate is that of the Girondine region, mild and damp, the temperature rarely rising above 77° or falling below 18° F.; 120 to 150 days of rain give an average annual rainfall of 25 in. The woodland is colder than the plain, and the marsh is unhealthy.

Vendée is served by the Ouest-État railway and has 81 mi of navigable rivers and canals. The *département* forms the diocese of Luqon, has its court of appeal and educational centre at Poitiers, and is in the district of the 11th army corps (Nantes). There are three arrondissements (La Roche-sur-Yon, Fontenay-le-Comte and Sables-d'Olonne), 30 cantons and 306 communes. The chief towns are La Roche-sur-Yon, the capital, Les Sables-d'Olonne, Fontenay-le-Comte and Luqon (*q.v.*). Foussais, Nieul-sur-l'Autise and Vouvant have Romanesque churches; Pouzauges has a stronghold of the 13th century; Maillezais has the ruins of a 12th century cathedral; Talmont and Tiffauges possess ruined castles; and Le Bernard, and Noirmoutier have dolmens.

VENDEE, WARS OF THE, a counterrevolutionary insurrection which took place during the French Revolution (*q.v.*), not only in Vendte proper but also in Lower Poitou, Anjou, Lower Maine and Brittany. The district was mainly inhabited by peasants; it contained few important towns, and the *bourgeois* were but a feeble minority. The ideas of the revolution were slow in penetrating to this Ignorant peasant population, which had always been less civilized than the majority of Frenchmen, and in 1789 the events which roused enthusiasm throughout the rest of France left the Vendéans indifferent. Presently, too, signs of discontent appeared. The priests who had refused to submit to the Civil Constitution of the Clergy perambulated these retired districts, and stigmatized the revolutionists as heretics. In 1791 two "representatives on mission" informed the convention of the disquieting condition of Vendée, and this news was quickly followed by the exposure of a royalist plot organized by the marquis de La Rouerie.

The signal for a widespread rising was the introduction of conscription acts for the recruiting of the depleted armies on the eastern frontiers In Feb. 1793 the convention decreed a levy on the whole of France, and on the eve of the ballot the Vendée, rather than comply with this requisition, broke out in insurrection. In the month of March 1793 the officer commanding at Cholet was killed, and republicans were massacred at Machecoul and St. Florent. Giving rein to their ancient antipathy, the revolting peasantry attacked the towns, which were liberal in ideas and republican in sympathies.

These first successes of the Vendéans coincided with grave republican reverses on the frontier—war with England, Holland and Spain, the defeat of Neerwinden and the defection of Charles Dumouriez. The *émigrés* then began to throw in their lot with the Vendéans. Royalist nobles like the marquis de Bonchamp, Charette de la Contrie, Gigot d'Elbée, Henri de la Rochejaquelein and the marquis de Lescure placed themselves at the head of the peasants. Although several of these leaders were Voltairians, they held up Louis XVI, who had been executed in Jan. 1793, as a martyr to Catholicism, and the Vendtans, who had hitherto styled themselves the Christian army, adopted the name of the Catholic and Royal army.

The Convention took measures against the *émigrés* and the refractory priests. By a decree of March 19, 1793, every person accused of taking part in the counterrevolutionary revolts, or of wearing the white cockade (the royalist emblem), was declared an outlaw. The prisoners were to be tried by military commissions, and the sole penalty was death with confiscation of property. The convention also sent representatives on mission into Vendée to effect the purging of the municipalities, the reorganization of the national guards in the republican towns and the active prosecution of the revolutionary propaganda. These measures proving insufficient, a decree was promulgated on April 30, 1793, for the despatch of regular troops; but, in spite of their failure to capture Nantes, the successes of the Vendéans continued.

At the end of Aug. 1793, the republicans had three armies in the Vendée—the army of Rochelle, the army of Brest and the *Mayençais;* but their generals were either ciphers, like Charles Philippe Ronsin, or divided among themselves, like Jean Antoine Rossignol and Count J. B. Camille Canclaux. They were uncertain whether to cut off the Vendéans from the sea or to drive them west ard; and moreover, their men were undisciplined. Although the peasants had to leave their chiefs and work on the land, the Vendéans still remained formidable opponents. They were equipped partly with arms supplied by England, and partly with fowling pieces, which at that period were superior to the small arms used by the regular troops, and their intimate knowledge of the country gave them an immense advantage.

The dissensions of the republican leaders and the demoralizing tactics of the Vendéans resulted in republican defeats at Chant",,~, Torfou, Coron, St. Lambert, Montaigu and St. Fulgent. The convention resolved to bring the war to an end before October, and placed the troops under the undivided command, first of Jean Léchelle and then of Louis Turreau, who had as subordinates such men as Francois Marceau, Jean Kléber and Francois Joseph Westermann. On Oct. 7 the various divisions concentrated at Bressuire, took Châtillon after two bloodv engagements, and defeated the Vendéans at Cholet, Beaupréau and La Tremblaye. After this repulse, the royalists, under Jean Nicolas Stofflet and Henri Louis Auguste, Marquis de la Rochejacquelein, attempted to rouse the Cotentin and crossed the Loire. Beaten back at Granville, they tried to re-enter the Vendée, but were repulsed at Angers. They re-formed at Le Mans, where they were defeated by Westermann, and the same officer annihilated the main body of the insurgents at Savenay (Dec. 1793).

Regular warfare mas now at an end, although Turreau and his "infernal columns" still continued to scour the disaffected districts. After the 9th Thermidor attempts were made to pacify the country. The convention issued conciliatory proclamations allowing the Vendéans liberty of worship and guaranteeing their property. Gen. Lazare Hoche applied these measures with great success. He restored their cattle to the peasants who submitted, "let the priests have a few crowns," and on July 20, 1795, annihilated an *émigré* expedition which had been equipped in England and had seized Fort Penthièvre and Quiberon. Treaties were concluded at La Jaunaie (Feb. 1j, 1795) and at La Mabillaie, and were fairly well observed by the Vendéans; and nothing remained but to cope with the feeble and scattered remnant of the Vendéans still under arms, and with the Chouans (*q v.*). On July *30,* 1796, the state of siege was raised in the western departments.

During the Hundred Days there was a revival of the Vendéan war, the suppression of which occupied a large corps of Napoleon's army, and in a measure weakened him in the northern theatre of war. (*See* WATERLOO CAMPAIGN, 1815.)

In 1832 again an abortive insurrection broke out in support of the Bourbons, at the instigation of the duchess of Berry; the Vendéan hero on this occasion was the Baron de Charette.

There are numerous articles on the Vendéan insurrection of 1793 in the *Revue du Bas-Poztou, Revue hzstorzque de l'Anjou, Revue de Bretagne de Vendée et d'Anjou, Revue historique de l'Ouest, Revue hzstorzque et arche'ologique du Maine* and *La Vendte hzstorzque. (R. AN.)

VENDETTA (Ital. from Lat. *vindicta,* "revenge," *vindicare,* "to defend oneself"), the term applied to the custom of the family feud, by which the nearest kinsman of a murdered man was obliged to take up the quarrel and avenge his death. From being an obligation upon the nearest, it grew to be an obligation on all the relatives, involving families in bitter private wars among themselves.

It was common to many primitive communities that an injury done was held to be more than personal—a wrong done to the whole gens. The term originated in Corsica, where the vendetta long played an important part in the social life.

If the murderer could not be found, members of his family were liable to fall victims to the vendetta. The feud was sometimes complicated by the *vendetta transversale,* when each of two branches of a family had a murder to revenge on the other. In Corsica it was regarded as the most sacred family duty. Mediators (*parolanti*) sometimes intervened successfully to end the feuds, and extort an oath to forgo vengeance.

See also LAW (PRIMITIVE).

VENDÔME, LOUIS JOSEPH, DUC DE (1654–1712), marshal of France, was the son of Louis, 2nd duke of Vendôme, and the great-grandson of Henry IV and Gabrielle d'Estrées. Entering the army he distinguished himself in the Dutch wars, and by 1688 had risen to the rank of lieutenant-general. In the War of the Grand Alliance he rendered conspicuous service and in 1695, in command of the army operating in Catalonia, he took Barcelona.

Soon afterward he received the marshalate. In 1702, after the first unsuccessful campaign of Catinat and Villeroi, he was placed in command of the Franco-Spanish army in Italy. (*See* SPANISH SUCCESSION, WAR OF THE.) During three campaigns in that country he proved a worthy antagonist to Prince Eugene, whom at last he defeated at Cassano.

Next year he was sent to Flanders to repair the disaster of Ramillies with the result that his successors Marsin and Philip of Orleans were totally defeated, while in the new sphere Vendôme was merely the mentor of the pious and unenterprising duke of Burgundy, and was unable to prevent the defeat of Oudenarde. He retired in disgust to his estates, but was soon summoned to take command of the army of Philip in Spain. There he won his last victories, crowning his work with the battle of Villaviciosa. Before the end of the war he died suddenly at Vinaros on June 11, 1712.

VENEER, a thin sheet of superior wood, covering the surface of inferior wood. Veneers may be sliced with a knife (knife-cut) or cut with a saw (saw-cut) from a section of a tree (flitch).

The art of producing and using veneers dates back to the earliest days of civilization, and it may be looked upon even as a standard of human development, since efficient veneering has always followed the wake of human progress. (*See* Wilkinson's *Manners and Customs of the Ancient Egyptians*, Perrot and Chipiez' *History of Art in Chaldea and Assyria,* etc.) Intarsia and marquetry work are closely allied to and interdependent upon the art of veneering.

In the usual process of manufacture, the flitches are steamed before being cut, and the sheet of veneer thus obtained is carefully dried. Veneers may be cut along the grain, through the log, or from cross sections of the log; the figure and design of the veneer obtained from the different methods employed vary widely and the art of veneering consists as much in the most effective utilization of the log as in the careful and suitable application and matching of the veneers afterward. Veneers are also produced by means of the rotary cutting process as a raw material for plywood. A part of a log is inserted lengthwise between two pins on a rotating lathe, and a knife, pressed against it, peels off an endless ribbon of veneer. (*See* PLYWOOD)

See Sidney J. Duly, *Timber and Timber Products* (1924); E. Vernon Knight and Meinrad Vulpi, *Veneers and plywood* (1927); E. Brocard, *L'Art de découper le bois comprenant également la Marquêterie et la Sculpture Simple* (Paris, 1873). (A. MOR.)

VENER (VÄNERN), the largest lake in Sweden and the third largest in Europe. The area is 2,141 sq mi., the maximum length, 87 mi., the maximum breadth, 47 mi. and the maximum depth, 322 ft. The surface of the lake is normally 144 ft. above the sea but may rise 10 ft. or more higher, for the lake receives numerous streams, the largest being the Klar, which drains the forests of Varmland and Kopparberg to the north. It is drained by the Gota (*q.v.*) river to the Cattegat.

The Vener is divided into two basins by two peninsulas and a group of islands. the western half being Lake Dalbo. The northern shores are high. rocky and in part wooded; the southern shores are open and low. though isolated hills occur such as the Kinnekulle (1,007 ft.).

By means of the Dalsland canal from Kopmannabro, midway on the west shore of Dalbo. communication between the lake. which has an extensive traffic in timber. iron and agricultural produce, and Halden in Norway nas established. The lake is traversed from Vanersborg on the south to Sjotorp on the east by the Gota canal route

The principal lake ports are. on the north shore, Karlstad and Kristinehamn. nith ironworks and tobacco factory; on the east, Mariestad, chief town of the district of Skaraborg; on the south, Lidkoping and Vanersborg with its iron foundries, tanneries and match and paper factories.

VENERABLE, worthy of honour, respect and reverence, especially a term applied to dignified or honourable age (from the Latin *venerabilis,* "worthy of reverence"). *See* CANONIZATION.

VENERABLE BEDE: *see* BEDE.

VENEREAL DISEASES comprise a number of contagious diseases that are most commonly acquired in sexual intercourse.

Included in this group are both a destroyer of life (syphilis) and a preventer of life (gonorrhea). The group includes at least three other diseases: chancroid, lymphogranuloma venereum and granuloma inguinale. These five are linked not because of similarity of causative agents, tissue reactions or symptoms produced, but because the principal means of spread of each disease is by sexual intercourse, especially promiscuous sexual intercourse, as implied by their group name, "venereal." Not only are the causative organisms different morphologically but they also represent five distinct classes of microorganisms: spirochetes, cocci. bacilli, viruses and the Donovan body (perhaps a bacterium).

Although much progress has been made in the control of venereal diseases, especially syphilis, and although the decline of syphilis in the United States has been outstanding, there is no evidence that gonorrhea is declining, nor do available world statistics indicate an over-all decline in the venereal diseases. Even in those countries where incidence has been reduced to a lon level, these diseases still represent a potential danger because the means of transmission is dependent upon intimate personal relationships that rarely, if ever, change.

This article is organized as follows:

I. SYPHILIS

A. History and Occurrence

Syphilis is a generalized systemic discasc initiated by infection with a microorganism known as *Spirochaeta pallida* or Treponema pellidurn. Two distinct forms of syphilis are recognized. The form that is spread venereally is of world-wide occurrence. The other, often referred to as endemic syphilis and bejel, is of nonvenereal spread and confined to parts of the world where economic, social and climatic conditions favour its development; it is not seen in the United States. Endemic syphilis and bejel are acute diseases of limited geographical distribution, predominantly household occurrence, and characterized clinically by an eruption of skin and mucous membranes, usually without evident initial primary sore. Early skin and mouth lesions are indistinguishable from those of venereal syphilis. In endemic syphilis, unlike venereal syphilis, the nervous and cardiovascular systems seem rarely to be involved and fatality is negligible. Serologic tests for syphilis are reactive in the early stages and remain so for many years of latency, gradually tending toward nonreactivity; response to treatment is as in venereal syphilis (see Bejel).

1. Causative Organism. — The causative organism of syphilis is a delicate corkscrew-shaped microbe with clear-cut, regular, tightly wound coils. It varies in length from 5 to 25 microns, usually two to three times the diameter of a red blood cell. It can be seen in the living state only under the dark-field microscope. It has a characteristic motion made up of three components: (1) slow undulation; (2) rotation on its own long axis like a corkscrew; and (3) slow propulsion backward or foraard.

The virulent organism has probably never been cultured on artificial mediums. It has one important biologic characteristic that appears to be solely responsible for the classification of syphilis as a venereal disease, namely, its requirement of moisture for life and transmission. The organism is killed by many chemicals, including soap, and by heat but not by cold. In the tissues it remains alive often for the lifetime of the infected person unless destroyed by treatment.

Endemic syphilis and bejel are initiated by a microorganism morphologically indistinguishable from the treponemes of venereal syphilis and those of yaws and pinta (*qq.v.*). These five disorders are closely related both from a historical viewpoint and from the viewpoint of control activities. This latter importance is emphasized by the fact that both the activities and the title of this control section of the World Health organization (WHO) is "Venereal Disease and Treponematoses."

2. Historical Background. — A historical review by E. Herndon Hudson (*Treponematosis,* 1946) gives the potential development of treponematosis and the social and environmental conditions that led to the different disease processes' being initiated venereally and nonvenereally by microorganisms indistinguishable from each other. The actual historical origin of syphilis is still obscure. There is no indisputable reference to this disease in European literature prior to the return of Christopher Columbus from the new world, but evidence of treponematosis has been found in the skeletal bones of pre-Columbian American Indians. These facts, coupled with its appearance in epidemic form in Europe shortly after Columbus returned. lend some support to the theory of the American origin of syphilis.

Hudson presents evidence against the theory of American origin. In view of the fact that leprosy prior to the time of Columbus was considered highly contagious. mas associated with sexual contact, had hereditary features and was said to respond to mercury therapy. it is likely that the so-called leprosy of that period was actually syphilis, since these are the characteristics of syphilis and not leprosy. In the 300 years following the post-Columbus outburst much was learned about syphilis: signs and symptoms were recognized; its infectiousness was proved; means of transmission were clarified; the duality of syphilis and gonorrhea was reaffirmed; the lesions of congenital syphilis were described; and treatment with mercury was widely used. In 1834 potassium iodide was introduced into the treatment of syphilis. Chancroid was differentiated from syphilis in 1852. In 1905 F. Schaudinn discovered *Treponerna pallidum,* thus making diagnosis more certain. In 1906 A. Wassermann, A. Neisser and A. Bruck introduced the Wassermann reaction. In 1909 Paul Ehrlich gave to the world Salvarsan (606) (*q.v.*). The history of drug treatment for syphilis may be divided into three periods: (1) that of mercury ending 1909 with the discovery of 606 by Ehrlich; (2) that of arsphenamines. 1910–43; and (3) that of the antibiotics beginning with the discovery of J. F. Mahoney and others.

3. Occurrence, Distribution and Trends. — Information of this kind, which defines the extent and significance of disease problems, requires the reporting of cases of the disease to a central agency, usually a department of health. Laws requiring compulsory notification vary throughout the world. and requirements may vary from year to year. Thus data on occurrence, distribution and trends may be very difficult to analyze on a comparative basis.

International.—It was estimated in the mid-1950s that 20,000,000 cases of syphilis existed in the world. There appeared to be a downward trend in the Scandinavian countries, Canada, Finland, France, Italy, Poland, the United Kingdom, the United States and several other countries, although according to a World Health organization study it aas difficult to appraise the statistical information accurately. Despite these apparent trends for each country as a whole, there was evidence of continuing problems in smaller local areas. From the international point of view there are extensive reservoirs of syphilis infection, both venereal and nonvenereal, in several vast regions of the world that are potential hazards to the remainder of the world if they are not brought under control. Occurrence is usually higher in ports than in inland cities. In the Americas in the mid-1950s there were rising syphilis rates in 11 countries out of 25 for which data were available. In 5 of 20 countries death rates from syphilis had risen.

United States. —The true incidence of syphilis (*i.e.,* the number of new cases occurring within a specified time) is not known because not all cases are detected in the early stages and also because many of those detected in the early stages are not reported to the health departments. When questioned, 31 state health officers stated they believed the numbers of reported cases mere not accurate indexes of the size of the syphilis problem in their states.

All states require that syphilis be reported, and each state submits to the U.S. public health service a quarterly summary of the cases reported to it. All cases not previously reported are included. Cases and rates for the country as a whole conceal what is happening in individual states. For example, rises in syphilis rates were reported in 17 states in 1953; in 20 states in 1954; in 13 states in 1955; and in 19 states in 1956—however, it was not until 1956 that these rises were reflected in the rates for the U.S. as a whole. In 1958 there was a national decline, but there were increases in 18 states and in 24 major cities.

Incidence of Syphilis in the U.S.

Year	No. of cases reported	Rate per 100,000 pop.
1945	359,114	282.3
1955	122,075	76.0
1958	125,542	82.02
	126,072	74.0

In 1953 the highest rates for early syphilis were in ages 20 to 24 (primary and secondary 24.46, early latent 88.83 per 100,000) and the next highest in ages 15 to 19 (primary and secondary 16.26, and early latent 45.89 per 100,000). In 1958, 22 states and 13 major cities reported increases in the 15–19 age group and 12 states and 13 cities reported increases in the 10–14 group.

Great Britain.—In England and Wales there was a steady decline in reported infectious syphilis from 1946, the year of highest postwar incidence, to 1955, when there was a slight rise. In 1957 Ambrose King made a critical review of the venereal disease problem and stated, "Thus, though at present there is no reliable evidence of a tendency to rise, it does seem that the progressive fall has come to an end." (Ambrose King, "These Dying Diseases: Venereology in Decline?", Lancet, 1958, i, 651–657.) Late and latent syphilis declined consistently from 1952 until 1955. Rises occurred in 1955 and again in 1956, when there were 4,297 reported cases, about the same number as in the mid-1940s. Congenital syphilis showed a steady decline after 1949, with no rise in 1955 or 1956. Cardiovascular syphilis, however, remained a serious problem, according to King. As a result of his survey King made a final statement, which shows the similarity of the problem in the United States and Great Britain and. indeed, in many parts of the world: "The postwar decline in incidence, and the introduction of new remedies, have inspired a false confidence and a move to dismantle some of the organization which has served the public well in the control of these diseases." (Ambrose King, "These Dying Diseases: Venereology in Decline?", Lancet, 1958, i, 651–657.)

Reported Mortality and Insanity Caused *by Syphilis*.—Mortality statistics are generally admitted to be inadequate, but the data compiled by the National Office of Vital Statistics (U.S.) from duplicates of death certificates filed with state and local registrars show a decline in syphilis mortality from a high of 10.7 per 100,000 in 1940 to 2.1 in 1958. Infant mortality has declined from 0.53 per 1,000 live births in 1940 to 0.006 in 1956. First admissions to mental hospitals due to syphilis declined from 6.1 per 100,000 population in 1940 to 0.8 in 1956. These are encouraging data, but a remaining serious problem is obvious when the losses due to uncontrolled syphilis are estimated: for example, in the United States the estimated man-years of disability due to insanity from syphilis were 32,000; losses due to syphilitic heart disease were 7,000; and those due to syphilitic blindness were 26,000. Loss of life expectancy is estimated at 68,850 man-years per year and loss of income to age 6j (based on 1956 income rates) $80,618,000. Other estimated economic costs are: maintenance of patients with syphilitic psychoses $47.555,000 yearly; maintenance of syphilitic blind $12,500,000. These are very conservative cost estimates, since they are based on maintenance costs in state institutions.

In England and Wales mortality from general paresis and tabes dorsalis declined steadily from 1940 to 1954, but after 1954 there was very little change in general paresis and only a slight decline for tabes dorsalis. Deaths from syphilitic aneurysm did not decline for males and rose for females after 1942.

There is no doubt that many persons receive no treatment for their syphilitic infections. Based upon a sound study of untreated syphilis in Norway, the following outcomes might be expected to occur among the untreated: heart disease, males 14.9%, females 8%; neurosyphilis, males 9.4%, females 5%; and deaths from syphilis, males 15.1%, females 8.3%.

B. The Disease Process

Before infection with syphilis takes place there are several factors that determine the transmission of the disease. The spirochete requires moisture to exist, so continuous moisture is a necessity for a transfer of the organism from one person to another. The social and economic environment in which people live plays a part in transmission. There is definitely more syphilis and greater hazard of infection in low social-economic groups and in communities where adequate venereal disease control measures have not been instituted. Organisms may be abundant in an area but no transmission takes place unless habits, customs. attitudes, sex education, etc., of people permit them to have sexual relations with infected persons.

1. Primary Syphilis.—After the germ (the spirochete) has gained admission to the body, usually through sexual intercourse, it reproduces itself at the admission site and within a matter of hours begins to spread by means of the blood stream throughout the body; it does not produce symptoms until after about 21 days (range of incubation ten days to ten weeks). The first manifestation is the primary sore (chancre). which appears at the site of the entrance of the germ. This highly infectious primary sore may be a typical chancre (painless, ulcerated. firm, with enlarged neighbouring lymph nodes), or it may be so slight as to go unnoticed. There are at least 13 diseases that primary genital syphilis may resemble and at least 12 from which the extragenital primary lesions must be distinguished. Any lesion of the genitalia of male or female should be regarded as possible primary syphilis until it is proved to be something else, and any chronic lesion anywhere on the body, particularly lips, tonsils or fingers, that fails to heal may be a primary syphilis lesion. Blood tests are usually not positive when the primary lesion first appears but become positive after several days. Even without treatment this sore heals and usually leaves no scar, but the disease is still present in the body.

2. Secondary Syphilis.—The spread of the spirochete throughout the body before the primary sore appears paves the way for secondary syphilis in the skin, mucous membranes, eye and nervous system. The organism multiplies in these areas of the body, and in about six weeks (or even months) after the appearance of the chancre the secondary signs and symptoms appear. In about one-half of the infected persons there are mild constitutional symptoms such as headache, vague pains in bones and joints, and sore throat. The skin rash is usually but not always symmetrical, generalized, does not itch, does not contain blisters and is often difficult to see. The palms and soles are often affected. The only visible lesions of secondary syphilis may appear on the mucous membranes of mouth or genitalia. the skin being entirely spared.

Other more or less common manifestations of secondary syphilis are a moth-eaten type of loss of hair from the scalp, external or internal inflammation of the eye, pain from bone involvement, jaundice from liver involvement, edema (swelling) and albumin in the urine from kidney involvement, and syphilitic meningitis with severe headache, convulsions, deafness, partial paralysis and sometimes coma.

The great variety of potential signs and symptoms in all stages of syphilis is the reason why the disease has been called "the great imitator." There are at least 40 skin diseases that secondary syphilis may resemble; 23 diseases that the mouth lesions may resemble; and at least 16 diseases that genital lesions may resemble.

The manifestations of secondary syphilis persist for a variable period of time, ranging from a few days to several months. and then disappear spontaneously. These early lesions of syphilis are characterized by a mild tissue reaction and the presence of large numbers of T. *pallidum*, the infectious agent. They are superficial, nondestructive, highly infectious lesions and usually heal without scarring. With healing the treponemes usually disappear from the skin and mucous surfaces.

During the first few years of untreated syphilis there may be a series of recurring infectious lesions of skin or mucous membranes (secondary relapse). According to the Norwegian study, this occurs in about one out of every four untreated syphilitics. It is from the often trivial-appearing and usually painless but highly infectious lesions of primary and secondary syphilis that infection of other persons occurs.

The diagnosis of early syphilis is a laboratory procedure, but careful physical examination suggests the diagnosis. Proof of the presence of early syphilis is obtained by demonstrating the causative microorganism in serum from a suspected lesion by a special attachment to the microscope known as the dark-field condenser. In ordinary light this micoorganism is invisible.

The failure to discover the organism by repeated dark-field examinations does not rule out syphilis. Repeated tests of the blood must also be made. These serologic tests are frequently negative during the first ten days after the appearance of the chancre and should be repeated at frequent intervals. By the fifth week the blood test is almost always positive.

In secondary syphilis it is strongly positive in more than 99% of the cases. In most instances one positive blood test should be confirmed by another before treatment is begun.

3. Latent Syphilis. — Following the spontaneous healing of the early lesions a period ensues, ranging in length from a few months to a lifetime, during which no outward sign of syphilis is recognizable. Syphilis recognizable only by means of routine serologic tests of the blood is known as latent syphilis. Unfortunately, it is in this noninfectious period that most cases of the disease are brought to medical attention. The majority of patients with latent syphilis do not progress to the development of late symptomatic manifestations, even if untreated. According to the Oslo study, at least 72 out of 100 untreated persons go through life without symptoms of late syphilis, but 28 out of 100 were known to have developed serious outcomes and there is no way to predict what will happen to an untreated infected person.

Women with latent syphilis, if untreated, frequently give birth to congenitally syphilitic children.

During this long latent period the disease loses some of its infectiousness. After the first few years the organism is rarely transmitted through sexual intercourse, but a syphilitic expectant mother can still transmit it to her unborn child.

4. Late Symptomatic Syphilis. — Of every 100 persons acquiring syphilis, at least 15 may be expected to develop, if untreated, a late (tertiary) manifestation that will incapacitate or kill, and 13 may be expected to develop a more benign late manifestation that may appear from 3 to 30 or more years after infection; almost any part of the body may be affected. Of the former group, the most important manifestations are cardiovascular syphilis (heart and blood-vessel involvement), neurosyphilis (brain and spinal-cord involvement) and ocular syphilis (eye involvement). The latter group of manifestations is called gummatous syphilis or benign late syphilis (skin, mucous membrane and bone involvement).

Cardiovascular Syphilis. — The fundamental lesion in most cardiovascular syphilis is located in the thoracic aorta, the largest blood vessel, directly adjacent to the heart. The elastic tissue is destroyed and the aorta dilates. **A** localized saccular dilatation (aneurysm) may occur, or the process may involve the aortic valve and a leakage may develop. The symptoms differ in no recognizable way from the symptoms of heart and vascular disorders of other origins. The diagnosis depends upon the findings on physical examination, fluoroscopy, X-rays, electrocardiography and blood serologic tests. The prognosis of cardiovascular syphilis is poor, and sudden death is not uncommon.

Neurosyphilis.—This may mimic any other neurologic disorder. It is responsible for many deaths and much invalidism. The presence of neurosyphilis may be detected by routine spinal fluid examination years before the appearance of obvious clinical damage in the nervous system. For this reason spinal punctures are an essential part of the examination in all syphilitics.

Paresis (general paralysis of the insane), the most dreaded late manifestation of syphilis, may strike down its victims in the prime of life. The symptoms are due to widespread destruction of the brain by large numbers of T. pallidurn. The mental changes are varied, perhaps the commonest being a gradual change in personality. First noted frequently is a decreased ability to work and impairment of concentration and judgment. The commoner signs of abnormal behaviour include delusions, loss of memory, lack of insight, apathy or violent rages, disorientation and incontinence. Convulsions are not uncommon. Temporary remissions may occur, but the course, unless arrested by treatment, is inevitably downhill to eventual death. The diagnosis is based upon neurologic, psychiatric and spinal fluid examinations.

Tabes dorsalis (locomotor ataxia) is the commonest manifestation of syphilis in the spinal cord, typically a degeneration of the posterior columns. Similar degeneration of the optic and other cranial nerves is common. The disease, though commonly progressive, may undergo arrest in any stage. The commoner symptoms include flashes of shooting, shifting pain, usually in the legs, difficulty in urination, numbness in hands or feet, a sense of constriction about the waist, unsteadiness on the feet with a wobbly broad-based gait, constipation, blurred or dim vision from atrophy of the optic nerve, double vision, drooping of the eyelids, loss of sexual power, loss of weight, deafness, severe sudden attacks of intense abdominal pain and vomiting and disintegration of one or more joints. Tabes is often confused with ulcerated stomach, gall-bladder disease, kidney stone and appendicitis. Differential diagnosis requires careful neurological and laboratory examinations.

Benign Late Syphilis. — The characteristic lesion of late syphilis of skin, mucous membranes or bone is the gumma. Gummata are noninfectious, and the name benign late is used because in most instances life is not endangered. Various organs may be involved, particularly the liver, testes or brain. The gummatous structure consists of granuiation tissue characterized by dense plasma and round cell infiltration, especially around the blood vessels, with impairment of blood supply and usually tissue breakdown. The symptoms depend upon the site involved. On the skin and mucous membranes gummata appear as chronic, usually painless, often ulcerated lesions, which may result in extensive disfigurement if treatment is delayed and particularly if the patient, because of incorrect diagnosis, is subjected only to surgery or X-ray therapy.

When bone is involved, deep-seated aching pain is usually, but not always, present. If the skull bones are involved, there is severe headache. There is tenderness to pressure over the involved bones, and often an obvious swelling with local heat. The diagnosis of gumma is based upon the appearance of the lesion, the positive blood serologic test and, often, upon the results of X-ray examination.

5. Syphilis in Pregnancy and Congenital **Syphilis.**—Prenatal paternal transmission of syphilis to infants does not occur directly but only through maternal infection. Untreated syphilis can have very serious effects on the outcome of pregnancy. Infection of the child may occur at any time from about the third month to the day of delivery.

Recognition of the existence of syphilis during pregnancy is usually possible only by a routine blood serologic test, which should be performed on all pregnant women.

If the mother's infection is untreated, the probability of premature stillbirth is increased fourfold over the normal, the probability of infantile death is almost doubled, and almost 20% of surviving children suffer from congenital syphilis. Adequate treatment of the syphilitic pregnant woman reduces syphilis as a cause of fetal death to a relatively minor role.

A congenitally syphilitic infant may show lesions at birth; may appear normal at birth and develop lesions within a few months; or may remain asymptomatic until adolescence, when late manifestations usually appear.

In general, the clinical manifestations of congenital syphilis parallel those of the acquired infection. The lesions of infantile congenital infection are comparable with, and as infectious as, the secondary lesions of acquired syphilis. Congenital syphilis passes through a latent stage and produces late lesions analogous to those of acquired syphilis.

The infant with clinically apparent congenital syphilis is usually malnourished, has lesions on the skin and mucous membranes, "snuffles" and bone lesions. The latter are often detectable only by X-ray, but sometimes there is loss of function of the affected extremity. Clinically manifest infantile congenital syphilis is usually easily diagnosed. Blood serologic tests are not diagnostic before three to four months of age because of the possible presence of maternal antibody in the infant's blood.

With adequate treatment, the prognosis in early congenital syphilis is, on the whole, favourable, although less so than in early acquired syphilis. Without treatment. a majority of congenital syphilitics ultimately develop some late manifestations in childhood, adolescence or early adult life. In order of decreasing frequency the common lesions are ocular, particularly involvement of the cornea, which exceeds in frequency all other manifestations combined; neurosyphilis, including juvenile tabes and juvenile paresis; nerve deafness; bone and joint lesions; and gummata of skin and mucous membranes.

The late congenital syphilitic usually bears some evidence of antecedent infection. Such changes are known as stigmata. The more important ones are extremely high brow; corneal scarring; flattened (saddle) nose; notched, widely spaced, peg-shaped upper central incisor (Hutchinsonian) permanent teeth; mulberry-shaped first molar teeth; deafness; radiating scars about the mouth (rhagades); a dish-shaped face; and anterior bowing of the tibia known as sabre shin. These stigmata do not mean that active infection exists. The diagnosis in late congenital syphilis is based upon the clinical picture and the positive blood serologic test. The prognosis in late congenital syphilis, with the exception of juvenile paresis, is good, although blindness is not uncommon and deafness occasionally occurs. Third-generation syphilis, barring reinfection in the second generation, is of doubtiul occurrence.

C. Diagnosis

Syphilis, "the great imitator," requires physical examinations and laboratory tests for diagnosis. Laboratory tests are made of serum taken from early lesions (dark-field examination) and of blood (serologic tests) and spinal fluid.

1. Dark-field Examinations. — These examinations are performed in an attempt to find the microorganism of syphilis in serum from a suspected lesion. In primary and secondary syphilis the organism is abundant in the tissues, lymph glands and skin lesions. Serum obtained from these lesions by excoriating the surface of the lesion or by puncture and aspiration from the glands is examined under a microscope with a special dark-field condenser attached.

2. Blood Serologic Tests. — The diagnostic (Wassermann, flocculation) tests for syphilis are highly specific and sensitive, but many factors other than syphilis may cause a false positive reaction. Technical error is by no means uncommon. In the absence of clinical findings, a single positive report should never be accepted at face value. Quantitative serologic tests for syphilis are helpful in certain circumstances.

In a few apparently healthy persons (1:3,000 to 1:5,000) and in many others under the influence of various infections and other nonsyphilitic conditions, false positive serologic tests occur that may disappear within a few days or months or may persist for many years. False positive reactions are common in leprosy, acute malaria, infectious mononucleosis, smallpox vaccination, ratbite fever, disseminated lupus erythematosus, upper respiratory infections and virus pneumonia. They occur with less frequency in a number of other conditions. Yaws, pinta and nonvenereal syphilis uniformly produce positive serologic tests for syphilis.

The physician should diagnose syphilis not from the blood serologic tests alone but only after careful consideration of the entire clinical picture, including a physical examination, often supplemented by spinal fluid examination, epidemiologic investigation of the family and sexual contacts, and by special procedures such as the *Treponema pallidum* immobilization (T.P.I.) test.

3. Spinal Fluid Examinations. — Examinations of the spinal fluid obtained by lumbar puncture is an essential part of the examination of all syphilitic patients. This permits the detection of central nervous system involvement years before the appearance of neurologic signs or symptoms.

D. Treatment

The purpose of treatment is to kill all remaining spirochetes, to initiate the healing of existing lesions and to prevent further damage and spread of the pathologic process. Treatment of early syphilis also serves to prevent spread of the disease to others. The earlier treatment is started, the more effective it is in accomplishing these purposes.

In the mid-1940s penicillin began to replace the arsenical products (arsphenamine, neoarsphenamine, oxyarsphenamine) and bismuth preparations in the treatment of syphilis. The arsenicals and bismuth were used either alternately or concurrently and were generally administered in weekly injections over a period of many months or years. The results of this type of treatment, when complete, were good, but the side effects were many and the course was long, so that a large percentage of patients did not complete their treatment.

Penicillin, with relatively few side effects and with equally good but more rapid results, has proved most etiective in the treatment, control and prevention of this disease. At first some medical authorities advocated combining penicillin with the arsenicals or bismuth or both, but experience has shown this to be unnecessary. The use of penicillin alone in the treatment of syphilis is practically universal. The widespread use of penicillin for treatment of a variety of other disorders has frequently added some difficulties in the diagnosis and subsequent management of syphilis because under these circumstances the syphilitic infection may be masked completely or its course changed.

Several types of penicillin have been used effectively in treatment, and a number of schedules of injections has been recommended. The primary consideration is not the exact schedule of injections but rather the maintenance of a penicillin level in blood and tissues for a minimum duration, depending on the stage of the disease; *e.g.*, in early syphilis the minimum is seven to ten days, while in some forms of late syphilis blood and tissue levels must be maintained for several weeks. To obtain these levels over the required periods, the frequency of injections and dosage depend upon the type of penicillin used. Research workers continued their efforts to find a penicillin product that will maintain these levels with a minimum number of injections.

The first type of penicillin used required an injection every two or three hours to maintain the required level; then with penicillin in peanut oil and beeswax it was necessary for it to be given only every 12–24 hours. The next product was procaine penicillin with aluminum monostearate (PAM), which could be given every two to four days. In the mid-1950s benzathine penicillin became available. For primary and secondary syphilis it is relatively easy to maintain the required level for seven to ten days with a single dose of benzathine penicillin; for later stages the required blood levels must be maintained for several weeks.

After the completion of treatment the patient should be periodically examined and have periodic blood tests performed so that further treatment may be given if necessary. Retreatment usually is given only for clinical relapse, serologic relapse, seroresistance at a high level or an abnormal spinal fluid. On the average, after successful treatment the blood test becomes negative from four to seven months later. Patients who are treated adequately for early syphilis are susceptible to reinfection by the usual routes.

If the pretreatment spinal fluid has been negative it is unnecessary to repeat this examination. Further treatment usually is given only in case of clinical relapse or progression. In all forms of late syphilis, a persistently positive blood test is the rule rather than the exception. This persistence does not usually mean a poorer prognosis. In some instances the tests become negative after a number of years, but this change is not necessarily hastened by additional treatment.

Cardiovascular syphilis (aortic insufficiency and aneurysm) is the most frequent basic cause of death from acquired syphilis. It can be prevented by the adequate treatment of early syphilis, and in most instances prevented even by treatment first given in the latent stage. Once overt cardiovascular involvement has developed, life may still be prolonged by a judicious combination of cardiac care and penicillin therapy and careful observation after treatment.

The various forms of neurosyphilis respond well to penicillin. Some authorities continued to recommend fever therapy in an occasional case. After treatment, periodic re-examination of the spinal fluid and neurologic and psychiatric examinations are essential as guides to the necessity for further therapy. Retreatment is given usually only in case of inadequate spinal fluid response.

Since destroyed nerve cells and tissues cannot be rebuilt, multiple courses of therapy given because of incomplete clinical response usually accomplish little. Best results are obtained when treatment is given early, before irreparable damage has been done. Thus early diagnosis is very important.

Congenital syphilis can be prevented almost completely by the routine serologic testing of all pregnant women and prompt treatment if syphilis is found. Penicillin is very effective. No infant should be treated for congenital syphilis until the diagnosis is proved. Best results are secured when treatment is given before the sixth month of age.

II. GONORRHEA

Gonorrhea (clap, "a dose," gleet, morning drop, running range) is an acute, self-limiting venereal disease that frequently progresses into a chronic state. It is initiated by a microorganism with a predilection for the type of mucous membranes found in the genitourinary tract and adjacent areas. This microorganism is known as the gonococcus (Neisseria gonorrhoeae).

All gonococcal infections except eye infections in newborn infants (ophthalmia neonatorum), some instances of vulvovaginitis of young girls living in institutions, and occasional accidental eye infections in adults are the result of direct sexual contact.

A. History and Occurrence

1. Historical Background. — Gonorrhea has apparently existed since prehistoric times. It was familiar to the Chinese more than 5,000 years ago, and was known to the ancient Arabs, Greeks, Hindus, Romans and other peoples of ancient times. It ranks among the oldest diseases. Hippocrates in 460 B.C. was aware of the existence of the disease, and Galen in A.D. 200 introduced the name by which it is known today. The name is based upon the belief that the discharge was an involuntary flow of semen (*gonos,* "seed"; *rhoia,* "flow"). The relation to sexual exposure was not understood until many years after this. It was not until 1790, however, that it was considered to be distinct from syphilis, and not until 1831 that the difference was proved. The isolation of the gonoroccus was made by Neisser in 1879.

2. Occurrence, Distribution and Trend. — Gonorrhea is an extremely common disease, present in all parts of the world. Its incidence is unknown because of self-treatment, undiagnosed cases (mainly in females) and very defective case reporting. According to statistical data of the World Health organization, there is no evidence that gonorrhea is declining in the world at large. In the mid-1950s there were increases in gonorrhea in one-third of the countries from which data were available. In the U.S. it was estimated in the mid-1950s that more than 1,000,000 cases occurred each year, about one-fourth of which were reported. During the decade 1948–57 the reported cases showed a downward trend, the significance of which was dubious (1948, 363,014 reported cases; 1957, 216,476). The mortality from gonorrhea is negligible, but its indirect effects on the population by its not infrequent sterilization of both sexes, particularly women, are incalculable.

B. The Disease Process

The same preinfection causative factors are important in gonorrhea as in syphilis. The gonococcus is sensitive to conditions outside the human body. Infection, therefore, usually requires direct deposit of the organism on or about the susceptible tissues of the genitalia, rectum and occasionally about the eyes either accidentally by deposit from hand to eye or in the eye of the newborn as a result of its passage through an infected birth canal (ophthalmia neonatorum). Gonococcal vulvovaginitis of children occurs as a result of intimate direct contact of children with infected adults, and as a result of the insertion of contaminated instruments and foreign bodies into the vagina and rectum.

The incubation period of gonorrhea is usually three to five, but occasionally two to ten, days. The signs, symptoms and outcome in male and female differ.

1. Male Gonorrhea. — The first symptoms are burning on urination and a purulent urethral discharge that may be severe or so mild as to go unnoticed. In the absence of treatment, the infection usually extends deeper to involve the posterior part of the urethra, the neck of the bladder and the prostate gland. Urgency and frequency of urination and, occasionally, hematuria (bloody urine) may follow. Complications are influenced by sexual excitement, alcohol and heavy lifting with a full bladder. Spontaneous recovery may occur within a few months to a year. Possible local complications are abscess of the prostate gland or seminal vesicles and inflammation of the spermatic cord and epididymis (which lies next to the testicle in the scrotal sac).

2. Female Gonorrhea. — The initial symptoms in most instances are so mild as to go unnoticed. Slight vaginal discharge and burning may be present. The disease is not usually suspected by either patient or physician until complications occur or a sexual partner is infected. Abscess of a vulvovaginal (Bartholin) gland occurs rarely as an early complication. Many women recover spontaneously from gonorrheal infections that extend no farther than the cervix (mouth of the womb). In many, however, there is extension through the uterus (womb) to involve the Fallopian tubes and ovaries. Fever usually accompanies these extensions to the pelvic organs, and lower abdominal pain is a prominent symptom. Pelvic abscess or peritonitis may result. The clinical picture is not infrequently confused with appendicitis. Eventual healing occurs without resort to surgery in most cases, often with some physical disability and sterility. In immature girls the infection is usually confined to the vagina.

In both male and female, arthritis is the commonest extragenital manifestation of gonorrhea. The process usually settles in one or two joints and may result in permanent disability in the absence of treatment. Involvement of the tendon sheaths in the region of the affected joint or joints is not uncommon.

3. Gonococcal Ophthalmia Neonatorum. — This condition (conjunctivitis in newborn infants) is one of several acute inflammatory conditions of the eye occurring within the first three weeks of life. The external eye and the eyelids become very red and swollen, and there is a profuse discharge. In the absence of treatment, complete blindness is the usual outcome. Its occurrence has been greatly reduced through the routine use of 1% to 2% silver nitrate (or equivalent preparation) in the eyes of infants at birth, a measure almost universally required.

4. Other Complications. — A few other very rare complications of gonorrhea are iritis, endocarditis (involvement of the heart valves), meningitis and skin lesions.

C. Diagnosis and Treatment

There is a nongonococcal urethritis that resembles gonorrhea, and its widespread occurrence seriously complicates the clinical diagnosis in the male. In addition to searching with a microscope for the double bean-shaped gonococcus in Gram-stained smears, it is frequently necessary, particularly in females, to isolate the suspected organism and try to culture it in an incubator.

Penicillin is the drug of choice for treatment, one injection usually being sufficient to cure uncomplicated gonorrhea. Gonorrhea with complications (eye involvement, prostatitis, arthritis, etc.) requires treatment over longer periods depending on the extent of damage and duration of signs and symptoms. Evidence of the success of prophylactic treatment of all persons exposed sexually to an infected person is rapidly accumulating, and many experts insist on immediate treatment of exposed persons with penicillin before diagnostic measures are undertaken. Furthermore, it is futile to treat one member of a sexual alliance for gonorrhea and neglect the treatment of the other, because reinfection of the treated person will surely occur. Patients sensitive to penicillin may be effectively treated with several other antibiotics. The sulfonamide drugs are far inferior to penicillin in the treatment of gonorrhea.

The administration of the small amount of penicillin necessary to cure gonorrhea may mask the early manifestations of coexisting syphilis and delay its diagnosis. An integral part of the treatment of gonorrhea, therefore, is the so-called serologic follow-up—a blood test for syphilis at least once a month for four months,

III. OTHER VENEREAL DISEASES

A. Chancroid

Chancroid (soft chancre, ulcus molle, chancre mou, soft sore) is an acute. specific, localized, self-limiting, autoinoculable infectious disease usually acquired through sexual contact. It is initiated by a microorganism known as the Streptobacillus of Ducrey (*Hemophilus* ***ducreyi***).

1. History.—In medieval times the distinction of chancroid from the initial lesion of syphilis was not made. Gonorrhea and syphilis were differentiated about 1831, but it was not until after 1850 that a soft chancre was distinguished from the initial lesion of syphilis and later designated chancroid. In 1889 Ducrey identified the microorganism that later was accepted as the causative agent. The genital ulcerations are variable in appearance and even now are occasionally confused with those of other venereal diseases unless all available diagnostic measures are utilized.

2. Occurrence, Distribution and Trend.—Chancroid occurs endemically throughout almost the entire world, being especially common in tropical and subtropical countries and commoner in seaports and urban areas than in rural areas. It is primarily a disease of the underprivileged and the unclean. In many countries it is not a reportable disease. Exact data as to its occurrence, distribution and trends are not available, but it is known to be common and universally distributed. In 1945, 5,515 cases were reported in the continental United States. In 1947 there were 9,039 and, in 1956, 2,322 reported cases. The trend of reported cases has been continuously downward, but these represent only a small fraction of actual cases because reporting is not required in all states. In British and U.S. armed forces stationed in tropical zones the incidence of chancroid was sometimes vastly greater than that of syphilis.

3. The Disease Process.—The same preinfection causative factors are important in chancroid as in syphilis, but chancroid can be definitely prevented by the proper use of soap and water immediately after exposure. About three to five days after exposure (sometimes later) there appears a small red area at the infection site; this enlarges into a papule, which soon breaks down. forming an ulcer with ragged edges exuding pus. The ulcers are painful and bleed easily. In about one-half of the cases there develops within a few days to two weeks a swelling in local lymph glands (buboes). These are acutely inflammatory, usually contain pus and may rupture spontaneously. Usually the disease is self-limited, but in particularly dirty persons, especially when the lesion is under the foreskin or about the clitoris where it cannot be properly exposed, relatively prolonged disability and tissue destruction may ensue. Extragenital chancroid is a rarity but it does occur.

4. Diagnosis.—The diagnosis is usually based on the clinical picture of the disease, provided syphilis has been adequately ruled out. The organism may occasionally be seen in stained smears from the ulcers and may sometimes be cultured. The intradermal test (Ito test) uith bacillary vaccine is of value.

5. Treatment.—The sulfonamides (sulfanilamide, sulfathiazole or sulfadiazine) are specific in therapy. As a rule, their administration need not be continued longer than one week. Penicillin has not been helpful, but the tetracycline antibiotics and chloramphenicol have been widely and successfully used. The bubo may be aspirated if necessary.

Local cleanliness is of great importance, with generous use of soap and water, supplemented often by the use of powdered sulfonamide locally and soaks of permanganate of potash. Local therapy is avoided until repeated dark-field examinations for syphilis have been performed. In any event, an integral part of the therapy of chancroid is prolonged follow-up with blood serologic tests to rule out syphilis.

B. Lymphogranuloma Venereum

Lymphogranuloma venereum is a venereally acquired virus infection of lymph channels and lymph nodes manifesting itself by swollen lymph nodes, ulcerations, enlargement of genital organs and rectal stricture. It is also known as lymphogranuloma inguinale, climatic bubo, poradenitis, lymphopathia venereum and Nicolas-Favre disease.

The microorganism is known as the virus of lymphogranuloma venereum. It is a so-called filtrable virus immunologically related to the virus of psittacosis (*q.v.*).

1. History.—Lymphogranuloma venereum was first described as a clinical entity in 1913, and detailed information became available in 1922 as a result of a study by Joseph Nicolas and M. Favre. It was proved to be a virus disease in 1930.

2. Occurrence, Distribution and Trend.—Exact data are not available. It is a relatively common disease, occurring throughout most of the world, especially in tropical and subtropical areas. In the mid-1950s the World Health organization published the reported cases since 1946 in 16 countries located in Africa, America, Asia, Europe and Oceania. It is endemic in the southern part of the United States, particularly among lower socioeconomic groups. The age incidence is that of greatest sexual activity. Sex differences are not great, and all races are affected. In the decade 1947–56 the number of cases reported in the U.S. fell from 2,688 to 602.

3. The Disease Process.—The primary lesion, usually on the genitalia, appears from 5 to 21 days after infection takes place. This lesion is often so transitory as to escape notice, and the first manifestation of the disease may be a swollen, hot, tender group of glands (buboes) in the inguinal region, appearing from 10 to 30 days after exposure. In the female, the inguinal bubo is frequently absent and the initial symptoms are referable to the rectum.

Fever, chills, headache and joint pains may be present. Abscess formation with drainage of pus from the inguinal lymph nodes is usual. Later manifestations of the disease include secondary ulceration and elephantiasis (great enlargement) of the genitalia in both sexes, polypoid growths about the anus, inflammation, ulceration and stricture of the rectum and, rarely, arthritis, conjunctivitis and nervous-system involvement. Extragenital infection is rare. The course of the disease varies from asymptomatic infection to extreme debilitation with chronic invalidism as the result of chronic late manifestations.

4. Diagnosis.—The diagnosis of lymphogranuloma venereum is usually made on a clinical basis, but a skin test known as the Frei test and a blood (complement-fixation) test are of considerable value. Microscopic examination of a bit of removed tissue from a lesion is sometimes indicated.

5. Treatment.—This varies with the stage of the disease: Chlortetracycline, along with sulfadiazine, is used in the bubo phase with moderate success; for the rectal lesions and other ulcerations, tetracycline antibiotics with chloramphenicol or sulfadiazine may be effective if administered for as long as 30 days after symptoms improve. Penicillin is not effective. Aspiration of pus from the bubo gives symptomatic relief. At times surgery or repeated dilatation is of value in stricture of the rectum. Plastic surgery may be indicated in elephantiasis.

Periodic follow-up blood tests for syphilis are essential.

C. Granuloma Inguinale

Granuloma inguinale is a chronic, mildly contagious, progressively autoinoculable venereal disease that usually but not always occupies the genital and inguinal regions. It is initiated by a microorganism known as the Donovan body (Donovania granulomatis), probably a bacterium. Among the other names given this disease are ulcerating granuloma, granuloma pudendi tropicum, granuloma contagiosa, chronic venereal sore and granuloma venereum.

1. History.—The first description mas made in 1882. In 1905 C. Donovan mentioned a "body" found in the diseased tissues, and about 1945 the Donovan body was cultivated in the yolk sac of the chick embryo.

2. Occurrence, Distribution and Trends.—Exact data on its incidence and prevalence are not available, but it seems to be the least common of the venereal diseases. It is commonest in the tropics but has been reported from all countries. In the United

States it is endemic in the south, particularly among the lower socioeconomic groups. In the decade from 1947 to 1956 in the United States the number of reported cases fell from 2,403 to 419.

3. The Disease Process. — Little is known about the incubation period because reports state it to be from 8 days to 12 weeks and sometimes more than 100 days. The process begins on the genitalia and slowly spreads to involve the inguinal regions and perineum. It takes the form of an extremely chronic, usually deep beefy red ulceration, with little tendency to heal. If secondary infection occurs, there may appear pain, fever and general symptoms. Ultimately, in some untreated cases, severe debility develops, ending in death. Lesions in other than the genital region are seen in about 6% of the cases, and on rare occasions the disease may become generalized.

4. Diagnosis. — The clinical picture may permit diagnosis, which should be confirmed, however, by the demonstration of the Donovan body in stained smears or sections from the lesion. Typically the microorganisms appear as small encapsulated bodies about one micron in length, lying within mononuclear cells. In all cases of diagnosed or suspected granuloma inguinale, syphilis should be ruled out by repeated serologic tests, performed monthly for at least four months.

5. Treatment. — Treatment with antimony compounds has been entirely replaced by antibiotic therapy. Streptomycin over a period of 5 to 10 days and chlortetracycline, chloramphenicol and oxytetracycline over a period of 15 to 20 days have been used successfully.

IV. CONTROL MEASURES

Although available world statistics do not indicate an over-all decline in the venereal diseases, much progress has been made in some areas. In order to continue this progress and to initiate progressive control measures throughout the world, constant vigilance must be maintained. . All areas of high venereal disease occurrence are potential hazards to the remainder of the world. Furthermore, the relationship of venereal and nonvenereal syphilis and other forms of treponematosis (yaws, pinta) make it essential that control measures be applied effectively to all forms of treponematosis in order to assure future protection of the world from these diseases that resemble syphilis in signs, symptoms and occasionally in outcome. This is the objective of the Division of Venereal Disease and Treponematoses of the United Nations World Health organization, which stimulates and assists national health administrations in the control of these diseases. By the late 1950s such treponematosis control projects had been carried out in Yugoslavia, Haiti, Indonesia, Thailand and the Philippines, and smaller programs had been conducted in Ceylon, Afghanistan, Iraq, Egypt, Burma, Ecuador and Venezuela. The Venereal Disease and Treponematoses division is in constant communication with venereal disease and treponematoses control programs all over the world.

In the United States, control of venereal diseases is carried out on a local basis with some state and federal support. Federal appropriations for venereal disease control decreased annually from a peak of $17,000,000 in 1948 to a low of $3,000,000 in 1954. It was soon realized that reductions had taken place too rapidly, so in the years after 1955 annual changes in appropriation in keeping with estimated needs were made.

Control of the venereal diseases and of nonvenereal treponematosis depends on both community and individual action. The community or mass measures comprise such health promotional measures as health and sex education, preparation for marriage, premarital and prenatal blood testing and improvement of social and economic conditions. Specific protection is rendered by attempts to suppress clandestine sexual promiscuity and by teaching methods of personal prophylaxis. All these control measures are accomplished by co-operative activities of the citizens in the community and the local health organizations. The citizens participate both individually and through such organizations as (in the U.S.) the American Social Hygiene association, a voluntary agency that devotes its time to collecting pertinent information and making it available to all who need it.

Mechanical prophylaxis by means of the condom is a practical prophylactic method. Local chemical prophylaxis has been used with decreasing frequency, and soap and water, while desirable for general hygienic purposes, is of dubious etiectiveness except in chancroid. Administration of penicillin after exposure has been extremely effective in the prevention of both syphilis and gonorrhea.

Additional community measures include the provision of facilities for case finding through contact investigation and selective serologic testing, as well as facilities for early diagnosis and treatment.

Control of infected individuals involves adequate diagnosis, investigation of contacts and sources of infection, proper treatment and notification of cases to health authorities. Investigation of contacts by interviewing patients and tracing their contacts in the family and the community is a basic *sine qua* non for venereal disease control. Notification of cases is essential if dependable data on occurrence, distribution and trends are to be available.

Control measures for nonvenereal syphilis are the same as those for yaws and pinta. Community activities include health education, improved sanitation and social-economic conditions, and provision for early mass diagnosis and treatment. It is recommended that all familial contacts of persons with any type of treponematosis be treated with penicillin as a community and family control measure.

VENETI, name of two ancient European tribes.

1. **A** Celtic people in the northwest of Gallia Celtica. They were the most powerful maritime people on the Atlantic and carried on a considerable trade with Britain. In the winter of 57 B.C., they took up arms against the Romans, and in 56 were decisively defeated in a naval engagement.

2. The inhabitants of a district in the north of Italy. It was at first included in Cisalpine Gaul, but under Augustus was the tenth region of Italy. The Veneti were a peaceful people, chiefly engaged in commercial pursuits. They carried on a trade in amber, which reached them overland from the shores of the Baltic.

They were famous for their skill in the training and breeding of horses. Homer (*Il.* ii. 85) speaks of the Paphlagonian *Henetoi* as breeders of "wild mules," and their fondness for horses is regarded as a proof of their descent from the "horse-taming" Trojans. Dionysius, tyrant of Syracuse, who assisted them in repelling the attacks of the Liburnian pirates, is said to have kept a stud in their country.

Herodotus mentions a curious marriage custom. Once a year the marriageable maidens of a village were collected together. Each young man chose a bride, for whom he had to pay a sum of money in proportion to her beauty., The sums thus obtained were used by the public officials to dower the less beautiful and thus afford them the chance of obtaining husbands.

The first historical mention of the Veneti occurs in connection with the capture of Rome by the Gauls. whose retreat is said to have been caused by an irruption of the Veneti into their territory. Sometime during the Second Punic War they passed under Roman rule. At first, they possessed complete autonomy in internal administration; in 89 B.C. Gnaeus Pompeius Strabo bestowed upon them the *ius Latinum*.

Under the empire Venetia and Istria were included in the tenth region of Italy with capital Aquileia. Down to the time of the Antonines the country enjoyed great prosperity, which was interrupted by the invasion of the Quadi and Marcomanni and a destructive plague. It was devastated at intervals in later times by the barbarians — by the Alamanni, Franks and Juthungi in 286; by the Goths under Alaric (beginning of the 5th century); by the I-Iuns under Attila (452), who utterly destroyed Aquileia and several other cities.

Under Theodoric the Great (ruler of Italy from 493 to 526) the land had rest, and in j68 was occupied by the Lombards.

See also VENETIA; VENETIC LANGUAGE.

VENETIA, a comprehensive name for the eastern half of northern Italy. The Latin name Venetia, from which the English is derived, meant simply the country of the Veneti (*q.v.*). In Italian, however, the etymologically equivalent form Venezia is the proper name of Venice itself and requires some qualifying epithet wherever it is used to denote anything beyond that city. Venetia, then, in the extended English sense, is the area bounded on the west by the Italian *regione* of Lombardy, on the northwest by the Swiss Grisons, on the north by the Austrian Tirol and by Carinthia, on the east by Slovenia and on the south by the Adriatic gulfs of Trieste and of Venice and by the vegione of Emilia-Romagna. It thus comprises three *regioni,* as follows: (1) the Veneto, or Venezia Euganea; (2) Friuli-Venezia Giulia; and (3) Trentino-Alto Adige. or Venezia Tridentina. The size and composition of the aggregate have varied in the course of history.

The mediaeval history of Venetia is inseparable from that of the republic of Venice (see VENICE). Further details are to be found under FRIULI, PADUA, VERONA, VICENZA and, for a territory that resisted the republic's encroachment, TRENTO. The comnion danger of Turkish expansion, from the end of the 15th century onward. led to a settlement of the long-standing dispute between Venice and the Habsburgs for the possession of the eastern territories, whereby Venice secured Friuli (with western Istria also). After the overthrow of the republic, however. France and Austria redistributed Venetia under the treaties of Campo Formio (1797) and Pressburg (1805). Next, on the downfall of Xapoleon. the whole territory was occupied by the Austrians.

In 1866. as a consequence of the Seven Weeks' War, the kingdom of Italy, unsuccessful though it had been in its own aggression against Austria: acquired those parts of Venetia that had belonged to the republic of Venice ('including Friuli but not Istria). lifter World War I, however. Italian Venetia was greatly expanded. acquiring not only Trieste and its hinterland. Istria and Fiume (as well as Zara on the Dalmatian coastj but also: under the treaty of St. Germain (1919), the Trentino and the southern Tirol.

These new frontiers remained unchanged until World War II. By 1944 control over most of the mountainous area in the east of Venezia Giulia had passed to Yugoslav partisans; and in the negotiations for a treaty of peace with Italy the Yugoslavs showed themselves most reluctant to abandon Istria and certain districts in the north to the west of the Isonzo. The treaty of 1947 eventually gave them the Istrian peninsula except Trieste and its immediate neighbourhood and advanced their northerly frontier west of the Isonzo. thus transferring to them Plezzo, Sonzia. Caporetto. Tolmino and some other formerly Italian towns. For the final partition of the Free Territory of Trieste in 1954 see TRIESTE.

The Trentino and the southern Tirol were retained by Italy after World War II. For the policy adopted with regard to the large German-speaking population, which had withstood Italianization since the 1920s, see TIROL.

In 1955, then, the total area of Venetia was about 15,390 sq.mi., with a population of 6,200,000.

For the geographical description of the country, it is most convenient to treat the three regioni separately. as follows:

Venezia **Tridentina.**—This area comprises the provinces of Bolzano and Trento and covers about 5,252 sq.mi. It includes the mountainous area of the Venoste, Brenner, Aurine and Pusteria Alps on the frontier. the Ortles Alps in the west, the Dolomites in the east and the high plateaus of the interior. The chief rivers draining the mountain masses are the Etsch (upper Adige), the Isarco. the Noce and the Avisio, tributaries of the Xdige (*q.v.*), which flows down the principal valley from north to south through Bolzano and Trento to Verona in the plain of Lombardy. The valleys of the larger rivers (particularly that of the Xdige) are well populated and fertile, especially in the Trentino. Some peaks of the border Alps are among the highest in Europe: Palla Bianca (Weisskugel) (12.257 ft.), l'Altissima (11,414) and Punto Lago Bianco (11,588) in the Venoste Alps in the west; Pan di Zucchero (Zuckerhutl) (11,519) and Tribulaun (10,1j7) in the Brenner Alps; and Gran Pilastro (Hochfeiler) (11,j16) and Monte Lavello (11,083) in the Aurine Alps. Passes breaching these Alps are the Stelvio (9,048 ft.) into Switzerland; the Resia (4,944) and the Brenner (4,511) into the Austrian Tirol; and the Dobbiaco (4,232) into Carinthia. South of the Alpine massifs, a large part of the province of Bolzano consists of a roughly rectangular area between the Adige, Passirio and Isarco valleys, much of it a plateau averaging from 4,300 to 5,600 ft. This province is inhabited mostly by German-speaking Austrians.

Much of the regione is forested (particularly Bolzano) but the valleys are quite thickly populated and intensively cultivated. Vines are grown extensively on the hillsides, and fruit trees flourish even up to 4,000 ft. North of Bolzano rye is more common than maize and wheat. Farther south the main cereal is maize and then wheat, oats and barley. Cattle raising and dairy farming are found on the lower hills and slopes in the valleys. Forestry has been particularly developed.

In addition the area contains certain mineral deposits, chiefly of zinc, lead, copper and iron ore, which the Italians have attempted to exploit. Some mechanical industries sprang up, and hydroelectric power stations were built to utilize the power of the rivers (principally the Adige and Noce). By 1954 there were about 100 small undertakings engaged in mining (with a labour force of around 900). Manufacturing concerns (most of them very small) numbered 11,274, employing about 34,000. A labour force of 10,300 was engaged in construction; and enterprises concerned with electricity, power gas and water employed 12,000 workers.

The tourist trade provides a large item of income. In the mid-1950s tourists numbered around 150,000 annually. The most famous resorts are Merano. Bressanone, Vipiteno, Dobbiaco and Brunico in Bolzano; and Madonna di Campiglio. Canazei. Levico and Roncegno in the province of Trento. From the Lombard plain several roads and railway lines converge on Trento (from Brescia, Verona. Vicenza and Padua). Road and railway follow the main valley (Val di Adige) to Bolzano. From there the Val Venosta strikes west (road and railway) toward Switzerland. and at Merano a road branches to the Brenner. A second road and railway goes north from Bolzano along the Val d'Isarco to the Brenner, throwing off a route (road and railway) eastward via Brunico into Carinthia. (See also TRENTINO.)

Venezia **Euganea.**—This is the original core of Venetia. It comprises the seven provinces of Venice, Padua, Rovigo. Verona, Vicenza, Treviso and Belluno, an area of 7,100 sq.mi., with a population of around 4,000,000 (1955). The territory comprises mountainous country to the northwest, where it is bordered by the Dolomites, and to the north, where the Carnic Alps form the frontier with Austria. Within its own northern area there are the Venetian Alps. Passes through the Carnic Alps into Carinthia are the Monte Croce (4,258 ft.) and, with both road and railway, the Camporossa. The southern part is an extension of the Lombard plain, through which run the Po, the Adige and the rivers draining the Dolomites and Venetian Alps (Brenta, Piave). These rivers (and particularly the Po) form an extensive delta area stretching along the Gulf of Venice, whose shore lagoons are kept healthful by the fairly considerable tides of the Adriatic.

The sunny slopes of the mountainous area are cultivated, vines and various fruit trees being the chief produce. The valleys provide good meadowland and arable soil in many places. Like Venezia Tridentina, the mountainous parts of the region are well known to tourists. The low-lying area of Venezia Euganea with its coastal fringe of lagoons and deltas is extremely fertile, and much use of irrigation has been made, together with a considerable effort to reclaim land. The population is largely agricultural; the principal crops are wheat and maize, with beans, sugar beet, potatoes and vines also important.

As in many other parts of Italy after World War II, a number of large estates were expropriated and divided among small holders and peasants.

The larger towns of the plain have various industries: textiles. silk, lace, hemp, paper, iron founding, shipbuilding, etc. Many are well supplied with hydroelectric power. Venice, population (1951) 174.632, is not only a city of historical. architectural and cultural fame. but also a considerable port and possesses a large industrial zone at Marghera. The traditional occupations of glass, lace and tapestry making are still carried on. Though the largest vessels can only be berthed nearby, Mediterranean trade is important. Adjacent are the small islands of Murano and Burano, specializing in glassware and in laces respectively. Verona (134,-636), below the southern spurs of the Dolomites. is also famous for its architecture and for its cultural and historical associations. It also does a considerable trade in silk, wool, leather and textiles. Padua (138,951), an equally ancient city, is likewise an agricultural centre of importance and has engineering, silk and textile and chemical industries. Vicenza (61,207) is another agricultural market and manufactures textiles, fertilizers and luxury goods. Treviso (53,165) has textile mills and industrial plants. Rovigo (17,588) is the agricultural centre for the Po delta. Valdagno is a centre of the textile industry. Apart from Venice, only Chioggia, an important fishing port and centre of the lace industry, is noteworthy.

Friuli-Venezia **Giulia.**—This division. to the east of Venezia Euganea, comprises the provinces of Udine and Gorizia, with the rump of Trieste.* The whole has an area of 3,033 sq mi. with a population of 1,226,121.

The Italian part of the Julian Alps (some reaching around 9,000 ft.) is a barren area. Farming of a limited nature is carried on, but there is little cattle raising. Friuli, lying between the Carnic Alps to the north, the Venetian Alps and the eastern Venetian plain to the west and the Julian Alps and the Isonzo to the east is partly hilly and partly plain; the plain is fertile and fairly thickly populated. The capital of Friuli is Udine (65.199 inhabitants), chiefly an agricultural centre. The hilly Carnia area to the north resembles the Dolomites in scenery and is economically of little value. The Carso (Karst) area, bordering on Yugoslavia, is a barren and arid stretch of limestone. There are small farms where sheep and goats are reared. The produce of the land is composed largely of vines, some root crops and a little maize. Nearer the coast fruit is also grown. On its coastal strip are the historic and decayed cities of Aquileia and Grado. Monfalcone, with its shipyards. is important. Most of the population on the coast live by fishing. Inland is Gorizia (1951) 34,607, principally an agricultural centre.

Trieste (259,167), the sole possession of Italy in the Istrian peninsula, is a beautiful and important metropolis. It was once the chief port of Austria-Hungary, from which it derived its prosperity. It has considerable maritime traffic; shipbuilding yards (with an output of 16% of Italy's total in this sphere) ; and an engineering industry, with metallurgical foundries and refineries.

(J. D. L.)

VENETIC LANGUAGE. The language of the Veneti (*q.v.*) is recorded in almost 200 short inscriptions, which have been dated to the last five centuries before Christ. It was spoken in northeastern Italy, in the plains around the head of the Adriatic and in the mountains to the north. The inscriptions are for the most part inscribed either as epitaphs or on objects dedicated to one or another deity. The principal sites which yielded the linguistic evidence are Este, Padua, Vicenza, Trieste, Pieve di Cadore and the Gurina plateau in Austrian Carinthia. These inscriptions are written in an alphabet characteristic of them, but which was obviously borrowed from the Etruscans who had established settlements in the Po valley toward the end of the sixth century B.C. It is preserved on several bronze tablets from Este, and in the transliteration here used runs as follows: *a e v d h 0 k 1 m n p ś r s t u b g o*. The symbols here transcribed *d b g* correspond graphically to the Etruscan and Greek letters *z* ϕ χ; but that the sounds indicated by them were voiced stops is clear from such correspondences as that of *triφus-* in the native alphabet, with *TRIBUS-* in the Latin. The digraph *vh* was used with the value of f, as in Etruscan; *t* and *0* were both employed for the sound *t*, as were *ś* and *s* for *s;* a letter *i* occurs in the texts but not in the alphabets; and a *k* of distinct form is found in the northern inscriptions. A remarkable feature of Venetic writing is the punctuation system: vowels not preceded by consonants, and consonants not followed by vowels (excepting those followed by *r, n, 1)* are regularly written with a point on either side of the letter. This system, apparently devised for a syllabary, is also found in a few Etruscan inscriptions.

In the inflectional system of Venetic at least four cases for the noun can be identified. Such nominative forms as *ve·r·ko·n·darna* (a feminine name), *va·n·t·s·*, and *e·kupeθari·s·* ("charioteer"?) are found. A certain instance of a genitive is *enoni,* and probable occurrences appear in *re·i·tii* and *makkno·s·* (all masculine names). Dative forms are recognized in *re·i·tiia·i·* and *lo·u·dera·i·* (both feminine divine names) and in *rako·i·*, *pupone·i·*, *ve·i·gno·i·* and *·o·stiiare·i·* (all names of men); *vda·n·*, *dono·m·* ("gift") and *e·kvo·n·* ("horse") are examples of accusatives. Among the few surely identified noun plural forms are the datives *lo·u·derobo·s·* ("children"?) and *andeticobos*. The following are verbs: *doto* and *dona·s·to* (both are third person singular preterite and are translated "gave"); *vhag·s·θo* ("made"); *tula·r·* (also *tole·r·*, *tola·r·*) ("offers"); and *·e·s·t·* ("is"). As pronouns *·e·go* ("I"), *mego* ("me"). and *sselboisselboi* ("for himself") are found. Other parts of speech are represented by the conjunction *ke* "and" and the prepositions *pe·r·* and *·o·p*.

The following texts are typical examples of Venetic inscriptions:

1. On a bronze pin found at Este: *mego dona·s·to vhugiia vho·u·-go·n·tiiaka śa·i·nate·i· re·itiia·i·* ("Fugiia Fougontiiaka dedicated me to Śainatis Reitiia").
2. On a vase from Padua: *voθo kluθiiari·s· vhag·s·θo* ("Voto Klutiiaris made [it *or* me]").
3. On a cinerary urn from Este: *va·n·te·i· vho·u·go·n·tio·i· ·e·go* ("I am for Vants, son of Fougonts").
4. On a bronze pin from Làgole di Calalzo, near Pieve di Cadore: *o·l·lo·s· aliisiko·s· doto dono·m· trumus katei* ("Ollos Aliisikos gave [this as a] gift to Katus Trumus[iiatis]").

It is clear that Venetic was an Indo-European language. Carl Pauli, the first scholar who discussed the question of its position within the family *(Die Veneter und ihre Schriftdenknzaler,* 1891), related it most closely to the scantily known idiom of ancient Illyria *(see* ILLYRIAN LANGUAGE), and for almost 60 years Venetic was regularly classified as an Illyrian tongue. This view, however, has now been abandoned by most students of the subject; some regard the language as closely related to Latin and to the other members of the Italic branch, while others classify it as a wholly independent member of the family. The evidence is not sufficient to afford a completely unambiguous answer to the problem.

VENETO, BARTOLOMMEO (c. 1480–1530), Venetian painter, whose portraits combine brilliant show of wealth with pensive or poetic mood to present notable embodiments of Renaissance man. The slightly rigid simplicity of style in Bartolommeo's portraits adds to the effect of objectivity and contrasts with Titian's treatment of the same people. The only extant documents pertaining to his life tell of his stay as court painter at Ferrara (1505–08). Ownership and signatures of paintings indicate an early career in Venice and a later one in Milan; his hypothetical stay at Bergamo has been refuted. One curious signature of 1502, to which he adds the phrase "half Venetian half Cremonese." doubtless refers to family origin and not to stylistic influence as is sometimes inferred. In a more important but less noted signature of 1509, he called himself a pupil of Gentile Bellini.

Bartolommeo's earliest works (1502–05), Madonnas of the Bellini type, are of little interest. His early, somewhat fanciful portraits (1505–08), of which the best known is at Frankfurt, were considered to have been painted under German influence. The famous portraits (c. 1512) were followed by his Milanese works such as the "Lute Player" (Gardner museum, Boston) in which poetic fancy dress has given way to Leonardo da Vinci's influence.

VENETTE, JEAN DE (c. 1307–*c.* 1370), French chronicler, born at Venette, near Compiègne, became prior of the Carmelite convent in the Place Maubert, Paris, in 1339, and was provincial of France from 1341 to 1366. In 1368 he was still living, but probably died within a year or two of that date. His Latin Chronicle, covering the years 1340 to 1368, was published by Achery (*Spicilegium,* vol. iii). Jean de Venette's sympathies were entirely with the peasants. Jean de Venette also wrote a long French poem, La Vie *des trois* Maries, about 1347.

VENEZIANO, DOMENICO: see Domenico Veneziano.

VENEZUELA, a republic of South America on the Caribbean coast, is approximately four times the size of the United Kingdom or one and one-third the size of the state of Texas. Venezuelans are predominantly of mixed ancestry. Indian, Negro and European strains are all present in significant quantities. Petroleum and iron ore have, in the 20th century, made Venezuela a treasure-trove of the modern world. The republic has derived relatively little from the exploitation of its natural resources, as officials have channeled a large share of fiscal revenues into the pockets of a few individuals rather than into the development of the national economy or social and cultural institutions. The gap separating the elite groups*from the masses has broadened noticeably since the large-scale development of the petroleum industry in the 1920s. Political and cultural lags have been at least as pronounced as that in the economic area. From 1899 to Jan. 1958, except for three years (1945–48), Venezuela was controlled by force through a military leadership from the Andean state of Táchira. This ruling element neglected basic education while it provided funds for a few institutions which could attract international recognition.

Many of the attitudes found in Venezuela in the second half of the 20th century can be traced back through the 19th century to the colonial period. After gaining its independence from Spain between 1810 and 1821, through the efforts of its most illustrious son, Simón Bolivar (*q.v.*), Venezuela for the remainder of the 19th century had a dilatory existence, punctuated by power struggles among those who constituted the narrow social and ruling class. The republic during this era had little to offer the world and was largely immune to impulses emanating from Europe and the United States. Still earlier, as a Spanish colony, the European settlers, after a brief but stormy period of searching for sudden wealth had accepted a prosaic way of life, based upon agriculture, in which they held sway over native Indians and imported Negroes.

Venezuela means "little Venice" and is a modification of the name Venecia (Venice) originally bestowed by Alonso de Ojeda in 1499 on an Indian village of pile dwellings on the shores of the Gulf of Maracaibo (called by him the Gulf of Venecia).

(J. J. J.)

I. PHYSICAL GEOGRAPHY

Geology and Structure.—In the basement complex of the Guiana highlands and in the axis of the Cordilleran and Maritime ranges of Venezuela are found some of the oldest rocks in northern South America. In the Venezuelan part of the Guianas these consist of a great mass of Archaean granite, gneiss and other crystalline rocks with overlying nearly horizontal bands of sandstone and shale. The core of granites and schists which forms the axis of the Cordilleran and Maritime chain is in large part flanked by sedimentary beds folded in anticlinal structure. Most of these latter are of early Cretaceous Age and are locally much altered. At places they are overlain by Pleistocene or Recent deposits into some of which are intruded dikes and masses of igneous rocks.

The llanos (plains) between these mountain systems are largely covered with broad Terciary and Quaternary deposits of gravel, sand and clay loam. In the delta region at the mouths of the Orinoco these deposits are thick and are accumulating rapidly. The depression in which lie Lake Maracaibo and adjoining lakes and lagoons is to some extent outlined by faults and has a surface deposit of Quaternary alluvium underlain by folded Cretaceous and Terciary beds. These beds are of particular importance because from them rise the petroleum seepages which led to the discovery of enormous quantities of oil. The sedimentary deposits of the northeastern llanos also are underlain in places by oil-bearing materials.

Physiography (or Relief and Drainage).—Venezuela's drainage system consists mainly of one large river, the Orinoco. Probably not less than four-fifths of the country's territory belongs to the Orinoco system. This river has several hundred tributaries, gathering the interior runoff from the northern mountains, draining most of the eastern slope of the Colombian Andes and collecting most of the water that runs northward and westward from the Guiana highlands, in addition to carrying off the water supplied by heavy seasonal rains over most of the llanos and some of the heavy all-year rainfall of the forests southward from these great plains. The Orinoco was long believed to head in the Guiana highlands but it was only in 1951 that its true head was discovered in the Cordillera Maigualida of the western Guiana plateau at lat. 2° 19′ 05″ N., long. 63° 21′ 43″ W., 3,523 ft. above sea level. From this point, after flowing for about 1,700 mi., the river makes an almost complete circle before heading eastward to the Atlantic. A unique feature of the upper Orinoco near its head is its bifurcation as it leaves the Guiana highlands, a part of its flow continuing northwest to form the lower river, while a branch, the Casiquiare, turns southwest and carries a large volume of water into the Rio Negro which, in turn, joins the Amazon. Among the larger tributaries of the Orinoco are the Caroni, Aro, Caura, Cuchivero and Ventuari which have their sources in the Guiana highlands; the Apure, Arauca, Capanaparo, Meta, Vichada and Guaviare (the last three being Colombian rivers) running across the llanos from the Andes; the Manapire, Suata, Pao and Caris from the central plains.

Apart from the Orinoco and its tributaries the rivers of Venezuela are short and comparatively small, and, except for those of the Maracaibo basin, are rarely navigable. The San Juan, the Guanipa and the Guarapiche flow from the eastern llanos to the Gulf of Paria; the Aragua. Unare and Tuy flow to the Caribbean coast east of Caracas; the Yaracuy, Aroa and Tocuyo reach the same coast west of Caracas; and the Motatán, Chama, Escalante, Catatumbo, Santa Ana, Apón and Palmar discharge their waters into Lake Maracaibo.

Lake Maracaibo (*q.v.*) is the largest body of inland water in Venezuela, being 133 mi. long and 72 mi wide. Though shallow along its margins, it is deep enough over much of its surface for ocean-going vessels. It is connected with the Gulf of Venezuela through a strait 40 mi. long and varying in width from 3 to 10 mi., being narrowest where the city of Maracaibo is situated. In the outlet there are about 13 channels, their number and depth varying from time to time, being partially obstructed by banks of sand and mud. The normal depth of the main channel at low tide is about 7 ft., and at high tide about 12 ft. The channel has been dredged by the Venezuelan government. This *makes the lake accessible for the first time to deep draft ships and allows oil to be exported without transferring from shallow draft lake vessels.*

Another important lake is Valencia. near which the city of the same name is located. in the Maritime Andes 1,339 ft. above sea level. There are also numerous small lakes both in the llanos and in the mountainous section of the country. One of the most unusual lakes is that called Bermúdez Lake or Lago hsfalto, about 25 mi. up the San Juan river from the Gulf of Paria. It has an area of 1,100 ac. and its surface is made up of asphalt in a layer about 3 ft. deep. Shipments of asphalt from the lake have been made to many parts of the world.

The delta of the Orinoco is even more complicated than the Lake Maracaibo depression. It is crisscrossed by a multitude of channels, locally called caños. The main outlet is the Boca Grande at the mouth of the Corosimi channel. but one of the central channels, the Caño Macareo, leads more directly to the Gulf of Paria, the Island of Trinidad and the Caribbean sea. This caño has been deepened sufficiently to allow the passage of ocean-going vessels. Since the lower Orinoco itself has been dredged for vessels of 23 ft. draft, this opens a deep draft water route through the delta and up to the newly constructed Puerto Ordaz, thus facilitating the development of the lower Orinoco region.

Coast Line.— *Venezuela fronts on the Caribbean sea for about 1,500 mi. and for 300 mi. on the Atlantic ocean. There are a number of indentations, particularly on the Caribbean coast and some of these provide the country with serviceable harbours. On the far northwest the spacious Gulf of Venezuela, sometimes locally called the Saco de Venezuela, with its enclosed Gulf of Coro and its much greater landward extension in Lake Maracaibo, offers good protection behind the peninsula of Paraguaná on the east and the peninsula of Guajira on the west. In the far northeast of the country the Gulf of Paria lies well sheltered between the peninsula of that name and the off-shore British possession of Trinidad. The Gulf of Cariaco, lying behind the peninsula of Araya, offers excellent shelter. The Golfo Triste is a rather open indentation in the coast, on a part of which is situated Puerto Cabello. The Gulf of Santa Fe is a small inlet lying behind a narrow strip of land on the northern coast of the state of Sucre. The shipping of the country uses a number of estuaries and open roadsteads, such as those of La Guaira and Carupano.*

Curiously enough, the country's principal port, La Guaira, is not situated in a protected natural harbour, but on an open roadstead, with mountains rising picturesquely but formidably out of the sea. The city is strung along the base of the hills, as are also its airport Maiquetía, and suburban settlements. Puerto Cabello, though on a nearly open coast, has the protection of shoals offshore, and a small. low-lying spur of land into which dredging has opened passages sheltered from heavy seas.

Islands.— *There are 71 islands, with an aggregate area of 14,633 sq.mi., according to official calculations. The largest of these is the Island of Margarita (q.v.), 23 mi. off the coast of the state of Sucre.*

Climate.— *The climate of Venezuela is everywhere tropical in that winter never comes there and the seasons are periods of rainfall rather than of temperature. The year is divided into two seasons, the rainy and the dry (locally known as winter and summer), the former extending from April to October or November, the latter most marked from November through March or April. Vegetation growth, therefore is timed in harmony with these two seasons. The wet and dry seasons also regulate agricultural activities, affect travel and transportation, determine vacation periods, and, to a degree, influence even aviation. Temperature differences, on the other hand, are slight throughout the year. Average temperature, for example, at Caracas is 67° F., and no month averages more than 69° or less than 64°. Altitude, however, affects temperatures in marked fashion. For example, Maracaibo-at sea level averages just over 82° for the year, and Mérida at 5,325 ft. averages just over 65°. On some of the higher mountain peaks temperatures are low enough to permit fields of permanent snow. Whatever the average temperature there is little difference from month to month. The only marked variation in temperature is from day to night, this difference being greater than that from month to month.*

Rainfall varies much from district to district within the country. The northeast trade winds blow across the low coastal districts without leaving much precipitation, in places less than 20 in. per year. La Guaira, for example, has only 11 in. Most of the coastal lands, consequently, have scant, dry vegetation. Areas lying behind topographic barriers also get little rain. Windward slopes, on the contrary. are generally well watered. In places enough rain falls to support a lush jungle growth, in places a true selva (rain forest). Most of the well-populated part of the country is dry rather than humid, but everywhere there is a marked seasonal variation. The llanos suffer severely from want of rain from about January to April and then suffer equally from an over-abundance that floods whole countrysides from June to October.

Vegetation.— *About half of Venezuela is covered with forests of some kind. A little less than half is still in native grass, though much of this is used for at least occasional grazing. Only about 2%, mostly in the valleys of the Andes and the coast ranges, is under permanent cultivation. The vast llanos of the Orinoco basin, much of the lofty tablelands of the Guiana highlands, and numerous smaller areas in the Andean paramos (high bleak plateaus), have little in the way of trees. In the better-watered places the grass is compact and tall, in drier areas, such as high Andean districts and parts of the Guiana tablelands it is sparse and hard. True selva covers a relatively small area but is found in the lower Orinoco basin and delta, in some of the far southern Orinoco drainage basin bordering on Colombia and Brazil, and in smaller extensions about the windward lower and middle slopes of the northern highlands.*

Most of the plant life of Venezuela is tropical in that it is non-deciduous, retaining its foliage through the year, or shedding its foliage little by little, never becoming entirely leafless. Even in the arid regions where the vegetation is sparse and the foliage scant, there is little change from season to season.

Both native and introduced plants cover a wide range because of the altitudinal climatic zones. The true tropical vegetation, whether moist or dry, extends to an altitude of about 1,500 ft., above which it gives way (except in the moister districts) to what map be called semitropical with tree ferns and orchids. which reaches up to about 5,000 ft. From this point, up to from 7.000 to 8,000 ft. there is a transition into a mountain type. and above 8,000 or 9,000 ft. the characteristic paramo vegetation begins, with plants of an alpine character dominating from this altitude upward. Whatever the altitude, native plants remain non-deciduous.

The principal plants of economic value grown in Venezuela are coffee, cacao, tonka beans, sisal and bananas, raised in part at least for export; while corn, beans, wheat, rice, potatoes, sugar cane, cotton. tobacco. sweet potatoes. and below about 5,000 ft., oranges, lemons, coconut palms, papayas, avocados, mangos, cashews. guavas, breadfruit, zapotes, granadillas, cassava (both bitter and sweet), are commonly grown for local consumption. With the rapid growth of population and the demand for labour in the oil fields and related business enterprises since the 1920s, little of any of these crops, except bananas. has been exported. In fact, wheat flour, potatoes and some other vegetable food products have had to be imported.

Animal Life.— *The fauna of Venezuela is quite similar to that of the neighbouring regions of Colombia. Brazil and the Guianas, the open llanos of the Orinoco being something of a neutral district between the great forested regions on the east, south and west. There are no effective natural barriers serving to isolate the country. Among the animals indigenous to the country are seven species of the cat family, including the puma. the jaguar and the ocelot; the wild dog (Canis azarae); representatives of the marten family, including two species of Galactis, two of the otters (Lutra braziliensis and L. pteronura) and one of the skunk; two species of bear (Ursus ornatus and O'. nasutus); and the kinkajou, a carnivorous. arboreal, prehensile-tailed quadruped about the size of a cat. There are 6 species of monkeys corresponding to those of Guiana and the Amazon valley; the sloth and anteater; 12* known genera of rodents, including many species of *Mures;* the cavy, the capybara, the paca, the nutria, the agouti, the tree porcupine (*Loncheres* cristnta), spiny rats (*Echimys cayen*) and the Brazilian hare. Among the pachyderms the tapir is found in the forests of the Orinoco. There are two species of the peccary (Dicotyles *torquatus* and D. *labiatus*). There are also two species of deer (*Cervus rufus* and C. *simplicornis*). There are three species of opossum. On the coast and in the Orinoco there may be found the manatee and the dolphin. The Reptilia include 11 species of the crocodile. alligator and lizard. including the savage jacare of the Amazon, several species of the turtle, 4 species of batrachians and 29 species of serpents. including the striped rattlesnake (*Crotalus durissus*), the bushmaster (Lachesis *mutus*) and a rather rare species of *Cophias.* Among the nonvenomous species of the last. the commonest are the boa constrictor, the anaconda (*Eunectes murinus*) and the Coluber *variabilis.* Bird life is represented chiefly by migratory species. particularly the genera that inhabit the shores of streams and lagoons. In the *garzeros* ("heron rendezvous") are to be found nearly every kind of crane, heron, stork and ibis, together with an incredible number of Grallatores. Ducks are also numerous, including a small one called the *guiriri,* in imitation of its cry. Birds of prey are numerous. One species, the guacharo (*Steatornis caripensis*), or oilbird, is commonly said to occur only in Venezuela, though it is found on the Island of Trinidad, in Colombia and Ecuador also. These birds live in caves, especially in Caripe, and are caught for the oil extracted from them. The bellbird (*Chasmorhynchus niveus*) is common in the forests of the Orinoco. In the 14 orders of insects there are no fewer than 98 families. There are 8 families of Coleoptera, 6 of Orthoptera, 23 of Hymenoptera, 14 of Lepidoptera and 7 of Diptera. Locusts are common in the interior, though seldom constituting a plague. Molluscs, including the pearl oyster, are common on the coasts and in the fresh-water streams and lakes.

Domestic animals common to other parts of the continent are found in Venezuela. The number of cattle is estimated at 6,700,000 and most of these are found in the great herds that pasture on the unfenced llanos. There also are about 920,000 goats, 176,000 sheep and 2,360,000 swine. Oxen and horses and a few mules are used as draft animals on some farms: farmyard poultry is as common as elsewhere. There is no sharp altitudinal zoning of domestic stock,,but in the extreme highlands some animals, notably horses and cattle! suffer from the altitude more than others. All animals taken from the lowlands to highlands require a short period of acclimatization, as does man, though not to the same extent as in the higher regions of the Andes in Colombia, Ecuador, Peru and Bolivia.

II. GEOGRAPHICAL REGIONS

The surface of Venezuela is broken into three major irregular divisions: (1) the mountainous area of the northwest and north; (2) the extensive, nearly level basin of the Orinoco river; and (3) the Venezuelan section of the Guiana highlands. A branch of the Cordillera Oriental (eastern range) of the northern Andes enters Venezuela in the west at about lat. 7° 30′ N. and proceeds northeastward and then eastward toward the Gulf of Paria and the Island of Trinidad. with gradually diminishing elevation. This branch consists of more or less parallel chains of mountains. bordered by numerous paramos in the far west and enclosing a number of valleys elevated well above sea level, but not so high as the great valleys of the Andes in Colombia. Ecuador, Peru and Bolivia. The western, higher section of the Venezuelan Andes is known as the Sierra Nevada de Mérida and contains five peaks reaching 16,000 ft. or more. The highest of these. Bolivar peak (16,411 ft.) is followed by several other snow-capped peaks of almost equal height (La Columna, Monte Humboldt, La Concha). The bordering paramos range from 8.000 to 10.000 ft. Numerous basins and valleys here lie at elevations of 4,000 or 5,000 ft., the city of Mérida in a valley of the same name being 5,325 ft One mountain pass, however, only 4.600 ft. high, runs from the Orinoco plains to the Caribbean lowlands of Lake Maracaibo, and through it has been laid the Venezuela-Colombia boundary line. Eastward from a 13,500 ft. pass near Mucuchies the enclosed valleys are much lower. That of Trujillo is less than 3,000 ft. high, that of Barquisimeto is 1,800 ft.. the Valencia basin, 1,500 ft., that of Caracas, 3,000 ft. Few of the mountains in this region rise more than 5,000 ft. above sea level. Farther to the east the mountain ranges, knonn as the Maritime Andes, become lower and almost disappear over a 100-mi. stretch. to reappear and continue as parallel low ranges to the Gulf of Paria. A number of spurs from 3.000 to 5,000 ft. high extend northward from the main range of the Venezuelan Andes, enclosing the Maracaibo depression on the east and constituting a wide region of broken terrain, low mountain ridges alternating with valleys that lie, in general, less than 1.000 ft. above sea level. The western part of this region, known as the Segovia highlands, contains a rather sparse population. because it is rather arid but, together with the better-natered region just east of it. constitutes the real Venezuela, historically the dominant part of the country. the other parts of the national territory forming mere appendages to this true heartland.

Bordering this mountain and valley country on the south lies the vast basin of the Orinoco, consisting mostly of an extensive, almost featureless alluvial plain, the llanos. This plain slopes gently southnard from the foot of the Andean country of central Venezuela for over 250 mi. to the river, and south of the river rises gently at first, then more abruptly into the Guiana highlands. From the foot of the Colombian Andes it extends eastward for over 600 mi. to the Atlantic coast where it merges into the ocean in the broad, many channeled delta of the Orinoco which, of itself, covers about 10,000 sq.mi. In all of this expanse there are no mountains and few small hills to break the monotony of the landscape. Numerous tributary streams cross the plains but they run in shallow channels and the flat-topped interfluves rise little above the water in the streams. Around the margins of the llanos the land lies about 600 to 800 ft. above the general level, but most of the plain does not rise more than 300 or 400 ft. above the sea. So uniform is the level over a great part of the area that, in the rainy season, many hundreds of square miles are inundated. North of the lower Orinoco, however, there is a series of low gravel-capped mesas of 1.000 ft. that form a divide and shunt a number of small rivers northward to the Caribbean and others eastward as independent streams to the delta.

South and southeast of the llanos the land rises, gradually at first then abruptly into a great upland, the Venezuelan section of the Guiana highlands, generally called the Gran Sabana (great plain) because of the high, flat-topped mesas that make up much of the region. Though comprising nearly half of the country's area, it contains less than 3% of the population, and is one of the least developed and least known parts of the nation, and, indeed, of all South America. The general level probably does not exceed 4,000 or 5,000 ft., but some of the broad plateaus. or mesas, are several thousand feet higher. Toward the Brazilian and British Guiana border the land rises still higher, the giant table mountain of Roraima having an elevation of 9,219 ft. Much of the Guiana highland is intricately dissected by streams that flow in deep, steep-sided canyons, thus creating a labyrinth of strikingly varied topography. At the brink of one of these great tablelands about 8,000 ft. high. about 160 mi. from Ciudad Bolivar was discovered in 1935 nhat is believed to be the highest waterfall in the world, Angel Falls, 3,280 ft. high and some 500 ft. wide at the base. This cataract is located on the Carrao river, an upper tributary of the Caroni. It was named for the U.S. adventurer, James Angel (d. Dec. 8, 1956), who first reported its existence.

Many spectacular falls of almost equal height, and a number of smaller ones are known to exist among the deep canyons of the Gran Sabana. Local maps mark many "saltos," as these falls are called. By mid-20th century the region attracted tourists, who follow poor roads from Orinoco river points or fly to little towns near the base of the cliffs. Northward these highlands drop off' gradually from their base toward the Orinoco river, low hills reaching the river's channel where Ciudad Bolivar is located. Together with corresponding low hills on the other side of the river they confine the channel to a width of only ½ mi. The city founded there in early colonial times bore the name La Angostura ("the Narrows") until 1849 when it was changed to honour the great

Liberator. Simón Bolivar.

The highlands of the Venezuelan Guianas descend toward the northeast into a depression which drains southward through the numerous tributaries of the Cuyuni river, into British Guiana, while between this depression and the delta of the Orinoco rises another chain of low mountains. the Sierra Imataca and the Altiplanicie de Nuria, a granite tableland, averaging 2,000 ft. in height. On the west the Guiana highlands of Venezuela are bordered by a series of lower ranges and uplands nhich extend northward and westward to the plains country of the upper Orinoco and upper Amazon tributaries. The southern margin of the highlands coincides approximately nith the Venezuelan boundary. The highest ridge in this extensive upland, generally called the Sierra Pacaraima and the Parima sierras, constitutes the watershed between the middle Orinoco and the Rio Negro tributaries of the Amazon and has been adopted as the boundary between Venezuela and Brazil for about 500 mi Because of the favourable climate, soil and natural vegetation of this great highland area and the enormous water power available in its many streams and the rich mineral deposits being discovered in places about its border. it gives promise of becoming a very important section of Venezuela.

III. THE PEOPLE

Racial Types. — Racially the bulk of the population is of mixed (mestizo) ancestry, the European element predominating. Between 1% and 2% of the people of Venezuela are purely indigenous, living mainly in the Orinoco-Amazon forests of the extreme south and in the extreme west along the lower slopes of the Colombian-Venezuelan Andes, not far from Lake Maracaibo settlements. Few remain from the relatively civilized Indians that had occupied the higher Andean regions near Mérida dnd Táchira. The number of those of unmixed African ancestry is also small, and settled mainly along the Caribbean coast in such centres as La Guaira, Puerto Cabello and Cumana. The number of those of unmixed European descent is larger, without, however, constituting the largest ethnic group. There are small groups of foreigners living in the more progressive parts of the country. After World War II the largest single group (about 100,000) came from Italy, the next from Spain (about 75,000) and the third a fluctuating population. mainly from North America, and largely associated with the oil industry, numbering normally from 30,000 to 40,000.

Languages. — Spanish, the official language of Venezuela, is spoken by 97% or 98% of the population. Members of the intellectual middle class and the upper class customarily speak at least one foreign language. Formerly German and French predominated, but English has become the principal second language. Indian languages are spoken by 2% or 3% of the population. For a detailed listing of the Indian languages of Venezuela, see INDIAN, LATIN-AMERICAN.

Religion. — Church-state relations are maintained under the terms of a law of July 28, 1824, which made Roman Catholicism the official religion. Freedom of worship, however, is guaranteed. Until about mid-20th century, the church ordinarily co-operated closely with the military. This situation has been changing, as increasingly church policy calls for closer association with labour circles and greater interest in the activities of the labouring classes. Almost the entire population is nominally Roman Catholic, although Jewish, Moslem and Protestant congregations are present. There are two archbishoprics, those at Caracas and at Mérida, and eight episcopal sees. A seminary for the secular clergy is maintained at Caracas, though the regular (cloistered) clergy are nearly all educated abroad in Spain and Italy.

(G. M. McB.; R. E. Ct.)

Customs and Culture. — A façade of modernization dating from the 1920s conceals a generally backward country in which 75% of the population is agricultural and pastoral and 70% of the land is held by 3% of the population. A rigidly stratified social structure based primarily upon ethnic background and economic status persists. The aristocracy is of Spanish origin and is largely concentrated in the Andean area, and in and around Valencia and Caracas. The mestizos, found most often in the lower middle income groups and working classes, predominate in the northern highlands and the adjacent plains. Negroes and Negro-mixtures are found in greatest numbers along the coast and in the city of Caracas. Few Negroes and Afro-Europeans have thus far been able to rise above the working-class level.

The middle classes — artisans, craftsmen. shopkeepers. professionals — are numerically weak but are improving their economic status and at the same time are becoming more politically alert. They have been strengthened by post-World War II European immigration, by improvements in educational facilities. and by the general prosperity within the business and professional communities due to oil.

The military caste, whose leaders come largely from the state of Tachira. has been a dominant political force (see History). The military leadership identifies itself with the aristocracy socially and like that group traditionally has been of European origins.

(J. J. J.)

IV. HISTORY

The coast of Venezuela was the first part of the American mainland sighted by Columbus in 1498 during his third voyage to the new world. Within a few years an intimate knowledge of the Venezuelan coast was gained, through the efforts of such explorers as Alonso de Ojeda, Juan de la Cosa, Amerigo Vespucci. Pedro Alonso Niño, Vicente Yáñez Pinzón and Rodrigo de Bastidas. No permanent settlements were made on the mainland of Venezuela before 1520 but earlier Margarita Island, Cubagua, Cumaná region had become the centre of an active trade in pearls, and slave hunters periodically raided the territory in search of Indians who could be captured and sold.

Gonzalo de Ocampo founded Nueva Toledo, later to be known as Cumana, in 1520. The permanent occupation of Cumaná dates from 1523 and was the work of Diego Castellon. Father Bartolomé de las Casas, "The Apostle of the Indians," was in the Cumaná region at the same time as was Ocampo. In 1527 Juan de Ampués founded Santa Ana de Coriana, generally referred to as Coro, on the Paraguaná peninsula, in western Venezuela. Charles V, in partial payment of a loan, turned the western portion of Venezuela over to the Welsers of Augsburg in 1528 and the German occupation continued until 1546. The representatives of the Welsers — Ambrosio Alfinger. Nikolaus Federmann and Jorge Espira among others — with headquarters at Coro, devoted themselves to the search for precious metals, and in this connection a number of expeditions were made into the interior. The most successful was that of Federmann, whose group arrived on the central plateau of Colombia in 1538, about the same time that Gonzalo Jiménez de Quesada and Sebastián de Belalcázar reached that region. Meanwhile, Diego de Ordaz, in the name of Charles V, in 1531 had explored the Orinoco area.

Venezuela did not prove to be a land of great wealth during the colonial period. Before the end of the 16th century the European conquerors had settled down to an agricultural existence based upon Indian and African slave labour. Further exploration and discovery was left largely to various religious orders. These "Crusaders of the Jungle" concentrated their efforts on the natives of the Orinoco drainage system.

French interlopers were on the Venezuelan coast by the 1520s, and as early as 1565 the Englishman John Hawkins was selling Negro slaves to Venezuelan planters. Thereafter Venezuelan settlements were quite regularly threatened by pirates, buccaneers and "sea dogs." English pirates raided and plundered Caracas in 1595. About the same time Sir Walter Raleigh sought unsuccessfully to occupy the Orinoco region in the name of England. Much later, in 1669, the notorious Henry Morgan raided the Lake Maracaibo area. Venezuela also became a focus of attention for smugglers, particularly English and Dutch. The Dutch, operating from the Island of Curacao, commanded an important share of the trade during the late 17th and early 18th centuries. The primary Venezuelan products to enter the illicit trade were cocoa, tobacco and hides.

Smuggling and the growing tendency for European wars to be fought in part in the Americas had a profound effect upon Venezuela during the 18th century. In 1728 the Caracas company, a

Basque controlled trading concern, was given a monopoly over much of the region in return for defending it and suppressing smuggling. Venezuela, which had been subordinate to the *audiencia* of Santo Domingo. mas made a captaincy general, subject to the viceroyalty of New Granada after 1741. It was freed from that connection in 1778.

The Caracas company was cordially disliked by many of the inhabitants because of its price fixing and its success in limiting smuggling. Despite the complaints of the residents, the company brought a degree of prosperity which continued after its trade monopoly was withdrawn in 1780. The Venezuelans were enjoying an era of rising prosperity when the Wars of Independence came.

Throughout the colonial period Venezuela was run first for the Spanish crown and second for the residents of the colony who could claim pure European lineage. This latter group owned most of the land and benefited from a system which gave them preference to the social and cultural institutions of the colony. "People of colour"; *i.e.,* Indians. Negroes and progeny of racially mixed marriage, were ostracized and left on the outskirts of society.

The Independence Movement. — On April 19, 1810. the *cabildo* of Caracas ousted the Spanish captain general and organized a junta to rule in the name of Ferdinand VII. who had been forced by Napoleon Bonaparte to abdicate as king of Spain. On July 5, 1811, the rights of Ferdinand VII were abandoned and the independence of the territory proclaimed. The Venezuelan people aere launched upon a prolonged and bloody conflict in which civil strife often competed with the independence struggle for the attention of the leadership. For a decade Venezuela felt the brunt of the Spanish fury. Large sections of the region were laid waste and Caracas changed hands on a number of occasions. So many thousands of Venezuelans lost their lives that the population level of 1810 was not again attained until 1850. Bolivar, who suffered repeated military defeats between 1810 and 1819, is generally credited with having kept the resistance movement alive. M'ith the assistance of such able Venezuelan lieutenants as Antonio José de Sucre and José Antonio Páez, Bolivar carried the war to the Spaniards in all of northern South America.

Independence for Venezuela, which was not recognized by Spain until 1845, was followed by several decades of turbulence during which bullets, not ballots, in effect ordinarily resolved political differences. The social and economic patterns, meanwhile, remained essentially unchanged, although the wars and subsequent commercial development added to the ruling elite persons who were unburdened by colonial tradition. Shortly after the battle of Carabobo (June 24, 1821) which broke the power of Spain in the area. I'enezuela became a part of Gran Colombia, which also comprised Colombia and Ecuador. After a brief period, regionalism gained the upper hand and by 1829 General Páez was able to lead Venezuela out of the union without serious opposition from nithin Venezuela or from Colombia. Venezuela at that time became a sovereign and independent state and has so remained.

Páez, who was representative of the new elements brought to the surface by the independence movement, in 1831 became the first president of the republic. As president and the maker of presidents he ruled until 1846 with considerable restraint. The press was allowed some freedom. A few public schools were constructed. Agriculture was promoted on a limited scale. Coffee grew important as an export commodity. Relations with the Roman Catholic Church were circumspect. The clergy was given national support but tithes u-ere abolished as were special ecclesiastical courts.

José Tadeo Monagas, sponsored by Páez won the presidency in an election in which only 60.000 voted out of a total population of about 1,275,000. Monagas promptly won the support of the army and then turned upon his patron, who was driven into exile. For more than a decade Monagas dominated the country amid civil war. Slavery as a legal institution was abolished in 1854. Paez returned to Venezuela in 1861 raised an army of hard-riding plainsmen. known as *llaneros,* and fought his way back into the presidency. He ruled as a stern dictator for two years (1861–63). Gen. Juan Crisóstomo Falcón established himself as chief executive in 1863.and exercised a precarious hold over the republic until 1868. Supported by young liberals under the influence of European revolutionary thinking, he made Venezuela a federalist republic against the wishes of those who would have preferred a strong central government. A revolt by Monagas. who still had political ambitions, forced Falcón to flee the country and to resign the presidency.

Out of the turmoil and confusion of the 1860s one figure loomed large, Antonio Guzmán Blanco. the son of a newspaper publisher. He assumed the presidency in 1870 and for 18 years, either as president or through puppets, dominated the nation. The new president. who was an anticlerical dealt the church some severe reversals. Monastic orders were closed, church property was confiscated and civil marriage laws and state control over registration of births and deaths were decreed. But the president brought a degree of order to Venezuela and gave a strong impetus to economic development. Foreign loans were contracted, railways and highways were constructed and public buildings were raised. Coffee became the principal item of export. International trade was increased. Some attention was paid to public education. Guzmán Blanco demanded discipline and efficiency from the bureaucracy, and tolerated little open criticism from his political opposition.

Guzmán Blanco's overthrow in 1888 paved the way for another decade of unrest and violence. Joaquin Crespo, who controlled provisionally before being elected to a regular presidential term, ran the country from 1894 to 1898. Foreign economic influence in Venezuela expanded significantly during Crespo's administration. His regime is remembered particularly for the I'enezuelan-British Guiana boundary controversy. which Pres. Grover Cleveland successfully insisted must be arbitrated.

Cipriano Castro controlled the republic from 1899 to 1908. Rough and unschooled. he fought in many civil wars before raising an army of his own and capturing Caracas and the presidency. As president his truculence incurred the ill-will of several foreign governments. In 1902 British. German and Italian naval units blockaded Venezuela in order to press demands for settlements of the claims of their nationals. Again the United States used its influence to force arbitration. Castro viewed the republic as a huge personal estate and before he left for Europe for medical treatment he had plundered the nation of much wealth and had made a mockery of responsible government.

When he sailed for Europe. Castro left his trusted lieutenant, Juan Vicente Gómez in charge. The lure of wealth and power was too great and Gomez struck out on his own. He soon consolidated his position and for 27 years ruled the republic with a mixture of stern discipline and paternal pride. The opposition was silenced by the threat of spies, political dungeons and devices for torture reminiscent of the Inquisition. Gómez built at public expense a tremendous fortune in farms, palaces. businesses, industries and bank balances abroad. But he was careful not to neglect the military upon whom his power rested. He encouraged the foreign exploitation of the nation's fabulously rich petroleum deposits. and by the early 1920s revenues were pouring into the public coffers at an unprecedented rate. Relatively little of the revenue went toward technological or cultural development. but the nation's entire external debt was liquidated. The death of "The Tyrant of the Andes" in 1935, released the pent-up resentments of the populace, who sacked and fired the homes of the Gómez family and those of the dictator's henchmen.

Gen. Eleazar López Contreras was named provisionally to succeed Gómez and was later elected to a five-year term. He gave Venezuela its first enlightened administration in generations. Education was promoted and public works were pushed. Civil liberties for a time were respected, but the abuse of newly non privileges in the form of strikes and disorders among workers, apparently incited by political radicals, gave López Contreras an excuse to take harsh measures against advocates of communism and anarchy.

Isaias Medina Angarita was selected by the Venezuelan congress. in April 1941, to succeed López Contreras, uho, in turn, was made chief of the army. During Medina's regime. which coincided with World War II, oil production was curtailed because of shipping difficulties. The oil companies were held responsible, and a new petroleum law more favourable to Venezuela was approved in 1943.

Medina drew much of his support from urban workers, and they were given political importance for the first time in Venezuelan history. Yet it was a combination of radical elements, represented by Acción Democrática, with military officers which effected a successful coup in Oct. 1945, and drove Medina into exile

Romulo Betancourt, leader of Accion Democrática, was named provisional president by a junta that had assumed control upon Medina's expulsion. He was subsequently elected president in an election in which women voted for the first time. Betancourt and his advisors were civilian and middle class and his election was looked upon as a victory of the people. Politically the regime was leftist. Betancourt approved a constitution which contained advanced social legislation and a provision that legalized the expropriation of oil properties.

In Dec. 1947, Rómulo Gallegos, recognized novelist and the candidate of Accion Democritica, was chosen president in a popular and honest election. Gallegos took office in Feb. 1948 Plans were made for land reform, larger royalties from petroleum and greater participation of the popular masses in public affairs. But before the decisions could be implemented, the military elements who had put Acción Democrbtica in power became restive and in Sovember ousted Gallegos, ending Venezuela's brief foray into democracy.

A junta of three military officers took over control of the republic in the name of the military and conservative civilian elements. The junta retained control through 1952.

On Dec. 2, 1952, Marcos Pérez Jiménez was declared president following an election in which he was clearly defeated in the voting. He assumed office in early 1953 and promptly imposed one of the most rigid and cruel dictatorships that Latin America had ever known. The bountiful wealth of the republic made possible large-scale, and at times wasteful, modernization and the development of basic sectors of the economy, including agriculture, and also the enrichment of a favoured few who enjoyed the blessing of the dictator and those close to him. The Venezuelan people refused to accept the fraud of a plebiscite held on Dec. 1j, 1957, in nhich Pérez Jiménez ran for a second term without opposition. Sustained public discontent had by the end of the year won converts within the military and on Jan. 23, 1958, the dictator was ousted and took refuge first in the Dominican Republic and then in the United States. Adm. Wolfgang Larrazabal headed a junta composed of military personnel and civilians which promised early elections. They were held in Dec. 1958 and Romulo Betancourt was elected president. (J. J. J.)

V. POPULATION

Venezuela ranks sixth among the South American countries in population as it does in area. The population rose from 2,890,000 in 1926 to 7,361,703 in 1961. In 1961 the capital, Caracas, had a population of 739,255. Maracaibo, the next largest city, had 432,902, and the third city, Barquisimeto, 196,557. The Federal District and the Lake Maracaibo region showed the greatest gains, but other parts of the country also increased their population decidedly. Most of Venezuela is sparsely inhabited, the great majority living in one-quarter or one-fifth of its territory, the hill and valley districts of the northern highlands and the adjoining coastal lands. About 150 mi. from the coast of the Caribbean or Lake Maracaibo, there is what may be called a frontier country.

Over most of this frontier, comprised chiefly of the vast llanos and the Guiana highlands, not only are there few inhabitants but the material advances that mark modern life are almost entirely lacking. Most of this country is not new. The llanos have been occupied for several hundred years, but, because of the nature of these great grasslands, the human population has remained far smaller than the animal population, and the inhabitants, living remote from the settled parts of the country—and from each other—have failed to keep pace with modern ways of life. The Guiana highlands have lagged still more and have remained almost unknown. Only since the 1930s has attention been directed toward this latter region, though a few places in it had been occupied, such as El Dorado, about 90 mi. in from the Orinoco river where a rich gold deposit had been worked for some years but then abandoned. A line of small settlements had been extended up the Orinoco even in colonial times. but they were far apart, farther still from the populous sections of the country and with no feasible means of contact. The river. their only easy highway, led away from rather than toward civilization. As a result of this situation. Venezuela remained for many years one of the minor, less significant countries of South America, with a small population and few known resources that interested the outside world, resulting in meager national income and little opportunity to improve its lot or expand its population into the sparsely inhabited regions.

VI. ADMINISTRATION AND SOCIAL CONDITIONS

Government.—The country's official name, since 1953, has been La República de Venezuela. During most of its history, it had been Los Estados Unidos de Venezuela. The change implied greater centralization of authority in the national government. Theoretically the individual 20 states were autonomous, however, each electing its legislative assembly, its governor, its two senators and its proportionate number of representatives in the national congress. This congress consists of 42 senators and 130 representatives (*diputados*), all elected for a five-year term. The suffrage is extended to both men and women and voting was compulsory. Illiterates voted by the use of differently coloured ballots. The fate of the constitution of 1953, in force under a provisional government with provisions for elections of president and national congress in 1958, was left undecided after the ouster of Jiménez and the rise to power of the new junta of early 1958. The national president administers the government of the Federal District and the two territories. Advanced social legislation, dating from 1947, governs relations of labour and capital and controls working conditions for women and children. Public health regulations reduced the incidence of malaria. tuberculosis, hookworm, dysentery and yellow fever in the vicinity of the larger population centres, but have not yet reached many of the rural regions.

(G. M. McB.; R. E. Ct.; J. J. J.)

Taxation.—As late as 1939 customs revenues accounted for 50% or more of Venezuela's budget receipts. Although collections from that source grew during the 1940s, by 1951, customs dropped to third place as a source of revenue—after taxes on minerals, chiefly petroleum, and income and other direct taxes. During the early 1950s indirect consumption taxes yielded only about 10% of federal receipts annually, a very low figure for Latin America. Petroleum royalties and taxes, despite some fluctuations, followed a steeply rising trend. The increase resulted from a sharp rise in petroleum production and generally higher world prices and increased royalties and taxes under the Hydrocarbon law of 1943. The first income taxes were collected in 1942–43 under Venezuela's Income Tax law enacted in 1942 (amended in 1944, 1946 and 1948). Of the indirect taxes on consumption, the most important are those on alcoholic beverages and cigarettes. Smaller amounts of income are derived from taxes on matches. Among miscellaneous revenues the principal item after World War II has been foreign exchange profits. (J. J. J.)

Living Conditions.—It is difficult to generalize on living conditions in Venezuela because since its great development by mid-20th century the petroleum industry exerted so great an influence on the total economy of the nation (more than $500,000,000 annually in royalties alone), and the impression was general therefore that the entire populace benefits. Sixty-five per cent of the government's revenues came from tax payments by the oil industry. Nonetheless, fewer than 75,000 persons were employed by the petroleum industry. Also there was the difference between urban and rural living and the vast chasm existing between the very rich (a thin veneer) and the very poor (the great mass of the population). Finally. both the official statistics and the general literature were unreliable and confusing.

Drawing conclusions from the decade of the Marcos Pérez Jiménez dictatorship. it would seem accurate to say that the rich became richer and the poor poorer. About one-half of the population eked out a bare living. These were largely rural dwellers. The Pérez

BY COURTESY OF HAMILTON WRIGHT

LOW-RENTAL HOUSING UNITS, CARACAS

Jiménez regime concentrated on the development of cities. stimulating the growth of an urban middle class. Yet so great was the movement from farm to city that. despite government construction of fine apartments for large numbers of people, thousands of citizens lived in misery in rude shacks under slum conditions. Yet the nation boasted the highest per capita income among the Central and South American countries. The cost of living, however. was higher than anywhere else in Central and South America and for Caracas possibly double that in New York city. In the 1950s few governments were working more assiduously to break the shackles of a one-product economy that contributed so much to the low level of living. as the same situation did throughout all of Latin America.

In the rural areas at least 40% of the farmers lived on small pieces of eroded land incapable of yielding an adequate diet. Not enough rice was grown domestically to feed the population, and the consumption of milk and meat was low. Rut even where fertile land was tilled. scarcity of labour and machinery, along with backward methods. limited output. The government claimed that 85% of the food required was produced within the country. This figure undoubtedly was too high. The level of living would not rise appreciably until agriculture was improved, for it was basic. Also the level of living was tied to the world market for oil: anything that affected exports affected the living conditions of the people, for Venezuela utilizes only about 5% of its oil production. (L. WE.)

Welfare Services. — Given the relatively vast economic resources of the Venezuelan nation. its achievements in welfare services up to the overthrow of Pérez Jimenez in early 1958 were insignificant. Although the military governments after 1948 felt it expedient to accede to some extent to social pressures. they showed a decided preference for public works over social welfare. However. nutritional programs, including workers' restaurants, which were first established during the Medina administration (1941–45) were continued. as were most of the provisions of the Labour law enacted in 1936 and amended in 194j and 1947. Repeated promises were made that the social and economic gains achieved by Venezuelan labour would he honoured. Nevertheless, the National Federation of Labour and many labour federations and unions were dissolved for purely political reasons. Under Pérez Jiménez, workers' housing in Caracas received much publicity and considerable was accomplished. Achievement, however, fell somewhat short of what propagandists for the regime would have had the public believe was accomplished. Outside of Caracas and a few other larger centres, welfare services, including medical care. were kept to a minimum.

Justice. — The supreme tribunal of Venezuela is the federal and cassation courts seated in Caracas. Its seven members, one from each of seven groups of states into which Venezuela is divided for this purpose, are elected by congress for five-year terms. The members of the courts choose their own president, vice-president and chancellor. A federal procurator-general is appointed for five years. There are lower federal courts.

The states each have a supreme court with three members in addition to a superior tribunal, courts of first instance, district courts and municipal courts. The territories are served by military and civil judges of first instance. (J. J. J.)

Education. — By law all children are required to attend school until the age of 14. Primary schools exist in nearly all communities. Secondary schools are maintained in most of the important centres. The Central University at Caracas (founded 172j) began elaborately rebuilding in 1953 on a new site. the Ciudad Universitaria. Some 25 buildings including a large open-air auditorium were already constructed by the mid-1950s and more were being added. The university has about 2,000 students and a full complement of faculties and special schools. The University hospital is one of the largest in South America. Two other government institutions. the University of the Andes at Mérida and the National University of Zulia at Maracaibo. have several faculties and full power to confer degrees. The three universities mentioned are supported by the federal government. There is a workers university in Caracas, and there are also two private universities in operation. the Universidad Catolica Andrés Bello and the Universidad de Santa Maria. A new university was created by government decree at Valencia in 1956. The Venezuelan Institute for Neurology and Brain Research, a federal government agency. was founded in 1954 near Caracas. Four national parks exist, partly for recreation, partly for natural history study. The most notable park, named for the Venezuelan botanist Henri Pittier. straddles the mountain range from the dry Caribbean coastal district through the cloud forests on the slopes and down to the interior valley about Lake Valencia. thus offering a great variety of climate, vegetation and animal life. The latest national park to be created (1958) is located in the Guatopo forest about 50 mi. S.E. of Caracas and is intended mainly to provide a better water supply to the capital.

Defense. — I'enezuela has compulsory military service for all adult males. In 1956, the active army numbered 10,000 men. The navy had three large destroyers and three light ones, four patrol launches. four frigates and several service vessels, There were an elaborate new military academy at Caracas, a naval school and several other institutes for the training of army and navy officers and an expanded air force academy at Maracay.

VII. THE ECONOMY

A. PRODUCTION

Agriculture. — As the result of confiscation, during years of political turmoil, many of the haciendas belong to the government. Cities and towns also own rural community property (ejidosj. Government legislation, beginning in 1949. effected some reforms in ownership, created a number of farm colonies, introduced new methods of cultivation, provided hetter seed and improved rural housing. Some of the revenue from oil was being utilized for the benefit of the farming population.

Stock raising is carried on in a relatively small scale over most of the 11-ell-settled rural regions but the number of those engaged in stock raising alone in these areas is small. On the extensive grasslsnds of the llanos the cattle business overshadows everything else. However, there, too, the number of men employed is not large. The number. both of herdsmen and of cattle, fluctuates with favourable and unfavourable weather and also with the demand for meat and hides. When the cattle business is good a considerable number of men are employed driving the herds to the fattening pastures in the central valleys or to the markets in the principal consuming centres.

Forestry. — Lumbering is a minor but still important occupation. Woodcutting is carried on most actively within and on the fringes of the more populous parts of the country, particularly on the foothills of the Andes and the Maritime ranges. Wood is in demand for charcoal, furniture making, fence posts, telephone and telegraph poles, doors. window frames and some flooring. Cement, brick, stone and adobe are the commoner building materials as in most of Central and South America. About 30,000 or 40,000 persons are normally engaged in lumbering and related occupations.

Mining. — Mining was never an important occupation in Venezuela until the mid-20th century. The variety of mineral products is great. Less than $\frac{1}{2}$ of 1% of the actively employed population is regularly engaged in mining or related occupations. Developments in iron mining on the lower Orinoco in the late 1940s and the stimulus given to gold mining in the same region increased the number of those employed in mining.

Iron became important, mainly in two rich fields a short distance from the mouth of the Orinoco. Existence of iron had been known in the region south of the Orinoco at the base of the Guiana highlands, but only in 1947 was the famous Cerro Bolivar, a mountain capped with iron, sometimes called "the century's greatest ore find," discovered. This field. with the smaller field at El Pao, jo mi. east, and several other nearby newly discovered deposits, assure the country of a fabulous wealth from iron ore mining for many years to come. Cerro Bolivar was estimated to contain from 400,000,000 to 500,000,000 metric tons of ore having 65% iron content. El Pao was estimated to have about 65,000,000 metric tons of equal grade. The total iron ore reserves of this general district were calculated to reach 2,000,000,000 tons. Shipments from El Pao began in 1951 and from Cerro Bolivar in 1954. In 1955 iron ore shipments from Venezuela to the United States amounted to 8,400,000 metric tons. The making of steel had just begun. One small plant operated near the Cerro Bolivar mines and in 1956 an Italian consortium was awarded the contract for construction of a plant expected to produce over 421,000 tons annually by 1959, primarily to supply the needs of the country. As with all other minerals, subsurface iron resources in Venezuela belonged to the state and most of the remaining lands thought to contain iron ore were subject to concessions by the government.

Gold has been at times an important product. The mines at El Callao. about 90 mi. south of the iron fields mentioned above, produced fabulously for several years but declined greatly after 1885, were revived in 1946 and became the largest producers in the country. They again encountered vicissitudes, however, mainly from labour troubles and the flooding of some workings. The government nationalized them in 1952. They continued to operate and in 1954, together with other mines in the vicinity, produced 1,744,088 g.

Diamonds have been found for many years in the streams (mainly the Caroni and its tributaries) descending from the Gran Sabana in the Guiana highlands and in some other adjacent areas. Indians and adventurers of European background had long collected them in small amounts. In 1950 a Venezuelan concern, largely government owned, began operations on a large scale in the far upper region of the Gran Sabana, with a landing field and a small power plant established there. Some smaller concerns joined in the search. Two companies. working under government concessions. were using modern equipment. Total production was reported to be (1954) 96.983 carats. These workings yielded gem stones and industrial diamonds in about equal amounts.

Some low-grade bituminous coal fields were worked for many years at Naricual, near Barcelona, the mines being connected by rail with the port of Guanta. Exploitation there, carried on mainly for the use of the Venezuelan navy, before the use of liquid fuel became general, has been suspended, partly because of a mine disaster. partly because of lack of demand. There is little need for coal for domestic uses, in part because of the tropical climate, in part because of the abundance of wood and natural gas for fuel. Other coal deposits are being worked in the states of Táchira and Zulia and along the base of the Maritime Cordillera in the states of Aragua and Guárico. Production from the Zulia region was utilized in the brick and clay products industry and in a cement plant operating there.

Other minerals, worked only on small scale, include asphalt, principally from the lake near the Gulf of Paria and from the Maracaibo region; asbestos, sulfur, copper, salt, mercury and others give promise of moderate future importance, for domestic use at least.

Fisheries. — Fishing occupies a considerable number of persons. The long coast line, the numerous small harbours, the growth of population in close proximity to the sea, have combined to make fish a more important part of the population's food than in most Central and South American countries. About 25,000 inhabitants normally make their living from this occupation and in marketing the fish. Most of the fish are consumed within the country. Pearl fishing is carried on about the Island of Margarita. With the recent marked economic development of the country several new industries have been established (*e.g.,* the manufacture of cement, footwear, flour, textiles and sugar). as yet mostly on a small scale.

(G. M. McB.; R. E. Ct.; J. J. J.)

Power. — Venezuela's production of energy increased substantially toward mid-20th century. The rapid increase in population must be regarded as the most important reason, because a steady expansion in energy output was imperative merely to maintain per capita use at a constant figure.

Venezuela possesses several important sources of power—vegetable fuels (wood, straw, bagasse). coal, petroleum, natural gas and water power. While considerable wood still was used for making charcoal in the more remote areas, the swelling migration from farms to cities was reducing the demand for it.

There is considerable coal in Venezuela, but the quality is not high, the deposits are not well located with respect to transport and population, and coal can not compete with petroleum and in some areas not even with natural gas. Some coal is used in iron-making. The wide distribution and active exploitation of petroleum have made Venezuela one of the world's most important producers (about 2,500,000 bbl. daily) and the largest exporter. The country is extremely rich in natural gas but only in the 1950s was it used to any extent; formerly it was wasted. By 1960 Venezuela hoped to consume in economic development more than 50% of the natural gas obtained with oil production.

Natural gas pipelines extended northward from central Guárico state to Caracas and La Guaira, and from Caracas westward to Maracay and Valencia. By the late 1950s Creole Petroleum corporation had completed two gas injector plants in Lake Maracaibo to save natural gas from drilled wells. This gas increased oil production by 50% and would increase by one-third the ultimate recovery of oil from the field where it is located. Although Venezuela does not possess the enormous potential water power reserves of Brazil: Chile, Argentina. Mexico, Peru or Colombia, it is believed to have more than 3,000,000 kw. The largest potential source and the one receiving the most attention in the late 1950s was the lower Caroni (six miles upstream from Puerto Ordaz) where 300.000 kw. of electrical power had been developed for the new iron and steel industry. Other rivers: such as the Chama and the Uribante, possess promising conditions for hydropower.

Industries. — Venezuela still had to be regarded as an agricultural nation in the late 1950s since about 75% of its people are on the land. Nevertheless, like most South and Central American nations. Venezuela is determined to industrialize and its progress is impressive. In the 1950s Venezuela's industrial production index has been the highest in South and Central America. The government actively encouraged establishment of new industries as a means of bringing new wealth into the country, of diversifying the internal economy, of providing greater employment opportunities, of raising the level of living and of helping in the growth of a

larger and stronger middle class. Those industries that make most efficient use of the vast natural resources were particularly encouraged.

The principal manufacturing area lies in the northern mountain region near the Caribbean. the heart of which includes the cities of Caracas. Maracay and Valencia. A part of this complex includes the petrochemical centres at Morón. Carabobo. state. and about 1 j mi. from Puerto Cabello.

Petroleum refining centres are located mostly on or near the coast; *e.g.*, at Las Piedras (Amuay), Caripito. Punta Cardón and El Palito. Yenezuela manufactures fertilizers. chlorine, caustic soda and explosives.

A new but potentially promising industrial area was that near the confluence of the Caroni and Orinoco rivers, particularly at Puerto Ordaz. There the government located its national iron and steel mills. This "seed" industry was expected to start many steel-using plants. With an abundance of water power on the lower Caroni and with large deposits of bauxite nearby. an aluminum industry is expected to arise soon.

Among Venezuela's principal industries are those engaged in food processing (the biggest industry, employing roughly one-half of the labour force engaged in manuiacturing). cement. textiles, glass, paper, ceramics. tobacco products, chemicals (including petrochemicals), rubber tires. paint. pharmaceuticals, soft drinks, matches and numerous others. Although for many years the refining of most Yenezuelan oil was neglected, being carried on at Curacao and Aruba in the Netherlands Antilles. it grew impressively in the 1950s. The various governments insisted that more oil be refined within the country (the law required new concessions to refine 15% of their output in Venezuela). By the latter 1950s Venezuela had more than 12 refineries. (L. WE.)

B. TRADE AND FINANCE

Imports and Exports.——Venezuela's natural resources are sharply divided into those for domestic consumption and those for export. Its agricultural productions are almost wholly for use within the country. Formerly it exported cacao. coffee and a few other products of the farms, but by mid-20th century few of these commodities nent abroad. Corn. rice. sugar. cacao, coffee. bananas. n-heat and a variety of tropical fruits and vegetables barely sufficed for increased home consumption. In spite of the great number oi cattle raised on Venezuela's extensive grasslands. meat was being imported in the 1950s.

Petroleum.— Products for export consist almost entirely of minerals, the most important. by iar. being petroleum. This comes mainly from the margin and shallow waters of Lake Maracaibo. which produced about two thirds of the nation's total. Since the 1940s oil production has extended to the eastern lowlands. halfway between the Orinoco and the Caribbean coast and also near the inner border of the Orinoco delta. Production of petroleum began in Venezuela in 191; and grew rapidly until by the mid-20th century it dominated the economy of the country and made Venezuela the second largest producer alter the United States. and the largest exporter of oil in the world. More than 12,000 wells were in operation and in 1957 an all-time high was reached with a daily average production of 2,801,27j bbl. A government petrochemical industry was founded in 1957. Oil made up from 90% to 95% of the nation's exports, accounting for about 60% of the government's revenue. providing 95% of the foreign exchange needs of the government itself. and about 80% of that for the entire country. Mainly because of its petroleum. Venezuela's per capita income exceeded that of any other country in South America. Moreover. its proven oil reserves amounted to about 10% of the world's total. Nearly all Venezuela's oil was produced for export (95%), about 14% in refined products. the rest as crude petroleum. Of the latter, more than 60% was merely shipped to the Dutch islands of Aruba and Curacao, to be refined there and then shipped overseas. Beginning in 1943, because of government requirements. refining n-ithin the country increased. with the erection of refineries at Las Piedras and Punta Cardón on the Paraguaná peninsula, and. in the east. at Caripito on the San Juan river. Tucupita in the Orinoco delta and at Puerto La Cruz on the Caribbean coast, north of the eastern fields. Pipelines lead to these refineries, which use about 23% of the oil production of the country.

(G. M. McB.; R. E. CT.)

Banking and Currency.— The Banco Central de Yenezuela S.A.: established in 1940, is the sole bank of issue for Venezuela. Half of the share capital of the institution is owned by the state. The Banco Central as well as the Banco Obrero and the Banco Agricola y Pecuario are important instruments of official policy. Foreign exchange rates are pegged by the Banco Central: however, commercial hanks are free to buy and sell. At the close of 1950 there were 16 commercial banks operating in Venezuela. Twelve were domestic banks and four were branches of foreign institutions. Commercial banks in Caracas in 1951 charged from 6% to 9% interest. Interest charged by government institutions ranged from 4% to 6%. The legal maximum rate in the latter 1950s was 1% per month and some loans were placed with individuals at that rate.

The monetary unit of Venezuela is the bolivar. which at the 1958 rate of exchange was equal to about 30 cents U.S. currency. Silver coins are circulated in denominations of 5 bolivares. 2 bolivares. 1 bolivar. 50 centimos and 2j centimos. Nickel coins of 12.j and j centimos are also circulated. Gold coins had been withdrawn from circulation and had been replaced by notes issued by the Banco Central in denominations of 1,000 bolivares. 500 bolivares, 100 bolivares, 50 bolivares, 40 bolivares, 20 bolivares and 10 bolivares. (J. J. J.)

National Finance.— The total foreign debt of the nation has been paid off. Except in wartime there has been no exchange control. The economy of the country is based mainly on one industry, oil production and the government's revenue derived mainly (about 60%) from that one source. According to the petroleum law of 1943 the gross profit from petroleum production was divided equally between the producer and the government.

C. TRANSPORT AND COMMUNICATION

Roads.— Extensive road building was pursued until, in the 1950s, few important centres north of the Orinoco were out of reach by some sort of highway or secondary road. Roads were being extended also southward from the Orinoco into the base of the Guiana highlands. Total extent of all-\yeather roads (1957) was about 15,000 mi. Nearly 1,000 mi. were being added to the system yearly. constructed mostly by the government with revenue from oil exports. Notable among such roads is the superhighway between Caracas and La Guaira and the airport of Maiquetía, a four-lane motor highway in which most of the former steep grades and sharp curves were eliminated, thus reducing the normal travel time from $1\frac{1}{2}$ hr. to about 20 min. Progress was also made in constructing the Venezuelan section of the Pan-American highway by which the distance from Caracas to the Colombian border would be reduced by zoo mi. and the roadbed much improved.

Railways.— In 1956 trackage measured about 700 mi. The network (if it can be so called) consisted of 11 main but disconnected lines of varying ownership and gauge. The longest single line (109 mi.) ran from Tucacas on the coast to Barquisimeto in the edge of the Andes. Built by British interests in 1877 to reach the copper mines at Aroa. this line was later cxtendcd to Puerto Cabello to connect with the railway running to Valencia and from there to Maracay and Caracas (about 150 mi.). The most used line was that between Valencia and Caracas (111 mi.), rivaled by the short (23 mi.) line, now electrified. betn-een Caracas and La Guaira. Several independent lines existed in the far western part of the country. One of them ran from Encontrados. river port on the Catatumbo reached by steamers from the lake. to the ton-n of Tachira and connected across the Colombian border to Cúcuta. A number of local lines were built by oil companies. and two short. but important. ones were constructed in the 1950s in the loner Orinoco region, one a go-mi. line from the iron mines at Cerro Bolivar to Puerto Ordaz; the other a 43-mi. line from similar mines at El Pao to the river port of Palua. The government was actively engaged in constructing connecting links. unifying the gauge and extending the system. The Bolivar railway was widened to standard gauge. A line was constructed from

El Palito on the coast near Puerto Cabello to Palma Sola on the Barquisimeto railway, thus linking two old important routes, and a short line has been built from Santa Barbara to Encontrados, connecting the two far western lines. A program of nationalization was also carried on. In 1936 the government purchased the British-owned Ferrocarril Central. In 1943 it nationalized the German-built railway connecting Valencia and Caracas (paying for it after World War II); and in 1949 it bought the British-owned line between La Guaira and Caracas.

This network fell far short of covering the country. or even the most thickly settled part. The vast area east and south of the capital to the Brazilian and Colombian borders and most of the higher Andean region lacked rail connection in the late 1950s. Highways only in part made up for this lack. The government's plan of "sowing oil" back into development of the country was intended to meet this deficiency. among others.

Shipping.— For its backwardness in highway and railway construction Venezuela has made up in part by the development of shipping. Since most of its populous districts lie on or near the coast: contact between these has been maintained largely by coastwise shipping. The Venezuelan coast is dotted with little ports. most of them with several short roads or railways leading inland. Small vessels transport freight and passengers from one port to another and to the larger ports, such as La Guaira and Puerto Cabello, which in turn give access to more distant points inland. Because of its coastwise shipping Venezuela has always maintained its contact with other countries better by sea than by land. Even its nearest neighbours. the Colombians, generally come to Venezuela by boat. For many years Venezuela collaborated with Colombia and Ecuador in maintaining a joint commercial fleet, the Flota blercante Grancolombiana. It began regular coastwise operations in 1946 and in 1949 extended these to ocean-going service, but in 1953 Venezuela withdrew from the partnership. It subsequently maintained a small fleet of vessels which operated under its own flag, mainly engaged in trade between its own ports and those of the United States and Canada. Since the chief export was petroleum and petroleum products the bulk of Venezuela's outgoing shipping centred in the three harbours best situated to handle that trade: Maracaibo, Las Piedras and the twin ports of Guanta–Puerto La Cruz, which together handled about two-thirds of the country's exports. Imports, however, entered mainly through La Guaira. Puerto Cabello and hlaracaibo. Puerto Cabello is considered the best natural harbour. but extensive improvements have made up for the lack of natural advantages at La Guaira, which in 1956 oifered berth space for 18 ocean vessels and 10 coastwise vessels at the same time. Dredging of the Maracaibo entrance has resulted in greatly increased trade through the ports there and has made Maracaibo a seaport. (G. M. McB.; R. E. Ct.)

Inland Waterways.— Venezuela is rich in rivers but most of them are of limited use because of remoteness, falls and rapids: great variability between high and low water (43 ft. on the Orinoco), and sand bars. Only since 1953 have large vessels been able to ascend the principal river—the Orinoco. In order to transport iron ore by large freighter from Puerto Ordaz to the United States, the United States Steel corporation was obliged to dredge about one-third of the 1j49 mi. between Puerto Ordaz and the Caribbean (33,000,000 cu.yd. of sand, gravel, clay and mud were removed). Ships carrying as many as 45,000 tons of ore could then regularly utilize the lower Orinoco.

The only other navigable inland body of water is Lake Maracaibo —Venezuela's leading oil-producing area. Until the mid-1950s only small oil tankers drawing at most 13 ft. could go from the lake to refineries on Aruba and Curaçao. Large tankers were prohibited by a 20-mi. sand bar at the neck connecting the lake with the Caribbean. At a cost of nearly $50,000,000, this obstacle was eliminated by dredging, thus allowing large tankers carrying 100,000 bbl. of oil to move out of the lake. This improvement aided the entire area and the port of Maracaibo was growing in economic stature. (L. We.)

Pipelines.— An important item in Venezuela's transportation system was the network of pipelines. There were about 2,000 mi. of these lines (1956), carrying crude petroleum and refined petroleum products. and several hundred miles carrying natural gas from the fields to the larger urban centres. Further extension of both types was planned. Though about 80% of the natural gas was flared off there was an increasing demand for it in the growing industrial activity in the country. Gas from the eastern oil fields was being considered as fuel for reducing the iron ore at the projected steel mills on the lower Orinoco.

Air **Transport.**—While at mid-20th century land and water transportation still lagged, Venezuela had advanced rapidly in air transport. There were four fully equipped airports. One at Maiquetía, a few miles west of La Guaira, served this port and Caracas, because the airport at the capital was small and the run irom the city to the coast by the new *autopista* ("superhighway") required less than half an hour. The Grano de Oro airport at Maracaibo handled passengers and freight connected with the oil industry there. At Maturín and Barcelona fully equipped fields were served by national and international carriers. In addition to these principal airports there were more than 80 lesser ones in regular service. Oil concerns and mining companies, ior example, maintained 20 airfields of their own. It was possible to reach by air most of the important centres of the country and many minor ones in the llanos and even back in the Guiana highlands. Some of these points had not yet been reached by rail or highway. Angel Falls was discovered irom the air and tourists visiting that region can fly to within a short distance of the site. There were landing fields also at Tumereno and iar into the Gran Sabana country at Luepa. (G. M. McB.; R. E. Ct.)

Postal Service.—-411 modern postal services are available in Venezuela and all means of communications are employed in order to provide adequate service. The majority of the post offices receive correspondence daily. In 1953 the postal system handled over 72,000,000 letters ior distribution within the national territory, over 18,000,000 ior distribution overseas and received over 18,000,000 from the outside for delivery within the national territory.

Telecommunications.— Telephones, telegraphs, radio telephones and radio telegraph provide rapid domestic communications. Radio telephone, radio telegraph and cable service are available for communications with other countries. In 1955, telephones in use numbered 104,500 (a vast majority of them in Caracas). More than 90% were in automatic systems. The State telegraph system had approximately 700 telegraph offices. There were 53 commercial radio broadcasting stations that were dependent upon advertising for their income and one government-run station. Caracas had three television stations, and there were relay stations to Maracaibo and other large towns. The Pérez Jimenez government often exercised strict censorship over all types of mass communications. (J. J. J.)

VENICE (Venezia), a city and seaport of Italy, occupying one of the most remarkable sites in the world. The city is an island linked with the mainland by a road and rail causeway $2\frac{1}{2}$ mi. long. The climate is mild.

At the head of the Adriatic, between the mountains and the sea, lies that part of the Lombard plain known as the Veneto. The whole of this plain has been formed by the deposits swept down from the Alps by the rivers Po, Ticino, Oglio, Adda, Mincio. Adige, Brenta, Piave, Livenza, Tagliamento and Isonzo. The substratum of the plain is a bed of boulders, covered during the course of time by a deposit of rich alluvial soil. The rivers when they debouch from the mountains assume an eastern trend in their effort to reach the sea. The result is that the plain is being gradually extended in an easterly direction, and cities like Ravenna, Adria and Xquileia. which were once seaports, lie now many miles inland. The encroachment of land on sea has been estimated to be at the rate of about 3 mi. in 1,000 years. A strong current sets around the head of the Adriatic from east to west. This current catches the silt brought down by the rivers and projects it in long banks, or *lidi*, parallel with the shore. In process of time some of these banks. as in the case of Venice. raised themselves above the level of the water and became the true shore line. while behind them lay large lagoons, formed partly by the fresh water brought down by the rivers, partly by the salt-water tide which found its way in by the channels of the river mouths. On a group of these banks about the middle of the lagoon of Venice stands the city of Venice. The soil only can be made capable of carrying buildings by the artificial means of pile-driving; there is no land fit for agriculture or the rearing of cattle; the sole food supply is fish from the lagoon.

The whole site of Venice is dominated by the existence of one great main canal, the Grand canal, which, winding through the town in the shape of a reversed letter S, divides it into two equal parts. This great canal was probably at one time the bed of a river flowing into the lagoons near Mestre. The smaller canals all serve as arteries to the Grand canal and their windings follow the lines of construction originally determined by the channels which traversed the islands of the lagoon. One other broad canal, once the bed of the Brenta, divides the island of the Giudecca from the rest of the city and takes its name from that island. The alleys or *calli* number 2.327, with a total length of about 90 mi.; the canals number 177 and measure 28 mi. There are frequent boat and launch services along the Grand canal to the Lido and other islands of the lagoon.

The ordinary Venetian house was built around a courtyard. and was one story high; on the roof was an open loggia for drying clothes; in front, between the house and the water, ran the *fondamenta* or quay. The earliest churches were built with cemeteries; and thus is the nucleus of the city of Venice. little isolated groups of dwellings each on its separate islet, scattered, as Cassiodorus, secretary to Theodoric the Great. says, in a letter dated A.D. j23. like sea birds' nests over the face of the waters. Some of the islets were then uninhabited. overrun with a dense low growth which served as cover for game and even for wolves.

Gondolas.—The famous gondolas (flat-bottomed boats) have been the characteristic conveyances on the canals of Venice for centuries. The history of these vessels, and even of the name. is obscure, but already in the 1 jth century they were an intimate part of Venetian life. There were 10,000 gondolas in Venice in the 16th century but the number has decreased. The gondola is a very long and narrow boat terminating at each end in a point or peak. Near the centre is a curtained cabin for passengers. Usually it is propelled by one gondolier standing on the stern cover and thrusting with a single oar, but sometimes by two gondoliers, as seen in the paintings of Vittore Carpaccio. One may also quote the description from Byron's *Beppo:*

> 'Tis a long cover'd boat that's common here
> Carved at the prow, built lightly, but compactly,
> Rowed by two rowers, each call'd "Gondolier,"
> It glides along the water looking blackly,
> Just like a coffin clapt in a canoe.

Before about the 15th century gondolas varied in shape and were often extravagantly coloured. A sumptuary order of the senate, however. restricted the gondola to a standard shape and one colour, black. The only outlet left for extravagance was the beautiful polish given to varnished surfaces. Old traditions of design are always maintained. The planks are of oak. the bottom of larch or fir, the decks of cherry or walnut. the covered part of lime wood, the *farcole* or forks in which the oars are placed are of walnut, while the oars are beech. The elegant. iron peak *ferro,* which resembles a halberd. serves both as an ornament and as a weight to balance the boat; it is made, according to traditional designs, in workshops at Maniago or Forno di Zoldo in the Dolomites. A gondola is about 32 ft. long and about 5 ft. wide. The weight is about 1,000 lb.. without cabin or other fittings.

Venetians still depend to a great extent on boat traffic for supplies. Thus the picturesque appearance of the boats on the lagoons —so graphically described by Gabriele D'Annunzio in *Il* Fuoco— is only one aspect of their importance in Venetian life.

St. Mark's.—The church of St. Mark's. originally the private chapel of the doge, is unique in respect of its richness of material and decoration. It was adorned with the spoils of countless other buildings. both in the east and on the Italian mainland. A law of the republic required every merchant trading to the east to bring back some material for the adornment of the fane. Indeed. the building is a museum of sculpture of the most varied kind. nearly every century from the 4th century down to the latest Renaissance being represented. The present church is the third on this site. Soon after the concentration at Rialto (see *History* below), a small wooden church was erected about the year 828 for the reception of the relics of St. hlark, brought from Alexandria. St. Mark then became the patron saint of Venice in place of St. Theodore. This church was burned in 976 along with the ducal palace in the insurrection against the doge Candiano IV.

Pietro Orseolo and his successors rebuilt it on a larger scale. About 1063 the doge Contarini began to remodel St. Mark's, Byzantine architects having a large share in the work, but Lombards were also employed. giving birth to a new style, peculiar to the district.

In plan St. Mark's is a Greek cross of equal arms, covered by a dome in the centre, 42 ft. in diameter. and by a dome over each of the arms. The plan is derived from the Church of the Holy Apostles at Istanbul, non covered by the mosque of Mohammed II, and bears a strong resemblance to the plan of St. Front at Périgueux in France (1120). The addition of a narthex before the main front and a vestibule on the northern side brings the whole western arm of the cross to a square on plan. In ele ation the façade seems to have connection with the five-bayed façade of the Kahriyeh Jame. or mosaic mosque, at Istanbul. The exterior façade is enriched with marble columns brought irom Alexandria and other cities of the east. Mosaics are employed to decorate the spandrels of the arches. Only one of the original mosaics now exists. It represents the translation of the body of St. Mark, and gives a view of the west facade of the church as it was at the end of the 13th century before the addition of the ogee gables. The top of the narthex forms a wide gallery, communicating with the interior at the triforium level. In the centre of this gallery stand the four colossal bronze horses which belonged to some Graeco-Roman triumphal quadriga. and were brought to Venice by the doge Enrico Dandolo in 1204. The south façade was restored in 1865–78.

Mosaic is the essential decoration of the church, and the architectural details are subordinated to the colour scheme. The oldest remaining belong to the 13th century, and many of them, for example those of the domes of the atrium, are among the finest of their kind; but some parts were restored in the 16th–19th centuries. Below the mosaics the walls and arches are covered with rare marbles, porphyries and alabaster from ancient columns sawn into slices and so arranged in broad bands as to produce a rich gamut of colour.

The eastern crypt, or *confessio,* extends under the whole of the choir and has three apses. like the upper church. Below the nave is another crypt. The floors of both crypts have sunk considerably and are often under water; this settlement accounts for the inequalities of the pavement. The original part of the magnificent mosaic pavement probably dates from the same period as the pavement at Murano, exactly similar in style, material and workmanship, which bears the date 1140. The pavement consists partly of *opus Alexandrinum* of red and green porphyry mixed with marbles. partly of tessellated work of glass and marble. v

The choir stands about 4 it. above the nave and is separated from it by a marble rood screen, on the architrave of which stand 14 figures. the signed work of Jacobello and Pier Paolo dalle Masegne, 1394.

The Pala d'oro, or retable of the high altar (within which rests the body of St. Mark), is one of the chief glories of St. Mark's. It is one of the most magnificent specimens of goldsmiths' and jewelers' work in existence. It was ordered in 976 at Istanbul by the doge Pietro I Orseolo. and was enlarged and enriched with gems and modified in form, first by a Greek artificer in 1105, and then by Venetians between 1209 and 1345. It is composed of figures of Christ, angels. prophets and saints, in Byzantine enamel run into gold plates. The treasury of St. Mark's contains magnificent church plate and jewels.

Byzantine Architecture. — The continuous growth of Venice can be traced through the successive styles of Byzantine. Gothic. early Renaissance and late Renaissance architecture. *(See* John Ruskin's *Stones* of *Venice*.) The two most striking buildings in Venice, St. Mark's and the doge's palace. at once give an example of the two earlier styles, the Byzantine and the Gothic, at least in their general design. though both are so capricious in development and in decoration that they may more justly be considered as unique specimens rather than as typical examples of their respective styles. In truth. because of its isolated position on the very verge of Italy. and of its close connection with the east, Venetian architecture was a distinctly independent development. The Piazza S. Marco, the famous square opposite the basilica of St. Mark, is dominated by the campanile of St. Mark. Under the buildings (see *Later Renaissance* below) forming the other three sides of the oblong runs a continuous colonnade with shops. cafés and offices. A feature of the piazza is the pigeons. which are regularly fed by the municipality. The piazzetta runs from the Riva degli Schiavoni between the west face of the doge's palace and Sansovino's library to meet the southwestern corner of St. Mark's and the open end of the great square, linking it with the Riva and the steamer services and gondolas plying thence. Through these two, the piazza and piazzetta. the life of Venice passes.

Fine examples of Venetian Byzantine palaces. at least of the facades, are still to be seen on the Grand canal and on some of the small canals. The interiors have been modified past recognition of their original disposition. The Byzantine palace seems to have had twin angle-towers, such as those of the Ca' Molin on the Riva degli Schiavoni. where Petrarch lived. The Fondaco dei Turchi (13th century!. now the natural history museum. also has two angle-towers. The facades presented continuous colonnades on each floor with semicircular high stilted arches, leaving a small amount of wall space. The buildings were usually battlemented in fantastic form. Specimens still in existence are Palazzo Loredan and Palazzo Farsetti (now the municipal buildings), and the splendid Palazzo Da Mosto, all on the Grand canal. The richest ornamentation was applied to the arches and string courses while plaques of sculpture. roundels and coats of arms adorned the facades. The remains of a Byzantine facade now almost entirely built into a wall in the Rio di Ca' Foscari offer an excellent illustration of this elaborate style of decorative work.

. Gothic Architecture. — Venetian Gothic, both ecclesiastical and domestic. shares most of the characteristics of north Italian Gothic generally. The materials, brick and terra-cotta, cause the characteristics of north Italian Gothic.

Soon after the concentration at Rialto. the doge Angelo Partecipazio began an official residence for the head of the state. This was a small. strongly fortified castle, one of whose massive angle-towers is now incorporated in St. Mark's and serves as the treasury. It was burned in 9;6 and again in 1106. Sebastian Ziani (1173–79) restored and enlarged the palace. Of his work some traces 'still remain in the richly sculptured bands built in at intervals along the 14th-century façade on the Rio. and part of the handsome larch-wood beams which formed the loggia of the piazzetta façade, still visible on the inner wall of the present loggia.

The ducal palace was begun by Pietro Gradenigo in 1309. Toward the end of the 14th century, this facade. with its lower colonnade. upper loggia with handsome Gothic tracery and the vast impending upper story, which give to the whole building its striking appearance and audacious design, had been carried as far as the tenth column on the piazzetta side. In 1424 the building was resumed and carried as far as the northwest angle. near St. Mark's. thus completing the sea and piazzetta façades of two stories with open colonnades, forming a long loggia on the ground and first floors, with 17 arches on the sea front and 18 on the other facade. Above this is a lofty third story. pierced with a few large windows, with pointed arches once filled with tracery, which is now lost. The whole surface of the ponderous upper story is covered with a diaper pattern in slabs of creamy white Istrian stone and red Verona marble, giving a delicate rosy-orange hue to the building. Beautiful sculpture. executed with an ivorylike minuteness of finish. is used to decorate the whole building with wonderful profusion. The great gateway, the Porta della Carta, was added in 1438–42 from designs by Giovanni Buon (or Bon) and his son Bartolomeo, The block of buildings in the interior, connecting the Porta della Carta with the Rio wing, was added about 1462. Later a fire consumed the earlier buildings along the Rio. which were replaced by the present structure.

The great internal court is surrounded with arcading. From the interior of the court access is given to the upper loggia by a beautiful early Renaissance staircase. built in 1484–1501 by Antonio Rizzo. Two colossal statues of Neptune and Mars at the top of these stairs were executed by Jacopo Sansovino in 1554—hence the name "giants' staircase." As a result of the fire of 1574, the fine series of early Paduan and Venetian frescoes in the chief rooms was lost. The magnificent council chambers for the different legislative bodies of the Venetian republic and the state apartments of the doges are highly decorated with gilt carving and panelling in the style of the later Renaissance. On the walls of the chief council chambers are a magnificent series of oil paintings by Tintoretto and others — among them his masterpiece, "Bacchus and Ariadne," and his enormous picture of "Paradise" which is probably the largest oil painting in the world.

Among the many Gothic churches of Venice the largest are the Franciscan church of Sta. Maria Gloriosa dei Frari (begun in 1338), and the Dominican church of SS. Giovanni e Paolo (1246–1430). The Frari is remarkable for its splendid works of art, including Titian's famous "Assumption of the Virgin" and its fine choir stalls and for the series of six eastern chapels which from outside give a good example of Gothic brickwork, comparable with the even finer apse of the now desecrated church of S. Gregorio. The church of SS. Giovanni e Paolo was the usual burying place of the doges, and contains many noble mausoleums of various dates. S. Stefano is an interesting building of central Gothic. The west entrance is later than the rest of the edifice and is of the richest Renaissance Gothic, a little earlier than the Porta della Carta.

But in the domestic architecture of Venice are the most striking and characteristic examples of Gothic. The introduction of that style coincided with the consolidation of the Venetian constitution and the development of Venetian commerce both in the Levant and with England and Flanders.

The finest example of the ogival style is undoubtedly the Ca' d'Oro. so-called from the profusion of gold employed on its facade. It was built for Marino Contarini in 1422–40, a comparatively late date. With a fine collection of pictures and furniture, it was given to the state by Baron Franchetti in 1916.

Contarini was to some extent his own architect. He had the assistance of Marco d'Amadeo, a master builder, and of Matteo Raverti, a Milanese sculptor, who were joined later on by Giovanni Buon and his son Bartolomeo. By the year 1431 the façade was nearly completed, and Contarini made a bargain with Martino and Giovanni Benzon for the marbles to cover what was yet unfinished. But Contarini mas not content to leave the marbles as they were. He desired to have the façade of his house in colour. The contract for this work. signed with Master Zuan de Franza, conjures up a vision of the Ca' d'Oro ablaze with colour and gleaming with the gold ornamentation from which it took its name.

Other notable examples are the Palazzo Ariani at S. Raffaele, with its handsome window in a design of intersecting circles; the beautiful window with the symbols of the four evangelists in the spandrels, in the façade of a house at S. Stae; the row of three Giustinian palaces at S. Barnaba; the Palazzo Priuli at S. Severo, with a remarkably graceful angle window. where the columnar mullion carries down the angle of the wall; the flamboyant balconies of the Palazzo Contarini Fasan; the Palazzo Bernardo on a side canal near S. Polo, a late central Gothic building (1380–1400).

Early Renaissance. — Toward the close of the 15th century Venetian architecture began to feel the influence of the classical revival; but, lying far from Rome and retaining still its connection with the east, Venice did not fall under the sway of the classical ideals either so quickly or so completely as most Italian cities. Indeed! in this as in the earlier styles. Venice struck out a line for itself and developed a style of its own. known as Lombardesque, after the Lombardo family (Solari) who came from Carona on the Lake of Lugano. The essential point about the style is that it is intermediary between Venetian Gothic and full Renaissance. It retains some traces of Byzantine influence in the decorated surfaces of applied marbles. and in the roundels of porphyry and *verde antico,* while it also retains certain characteristics of Gothic. as. for instance, in the pointed arches of the Renaissance faqade in the courtyard of the ducal palace designed by Antonio Rizzo (1499).

The most perfect example of this style in ecclesiastical architecture is the little church of Sta. Maria dei Miracoli begun by Pietro Lombardo in 1481. The church is without aisles, and has a semicircular roof. and the choir is raised 12 steps above the floor of the nave. The walls, both internally and externally, are encrusted with marbles. The facade has the characteristic circular pediment with a large west window surrounded by three smaller windows separated by two ornamental roundels in coloured marble and of geometric design. Below the pediment comes an arcade with flat pilasters, which runs all round the exterior of the church. Two of the bays contain roundheaded windows; the other three are filled in with white marble adorned by crosses and roundels in coloured marble.

Similar results are obtained in the magnificent faqade of the Scuola di S. Marco, at SS. Giovanni e Paolo, which has six semicircular pediments of varying size crowning the six bays. in the upper order of which are four noble Romanesque windows. The lower order contains the handsome portal with a semicircular pediment. while four of the remaining bays are filled with quaint scenes in surprisingly skillful perspective. The faqade of S. Zaccaria (1458–1515), the stately design of Anton Marco Gambello and Mauro Coducci. offers some slight modifications in the use of the semicircular pediment, the line of the aisle roof being indicated by quarter-circle pediments abutting on the faqade of the nave. S. Salvatore. the work of Tullio Lombardo (1530), is severer and less highly ornamented than the preceding examples, but its plan is singularly impressive, giving the effect of great space in a comparatively small area. . In this connection must be mentioned the Scuola of S. Giovanni Evangelista at the Frari, with its forecourt and screen adorned by pilasters delicately decorated with foliage in low relief, and its noble staircase whose double flights unite on a landing under a shallow cupola. This also was the work of Pietro Lombardo and his son Tullio.

Early Renaissance palaces occur frequently in Venice and form a pleasing contrast with those in the Gothic style. The Palazzo Dario with its dedication. *Urbis genio,* and the Vendramin-Calergi or *Non nobis* palace, whose facade is characterized by its roundheaded windows of grouped twin lights between columns, are among the more important; though beautiful specimens. such as the Palazzo Trevisan on the Rio della Paglia. and the Palazzo Corner Reali at the Fava, are to be found all over the city.

Later Renaissance.— In this period architecture in Venice lacks any peculiarly individual imprint. It is still characterized by great splendour; indeed. the library of S. Marco. begun by Jacopo Sansovino in 1536, is justly considered the most sumptuous example of Renaissance architecture in the world. It is rich. ornate, yet hardly florid, distinguished by splendid effects of light and shade, obtained by a far bolder use of projections than had hitherto been found in the somewhat flat design of Venetian faqades.

The old Procuratie were built by Bartolomeo Buon about 1514, the new by V. Scamozzi in 1580, yet it is clear that each belongs to an entirely different world of artistic ideas. The Procuratie Vecchie is perhaps the longest arcaded faqade in the world and certainly shows the least amount of wall space; the whole design is simple, the molding and ornamentation severe. The Procuratie Nuove, which after all is merely Scamozzi's continuation of Sansuovino's library, displays all the richness of that ornate building. It contains the museum of ancient sculpture, founded by Cardinal Domenico Grimani in 1523, and the Correr museum.

Among the churches of this period those of S. Giorgio Maggiore and of the Redentore are both by Palladio. In 1631 Baldassare Longhena began the fine church of Sta. Maria della Salute. With a large and handsome dome, a secondary cupola over the altar, and a striking portal and flight of steps. it occupies one of the most conspicuous sites in Venice on the point of land that separates the mouth of the Giudecca from the Grand canal. In plan it is an octagon with chapels projecting one on each side. The faqades of S. Moist: and of Sta. Maria del Giglio are good specimens of the baroque style.

Among the palaces of the later Renaissance the more remarkable are Sansovino's Palazzo Corner della Ca' Grande, Sammicheli's Palazzo Corner Mocenigo at San Polo, Longhena's massive and imposing Palazzo Pesaro, the Palazzo Rezzonico, from designs by Longhena with the third story added by G. Massari, and Massari's well-proportioned and dignified Palazzo Grassi at S. Samuele, built around 1750.

The "Scuole."—Among the most remarkable buildings in Venice are the *scuole,* or guild halls, of the various confraternities. The six *scuole grandi,* San Teodoro. Santa Maria della Carità, San Giovanni Evangelista. San Marco, della Misericordia and San Rocco, built themselves magnificent guild halls. The Scuola di San Marco is now a part of the town hospital, and besides its façade, it is remarkable for the handsome carved ceiling in the main hall (1463). Other beautiful ceilings are to be found in the great hall and the hall of the Albergo in the Scuola della Carita, now the Accademia containing the famous picture gallery, with a number of works, returned by Austria in 1919, by Marco Cozzi of Vicenza. But the most magnificent of these guild halls is the Scuola di San Rocco, designed by Bartolomeo Buon in 1517 and carried out by A. A. Scarpagnino and Sante Lombardo. The faqade on the Campo is large and pure in conception. The great staircase and the lower and upper halls contain an unrivaled series of paintings by Tintoretto.

Campaniles.--Among the more striking features of Venice are the campaniles or bell towers. (See CAMPANILE.) These were at one time more numerous! for earthquakes and subsidence of foundations have brought many of them down, the latest to fall being the great tower of San Marco itself, which collapsed on July 14, 1902. Its reconstruction was at once undertaken. and completed in 1912, together with that of Sansovino's beautiful Loggetta, on its east side. In a few other cases, for example at S. Giorgio Maggiore, the fallen campaniles were restored; but for the most part they were not replaced. The Venetian campanile usually stands detached from the church. It is almost invariably square. The campanile is usually a plain brick shaft with shallow pilasters running up the faces. It has small angle windows to light the interior inclined plane or staircase, and is not broken into stories with grouped windows as in the case of the Lombard bell towers. Above the shaft comes the arcaded bell chamber, frequently built of Istrian stone; and above that again the attic, either round or square or octagonal, carrying either a cone or a pyramid or a cupola. Among the existing campaniles the oldest are S. Geremia, dating from the 11th century, S. Samuele from the 12th. S. Barnaba and S. Zaccaria from the 13th.

Public Monuments.— Venetian sculpture is for the most part ancillary to architecture; for example, Antonio Rizzo's "Adam" and "Eve" (1464), which once faced the Giants' staircase in the ducal palace and are non replaced by marble copies, the originals being preserved in the ducal apartments. are parts of the decorative scheme; Sansovino's splendid monument to Tomaso Rangone is an essential feature of the façade of S. Giuliano. The most successful Venetian sculpture is to be found in the many noble sepulchral private monuments. The jealousy of the Venetian republic forbade the erection of monuments to its great men. The sole exception is the superb equestrian statue in honour of the general Bartolomeo Colleoni, standing on the Campo SS. Giovanni e Paolo. It is by the Florentine Andrea del Verrocchio, and was cast by Alessandro Leopardi, who was responsible for the graceful pedestal. Leopardi was also the creator (1505) of the three handsome bronze sockets in front of St. Mark's which held the flagstaffs of the banners of Cyprus, Morea and Crete, when the republic ruled them.

By the side of the sea in the piazzetta, on to which the west façade of the ducal palace faces. stand two ancient columns of Egyptian granite, brought as trophies to Venice by the doge Domenico Michieli in 1126. In 1180 they were set up with their present fine capitals and bases. The gray column is surmounted by a fine bronze lion in oriental style, brought to Venice for the doge Ziani about 1178. In 1329 a marble statue of St. Theodore, standing upon a crocodile. was placed on the other column.

Painting. — Painting developed relatively late in Venice, as is shown by the dates of the activity of Jacopo Bellini (1424–70) and his sons Gentile (1429–1507) and Giovanni (1430–1516), of the Vivarini family of Murano (1440–1505); and of Vittore Carpaccio (c. 1460–1525/26). The greatest artists of the Venetian school are Titian *(c.* 1477–1576), Tintoretto (1518–94) and Paolo Veronese (1528–88) but Palma il Vecchio *(c.* 1480–1528), Bonifazio Veronese and Paris Bordone, are also important. Later masters are G. B. Tiepolo, A. Canal and F. Guardi.

Institutions. — Thearsenal mas founded about the year 1104 by the doge Ordslafo Falier. In 1304, on the design of Andrea Pisano, new building sheds and the rope walk nere erected. Pisano's building sheds, nine in a row, with peculiarly shaped roofs, have been modified. In 1325 the second addition, the *arsenale nuovo,* was made, and a third, the *arsenale nuovissimo,* in 1473; a fourth. the *Riparto delle Galeazze,* about 1539; and in 1j64 the fifth enlargement, the *Canal delle Galeazze e Vasca,* took place. The entire circuit of the arsenal, about two miles in extent, is protected by a lofty wall with turrets. The main door of the arsenal is the first example in Venice of the purely classical style. It is a noble portal, erected in 1460, from designs by Fra Giocondo. with the lion of St. Mark in the attic. The statuary, with S. Giustina on the summit. of the tympanum. was added in 1j71 and 1578. The whole design was modified in 1688 so as to represent a triumphal arch in honour of Morosini Peloponnesiaco, who brought from Athens to Venice the four lions in Pentelic marble which now stands before the gate. (On the largest of these lions is cut a runic inscription recording an attack on the Piraeus in the 11th century by Norse warriors of the Varangian guard, under Harald Hardrada, afterward, in 1047, king of Norway.) The arsenal suffered frequently and severely from fires, the worst being those of 1509 and 1569; yet such was the wealth of Venice that its fleet crushed the Turks at Lepanto in 1571.

Festivals. — Venice is still famous for its festivals: The chief events in its history always have been celebrated either by civic or religious functions. The 11th centenary of the "pious theft" of St. Mark's body from Alexandria was celebrated in the spring of 1928 with a procession around the Piazzetta and the Piazza of S. Marco, in which 50 bishops of Venetia and mitred Canons of San Marco, as well as other dignitaries of the church, took part, robed in gorgeous vestments and recalling the pictures of Bellini and Carpaccio.

The most characteristic feasts are the following: on Holy Thursday the Venetians used to celebrate the victory over Urico, the patriarch of Aquileia. He was forced to pay tribute of a bull and 12 pigs which were meant to represent the primate and the canons of the chapter. Art and literature have immortalized the celebration of Ascension day when the doge used to be rowed out to the lagoon by the Lido in his gala gondola, *il Bucintoro* (or *Bucentaur*), to perform the symbolic rite of throwing a ring into the waters, and espousing the Adriatic with these words: *Ti sposiamo, o mare nostro, in segno di vero e perpetuo domino* ("We wed thee, o our sea, in sign of true and perpetual dominion.") The ceremony originated from Ascension day of the year A.D. 1000, when Pietro Orseolo II set sail from Venice to conquer Istria and Dalmatia.

Two eminently popular festivals of votive origin are still kept: the feast of the Madonna della Salute (Our Lady of Health) and that of the *Redentore* (Redeemer). to whose patronage the Venetians believed they owed their deliverance from the plague in 1576 and 1630. and in whose honour they built the churches of the Salute and the Redentore.

On the feast of the Salute (Nov. 21) the Venetians take votive offerings to the church, and end the day with private banquets for which it was formerly customary to procure Dalmatian mutton as the chief dish. The feast of the Redentore is celebrated on the third Sunday of July with a characteristic vigil kept by the people singing as they row about in boats of every size and shape which are festooned with lights. At dawn they row out to the Lido in great numbers for the sunrise. International film, sculpture and other festivals also take place in Venice.

Libraries, Museums and Galleries. — The library of San Marco contains about 550,000 printed volumes and about 13,000 manuscripts. The true foundation of the library may be dated to the donation of John Cardinal Bessarione. The principal treasures of the collection, including splendid Byzantine book covers, the priceless codices of Homer, the Grimani breviary, an early Dante, etc., are exhibited under cases in the Sala Bessarione in the Zecca or mint where the library has been installed. Another library was left to the public by the munificence of Count Querini-Stampalia. who bequeathed his collections and his house at Sta. Maria Formosa to be held in trust for students.

An up-to-date art library is kept in the Correr museum in St. Mark's square. The state archives are kept in the Franciscan monastery adjoining the Frari. It contains the so-called Golden Book of the patricians, and documents dating from the time of Charlemagne.

The doge's palace, adjoining St. Mark's, has frescoed walls and ceilings, and easel-pictures by Titian, Tintoretto, Paolo Veronese, etc. The names of the various halls: Sala del Collegio, del Senato, del Consiglio dei Dieci, del Maggior Consiglio, etc., recall the days of the proud republic. The Museo Archeologico occupies that part of the doge's palace where the doge used to have his apartment.

The Museo Civico Correr (the Correr museum), in the royal apartments, Piazza S. Marco, has valuable collections of pictures, armour, coins, maps, costumes of state, etc. The Museo Storico Navale, in the arsenal, has models of ancient ships and of the Bucintoro, or Bucentaur (*q.v.*).

The Accademia delle Belle Arti, on the Grand canal, contains a unique collection of masterpieces of the Venetian school. The Galleria Internazionale d'arte Moderna, inaugurated in 1902, has an important collection of international works of art which have been purchased in greater part from the Biennial International Exhibition of Modern Art. This was instituted in 1895 in honour of the silver wedding of King Humbert and Queen Margherita, and is held in the public gardens.

The Pinacoteca Comunale, in Palazzo Querini, once the residence of the patriarch of Venice, has a notable collection of pictures and prints.

Population and Administration. — In 1548 the population of Venice was 158,069; in 1607–29, 142,804; in 1706, 140,256; in 1785, 139,095; in 1881, 132,826; in 1931, 172,654; in 1951, 174,632; in 1957, 336,909 (commune).

Under the republic, and until modern times, the water supply of Venice was furnished by the storage of rain water supplemented by water brought from the Brenta in boats. The famous Venetian *pozzi,* or wells for storing rain water from the roofs and streets, consisted of a closed basin with a watertight stratum of clay at the bottom, upon which a slab of stone was laid; a brick shaft of radiating bricks laid in a permeable jointing material of clay and sand was then built. On the ground level perforated stones set at the four corners of the basin admitted the rain water, which was discharged from the roofs by lead pipes; this water filtered through the sand and percolated into the shaft of the well, whence it was drawn in copper buckets. The present drinking water supply comes from San Ambrogio di Grion near Castelfranco Veneto about 20 mi. away.

All the drains of the houses in Venice are of the kind known as *bottino mouras,* the openings of which have to be more than three feet below the level of the average high tide, all drainage being carried out to sea. With the rise and fall of the tide the discharge pipes are flushed at the bottom. An investigation undertaken by the Bacterioscopical laboratory, with regard to the pollution of the Venetian canals by the city sewage, led to the discovery that the water of the lagoons possesses self-purifying power, not only in the large canals but even in the smallest ramifications of the waterways.

Venice has a patriarch who is usually a cardinal. The patriarchate dates from 1451, when on the death of Domenico Michiel, patriarch of Grado, its seat of that honour was transferred to the cathedral church of Castello in Venice, and Michiel's successor, Lorenzo Giustinian, assumed the title of patriarch of Venice. On the fall of the republic St. Mark's became the cathedral church of the patriarch. There are 30 parishes in the city of Venice and 15 in the lagoon islands and on the littoral.

There is a football and sports ground in Venice, but perhaps more typical sports are those that take place on the water, especially the historic regatta held annually on the first Sunday in September on the Grand canal.

Port, Communications and **Industries.**—Under the republic commercial shipping used to enter Venice by the port of S. Nicolò del Lido and lie along the quay called the Riva degli Schiavoni, in the basin of S. Marco, and up the broad Giudecca canal. But the mouth of the Lido entrance gradually silted up and, when trade expanded, the Italian government resolved to reopen it. Two moles were run out in a southwesterly direction; the westerly is about 2 mi., the easterly about 3 mi. in length. The natural scour thus created gave a depth of 26 ft. of water through the sandbank. The mean rise and fall of the tide is about 2 ft., but under certain conditions of wind the variation amounts to j ft. and over. Docks were constructed near the railway station, but in 1917 plans were made for a new port for Venice on the mainland, at Marghera, south of the railway line to Padua; in 1922 the canal of approach was opened by King Victor Emmanuel III, and named after him, and in 1924 the construction of the main works was begun. The port is accessible at all times to vessels drawing 30 ft. It was the first in Italy n-here railway trucks could be loaded and unloaded on the quays, which are in direct communication with Mestre station.

The maritime station, connected with the mainland by a bridge, and the Marghera industrial port were both dredged to a depth of 33 ft. The maritime station, which includes Mole A at Porto Marghera, has a total length of 18,168 ft.; the whole commercial zone has an area of 27 ac., and the industrial area of Porto Marghera has a total length of 45,932 ft. It has a yearly potential in loading and unloading of at least 1,000 tons of merchandise to every 3 ft. of port frontage. The three industrial zones lying to the north, west and south of the commercial port were nearly all secured by business firms, and a number of factories were built. Each zone has exit to the sea by means of canals; for example, the northern zone communicates with the sea by the Canale Industriale Nord.

Venice is linked by rail with main lines to Milan and Bologna and through Tarvisio and Trieste to Austria and Yugoslavia respectively. The Santa Lucia station, a modern low-pitched building, beautiful in the grace and clarity of its design, is at the western end of the Grand canal. The city is generally served by Treviso airport, 21 mi. away, and occasionally by the small San Nicolò airport at the northern end of the Lido.

A garden city, built on the Mestre-Padua road, provides links with the industrial area.

The ancient glass-bead industry (*conterie*) has regained its position through the union of the different factories. Venetian beads are ordinarily sent in large quantities to Africa and to India, Sumatra and Borneo. Similarly, the glass industry has revived. New amalgams and methods of colouring have been discovered, and fresh forms have been diligently studied. Special progress has been made in the production of mirrors, electric lamps, candelabra and mosaics. There are worked iron and copper industries, and much carved furniture is produced. Venetian filigree jewelry, and long, fine gold chains are also beautifully made.

New industries are those of tapestry, brocades, imitation of ancient stuffs, cloth of silver and gold, and Venetian laces for the manufacture of which there is a government school, with 500 girl pupils. (*See* LACE.)

The Lido.—Bathing establishments were set up on a long beach or strand that separates Venice from the open sea. These proved so popular that a whole town with bathing huts, hotels, gardens and tree-lined avenues grew up facing the Adriatic. Instead of gondolas or ferries there are trolley buses, motor cars and carriages. The curved beach with its firm sands attracts visitors from all parts of the world.

The Islands in the Lagoon.—These include Murano, where an ancient and celebrated tradition of artistic glassmaking still flourishes; Burano, an island of fisherfolk also known for lacework; S. Francesco del Deserto, legend tells of several miracles performed there by St. Francis of Assisi during his journey in 1200; Torcello, farthest to the north, 6½ mi. away, was the political centre of the lagoon before Venice rose to power on the other islands. But more than 1,000 years ago the city that had arisen around the cathedral and the Church of Sta. Fosca was partly dismantled to build the palaces of Venice; S. Lazzaro degli Armeni is an Armenian monastery in the immediate Venice basin, a centre of studies for Roman Catholic monks of the Armenian rite. Lord Byron often visited the monastery. (X.)

HISTORY

It is usually affirmed that the state of Venice owes its origin to the barbarian invasions of north Italy; that it was founded by refugees from the mainland cities who sought refuge from the Huns in the impregnable shallows and mudbanks of the lagoons. Venice, like Rome and other famous cities, was an asylum city. But it is nearly certain that long before Attila and his Huns swept down upon the Venetian plain in the middle of the 5th century, the little islands of the lagoon already had a population of poor but hardy fisherfolk living in quasi-independencc, because of their poverty and their inaccessible site. This population was augmented from time to time by refugees from the mainland cities of Xquileia, Concordia, Opitergium, Altinum and Patavium. But these did not mingle readily with the indigenous population; as each wave of barbarian invasion fell back, these refugees returned to their mainland homes, and it required the pressure, of many successive incursions to induce them finally to abandon the mainland for the lagoon, a decision which was not reached till the Lombard invasion of j68. On each occasion, no doubt, some of the refugees remained behind in the islands, and gradually built and peopled the 12 lagoon townships, which formed the germ of the state of Venice and were subsequently concentrated at Rialto or in the city known as Venice. These 12 townships were Grado, Bibione, Caorle, Jesolo, Heraclea, Torcello, Murano, Rialto, Malamocco, Poveglia, Chioggia and Sottomarina. The effect of the final Lombard invasion is shown by the resolve to quit the mainland and the rapid building of churches which is recorded by the *Cronaca altinate*. The people who finally abandoned the mainland and took their priests with them are the people who made the Venetian republic. But they were not as yet homogeneous.

Independence.—There is little doubt that the original lagoon population depended for its administration, as far as it had any, upon the larger cities of the mainland. There is a tradition that Venice was founded hy "consuls from Padua"; and Padua claimed complete control of the course of the Brenta down to its mouth at Malamocco. The destruction of the mainland cities, and the flight of their leading inhabitants to the lagoons, encouraged the lagoon population to assert a growing independence, and led them to advance the doctrine that they were "born independent." Their development as a maritime people, engaged in small trading and intimately acquainted with their home waters, led Belisarius to seek their help in his task of recovering Italy from the Goths. He was successful: and the lagoons became, theoretically at least, a part of the eastern empire. But the empire was vast and weak, and its capital lay far an-ay: in practice, no doubt, the lagoon population enjoyed virtual independence.

It was from Byzantium that the Venetian people received the first recognition of their existence as a separate community. Their maritime importance compelled Narses, the imperial commander, to seek their aid in transporting his army from Grado; and when the Paduans appealed to the Eunuch to restore their rights over the Brenta, the Venetians replied by declaring that islands of the lagoon and the river mouths that fell into the estuary were the property of those who had rendered them habitable and serviceable. Narses declined to intervene. Padua was powerless to enforce its claims and Venice established a virtual independence of the mainland. Nor was it long before Venice made a similar assertion to the imperial representative, Longinus, who invited the Venetians to give him an escort to Constantinople (which they did) and also to acknowledge themselves subjects of the empire. By dint of promising large concessions and trading privileges, he induced the Venetians to make an act of submission — though not upon oath. The terms of this pact resulted in the first diploma conferred on Venice as a separate community (584). But it was inevitable that, when the barbarians, Lombard or Frank, were once established on the mainland of Italy. Venice should be brought first into trading and then into political relations with its near neighbours, who as masters of Italy also put forward a claim to sovereignty in the lagoons. It is between the two claims of east and west that Venice struggled for and achieved recognized independence.

Internal Fusion and Consolidation.——In 466, 14 years after the fall of Aquileia, the population of the 12 lagoon townships met at Grado for the election of one tribune from each island for the better government of the separate communities, and above all to put an end to rivalries which had already begun to play a disintegrating part. But when the lagoon population was largely augmented in 568 as the result of Alboin's invasion, these jealousies were accentuated, and in 584 it was found expedient to appoint 12 other tribunes, known as the *Tribuni Maiores,* who formed a kind of central committee to deal with all matters affecting the general weal of the lagoon communities. But the *Tribuni Maiores* were equally powerless to allay the jealousies of the growing townships which formed the lagoon community. Rivalry in fishing and in trading. coupled with ancient antipathies inherited from the various mainland cities of origin, were no doubt the cause of these internecine feuds. A crisis was reached when Christopher, patriarch of Grado. convened the people of the lagoon at Heraclea, and urged them to suppress the 12 tribunes and to choose a single head of the state. To this they agreed, and in 697 Venice elected its first doge, Paulo Lucio Anafesto.

The growing importance of the lagoon townships, due to their maritime skill: their expanding trade, created by their position between east and west: their monopoly of salt and salted fish, which gave them a strong position in the mainland markets. rendered it inevitable that a clash must come over the question of independence. when either east or west should claim that Venice belonged to them; and inside the lagoons of growing prosperity, coupled with the external threat to their liberties, concentrated the population into two well-defined parties—what may be called the aristocratic party, because it leaned toward imperial Byzantium and also displayed a tendency to make the dogeship hereditary, and the democratic party, connected with the original population of the lagoons, aspiring to free institutions. and consequently leaning more toward the church and the Frankish kingdom which protected the church. The aristocratic party was captained by the township of Heraclea, which had given the first doge, Anafesto, to the newly formed community. The democratic party was championed first by Jesolo and then by Malamocco.

The Franks. — The advent of the Franks determined the final solution. The emperor Leo, the Isaurian, came to open rupture with Pope Gregory II over the question of images. The pope appealed to Liutprand, the powerful king of the Lombards, to attack the imperial possessions in Ravenna. He did so, and expelled the exarch Paul, who took refuge in Venice and was restored to his post by the doge of the Heraclean or Byzantine party, Orso, who in return for this assistance received the imperial title of *hypatos,* and trading rights in Ravenna. The pope, however, soon had cause for alarm at the spread of the Lombard power which he had encouraged. Liutprand proceeded to occupy territory in the Ducato Romano. The pope, looking about for a saviour, cast his eyes on Charles Martel, whose victory at Tours had riveted the attention of the world. Charles's son, Pippin. was crowned king of Italy, entered the peninsula at the head of the Franks, defeated the Lombards, took Ravenna and presented it to the pope, while retaining a feudal superiority. Desiderius, the last Lombard king, endeavoured to recover Ravenna. Charlemagne. Pippin's son. descended upon Italy, broke up the Lombard kingdom (774), confirmed his father's donation to the pope. and in reprisals for Venetian assistance to the exarch. ordered the pope to expel the Venetians from the Pentapolis. Venice was now brought face to face with the Franks under their powerful sovereign. who soon showed that he intended to claim the lagoons as part of his new kingdom. In Venice the result of this menace was a decided reaction toward Byzantium. In opposition to the Frankish claim, Venice resolved to affirm its dependence on the eastern empire. But the democratic party. the Frankish party in Venice. was powerful. Feeling ran high. A crisis was rapidly approaching. The Byzantine doge Giovanni Galbaio attacked Grado, the see of the Francophil Patriarch Giovanni, captured it, and flung the bishop from the tower of his palace. But the murdered patriarch was succeeded by his no less Francophil nephew Fortunatus, a strong partisan, a restless and indomitable man, who along with Obelerio of Malamocco now assumed the lead of the democratic party. He and his followers plotted the murder of the doge. were discovered. and sought safety at the court of Charlemagne, where Fortunatus strongly urged the Franks to attack the lagoons.

Meantime the internal politics of Venice had been steadily preparing the way for the approaching fusion at Rialto. The period from the election of the first doge to the appearance of the Franks was characterized by fierce struggles between Heraclea and Jesolo. At length the whole population agreed to fix their capital at Malamocco, a compromise between the two incompatible parties, marking an important step toward final fusion at Rialto.

That central event of early Venetian history was reached when Pippin resolved to make good his title as king of Italy. He turned his attention to the lagoon of Venice, which had been steadily growing in commercial and maritime importance, and had, on the whole, shown a sympathy for Byzantium rather than for the Franks. Pippin determined to subdue the lagoons. He gathered a fleet at Ravenna, captured Chioggia. and pushed on up the Lido toward the capital of the lagoons at Malamocco. But the Venetians. in face of the danger, once more moved their capital, this time to Rialto, that group of islands now called Venice, lying in mid-lagoon between the *lidi* and the mainland. This step was fatal to Pippin's designs. The intricate waterways and the stubborn Venetian defense baffled all his attempts to reach Rialto; the summer heats came on; the Lido was unhealthy. Pippin was forced to retire. A treaty between Charlemagne and Nicephorus (810) recognized the Venetians as subjects of the eastern empire, while preserving to them the trading rights on the mainland of Italy which they had acquired under Liutprand.

The concentration at Rialto marks the beginning of the history of Venice as a full-grown state. The external menace to their independence had welded together the place and the people; the same pressure had brought about the fusion of the conflicting parties in the lagoon townships into one homogeneous whole. There was for the future one Venice and one Venetian people dwelling at Rialto. the city of compromise between the dangers from the mainland, exemplified by Attila and Alboin, and the perils from the sea, illustrated by Pippin's attack. The position of Venice was now assured.

The first doge elected in Rialto was Angelo Partecipazio, a Heraclean noble. and his reign was signalized by the building of the first Church of S. Marco, and by the removal of the saint's body from Alexandria, as though to affirm and to symbolize the creation of united Venice.

Growth of The Republic

The history of Venice during the next 200 years is marked externally by the growth of the city, the result of its increasing trade. In the mainland Venice gradually acquired trading rights, partly by imperial diploma, partly by the establishment and the supply of markets on the mainland rivers. the Sile and the Brenta. Internally this period is characterized by the attempt of three powerful families, the Partecipazi. the Candiani and the Orseoli, to create an hereditary dogeship, and the violent resistance offered by the people. There were seven of the Particiachi. five Candiani and three Orseoli reigning in almost unbroken succession. until. with the ostracism of the whole Orseolo family in 1032, the dynastic tendency was crushed forever.

The growing wealth of Venice soon attracted the cupidity of its piratical neighbours on the coast of Dalmatia. The swift Liburnian vessels began to raid the Lido. compelling the Venetians to arm their own vessels and thus to form the nucleus of their famous fleet. the importance of which was recognized by the Golden Bull of the emperor Basil. which conferred on Yenetian merchants privileges far more extensive than any they had hitherto enjoyed. on condition that the Venetian fleet was to be at the disposition of the emperor. But the Dalmatian raids continued to harass Yenetian trade. till. in 1000. the great doge Pietro Orseolo II attacked and captured Curzola and stormed the piratical stronghold of Lagosta. crushing the freebooters in their citadel. The doge assumed the title of duke of Dalmatia. and a great step was taken toward the supremacy of Venice in the Adriatic. which was essential to the free development of its commerce and also enabled it to reap the pecuniary advantages to be derived from the Crusades. It now commanded the route to the Holy Land and could supply the necessary transport. nnd from the crusades its growing aristocracy reaped large profits. Orseolo's victory was commemorated and its significance affirmed hy the magnificent symbolical ceremony of the "wedding of the sea" (*Sposalizio del Mar*). celebrated henceforward every Ascension day. The result of the first three crusades was that Venice acquired trading rights. a l'enetian quarter. church. market. bakery. etc.. in many of the Levant cities: *e.g.*, in Sidon (1102) and in Tyre (1123). The fall of Tyre marks a great advance in development of Venetian trade; the republic had now passed beyond the Adriatic. and had taken an important step toward complete command of the Levant.

Rise of the **Aristocracy.**—This expansion of the trade of Venice resulted in the rapid development of the wealthier classes, with a growing tendency to draw together for the purpose of securing to themselves the entire direction of Venetian politics in order to dominate Venetian commerce. To achieve their object. a double line of conduct was imposed upon them: they had to absorb the powers of the doge. and also to deprive the people of the voice they possessed in the management of state affairs by their presence in the *concione* or genera1 assembly of the whole community, which was still the fountain of all authority. The first step toward curtailing the power of the doge was taken in 1032, when the family of the Orseoli was finally expelled from Venice and the doge Domenico Flabianico was called to the throne. X law was then passed forbidding for the future the election of a doge-consort. a device by which the Particiachi. the Candiani and the Orseoli had each of them nearly succeeded in carrying out their dynastic ambitions. Further, two ducal councilors were appointed to assist the doge, and he was compelled. not merely permitted, to seek the advice of the more prominent citizens at moments of crisis. By this reform two important offices in the l'enetian constitution — the privy council (*consiglieri ducali*) and the cenate (the *pregadi* or invitedj — came into being. Both were gradually developed on the lines desired by the aristocracy, until the year 1171.

The growth of Venetian trade and wealth in the Levant roused the jealousy of Genoa and hostility of the imperia1 court at Constantinople. where the Venetians are said to have numbered 200,000 and to have held a large quarter of the city in terror by their brawls. The emperor Manuel I. urged on by the Genoese and other rivals of Venice. seized the pretext. The Yenetians were arrested and their goods confiscated. Popular feeling at Yenice ran so high that the state was rashly swept into war with the empire. The doge Vitale Michiel II led the expedition in person. It proved a disastrous failure, and on the return of the shattered remnants (1171) a great constitutional reform seemed necessary. The Venetians resolved to create a deliberative assembly. which should act with greater caution than the *concione,* which had just landed the state in a ruinous campaign. Forty members were elected in each of the six divisions of the city, giving a body of 480 members. who served for one year and on retiring named two deputies for each *sestiere* to nominate the council for the succeeding year. This was the germ of the great council, the Maggior Consiglio, which was rendered strictly oligarchic in 1296. As the duties of this council were to appoint all officers of state. including the doge. it is clear that by its creation the aristocracy had considerably curtailed the powers of the people, who had hitherto elected the doge in general assembly; and at the creation of Michiel's succescor. Sebastiano Ziani (1172), the new doge was presented to the people merely for confirmntion.

The assembly protested. but was appeased by the empty formula. "This is your doge if it please you." Moreover. still further to limit the power of the doge, the number of ducal councilors was rnised from two to six. In 1198. on the election of Enrico Dandolo. the aristocrncy carried their policy one step farther, and hy the *promissione ducale*, or coronation oath. which every doge was required to swear. they acquired a powerful weapon for the suppression of all that remained of ancient ducal authority. The *promissione ducale* was binding on the doge and his family. and could he. and frequently was. altered at each new election. a commission. *Inquisitori sopra il doge defunto,* being appointed to scrutinize the actions of the deceascd doge and to add to the new oath whatever provisions they thought necessary to reduce the dogeship to the position of a mere figurehead.

The 4th **Crusade.**—In spite of the check to their trade reteil-ed from the emperor Manuel in 1171, Yenetian commerce continued to Aourish. the Yenetian fleet to grow and the Yenetians to amass wealth. When the fourth crusade was proclaimed at Soissons. it was to Venice that the leaders applied for transport, and it agreed to furnish transport for 4,500 horses. 9.000 knights, 20,000 foot, and provisions for one year: the price was 85.000 silver marks of Cologne and half of all conquests. But Zara and Dalmatia had revolted from Yenice in 1166 and were as yet unsubdued. Venetian supremacy in the Xdriatic had been temporarily shaken. The 85.000 marks, the price of transport. were not forthcoming. and the Venetians declined to sail till they were paid. The doge Dandolo now saw an opportunity to benefit Venice. He offered to postpone the receipt of the money if the crusaders n-ould reduce Zara and Dalmatia for the republic. These terms were accepted. Zara was recovered. and while still at Zara the leaders of the crusade. supported by Dandolo. resolved for their own private purposes to attack Constantinople. instead of making for the Holy Land. Constantinople fell (1204), chiefly because of the ability of the Venetians under Dandolo. The city was sacked. and a Latin empire. with Baldwin of Flanders as emperor, was established at Constantinople. (See BYZANTINE EMPIRE.)

In the partition of the spoils Venice claimed and received. in its own phrase. "a half and a quarter of the Roman empire.!' To Venice fell the Cyclades. the Sporades. the islands and the eastern shores of the Xdriatic. the shores of the Propontis and the Euxine. and the littoral of Thessaly, and it bought Crete from the marquis of Monferrat. The accession of territory was of the highest importance to Venetian commerce. Venice now commanded the Xdriatic. the Ionian islands. the archipelago, the Cea of Marmora and the Black sea. the trade route between Constantinople and western Europe. and it had already become established in the seaports of Syria. and thus held the trade route between Asia Minor and Europe. It was raised at once to the position of a European power. In order to hold these possessions. it borrowed from the Franks the feudal system. and granted fiefs in the Greek islands to its more powerful families. on condition that they held the trade route open for Venice. The expansion of commerce which resulted from the fourth crusade soon made itself evident in the city by a rapid development in its architecture and by a decided strengthening of the commercial aristocracy, which eventually led to the great constitutional reform — the closing of the Maggior Consiglio in 1296. whereby Venice became a rigid oligarchy. Externally this rapid success awoke the implacable hatred of Genoa. and led to the long and exhausting Genoese wars which ended at Chioggia in 1380.

The Venetian Constitution.— The closing of the great council was. no doubt, mainly due to the slowly formed resolution on the part of the great commercial families to secure a monopoly in the Levant trade which the fourth crusade had placed definitely in their hands. The theory of the government, a theory expressed throughout the whole commercial career of the republic, the theory which made Venice a rigidly protective state. was that the Levant trade belonged solely to Venice and its citizens. No one but a Venetian citizen was permitted to share in the profits of that trade. But the population of Venice was growing rapidly. and citizenship was as yet undefined. To secure for themselves the command of trade the leading commercial families resolved to erect themselves into a close guild. which should have in its hands the sole direction of the business concern, the exploitation of the east. This policy took definite shape in 1297, when the doge Pietro Gradenigo proposed and carried the following measure: the supreme court, the Quarantia, was called upon to ballot, one by one, the names of all who for the last four years had held a seat in the great council created in 1171. Those who received 12 favourable votes became members of the great council. A commission of three was appointed to submit further names for ballot. The three commissioners at once laid down a rule that only those who could prove'that a paternal ancestor had sat in the great council should be eligible for election.

This measure divided the community into three great categories: (1) those who had never sat in the council themselves and whose ancestors had never sat; there were of course the vast majority of the population, and they were excluded forever from the great council; (2) those whose paternal ancestors had sat in the council; these were eligible and were gradually admitted to a seat, their sons becoming eligible on majority; (3) those who were of the council at the passing of this act or had sat during the four preceding years; their sons likewise became eligible on attaining majority. As all offices were filled by the great council: exclusion meant political disfranchisement. A close caste was created which very seldom and very reluctantly admitted new members to its body. The Heralds' college, the *avvogadori di comun*, in order to ensure purity of blood: were ordered to open a register of all marriages and births among members of the newly created caste, and these registers formed the basis of the famous *Libro d'oro.*

The closing of the great council and the creation of the patrician caste brought about a revolution among those who suffered disfranchisement. In the year 1300 the people, led by Marin Bocconio, attempted to force their way into the great council and to reclaim their rights. The doors were opened. the ringleaders were admitted and immediately seized and hanged. Ten years later a more serious revolution, the only revolution that seriously shook the state, broke out ahd was also crushed. This conspiracy was championed by Bajamonte Tiepolo, and seems to have been an expression of patrician protest against the *serrata,* just as Bocconio's revolt had represented popular indignation. Tiepolo, followed by members of the Querini family and many nobles with their followers, attempted to seize the Piazza on June 1j, 1310. They were met by the doge Pietro Gradenigo and crushed. Querini was killed, and Tiepolo fled.

The chief importance of the Tiepoline conspiracy lies in the fact that it resulted in the establishment of the Council of Ten. Erected first as a temporary committee of public safety to hunt down the remnant of the conspirators and to keep a vigilant watch on Tiepolo's movements! it was finally made permanent in 1335. The secrecy of its deliberations and the rapidity with which it could act made it a useful adjunct to the constitution, and it gradually absorbed many important functions of the state.

With. the creation of the Council of Ten the main lines of the Venetian constitution were completed. As the base of the pyramid there was the great council, the elective body composed of all who enjoyed the suffrage; *i.e.,* of the patrician caste. Above the great council came the senate, the deliberative and legislative body par excellence. To the senate belonged all questions relating to foreign affairs. finance. commerce, peace and war. Parallel with the senate, but extraneous to the main lines of the constitution, came the Council of Ten. As a committee of public safety it dealt with all cases of conspiracy; for example, it tried the doge Marino Falier and the General Carmagnola; on the same ground all cases affecting public morals came within its extensive criminal jurisdiction. In the region of foreign affairs it was in communication with envoys abroad, and its orders would override those of the senate. It also had its own departments of finance and nar. Above the senate and the Ten came the *Collegio* or cabinet, the administrative branch of the constitution. All affairs of state passed through its hands. It was the initiatory body; and it lay with the *Collegzo* to send matters for deliberation either before the senate or before the Ten. At the apex of the pyramid came the doge and his council.

The Genoese Wars.—To turn now to the external events which followed on the fourth crusade. These events are chiefly concerned with the long struggle with Genoa over the possession of the Levant and Black sea trade. By the establishment of the Latin empire Venice had gained a preponderance. But it was impossible that the rival Venetian and Genoese merchants. dwelling at close quarters in the Levant cities, should not come to blows. They fell out at Acre in 1253. The first Genoese war began and ended in 1258 by the complete defeat of Genoa. But in 1261 the Greeks, supported by the Genoese, took advantage of the absence of the Venetian fleet from Constantinople to seize the city and to restore the Greek empire in the person of Michael VIII Palaeologus. The balance turned against Venice again. The Genoese were established in the spacious quarter of Galata and threatened to absorb the trade of the Levant. To recover its position Venice went to war again, and in 1264 destroyed the Genoese fleet off Trepani, in Sicilian waters. This victory was decisive at Constantinople. where the emperor abandoned the defeated Genoese and restored Venice to its former position. The appearance of the Ottoman Turk and the final collapse of the Latin empire in Syria brought about the next campaign between the rival maritime powers. Tripoli (1289) and Acre (1291) fell to the Mohammedan. and the Venetian title to its trading privileges.

To the scandal of Christendom, Venice at once entered into treaty with the new masters of Syria and obtained a confirmation of ancient trading rights. Genoa replied by attempting to close the Dardanelles. Venice made this action a *casus belli.* The Genoese won a victory in the gulf of Alexandretta (1294); but on the other hand the Venetians under Ruggiero Morosini forced the Dardanelles and sacked the Genoese quarter of Galata. The decisive engagement, however. of this campaign was fought at Curzola (1299) in the Adriatic. when Venice suffered a crushing defeat. A peace. honourable to both parties, was brought about by Matteo Visconti. lord of Milan. in that same year. But the quarrel between the republics, both fighting for trade supremacy—that is to say, for their lives—could not come to an end till one or other was thoroughly crushed. The fur trade of the Black sea furnished the pretext'for the next war (1353–54), which ended in the crushing defeat of Venice at Sapienza, and the loss of its entire fleet. But though Venice itself seemed to lie open to the Genoese, they took no advantage of their victory; they mere probably too exhausted. The lord of Milan again arranged a peace (1355).

Then followed the last phase of the struggle for maritime supremacy. Under pressure from Venice the emperor John V Palaeologus granted possession of the island of Tenedos to the republic. The island commanded the entrance to the Dardanelles. Genoa determined to oppose the concession, and war broke out. The Genoese Adm. Luciano Doria sailed into the Adriatic, attacked and defeated Vettor Pisani at Pola in Istria, and again Venice and the lagoons lay at the mercy of the enemy. Doria resolved to blockade and starve Venice to surrender. The situation was extremely critical for Venice. but it rose to the occasion. Vettor Pisani was placed in command. and by a stroke of naval genius he grasped the weakness of Doria's position. Sailing to Chioggia he blocked the channel leading from the lagoons to the sea. and Doria was caught in a trap. Finally, in June 1380 the flower of the Genoese fleet surrendered at discretion. Genoa never recovered from the blow. and Venice remained undisputed mistress of the Mediterranean and the Levant trade.

Expansion to the Mainland.— But as the city became the recognized mart for exchange of goods between east and west, the freedom of the western outlet assumed the aspect of a paramount question. It was useless for Venice to accumulate eastern merchandise if it could not freely pass the goods on to the west. If the various states on the immediate mainland could levy taxes on Venetian goods in transit, the Venetian merchant would inevitably suffer in profits. The geographical position of Venice and the commercial policy alike compelled it to attempt to secure the command of the roads of the mainland. at least up to the mountains. and of the rivers, of the northwestern outlet, just as the command of the southeastern inlet had been obtained. Venice was compelled to turn its attention. though reluctantly. to the mainland of Italy. Another consideration drove it in the same direction. During the long wars with Genoa the Venetians realized that, as they owned no meat- or corn-producing territory, a crushing defeat at sea and a blockade on the mainland exposed them to the grave danger of being starved into surrender. Both these pressing necessities, for a free outlet for merchandise and for a food-supplying area, drove Venice onto the mainland. and compelled it to initiate a policy which eventually led to the disastrous wars of Cambrai. This period is the epoch of the despots. the ***signori,*** and in pursuit of expansion on the mainland Venice was brought into collision first with the Scaligeri of Verona, then with the Carraresi of Padua. and finally with the Visconti of Milan. Hitherto Venice had enjoyed the advantages of isolation; the lagoons were virtually impregnable; there was no land frontier to defend. But when it touched the mainland it at once became possessed of a frontier which could be attacked, and was compelled either to expand or to lose the territory acquired.

Venice had already established a tentative hold on the immediate mainland as early as 1339. It was forced into war by Mastino della Scala. lord of Padua. Vicenza, Treviso. Feltre and Belluno, as well as of Verona. who imposed a duty on the transport of Venetian goods. A league against the Scala domination was formed, and the result was the fall of the family. Venice took possession of Padua. but in the terms of the league at once conferred the lordship on the Carraresi, retaining Treviso and Bassano for itself. But it is not until the opening of the next century that Venice definitely acquired land possessions and found itself committed to all the difficulties and intricacies of Italian mainland politics. On the death of Gian Galeazzo Visconti in 1402. his large possessions broke up. His neighbours and his generals seized what was nearest to hand. Francesco II Carrara, lord of Padua, attempted to seize Vicenza and Verona. But Venice had been made to suffer at the hands of Carrara, who had levied heavy dues on transit, and moreover during the Chioggian War had helped the Genoese and cut off the food supply from the mainland. Venice was therefore forced in self-defense to crush the family of Carrara and to make itself permanently possessor of the immediate mainland. Accordingly when Gian Galeazzo's widow applied to the republic for help against Carrara it was readily granted, and after some years of fighting, the possessions of the Carraresi, Padua, Treviso. Bassano. commanding the Valsugana route, as well as Vicenza and Verona. passed definitely under Venetian rule. This expansion of mainland territory was followed in 1420 by the acquisition of Friuli after a successful war with the emperor Sigismund, thus bringing the possessions of the republic up to the Carnic and Julian Alps, their natural frontier.

Isolation of Venice.— Venice was soon made to feel the consequences of having become a mainland power, the difficulties entailed by holding possessions which others coveted, and the weakness of a land frontier. To the west the new duke of Milan, Filippo Maria Visconti. was steadily piecing together the fragrnents of his father's shattered duchy. He was determined to recover Verona and Vicenza from Venice. and intended. as his father had done, to make himself master of all north Italy. The conflict between Venice and Milan led to three wars in 1426. 1427 and 1429. Venice was successful on the whole. It established a hold permanently on Verona and Vicenza. also acquired both Brescia and Bergamo and later occupied Crema. The war of Ferrara and the peace of Bagnolo (1484) gave Venice Rovigo and the Polesine. This. with the exception of a brief tenure of Cremona (1499–1512). formed a permanent territory down to the fall of the republic. The frontiers now ran from the seacoast near Monfalcone. following the line of the Carnic and Julian and Raetian Alps to the Adda, down the course of that river till it joins the Po, and thence along the line of the Po back to the sea. But long and exhausting wars were entailed upon Venice for the maintenance of its hold. The rapid formation of this land empire, and the obvious intention to expand. called the attention not only of Italy hut of Europe to this power which seemed destined to become supreme in north Italy. and eventually led to the league of Cambrai for the dismemberment of Venice.

In 1453 Constantinople fell to the Ottoman Turks, and although Venice entered at once into treaty with the new power and desired to trade with it. not to fight with it, yet it was impossible that Venetian possessions in the Levant and the archipelago should not eventually bring Venice into collision with the expanding energy of Mohammedan. Europe persistently refused to assist the republic to preserve a trade in which was established a rigid monopoly. and Venice was left to fight the Turk single-handed. The first Turkish war lasted from 1464 to 1479, and ended in the loss of Negropont and several places in the Morea. and the payment by Venice of an annual tribute for trading rights. The republic was consoled, however, by the acquisition of Cyprus, which came into its possession (1488) on the extinction of the dynasty of Lusignan with the death of James II and his son James III, Caterina Cornaro, James II's widow. ceding the kingdom of Cyprus to Venice, since she could not hope to maintain Cyprus unaided against the Turks. The acquisition of Cyprus marks the extreme limit of Venetian expansion in the Levant; from this date onward there is little to record save the gradual loss of her maritime possessions.

Decline

Exhausting as the Turkish nars were to the Venetian treasury, trade was still so flourishing that Venice might have survived the strain had not the discovery of the Cape route to the Indies cut the taproot of Venetian commercial prosperity by diverting the stream of traffic from the Mediterranean to the Atlantic. When Diaz rounded the Cape in 1486 a fatal blow was struck at Venetian commercial supremacy. The discovery of the Cape route saved the breaking of bulk between India and Europe, and saved the dues exacted by the masters of Syria and Egypt. Trade passed into the hands of the Portuguese, the Dutch and the English. Venice lost its monopoly of oriental traffic.

League of Cambrai.—To complete Venice's misiortunes, the European powers, the church and the small states of Italy, partly from jealous greed of its possessions, partly on the plea of its treason to Christendom in making terms with Islam, partly from fear of expansion in north Italy, coalesced at Cambrai in 1508 for the partition of Venetian possessions. The war proved disastrous for Venice. The victory of Agnadello (1510) gave the allies the complete command of Venetian territory down to the shores of the lagoon. But the mutual jealousy oi the allies saved Venice. The pope, having recovered the Romagna and secured the objects for which he had joined the league, was unwilling to see all north Italy in the hands of foreigners, and quitted the union. The emperor Maximilian failed to make good his hold on Padua, and was jealous of the French. The league broke up, and the mainland cities of the Veneto returned of their own accord to their allegiance to St. Mark. But the republic never recovered from the blow, coming as it did on the top of the Turkish wars and the loss of trade by the discovery oi the Cape route. Venice ceased to be a great power, and was henceforth entirely concerned in the effort to preserve its remaining possessions and its very independence. The settlement of the peninsula by Charles V's coronation at Bologna in 1530 secured the preponderance to Spain, and the combination of Spain and the church dominated the politics of Italy. Dread of the Turks and dread of Spain were the two terrors which haunted Venice till the republic fell.

Turkish Wars.—But the decline was a slow process. Venice still possessed considerable wealth and extensive possessions. Between 1499 and 1516 the republic went to war four times with the Turks. emerging from each campaign with some further loss of maritime territory. The fourth Turkish war (1570–73) was signalized by the glorious victory of Lepanto (1571), chiefly through the prowess of the Venetians under their doge Sebastian Venier. But its allies iailed in support. They reaped no fruits from the victory, and Cyprus was taken from Venice after the heroic defense of Famagusta by Bragadino, who was flayed alive, and his skin, stuffed with straw, borne in triumph to Constantinople. The fifth Turkish war (1645–68) entailed the loss of Crete; and though Morosini reconquered the Morea for a brief space in 1685, that province was finally lost to Venice in 1716.

So iar as European politics are concerned, the latter years of the republic are made memorable by one important event: the resistance which Venice, under the guidance of Fra Paolo Sarpi, offered to the growing claims of the Curia Komana, advanced by Pope Paul V. Venice was placed under interdict (1606), but asserted the rights of temporal sovereigns with a courage which was successful and won the esteem and approval of most European sovereigns. But the chief glory of the republic's declining years was undoubtedly its splendid art. Giorgione, Titian, Sansovino, Tintoretto, Paolo Veronese and Palladio all lived and worked after the disastrous wars of the league of Cambrai. During these years Venice became the great pleasure city of Europe.

United Italy.— The end of the republic came when the French Revolution burst over Europe. Napoleon was determined to destroy the oligarchical government, and seized the pretext that Venice was hostile to him and a menace to his line of retreat while engaged in his Austrian campaign of 1797. The peace of Leoben left Venice without an ally. The government resolved to offer no resistance to the conqueror. and the doge Lodovico Manin abdicated on May 12, 1797. On Oct. 17. Napoleon handed Venice over to Austria by the peace of Campo Formio, and between 1798 and 1814 Venice was passed from France to Austria and Austria to France till the coalition of that latter year assigned it definitely to Austria. In 1848 a revolution broke out and a provisional republican government under Daniele Manin (*q.v.*) maintained itself for a brief space. In 1866 the deieat of Austria by the Prussians led to the incorporation of Venice in Cnited Italy. (H. F. Br.)

VENIZELOS, ELEUTHERIOS (1864–1936), Greek statesman, was born in Crete Aug. 23, 1864 of a family which had emigrated from Greece in 1770 Having been educated in the schools of Syra and Athens and having taken a degree in the University of Athens at the age of 23, he practised law in Crete, but soon became a politician, and in the insurrection of 1889 was compelled to flee from the island After his return and the re-establishment of tranquillity, Venizelos was elected a member of the Cretan Assembly, and in 1897 came into prominence as one of the leaders of the Cretan uprising; it was he who received the British, French and Italian admirals when they came to negotiate a settlement between the insurgents and the Turks early in Feb. of that year.

In Dec 1898 Prince George of Greece landed in Crete as the High Commissioner of the Great Powers, and a few months later Venizelcs became head of the Island Executive. But he soon found himself at variance with the Prince's autocracy, and in 1904 a complete rupture occurred. Subsequently the Venizelists were defeated at the polls. but the Cretan leader organized a revolt, which greatly increased the unpopularity of the High Commissioner who was accused of misruling the people. In Sept. 1906 the Prince left the island, his place being taken by Alex. Zaimis, who was appointed not by the Powers, but by the King of Greece From that time until 1909 Venizelos was sometimes Chief of the Cretan Government and sometimes Leader of the Opposition But whilst the Cretans often came into sharp conflict with the Protecting Powers. Venizelos' wisdom and moderation were responsible for the generally friendly relations which existed, and his far-sightedness, particularly after the departure of M. Zaimis in Oct 1908, and during the crisis of 1909, facilitated the union of Crete with Greece, which ultimately took place as a result of the first Balkan War.

In 1909 the military league headed a bloodless revolution against political corruption and court favouritism in Greece and invited Venizelos to come to Athens. He persuaded King George and the League that the best way out of a dangerous situation would be the revision of the Constitution by a National Assembly. Elections were held in Aug. 1910, and Venizelos, who had remained technically a Greek citizen during his Cretan political life, took his seat at Athens for the first time. The Chamber having been opened in September, a month later Venizelos became Prime Minister.

He was in a position to enforce practically any situation, including a republic, which he wished; but decided to work loyally with the King and his successors. The Constitution was successfully revised in 1911, reforms in the public services were introduced, and the reorganization of the army and of the navy mere respectively placed in the hands of French and British Missions. In the spring of 1912 Venizelos was returned to power as the leader of an overwhelming majority in an ordinary Chamber which then replaced the Revisionary Assembly. By that time, too, the Prime Minister was busily occupied with the formation of the Balkan League, and on May 29, 1912, the Greco-Bulgarian Treaty was signed.

Whilst the Balkan Wars and Venizelos' diplomacy led to an unexpected Hellenic expansion, the assassination of King George at Salonika on March 18, 1913, removed a man who had always been in favour of moderation, and placed upon the throne his son Constantine, who had not forgiven, and who never really forgave, Venizelos for his attitude towards Prince George in Crete. When the World War broke out, therefore, the position of Greece was greatly complicated by the facts that she was bound to Serbia by a Treaty signed in the summer of 1913; that from the first Venizelos was an ardent supporter of the Allied cause; and that the King was in sympathy with the Central Powers. Before the entry of Turkey into the War, Venizelos openly favoured Hellenic assistance for the Entente in case of that entry, and early in 1915 the Prime Minister advocated concessions to Bulgaria, Greek support for Serbia. and Greek co-operation at the Dardanelles in exchange for the promise of important future compensations in Western Asia Minor But though he appears originally to have approved of the idea, the King vetoed Venizelos' decision to accept this offer, and he was forced to resign, though he possessed a strong majority in the Chamber. In the election which followed in June the Venizelist party secured the return of 190 deputies out of a total of 316, of which the Chamber was then composed.

In spite of this. and with the excuse of the King's illness, Venizelos was not recalled to power until after the meeting of the Chamber in Aug. and by that time the situation had become seriously modified. The mobilization of Bulgaria on Sept. 29, 1915 brought into operation in equity if not in law, the Greco-Serbian Treaty of 1913 and bound Greece to help Serbia. A few days later, Venizelos extorted from the King reluctant consent to a Greek mobilization and to a Greek request that the Allies should furnish an army of 150,000 men to take the place of the contingent Serbia should have supplied under the Treaty.

Immediately after the original Allied landing at Salonika on Oct. 1 Venizelos secured a vote of confidence during an historic and stormy meeting of the Chamber, when he declared that if in aiding Serbia Greece was brought into contact with Germany she would act as her honour demanded. In spite of a formal protest against the Allied passage through Hellenic territory, this speech led to the second dismissal of Venizelos and to the open and final rupture between that statesman and the King, who, it would seem, always intended to withdraw his consent to an Hellenic entry into the War. Zaimis, the new Prime Minister, maintained his position for a month as a result of the patriotism of Venizelos his friend from Cretan times. but, with the accession of Skouloudis to power, on Nov. 6 the Chamber was dissolved and a new election ordered for Dec. 19. Venizelos' party abstained from the polls in protest, M Gounaris securing an overuhelming majority for his policy of neutrality.

Venizelos spent that winter and spring (1915–16) in endeavouring to compel the King to change his point of view. But the surrender of Eastern Macedonia to the Bulgarians in the summer of 1916 and the delay in the success of the Allied Campaign at

Salonika had strengthened the position of Constantine, and on Sept. 25, 1916, Venizelos, together with his principal supporters, sailed for Crete, whence he sent out proclamations calling upon all true patriots to flock to the standard of the Entente. Proceeding thence to Salonika, early in Oct. he founded a provisional government, which was recognized about two months later by Great Britain and France, though not by Italy,

After the dethronement and enforced departure of King Constantine, Venizelos returned to Athens on June 26, 1917, and took over the government of the whole country. The June 15 chamber was convoked, general mobilization was ordered, and Greece formally opened up hostilities upon the Allied side. But the removal of the king, the successes of the central powers, particularly in the Balkans, and an increased Greek desire for neutrality, backed up by German propaganda, were responsible for a great diminution of the prime minister's popularity.

Between the armistice of Nov. 1918 and his fall two years later, Venizelos and his colleagues, who represented Greece at the peace conference, were almost continuously absent in Paris and London and, during this period, they seemed to be reaping for Greece harvests beyond her dreams. About the end of April 1919, the Greeks were permitted, or encouraged, to land at Smyrna; a year later the conference of San Remo promised large areas to Greece, and the treaty of Sèvres (Aug. 10, 1920) coupled with the earlier treaty of Neuilly (Nov. 27, 1919) gave Greece extraordinary advantages. However, at a moment when Venizelos' triumph appeared to be complete, an attempt was made upon his life at a Paris station (Aug. 1920), and three months later (Nov. 14) he received a crushing defeat at the hands of the Greek electorate.

Many factors were present in this: the unpopularity of the war in Asia Minor and the continued mobilization, the maintenance of martial law, the bad administration of Venizelos' subordinates and injustices practised by the Corps de la Sûreté. Further, there was Venizelos' own continued absence; recollection of the foreign support on which he had called so largely, and Constantine's own increasing popularity. After the unexpected death of the young king Alexander, immediately before the election, the dynastic question, open mention of which had previously been prohibited, was brought into the forefront of the political struggle and, in what then became the direct issue between Constantine and Venizelos, the king won an overwhelming victory.

From the arrival of the king in Athens on Dec. 20, 1920, until his final abdication and second departure on Sept. 30, 1922, Venizelos took no official part in Greek affairs. After the revolution (Sept. 1922), however, he represented Greece for a time in western Europe, *inter alia* at the conference of Lausanne which culminated in the peace signed with Turkey on July 24, 1923. In the following December, when the publication of that document and various other events had aggravated the existing internal dissension and when the election (Dec. 16) had again given his party a majority, Venizelos was persuaded to return to Athens, where he arrived on Jan. 4, 1924. King George was already then on leave of absence and Venizelos was prime minister from Jan. 11 till Feb. 4, when he resigned. In 1928, he began to prepare a return to politics. M. Kaptrandair resigned from the leadership of his section of the Liberals, and Venizelos took his place, declaring this to be the best guarantee against a dictatorship. He brought about the fall of the government, formed a new government with himself as premier on July 4, and secured a large majority in the election held on Aug. 19. Thereafter he negotiated a treaty of friendship and arbitration with Mussolini, and treaties of commerce and friendship with Yugoslavia.

Venizelos resigned in May 1932, but was again premier from June to Nov. 1932, and from Jan. to March 1933. In March 1935 he put himself at the head of the republican revolt in Crete, and was sentenced to exile. He died March 18, 1936.

VENLO, a frontier town in the province of Limburg, Netherlands, on the right bank of the Maas, and a junction station 43 mi. N.N.E. of Maastricht by rail. Pop. (1957 est.) 51,719. Venlo, with narrow streets irregularly built, is not of the ordinary Dutch type in architectural style. The town hall (1595) contains some interesting paintings by Hubert Goltzius (1526–1583). The church dates from 1304. The leading industries are distilling, brewing, tanning, spinning, needlemaking and tobacco manufacture. There is also a considerable trade by river with Rotterdam. Venlo is joined by a bridge with the opposite village of Blerik.

VENNOR, HENRY GEORGE (1840–1884), Canadian geologist, ornithologist and meteorologist, who revised the classification of the Laurentian system of rocks, was born at Montreal, Que., on Dec. 30. 1840. After graduating from McGill university, Montreal. in 1860, he was placed, in 1866, on the staff of the Canadian Geological survey, with which he continued until 1880. His studies of the great Laurentian system brought him a wide reputation and election to the Royal Geographical society. He traced the Lièvre, Rouge and Gatineau rivers to their sources and called attention to the phosphate deposits between the Gatineau and the Lièvre. Over a period of many years he studied the characters and courses of storms, deducing a number of general principles. From 1877 to his death in Montreal on June 8, 1884, he published Vennor's Almanac. He also wrote Our Birds of Prey (1876).

VENOM. Venoms are toxic secretions of animal origin produced by specialized glands often associated with spines, teeth or other piercing devices; some are skin or cuticular secretions. Venom apparatus may be primarily for killing or paralyzing prey or may be a purely defensive adaptation. Venoms of snakes, centipedes and some marine invertebrates are also digestive fluids.

Few venoms are toxic by mouth or injurious when deposited on unbroken skin or mucous membranes. Most are effective only when introduced into the skin or deeper tissues. Among the local effects are wheals, blisters. violent inflammation often followed by necrosis, muscle spasm and disturbances in sensation. Systemic effects include local or widespread hemorrhages, destruction of blood cells and disturbances that render the blood less coagulable or cause abnormally rapid clotting. Irritative effects on the nervous system may include excitement, convulsions, vomiting, diarrhea or tetany; depressive symptoms seen include clouding of senses, paralysis and weakening or arrest of respiration and heartbeat.

Most major animal phyla contain venomous species, but relatively few are significantly dangerous to human life. Among these are some snakes of the families Elapidae (cobras, coral snakes, etc.) and Viperidae (true vipers, rattlesnakes and other pit vipers), some scorpions (chiefly *Buthus,* Centruroides, *Tityus*), a few spiders (*e.g.,* Latrodectus, Atrax, Loxosceles), some social Hymenoptera (bees, wasps and ants), a few jellyfish (*e.g., Chiropsalmus*). Dangerous but causing few accidents because of habitat or habits are sea snakes (Hydrophidae), scorpion fish (Synanceja) and some cone shells. Common venomous animals that rarely or never cause human fatalities include sea anemones, fire corals, most jellyfish, some sea urchins, centipedes, most spiders and scorpions, certain ticks and mites, many insects (nonsocial Hymenoptera, assassin bugs, some caterpillars, blister beetles, black flies), fishes with poisonous spines (sting rays, weever fish, certain catfish) and many mildly poisonous snakes. Of biological interest but little medical significance are the amphibians with toxic skin secretions, venomous lizards (*Heloderma*) and venomous mammals (the platypus and a shrew, Blarina.)

Venom poisoning is primarily a problem of rural tropical regions. Statistical data are frequently unreliable; however, the total morbidity may be roughly estimated as 1,000.000 cases annually. World mortality from snake bite is estimated at 30,000 annually; fatalities from other bites and stings might add another 5,000. The greatest number of deaths occur in the Indian subcontinent and southeastern Asia.

Principles of venom poisoning therapy involve: (1) immobilization of the toxin at the site of injection by ligature or application of cold followed by slow release or removal by incision and suction; (2) neutralization by immune sera; (3) administration of pharmacological antagonists, *e.g.,* corticosteroids, antihistamine drugs; (4) supportive and symptomatic measures, such as blood transfusion and analgesics. Treatment must be carefully adjusted to the situation.

Antivenins are obtained from serum of animals immunized by repeated sublethal doses of venom or detoxified venom. Antivenins possess the usual immunological specificity. Serum produced against one kind of rattlesnake venom will, for example, neutralize to some extent venoms of other rattlesnake species but will be ineffectiveagainst cobra venoms. Antivenins are usually less potent than bacterial antitoxins, and large doses are required. Human immunization against venoms is possible but rarely done. The immunity is of short duration and not highly effective.

The chemical composition of many venoms is imperfectly known. The majority contain several active principles. Chromatography, electrophoresis and antigenic analysis show 4 to 14 protein fractions in snake venoms, and apparently pure protein toxins have been isolated from rattlesnake (*Crotalus durissus terrificus*) and tiger snake (*Notechis scutatus*) venoms. Venom of the spider, *Latrodectus tredecimguttatus,* contains at least 5 protein fractions. Most venoms show enzyme activity; 13 enzymes have been reported in Indian cobra venom. Some scorpion venoms contain a toxin of low molecular weight bound to protein. Bee and wasp venoms contain histamine and acetylcholine, as well as active protein components. Some venoms are relatively simple organic compounds; *e.g.,* bufotoxins from toads, canthardin from blister beetles.

See E. E. Buckley and N. Porges (eds.), Venoms, Publication 44, American Association for the Advancement of Science (1956); Marie Phisalix, *Animaux Venimeux* et *Venins,* 2 vol. (1922). (S. A. M.)

VENOSA (anc. VENUSIA), a town in Potenza province of southern Italy, lies 84 km. (52 mi.) S.S.E. of Foggia by rail. Pop. (1951) 13,154. The town, situated between two ravines on the lower slope of Monte Vulture (4,354 ft.), is an episcopal see and an agricultural centre. Stones from the Roman amphitheatre are built into the walls of the abbey church of Sta. Trinità, consecrated in 1059 but much restored. It contains the tombs of the Norman soldier of fortune Robert Guiscard (*q.v.*), his wife and half-brothers. There is a massive 15th-century castle, and north of the town are Jewish catacombs with inscriptions of the 4th–5th centuries A.D.

Originally a Lucanian settlement, the place was taken by the Romans after the Samnite War (291 B.C.); from its position on the Appian way it became a Roman garrison town of the first importance. The poet Horace was born there and his poems (such as the "Carmen Saeculare") mention places in the vicinity.

VENTIDIUS, BASSUS, Roman general, was born at Asculum. He took part in the Social War and was made prisoner by Pompey the Elder. As a contractor for military transport he aided Caesar in raising an army for the conquest of Gaul and was later given a command under Caesar. In A.D. 46 he became a senator and tribune. After Caesar's death he supported Antony and rendered important aid in the war against D. Brutus by taking three legions, which he raised himself, in a spectacular march over the Apennines to join in the battle. He became Antony's chief lieutenant and for a brief period was consul of Rome. He was afterward sent to the east, where he carried on the wars against the Parthians with brilliant success.

VENTILATION: see HEATING AND VENTILATION.

VENTIMIGLIA (Fr. VINTIMILLE, anc. ALBCM INTIMILIUM or ALBINTIMILIUM), a seaport on the Gulf of Genoa and episcopal see of Liguria, Italy, in the province of Imperia, 94 mi. S.W. of Genoa and 4 mi, from the Franco-Italian frontier. Pop. (1951) 10,957. The new town is important as a frontier station. The Gothic cathedral is built on the ruins of an earlier Lombard church. The ruins of the ancient town are situated in the plain of Nervia, 3 mi. E. of the modern. It was a *municipium* with an extensive territory, and of some importance under the empire, but was plundered by the partisans of Otho in A.D. 69. Remains of a theatre are visible, and remains of many other buildings have been discovered, among them traces of the ancient city walls, a fine mosaic pavement and a number of tombs to the west of the theatre. The caves of the Balzi Rossi near the village of Grimaldi have proved rich in paleolithic remains of the Quaternary period. Around Monte Bego above S. Dalmazzo di Tenda, north of Ventimiglia, are numerous engravings assignable to the Bronze Age.

VENTNOR, urban district on the southeast coast of the Isle of Wight, Eng. Pop. (1951) 7,314. Area 5.6 sq.mi. It is in the Undercliff district at the foot of St. Boniface down, a chalk cliff 787 ft. high, the highest point in the island and belonging to the National trust. The town, built on a succession of terraces, is one of the most popular holiday and health resorts in England. From a small fishing hamlet it grew in the 19th century into a fashionable town. Bonchurch, where Charles Dickens lived and A. C. Swinburne is buried, St. Lawrence and Wroxall are in the urban district. Market gardening and agriculture are carried on.

VENTRILOQUISM, the art of producing the voice in such a manner that it shall appear to proceed from some place altogether distant from the speaker (Lat. *venter,* "belly," and *loqui,* "to speak"). The art of ventriloquism mas formerly supposed to result from a peculiar use of the stomach (whence the name) during the process of inhalation. As a matter of fact, the words are formed in the normal manner, but. the breath is allowed to escape slowly, the tones being muffled by narrowing the glottis, and the mouth being opened as little as possible. while the tongue is retracted and only its tip moves. This pressure on the vocal chords diffuses the sound, and the greater the pressure the greater is the illusion of distance. A figure or dummy is sometimes used by the ventriloquist to assist in the deception. The ventriloquist animates the dummy by moving its mouth at the same time his own lips remain still, thereby completing the illusion that the voice is coming from the dummy. When not using a dummy the ventriloquist employs pantomime to direct the attention of his listeners to the location or object from which the sound presumably emanates. Ventriloquism, which is still a recognized form of conjuring entertainment. is of ancient origin. Traces of the art are found in Egyptian and Hebrew archaeology. Eurycles of Athens was the most celebrated of Greek ventriloquists, who were called after him Eurycleides, and also Engastrimanteis (belly prophets). It is not impossible that the priests of ancient times were masters of this art, and that to it may be ascribed such miracles as the speaking statues of the Egyptians. the Greek oracles and the stone in the river Pactolus. the sound of which put robbers to flight. Many primitive peoples of modern times are adepts in ventriloquism, as the Zulus! the Maoris and the Eskimos. It is well known also in Hindustan and China. (E. J. BN.)

VENTRIS, MICHAEL GEORGE FRANCIS (1922–1956), British archaeologist and architect. won renown in 1953 for deciphering inscriptions on tablets of about 1500–1200 B.C. (See MINOAN LINEAR SCRIPTS.) The brief inscriptions on these tablets, found on the mainland of Greece near Pylos and elsewhere and in the island of Crete, were proved to have been written in Greek. The dialect (conventionally known as Mycenaean) is the oldest Greek known and belongs to the Achaean subdivision. which includes Aeolic. the dialect of Alcaeus and Sappho, as well as of the oral poetry, known only in an Ionic transformation. in which were composed the songs which went into Homer's Iliad.

Born at W'heathampstead, Eng., July 12, 1922, Ventris was an architect by profession, with an interest in Greek archaeology that inspired him to seek the correct interpretation of the tablets, many of which were discovered around 1900 at Cnossus, in Crete. His method was essentially that of statistical analysis, helped out from the stray hints obtained by the so-called combinatory method, and his results, which might have been obtained much earlier but for the opposition of established archaeological authority. were at once acclaimed as correct and supplemented by the co-operation of many Greek scholars. His authoritative work on the tablets, written in collaboration with John Chadwick. was published posthumously in 1956. Ventris died near Hatfield. Eng., on Sept. 6, 1956, as the result of an automobile accident. (J. WH.)

VENTSPILS (Russian VINDAVA), an ice-free seaport and sea-bathing resort of Latvian S.S.R., U.S.S.R., at the mouth of a river of the same name, on the Baltic sea; in 57° 24' N., 21° 32' E. Pop. (1956 est.) 26.200. Its 15-ac. harbour, protected by two long breakwaters, has ample quay space with a depth of 23 to 30 ft. The harbour has been deepened to accommodate large ocean steamers. The imports are coal and various transit goods; the exports are timber, pit props, butter, flax, hemp and grain. The castle dates from 1290, the town from 1343. Ventspils was occupied alternately by the U.S.S.R. and Gerrnany in World War II.

VENTURA (officially SAN BUENAVENTURA), a city in southern California, U.S., and seat of Ventura county. occupies a splendid site on the Pacific coast overlooking Santa Barbara channel. 65 mi. N.W. of Los Xngeles. Incorporated in 1866, the city, the oldest in the county. developed from a settlement outside the Franciscan mission which Father Junipero Serra founded in 1782 and named for St. Bonaventura.

The city's economy depends mainly upon adjacent oil fields; upon a varied agricultural production of the hinterland, including citrus fruits and lima beans, and upon three important nearby military installations. Ventura is not a port: although it was once a stop for coastwise shipping and, at a few moorings in Pierpont hay, ocean-going tankers receive oil pumped through underwater lines.

Under its charter of 1932, the city has a council-manager form of government. Ventura (junior) college was established in 1925.

For comparative population figures *see* table in CALIFORNIA: *Population: San Buenaventura.* (AL. H. C.)

VENTURI TUBE, a short pipe with a constricted inner surface. used to measure fluid flow and as a pump. Named for G. B. Venturi (1746–1822), the Italian physicist who first noted the effects of constricted channels on the flow of fluids, the venturi tube (fig. 1) has a converging portion, or nozzle: and a narrow portion, or throat. If the fluid velocity is t', and the fluid pressure P_1 at the entrance to the converging portion (as indicated by gauge no. 1). the velocity mill increase as the fluid passes through the converging portion, whereas the pressure will drop. At the throat the velocity V_2 is higher than V_1, and the pressure P_2 is lower than P,. The fluid in the converging portion is accelerated. This acceleration is caused by a force due to the pressure difference; thus. P_1 is greater than P_2.

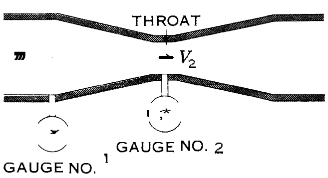

FIG. 1.—VENTURI TUBE

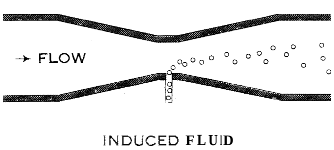
There are countless applications of the venturi principle. Fig. 1 illustrates a venturi meter for measuring rate of fluid flow. The flow rate is correlated with the pressure difference. There are various devices in which the low pressure at the venturi throat is used to cause or induce the flow of some fluid into the venturi tube. As illustrated in fig. 2, the low pressure at the venturi throat can be used to pump or induce the flow of some other fluid.



2.—VENTURI PUMPING DEVICE

In the carburetor of most internal-combustion engines, air flows through a venturi channel; at the venturi throat gasoline vapour is drawn into the air stream. In the usual aspirator pump. water passes through a venturi channel, and air is drawn into the venturi throat by the low pressure.

See F. W. Sears and M. W. Zemansky, College *Physics* (1955); *R. C.* Binder, *Fluid Mechanics* (1955). (R. C. BR.)

VENUE, in law, place of trial. At common lam, trial could be had only in the locality in which the relevant events occurred: since the jury based its verdict on its own knowledge of the facts rather than on the testimony of witnesses. Hence there was only one proper venue. or place of trial. In the course of time most actions came to be recognized as transitory; *i.e.,* such as need not be limited to one particular forum. It then became necessary to regulate the permissible places of trial in the interest of convenience and fairness to the parties. While the term is sometimes used in a loose sense with reference to the appropriate choice between independent states or nations. it is perhaps more appropriately applied to the choice between countries, districts or other localities within a single judicial system. In this sense venue is almost universally prescribed by statutes, although common-law influences remain. Thus it is commonly true still that actions respecting title to, or possession of, land must be brought in the locality where the land lies.

Modern statutes in both England and the United States commonly provide for change of venue for various reasons. such as local prejudice or the convenience of parties and witnesses.

The objection that an action is brought in the wrong place formerly resulted in dismissal, sometimes with harsh consequences, but in modern times the alternative of transfer to a proper venue is often available. The objection is waived if not asserted in timely fashion. Venue should not be. though it often is. confused with jurisdiction of the person of the defendant. (B. CE.)

VENUS is the second of the planets in order of distance from the sun. At its maximum elongations it recedes about 47° or 48° from the sun, so that in middle latitudes it can set or rise more than 3 hours after or before the sun. When seen in the western sky in the evenings, *i.e.*, at its eastern elongations. it was çalled by the ancients Hesperus, and when visible in the mornings, *i.e.,* at its western elongations, Phosphorus.

Like the earth. Venus is enveloped in an atmosphere. This is shown by the fact that near inferior conjunction with the earth the extremely thin crescent of the visible portion of the illuminated hemisphere has often been observed to exceed 180°, while at the time of actual entry on the sun's disk during the transit of 1882. as soon as about three-quarters of the planet's body was in front of the sun, the remaining portion was completely outlined by a narrow border of light. This atmosphere of Venus is apparently heavily cloud-laden. and. since the intensity of the solar radiation is almost exactly twice what it is at the earth's distance, the planet shines with a dazzling lustre, its stellar magnitude varying from −3.3 to −4.4. Its greatest brightness is attained at about 36 days on either side of inferior conjunction, its elongation from the sun then being 39°, and its phase similar to that of a 5-day-old moon. When suitably situated the planet is easily visible at noonday with the naked eye, and after dark it readily casts a shadow.

The Atmosphere of Venus.—Venus is a very disappointing object when viewed through the telescope, because it usually presents nothing but a cloud-covered disk that shows only a general fading of light toward the terminator and perhaps a brightening at the cusps. especially the southern cusp. Faint diffuse markings have occasionally been detected visually, but they are so rare and indefinite in character as to make the planet of scant interest except to the most patient of observers.

Apparently the first photographs of Venus that showed markings were taken by F. Quénisset in 1911. Photographs of Venus in infrared and violet light were taken by W. H. Wright at the Lick observatory in 1921. Contrary to expectation the infrared photographs showed nothing. but faint shadings appeared on the violet images. The first systematic series of photographs of Venus in ultraviolet light was taken by F. E. Ross at the Mount Wilson observatory in 1927. The photographs of Venus in ultraviolet light of effective wave length about λ 3.600 always showed definite markings upon the disk. The markings are predominantly of a banded type that are presumably cloud formations in the upper atmosphere. Since the markings change from day to day, the atmosphere is evideatly in a state of violent turbulence.

Composition of the Venusian Atmosphere.— In 1932 absorption bands in the spectrum of Venus at hh'7.820.0. 7.882.9 and 8.688.i. which later were identified with carbon dioxide·(CO_2), were discovered by W. S. Adams and Theodore Dunham. Jr. G. Herzberg found that the amount of CO_2 above the reflecting layer of Venus corresponds to a path length of 1.000 m. at atmospheric pressure, compared with 2.2 metre-atmospheres for the earth. There can be no doubt of the great abundance of CO_2 in the

Venusian atmosphere.

Repeated attempts to detect oxygen and water vapour in the atmosphere of Venus failed until 1959, when evidence for water vapour was obtained from records of the planet made from a manned balloon flying 15 mi, above the earth's surface.

From spectra of the night sky of Venus, N. A. Kozyrev found many bands which he identified with those arising from molecules of nitrogen and ionized nitrogen. Other bands photographed by Kozyrev have been tentatively identified by H. C. Urey and A. W. Brewer with those of ionized carbon monoxide and ionized carbon dioxide.

In 1959 a broad shallow band between about 3800 and 4500 Å was found in the spectrum of Venus by C. C. Kiess and his co-workers. This structureless band is virtually identical with that produced by nitrogen tetroxide (N_2O_4). Finding nitrogen tetroxide in the planet's atmosphere may explain why free oxygen has never been found. The oxygen apparently is all locked up in other chemical compounds.

Temperature of Venus.—Radiometric measures on the temperature of Venus were made in 1923 and 1928 at Mount Wilson by S. B. Nicholson and E. Pettit, but the details were not published until 1955. They found a mean temperature of −33° C. for the night side and −38° C. for the daylight side. John Strong and W. M. Sinton in 1953–54 obtained a temperature of −40° C. for both dark and light sides. A temperature of 12° C. has been obtained from the distribution of intensity in the infrared carbon dioxide bands. Measures on the radiation from Venus on 3.15 cm. with the 50-ft. radio telescope of the Naval Research laboratory by C. H. Mayer. T. P. McCullough and R. M. Sloanaker gave an apparent black-body temperature of about 320° C. The wide range of these temperatures indicates that they refer to different emitting layers, but just what and where they are it is impossible to say.

The Rotation of Venus.—Visual observations of occasional vague markings are so contradictory as to be useless for discussion. The markings on the ultraviolet photographs of Venus consist of bands that cannot be used for rotation determinations.

V. M. Slipher in 1903 was unable to detect from spectroscopic measures any evidence of rotation from the Doppler effect; neither were C. E. St. John and S B. Nicholson in 1923. Using improved techniques, R. S. Richardson tried to detect spectroscopic evidence for the rotation of Venus in 1956–57 but without result. The negative evidence of the spectroscope indicates a rotation period longer than a week. Yet the fact that the radiometric measures give the same temperature for the dark and illuminated sides indicates a moderately rapid rotation period. The banded form of the ultraviolet clouds also indicates a moderate rotation period. Ross in 1927 from a discussion of all results adopted a compromise period of 30 days. which is still the best guess for the rotation period of the planet.

Position of the Axis of Rotation.—The orientation of the axis of rotation may be calculated on the assumption that the ultraviolet cloud bands are parallel to the planet's equator. Using this method, G. P. Kuiper in 1954 found that the north pole of Venus is directed toward a point in the sky at right ascension (R.A.) 53°, declination (dec.) +81°. The inclination of the equator of Venus to the plane of its orbit is 32". From similar observations the writer found the position of the north pole to be R.A. 311°, dec. +64°, with an inclination of 14°. The difference in position of the axis from the two determinations is 29°, which is about as good agreement as can probably be expected, considering the uncertainties involved.

The Nature of the Surface and Cloud Layer.—Early in the 20th century the cloud layer of Venus was believed to consist of water vapour and the surface to be covered by steaming marshes and oceans similar to those of the earth in its early history. When, in 1932, high dispersion spectra of Venus failed to disclose evidence of water vapour, the composition of the cloud layer was left more of a mystery than ever. The radiometric temperature of −40° C. is too high for the clouds to be condensed carbon dioxide.

The water vapour hypothesis was revived in 1955 by D. H. Menzel and F. L. Whipple. They pointed out that no one had been able to suggest a convincing substitute substance for the cloud layer that is likely to be present in abundance in the atmosphere of a planet. Their contention was supported by the balloon studies of 1959. Also, they pointed out that polarization measures on Venus by B. Lyot are in reasonably good agreement with polarization measures on water droplets made in the laboratory. The great abundance of carbon dioxide in the Venusian atmosphere has been puzzling. On the earth much of the original carbon dioxide in the atmosphere has combined with the surface rocks to form limestone. But if it is assumed that the entire surface of Venus is covered by water, then the abstraction of carbon dioxide from the atmosphere would cease, as soon as a buffer layer of carbonates was formed from the silicates of the ocean bed.

Satellite.—There is no significant evidence for a satellite of Venus. It seems unlikely that the planet can have a companion more than 50 mi. in diameter.

Transits of Venus.—As is the case with Mercury, Venus, revolving round the sun inside the earth's orbit, sometimes transits the sun's face and is seen projected on it as a small black disk. Were the planet's orbit plane coincident with that of the earth, these transits would. of course, occur at each inferior conjunction, but, because of its inclination, a transit can happen only when the two planets pass near one of the nodes of Venus at about the same time, which is possible at present only in June and December. Actually a transit happens but four times in 243 years, and the intervals between transits are successively 8, 105½, 8, 1213, 8, 105½ years et *seq.,* as illustrated in the following table of dates of these phenomena:

1518, June 2	1761, June 6	1882, Dec. 6
1526, June 1	1769, June 3	2004, June 8
1631, Dec. 7	1874, Dec. 9	2012, June 6
1639, Dec. 4		

The first transit to be actually observed was that of 1639, the occurrence of the event having been calculated by Jeremiah Horrocks. a young clergyman, who was curate of Hoole. near Preston, in Lancashire, Eng. Dec. 4 in that year happened to be a Sunday, and Horrocks missed seeing the beginning of the transit through having to take a service in church that afternoon. but on returning home he found to his great delight the black body of the planet clearly projecting on the sun's disk.

Following on the suggestions of Edmund Halley a century later, transits of Venus were utilized for the determination of the solar parallax, which gives the distance of the sun—a quantity of fundamental importance to the astronomer. Practical difficulties, however, in the observations, arising from the effect of irradiation in introducing uncertainties as to the precise moments of the internal contacts between the limbs of the sun and planet, rendered the method unsatisfactory, and far more effective ways of attacking the problems are now available.

In the following data, figures on the orbit of Venus are reliable, but those on the planet itself are very uncertain and may be revised considerably in the future as better values become available.

Mean distance from the sun	67,270,000 mi.
Minimum distance from the Earth	24,600,000mi.
Eccentricity of orbit	0.00680
Sidereal period	224.7 days
Synodic period	584 days
Orbital velocity	22 mi./sec.
Diameter	7,848 mi.
Mass	0.826 (Earth=1)
Density	0.88 (Earth=1)
Density	4.9 (water=1)
Velocity of escape	6.3 mi./sec.
Surface gravity	0.84 g.
Inclination of equator to orbit	32" (Kuiper) 14° (Richardson)
Albedo	0.76
Color index	0.80
Rotation period	Unknown

(T. E. R. P.; R. S. Rn.)

VENUS is an Italian goddess of very obscure origins and basic functions. The Latin form of her name is Venus, genitive Veneris, plural Veneres. It is generally held that she is connected with vegetable gardens, on the strength of several passages in Latin literature that associate her with gardening, and especially a fragment of a comedy of Gnaeus Naevius (3rd century B.C.), in which *Venerem expertam Volcanum,* "Venus who has felt Vulcan's embrace," means cooked potherbs. *olera cocta.* Naevius is clearly referring not only to the native goddess but also to Aphrodite as wife of Hephaestus, the Greek god of fire. Hence his testimony is somewhat weakened for the earliest period of Venus' cult. On the other hand Venus' name is more or less certainly associated with words, Latin and other, that contain the idea of "charm, winsomeness, beauty." Perhaps the two types of evidence may best be reconciled by comparing her with the Greek Charites *(see* GRACES, THE), who seem originally to have been agricultural deities. In both cases, the "beauty" or "charm!' would be, not that of wild nature, but that of a garden plot producing a good crop and so delighting the eye of its cultivator.

Venus had no worship in Rome in early times, as Varro shows, attesting that he could find no mention of her name in old records. This is corroborated by the absence of any festival for her in the oldest calendar, and by her lack of a *flamen* (special priest). Her cult among the Latins, however, seems to be immemorial, for she had apparently at least two ancient temples, one at Lavinium, the other at Ardea, at which festivals of the Latin cities were held. Hence it was no long step to bring her to Rome, apparently from Ardea itself. But how she came to be identified with so important a deity as Aphrodite remains a puzzle, as does her name, which ought to be neuter, by analogy with, for example, *funus, -eris; munus, -eris.*

That Venus' identification with Aphrodite took place fairly early is certain. A contributory reason for it is perhaps the date (Aug. 19) of the foundation of one of her Roman temples. Aug. 19 is the Vinalia Rustica, a festival of Jupiter; hence he and Venus came to be associated, and this facilitated their equation, as father and daughter, with the Greek deities Zeus and Aphrodite. But the most important cause of the identification was the reception into Rome of the famous cult of Venus Erucina—*i.e.,* of Aphrodite of Eryx (Erice) in Sicily—this cult itself resulting from the identification of an oriental mother-goddess with the Greek deity. This reception took place during and shortly after the second Punic War.

A temple was dedicated to Venus Erucina on the Capitol in 21j B.C., and a second outside the Colline gate in 181 B.C. The latter developed in a way reminiscent of the temple at Eryx with its harlots, becoming the place of worship of Roman courtesans, hence the title of *dies meretricum* ("prostitutes' day!') attached to April 23, the day of its foundation.

The importance of the worship of Venus-Aphrodite was increased by the political ambitions of the *gens Iulia,* the clan of Julius Caesar, and, by adoption, of Augustus. They claimed descent from Iulus, the son of Aeneas; Aeneas was the alleged founder of the temple of Eryx and, in some legends, of the city of Rome also. From the time of Homer onward, he was made the son of Xphrodite—that is, the Trojan clan of the Aeneadae probably had a hereditary cult of their local mother-goddess—so that his descent gave the Iulii divine origin. Others than the Iulii sought to connect themselves with a deity grown so popular and important. notably Gnaeus Pompeius, the triumvir. He dedicated a temple to Venus as Victrix in jj B.C. Caesar's own temple, however (46 B.C.), was dedicated to Venus Genetrix, and as Genetrix she was best known until the death of Nero in A.D. 68. But despite the extinction of the Julio-Claudian line she remained popular, even with the emperors; Hadrian completed a temple of Venus and Rorne in A.D. 135.

As a native Italian deity, Venus had of course no myths whatever. She therefore took over those of Xphrodite, and through her became identified with various foreign goddesses. The most noteworthy result of this development is perhaps the acquisition by the planet Venus of that name. The planet was at first the star of the Babylonian goddess Ishtar, and thence of Aphrodite. By metonymy, Venus' name often means "beauty! charm, (power of) love" and the like.

See G. Wissowa, *Religion und Kultus der Ronzer,* 2nd ed., pp. 288–293 (1912); R. Schilling, *La Religion romaine de Vénus depuis les origines jusqu'au temps d'Auguste* (1954). (H. J. R.)

VENUSIA: *see* VENOSA.

VENUS'S-FLYTRAP *(Dionaea muscipula),* a remarkable carnivorous plant of the sundew family (Droseraceae). First discovered by Arthur Dobbs, governor of North Carolina, it was reported by him to Peter Collinson in a letter dated Jan. 24, 1760, in which he called the plant the "Fly Trap Sensitive." This letter did not become public until 1843. From some plants sent to England and introduced in Kew gardens, John Ellis, a London merchant and by avocation a botanist. drew a description and figure which he sent to Linnaeus in 1770. The latter rewrote the description in Latin and published it in 1773. Though Dobbs had recognized the sensitivity of the leaves. this was also seen independently by Ellis, who drew Linnaeus' attention to the phenomenon. He so far appreciated the nature of the plant that he called it *miraculum naturae,* a miracle of nature. Though Ellis thought that the plant caught insects (flies) and held them, Linnaeus was not of this opinion.

The plant is a small perennial herb, with a native distribution limited to the states of North and South Carolina. It has a rosette of leaves bearing tall scapes with white fiowers. The leaf shows two regions, the leaflike footstalk narrowly to broadly cordate, which is separated from the blade by a narrow isthmus. The blade consists of two trapezoidal lobes which stand at an angle of 40°–50°. The upper surface of each lobe is the site of numerous low glandular trichomes or hairs containing red sap and lending this hue to the whole surface. These are digestive glands and become active after prey has been caught. The outer edge of the lobe is armed with a series of strong projections, suggesting fingers, about 13 in number. On the surface between them and occupying a narrow zone within the margin there are numerous nectar glands. F. M. Jones observed ants. etc., feeding on them. In addition there are, normally, three longish, bristlelike hairs, jointed near the base, and readily bent by the body of an intruding insect. The cells of the joint are extremely sensitive to unequal pressure which is provided by the bending, and, though the blade has been shown to be slightly sensitive elsewhere, it is here that the normal stimulus is received. But a single stimulus does not suffice. It normally requires two stimuli (at normal temperatures): received either by the same or by different hairs, the second not less than I.j seconds nor longer than 20 seconds after the first, to initiate a response. This consists of the rapid apposition of the two lobes, which occurs within one-fourth of a second. at normally high temperatures, until the margins approximate and the fingerlike projections overlap. If prey is present, the movement continues quite slowly until the surfaces of the lobes press against the body of the prey. The secretion of digestive enzymes then sets in and the insect body is disintegrated. This action takes about ten days, after which the lobes reopen. The process can be repeated three times, until the limit of growth is reached; it has been shown that the movement involves growth. The first rapid movement bringing the fingers into overlapping position results in a mutual posture of the lobes which, Charles Darwin held, allows very small insects of little value as food to escape. Darwin also observed that, during the period of digestion, the flow of digestive fluid was so abundant that, on cutting a small hole at the base of the trap, it flowed down the petiole or dropped to the ground.

The closure of the trap is accompanied by electrical disturbances, studied by J. Burdon-Sanderson and by H. Munk. Such disturbances have been likened to those which occur during the stimulation of muscle. and some attempt has been made to find a structural equivalence, without result. The movement resulting from a stimulus is a result of slight changes in the tensions on the parenchyma of the lobes. The mechanism of transmission of the stimulus can be only vaguely guessed. It is little wonder that Darwin said of this plant that it is the "most wonderful" in the world.

Closely related to *Dionaea,* though placed *by* the taxonomists in another genus, is *Aldrovanda vesiculosa,* a freely floating freshwater plant distributed from Spain to Japan, and south to the Chobe swamp in South-West Africa. though it appears to be not generally abundant. It was found in India before 1696 and later in Italy previous to 1747. It was named by Gaetano Monti in honour of an Italian naturalist. Ulisse Aldrovandi. The name was published by Linnaeus as *Aldrovanda*, apparently the result of a mistake in copying. Otherwise it should have been *Aldrovandia,* under which it has often been cited.

The plant is small, about three inches long. and flaccid. floating horizontally in the water. It produces small inconspicuous flowers. The leaves occur in whorls of eight, and each shows the same regional areas as that of *Dionaea*. The basal portion is narrow and wedge-shaped and bears, at its upper end. the trap and usually four bristlelike extensions. The lobes of the trap are approximately semicircular and have turned-in margins, which. when the lobes are approximated, act as valves when pressing against each other. Each lobe has two regions. The inner region, against the midrib, is relatively thick and concave. When the lobes are closed the two inner regions fit together to form an ovate hollow container holding the prey if caught. The outer regions are thin and come slowly into close contact if prey is caught. Within the inner region there are numerous digestive glands and about 40 sensitive hairs, which work like those of *Dionaea* but are of much simpler structure. Prey coming into contact with these stimulate the lobes to close, bringing the marginal valves together. The water escapes between reaches of the margins near the midrib where the valves are absent. Small insect larvae, copepods, acarids, etc., are caught as prey, the trap closing with speed. The number of stimuli required depends on the age of the leaf.

This plant never produces roots subsequent to the seedling radicle, which is of limited growth. The latter end of the plant decays as the growing end extends. *See* also CARNIVOROUS PLANTS.

VENUS'S-LOOKING-GLASS, a popular garden name for blue- or purple-blossomed plants of the genus *Specularia* in the bluebell family. In North America four native species occur, of which the American Yenus's-looking-glass or clasping bellflower (*S. perfoliata*) and the small Yenus's-looking-glass (*S. biflora*) are found across the continent, the latter extending to South America. A European species. *S. speculum veneris,* is a common field plant in the south of Europe and is grown in gardens because of its brilliant purple flowers.

VERACRUZ, a central gulf state of Mexico, with its capital at Jalapa (*q.v.*). Pop. (1960) 2,749,235; area 27.759 sq.mi. It extends for a 50 mi. strip northwest to southeast along the gulf. averaging 435 mi. in width, bounded north by Tamaulipas. west by the mountain states of San Luis Potosi. Hidalgo. Puebla and Oaxaca and southeast by Chiapas and Tabasco. The principal rivers rising in these inland states terminate in Veracruz, carrying rich soils to the gulf and creating sand bars at their deltas. In addition to the major seaport of Veracruz (*q.v.*), the state also contains minor ports. notably Tuxpan, Xlvarado, Coatzacoalcos (Puerto Mexico) and Tonalá. Lying in tropical lowlands, the area is generally hot, humid and insalubrious, especially in the low, level, sandy strips along the gulf. a zone much broken by tidewater streams and lagoons. Behind the coastal strips the land rises rather sn·iftly to the central plateau of Mexico, cut into rich valleys but often characterized by overwhelming vegetation of a drenched tropical rain forest; in places there is 120 in. of precipitation annually. In the west-central parts of Veracruz terminate major mountain chains of the Mesa and a volcanic axis. which provide the high peaks of Nauhcampatépetl (Cofre de Perote) and Orizaba, the latter perpetually snow-capped. More than 40 rivers cross the state, providing hydroelectric power but also frequent inundations. A massive reclamation project involving drainage, hydroelectric installations. preplanned cities and a balancetl industrial-agricultural economy was inaugurated in 1947 by the national government in the basin of the Papaloapan river system. By the late 1950s three dams were completed and modern farm methods successfully introduced. Veracruz is a rich state, potentially and actually, with its wealth based on commerce. agriculture and manufacturing, supplemented by production and processing of petroleum at its northern and southern extremities. Tropical agricultural products of great importance include cotton. sugar, rum. pineapples, tobacco. cacao. vanilla. oranges and bananas and other fruits. Veracruz coffee is excellent and abundant! while for subsistence the state grows surpluses of maize and beans. Pastoral activities furnish cattle and hides for national consumption. Forest industries supply rubber, cabinet woods. chicle, orchids and numerous medicinal plants. Industries include sugar refining and rum making (centred near Yeracruz port). with scattered plants producing beer, matches. candies. soap, shoes, cement. chemicals and a great range of light industrial products. Manufacturing of cotton and other textiles is also carried on at Orizaba (*q.v.*) and at Cordoba.

The state is rich in archaeological remains of pre-Columbian cultures. Olmec, Totonac and Huastec. one of the most noted ruins being those at Cempoala. A part of the coast of Veracruz was explored in 1518 by Juan de Grijalva. although the first landing in the state was made by Hernán Cortés on Good Friday in 1519 at San Juan de Ulúa. Veracruz became a state in 1824.

(HD. C.; R. B. McCK.)

VERACRUZ (VERACRUZ LLAVE), city and principal seaport of Mexico. on the Gulf of Mexico. in Yeracruz state. Pop. (1950) 101.469; (1958 est.) 121,408. Lying on a slight indentation of the coast line. Veracruz is 263 mi. E. of Mexico City. with which it is connected by two railways and several highways. It is a main entrepôt and communication centre for the gulf littoral and tropical hinterland; it also taps the industrial areas of Puebla and Orizaba. and central areas of the republic to the Isthmus of Tehuantepec, with which it is connected by rail. Built on a hot, low and barren sandy beach only a few feet above sea level, the port site is generally cramped and unhealthful. and natural advantages of the harbour are few. It is a narrow channel bounded by reefs and small islands. guarded by the island of San Juan de Ulúa. a naval base and erstwhile prison. Much of the equipment placed in Veracruz before 1910. including breaknaters to protect it from storms. deteriorated badly, but a rehabilitation program was begun in 1946 to replace and expand unloading equipment, warehousing facilities and cargo-handling devices to expedite the large trade that passes through this chief entrance to Mexico. The port contains three main dock works, capable of handling vessels up to 7,000 tons: a dry dock was completed in 1951. The modern port and city dates from about 1.599, though La Villa Rica de la Yeracruz (Rich Town of the True Cross) was founded as the first Mexican municipality by Cortés in 1519 anti shifted its position a number of times. As the chief link between New Spain (colonial Mexico) and Cádiz (Spain), Veracruz was a thriving place despite its insalubrity, but also a prize of war and pillage. In 1653 and 1712 attacks by privateers led to construction of the fort on San Juan de Ulúa. Captured by the French in 1838 and again by Americans under \\'infield Scott in 1847. it fell into French hands in 1861 and under U.S. occupation in 1914. Numerous revolutionary governments and coups aimed at its capture and customs revenues following Mexican independence (1821). The name Llave was added in honour of Gen. Ignacio de la Llave, governor of Yeracruz state (1857–60). (HD. C.; R. B. McCK.)

VERAGUAS, a province of Panamá. extending across the isthmus between the Caribbean sea and the Pacific. Area 1.336 sq.mi.; pop. (1960) 130,934, of which 85% was rural. Most of the people are in the Pacific lowlands and the lower southern slopes of the central highland. which are important agricultural districts, producing rice. corn and coffee. Pigs, poultry and cattle are also significant.

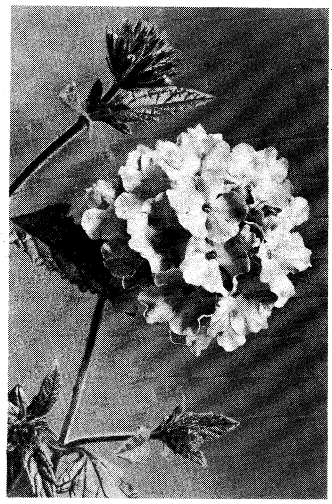
The provincial capital, Santiago (pop. [1950] 5.886). is one of the oldest colonial settlements in Panamá. (C. F. J.)

VERATRUM, a genus of herbaceous plants belonging to the family Liliaceae. Greek physicians were acquainted with a poisonous herb called white hellebore. which has been supposed to represent the *Veratrum album* of modern botanists. *Veratrum* is a tall-growing herb, having a fibrous rootstock, an erect stem with numerous broad, plicated leaves placed alternately, and terminal, much-branched clusters of greenish or purplish polygamous flowers. Each perfect flower consists of six regular petals, as many stamens, whose anthers open outwardly, and a three-celled superior ovary which ripens into a three-celled, many-seeded capsule. The genus comprises ten species, natives of the temperate regions of the northern hemisphere, generally growing in pastures or woods. *V. album* and the North American species *V*. viride are commonly grown in gardens as ornamental perennials, but their poisonous qualities should be kept in mind, particularly as they bear a considerable resemblance in foliage to the harmless *Gentiana lutea*. Both contain the potent alkaloid veratrine. See also HELLEBORE.

VERBASCUM, a genus of weedy biennial herbs. commonly known as mulleins, native to Europe and Asia and naturalized in North America. Of about 250 species, a few are cultivated for ornament. Most have woolly leaves and large spikes of usually yellow but occasionally white or purple blossoms.

See MULLEIN.

VERBENA. The plant genus Verbena (vervain) gives its name to the family (Yerbenaceae) of which it is a member. The species are herbaceous or somewhat shrubby, with opposite or whorled leaves. generally deeply cut. The sessile flowers are aggregated into close spikes. Each flower has a tubular. ribbed calyx, a more or less irregular, tubular, two-lipped corolla. with four (didynamous) stamens springing from the interior of the corolla tube. The anthers are two-celled, The ovary is entire or four-lobed. and always four-celled. with a single ovule in each cell. The fruit consists of four hard nutlets within the persistent calyx. There are about 100 species. mostly natives of tropical and subtropical America, about 20 being native to the United States, a very few species occurring also in the old world. The garden verbenas are mostlv derivatives from a few South American species, such as *V. teucrioides* of southern Brazil and *V*. chamaedrifolia from Argentina and southern Brazil. Various cultivated forms have been derived also from the North American V. canadensis. The range of colours extends from pure white to rose coloured. carmine, violet and purple. Striped forms also are cultivated. The lemon-scented verbena of gardens, much valued for the fragrance of its leaves, was once referred to this genus under the name V. triphylla, subsequently called Aloysia, but is now referred to the genus Lippia as L. *citriodora;* it differs from *Verbena* in having two, not four, nutlets in the fruit. Sand verbena (*q.v.*) belongs to the genus *Abronia.*



J. HORACE MCFARLAND CO

VERBENA

The garden verbenas are easily raised from seeds sown in heat in February or March. but choice varieties can be kept true only when raised from cuttings. These are best secured from old plants cut down in the autumn and started into growth in gentle heat and moisture the following spring. They root readily in a compost of sandy loam. See VERBENACEAE; VERVAIN.

VERBENACEAE, a family of herbs, shrubs and trees, nearly all tropical and subtropical. There are about 70 genera and about 750 species. Vervain (*q.v.*) is widespread in North America, Europe and Asia. Lippia and *Cymbopogon* (a grass) yield verbena oil. and several species, as teak (*Tectona* grandis), supply useful timber. Many are lianas or climbing plants. Some species bear thorns; others are xerophytic. Numerous species are cultivated for ornament. as the verbena (*q.v.*), chaste tree (*Vitex agnuscastus*), glory bower (*Clerodendron*), purple wreath (Petrea *volubilis*), golden dewdrop (*Duranta repens*), bluebeard (Caryopteris *incana*) and French mulberry (*Callicarpa americana*).

VERBOECKHOVEN, EUGÈNE JOSEPH (1798–1881), Belgian painter whose paintings of sheep, horses and cattle in landscape. somewhat after the manner of Paul Potter. brought him universal iame, was born at Warneton in West Flanders on June 9, 1798. He received instruction in drawing and modeling from his father, the sculptor Barthélemy Verboeckhoven. Precise and careful finish is the chief quality of his art, which is entirely objective and lacking in inspiration. Yerboeckhoven visited England in 1826, Germany in 1828 and France and Italy in 1841. He died in Brussels on Jan 19, 1881. In addition to his painted uork he executed about 50 etched plates.

His brother CHARLES LOUIS (1802–1889) was a painter of marine scenes.

VERCELLI (anc. VERCELLAE), a provincial capital and archiepiscopal see of Piedmont, Italy, in the province of Vercelli, 13 mi. S.W. of Novara by rail. Population (1951) 38.898. It is situated 430 ft. above sea level on the river Sesia, at its junction nith the Canterana. Vercelli is a point at nhich railways diverge for Novara, Mortara, Casale Monferrato and Santhia (for Turin). The Piazza Cavour has a statue of Cavour. The cathedral library contains many ancient manuscripts, especially the Codex *Vercellensis* (see VERCELLI BOOK). The church of S. Andrea is a Romanesque Gothic building of 1219–24, with lofty towers and an interior in the French Gothic style and a museum of Roman antiquities in the adjacent cloister. S. Paolo, S. Francesco and S. Cristoforo possess valuable examples of the work of Gaudenzio Ferrari (1471–1546) and of his follower Lanini. The castle of the Visconti is now a prison. Vercelli was the birthplace of the painter Giovanni Antonio Bazzi, called Sodoma (1477–1549). Vercelli is one of the principal Italian centres of the exportation of cereals and especially of rice.

Vercellae, originally the chief city of the Libici (a Ligurian tribe). was at the junction of Roman roads to Eporedia, Novaria and Mediolanum. Laumellum (for Ticinum) and perhaps Hasta Remains of the theatre and amphitheatre were seen in the 16th century, and ancient streets have been traced. Close by (near Rotto on the Sesia) are the Raudii Campi where Hannibal uon his first victory on Italian soil (218 B C.), and uhere in 101 B.C. Marius and Catulus routed the Cimbri. From about 1228 till 1372 Vercelli was the seat of a university. (T. A)

VERCELLI BOOK (CODEX VERCELLENSIS), an Old English manuscript, written in the late 10th century, containing texts of the poem *Andreas,* two poems by Cynewulf (*q.v.*), namely The Fates of the Apostles and Elene, The Dream of the Rood, an Address of the Soul to the Body and a fragment of a homiletic poem, as well as 22 prose homilies and a prose Life of St. Guthlac. It nas found in the cathedral library at Vercelli, north Italy, by F. Blume in 1822. K. Sisam has shown that marginalia in the manuscript prove it to have been in English use in the 11th century, and that an excerpt from a Latin psalm, with neumes (a plainsong form of notation), on folio 24 b, was probably added in Italy, either in the late 11th or first half of the 12th century. This excludes the possibility that the manuscript was taken to Italy, either in the 13th century, by Cardinal Guala, a native of Vercelli, on his return from England where he had been papal legate, or after the Renaissance, as had been previously suggested. It was probably taken there by one of the numerous Anglo-Saxon pilgrims on the nay to Rome. But for the survival of this manuscript, we should possess only two "signed" poems of Cynewulf, and should knon one of the greatest Old English poems, The *Dream* of *the* Rood, only in the brief fragments inscribed on the Ruthwell cross. The homilies include important examples of prose uninfluenced by Aelfric.

For comment on the individual works in the Vercelli Book, see the article ENGLISH LITERATURE.

BIBLIOGRAPHY.—There is a facsimile, with introduction, by M. Forster, *Il Codice Vercellese* (1913). All the verse texts were ed. by R. P. Wülker, *Bibliothek der angelsachsischen Poesie,* ii (1894), and by G. P. Krapp, *The Vercelli Book* (1932), where bibliographies of earlier works are given. The prose homilies ii, vi, ix, xv and xxii were ed. by M. Forster, *Der Vercelli-Codex CXVII* in *Festschrift für Lorenz Morsbach* (1913). Forster also edited homilies i–viii in *Bibliothek der angelsächischen Prosa,* xii (1932). The *Lije of St. Guthlac* was ed. by P. Gonser in *Anglistische Forschungen,* xxvii (1909). *See* also K. Sisam, "Marginalia in the Vercelli Book," *Studies in the History of Old English Literature* (1953). (D. WK.)

VERCINGETORIX (d. 45 B.C.), Gaulish chieftain, waged war with ability against Caesar in 52 B.C. For the history of the campaign *see* CAESAR, GAIUS JULIUS. He fell into Caesar's hands at the capture of Alesia, was exhibited at Caesar's triumph in 45 and was then put to death.

See Caesar, *B.G.* VII.

VERDI, GIUSEPPE FORTUNINO FRANCESCO (1813–1901), Italian composer, was born on Oct. 10, 1813, at Le Roncole, near Busseto. His parents named him Giuseppe Fortunino Francesco but the duchy of Parma being then under French rule, he is entered in the certificate of baptism as Joseph Fortunin François. His father, Carlo Verdi, was a poor innkeeper and grocer, and the house in which he was born is among the lowliest of great composers' birthplaces. The Austrian invasion in 1814 did not improve the family's fortunes and at one time his mother was forced to take refuge with him in the belfry of the village church. His first musical impressions were primitive. What he heard at the church and sang there after the age of seven when he became a chorister, cannot have been of any quality, and the only secular music he knew at that time was that of the barrel organ and the military band. These early impressions are significant: his church scenes (*e.g.*, in *La forza del destino* and even the temple scene in *Aida*) are the weakest. He became the great favourite of organ grinders, who made many of his tunes familiar to those who could not afford visits to the opera house. Up to the time of his fullest maturity he often scored his operatic choruses as though their parts were intended for hand instruments. These casual early influences had to undergo a later process of refinement but perhaps bore more fruit than the formal lessons given him by the local organist on an old keyboard instrument. At the age of 10 he began to deputize for the organist in church, and he succeeded to his post soon after. He continued his duties once or twice a week after 1823, when his father sent him to Busseto, to lodge at a poor cobbler's and to pick up some kind of schooling. He walked to Le Roncole and back on these occasions, a matter of three miles each way, since a salary of about £4 a year did not justify extra outlay.

In 1826 a friend of his father's at Busseto, Antonio Barezzi, took the boy into his business and his home. There he heard the rehearsals of the local amateur orchestra, conducted by Ferdinando Provesi, organist of the collegiate church, who soon offered to teach him free. He was also allowed to practise on the piano of Barezzi's daughter Margherita. A warm childhood attachment later ripened into love, and Margherita became Verdi's first wife in 1836. Meanwhile the gifted boy learned much from Provesi, from the scores in the orchestra's library, which he copied to learn orchestration, and from his own early essays in composition: marches for military band and an overture which Provesi performed at Easter 1828. In 1829, aged 16, he began to assist Provesi in conducting and at the organ.

Barezzi in 1831 contrived to obtain a scholarship for Verdi from a local charitable institution and supplemented this by an allowance of his own in order to send him to Milan for more systematic study. There the youth was examined at the conservatory, but rejected. The director, Francesco Basili, later came in for much opprobrium for having failed to recognize genius; but apart from this the fact was that as a candidate in his 19th year he was past the age for enrolment. A conductor at the Teatro alla Scala, Alessandro Rolla, then advised Verdi to study under Vincenzo Lavigna, who was coach at the famous opera house, and from him young Verdi learned much technically. He was also able to hear the performances, although he did not hear much foreign work, and his acquaintance with Bellini, Donizetti and Rossini, who were then the moderns of Italian opera, meant invaluable experience. Rossini's influence, however, is far less perceptible even in his earliest works than that of the other two masters.

In 1833 Verdi returned to Busseto, where, although he failed to obtain the succession to Provesi's church post—fortunately for posterity—the musical association made him an allowance for three years. During that time he married Margherita Barezzi and wrote his first opera, *Oberto, Conte di San Bonifacio*. This was produced at the Milan Scala on Nov. 17, 1839. It had no great immediate success, but the impression of its crudely vital music lasted for some time.

Verdi had settled again with his family at Milan in 1838, his three years' engagement at Busseto having come to an end. This was a period of terrible tragedy. His infant daughter Virginia died that year, his son Icilio in 1839 and his wife in June 1840. (It is curious that later on Verdi left an account of having lost his wife and children within the space of less than two months. He cannot have forgotten the facts, and this statement has never been satisfactorily explained.) Left utterly alone, he lived in a state of despair bordering on a mental breakdown, when he was asked by the director of the Scala, Bartolomeo Merelli, to write a comic opera, *Un giorno di regno*. This looks like bitter irony, but was no doubt a kindly attempt to take his mind off his unhappiness. The work was a complete failure, and he never attempted another comic opera until he wrote *Falstaff*, his crowning masterpiece, at the end of his long life. That he could have produced admirable works of this kind much earlier is proved by such things as the abduction scene in *Rigoletto*, several incidents in *Un ballo in maschera*, the character of Melitone in *La forza del destino* and even the chorus of murderers in *Macbeth*.

After 1840 Verdi's life was relatively uneventful except in operatic productivity, where it became continually exciting—a tale of gradual progress from success to success, with here and there a failure, and a steady advance in diversity of invention, power of characterization and subtlety of craftsmanship; it might be added, an advance in dramatic force and insight, were it not that this is a quality he evidently possessed from the very first. With only temporary relapses caused by some uncongenial libretto (*e.g.*, *I masnadieri*, 1847) or an unwelcome commission (*e.g.*, *Les Vêpres siciliennes*, 1855), everything worked up to the magnificent last masterpieces: the splendid and profoundly musical *Aida*, the poignant, poetical and sensitive *Otello*, and the sparkling and indulgently human *Falstaff*. Even such comparatively superficial aspects of a composer's workmanship as harmony or orchestration are seen to become gradually more resourceful and refined. The fairylike poetry that invades *Falstaff* during the progress of the third act, for instance, could not have been dreamed of by those who first heard *Rigoletto* (1851) or *Il Trovatore* (1853), though hints of it emerge in such a splendid middle-period work as *Un ballo in maschera* (1859) and more than hints in the revised versions of *Macbeth* (1865) and *Simon Boccanegra* (1881)—the latter actually 10 years later than *Aida*, but still preceding *Otello* and *Falstaff* by 6 and 12 years respectively.

In 1840, after the fiasco of *Un giorno di regno* Verdi, then a prey to artistic as well as personal despair, made up his mind to give up composition forever. But Merelli, undaunted by his previous failure to help him, cunningly asked him to read T. Solera's libretto of *Nabucodonosor*, simply, he said, for his opinion of it. As Merelli had doubtless hoped, the sight of a libretto awakened musical invention in Verdi, who did not rest till the opera was composed. It was produced at the Scala on March 9, 1842, with resounding success, and became affectionately known as *Nabucco*. A soprano, Giuseppina Strepponi, was in the cast. She gave Verdi sound practical advice about the ice he was to ask for his next opera, *I Lombardi alla prima crociata* (Milan, Feb. 11, 1843). She lived with him from 1849, but long regarded herself as unworthy to be his second wife and was not married to him until 10 years later.

Both *I Lombardi* and *Ernani* (Venice, March 9, 1844), with their fiery patriotic tunes, brought Verdi into conflict with the authorities by provoking public demonstrations against the Austrian rule. This was not Verdi's direct intention, but he was as ardently in favour of the liberation and unification of Italy in his own way as Garibaldi and Mazzini were in theirs. So he cannot have failed to feel inspired to write such stirring melodies or to be pleased by the effect they had on his audiences. He was becoming so popular that regulations were powerless to suppress him, though they sometimes induced him to consent to certain changes in the words or action of his operas, but never the music. And it was the music which agitated the Italian blood.

Among the nine works which followed *Ernani* between 1844 and 1849, including *I masnadieri*, written for Jenny Lind (London, July 22, 1847), and *Jérusalem*, a revision in French of *I Lombardi* (Paris, Nov. 26, 1847), none later is important except *Macbeth* (Florence, March 14, 1847), and even that has kept the stage only in the admirable revised version (Paris, April 21, 1865). Verdi was a keen student of Shakespeare, though he knew no English, but *Macbeth* is the only work he drew from that master apart from the last two operas. He did work spasmodically on a *King Lear* for several years, but the magnitude of the undertaking seems to have discouraged him, and the sketches are lost.

Several of the operas dating from before Verdi's 36th year are worth study and occasional revival. The first capable of holding a place in the repertory dates from the end of that year: *Luisa Miller* (Naples, Dec. 8, 1849), which has something of the lyrical quality of *La Traviata* and shows distinct anticipations of the later and more refined manner.

The three most generally popular of Verdi's operas followed each other in quick succession: *Rigoletto* (Venice, March 11, 1851), *Il Trovatore* (Rome, Jan. 19, 1853) and *La Traviata* (Venice, March 6, 1853). The first two at once had enormous success, but the last failed utterly, partly because the subject (Alexandre Dumas's *La Dame aux camélias*) was thought shocking and the breach with tradition in presenting an opera in contemporary dress even more so, but mainly because the cast happened to be grossly inadequate. After its revival later in the year at a different Venetian theatre it became perhaps the first favourite, not to be displaced in many Italian opera lovers' affections even by the final masterpieces.

The first version of *Simon Boccanegra* (Venice, March 12, 1857) is no longer important, but *Un ballo in maschera* (Rome, Feb. 17, 1859) contains some of the finest music in Verdi's fully matured manner, as does *La forza del destino* (St. Petersburg, Nov. 10, 1862), which is marred only by too many irrelevant, merely picturesque incidents. *Don Carlos* (Paris, March 11, 1867), composed, like the less interesting *Vêpres siciliennes,* on a French libretto, is also rather too episodic, but the episodes are striking and there is great mastery in characterization.

Then came the final phase, perhaps the most wonderful summing up of a creative musician's work in extreme old age known to musical history. With all his skill and endless invention, Verdi had up to that time often shown a certain bluntness of imagination and striking deficiencies in taste, only at last, in *Falstaff* (Milan, Feb. 9, 1893), to reach, as a veteran of 79, a flawless refinement comparable with Mozart's alone (though his music is quite different, having something in common rather with Domenico Scarlatti and being for the rest wonderfully original). But as masterly in their way are not only the work commissioned for the opening of the Suez canal, the resplendent *Aida* (Cairo, Dec. 24, 1871), with its quite un-Wagnerian use of a *Leitmotiv* (*q.v.*), and the subtle and profoundly moving *Otello* (Milan, Feb. 5, 1887), but also the wonderful *Requiem* performed in 1874 in memory of Alessandro Manzoni, which incorporates (with alterations) a *Libera me* written for a funeral mass lor Rossini suggested by Verdi in 1868, with music by various Italian composers, which was never performed.

After *Falstaff* Verdi lived in retirement at his estate of Sant' Agata near Busseto. He died at the age of 87 in a Milan hotel on Jan. 27, 1901. He had become increasingly lonely aiter Giuseppina's death in 1897 and wrote nothing more for the stage, but he did produce four sacred pieces, which are as poignantly lovely as the *Requiem.* These works are not church music in any liturgical sense, but are great music and show that Verdi must not be thought of as exclusively an operatic composer, though the musical conditions of his time in Italy as well as his temperament drew him to the theatre in the first place. His string quartet (1873) should also be remembered and if (like the work by Hugo Wolf it slightly resembles) it had been called *Italian Serenade,* it would have been admired as a thing of great charm instead of being criticized as unsatisfactory chamber music.

VERDUN, a garrison town of northeastern France, capital of an *arrondissement* in the *département* of Meuse, between Paris and Metz, 42 mi. N.N.E. of Bar-le-Duc. Pop. (1954) 16.111.

Verdun (*Verodunum*), an important town at the time of the Roman conquest, was made a part of Belgica Prima. The bishopric, held by St. Vanne (498–525), dates from the 3rd century. Verdun was destroyed during the period of the barbarian invasions and recovered only at the end of the 5th century. Clovis seized the town in 502, and it afterward belonged to the kingdom of Austrasia. In 843 the famous treaty was signed there by the sons of Louis the Pious. *(See* GERMANY: *History.)*

In the 10th century Verdun was conquered by Germany and put under the temporal authority of its bishops. Together with Toul and Metz, the town and its domain formed the territory of the Trois-Évêchés. In the 11th century the burghers began a struggle with their bishops, which ended in their obtaining certain rights in the 12th century. In 1552 Henry II of France took possession of the Trois-Évêchés, which finally became French by the peace of Westphalia. In 1792 the citizens opened their gates to the Prussians. In 1870 the Prussians invested and bombarded it three times, till it capitulated in the beginning of November. (For the part played by Verdun in World War I *see* VERDUN, BATTLES *OF;* WORLD WAR I.)

Verdun stands on the Meuse, canalized there, and was a great fortress. The chief quarter of the town lay on the slope of the left bank of the river and was dominated by the citadel which occupied the site of the old abbey of St. Vanne, founded in the 10th century. The whole town was surrounded by a bastioned enceinte, pierced by four gates; that to the northeast, the Porte Chausshe, 15th–17th century, with two crenelated towers, was little damaged in World War I. The cathedral of Notre Dame, in process of restoration, stands on the site of two previous churches of the Romanesque period, the first of which was burned down in 1017. There are double transepts, and till the 18th century, when the western apse was replaced by a façade, there was an apse at each extremity. To the southwest of the cathedral is a fine 15th-century cloister. The *hôtel-de-ville* (17th century) has been restored.

VERDUN, BATTLES OF. The invader of France coming from the east is confronted by a series of ridges between the Moselle and Paris. The second of these ridges is formed by the historic escarpment 400 metres high, above the Meuse, called the Heights of the Meuse. There is the fortress of Verdun, one of the main barriers on the road to Paris. It was the primary objective of the German campaign of 1916, and the failure to secure it had a far-reaching influence on the course of World War I.

History of the Fortress.— After the war of 1870 Gen. Shrh de Rivière, who was entrusted with the task of organizing the frontier defenses, constructed a protective curtain stretching from Verdun on the north to Toul on the south. Fortresses guarded the routes between these two places. On this rampart of the Heights of the Meuse Verdun formed the northern muzzle, opposite the fortified camp at Metz some 10 mi. away. The fortress was planned so that the principal line of resistance faced north. Inside the two lines of forts was an old fortified enclosure of Vauban's time and a citadel dating back to Henry II.

Verdun in 1914.—At the beginning of the war the fortress was an independent command. After the battle of the Frontiers the III army in retreat pivoted its right upon it as a breakwater against the German tide of advance, which turned on Sept. 13, 1911, by reason of the defeat of the German armies before Paris. (*See* MARNE, FIRST BATTLE OF.) The French lines were then established 10 km. north of Verdun, and the sector was quiet for nearly 18 mo.

The autonomy of the great fortresses was cancelled on Aug. 5, 1915, in order to make their garrisons and equipment available for the armies in the field. Dunkirk, Verdun and Belfort, the three great fortresses on the area of battle, became fortified regions linked up with the armies. The fortified region of Verdun (R.F.V.) was placed under Gen. Herr.

I. THE GERMAN OFFENSIVE

On Feb. 8. 1916, it was discovered that the Germans had brought a mass of maneuver to the neighbourhood of Verdun. A deserter disclosed the presence of two corps. On the 11th an intelligence officer reported a concentration of troops on the east bank of the Meuse. The French command at once took precautions.

On Feb. 21, 1916, at 7:15 A.M., the Germans commenced bombardment on a front of 25 m. from the Bois d'Avocourt to Étain. About 4:15 P.M. the first infantry attack was launched. The Germans, to effect a surprise, had not dug parallels from which to issue and moved from their lines at distances from the French lines which varied from 600 to 1.100 metres. Gillet describes their new tactics thus: "Each troop had a specific task, with an objective of limited breadth and depth. . . . The attack took place in waves about 80 metres apart. . . . Shell fire would support the advance continually. On no account should troops attempt to overcome resistance which has not been broken by artillery fire. Units when held up must wait for fresh artillery action."

Early German Successes.—The French line rested on the village of Brabant, then on the Bois de Consenvoye, Bois d'Haumont, Bois de Caures, Bois de Ville and on Herbebois. A little in the rear the Bois de La Wavrille (southeast of the Bois de Ville) and the village of Beaumont had been strengthened. At Herbebois the Germans captured the first lines but were stopped in front of the supporting trenches. The Bois de Cnures was lost, but its northern part was retaken during the night. The loss of the Bois d'Haumont was a serious matter. A French counter-attack on the 22nd at 6 A.M. failed. The line had been pierced.

The Germans made good use, on the 22nd, of the advantage gained at the Bois d'Haumont. The village of Haumont was destroyed by shell fire and at 5:00 P.M. was attacked by three columns. The main redoubt, built of concrete, collapsed and buried 80 men. The remaining defenders were hunted from the cellars by bombs and liquid fire but rallied at Samogneux. Bois de Ville was lost. Bois de Caures was then enveloped on the right and left and Col. Driant decided to withdraw his chasseurs to Beaumont. He was the last to leave the wood and was then killed. On the 23rd the village of Samogneux was overwhelmed by shells and set on fire but the garrison held on till night fell. On the extreme left the village of Brabant outflanked by the German advance became untenable and was evacuated. On the right Wavrille and Herbebois were lost and the front passed along the northern edges of Bois des Fossés and La Chaume.

In three days the Germans had captured the first of the French positions. Each side was reinforced on the 24th. A fresh regiment from the V. Res. Corps was sent to each of the German corps. The corps on the right which, having gained the greatest success, thereby became as it were a pivotal wing, also received a battalion of Jagers. On the French side the two divisions in line from the 21st were relieved, on the left by a division of the VII. Corps, on the right by two brigades from the XX. Corps. These troops, thrown at night into doubtful. positions in the open country, were immediately destroyed. The 24th was the most critical day of the whole battle. On their right, where the Germans sought to move out from Samogneux, they were nailed down by the French artillery on the left bank. But they started a fresh attack immediately eastwards and captured all the line Beaumont, Bois des Fossés, Bois des Caurières. Further they penetrated towards Douaumont along the ravine of the Vauche.

The second French position was lost in one day. In the evening the situation was so grave that Gen. Langle de Cary, commanding the Centre group of Armies, ordered the II. Corps, then closely engaged in the Woëvre, to fall back on the Heights of the Meuse. This movement was carried out during the night. That same evening (24th) Gen. Joffre handed over the operations before Verdun to a fresh army, the II., commanded by Gen. Pétain, who after the Battle of Champagne had been resting at Noailles. The X. Army, on relief by the British Army, was placed in the general reserve.

New French Dispositions.—The initial task of the army under instructions of Feb. 25 at 9.00 A.M. was to concentrate the troops of the Verdun area on the west bank and to prevent the Germans from crossing the Meuse. But on the 24th at midnight Gen. Castelnau set out for Verdun armed with full powers from the commander-in-chief. He halted at Avize, headquarters of Gen. Langle de Cary, whence at 5.45 A.M. on the 25th he telephoned to Gen. Herr to order him to hold at all costs the line on the east bank facingnorth between the Meuse apd Douaumont and, facing east, on the Heights of the Meuse. Gen. Pétain went on the morning of the 25th to Chantilly and thence to take charge of the battle, from the 25th at midnight.

During the 25th, on the French left, the Germans advanced 1,500 metres south of Samogneux up to the mill of Cotelettes. Further east they captured Bezonvaux. A party of Brandenburgers crept up to the fort of Douaumont, found it empty and took possession of it. Gen. de Bonneval, commanding the 37th Div. on the French left on the Talou and the Poivre Hills was afraid of being surrounded and ordered retreat on the Bellevilie Hills. This order was only partially carried out. The Zouaves held their position on the west of the Poivre. On the other hand while the 37th Div. retreated, the 39th Div. of the XX. Corps, going up into the line, passed it and covered the line Bras-Hardaumont.

On the 26th Gen. Pétain, at his headquarters at Souilly, reorganized the battle plan. He drew a sharp line—Bras-Douaumont—which he entrusted to the XX. Corps. He divided the area into four sections: (1) under Duchesne in the Woevre, (2) under Balfourier from the Woëvre to Douaumont, (3) under Guillaumat astride the Meuse, and (4) under Bazelaire on the left bank. The artillery as it arrived was divided between these four commands. On Feb. 21 it consisted of 388 field guns and 244 heavy guns. In a few weeks there were 1,100 field guns, 225 guns of calibres from 80 to 105 mm. and 590 heavy guns. The French regained the mastery of the air. The 59th Div. was set to build two defensive positions chosen on the 27th and redoubled on March 2 by two intermediate lines. Three thousand territorials repaired and widened the Sacred Way.

Reinforcements arrived. The I. Corps was at Souilly on the 25th and the XIII. Corps at Revigny. The XXI. Corps followed it two days later. The XIV. Corps detrained on the 20th and the III. Corps on the 29th. Between the 26th and the 29th the Germans hurled violent attacks against Douaumont. On the east they reached the position of Hardaumont and attacked Bois de la Caillette. They stopped, exhausted, on the 29th.

The Second Phase.—The Germans failed to gain an immediate decision at Verdun. They soon realised that the British Army was about to attack them on the Somme. For four months they kept the battle of Verdun going with furious tenacity in order to disorganize the attack prepared by the Allies in Picardy. For the French Staff the problem was to hold on at Verdun without ceasing to prepare for the Somme. On March 6, as Gen. Pétain had expected and feared from the beginning, the Germans extended the action to the west bank. The attack was made by two corps, the VI. Res. and the X. Res., the latter taken from the General Reserve. On the 6th they captured the Hill de l'Oie and on the 10th Bois de Cumiiires. They were thus enabled to attack one of the pillars of the main line of defence, the Mort Homme. On the 14th they captured the lower crest of that double hill. The higher crest, Peak 295, could be held by neither side and was No Man's Land.

The second pillar of the French line, further to the west, and known as Hill 304, was attacked on March 20 by the 11th Bavarian Div. which took the Bois d'Avocourt but could not issue thence.

The Germans brought up fresh troops and the battle began again on March 28 on the west bank. It ended on April 8 by the French losing all that remained of their former front line. The new front passed thereafter by the redoubt at Avocourt, the first slopes of Hill 304, the southern reverse of the Mort Homme and the north of Cumières. On the right bank on March 31 the Germans captured the village of Vaux, which had held out till then, and on April 2 took the lake behind the village. Then on April 9 the Crown Prince attacked on both banks on a scale not known since the first attacks in February. The results were insignificant. On the morrow Gen. Pétain wrote in his orders of the day "the 9th April was a glorious day for our Armies . . . Courage. *Nous les* aurons."

On April 20 the French counter-attacked on the east bank in order to clear the Mort Homme. But on May 3 the Germans renewed the offensive by an attack on Hill 304. On the 8th they captured Bois Camard, west of the Hill. On the 13th and 16th they attempted without success to advance from this position. They then organized a new attack on the 18th with a fresh corps, the XVIII. Res. Corps and two divisions of the XVIII. and added on the 22nd the 22nd. Res. Division. This violent battle ended on the 24th with the capture of Cumières. As the Germans had no reserves available the tired units could not be relieved and on the 26th they lost a portion of the trenches they had won.

There had been changes in the command. On April 2 the east bank sector had been placed under the orders of Gen. Nivelle, the west bank under Gen. Berthelot. At the end of April Pétain was called to command the Armies of the Centre and handed the II. Army over to Nivelle. The Germans, too, from March had divided the field of battle into two sections, Gen. von Mudra commanding on the right bank, Gen. von Gallwitz on the left bank. In April Mudra was replaced by Lochow. In July François relieved Gallwitz. The Allies' preparations on the Somme took definite shape. Before all things the Germans had to prevent the French from taking part in these operations. For this *a* new success in the Meuse was necessary.

The main French line of defence on the east bank was the Côte de Froide Terre—Fleury—Fort de Souville. On the right this position was covered by the fort of Vaux, on the left by the crest of Thiaumont It was first necessary to capture Vaux and Thiaumont. On June 1 these two positions were attacked. Vaux was taken on the 9th. Thiaumont farm, taken by the Germans on the 1st, was recaptured by the French on the 2nd, who lost it again on the 9th. German attacks on the Thiaumont outworks behind the farm failed completely. They succeeded in establishing themselves on the west and opposite side in the ravine of La-Dame. At the same time battle was resumed on the west bank. Between May 29 and 31 the Germans took Cumières but tried vainly to move out of Bois Camard against Hill 304.

Time pressed more and more. On June 4 Gen. Brusilov started a wide offensive in Volhynia. In these conditions the Germans delivered a large scale attack on the line Froide Terre–Souville on June 21. On the west the Bavarian Corps took the fortified post of Thiaumont but was checked in front of the fort at Froide Terre. In the centre the Alpine Corps captured Fleury. On the west the 103rd Div. took the first line of trenches in front of Souville but failed before the second line. So serious was the situation for the French that on June 23 Pétain warned Gen. Joffre and suggested moving to the west bank if the enemy reached the counterscarps. Joffre's answer on the 27th was a peremptory order to hold on to the east bank.

Meanwhile the preliminaries of the great Franco-British offensive on the Somme started on June 24 and the actual battle began on July 1. On July 11 the Germans made yet another attack on Verdun—from Vaux to Souville. It crumpled up on the slopes of Souville, the principal objective. On Aug. 3 the French retook Thiaumont and Fleury on Aug. 4. The Germans regained Thiaumont on the 8th. Throughout the whole month there was local fighting. The last German attack on Sept. 3 also failed. The battle of Verdun, properly called, had come to an end. From Feb. 21 to June 1j the Army at Verdun had seen 66 divisions on its front. Up to July 1 the Germans had used up 433 divisions. It is true that they maintained them on the ground by depots situated a march behind the front and left them fighting till worn out. The French artillery fired 10,300,000 rounds with the field artillery, 1,200,000 rounds of medium and 600,000 rounds of large calibre.

II. THE FRENCH COUNTER-OFFENSIVE

On Sept. 13 M. Poincaré handed to Verdun the cross of the Legion of Honour and Allied decorations. The ceremony took place in the casemates of the citadel. From that moment began a new phase, that of the liberation of Verdun. To a large extent the glory of this feat belongs to Gen. Mangin. Called from the battlefield of Verdun on June 22 he was placed in command of Group D, which then stretched from the Meuse to Fleury and was progressively enlarged right up to the cliffs of the Meuse. On Sept. 17 in a report to Nivelle he set forth reasons for abandoning operations in detail and for seeking to free Verdun by a plan on broad lines.

The first scheme, approved by Nivelle on Sept. 21, dealt only with an advance up to 300 metres north of the farm of Thiaumont. The scheme of the 24th went further and included the fort of Douaumont as far as possible. A third scheme, that of Oct. 9, covered the capture of the fort of Douaumont and perhaps that of the fort of Vaux. A formidable artillery preparation with 650 guns started on Oct. 21. The assault was delivered on Oct. 24 at 11.40 A.M. by three divisions, the 38th on the left, 133rd in the centre, and 74th on the right. The first waves marched under a creeping barrage which progressed according to a set time-table, so that the infantry were as it seemed fastened to a wall of steel. By night Douaumont was taken with 6,000 prisoners. The division on the right had not reached the fort of Vaux which was evacuated by the Germans on Nov. 2, the day before the date fixed for attack by the 63rd Division.

In order to develop this success to the full Gen. Mangin was obliged to restore his ammunition reserves by continued economy. He intended to attack again on Dec. 5 over a front of 10 m. in order to retake at one blow the whole of the former second French line which had been lost on Feb. 24. Artillery preparation started on Nov. 29 with 750 guns. Bad weather intervened. The Germans had been warned and the value of a surprise was lost. In order to upset the plans of the French the Germans made a violent attack on Dec. 6 and captured Hill 304. Fine weather returned on the 9th and Nivelle recommenced the. artillery preparation. On the 15th at 10 AM. the attack was made The German barrage started two minutes too late. The attack had started, four divisions being in line. By night they had retaken the whole of Poivre Hill. The line ran in front of Hill 378, stopped 20 metres south of the farm at Chambrettes, then turned south across Bois d'Hardaumont and la Vauche up to the outwork at Bezonvaux. The French captured 11j guns and 9,000 prisoners, This, known as the battle of Louvemont, was completed on the 18th by the recapture of Chambrettes. The spring passed in organising the area conquered and preparing for the final battle.

The Final Battle.—In the summer of 1917 Pétain formulated plans for a series of limited offensives for the purposes of raising the spirit of the army and decided on an operation on the northern front of Verdun on both banks having as objectives Mort Homme on the left and Samogneux and Beaumont on the right. The attack planned by Pétain was delivered on Aug. 20 after six days' heavy artillery preparation. The XIII. and XVI. Army Corps attacked on the left bank, the XV. and XXII. on the right bank, 16 divisions in all being engaged. Mort Homme was captured on the 20th, Hill 304 on the 24th. On the right bank Hill 344 was taken on the 20th, Samogneux on the 21st. More than 10,000 prisoners were taken. Beaumont alone remained in German hands. This was the final battle of Verdun.

VERE, the name of an English family extolled by Macaulay as "the longest and most illustrious line of nobles that England has seen." is derived from the village of Ver. near Bayeux. Its founder. Xlberic de Ver (d. 1088) held lands in Middlesex, Suffolk, Cambridgeshire and Essex (Castle Hedinpham) ; the family badge, the blue boar, is still found in Essex churches. In 113j his son, Aubrey de Vere (d. 1141) was made great chamberlain of England; this office was confirmed to Aubrey, his successor, by the empress Maud, who also made him 1st earl of Oxford (1142). Robert (1170?–1221), who became 3rd earl of Oxford in 1214. was one of the 25 executors of Magna Carta. The 5th earl. also Robert (1240–1296), sided with Simon de Montfort, and temporarily forfeited his earldom and offices. John. the 7th earl (1313–1360), fought at Crécy and Poitiers. His grandson Robert, the 9th earl of Oxford (*q.v.*), Richard II's favourite, was attainted in 1388. His uncle. Aubrey, was restored in 1393, and was succeeded by his elder son Richard (d. 1417) who fought at Xgincourt. The 12th earl. John. was beheaded (1462). with his eldest son, as a Lancastrian; their death was avenged by his younger son, John (*q.v.*). On the death of the 14th earl. also John, without issue, in 1526, the family baronies fell to his sisters, but the earldom passed to his cousin John (d. 1540?), grandfather through his younger son of "the fighting Veres" (*see* below). His eldest son John became 16th earl and regained the great chamberlainship which had been lost in 1526.

Edward, 17th earl of Oxford (*q.v.*), squandered much of the family wealth. When his son Henry (1593–1625) died at the siege of Breda, the titles were disputed between Robert Vere, his second cousin. who became earl, and Lord Willoughby d'Eresby, con of his aunt. who became great chamberlain. The 19th earl n-as killed at the battle of Maastricht (1632) and his son. Aubrey (1626–1703), became 20th and last earl. A royalist during the Great Rebellion, he received various rewards at the Restoration, including command of a regiment of horse called after him "the Oxford Blues" (later "the Blues"; the royal horse guard). His only surviving descendant. Diana. married the 1st duke of St. Albans (*q.v.*), and their descendants received the barony of Vere in 17jo.

VERE, SIR FRANCIS (1560–1609), English soldier, was a nephew of the 16th earl of Oxford. He served under the earl of Leicester and Lord Willoughby in the Netherlands. 1585–89, distinguishing himself at Sluys (1587) and Gergen-op-Zoom (1588).

As sergeant major general he commanded the English forces in the field there after Willoughby's resignation and played a prominent part in the campaigns of Maurice of Nassau, which finally drove the Spaniards out of the provinces east of the Ijsel river (1590–95). In 1596 he served as lieutenant general in the Cadiz expedition and in 1597 took part in the islands' voyage.

Returning to the Yetherlands. Sir Frances helped to take Turnhout and then to negotiate a new treaty with the Dutch in 1598. He was made general of all the English forces there and governor of the Brielle. Wounded helping Maurice to win the victory of Nieuport in 1600, he then conducted the defense of Ostend (1601–02). He returned to England on the conclusion of peace with Spain in 1603 but went on another mission to the Dutch in 1605–06. He died in London on Xug. 28. 1609.

SIR HORACE VERE, BARON VERE OF TILBURY (1565–1635), Sir Francis' younger brother, served under him in the Netherlands (1590–94), took part in the Cadiz expedition and fought at Nieuport and Ostend. On Sir Francis's retirement, Sir Horace was left as senior English colonel in the Netherlands. From 1609 till 1616 he was governor of the Brielle and in 1610 he was present at the siege of Julich.

After the outbreak of the Thirty Years' War he commanded the expedition to assist the elector palatine in 1620 but, ill-supported and with inadequate forces: he was compelled to capitulate at Mannheim in 1622. Returning to Dutch service in 1623, he made a brilliant but unsuccessful attempt to relieve Breda (1625) and took a leading part in the sieges of 's Hertogenbosch (1629) and Maastricht (1632). He was created Baron Vere of Tilbury in 1625. Sir Horace died on May 2, 1635. (R. B. WM.)

VERESCHAGIN (VERESTCHAGIN), **VASILI VASILIEVICH** (1842–1904), Russian painter, noted for his war canvases, was born at Cherepovets on Oct. 26. 1842. He attended the St. Petersburg academy and studied under Jean Léon Gérôme in Paris. Devoting his life to travel, he acquired subjects for canvases from on-the-spot impressions in the Caucasus. in the Crimea, along the Danube and in Turkistan with the Russian army. In the Balkans during the Russo-Turkish War (at which time he was wounded), Vereschagin was provided with the themes of some famous war pictures. He also painted in Syria and in Palestine and between 1885 and 1903 traveled in Russia, the United States and Japan. He died at Port Arthur on April 13. 1904, during the Russo-Japanese War. while aboard the flagship of Xdm. Stepan Makárov. Vereschagin's historical scenes of the invasion of Russia by Napoleon in 1812 enjoyed extraordinary popularity: innumerable reproductions of them were made. The pacifist and humanitarian movement of the time made use of a painting of his representing a pyramid of skulls ("The Apotheosis of War"), and of the series of three representing a Roman execution ("The Crucifixion"). sepoys blown from the guns in India and the execution of Nihilists in St. Petersburg. His works are to be found in Moscow at the Tretyakor gallery and in Leningrad at the Russian museum. His memoirs were published in English in 1887.

See Eugen Zabel, *Weretschagin* (1900); A. Lebediev, *Vereschaguin* (1959). (M N B.)

VERGA, GIOVANNI (1840–1922), Italian novelist. was born at Catania. Sicily. In 1865 he published *Stovia di una peccatrice* and *I Carbonari della montagna,* but his literary reputation was established by his *Eva* and *Stovia di una capinera* (1869). Other novels followed. *Malavoglia* (1881) and *Maestro Don Gesualdo* (1889. Eng. trans. 1923). His finest work. however. is seen in his short stories and sketches of Sicilian peasantry. *Medda* (1874) and *Vita dei campi* (1880); and his *Cavalleria Rusticana* (Eng. trans. of this and other stories 1928) acquired new popularity from its dramatization and from Alascagni's opera on this subject. Verga and Fogazzaro between them may be said to have faithfully chronicled the inner and popular life of southern and northern Italy. D. H. Lawrence translated many of Verga's works into English. Verga died in Rome on Jan. 27, 1922.

VERGENNES, CHARLES GRAVIER, COMTE DE (1717–1787), French statesman. was born at Dijon on Dec. 20, 1717. He entered the diplomatic service under his uncle M. de Chavigny, at Lisbon. He became ambassador at Constantinople and then in Sweden, where he assisted Gustavus III in the revolution of 1772.

With the accession of Louis XVI Vergennes became foreign minister. His general policy was one of friendly relations with Austria, combined with the limitation of Joseph II's ambitious designs; the protection of Turkey; and opposition at all points to England. His hatred of England led to his support of the American States in the War of Independence. Vergennes sought to secure the armed neutrality of the Northern Powers eventually carried out by Catherine II; he ceded to the demands of Beaumarchais that France should secretly provide the Americans with arms and volunteers. In 1777 he informed the American commissioners that France was willing to form an offensive and defensive alliance with the new Republic. In 1781 he became chief of the council of finance.

Vergennes died on Feb. 13, 1787.

VERGIL: *see* VIRGIL.

VERGNIAUD, PIERRE VICTURNIEN (1753–1793), French orator and revolutionist, was born on May 31. 1753, at Limoges. The son of a merchant of that town, he attracted the notice of Turgot, who was then intendant of Limousin. Turgot secured his admission to the college of Plessis in Paris. where he received a solid classical education. On leaving college he became secretary to Duputy. president of the parlement of Bordeaux. Vergniaud was thereafter called to the bar (1782). In 1789 Vergniaud was elected a member of the general council of the department of the Gironde. He was chosen a representative of the Gironde to the National Legislative assembly in August 1791.

The extremists used the passions which his oratory awakened for objects he did not foresee. This happened even with his first assembly speech, on the *émigrés.* His proposal was mainly that a treble annual contribution should be levied on their property; but the assembly confiscated their goods and decreed their deaths. Step by step he was led on to palliate violence and crime, to the excesses of which his eyes were only opened by the massacres of September, and which ultimately overwhelmed the party of Girondists which he led. It has always been held against him that on March 19. 1792, when the perpetrators of the massacre of Xvignon had been introduced to the assembly by Collot d'Herbois. Vergniaud spoke indulgently of their deeds and lent the authority of his voice to their amnesty. In language sometimes turgid. but nearly always of pure and powerful eloquence, he worked at the theme of the *émigrés,* as it developed into that of the counterrevolution; and the project of an address to the French people which he presented to the assembly on Dec. 27, 1791, shook the heart of France; and, especially by his call to arms on Jan. 18, he shaped the policy which culminated in the declaration of war against the king of Bohemia and Hungary on April 20. This policy in foreign affairs, which he pursued through the winter and spring of 1791–92, he combined with another—that of fanning the suspicions of the people against the monarchy, which he identified with the counterrevolution, and of forcing on a change of ministry. On March 10. Vergniaud delivered a powerful oration in which he denounced the intrigues of the court and uttered his famous apostrophe to the Tuileries: "In ancient times fear and terror have often issued from that famous palace; let them re-enter it to-day in the name of the law!" The speech overthrew De Lessart, whose accusation was decreed; and Roland, the nominee of the Girondists, entered the ministry. The Mountain used Vergniaud, whose lofty and serene ideas they applauded and travestied in action. Then came the ribt of June 20, and the invasion of the Tuileries. He rushed among the crowd. but was powerless to quell the tumult. But his speeches breathe the very spirit of the storm, and they were perhaps the greatest single factor in the development of the events of the time. On Xug. 10, the Tuileries was stormed, and the royal family took refuge in the assembly. Vergniaud presided. To the request of the king for protection he replied in dignified and respectful language.

On Dec. 31, 1792, Vergniaud delivered one of his greatest orations. He pictured the consequences of that temper of vengeance which animated the Parisian mob and was fatally controlling the policy of the Convention, and the prostration which would ensue to

France after even a successful struggle with a European coalition. which would spring up after the murder of the king. On Jan. 16, 1793. the vote began to be taken in the Convention upon the punishment of the king. On the 17th Vergniaud announced the fatal result of the voting. When the institution of a revolutionary tribunal was proposed. Vergniaud vehemently opposed the project. and on March 10 had to go into hiding. On March 13 Vergniaud boldly exposed the conspiracy in the Convention. The antagonism caused by such an attitude had reached a significant point n-hen on April 10 Robespierre himself laid his accusation before the Convention. Vergniaud made a brilliant reply, and the attack for the moment failed. On June 2, 1793, things came to a head. The Convention nas surrounded with an armed mob. who clamoured for the "twenty-two." The decree of accusation was voted, and the Girondists were proscribed. Vergniaud was offered a safe retreat. He accepted it only for a day. and then returned to his own dwelling. In July he was imprisoned in La Force. The Girondists appeared before the Revolutionary tribunal on Oct. 2i. On Oct. 31, 1793, they went to the scaffold. Vergniaud was executed last. (Sh.; X.)

VERHAEREN, ÉMILE (1855–1916), the most outstanding Belgian poet to write in French, whose work, by its strength and range. will stand comparison with that of Victor Hugo. Born May 21. 1855. at Saint Amand lez-Puers. a village on the river Scheldt. he was educated at Brussels and Ghent and from 1875 to 1881 studied law at Louvain. where he became acquainted with Max Waller. the founder of the influential periodical *La Jeune Belgique* (1881). Articled to the barrister and patron of the arts Edmond Picard, he became one of the group in Brussels who brought about the literary and artistic renaissance of the 1890s. His first hook—a collection of violently naturalistic poems (*Les Flamandes,* 1883) created a sensation. It was followed by short stories and a monograph on Joseph Heymans, but *Les Moines* (1886). *Les Soirs* (1887; Eng. trans., 1918), *Les Débâcles* (1888), *Les Flambeaux noirs* (1890), *Au Bord de la route* (1891; later retitled *Les Bords de la route*), *Les Apparus dans mes chemins* (1891) and *Les Campagnes hallucinées* (1893) confirmed his reputation as a lyrical poet. In 1895 growing concern for social problems inspired *Les Villages illusoires* and *Les Villes tentaculaires. Lcs Heures claires* (1896; Eng. trans.. *The Sunlit Hours*, 1917), an avowal of his love for his wife. led to the series of his major works. among which the most outstanding are *Les Visages de la Vie* (1899), *Les Forces tumultueuses* (1902). *Les Tendresses premières* (1903, the first part of the five-part *Toute la Flandre*), *La Multiple Splendeur* (1906), *Les Rythmes souverains* (1910) and *Les Blés mouvants* (1912). During this period he also published books on art. two further collections of personal lyrics to his wife and plays—*Les Aubes* (1898; Eng. trans. by A. Symons), *Le Cloître* (1900: Eng. trans.! 1915), *Philippe II* (1901; Eng. trans.. 1916) and *Hélène de Sparte* (1912; Eng. trans.. 1916).

Deeply stirred by the outbreak of war in 1913. Verhaeren took refuge in France where he addressed meetings in many towns to rally support for his country. On Nov. 27. 1916. after one such meeting. he was accidentally killed when catching a train at Rouen station.

The qualities most characteristic of Verhaeren's considerable poetic output — more than 30 collections — are vigour and breadth of vision. His unusually strong lyrical gift, his burning vitality and originality, by which he transforms the technique of the Symbolists into a highly personal instrument, are expressed in a fresh. unpolished language of great power and flexibility. His three main themes are Flanders, human energy (expressed in the desire for progress. for the brotherhood of man and for the emancipation of the working classes) and his tender, understanding love ior his wife. It is perhaps in the poems celebrating the quiet joys of hearth and home that he is most moving. More generally popular are those glorifying Flanders — the greatness of its painters and the pleasures of its common people—and those which exalt. the triumph of human intelligence over matter and praise the epic beauty of the industrial age, in which man's servitude has power to bring about his liberation.

His plays in verse. although often showing dramatic power and poetic inspiration. are marred by an over-rhetorical style and are rarely produced. His works on art show sympathy with those painters — Remhrandt. Rubens, James Ensor and others — who depict life at its boldest, most picturesque and most colourful.

VERLAINE, PAUL (1844–1896), French lyric poet, was born at Metz on March 30. 1844. He was the son of one of Napoleon's soldiers. who had become a captain of engineers. Verlaine was educated in Paris. and became clerk in an insurance company. He was a member of the Parnassian circle. with Catulle Mendès, Sully Prudhomme, François Coppée and the rest. His first volume of poems, the *Poèmes saturniens* (1866), was written under I'arnassian influences, from which the *fêtes galantes* (1869), as of a Watteau of poetry, began a delicate escape; and in *La Bonne Chanson* (1870) the defection was still more marked. He married in 1870 Mlle. Mautet. During the Commune he was involved with the authorities for having sheltered his friends, and was obliged to leave France. In 1871 the strange young poet Jean Arthur Rimbaud came somewhat troublingly into his life: into which drink had already brought a lasting disturbance.

With Rimbaud, he wandered over France, Belgium, England, until a pistol shot. fortunately ill-aimed, against his companion brought upon him two years of imprisonment at Mons. Solitude, confinement and thought converted a pagan into a Catholic, without, however, rooting out what was most human in the pagan; and after many years' silence he published *Sagesse* (1881), a collection of religious poems, which, for humble and passionate conviction, as well as originality oi poetic beauty, must be ranked with the finest religious poems ever written. *Romances sans paroles,* composed during the intervals of wandering. appeared in 1874, and shows us Verlaine at his most perfect moment of artistic self-possession. before he has quite found what is deepest in himself. He returned to France in 1875. His wife had obtained a divorce from him. and Verlaine made another short stay in England, teaching French. After about two years' absence Verlaine was again in France. He taught in more than one school and even tried farming. The death of his mother dissolved the ties that hound him to "respectable" society. During the rest of his life he lived in poverty. often in hospital, but always with the heedless and unconquerable cheerfulness oi a child. After a long obscurity, famous only in the Latin Quarter, among the cafés where he spent so much of his days and nights. he enjoyed at last a European celebrity. In 1894 he paid another visit to England, this time as a distinguished poet. He died in Paris on Jan. 8, 1896.

His 18 volumes of verse, which also include *Jadis et naguère* (1884), *Amour* (1888), *Parallèlement* (1889). *Bonheur* (1891) vary greatly in quality (A Sy.)

His *Oeuvres complètes* were published in 1899 and in later editions and his *Oeuvres posthumes* in 1903 His *Poètes maudits* (1888) and *Confessions* (1895) thron light on his own life -1 bibliography of Verlaine. with an' account of the existing portraits of him, is included in the *Poètes d'aujourd'hui* (11th ed.. 1905) of A. van Bever and P. Léautaud. *See* monographs by C. Morice (1888), M. Dullaert (1896), B. E. Delahaye (1919), and H. Nicolson (1921); E. Lepelletier. *Paul Verlaine, sa vie, son oeuvre* (1907, Eng. trans. 1909); F. A. Cazals and G. Le Rouge, *Les Derniers Jours de P. Verlaine* (1923); L. Eckhoff, P. *Verlaine og Symbolismen* (1923).

VERMEER; JAN (Jan van der Meer van Delft) (1632–167j). Dutch painter, mainly of interior genre subjects. was baptized in Delft on Oct. 31. 1632. He lived all his life in Delft; among the sparse records of him in the city archives are those of his marriage in April 1653 and his enrollment in December of that year in the Guild of St. Luke. of which he was chairman in 1662–63 and 1670–71. He was buried in the Old church on Dec. 15, 1675. Further records are mainly concerned with his financial troubles. He died insolvent. owing a large sum to his mother-in-law. and his widow had to part with two of his paintings in settlement of a baker's bill. Thus Vermeer's life and character are mysteries of which the only key is his mysterious art. It seems that he looked principally to his activities as an art dealer to support his large family. and not to the sale of his own pictures. This helps to explain the rarity of his works (only 35 unquestionably authentic paintings survive) and his independence of popular taste and values. He worked slowly, with a refinement of perception that goes far beyond that of any contemporary, for his analysis of

"SERVANT POURING MILK" BY JAN VERMEER. IN THE RIJKSMUSEUM. AMSTERDAM

optical experience had no parallel until the age of photography in the second half of the 19th century, when — significantly — his unique qualities were first understood and prized.

Vermeer's pictures yield little evidence as to his early training, though the example of Carel Fabritius was not lost on him. Only two of the paintings are dated — the "Procuress" (1656, Dresden) and the "Astronomer" (1668, in a French collection) — but these provide some basis for studying his development. The paintings of his early years tend to be larger in scale than the late works, and include experiments with historical subjects and landscape as well as genre. Among the earliest of all are "Christ in the House of Mary and hfartha" (Edinburgh) and "Diana With Her Companions" (The Hague), together with the "Procuress" and the "Sleeping Girl" (New York). These are fairly fluent and "painterly" in execution. though in places the pigment is applied quite thickly in successive layers. A noticeable impasto persists in the works attributable to his next phase, about the years 1658–62. These include the "Servant Pouring Milk" (Amsterdam), "Soldier and Laughing Girl" (New York). the "Street in Delft" (Amsterdam) and the celebrated "View of Delft" (The Hague). From this point onward Vermeer confined himself to genre subjects and portrait heads of a genre character, the one exception being the comparatively unsuccessful "Allegory of the New Testament" (New York). His technique became progressively more polished and refined, until in the late works the individual brush strokes can.seldom be distinguished. Characteristic genre pictures are the "Concert" (Boston), the "Music Lesson" (Buckingham palace), "Woman With a Jug" (Kew York), "Artist in His Studio" (Vienna) and "Lady Standing at the Virginals" (National gallery, London). Among the genre portraits one may mention the "Girl's Head" (The Hague) and also the "Girl With a Flute" and the "Girl in a Red Hat" (both in Washington. D.C.).

Vermeer had an unerring grasp of pictorial design and a pure and individual colour sense. But the most extraordinary element in his art is the unswerving objectivity with which he recorded the eye's experience of the soft play of daylight on varied shapes and surfaces. achieving thus a timelessness and truth both satisfying and deeply moving. (R. E. W. J.)

VERMES, the term used by Linnaeus to include all invertebrates except insects. Restricted and modified by subsequent authors, and considered by many to be obsolete, it remains in use in the 20th century. as in Kiikenthal and Krumbach's *Handbuch* der *Zoologie,* and comprises a heterogenous assemblage of segmented and unsegmented wormlike animals. (G. E. P.)

VERMICELLI: see MACARONI.

VERMICULITE is a hydrated magnesium silicate resembling mica in appearance and in basic atomic structure (see MICA). It differs from mica in that when heated the mineral flakes expand (exfoliate) perpendicular to the plane of easy cleavage as a result of very rapid loss of water of hydration. The swelling may amount to 20 or more times the original thickness. The exfoliated product is extremely light (density as low as 0.09) and is used for lightweight concrete and plaster, for thermal and acoustic insulation, as a packing medium, a soil conditioner, a starting medium for seeds and for many other purposes. The mineral is formed in various ways, for example, in the soil by the weathering of micas, and by hydrothermal processes (*i.e.,* action of water vapour at elevated temperatures and pressures). Large deposits occur in the United States (in Montana. the Carolinas and other states), in South Africa. Australia, U.S.S.R., Brazil and elsewhere. Annual production in the U.S. increased from about 20.000 tons in 1940 to about 200.000 tons by the second half of the 20th century. Annual production in South Africa ranged from about 30.000 tons to 62.000 tons.

VERMIGLI, PIETRO MARTIRE, known as PETER MARTYR (1500–1562), was born at Florence, Italy, on May 8, 1500, and educated in the Augustinian cloister at Fiesole and the convent of St. John of Verdara near Padua. graduating D.D. about 1527. About 1533 he read Bucer's commentaries on the Gospels and the Psalms and also Zwingli's De *vera* et *falsa religione;* and his Biblical studies began to affect his views. He was accused of erroneous doctrine, and the Spanish viceroy of Naples prohibited his preaching. The prohibition was removed on appeal to Rome, but in 1541 Vermigli was transferred to Lucca. where he again tell under suspicion. Summoned to appear before a chapter of his order at Genoa, he fled in 1542 to Pisa and thence to another Italian reformer. Bernardino Ochino, at Florence.

Ochino escaped to Geneva, and Vermigli to Zürich and finally to Strasbourg, where, with Bucer's support, he was appointed professor of theology. Vermigli and Ochino were invited to England by Cranmer in 1547, and given a pension by the government. In 1548 Vermigli was appointed regius proicssor of divinity at Osiord. In 1549 he took part in a great disputation on the Eucharist.

He had abandoned Luther's doctrine of consubstantiation and adopted the doctrine of a Real Presence conditioned by the faith of the recipient. This was similar to the view now held by Cranmer and Ridley, but it is difficult to prove that Vermigli had any great influence in the modifications of the Book of Common Prayer made in 1552. He was consulted on the question, but his recommendations seem hardly distinguishable from those of Bucer, the effect of which is itself disputable. He was appointed one of the commissioners for the reiorm of the canon law. On Mary's accession \-ermigli returned to Strasbourg, and was reappointed professor of theology, but his increased alienation from Lutheranism drove him to Switzerland. Re was professor of Hebrew at Zurich, where he died on Nov. 12. 1562.

VERMONT, the "Green Mountain state," named from the evergreen forests of its mountains (Fr. *verd mont,* "green mountain"), is a North Atlantic state of the United States, the most northwesterly of the so-called New England group. It is bounded north by the Canadian province of Quebec; east by New Hampshire. from which the Connecticut river separates it: south by Xlassachusetts; and west by New York,' from which Lake Champlain separates it for about two-thirds of the distance. In length. north and south, the state measures 157.6 mi.: its approximate width at the northern border is 90 mi.. at the southern border 40 mi. Its total area is 9,609 sq.mi., and of this 333 sq.mi. is water surface; among the states it ranks 43rd in size. Vermont was admitted to the union in 1791 as the 14th state. Its flap consists of a blue field on which is represented the state coat of arms. The state floner is the red clover (*Trifolium pratense*), the tree the sugar maple. the bird the hermit thrush (*Hylocichla guttata*), the motto "Freedom and Unity." The capital is at Montpelier.

PHYSICAL GEOGRAPHY

Physical Features. — The mean elevation of the state (which lies between the extremes of approximately latitude 42° 44' and 45° 1' N. and longitude 71° 33' and 73° 26' W.) above the sea is approximately 1.000 ft., extremes varying from 95 it.. the surface of Lake Champlain, to 4.393 ft. at the summit of Mt. Mansfield, 25 mi. E. of that lake. Mountain ranges break much of the general surface, the most prominent of these being the Green mountains extending nearly north and south through the state a little west of the middle (see GREEN MOUNTAINS). The crest line is generally more than 2,000 ft. high, with the following summits: hft. Mansfield, 4,393 ft.; Killington peak, 4,241 ft.; Mt. Ellen, 4,135 ft.; Camel's Hump (Lyon Couchant), 4,083 ft.; and Mt. Abraham. 4,049 ft. More than 900 peaks rise above 2,000 ft. The eastern border has several cone-shaped mountain masses. Mt. Ascutney rises abruptly from the floor of the Connecticut valley to a height of 3,144 ft. In the north, Jay peak and Burke and Belvidere mountains are prominent. In the south and near the western border the Taconic mountains nearly parallel the Green mountains and extend northward toward the centre of the state.

Lake Champlain (*q.v.*) lies in a beautiful valley between the Green and Adirondack mountains. About two-thirds of its area is in Vermont; and the northern portion contains numerous islands, several of which are large. Connected with each other and with the mainland by bridges, the islands constitute a county in themselves. On the northern border of the state is Lake Memphremagog, with a rugged prominence known as Owl's Head on its west border. Jay peak farther back and farming country eastward. The lake is 27 mi. long and from 1 to 4 mi. wide, two-thirds of it lying in Canada.

There are many other lakes and ponds. Willoughby lake, one of the largest, lies in a narrow valley between Mt. Pisgah and Mt. Hoar (Hor) in the north. Lakes Morey and Fairlee are in the Connecticut river valley. Lake Dunmore in the towns of Salisbury and Leicester, Lake Bomoseen in Castleton and Hubbardton, Lake St. Catherine in Wells and Poultney, and Lake Hortonia in Sudbury, all west of the Green mountains, are noted for their scenery.

The Winooski and Lamoille rivers rise in the east, cut deeply into the Green mountains on their westward course. and empty into Lake Champlain. The hlissisquoi also rises east of the range but flows just north of the Canadian boundary, then back into Vermont and west to Lake Champlain. The Mettawee, Poultney Otter and La Platte flow generally west and north, also into Lake Champlain The Vermont tributaries to Lake hlemphremagog are the Barton and Black rivers from the south and the Clyde river from the east. Most important of the Vermont tributaries of the Connecticut river (*q.v*) are the Nulhegan, Passumpsic, Wells, Waits, Ompompanoosic, White, Ottauquechee. Black, Williams. Saxtons, West and Deerfield. The southwestern part of the state is drained to the Hudson river by the Batten Kill and Hoosic rivers. Vermont streams are usually swift-flowing and in comparatively narron and scenic valleys. Among the most spectacular cuts are the Williamstown gulf. the Proctorsville gulf in the centre of the state, and Quechee Gorge near Woodstock.

Climate. — The mean annual temperature varies from 40° to 47° F., the eastern part of the state being generally colder than the western, and the centre mountainous part coldest of all. Average annual precipitation over a long period is approximately 37.5 in. Snow often appears in November in the higher altitudes but does not come to stay before December, generally remaining until March. The average snowfall throughout the state is about 90 in. annually, but there is less snow near Lake Champlain and in the southwestern part than in central and eastern Vermont. Spring comes earliest in these sections and in the lower portions of the Connecticut valley.

Soils and Vegetation. — Agricultural classification of Vermont soils shows a division of the land into seven classes: (1) smooth, well-drained, highly productive land suitable for all crops grown in the state (10%); (2) highly productive land nith imperfect drainage. which is smooth and contains no stone (5%); (3) medium productive land but iimited in crop range. smooth. and containing some stone (20%); (4) medium productive land located at elevations allowing a wide range of crops including fruit (15%); (5) smooth to strongly rolling land of relatively low productivity containing varying quantities of stone (15%); (6) strongly rolling land of low productivity, containing stone which interferes somewhat with use of machinery (20%); and (7) steep stony land having little or no agricultural value, which may be used for limited pastureland (15%).

White pine and hemlock are abundant on lower slopes; spruce and fir are common on higher slopes. Among the deciduous trees, the state is especially noted for its sugar maples. Birch and beech grow on the hills, and in the lower areas. oak, elm, hickory, ash, poplar, basswood, willow and butternut are found. Indigenous fruit-bearing trees, shrubs, vines and plants include the plum, cherry, grape, blackberry, raspberry, cranberry and strawberry. More than two-thirds of the land area is covered with forest growth.

Animal Life. — Vermont provides a natural habitat for wild animals, to the delight of hunters and tourists and sometimes to the annoyance of farmers and motorists. Early in the state's history, wolves, panthers, bears and wildcats were abundant. Wolves and panthers have declined in numbers, but bear is today a big game animal and wildcats or bobcats are still found. Muskrat, beaver and red fox abound in Vermont in addition to small game such as squirrels, pheasants and waterfowl.

The wild animal that is taken in greatest numbers by hunters is the white-tailed deer. Prior to 1907 the annual deer kill was less than 1,000. The population of both deer and hunters has increased enormously: in the late 1950s, 150 deer were taken during one special archery season and 10,510 during the regular season.

Parks, Historic Sites and Recreation. — The tourist business, based on the state's beautiful scenery, historic places and facilities for outdoor sports, is one of Vermont's largest income producers.

From November to March, about two dozen ski areas are in operation. Mt. Mansfield in Stowe. Mad River glen in Waitsfield, Sugarbush in Warren, Pico peak near Rutland, Big Bromley in Manchester and Jay peak in the north are among the best known. Other seasons bring many tourists to enjoy fishing and hunting, to occupy cottages on the many lakes, to hike in the mountains or to see the autumn foliage. The state has built numerous roadside picnic areas and access areas to lakes and streams, and has developed 28 state forests and 27 state parks with a total acreage nearing 90,000. Green Mountain National forest, in the main range of the Green mountains, occupies land in 33 towns and comprises a gross area of 580.000 ac.

The Vermont Historic Sites commission has saved or has developed in the public interest some of the many historic places and structures in the state. Among these are the Calvin Coolidge home in the small village of Plymouth; the Bennington battle monument at Old Bennington, commemorating Gen. John Stark's victory over Gen. John Burgoyne on Aug. 16, 1777; the Hubbardton battlefield and museum, on the site of the only Revolutionary battle fought on Vermont soil (July 7, 1777); the Chester A. Arthur birthplace at Fairfield; the Hyde log cabin at Grand Isle, built in 1783 and considered the oldest log cabin in the United States still standing in its original condition; and the Scott covered bridge at Townshend, the longest single span in the state.

HISTORY

Exploration and Settlement. — French explorations first opened up the area now known as Vermont. On July 4, 1609, Samuel de Champlain and two French companions crossed the lake to which he gave his name while traveling with an Algonkin war party into Iroquois country. This is the earliest known visit of white men to the area. For almost a century and a half thereafter, the Champlain valley was French territory. Lake Champlain and the Richelieu river form a great trunk water route between the valley of the St. Lawrence and the area of southern New England and the Hudson valley. Increase of the Iroquois compelled the French to erect a chain of forts to command the approach to Canada from the south; thus Ft. Ste. Anne, built in 1666 on Isle La Motte in Lake Champlain, became the first white settlement. As the English settlements in Massachusetts and adjacent colonies grew stronger. the Indians withdrew into Canada, from which they joined the French in raids upon English settlements. After the second raid upon the Deerfield settlement in Rlassachusetts in 1704, French and Indians took prisoners through the Connecticut, White, Winooski and Champlain valleys to Canada.

'The first permanent English settlement dates from 1724 when Ft. Dummer was erected on the Connecticut river just north of the present Massachusetts border, for the protection of Deerfield and other settlements. Later in the same year a group of Dutch squatters settled in the southwestern corner of Vermont. By mid-18th century. Benning Wentworth, royal governor of New Hampshire, was pushing further settlement. Assuming that the vague limits of his province, like those of Connecticut and Massachusetts, extended westward to a line 20 mi. E. of the Hudson river, he made grants of land between the Connecticut river and Lake Champlain in the region commonly known as the New Hampshire grants. From 1749 to 1764 he provided for 138 towns. New York officials challenged his right to grant these lands, however, and for 14 years ownership of the region was debated. On July 20, 1764, an order of the king in council decided in favour of New York, the governors of which proceeded to issue grants though the debate continued. After the French and Indian War ended, several thousand persons, largely from Connecticut and Massachusetts, purchased lands in the New Hampshire grants, cleared farms, built houses and planted crops. New York left the settlers in the Connecticut river towns relatively alone. though its authority there was recognized nominally for a period. West of the Green mountains, New York titles were successfully defied in defense of New Hampshire titles. In 1770 the New York courts refused to consider the New Hampshire charter as evidence in an ejectment suit concerning property in Shaftsbury. Ethan Allen, in charge of the defense, returned to Bennington where the town voted to protect its rights under Wentworth's charter, by force if necessary. A militia had been formed there in 1764 and subsequently in several other towns. With Ethan Allen as commander, these groups formed an association that came to be known as the Green Mountain Boys, and their resistance continued for many years.

Revolution, Independence and Statehood. — The Green Mountain Boys were soon in conflict with foreigners as well as with neighbours. On May 10, 1775, with the aid of some sympathizers from Rlassachusetts and Connecticut, they captured the Lake Champlain fortress at Ticonderoga in the first aggressive act of Americans in the Revolutionary War. Green mountain settlers continued an active role in the fight for independence. They were among the American forces defeated at Hubbardton, Vt., July 7, 1777, in retreat from Ticonderoga. With New Hampshire and Massachusetts troops under Gen. John Stark, they helped defeat (Aug. 16, 1777) the British detachments attempting to capture American stores at Bennington; this was the beginning of Burgoyne's reverses, which ended in his surrender to Gen. Horatio Gates on Oct. 17, 1777. Green mountain men participated in the invasion of Canada in the autumn of 1777.

Town government appeared in the New Hampshire grants at settlement. 'Town committees of safety emerged after 1770, in the conflicts with New York. In the movement toward statehood in 1776, a general convention mas formed. It held several sessions, ultimately with delegates from the towns on the east as well as the west side of the Green mountains. Ira Allen, Ethan's brother, was among the most active in the movement. During an adjourned session of the general convention on Sept. 27, 1776, a covenant or compact was "made and subscribed by the members." On Jan. 16, 1777, they adopted a declaration of independence, deciding on New Connecticut as the name of the state; in June they abandoned this name. as it had been used elsewhere, and substituted the name Vermont. In July a state constitution was adopted in convention in Windsor. This was the first U.S. state constitution to forbid slavery and to establish manhood suffrage. The convention also appointed a council of safety to govern the state temporarily. with 'Thomas Chittenden as president, Jonas Fay as vice-president and Ira Allen as secretary. Elections were held on March 3, 1778, and the new state government came into existence on March 12, with Chittenden as governor.

Despite external opposition. Vermont continued to function as an independent republic for 14 years. In 1790 New York conceded the independence of Vermont conditional upon the payment of $30.000; New Hampshire and Massachusetts abandoned claims which they had developed. In Jan. 1791 Vermont adopted the U.S. constitution, and on March 4 became the 14th state to enter the union.

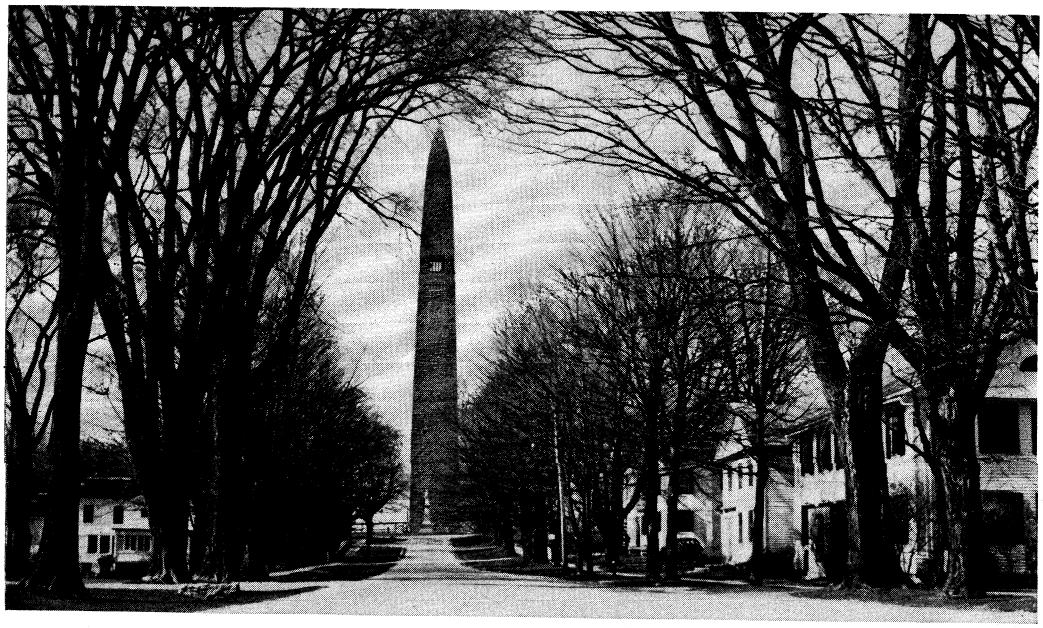
After its declaration of independence, Vermont issued its own land grants and chartered towns. Early historians estimated that about 7,000 people had settled there by 1771. In 1779 the legislature planned that lands were to be in towns six miles square, each including 70 rights or divisions, five of which were reserved, one each for the support of a college, a county grammar school, an English school. the support of preaching and the first settled minister. Settlement was rapid during the latter years of the Revolutionary War, and in 1781 the population was estimated at 30,000.

During the first 30 years the legislature convened successively in the larger towns. Montpelier was chosen as the capital in 1805, and on completion of the first statehouse the legislature met there in 1808. A second statehouse was completed in 1838. The present (third) statehouse was built after the second was nearly destroyed by fire in 1857.

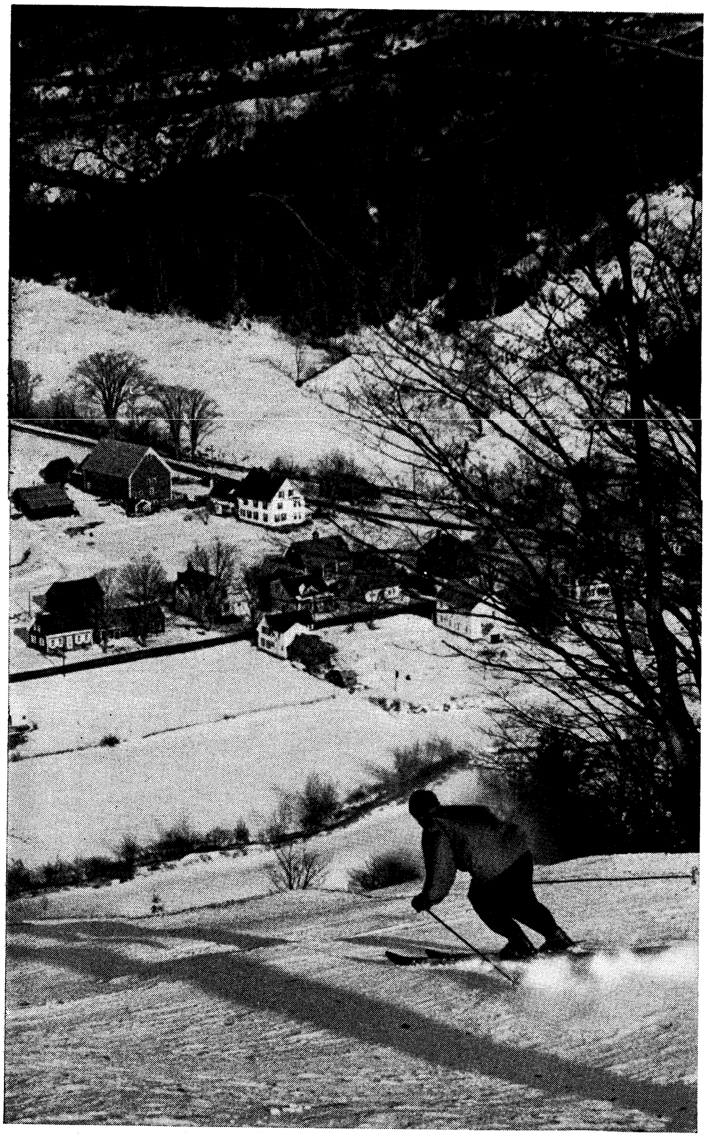
Business activity was stimulated by population growth and by the War of 1812. In that war Vermont troops took part in the battles of Chippewa, Lundy's Lane, Lake Erie and Plattsburg, but the only engagement in the state itself was that in defense of Ft. Cassin at the mouth of Otter creek in 1813. Steady expansion followed the war. Farm produce and cattle were sold south to older markets. The breed of Morgan horses was developed; ultimately these horses became a leading export to all parts of the country. Lumber business expanded along the shores of the Connecticut and Lake Champlain where water transportation mas available. During the winter, sledges took Champlain valley produce to Montreal. Produce from the southwest went to Albany, that from the Connecticut valley to Portsmouth or Boston.

After 1830 many Vermonters joined the westward movement, helping to build many of the northern states of the Mississippi valley. Others went south to the growing industrial centres of Massachusetts and Connecticut. Despite these losses, however, the population increased. Vermont sent to the American Civil War 34.328 men. of whom 5,128 died. On Oct. 19, 1864, a small band of Confederates crossed the frontier from Canada and raided the town of St. Albans, robbing the banks and then escaping back into Canada. In 1870 St. Albans was the headquarters of an attempted Fenian (*q.v.*) invasion of Canada.

Post-Civil War Period. — After the Civil War, the attention of Vermonters returned to domestic affairs. In 1870 the governor's term was increased from one to two years and legislative sessions became biennial, Kinety years later the legislature held an unprecedented adjourned session. A state court reorganization in 1906 relieved the supreme court justices from riding circuit to preside over the 14 county courts, by providing for six superior judges to perform this service. During the late 1800s the expansion in activities of state government increased. The state board of health was organized in 1886, and the office of state highway commissioner was created in 1897. State administration was centralized in Montpelier in 1917, a departmental organization was created in 1923, numerous separate agencies were added during the following three and one-half decades, and in 1960 a general reorganization was ordered by the legislature; this last was highlighted by creation of a department of administration. Central purchasing dates from 1912, a budget system was developed



Battle monument at Old Bennington commemorating Revolutionary War victory of Gen. John Stark's New England troops over detachments of Gen. John Burgoyne's army in 1777



Vermont state house at Montpelier. Constructed of native granite, the capitol was first built in 1836, renovated in 1859. The portico is designed after the Greek temple of Theseus, Athens

VIEWS OF VERMONT

BY COURTESY OF (TOP, CENTRE LEFT. RIGHT) VERMONT DEVELOPMENT COMMISSION: PHOTOGRAPH, (BOTTOM LEFT) JACK J. ZEHRT FROM F.P G during the period 1917 to 1923, and a personnel system following World War II. In 1953 the house of representatives elected its first woman speaker, and in 1954 the people elected the first woman lieutenant governor.

Large numbers of Vermonters served in the armed forces during the 20th century; 642 lost their lives in World War I and 1,233 in World War II. A flood in 1927 was devastating, and a tropical storm that struck the state in 1938 also caused enormous damage. After World War II, the state carried out a comprehensive program of road construction and park development.

In presidential campaigns the state has been Federalist, 1792–1800; Democratic-Republican, 1804–20; Adams-Republican, 1824–28; Anti-Masonic, 1832; Whig, 1836–1852; and Republican since 1856.

GOVERNMENT

Units of government in Vermont include the state, the 14 counties into which the state is divided, the 238 towns and the 8 cities that also occupy most of the area, and certain other districts and areas. Five unorganized towns, five areas called gores, and one called a grant are administered by the state. Within the towns. there are 65 incorporated villages, 54 fire districts, 2 lighting districts and 13 soil conservation districts. Each town also constitutes a school district, and there are 20 specially incorporated school districts, as well.

The people are governed under a constitution first adopted in 1777, which includes a "Declaration of Rights" and a "Plan or Frame of Government." The preamble adopted in 1777 was omitted in 1793. As amended, the "Plan or Frame" provides for the delegation and distribution of powers; legislative, executive and judiciary departments; qualifications of freemen; elections and terms of office; and other basic features of government. The Vermont constitution is the shortest of U.S. state constitutions.

For nearly a hundred years, amendments were effected by constitutional conventions called by successive Csuncils of Censors elected every seven years to perform several specified duties "in order that the freedom of this Commonwealth may be preserved inviolate, forever." The use of councils of censors and conventions mas eliminated in 1870, and under the amending process which dates from that year the senate (established in 1836) may propose amendments, by a two-thirds vote, in every tenth year. If the house concurs in the proposal by majority vote, the proposal is published in the principal newspapers; if both houses approve it by majority votes in the next regular session, the proposal is submitted to the people, and a majority of the popular votes cast is decisive.

Suffrage is possessed by all citizens 21 or more years old who have lived in the state for one year, are "of a quiet and peaceable behavior" and will take the freeman's oath, as follows:

> You solemnly swear (or affirm) that whenever you give your vote or suffrage, touching any matter that concerns the State of Vermont, you will do it as in your conscience you shall judge will most conduce to the best good of the same, as established by the Constitution, without fear or favor of any person.

This practice, through which one becomes a freeman, or full-fledged member of the political community, was used in several of the New England colonies! having been inherited from post-feudal England. The freeman's oath now exists only in Vermont.

Executive. — The executive officers of the state are the governor, lieutenant governor, treasurer, secretary of state and auditor of accounts: as provided in the constitution; and the attorney general, whose office was created by statute. The officers are elected by the freemen for terms of two years. The adjutant general, the sergeant-at-arms and 9 of the 23 trustees of the University of Vermont and State Agricultural college are elected by the joint assembly composed of members of the senate and house. The administrative organization consists of nearly 60 separate agencies. During a two-year term, a governor appoints nearly 100 state officers with senate approval, and more than 200 others. About 40 agencies have regular staffs. Most state positions are covered by a merit system for personnel management.

Legislature. — The Vermont constitution provides for a legislative department consisting of a senate of 30 members (to be apportioned among the counties according to population, with a proviso that each county is to have at least one) and a house of representatives with one member from each town and city (246). Members of both houses are elected biennially. The regular biennial session begins on the first Wednesday after the first Monday of January in odd-numbered years. The governor may call special sessions.

Judiciary. — The supreme court, consisting of one chief justice and four associates, holds five general terms annually at Montpelier and special sessions elsewhere. The justices are elected biennially by the joint assembly, along with six superior judges who preside over the county courts to which they are assigned by the chief superior judge, in rotation. Two assistant judges, elected by the freemen in each county, sit with the assigned superior judge to compose the county court, nhich holds two sessions annually in each county. The superior judge sits alone, as chancellor, to hold chancery court in each county. The governor appoints judges to fill supreme and superior bench vacancies occurring in the interim between legislative sessions. It is the practice of the joint assembly to elect the interim appointees, to re-elect justices and judges and to promote from within the bench.

The general assembly created 20 probate courts in the state, with at least one in each county. Probate judges are elected by the freemen in districts; their salaries differ from district to district and are supplemented by fees. The general assembly also created 17 municipal courts. with at least one in each county. Municipal judges are appointed by the governor, with consent of the senate, and they also are paid varying salaries. supplemented by fees. The jurisdiction of municipal courts is limited. Justices of the peace also may exercise limited jurisdiction.

Local Government. — The organization of county government is relatively spare, consisting of two assistant judges of the county court, who commonly are called side judges and constitute a county board, a state's attorney, a sheriff, a high bailiff, a treasurer and a clerk. Each of the eight cities operates under a special charter enacted as a "municipal act" by the legislature. All towns but one have the traditional town meeting form of local government. A moderator presides over annual and special town meetings in each town, and business is conducted between meetings by selectmen, a clerk and other officers, elected annually. Under legislation adopted in 1959, the town of Brattleboro in 1960 became the first in Vermont to establish the representative, or limited, town meeting form of government.

Finance. — The increase in responsibilities and activities which the state government experienced in the first quarter of the 20th century accelerated during the second quarter and continued into the third. Local governments continued to perform the traditionally local services, although some transfer to the state occurred. A relatively steady increase in state expenditures was a consequence of these developments. The largest shares of expenditures have been for education, highways, social welfare and institutional care.

Traditionally, Vermont borrows only for emergencies; *e.g.,* for support of the Civil War and for flood reconstruction in 1927. This tradition has been modified because of the need of funds for construction of state buildings, highway development and aid to local communities in improving school plants. For several decades major sources of state revenue have been gasoline. liquor, cigarette. income and franchise taxes and sale of nonbusiness licences. Financial grants from the U.S government ha e become an increasingly large source of income, representing 14.5% for the years 1939–42 and about 20% at the end of the 1950s.

POPULATION

The population in Vermont in 1790 was 85.425. In 1830 it was 280.652; in 1870, 330,551: in 1910, 355.956; in 1940, 359.231; in 1950, 377,747; and in 1960, 389,881. The last figure represents an increase of 12.134 or 3.2% over 1950 The population per square mile in 1960 nas 42.0%, compared with 40.7 in 1950 and with 49.6 for the U.S. in 1960.

The urban population in 1960 was 149,921, or 38.5% of the state

*Vermont: Places of 5.000 or More Population (1960 Census)**

Place	Population 1960	1950	1940	1920	1900
Total state	389,881	377,747	359,231	352,428	343,641

*Populations are reported as constituted at date of each census. †Township.

total, compared with 36.4% in 1950 and 34.3% in 1940. The state has no standard metropolitan statistical areas. Rural population in 1960 was 239.960, a decrease of 0.1% from 1950. Of the total rural population, 10.2% was rural nonfarm and 51.4% was rural farm.

The number of occupied dwelling units: or households, in 1960 was approximately 110.732, as compared with 101.000 in 1950. The average per household declined from 3.9 persons in 1940 to 3.5 in 1950 and to 3.4 in 1960. Population distribution by colour and nativity in 1950 was: 92.2% native white; 7.6% foreign-born white; and 0.1% nonwhite, practically all Negro. There were 99.2 males per 100 females in the native white population; 10.5% of the people were 65 years old or over: 52.4% who were 14 years old and over were in the labour force. Of all employed males, 23.8% were in agriculture. 7.0% in construction. 25.5% in manufacturing and 20.4% in transportation and trade.

EDUCATION

Vermont's system of public education extends from the primary grades through several branches of higher education. Numerous private academies, colleges and other institutions increase substantially the educational opportunities. Attendance is compulsory for all children between 7 and 16 years of age.

Public interest in education dates from the earliest years. Vermont was the first state to make constitutional provision for a complete state system (1777), to include town common (primary) schools. a grammar school in each county and a state university. Girls as well as boys have attended the common schools from the beginning. The town of Middlebury established an academy for girls in 1800, and a few years later, Emma Hart (Willard) there opened one of the first private schools for girls in America. The first normal school in America was established in Concord in 1823. The state library dates from 1825. The legislature first created a state board of commissioners of common schools in 1827.

Public Schools.—In the towns and cities, locally elected boards maintain public schools under the provisions of state law. A superintendent serves each of the larger communities; smaller communities are grouped into superintendency unions. The state department of education, headed by a board appointed by the governor and a board-appointed commissioner. provides services in teacher training and certification, curriculum development and planning of school buildings. as well as programs in vocational education, vocational rehabilitation. health education, preservation of skills in arts and crafts and education of the mentally retarded and physically handicapped.

The state apportions large sums annually among the local school districts for current expenses and grants small special-purpose sums for standardization, special education of handicapped children, tuition of war orphans, vocational education and visual education equipment. During the mid 20th-century it distributed several million dollars for aid in school construction.

Every town and city (except nine local units that have contracts with their neighbours) maintains at least one elementary school. The secondary level includes more than 80 public high schools and 25 academies. Business schools are located in Rutland, Montpelier and Bennington. Commerce is a principal subject in Champlain college, a junior college in Burlington, and is among the offerings of other colleges. Vermont college in Montpelier and Green Mountain college in Poultney are junior colleges. The state maintains an agricultural and technical institute at Randolph. Nursing education is offered in several hospitals not connected with the universities and colleges.

Higher Education.—The University of Vermont and State Agricultural college, in Burlington, is the first U.S. institution founded by state legislative action to offer instruction at the university level. The university mas chartered in 1791; Vermont Agricultural college was chartered under the Morrill act in 1864. and the two were combined in 1865. The university is governed by a board of trustees of 23 members. It includes colleges of arts and sciences, agriculture, medicine, technology, and education and nursing, a graduate college, a school of dental hygiene and a summer session and adult education division. The university libraries comprise a collection of more than 200.000 volumes, including a collection of Vermontiana and supplemented by U.S. government depository documents.

Teacher training courses are offered in the state teachers' colleges in Castleton, Johnson and Lyndon Center, for elementary and junior high school teaching. Some secondary teacher training is available in private colleges.

Several private institutions also have excellent standing. Middlebury college in Middlebury, chartered in 1800, is a liberal arts college; its world-famous English and foreign language schools provide graduate instruction on the Middlebury campus, at its Bread Loaf Mountain campus and abroad. Norwich university, founded in 1819 and located in Northfield, is the nation's oldest private military college, emphasizing several branches of engineering. Bennington college for women (founded 1932) is located in Bennington (*q.v.*). Trinity college for women (Roman Catholic; 1925) is in Burlington, and St. Michael's college for men (Roman Catholic; 1904) in Winooski Park. Three other four-year colleges are Goddard (1863), in Plainfield; Marlboro (1947), in Marlboro; and Windham (1951), in Putney.

HEALTH, WELFARE AND CORRECTIONS

State institutions include the State Prison and House of Correction for men at Windsor; the Women's Reformatory at Rutland, which operates under an interstate agreement: the Weeks school for training and rehabilitation of boys and girls, at Vergennes; a sanatorium for tuberculosis patients at Pittsford; a training school for mentally deficient persons at Brandon; the Kinstead home for children in Montpelier; and several "half-way houses" for mental rehabilitation. The state also assigns patients to the Brattleboro Retreat, well known for care and rehabilitation of the mentally ill.

Providing public health services is largely a state function in Vermont. The state health department carries out preventive programs in cancer and chronic disease control; communicable disease control; child health services, for crippled children. maternal and child health. and guidance; environmental sanitation programs including inspection and licensing and regulation for proper sanitation of schoolhouses and public buildings generally and of public water supply; hospital services, including hospital survey and construction, and inspection and licensing of hospitals, nursing homes and homes for the aged; laboratory services, including chemical and bacteriological examinations of water. milk. foods. drugs, materials and substances helpful in the diagnosis of disease; free distribution of certain vaccines; public health education; keeping and publishing certain statistics; public health nursing, industrial hygiene and public dental health programs.

More than two dozen licensed hospitals and more than 150 nursing homes are located throughout the state. The third quarter of the 20th century witnessed considerable improvement in hospital standards and facilities. The hospitals in the Burlington area are associated with the University of Vermont medical college and form with it a major medical centre for the area.

THE ECONOMY

Agriculture.—Approximately one-half the land area of Vermont is in farm land. The number of farms (about 16.000) is decreasing. but individual units are growing in size (average about

200 ac.) and the output per worker is increasing. Both before and after the American Civil War, sheep raising was a dominant pursuit. but after 1880 it declined rapidly because of competition from the western states and Australia.

A cool climate, irregular topography and inherently fertile soils enable Vermont to produce hay and pasture better than other farm crops. Dairying thus has become the most important agricultural industry. Vermont has a bonding law to protect dairy farmers. Farms producing milk for local consumption are subject to state regulation and inspection. In 1936 the state became a bovine tuberculosis-free area. In 1957 it was the ninth state declared a modified certified brucellosis-free area. Approximately 100 creamery companies operate about 135 dairy plants. The total fluid milk distribution exceeds 1,600,000,000 lb. annually, of which 400,000,000 lb. is converted into other milk products.

A large percentage of farm land is used to produce hay. Other crops include potatoes, corn and northern grains. Poultry raising. beekeeping, apple growing and maple sugaring are important. A new farm crop, birds-foot trefoil, was developed in Vermont.

Mining. — Virtually every section of the state contains mineral deposits: the chief slate deposits are in the Taconic mountains; the Vermont valley between the Taconic and Green mountains contains the world-famous marble deposits; the Green mountains contain talc, marble and other deposits; great granite deposits and the copper mines lie in the Vermont piedmont between the Green mountains and the Connecticut river; asbestos deposits are located in the north.

The first granite quarry was opened in Barre in 1815, and more than 36,000,000 cu ft. have been quarried there since that time. Vermont marble, distinguished for its quality and constituting more than half the fine marble used for monuments in the U.S., is quarried principally at Proctor. Commercial quarrying dates from 1785. Vermont produces 96% of the domestic asbestos supply, serving about 5% of national requirements. Other mineral industries are slate, copper, silver, gold, limestone, talc and China clay.

Manufacturing — While most Vermont manufacturing plants are small, they are noted for quality production and are distributed among more than half of the state's cities and towns. Industries multiplied rapidly in the early 1800s. In St. Johnsbury, the manufacture of knife-edged scales dates from 1830. In Rutland, the making of ball-bearing scales dates from 1856. Inventive men of those and subsequent years laid foundations for the high-grade machine-tool industry that is centred in Windsor and Springfield. Burlington is noted for quality printing and Brattleboro for organs. Other industrial centres include Barre, Bellows Falls, Bennington, Montpelier and St. Albans.

The state's major manufacturing industries include food and kindred products; metalworking; paper and allied products; and mining, quarrying and manufacturing stone and mineral products. Other Vermont products include furniture, textiles, slate, rubber goods, garden tools, paints, hosiery, cereals, dyes, clothespins, roofing, electric equipment and ceramics.

Electrical energy is supplied by private and municipal electric utilities and by electric co-operatives. Much power is generated in plants on the Connecticut, Deerfield and other rivers, and the state's 30-year contract for St. Lawrence power adds 100,000 kw. of power annually.

Transportation and Communication. — Water, rail, motorbus and air services are available for transportation. Opening of the Champlain canal in 1823, connecting the lake with the Hudson river, increased commerce with New York. This waterway extends also through the Richelieu river to the St. Lawrence. Vermont had a period of energetic construction of canals and waterways and also roads and turnpikes; stagecoach lines carried mail and passengers throughout the state. By 1849 the Vermont Central railroad reached Burlington from Windsor and the Rutland reached there from Bellows Falls. Railroad building ceased after 1910, when the mileage was 1,100; by 1950 it had been reduced to 889 and by 1956 to 846. Two lines run north and south along the western and eastern borders, and four cross in a general east and west direction.

After World War I motorbus lines became a principal means of transportation, covering more than 1,000 route miles and reaching many places not served by rail. The trucking business also became extensive. By the late 1950s nearly 4,000 of the 13,800 mi. of road were hard surfaced. Bridges cross the Connecticut river at several points. Bridges cross Lake Champlain at Chimney Point and at East Alburg, under an interstate compact. Five ferry routes also provide lake crossings; those from Charlotte, Burlington and Grand Isle are operated by the oldest steamship company in the U.S. By the late 1950s, the state had 23 airports and airfields, of which 13 were public and 10 limited.

Telephone service is provided through about 90 central offices. Of 15 broadcasting stations, 14 are AM radio and one is television. There are ten daily newspapers.

BIBLIOGRAPHY.—M. D. Gilman, *Vermont Bibliography* (1897) approaches completeness for the period before the date of its publication. For physical description, geology and minerals the many papers in the annual *Reports of the State Geologist* are most valuable. For education *see* G. G. Bush, *History of Education in Vermont* (1900) ; and J. C. Huden, *Development of State School Administration in Vermont* (1943).

R. E. Robinson, *Vermont* (1892) is representative of the more famous of the earlier histories. *History of Vermont* in 4 vol. by Walter H. Crockett was published 1921–23. Edmund Fuller, *Vermont: a History of the Green Mountain State* (1952), is a text for secondary schools. *See* also W. Nutting, *Vermont Beautiful* (1922) ; Champlain Society, *Works of Samuel de Champlain*, 6 vol (1922–25) ; J. B. Wilbur, *Ira Allen, Founder of Vermont*, 2 vol. (1928) ; J. Current statistics on production, employment, industry, etc., may be obtained from the pertinent state departments; the principal figures, together with the current history, are summarized annually in the *Britannica Book of the Year*, American edition. (R. N. B. H.)

VERNE, JULES (1828–1905), French author, was born at Nantes on Feb. 8, 1828. After completing his studies at the Nantes lycée, he went to Paris to study law. About 1848, in conjunction with Michel Carré, he wrote librettos for two operettas, and in 1850 his verse comedy, *Les Pailles rompues*, in which Alexandre Dumas fils had some share, was produced at the Gymnase. For some years his interests alternated between the theatre and the bourse, but some travelers' stories which he wrote for the *Musée des Familles* revealed to him the true direction of his talent — the delineation, viz., of delightfully extravagant voyages and adventures, in which he foresaw, with marvelous vision, the achievements of scientific and mechanical invention of the generation of 1900. Verne was a real pioneer in the wide literary genre of *voyages imaginaires*. His first success was obtained with *Cinq semaines en ballon*, which he wrote for Hetzel's *Magazin d'Éducation* in 1862, and thenceforward, for a quarter of a century, scarcely a year passed in which Hetzel did not publish one or more of his amazing stories. The most successful include: *Voyage au centre de la terre* (1864) ; *De la terre à la lune* (1865) ; *Vingt mille lieues sous les mers* (1869); *Les Anglais au pôle nord* (1870) ; and *Voyage autour du monde en quatre-vingts jours*, which first appeared in *Le Temps* in 1872. The adaptation of this last (produced at the Porte St. Martin theatre on Nov. 8, 1874) and of another excellent tale, *Michael Strogoff* (at the Chbtelet, 1880), both written in conjunction with Adolphe d'Ennery, proved the most acceptable of Verne's dramas.

He died at Amiens on March 24, 1905. The novels of Jules Verne are dreams come true, dreams of submarines, aircraft, television; they look forward, not backward. Therefore they are still the books of youth.

VERNET, the name of a family of eminent French painters.

CLAUDE JOSEPH VERNET (1714–1789), born at Avignon, Aug. 14, 1714, began as painter of decorations at Avignon and Aix. In Rome during 1734–53, he studied landscape, being particularly influenced by Claude Lorrain and Salvator Rosa. The stormy sea and picturesque shores became his own specialty.

His shipwrecks, sunsets and conflagrations reveal an unusually subtle observation of light and atmosphere and won the highest praise of contemporary critics (*e.g.,* Diderot). Back in France, he painted a series of the "Harbours of France" (1753–63, Louvre) at royal command. They are not only among his best works but constitute a remarkable record of 18th-century life. His later work shows a marked decline, the consequence of overproduction. In his Livres de raison he recorded his transactions. He died in Paris on Dec. 3, 1789.

CARLE (ANTOINE CHARLES HORACE) VERNET (1758–1836), the son of Claude, was born on Aug. 14, 1758, at Bordeaux. After insignificant beginnings as a neoclassical history painter ("Triumph of Paulus Aemilius," 1789; New York), and an unhappy stay at Rome (1782–83), he found his true avocation in the field of sporting art, his chief patron being the anglophile duke of Orléans. In temporary eclipse during the Revolution, he became productive again with the revival of luxury during the Directory. His long series of fashionable and often satirical commentaries on contemporary manners and costume were reproduced by the best engravers of the time. Kapoleon made him paint vast battles ("Marengo," 1804; "Morning of Austerlitz"), but Carle's real talent was for intimate genre, and for drawing rather than painting. Under the Restoration he produced innumerable sporting subjects and pioneered in lithography. He died in Paris on Nov. 27, 1836.

HORACE VERNET (1789–1863), the son of Carle, was born in Paris, June 30, 1789. Extremely precocious and facile, he began at an early age a copious production of sentimental and patriotic pictures, eventually becoming one of the most famous and richest artists of the century. His earliest works include fashion engravings which are still esteemed, as are some early portraits and caricatures. Having fought in the last battles of the empire, he made the glorification of the Kapoleonic era his particular specialty as painter and lithographer ("Defense of the Barrière de Clichy," 1820; Louvre).

During the Restoration, his studio was a centre of Bonapartist and Orléanist intrigue, as well as a fashionable meeting place of sportsmen, artists and writers (cf. "My Studio," Louvre). After serving 1829–35 as director of the French Academy in Rome, he was commissioned by Louis Philippe and, later, by Napoleon III to execute vast battle panoramas. particularly in the historical galleries of Versailles. He improvised these with reckless speed, but, for all their verve, they appear to modern eyes dismally trivial. Horace died on Jan. 17, 1863.

ÉMILE CHARLES HIPPOLYTE VERNET-LECOMTE (1821–1900), a grandson of Carle, was a painter of genre and landscape.

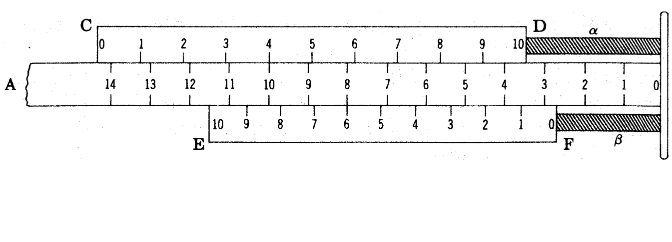
(L. E. A. E.)

VERNIER INSTRUMENT, a measuring device invented by a Frenchman, Pierre Vernier (c. 1580–1637), which enables either linear or angular magnitudes to be read with a degree of accuracy many times greater than is possible with a scale as ordinarily divided and subdivided.

The principle of the vernier is readily understood from the following figure and illustration.

Let AB (see fig.) be the normal scale, *i.e.* a scale graduated according to a standard of length, CD, a scale (placed in contact with AB for convenience) graduated so that 10 divisions equal 11



divisions of the scale AB, and EF a scale placed similarly and graduated so that 10 divisions equal 9 divisions of the scale AB. Consider the combination AB and CD. Obviously each division of CD is $\frac{1}{10}$th greater than the normal scale division. Let a represent a length to be measured, placed so that one end is at the zero of the normal scale and the other end in contact with the end of the vernier CD marked 10. It is noted that graduation 4 of the vernier coincides with a division of the standard, and the determination of the excess of a over 3 scale divisions reduces to the difference of 7 divisions of the normal scale and 6 divisions of the vernier. This is 0·4, since each vernier division equals 1·1 scale divisions. Hence the scale reading of the vernier which coincides with a graduation of the normal scale gives the decimal to be added to the normal scale reading. Now consider the scales AB and EF, and let β be the length to be measured, the scale EF being placed so that the zero end is in contact with an end of β. Obviously each division of EF is $\frac{1}{10}$th less than that of the normal scale.

It is seen that division 6 of the vernier coincides with a normal scale division, and obviously the excess of β over two normal scale divisions equals the difference between 6 normal scale divisions and 6 vernier divisions, *i.e.,* 0·6. Thus again in this case the vernier reading which coincides with a scale reading gives the decimal to be added to the normal scale. The second type of vernier is the one commonly used, and its application to special appliances is quite simple.

VERNIS MARTIN, a brilliant translucent lacquer used for the decoration of furniture and small articles such as snuffboxes and fans. The name derives from that of a family of 18th-century artist-artificers which included four brothers: Guillaume (d. 1749), Simon Étienne (d. 1770), Julien (d. 1782) and Robert (1706–65).

The Martins did not invent the lacquer but perfected its composition and application in their attempts to imitate the far eastern lacquers then-winning great favour in France.

Vernis *Martin* was made in several colours, of which green was perhaps the most characteristic.

See LACQUER.

VERNON, EDWARD (1684–1757), English admiral, was born in Westminster on Nov. 12, 1684, the second son of James Vernon, secretary of state in 1697–1700. Edward Vernon entered the navy in 1707, and saw much active service in various seas. During the long peace under Walpole he sat in the house of commons (1722–34); he clamoured for war with Spain and in 1739 declared he would capture Portobello with a squadron of six ships.

He got the command and the ships and captured Portobello on Nov. 22, with a loss of only seven men. In 1740, with a large squadron. he attacked Cartagena without success and had to retire to Jamaica (this episode is described in Roderick Random, chap. xiii, etc.).

Vernon suffered another reverse at Santiago de Cuba in 1741 and returned home in 1743. He had been elected M.P. for Ipswich in 1741 and continued to sit for that borough. He was in command in the Downs in 1745, but in annoyance at intervention from Whitehall, he published some of his instructions and was struck off the flag list. He died on Oct. 30, 1757, at Nacton, Suffolk.

VERONA, a city and episcopal see of Veneto, Italy, the capital of the province of Verona, situated 194 ft. above sea level in a loop of the Adige (anc. Athesis). Pop. (1957 est.) 198,337 (commune).

Churches.—The Romanesque basilica of S. Zeno (the first bishop of Verona and its patron saint) was remodelled in 1117–38, including the richly sculptured west front and the open *confessio* or crypt, raising the choir high above the nave.

The cathedral, consecrated in 1187. is smaller than S. Zeno, but has a fine west front, rich with Romanesque sculpture (1135); the upper part was added during 1565–1606 It has a noble Romanesque cloister, with two stories of arcading. The campanile by Sammicheli is unfinished. Its baptistery, rebuilt early in the 12th century, is a quite separate building, with nave and apse, forming a church dedicated to S. Giovanni in Fonte. Pope

Lucius III (d. 1185) is buried in the cathedral. The very fine Gothic Dominican church of S. Anastasia (1290–1481) consists of a nave in six bays, aisles, transepts, each with two eastern chapels, and an apse, all vaulted with simple quadripartite brick groining. The vaults are gracefully painted with floreated bands along the ribs and central patterns in each "cell," in rich soft colours on a white plastered ground. There are many fine frescoes in the interior including Pisanello's beautiful painting of St. George. This church also contains fine sculptured tombs of the 14th and 15th centuries. S. Fermo Maggiore was rebuilt in 1313 at a higher level than the earlier church (1065–1138). The roof is magnificent. Delicate patterns cover all the framework of the panelling and fill the panels themselves. Rows of half-figures of saints are painted on blue or gold grounds, forming a scheme of indescribably splendid decoration. The church of Sta. Maria in Organo (1481), with a façade of 1592 from Sammicheli's designs, contains paintings by various Veronese masters, and some fine choir-stalls of 1499 by Fra Giocondo. The church of S. Giorgio di Braida was also designed by Sammicheli.

The strongly fortified castle (Castel Vecchio) built by Cangrande II della Scala (1354) stands on the line of the wall of Theodoric, close by the river. It contains the municipal museum and picture gallery. There are five bridges across the Adige: one, the graceful Ponte di Pietra. rests upon ancient foundations, while the two arches nearest to the left bank are Roman; but it has been frequently restored. Remains of another ancient bridge were found in the river itself behind S. Anastasia. On a steep elevation stands the castle of St. Peter, founded by Theodoric, on the site, perhaps, of the earliest citadel, mostly rebuilt by Gian Galeazzo Visconti in 1393 and dismantled by the French in 1801. The episcopal palace contains the ancient and valuable chapter library. (See GAIUS.) The Piazza delle Erbe (fruit and vegetable market) on the site of the ancient Forum and the Piazza dei Signori, adjoining one another, are surrounded by many fine mediaeval buildings, notably the Palazzo del Comune, with a tower 273 ft. high, while in the northeast corner of the latter piazza is the fine early Renaissance Loggia del Consiglio (1476–93).

Roman Remains. — The Roman remains of Verona surpass those of any other city of northern Italy The most conspicuous of them is the great amphitheatre, a building of the end of the 1st century A.D., which closely resembled the Flavian amphitheatre (Colosseum) in Rome. Its axes measured 505 and 404 ft. Almost the whole of its external arcades, with three tiers of arches, have now disappeared; it was partly thrown down by an earthquake in 1183, and subsequently used to supply building materials. The interior, with seats for about 25,000 people, has been restored. There are also remains of a well-preserved Roman theatre, close to the left bank of the river adjacent to which is the archaeological museum. The Museo Lapidario contains a fine collection of Roman and Etruscan inscriptions and sculpture, begun by Scipione Maffei in 1714.

Veronese Art, Painting and Sculpture. — Painting in Verona may be divided into four periods. (i.) The first is characterized by wall paintings of purely native style, *e.g.*, in SS. Nazaro e Celso (996). (ii.) The Byzantine period lasted during the 12th and 13th centuries. (See S. Zeno for examples.) (iii.) The Giottesque period begins contemporaneously with Altichieri and Giacomo d'Avanzo (second half of the 14th century). These two painters, among the ablest of Giotto's followers, adorned Verona and Padua with very beautiful frescoes, rich in composition, delicate in colour, and remarkable for their highly finished modelling and detail. (iv.) To the fourth period belong several important painters. Pisanello or Vittore Pisano, a charming painter and the greatest medallist of Italy, probably a pupil of Altichieri, has left a beautiful fresco in the church of S. Anastasia, representing St. George and the Princess after the conquest of the Dragon. His only other existing fresco is an Annunciation in S. Fermo Maggiore (See PAINTING.) His pupils include Liberale da Verona, Domenico and Francesco Morone, Girolamo dai Libri (1474–1556), etc. Domenico del Riccio, usually nicknamed Brusasorci (1494–1567), was a prolific painter whose works are very numerous in Verona. Paolo Cagliari or Paul Veronese, and Bonifacio, though natives of Verona, belong rather to the Venetian school.

Verona is specially rich in early examples of decorative sculpture. (i.) The first period is that of northern influence, exemplified in the reliefs which cover the western façades of the church of S. Zeno and the cathedral, dating from the 12th century, and representing both sacred subjects and scenes of war and hunting, mixed with grotesque monsters. Part of the western doors of S. Zeno are early examples of caste bronze reliefs. (ii.) In the 13th century the sculpture lost its vigour, without acquiring grace or refinement, *e.g.*, the font in the cathedral baptistery. (iii.) The next period is that of Florentine influence, exemplified in the magnificently sculptured tombs of the Della Scala lords, those of Cangrande I. (d. 1329), Mastino II. (d. 1351) and (the most elaborate of all) of the fratricide Can Signorio, adorned with statuettes of the virtues, executed during his lifetime (*c.* 1370), by the sculptor Bonino da Campione. (iv.) In the 15th century Florence influenced Verona by way of Venice.

Architecture. — The architecture of Verona, like its sculpture, passed through Lombard, Florentine and Venetian stages. The early Renaissance developed into very exceptional beauty, mainly through the genius of Fra Giocondo (1435–1514), a native of Verona, who was at first a friar in the monastery of S. Maria in Organo. He rose to great celebrity as an architect, and designed many graceful and richly sculptured buildings in Venice, Rome and even in France; he used classical forms with great taste and skill, and with much of the freedom of the older mediaeval architects, and was specially remarkable for his rich and delicate sculptured decorations. Another of the leading architects of the next stage of the Renaissance was the Veronese Michele Sammicheli (1484–1559), a great military engineer, and designer of an immense number of magnificent palaces in Verona, among which the most outstanding are the Bevilacqua, Canossa and Pompei palaces.

History. — The ancient Verona was a town of the Cenomani, a Gaulish tribe, whose chief town was Brixia. It became a Latin colony in 89 B.C. Inscriptions testify to its importance, indicating that it was the headquarters of the collectors of the 5% inheritance tax under the Empire in Italy beyond the Po. Its territory stretched as far as Hostilia on the Padus (Po), 30 m. to the south. It lay on the road between Mediolanum and Aquileia, while here diverged to the north the roads over the Brenner. It was the birthplace of the poet Catullus. In A.D. 69 it became the headquarters of the legions which were siding with Vespasian. It was defended by a river along two-thirds of its circumference. The existing remains of walls and gates date from the period between the 3rd of April and the 4th of December of the year 265. A very handsome triumphal arch, now called the Porta de' Borsari, was restored in this year by Gallienus and became one of the city gates. The same was the case with the Porta dei Leoni, on the east of the city, and with a third arch, the Arco dei Gavi, demolished in 1805. The emperor Constantine, while advancing towards Rome from Gaul, besieged and took Verona (312); it was here, too, that Odoacer was defeated (499) by Theodoric the Goth, Dietrich von Bern—*i.e.*, Verona—of German legends, who built a castle at Verona and frequently resided there.

In the middle ages Verona gradually grew in size and importance. Alboin, the Lombard king, captured it in 568, and it was one of the chief residences of the Lombard and later of the Frankish monarchs; and though. like other cities of northern Italy, it suffered much during the Guelph and Ghibelline struggles, it rose to a foremost position both from the political and the artistic point of view under its various rulers of the Scaliger or Della Scala family. The first prominent member of this family and founder of his dynasty was Mastino I della Scala, who ruled over the city from 1260 till his death in 1277. Verona had previously fallen under Ezzelino da Romano (1227–59). Alberto della Scala (d. 1301) was succeeded by his eldest son, Bartolomeo, who was confirmed as ruler of Verona by the popular vote, and died in 1304. It was in his time that Romeo and Juliet are said to have lived. Alboino, the second son, succeeded his brother, and died in 1311, when the youngest son of Alberto, Can Grande, who since 1308 had been joint lord of Verona with his brother, succeeded to the undivided power. Can Grande (Francesco delln Scala, d. 1329) was the best and most illustrious of his line, and is specially famous as the hospitable patron of Dante (*q.v.*). In 1387 Gian Galeazzo Visconti, duke of Milan, became by conquest lord of Verona. Soon after his death the city fell by treacherous means into the hands of Francesco II. di Carrara, lord of Padua. In 1404–05 Verona, together with Padua, was finally conquered by Venice, and remained subject to the Venetians till the overthrow of the republic in 1797 by Napoleon, who in the same year, after the treaty of Campo Formio, ceded it to the Austrians with the rest of Venetia. They fortified it strongly in 1814, and with Peschiera, Mantua and Legnago it formed part of the famous quadrilateral which until 1866 was the chief support of their rule in Italy. The town was greatly damaged by a flood in 1882. During World War II Verona suffered considerable damage from bombings; in most cases, historic landmarks were later reconstructed. (J. H. Mi.; T. A.; X.)

VERONA, CONGRESS OF, the last of the series of international conferences or congresses based on the principle enunciated in article six of the treaty of Paris of Nov. 20, 1815 (see EUROPE. History).

It met at Verona on Oct. 20, 1822. The emperor Alexander I of Russia was present in person. There were also present Count Nesselrode, the Russian minister of foreign affairs; Prince Metternich, representing Austria; Prince Hardenberg and Count Bernstorff, representing Prussia; Duc de Montmorency and Vicomte de Chateaubriand, representing France; and the duke of Wellington, representing Great Britain in place of Lord Londonderry (Castlereagh), who died on the eve of his leaving for Verona.

In the instructions drawn up by Londonderry for his own guidance, which had been handed to Wellington by Canning without alteration, was clearly defined the attitude of Great Britain toward the three questions which it was supposed would be discussed: the Turkish question (Greek insurrection); the question of intervention in favour of the royal power in Spain together with that of the revolted colonies; and the Italian question.

As regards the last, it was laid down that Great Britain could not charge itself with any superintendence of a system in which it had merely acquiesced, and the duty of the British minister would be merely to keep himself informed and to see that nothing was done "inconsistent with the European system and the treaties." To make this attitude quite clear, Wellington was not to hand in his credentials until this question had been disposed of In the Spanish question Wellington was to give voice to the opposition of Great Britain to the principle of intervention.

In the Turkish question, he was to suggest the eventual necessity for recognizing the belligerent rights of the Greeks and, in the event of concerted intervention, to be careful not to commit Great Britain beyond the limits of good offices. The immediate problems arising out of the Turkish question had been settled between the emperor Alexander and Metternich at the preliminary conferences held at Vienna in September, and at Verona the only question raised was that of the proposed French intervention in Spain.

The discussion was opened by three questions which were formally propounded by Montmorency: (1) Would the Allies withdraw their ministers from Madrid in the event of France's being compelled to do so? (2) In case of war, under what form and by what acts would the powers give France their moral support, so as to give to its action the force of the alliance and inspire a salutary fear in the revolutionaries of all countries? (3) What material aid would the powers give, if asked by France to intervene, under restrictions which it would declare and they would recognize?

The reply of Alexander, who expressed his surprise at the desire of France to keep the question "wholly French," was to offer to march 150,000 Russians through Germany to Piedmont. where they could be held ready to act against the Jacobins whether in Spain or France. This solution appealed to Metternich and Montmorency as little as to Wellington; but although they were united in opposing it, four days of "confidential communications" revealed a fundamental difference of opinion between the representative of Great Britain and those of the continental powers on the main point in issue.

Wellington, who had been instructed to express the uncompromising opposition of Great Britain to the whole principle of intervention, refused to accept Metternich's suggestion that the powers should address a common note to the Spanish government in support of the action of the government of France.

Finally, Metternich proposed that the Allies should "hold a common language, but in separate notes, though uniform in their principles, and objects." This solution was adopted by the continental powers; and Wellington, in accordance with his instructions, took no part in the conferences that followed. On Oct. 30 the powers handed in their formal replies to the French.

Russia, Austria and Prussia would act as France should in respect of their ministers in Spain and would give to France every countenance and assistance it might require, the details "being reserved to be specified in a treaty." Wellington. on the other hand, replied on behalf of Great Britain that "having no knowledge of the cause of dispute, and not being able to form a judgment upon a hypothetical case, he could give no answer to any of the questions."

Thus was proclaimed the open breach of Great Britain with the principles and policy of the Great Alliance. (W. A. P.)

VERONESE, PAOLO (PAOLO CAGLIARI or CALIARI) (1528–1588), a major painter in Venice and the Veneto after 1550, was known after his birthplace, Verona. Paolo's father had come to Verona from Lake Lugano to pursue the family trade of stonecutting, and the young Paolo was at first apprenticed in this trade. He showed so marked an interest in painting, however, that in his 14th year he was apprenticed to his uncle and future father-in-law, Antonio Badile, a minor painter. From him the young Paolo derived. in addition to a sound basic painting technique, a Veronese passion for paintings in which people and architecture were integrated, a tradition ultimately traceable to the late medieval painter Altichiero.

Paolo was influenced in Verona by two other local masters, Paolo Farinato and Brusasorci; from the latter he derived a characteristic attitude about the use of colour and application of paint. Vasari states that he was, in addition, a pupil of Giovanni Caroto, who was an architect as well as a painter, but this seems improbable, as little or no resemblance can be discovered in the styles of the two men. He was influenced by the Mannerist painters Francesco Primaticcio and Parmigianino, and by Raphael himself, whose "Sistine Madonna" was in Vicenza and "Madonna of the Pearl" (from Raphael's studio) was in Mantua. The young Paolo copied the latter work. Added to these major influences were the minor ones of Lorenzo Lotto, Girolamo Romanino, Moretto, Titian and even Diirer whose prints Paolo is said to have studied. Though

ALINARI

DETAIL FROM "THE DISCIPLES AT EMMAUS" BY PAOLO VERONESE. IN THE LOUVRE, PARIS these influences may be traced by the discerning eye, Paolo arrived, early in his career, at a mature and essentially unchanging style.

The hallmarks of Paolo's style are: an amplitude of form and an academic correctness of drawing of a sort always ignored by Titian; a generally blond tonality with an emphasis upon clear and cool colours, which give the impression of lightness in spite of their real sombreness; an interest in two-dimensional patterns (both in the structure of the paintings and in the objects portrayed); a clarity of architectural rendering with a concomitant clarity of relationship between the space and the objects in the space; and a gently noble type of personage as his typical subject. These characteristics appear in such early works as the decorations for the Villa Soranzo of 1551 and the "Faith" (S. Liberale, Castelfranco). In these earliest works Paolo struck a protorococo note nhich anticipated Tiepolo by more than a century and a half. In 1553 he executed the "Temptation of St. Anthony" (Caen) for Ercole Cardinal Gonzaga for the cathedral at Mantua; this work shows an amazing accomplishment in crowding ample forms into a small area and a virtuosity which later became more subtly expressed.

By 1554 Paolo had received a commission for decorations in the hall of the council of ten for the doge's palace, Venice, and by 1555 he was permanently established in that city. The "Jupiter Striking His Thunderbolts" (Louvre) shows his development of the illusionism of Giulio Romano and Andrea Mantegna, whom he knew in Mantua, into a form which anticipates the great baroque ceiling designs of the 17th century. His principal early altarpiece, done for the Giustianini family for S. Francesco della Vigna, is a variation on the plan of Titian's Pesaro altarpiece. In slightly later works done for S. Sebastiano and SS. Giovanni e Paolo, Venice, his hesitancy disappears, and his thorough assimilation of the grand manner in composition becomes evident. The monastic establishment of S. Sebastiano in Venice was in his career what the Scuola di S. Rocco was in Tintoretto's, and by 1556 he had begun his major decorations for this establishment. of which his uncle uas prior. In 1556 he received a commission for three allegorical *tondi* for the Marcian library. Venice, and his work done in competition with others is clearly the best.

C. Ridolfi states that Paolo went to Rome in 1j60 in the company of the Venetian ambassador to the Holy See, but this has been doubted. At any rate, there is a sudden maturity and consolidation visible in his work after this date. His frescoed decorations for the Villa Barbaro at Maser, near Asolo, built by Andrea Palladio with sculptural ornament by Alessandro Vittoria. crowned that lovely villa and made it one of the supreme examples of interior decoration in the world. Not only are there ample compositions of gods at play. but there are also homely genre bits, such as the *trompe-l'oeuil* detail of the door opened by a servant with a dog at his feet. An implied confirmation of the Roman visit may be seen in the landscape details which seem to reflect examples of Roman wall painting uhich by 1560 were being uncovered in Rome. The technique is the purest fresco method of water colour on wet plaster, and not even Nicolas Poussin in the 17th century. Hubert Robert in the 18th or Jean Baptiste Corot in the 19th was able to achieve more glowingly luminous atmospheric effects than Paolo achieved from meagre earth colours with a few touches of lapis blue added.

In the late 1560s Paolo painted the "Madonna of the Cuccina Family" (Dresden), one of his mature masterpieces. In the left third. the Virgin. Child. St. Jerome. St. John the Baptist and an angel are isolated; to the right. the Cuccina family kneels in adoration, presented by the allegorical figure of Faith, who is dressed in a radiant nhite. Paolo gives a cogent series of portraits of the family seen in dramatic relationship to one another, and he adds the homely detail of the youngest Cuccina child shyly gripping the column as he peers out at the beholder. At the extreme right the façade of the family palazzo is visible in the distance. All of Paolo's virtues appear in this picture: his poetry, his uncanny knack for the just accent in design, his noble amplitude of concept, his soft and glowing colour and lovely surfaces and his quiet insistence on veristic detail.

In 1562 Paolo received the commission for "The Marriage at Cana" for the refectory of S. Giorgio Maggiore in Venice. This picture was installed in 1563 and completed magnificently the vista formed by Palladio's architecture. The picture was carted off to France during the revolutionary wars and after the peace settlement in 1815 the French used its colossal size as a pretext for not restoring it to Italy; they consistently maintained this excuse, and the picture is still in the Louvre.

In 1566 Paolo executed another monumental work, this time for his own former parish church at Verona, and in 1572 a "Feast of St. Gregory" for Monte Berico, Vicenza. In 1573 he painted for SS. Giovanni e Paolo. Venice. "The Feast in Levi's House" (now in the Accademia. Venice), which work he had to justify before the council of the Holy Office. This body recommended that Paolo make some changes in the interest of historical propriety, after Paolo had explained that his usual practice was to put into his pictures those elements he thought looked well; the changes he made in the work seem slight enough in the light of the Holy Office's instructions.

After 1577 he began more works for the doge's palace, of which the most important is the "Apotheosis of Venice," a complicated, monumental design in which a great horde of elegant Venetians is set between and in front of a colossal pair of columns seen in sharply receding perspective. The design befits its principal ceiling position, and the work seemed to be the most brilliant of a long series still to come. but Paolo contracted a fever and after a few days of illness died April 19, 1588. His brother and sons had him buried in S Sebastiano Venice, where a bust was placed above his grave. The firm was continued in business for a number of years by these men who, with his nephew, signed their works *Heredes Paoli* ("Paul's heirs").

Paolo's work represents the hedonistic best of the Venetian Renaissance in its last phase. With his emphasis on softly used colour and elegant forms, he was not only continuing an old Venetian tradition but also was pointing a way for the future which was to be reaffirmed not only by Tiepolo but also by Francesco Guardi.

Important examples of his work include: the "Family of Darius Before Alexander" (London); the early "Presentation," the "Epiphany." "The Marriage at Cana." the "Via Dolorosa," the "Resurrection" and the late "Christ and the Centurion" (all in Dresden); the "Lady" (Dublin); the "Lady and Girl" (Baltimore); "Mars and Venus" (Edinburgh); the four "Allegories" and the "Vision of St. Helena" (London); the "Susannah." the "Venus and Adonis," the "Christ Among the Doctors," the "Magdalen" and the "Youth Betneen Virtue and Vice" (all in Madrid); the "Rest on the Flight" (Sarasota, Fla.) and "Mars and Venus" (New York).

VERONICA, SAINT, was according to legend a pious woman of Jerusalem who, moved with pity by the spectacle of Jesus carrying His cross to Golgotha. gave Him her kerchief in order that He might nipe the drops of agony from His brow. He accepted the offering, and after using the napkin handed it back to her with the image of His face miraculously impressed upon it.

This. however, is not the primitive form of the legend, which close examination shows to be derived from a story related by Eusebius in *Historia Ecclesiastica* (vii. 18). He tells how, at Caesearea Philippi, lived the woman whom Christ healed of a hemorrhage (Matt. ix. 20). At the door of her house stood, on one side, a statue of a woman in an attitude of supplication and, on the other side, a statue of a man stretching forth his hand to the woman. It was said that the male figure represented Christ and that the group had been set up in recognition of the miraculous cure.

Legend was not long in providing the woman of the Gospel with a name. In the west she was identified with Martha of Bethany; in the east she was called Berenike. or Beronike. the name appearing in as early a work as the *Acts of Pilate,* the most ancient form of which goes back to the 4th century.

Toward the 6th century the legend of the woman with the hemorrhage became merged in the legend of Pilate, as is shown in the writings known in the middle ages as *Cura sanitatis Tzberii* and *Vindicta Salvatoris.* According to the former of these accounts Veronica caused a portrait of the Saviour to be painted. The emperor Tiberius, when sick, commanded the woman to bring the portrait to him, worshiped Christ and was cured. The legend continued to gather accretions, and a miraculous origin came to be assigned to the image. According to the legends in France, Veronica was married to Zaccheus, who had been converted by Christ, and went with him to Quiercy, where he became a hermit. She then joined Martial in his apostolic preaching. In the Bordeaux district, Veronica is said to have brought relics of the Virgin to Sonlac, where she died and was buried. In the 12th century the image began to be identified with one at Rome, and in the popular speech the image too was called Veronica. St. Veronica's feast is kept on July 12.

VERPLANCK, GULIAN CROMMELIN (1786–1870), U.S. writer and politician, was born Aug. 6, 1786, in New York city. Graduated from Columbia college in 1801, he was admitted to the bar in 1807. In 1811 he was involved in the Columbia college commencement riot, and his long antagonism to DeWitt Clinton resulted from the trial that followed. Verplanck was a member of the New York assembly (1820–23), of the U.S. house of representatives (1825–33) and of the New York senate (1837–41). He was professor of the evidences of revealed religion and moral science in the General Theological seminary of the Episcopal Church. He died May 18, 1870, in New York city.

Besides published addresses, political pamphlets and contributions to magazines, Verplanck's principal writings are *The Bucktail Bards* (1819); *Essays on the Nature and Uses of the Various Evidences of Revealed Religion* (1824); *An Essay on the Doctrine of Contracts* (1825); *The Talisnzan* (1827; 1828; 1829), an annual on which he collaborated with William Cullen Bryant and Robert C. Sands; *Discourses and Addresses on Subjects of American History, Arts, and Literature* (1833); *The Advantages and Dangers of the American Scholar* (1836); and *Shakespeare's Plays: With His Life,* 3 vol. (1847), the best edition of Shakespeare produced in the United States to that time. (S. K. Hy.)

VERRES, GAIUS (*c.* 120–43 B.C.), Roman magistrate, notorious for his misgovernment of Sicily. It is not known to what gens he belonged. He at first supported Marius but soon went over to Sulla, nho gave him land at Beneventum and secured him against punishment for embezzlement. In 80, Verres was legate in Asia on the staff of Cn. Cornelius Dolabella, governor of Cilicia. The governor and his subordinate plundered in concert, till in 78 Dolabella had to stand his trial at Rome and was convicted, mainly on the evidence of Verres, who thus secured a pardon for himself. In 74, by a lavish use of bribes, Verres secured the city praetorship and as a creature of Sulla abused his authority to further the political ends of his party. He was then sent as governor to Sicily, the richest of the Roman provinces.

The people were for the most part prosperous and contented, but under Verres the island experienced more misery and desolation than during the time of the first Punic or the recent servile wars. The corngrowers and the revenue collectors were ruined by taxation and the canceling of contracts; temples and private houses were robbed of their works of art; and the rights of Roman citizens were disregarded. Verres returned to Rome in 70, and in the same year, at the request of the Sicilians, Cicero prosecuted him. Verres was defended by the most eminent of Roman advocates, Q. Hortensius. The court was composed exclusively of senators, some of whom might have been his personal friends. But the presiding judge, M. Acilius Glabrio, was not corruptible. Verres tried to get the trial postponed till 69 when his friend Metellus nould be the presiding judge, but in August Cicero opened the case.

The effect of the first brief speech was so overwhelming that Hortensius refused to reply and recommended his client to leave the country. He went to Massilia and lived there till 43, when he was proscribed by Antony.

VERRI, PIETRO, CONTE (1728–1797), Italian political economist and gifted man of letters who devoted his life to the reform of public administration and the spread of useful knowledge, was born at Milan on Dec. 12, 1728. After serving as a captain in the Seven Years' War (1759), he became the moving spirit in an "enlightened" group of young Milanese intellectuals called the *Società dei Pugni* (1761) and contributed some 38 articles to their periodical, of which he was director, known as *Il Caffè* (1764–66. "Il tempio dell'ignoranza." "La coltivazione del lino," "Pensieri sullo spirito della letteratura d'Italia"). Verri later wrote treatises on economic and philosophical matters (*Sulle leggi vincolanti il commercio dei grani,* 1769; *Sull'economia politica,* 1771; and *Discorso sull'indole del piacere e del dolore,* 1773). His other works include *Osservazioni sulla tortura* (1777), a highly esteemed *Storia di Milano,* 2 vol. (1783–98) and a correspondence (1766–97) with his brother which provides a vibrant document of contemporary Italian life. Verri died at Milan on June 28. 1797.

Valeri (1947). *See* also E. Bouvy, *Le comte P. Verri* (1889); A Ottolini, P. *Verri e i suoi tempi* (1921); N. Valeri. *Pietro Verri* (1937); C. Rosso, *L'illuminismo francese e P Verri* (1956).

His brother, CONTE ALESSANDRO VERRI (1741–1816), Italian novelist of preromantic sensibility, was born at Milan on Nov. 9, 1741, and died at Rome on Sept. 23, 1816. As a young man he collaborated in the production of *Il Caffè;* in 1767, after visiting France. England and Germany, he settled in Rome where he wrote among other works the *Avventure di Saffo* (1780), the *Vita di Erostrato* (1793; published 1815) and the *Notti ronzane al sepolcro degli Scipioni* (1792–1804), a sequence of imaginary conversations between the shades of the ancient Romans, mournful in tone and influenced by the *Night Thoughts* of Edward Young.

VERRILL, ADDISON EMERY (1839–1926), U.S. zoologist and naturalist, a specialist in the study of marine invertebrates. was born in Greenwood, Me., Feb. 9, 1839. He graduated from Harvard and attended Yale. and from 1860 to 1864 worked as assistant to Louis Agassiz (*q.v.*). In the latter year he was named professor of zoology at Yale. In 1865 Verrill became curator of the Peabody zoological museum at Yale and in 1868 nonresident professor of comparative anatomy and entomology at the University of Wisconsin, Madison. In 1870 he became instructor in geology at the Sheffield scientific school, Yale, and was elected to the National Academy of Sciences in 1872. From 1871 to 1887 he was in charge of scientific explorations by the U.S. Commission of Fish and Fisheries. In that capacity he was responsible for important technical improvements in the equipment used for the collection of marine specimens. His investigations of marine invertebrates took him along both coasts of North America, as well as to South and Central America and Hawaii. He found and described many hundreds of previously undiscovered specimens and made a valuable collection for the Peabody museum. Verrill died at Santa Barbara, Calif., on Dec. 10, 1926.

Of his more than 300 papers, many have become standard references, particularly his *Report on the Invertebrate Animals* of *Vineyard Sound and Adjacent Waters* (1873) and his monographs on the coelenterates of the Canadian arctic. He was also the author of a number of works on the Bermuda Islands.

VERRIO, ANTONIO (1639–1707), Italian painter, was born at Lecce, in the Neapolitan province of Terra di Otranto. In 1660 at Naples he executed a large fresco work "Christ Healing the Sick," for the Jesuit college. He subsequently went to France nhere at Toulouse he painted an altarpiece for the Carmelites. He was invited to England by Charles II and employed in the decorating of Windsor castle. Little of his work is extant. He was a rapid painter, fertile in invention and best at covering large surfaces in decorative frescoes. Charles II named him "master gardener," gave him a lodge in Hyde Park and paid him lavishly. He was employed by James II on Cardinal Wolsey's tombhouse. He painted James and several of his courtiers in the hospital at Christ Church, London, and also executed a number of decorative frescoes at St. Bartholomew's hospital. He was later employed by Lord Exeter at Burleigh and painted the large staircase at Hampton court for King William. He was very successful but his work was often criticized by his contemporaries for gaudy colours, bad drawing and, senseless composition. He died at Hampton Court on June 17, 1707.

VERRIUS FLACCUS, MARCUS (fl. late 1st century B.C.), a Roman freedman who became a learned scholar and grammarian and the most famous teacher of his day. He introduced the principle of competition among his pupils and awarded old books, beautiful or rare, as prizes. Augustus entrusted the education of his two grandsons to him and thenceforward his school was in the imperial house on the Palatine. He died at an advanced age during the reign of Tiberius. His works are lost. He is known to have written *fasti* (*q.v.*, a type of calendar), which were set up at Praeneste, where in fact *fasti* have been found which have been accepted as his, though some scholars have held that these Praeneste *fasti* were excerpted by Verrius Flaccus from an otherwise unknown work on *fasti*. A work of his, which was much used, was his *De verborum significatu,* a large lexicon which was the first of its kind and a storehouse of antiquarian learning in which Latin authors were quoted extensively. Some idea of its value is obtainable from what remains of the abridgement made by Festus (*q.v.*) in the 2nd or 3rd century and from the abridgement of that made by Paulus Diaconus in the 8th century.

BIBLIOGRAPHY.—The *fasti* found at Praeneste were ed. by T. Mommsen, in *Corpus inscriptionum Latinarum,* vol. 1, *pt.* 1, *pp* 230–239 (1861). For fragments of Verrius Flaccus *see* G Funaioli (ed.), *Granzmaticae Romanae fragmenta,* vol. 1, *pp.* 509–532, "Teubner Series" (1907). *See* also Pauly-Wissowa, *Real-Encyclopadie der classischen Altertumswissenschaft,* 2nd series, vol. 16, col. 1636–45 (1958).

VERROCCHIO, ANDREA DEL (1435–1488), Florentine painter and sculptor, properly Andrea di Michele di Francesco Cioni, best known as the author of the Colleoni monument in Venice and as the master of Leonardo da Vinci, was born at Florence in 1435. He was trained initially under a goldsmith Giuliano Verrocchio. As a painter he was perhaps a pupil of Alesso Baldovinetti, and as a sculptor he is traditionally supposed to have worked with Donatello; however, the affinities of his early sculptures are rather with Antonio Rossellino.

Verrocchio's single documented painting, an altarpiece in the cathedral at Pistoia (completed 1486), was executed in large part by his pupil Lorenzo di Credi; its handling is inconsistent with that of a "Baptism of Christ" in the Uffizi gallery, Florence, from S. Salvi, which, from the time of G. Vasari, has been unanimously given to the artist. In the latter picture (painted about 1470–72) one of the two angels and part of the distant landscape were painted by Leonardo da Vinci. Other paintings ascribed to Verrocchio are Madonnas in the Kaiser Friedrich museum, Berlin (two), the Städel institute at Frankfurt, the Metropolitan museum, New York, and the National gallery, London. The few paintings that can be looked upon as autograph works by Verrocchio probably date from before 1475, and it seems that from this time on he dedicated himself in the main to sculpture, in which from the first he manifested the strong personal convictions and the inventive ability that are absent from his paintings.

According to his brother Tommaso, Verrocchio was responsible for an inlaid slab in S. Lorenzo recording the place of burial of Cosimo de' Medici (1467). Before 1469 he also carved the marble lavabo of the old sacristy of the same church. This was followed by his first major commission, the tomb of Piero and Giovanni de' Medici in the old sacristy, completed in 1472. This deeply impressive work is double-sided and consists of a sarcophagus set inside a high arch carved with foliated ornament Composed of a number of different mediums—porphyry in the sarcophagus, green marble in the inscribed medallions in the centre of the sides, marble in the platform and containing arch and bronze in the feet and ornament of the sarcophagus and in the ropework decoration

aith which the arch is filled—the tomb contains no figurated sculpture. In its over-all design, however, its inspired use of colour and its rich bronze ornament, it reveals a creative intelligence of the first rank.

In 1468–69 Verrocchio received payments for a bronze candlestick for the Sala dell'Udienza of the Palazzo della Signoria; this is now in the Rijksmuseum, Amsterdam. Verrocchio's earliest figure sculpture, a small bronze statue of David in the Museo Nazionale, Florence. is undated, but was executed before 1476. A second bronze figure. the "Child With Dolphin," is somewhat later in date. Commissioned about 1480 for the Medici villa of Careggi, this was set up in the 16th century in the position it still occupies in the courtyard of the Palazzo della Signoria (Palazzo Vecchio). This fountain figure has an important place in the history of the freestanding statue, since its spiral design represents a first successful effort to evolve a pose in which all views are of equal significance.

In 1477 it was decided to extend the silver altar in the Florentine baptistery (now in the Museo dell'Opera del Duomo, Florence), and one of the four supplementary scenes, with the "Beheading of the Baptist." was allotted to Verrocchio. This was completed in 1480. On a larger scale Verrocchio emerges at this time as one of the great relief artists of the 15th century. The only autograph Madonna from his hand, a terra-cotta relief of about 1480 from Sta. Maria Nuova, now in the Museo Nazionale, Florence, is treated with a freedom and plasticity that recalls the work of Donatello. In a marble relief of Alexander the Great, in the National Gallery of Art in Washington, these same characteristics are preserved.

When in 1476–77 Verrocchio designed the cenotaph of Niccolo Cardinal Forteguerri for the cathedral at Pistoia, this was also conceived in terms of deep-cut relief. On Verrocchio's death in Venice in 1488 it was still unfinished. Its completion was entrusted initially to Lorenzo di Credi, was subsequently taken over by Giovanni Francesco Rustici (who completed Verrocchio's figure of the cardinal) and by Lorenzo Lotti (who carved the central figure of Charity). After 1753 it uas revised and set up by Gaetano Masoni in its present confused form. Though its effect is now neutralized by changes and additions foreign to Verrocchio's scheme, the Forteguerri monument contains some of the artist's finest marble sculptures.

Verrocchio also practised as a portrait sculptor. This aspect of his work is represented by two marble busts of women, one in the John D. Rockefeller collection, New York, dating from about 1470–75, and the other, the "Lady With the Primroses" in the Museo Nazionale, Florence, from about 1480. Terra-cotta busts of Lorenzo and Giuliano de' Medici are in the National Gallery of Art in Washington, D.C.

Between 1466 and 1483 Verrocchio was also occupied with the important bronze group of "Christ and St. Thomas" commissioned by the *mercanzia* for the tabernacle in which it still stands on the east side of Or San Michele in Florence. This is remarkable for its intellectual elevation and for its technical mastery. In 1479 Verrocchio was commissioned by the Venetian *signoria* to undertake a second major work in bronze, a commemorative statue of the *condottiere* Bartolommeo Colleoni destined for a position near the church of SS. Giovanni e Paolo at Venice. At Verrocchio's death the model was not yet cast, and the work of casting and chasing was entrusted to a Venetian sculptor Alessandro Leopardi. It was erected in 1496. After the Gattamelata monument of Donatello at Padua, Verrocchio's Colleoni monument is the most important equestrian statue of the Renaissance. Contrived with great technical assurance and modeled with remarkable power and sensibility, it forms a fitting climax to Verrocchio's sculptural career.

In the literature of Italian art Verrocchio is presented in something less than his true stature, and his surviving works leave little doubt that, after Donatello, he was the most original and forceful Florentine sculptor of the 15th century.

VERSAILLES, a town of northern France, capital of the *département* of Seine-et-Oise, 12 mi. W.S.W. of Paris, with which it is connected by rail and streetcar. Pop. (1954) 72,038. Versailles owes its existence to the palace built by Louis XIV. It stands 460 ft. above the sea, and the fresh healthful air and nearness to the capital attract many residents. The three avenues of St. Cloud, Paris and Sceaux converge in the Place d'Armes. Between them stand the former stables of the palace, later occupied by the artillery and engineers. To the south lies the quarter of Satory the oldest part of Versailles, with the Cathedral of St. Louis, and to the north the new quarter. with the church of Notre Dame.

The Palace.—To the west of the Place d'Armes a gilded iron gate and a stone balustrade mark off the great court of the palace. In this court stand statues of Richelieu, Condé, Du Guesclin and other famous Frenchmen. At the highest point there is an equestrian statue in bronze of Louis XIV. To the right and left of this stretch the long wings of the palace, while behind extend the Cour Royale and beyond it the smaller Cour de Marbre, to the north, south and west of which rise the central buildings. To the north the Chapel court and to the south the Princes court, with vaulted passages leading to the gardens, separate the side from the central buildings. The palace chapel (1696–1710), the roof of which can be seen from afar rising above the rest of the building, was the last important work of J. Hardouin-Mansart.

The north wing contains galleries and halls of historical pictures and sculptures, and other great apartments, the most famous of which historically is the theatre built under Louis XV where the banquet to the Gardes du Corps was held, the toasts at which provoked riots that drove Louis XVI from Versailles. Here the national assembly met from March 10, 1871, till the proclamation of the constitution in 1875, and the senate from March 8, 1876, till the return of the two chambers to Paris in 1879. The central buildings include the former dauphin's apartments and many others on the ground floor and fine staterooms on the first floor with the great Galerie des Glaces (Hall of Mirrors) (1678) overlooking the park. The Hall of Hercules was till 1710 the upper half of the old chapel famed for its associations with Bossuet, Massillon and Bourdaloue. The queen's apartments and the rooms of Louis XIV are on this floor. The Oeil de Boeuf, named from its oval window, was the anteroom where the courtiers waited till the king rose. It leads to the bedroom which Louis XIV used from 1701 and in which he died and which Louis XV occupied from 1722 to 1738. In the south wing of the palace, on the ground floor, is the gallery of the Republic and the first empire. In the south wing is also the room where the chamber of deputies met from 1876 till 1879, and where the congress later sat to revise the constitution voted at Versailles in 1875 and to elect the president of the republic. The first floor is almost entirely occupied by the Battle gallery. In the window openings are the names of soldiers killed while fighting for France, with the names of the battles in which they fell, and there are more than 80 busts of princes, admirals, constables, marshals and celebrated warriors who met a similar death. Another room contains exhibits connected with the events of 1830 and the accession of Louis Philippe.

The Gardens.—The gardens of Versailles were planned by André Le Nôtre. The ground falls away on every side from a terrace adorned with ornamental basins, statues and bronze groups. Westward from the palace extends a broad avenue, planted with large trees, and having along its centre the grass of the Tapis Vert; it is continued by the Grand canal, 200 ft. wide and 1 mi. long. On the south of the terrace two splendid staircases lead past the Orangerie to the Swiss lake, beyond which is the wood of Satory. On the north an avenue, with 22 groups of three children, each group holding a marble basin from which a jet of water rises, slopes gently down to the basin of Neptune, remarkable for its fine sculptures and abundant water.

The Orangerie (built in 1685 by Mansart) is the finest piece of architecture at Versailles; the central gallery is 508 ft. long and 42 ft. wide, and each of the side galleries is 375 ft. long. There are 1,200 orange trees, one of which is said to date from 1421, and 300 other kinds of trees.

The alleys of the parks are ornamented with statues, vases and regularly cut yews, and bordered by hedges surrounding the shrubberies. Under Louis XIV the Grand canal was covered with Venetian gondolas and other boats. Around the Tapis Vert are numerous groves, the most remarkable being the Ballroom or Rockery. with a waterfall; the Queen's shrubbery, the scene of the intrigue of the diamond necklace; that of the Colonnade, the King's shrubbery, the Grove of Apollo. and the basin of Enceladus.

Among the chief attractions of Versailles are the fountains and waterworks made by Louis XIV in imitation of those he had seen at Fouquet's chbteau of Vaux. Because of the scarcity of water at Versailles, the works at Marly-le-Roi were constructed in order to bring water from the Seine; but part of the supply thus obtained was diverted to the newly erected château of Marly. Vast sums of money were spent and many lives lost in an attempt to bring water from the Eure, but the work was stopped by the war of 1688. At last the waters of the plateau between Versailles and Rambouillet were collected and led by channels (total length 98 mi.) to the gardens, the soil of which covers innumerable pipes, vaults and aqueducts.

The **Trianons.**—Beyond the present park, but within that of Louis XIV, are the two Trianons. The Grand Trianon was originally erected as a retreat for Louis XIV in 1670, but in 1687 Mansart built a new palace on its site. Louis XV, after establishing a botanic garden, made Gabriel build in 1766 the small pavilion of the Petit Trianon. It was a favourite residence of Marie Antoinette, who had a garden laid out in the English style, with rustic villas in which the ladies of the court led a mimic peasant life. The Grand Trianon contains a museum of state carriages, old harness. etc.

The Town.—The church of Notre Dame, built by Mansart, and the Cathedral of St. Louis, built by his grandson, are uninteresting. The celebrated tennis court (Jeu de Paume) is now used as a museum. The palace of the prefecture, built during the second empire, was a residence of the president of the republic from 1871 to 1879. The military hospital formerly accommodated 2.000 people in the service of the palace. A school of horticulture was founded in 1874, attached to an excellent garden, near the Swiss lake.

Versailles is the seat of a bishop, a prefect and a court of assizes and has tribunals of first instance and of commerce, a board of trade arbitrators, a chamber of commerce and a branch of the Bank of France and, among its educational establishments, *lycées* and training colleges for both sexes and a technical school. It is an important garrison town and has a school of military engineering and artillery. Distilling, boot and shoe making and market gardening are carried on.

History.—Louis XIII often hunted in the woods of Versailles, and built a small pavilion at the corner of what is now the rue de la Pompe and the avenue of St. Cloud. In 1627 he entrusted Jacques Lemercier with the plan of a chkteau. In 1661 Louis Levau made some additions which were further developed by him in 1668. In 1678 Mansart took over the work. the Galerie des Glaces, the chapel and the two wings being due to him. In 1682 Louis XIV took up his residence in the chkteau. Till his time the town was represented by a few houses to the south of the present Place d'Armes; but land was given to the lords of the court and new houses sprang up, chiefly in the north quarter. Under Louis XV the parish of St. Louis was formed to the south for the increasing population, and new streets were built to the north on the meadows of Clagny. Under Louis XVI the town extended to the east and received a municipality; in 1802 it gave its name to a bishopric.

In 1783 the armistice preliminary to the treaty of peace between Great Britain and the United States was signed at Versailles. The states-general met here on May 5, 1789, and on June 20 took the solemn oath in the tennis court by which they bound themselves not to separate till they had given France a constitution. Napoleon neglected, and Louis XVIII and Charles X merely kept up. Versailles, but Louis Philippe made great alterations. some of which were later altered back to the original designs, partly with the help of a large gift from the United States. In 1870 and 1871 the town was the headquarters of the German army besieging Paris, and in the Galerie des Glaces William I of Prussia was crowned German emperor in 1871.

After the peace Versailles was the seat of the French national assembly while the commune was triumphant in Paris, and of the two chambers till 1879, being declared the official capital of France.

After World War I the treaty between the Allied powers and Germany was signed in the Galerie des Glaces.

See A. P. Gille, Versailles et *les* deux Trianons, with illustrations by M. Lambert **(1899)**; P. **de** Nolhac, La *Création* de Versailles (1901); J. **E.** Farmer, Versailles and the Court Under Louis XIV (1905).

VERSAILLES, TREATY OF, the treaty of peace signed at the close of World War I by the Allied and Associated powers and Germany at Versailles, France, on June 28, 1919, and brought into force on Jan. 10. 1920. The original intention had been that it should be only one part of a general and inclusive settlement with Austria, Hungary, Bulgaria and Turkey as well as with Germany but the delays in dealing with the smaller states. particularly Hungary and Turkey, not only separated the German treaty from the others, but caused it to be the first to be signed and the first to come into force, just as it was the first in importance.

NEGOTIATIONS BEFORE THE ARMISTICE

On Oct. 4, 1918, the German government requested the president of the United States to bring about the immediate conclusion of a general armistice as a preliminary to the restoration of peace and declared its acceptance of the fourteen points (*q.v.*) formulated by him on Jan. 8. 1918. After lengthy negotiations with Germany. Pres. Woodrow Wilson communicated its request to the Allied governments and inquired whether they were willing to grant an armistice and to make peace on the basis of the fourteen points. The Allies accepted the proposal, but made two reservations: (1) they excluded the "freedom of the seas" (point 2); and (2) they demanded that "compensation will be made by Germany for all damage done to the civilian population of the Allies and their property by the aggression of Germany by land, by sea and from the air." These conditions were communicated to the German government by President Wilson on Nov. 5, 1918. The German government made no reply in writing to these terms. but in fact accepted them by getting in touch with Marshal Foch, asking for an armistice and accepting the conditions set forth by the marshal. Thus the note of Nov. 5 became a kind of contract between Germany and the Allied and Associated powers. The exact meaning of the language concerning reparation was, however. obscured by the insertion in the Armistice of a reservation, which was accepted by Germany, to the effect that "any subsequent concessions and claims by the Allies and the United States remain unaffected" (art. 19).

For the negotiations leading to the treaty of Versailles see PARIS, CONFERENCE OF.

ANALYSIS OF THE TREATY

Part **i, the** Covenant.—Part i (art. 1–26) deals with the covenant of the League of Nations (*q.v*). The covenant united its signatories in a league guaranteeing their independence and territorial integrity (art. 10); according to President Wilson, this was the "heart" of the matter. The entrance of Germany into the League was opposed by some of the Allies and did not take place until after the signature of the agreements of Locarno on Dec. 1, 1925, and their ratification in 1926. The most important power granted to the League was the supervision of mandated territories (art. 22). by which the government of the former German colonies and parts of the former Ottoman empire, after having been assigned to various mandatory powers, was subject to supervision by a permanent mandates commission. This was appointed hy the League and inspected the annual reports of the mandatory powers on the territory committed to their charge (see MANDATE). Other duties of the League were to formulate plans for the reduction of armaments (art. 8) and to supervise the trade in arms and ammunition with "the countries in which the control of this traffic is necessary in the common interest" (art. 23).

There were also provisions for international co-operation in labour questions (art 23) and for voluntary international control of health and disease (art. 2 j); in the 20 years that followed. these responsibilities of the League were widely and successfully extended.

The most important obligation of the covenant was found in art. 12–16, by which members of the League bound themselves not to go to war in disregard of its covenants until three months after an award of arbitration or a report by the council of the League; art. 16 provided for the application of economic sanctions against a member who resorted to war in disregard of its covenants. These articles of the covenant were put to the test, unsuccessfully, against Japan in Manchuria in 1931–33 and against Italy in Ethiopia in 1935–36.

The machinery through which the League functioned consisted of a council and an assembly. The council was to have five members, the United States. France, Great Britain. Italy and Japan being permanent members (in order to give the great powers a majority). The failure of the United States to join the League upset this plan, and ultimately the number of seats held hy the smaller powers was increased to ten, of which three were "semi-permanent"; these seats were filled by the assembly. Germany entered the League in 1926 and occupied a permanent seat until its withdrawal from the League in 1933. Japan withdrew from the League in 1933, and Italy in 1937. The U.S.S.R. entered the League in 1934 and occupied a permanent seat until its expulsion in 1939 following the attack on Finland. The assembly consisted of representatives of all member states, and was a kind of international parliament.

Two institutions connected with, but actually separated from, the League were the Permanent Court of International Justice (art. 14) (see INTERNATIONAL COURT OF JUSTICE) and the International Labour organization (*q.v.*) (part xii. art. 387–427).

Other duties of the League, nssigned to it by other articles of. the treaty, were the governance of the Saar basin and the free city of Danzig, the supervision of German disarmament after the dissolution of the inter-Allied naval and military commissions in 1925, and the supervision of the racial and religious minorities' treaties which were signed as part of the general settlement of 1919–20. (See MINORITIES.)

Parts **ii** and **iii,** Territorial Dispositions.—Western Frontier.—Germany lost territory in the west, north and east, and had its influence greatly weakened beyond its own borders. Belgium, which ceased to be a neutral state (art. 31), acquired from Germany the districts of Moresnet, Eupen and Malmédy (art. 32–34) as compensation for damage resulting from the German occupation. Luxembourg ceased to be a neutral state and to form part of the German *Zollverein* (art. 40); later it entered into an economic union with Belgium. The Saar basin, a rich mining area vainly claimed by France, was placed under the control of the League, which governed it by an international commission, and its coal mines were ceded to France as compensation for the destruction of coal mines in northern France by the German army (art. 45–50). At the end of 15 years a plebiscite was to be taken, whereby the inhabitants would vote as to their preference for (1) the existing international regime, (2) union with France, (3) union with Germany. In 1935 the Saar voted to return to Germany. Finally. Alsace and Lorraine were ceded by Germany to France (art. 51–79) "to redress the wrong done by Germany in 1871." France thus gained nearly 2.000.000 inhabitants, great strategic advantages and valuable economic resources, particularly the iron fields of Lorraine.

The left bank of the Rhine and the right bank to a line drawn 50 km. to the east of the Rhine were demilitarized. Fortifications were to be dismantled, and no permanent works for maneuver or mobilization were to be permitted (art. 42–43). Violation of these articles by Germany was to be regarded as "a hostile act" (art. 44). The articles were violated by Germany in March 1936 when German troops reoccupied the Rhineland — and the signatories of the treaty contented themselves with a verbal protest.

Northern Frontier. — In the north Germany lost northern Schleswig to Denmark as the result of a plebiscite held in two zones (art. 109–114). The northern zone voted for return to Denmark, the southern or Flensburg zone elected for Germany. Thus Denmark finally received that plebiscite which Bismarck had promised in 1866 but which Germany had never allowed to be held.

Eastern Frontier. — Beginning at the Baltic, Germany ceded to Poland West Prussia and most of the province of Poznan (art. 87); this meant that a "corridor," as the Germans called it, was run between Pomerania and East Prussia and separated the latter province from the main body of Germany. On the other hand. the territory was historically Polish (*i.e.*, before the partitions of Poland) and was inhabited by a Polish majority. No provision of the treaty caused so much animosity and resentment as this arrangement which, it should be noted, accorded with President Wilson's 13th point for giving Poland "a free and secure access to the sea." The territory ceded did not, however, include Danzig, a purely German town, which was established as a free city under the sovereignty of the League (art. 100–108). In East Prussia plebiscites were provided for in the Allenstein and Marienwerder districts (art. 94–98). where there was a mixture of Germans and Poles; both plebiscites went in favour of Germany (1920). The city and hinterland of Memel were ceded to the principal Allied and Associated powers (art. 99), who in 1924 awarded the territory to Lithuania. Farther south. a plebiscite was provided for in upper Silesia (art. 88). where the population was partly German, partly Polish. This resulted (1921) in a majority for Germany, but inasmuch as the treaty clearly implied a partition of the territory. the League of Nations — at the request of the Allies and Germany — rendered a decision by which the southern half of the area — including valuable mines — passed to Poland, the northern half returning to Germany. Less than one-third of the population ceded by Germany to Poland and Lithuania were German. Provision was made (art. 91) by which Germans who did not wish to become Polish nationals might opt for German nationality and leave Poland.

Altogether, Germany ceded to the various powers about 25,000 sq.mi. of territory and nearly 6.000.000 inhabitants. This loss was, however, probably less serious than the loss of iron ore (65% in Lorraine and Luxembourg). coal (45% in the Saar and Silesia), zinc (72%), lead (57%) and potash (Alsace).

Part iv, German Rights and Interests Outside Germany. — Germany ceded its oversea colonies to the principal Allied and Associated powers (art. 119), which distributed them to mandatories. In Africa the Cameroons and Togoland were divided between France and Great Britain, and East Africa between Great Britain and Belgium; South-West Africa was awarded to the Union of South Africa. These territories contained about 18,000 Germans and more than 12,000,000 natives. In the Pacific Germany lost the Marshall Islands to Japan. New Guinea to Australia, Western Samoa to New Zealand and Nauru to Great Britain, Australia and New Zealand. It also renounced outright to Japan the province of Shantung (art. 156–158), which Japan returned to China in 1923. In addition to these cessions of territory, Germany lost all its state property. movable and immovable, in its colonies and was obliged to cancel all its treaty rights, capitulations (*q.v.*) and concessions in China, Siam, Liberia. Egypt and Morocco (art. 128–154). (For provisions regarding German missionaries, see part xv, miscellaneous provisions.)

Part v, Military, Naval and Air Clauses. — "In order to render possible the initiation of a general limitation of the armaments of all nations." Germany agreed to reduce its army to 100.000 men, with stores of guns, ammunition, etc., in proportion. Beyond this figure all existing munitions were to be surrendered and destroyed and the manufacture of munitions closely restricted; the importation of munitions of war was prohibited (art. 159–170). Conscription was abolished, and Germany was required to adopt a system of voluntary enlistment of at least 12 consecutive years for the men and 25 consecutive years for officers. Military training outside the army was forbidden (art. 173–179) and the existence of a general staff prohibited (art. 160).

The naval clauses were equally severe, for the German navy was restricted to 6 battleships of an antiquated type, 6 light cruisers, 12 destroyers, and 12 torpedo boats and submarines were forbidden (art. 181). For purposes of replacement no ship was to be built in excess of 10.000 tons. Other ships of the German navy were to be handed over to the Allies (art. 185). The personnel were to be recruited in the same manner as the army and were limited to a total of 15,000 men and 1,500 officers and warrant officers (art. 183). Naval works and fortifications within 50 km. of the coast were to be demolished. The fortifications of Heligoland were to be dismantled.

The air clauses (art. 198–202) were the most drastic of all for they absolutely prohibited all naval and military air forces and called for the destruction of all air matériel. Inter-Allied commissions of control were provided for each arm of the service and functioned until 1925, when their work was taken over by the League of Nations. This supervision was never fully effective and gradually ceased to be exercised; there was no kestraint when Hitler decided on the rearmament of Germany in 1935. (See also DISARMAMENT.)

Part vi, Prisoners of War and Graves. — This section (art. 214–226) provided for the return of prisoners of war and for the upkeep and maintenance of graves.

Part vii, Penalties. — William II, "formerly German emperor," was arraigned "for a supreme offence against international morality and the sanctity of treaties" (art. 227). although in 1914 war was a legal procedure and had not been officially renounced as an instrument of national policy. The principal Allied powers proposed to try the former emperor, but the Netherlands government, in whose territory he had taken refuge, refused to surrender him and nothing came of the project.

There were further provisions (art. 228–230) for the punishment before Allied military tribunals of Germans "accused of having committed acts in violation of the laws and customs of war." Eventually a list of more than 100 such criminals was drawn up and their extradition was demanded of Germany. On account of the excitement produced in Germany, the demand was not insisted upon; instead. the Allies agreed to about a dozen being tried in Germany by Germans, and when a few had been convicted and given mild sentences. the Allies dropped the matter. In 1925 Field Marshal Hindenburg, himself a "war criminal," was elected president of the German Reich without any Allied protest. (See also WAR; WAR CRIMES.)

Part **viii**, Reparation. — This (art. 231–243) was perhaps the most important section of the treaty, for it produced bitter controversy almost from the beginning and was much affected by outside and popular influences. In the pre-Armistice agreement of Nov. 5, 1918 (see above), Germany had undertaken to make compensation for "all damage done to the civilian population of the Allies and property by the aggression of Germany by land, by sea and from the air." In the treaty this obligation was rephrased thus (art. 231): "The Allied and Associated Governments affirm, and Germany accepts, the responsibility of Germany and her allies for causing all the loss and damage to which the Allied and Associated Governments and their nationals have been subjected as a consequence of the war imposed upon them by the aggression of Germany and her allies." Although the Germans, partly because of a faulty translation, interpreted this clause to imply that Germany was solely responsible for the war, the intention of the Allies was, as has been disclosed by a study of the records of the peace conference, merely to reaffirm the obligation assumed by Germany when it signed the Armistice. The fact that the same language is used. *mutatis mutandis,* in the treaties with Austria, Hungary and Bulgaria adds further proof. In the definition (art. 232; annex 1) of the categories of loss and damage under which Germany mas liable, however, pensions to military persons and separation allowances to civilians were included, which seems contrary to the definition laid down in the note of Nov. 5, 1918 (but may possibly be justified by the reservation in the armistice that subsequent claims remained unaffected; see above). A memorandum Justifying the inclusion of these items was prepared by Gen. Jan C. Smuts of South Africa, but its argument was not generally accepted.

There was sharp disagreement among the Allies as to how much Germany could pay on account of reparation. British experts placed the figure at something like £2,000,000,000 or $10,000,000,000, and the Americans at £3,000,000,000 or $15,000,000,000; some sanguine British and French estimates ranged as high as £20,000,000,000 or $100,000 000,000 (in 1871 Germany imposed an indemnity of $1,000,000,000 on France). As no sum could be agreed upon, a scheme was adopted of postponing the fixing of the amount until more data about the damage done was available and passions had cooled. A reparation commission was established aith extensive powers, to assess the German obligation not later than May 1, 1921 (art. 233); in the meantime, Germany was to make certain preliminary payments in kind and in gold (£1,000,000,000 or $5,000,000,000), which would tide over the immediate needs of the Allies. The commission was to be composed of representatives of the United States, France, Great Britain and Italy, and a fifth member from Japan, Belgium or Yugoslavia, according to the claims being considered; it was to give Germany "a just opportunity to be heard," but was not bound to accept the German argument. It was expected that the United States would become a kind of arbiter between conflicting claims and that the commission uould be able to reduce the demands on Germany to a reasonable figure. But the failure of the Cnited States to ratify the treaty reduced the commission to four; ordinarily France and Belgium voted together against Britain and Italy; France, as the country nhich had suffered the greatest devastation, held the presidency of the commission and in this capacity possessed a casting vote in case of a tie (part xv, art. 437). In consequence, France and Belgium were able to outvote Britain and Italy and often did so. On April 28, 1921 the commission determined the debt of Germany to be approximately $33,000,000,000, in addition to the war debt of Belgium ahich Germany had assumed as "a consequence of the violation of the treaty of 1839" (art 232); this was more. than twice the American estimate of Germany's "capacity to pay," and about one-half of this sum was accounted for by the inclusion of pensions and separation allowances. It should be noted. honever, that in their counterproposals to the treaty, the Germans offered to pay 100,000 000.000 gold marks, or approximately $2 5,000,000,000.

Although Germany's obligations were reckoned in gold marks. the actual payments had to be made largely in kind, and the treaty contained elaborate provisions for the transfer by Germany to the Allies of various commodities (art. 236 and annexes). They included the replacement by German ships, on the basis of "ton for ton and class for class," of Allied vessels sunk by German submarines. Great Britain received most under this head. France obtained large deliveries of coal and coal derivatives; Belgium received much livestock. Germany had also to furnish much material for the restoration of the devastated regions, and to renounce numerous ocean cables.

Since German resistance to the payment of reparation was to be expected, the treaty provided that the Allies might employ "economic and financial prohibitions and reprisals and in general such other measures as the respective governments may determine to be necessary" and that Germany was not to regard them as "acts of war." From the beginning Germany protested that the terms were not only impossible of execution but were contrary to the pre-Armistice agreement. The French, for their part, insisted that Germany could pay if it wished to or were forced to pay, and they tried to insist on the letter of the treaty. British opinion took a middle ground and opposed pressing Germany to the point where payment would really "hurt." In the United States there was much confusion of thought, for many persons aho advocated reducing the burden on Germany were insistent that the Allies should pay their "war debts" to the United States. Ultimately it became clear that the colossal sums involved in reparation could not be transferred from one country to another without seriously upsetting the internal economy of both. For the history of reparations (1920–32) see REPARATIONS. (See also WAR FINANCE: COST OF WORLD WARS I AND II.)

Part ix, Financial Clauses.—This section (art. 248–263) was largely technical, dealing with the order of priority of German payments, the meeting of special debts from special assets. currency questions. and the like. and was closely connected with the reparation clauses. The powers to which German territory was ceded had to assume a portion of the German debt as it stood at the outbreak of the nar (art. 254), but "inasmuch as in 1871 Germany refused to undertake any portion of the burden of the French debt," France was exempted from any obligation in respect of recovered Alsace-Lorraine (art. 255). The powers which assumed mandates of the former German colonies were also exempted from taking over the debts of those colonies (art. 2j7). (See also SUCCESSOR STATE.)

Part x, Economic **Clauses.**—Sec. i (art. 264–281) dealt with the restoration of commercial relations. The most important provision nas that securing "most favoured nation" treatment from Germany for five years aithout reciprocity (art. 267). France obtained the exemption from customs duties of products of Alsace-Lorraine for five years (art. 268). Sec. ii (art. 282–295) dealt with the revival of treaties which had been nullified by the war.

Sec. iii–viii (art. 296–312) provided for the collection of debts and the regulation of various property rights and interests, contracts. patents, insurance, etc. In the liquidation of German property in foreign countries the principle was adopted of giving the Allies power to confiscate the private property of German nationals and of crediting the sums obtained to the amount paid as reparation by the German government (art. 297); Germans whose property was thus taken were left to collect compensation from their government. This departure from long-established practice was of course challenged by the Germans and was sometimes criticized in Allied countries as "socialistic." The Allies justified their position by saying that "all available means" must be used to meet Germany's obligations and that they themselves had taken over the foreign property of their own nationals. A considerable sum was obtained by this device.

Part xi, Aerial Navigation.——This provided for full liberty of passage and facilities for Allied aircraft flying over Germany until Jan. 1. 1923, unless Germany had been previously admitted to the League of Nations (art. 313–320).

Part **xii,** Port, **Waterways** and Railways.—This (art 321–386) mas a highly technical section. Its aim was to secure international control over rivers nhich flowed through more than one country—a rather striking development of the doctrine as to international rivers laid down at Vienna in 1815. There was a natural desire. honever. to provide access to the sea for countries like Snitzerland and Czechoslovakia. nhich were landlocked but were the sources of rivers running to the sea. International commissions were accordingly set up to control the Rhine. Elbe, Oder, Niemen and Danube rivers, with the result that Germany was left in a minority position as regards three rivers regarded as essentially German, the Rhine, the Elbe and the Oder. The Kiel canal was in effect internationalized so as to give freedom of access to all vessels of whatever country at peace with Germany (art. 380), but was left under German administration. Access to the sea was provided for Czechoslovakia by the establishment of free zones in the harbours of Hamburg and Stettin. Certain clauses governing international transport through Germany were of a temporary nature and were replaced by the decisions of an international transport conference held at Barcelona in 1921 under the auspices of the League of Nations. This section of the treaty was denounced by Germany in Nov. 1936. Several powers protested individually against this unilateral action, but to no effect. (See also WATERWAYS, INTERNATIONAL.)

Part xiii, Labour. — This section (art. 387–427) created the International Labour organization as the instrument to carry out art. 23a of the covenant of the League of Nations, by which the members undertook "to endeavour to secure and maintain fair and humane conditions of labour for men, women and children, both in their own countries and in all countries to which their commercial and industrial relations extend." Three representatives of labour took part in the formulation of the plan: Samuel Gompers of the U.S.. George N. Barnes of Great Britain and Albert Thomas of France, the last named of whom became the head of the International Labour office. The office was established at Geneva, side by side, but not identical with, the secretariat of the League of Nations; though an integral part of the League. its character and organs were autonomous. Its governing body consisted at first of 24 members, 12 representing governments, 6 elected by employers' delegates to the general conference. 6 by workers' delegates. Later the number was increased to 32, in the same proportion, with the proviso that 8 of the government members must represent Canada, France, Great Britain. India, Italy. Japan, the U.S.S.R. and the United States. thus ensuring adequate representation to the states of greatest industrial importance. The general conference, which met annually, consisted of four delegates from each member state, two chosen by the government, one by employers. one by labour. The conference acted by recommendations, and the governments were pledged to submit such recommendation to their respective competent authorities, who then decided what action, if any, to take. All members of the League were automatically members of the International Labour organization. Germany was admitted in 1919, long before it joined the League; when it left the League in 1933, it left the labour organization also. Japan and Italy, however, continued in the organization after they had resigned from the League. In 1934 the United States joined the organization without joining the League. In 1939 there were 57 member states.

After the defeat of France in 1940, the International Labour office was transferred to Montreal, Que. For work of the office. see the article INTERNATIONAL LABOUR ORGANIZATION. THE.

Part xiv, Guarantees. — In addition to the provisions for the demilitarization of the Rhineland (see above parts ii and iii), a military occupation by Allied troops was also provided for (art. 428). The whole of this area, together with bridgeheads across the Rhine, was to be occupied for 15 years from the coming into force of the treaty (Jan. 10, 1920). If, however, Germany "faithfully carried out" the terms of the treaty, the bridgehead and zone of Cologne was to be evacuated in 5 years, that of Coblenz in 10 and that of Mainz in 15 (art. 429). Because of suspicion that Germany was evading the military clauses, the evacuation of the Cologne zone was postponed from Jan. to Dec. 1925.

In June 1930 both the Coblenz and the Mainz zones were evacuated as part of a general settlement with Germany.

There was also a provision (art. 420) that if any time during the occupation or after the expiration of the 15-year period the reparation commission found Germany not observing its obligations with regard to reparation. the whole or part of the areas evacuated would be immediately reoccupied. It seems doubtful whether this article justified the action taken by the Allies in 1921 when they occupied areas in Germany east of the bridgeheads. That it justified the occupation of the Ruhr by France and Belgium in 1923 was warmly disputed by the British government. As a guarantee for the settlement of the eastern frontier of Germany, Germany was required to abrogate the treaty of Brest-Litovsk and other agreements made with the U.S.S.R. and to withdraw its troops in the east within its new frontiers when the Allies "shall think the moment suitable" (art. 433).

Part xv, Miscellaneous Provisions. — This section (art. 434–440) consists of a number of miscellaneous and technical matters which were accidentally omitted elsewhere. The most important was the recognition that the free zones of upper Savoy and Gex, lying between France and Switzerland, established in 1815 were "no longer consistent with present conditions" and that it was "for France and Switzerland to come to an agreement" for modification (art. 435). Switzerland, however, resisted the proposals of France for modification. and its position was sustained by the Permanent Court of International Justice in 1932. The property and stations of German missionaries overseas were to be handed over to trustees and individual missionaries were to be controlled or expelled at the will of the mandatory power (art. 438).

The treaty was drawn up in English and French, and the texts in both languages were authentic.

ESTIMATE

The treaty of Versailles was bitterly criticized by the German government and people and by many people in other lands. The first complaint was that the treaty had been "dictated," not merely in the sense that it had been imposed on a defeated enemy (the usual result of a lost war). but that no opportunity had been allowed for verbal negotiations. This was true, and the Allies may have blundered psychologically in refusing to meet the Germans for personal negotiations; it may be doubted, however, whether this procedure would have resulted in any large modification of the treaty.

Secondly, the Germans contended that the treaty was not in harmony with the fourteen points, which the pre-Armistice agreement provided should form the basis of peace. There was some truth in this contention. Point 3 calling for "the removal. as far as possible, of all economic barriers and the establishment of an equality of trade condition" was not observed, although the restrictions imposed on Germany were temporary. The provisions of part v of the treaty relating to German disarmament were far from fulfilling the promise of point 4 for "adequate guarantees given and taken that national armaments will be reduced to the lowest point consistent with domestic safety," although they marked a step in that direction. The "free, open-minded, and absolutely impartial adjustment of all colonial claims" demanded in point 5 was not satisfied, even though the adoption of the mandate system was somewhat less selfish than outright annexation. Also, on various points of detail, it could be maintained that the treaty failed to observe that "impartial justice" which President Wilson talked of so often in his speeches of 1918. On the other hand, the territorial clauses of the treaty were substantially in accord with points 7 (Belgium), 8 (Alsace-Lorraine) and 13 (Poland). Germany was not made an original member of the League of Nations, as it was perhaps entitled to expect under point 14, but at least it was assured that in due course it would be admitted. The treaty, then, was not a complete realization of the fourteen points, so far as they concerned Germany, but neither was it the complete travesty of them so often represented.

The third German complaint was that the treaty demanded intolerable sacrifices of Germany and that it could not be carried out without wrecking the economic life of the country. What the Germans really meant was that the treaty would make it impossible to restore the standard of living which had existed in 1914. No doubt the various items of loss and obligation, when assembled together, made the treaty as a whole appear much more crushing and severe than they did to the numerous committees which worked them out separately, and apparently the treaty in its definitive form was not reviewed by the Big Four from the point of view of its cumulative effect on the Germans. On the other hand, they were under such strong popular pressure not to make a lenient peace that they would not have dared to reduce the German burden in any large measure. The Germans, for their part, made the mistake of challenging almost every article of the draft treaty, instead of concentrating on a few fundamental issues, with the result that their objections were regarded as largely factious and only a few concessions were made. Apart, however, from such considerations, the Germans greatly exaggerated the probable effects of the treaty on their economic position. A competent U.S. authority, not unfriendly to Germany, has shown that the burden of taxation in Germany after 1919 was only a quarter as heavy as the burden in Britain and only half as heavy as in France or Canada. Furthermore, Germany's claim that it was ruined by reparation was not justified, for the total amount paid by Germany between 1920 and 1931 (when the Hoover moratorium was proclaimed) amounted to 21,585,000,000 gold marks, and it borrowed more than twice that amount in the United States alone and then defaulted on most of those loans. What ruined the German economy was the four years of war, during which the German government floated loans to the amount of 98,000,000,000 marks (or four times the amount paid in reparations); the total cost of the war to Germany was about $100,000,000,000 (or 20 times the amount paid in reparations). It can be argued that although Germany lost the war in a military sense and was then forced to yield certain territories. it won the peace in an economic sense.

Even if the harshest view be taken of the treaty of Versailles, the fact remains that no other diplomatic instrument was ever so speedily modified, revised or altered. Part i was modified to admit Germany to the League of Nations. Part v was torn up unilaterally by Germany when it began to rearm. Part vii went largely by default. Part viii was repeatedly whittled away and finally abandoned. Parts x, xi were modified or abandoned in large measure. Part xii was denounced by Germany. Part xiv, the section on guarantees, the crux of the treaty, was abandoned by the Allies five years ahead of schedule. Except as regards parts v and xii, these concessions were made to Germany before the advent of Adolf Hitler to power. Hitler's denunciations of parts v and xii evoked only faint and futile protests.

Thus, in 1938, only parts ii, iii and iv of the treaty remained; these concerned the territorial settlements of 1919. The real German grievance against the treaty of Versailles was not so much the burden of reparation or the so-called "war guilt" clause (art. 231) as the loss of territory in Europe and elsewhere. By the *Anschluss* of Austria in March 1938 (forbidden by art. 80), the partition of Czechoslovakia in Sept. 1938, and the occupation of Bohemia and Moravia in March 1939 (contrary to art. 81), the seizure of Memel in March 1939 (contrary to art. 99), Germany largely destroyed the political structure of eastern Europe as erected by the treaty of Versailles. The last step was to make war on Poland on Sept. 1, 1939.

Whereas Germany complained that the treaty was too severe, French opinion considered the treaty inadequate for the defense of France and Georges Clemenceau was defeated for the presidency of the republic in 1920 because he had made too weak a settlement. Curiously enough, when France. in the years following the negotiation of the treaty, tried to enforce it against Germany, it was not supported by its associates who had compelled it to accept the treaty against its better judgment. the United States retiring altogether from European politics. Great Britain and Italy constantly demanding that France make concessions to Germany. It is true that the treaty of Versailles failed to bring peace, order and prosperity to Europe; it is also true that the treaty was never fully applied. Rigorous enforcement of the treaty might have convinced Germany not only that it had lost the war, but also that war did not pay. Once the Allies began not to enforce the treaty and to modify it, they lost all chance of reconciling Germany to its provisions and encouraged it to nullify them. It is only from that point of view that the treaty of Versailles can be considered the cause of the war of 1939.

(B. E. S.)

VERS DE SOCIETE, a term for social or familiar poetry, originally borrowed from the French, which came to rank as an English expression. The use of the phrase as an English one is first met at the opening of the 19th century, and it is to be observed that the English meaning is not wholly equivalent to that of the French original. The prince of the French graceful triflers was the Abbé de Chaulieu (1639–1720), of whom it was said that he made verses solely for the amusement of his friends, without the smallest intention of seeing them in print.

An enormous collection of *vers de société* was brought together by Titon du Tillet (1676–1762), in his *Parnasse françois,* where those who are curious about the subject may observe to satiety how ingenious and trifling these artificial verses of the French 18th century could be. The fashion for them followed upon the decline of interest in rondeaux, ballades and villanelles, and Chaulieu himself had not a little to do with throwing these ingenuities out of fashion. Of the writers of *vers de socie'te'* in France, J. B. Rousseau had the most poetical faculty.

If in England the expression *vers de société* carries with it more literary dignity, this is mainly due to the genius of one man—Matthew Prior. Prior's *Poems on Several Occasions,* collected in 1709, presents us with some of the earliest entirely characteristic specimens, and with some of the best. Here the poet consciously, and openly, resigns the pretension of high effort and an appeal to Parnassus. He is paying a visit at Burghley House, where the conversation turns on the merits and adventures of Fleetwood Shepherd; Prior then and there throws off, in extremely graceful verse, a piece appropriate to the occasion. He addresses it, and he dates it (May 14, 1689); and this is a typical example of *vers de socie'te'.* It will be seen that Prior, who learned much from his residence in the heart of the French world of fashion between 1711 and 1715, treats very much the same subjects as did Chaulieu and La Fare, but he does so with more force of style and dignity of imagination. As the 18th century progressed, the example of Prior was often followed by English poets, and the *vers de socie'te'* tended to merge with the epistle and the epigram. Swift, however, when he was neither coarse nor frigid, sometimes achieved a genuine success, as in the admirable verses on his own death. The odes of Ambrose Philips (1671–1749), addressed by name to various private persons, and, most happily, to children, were not understood in his own age, but possess some of the most fortunate characteristics of pure *vers de socie'te'.* In his "Welcome from Greece," a study in *ottava rima,* Gay produced a masterpiece in this delicate class, but most of his easy writings belong to a different category. Nothing of peculiar importance detains us until we reach Cowper, whose poems for particular occasions, such as those on "Mrs. Throckmorton's Bullfinch" and "The Distressed Travellers," are models of the poetic use of actual circumstances treated with an agreeable levity, or an artful *naïveté.* In a later age Byron, who excelled in so many departments of poetry, was an occasional writer of brilliant *vers de socie'te',* such as the epistle "Huzza, Hodgson," but to find a direct successor to Prior it is necessary to pass Henry Luttrell (1765–1851) and W. R. Spencer (1769–1834), and come down to Winthrop M. Praed (1802–39). A certain character was given to English *vers de société* by Hood and Barham, but the former was too much addicted to a play upon words and the latter was too boisterous to be considered as direct continuers of the tradition of Prior. That tradition, however, was revived by Frederick Locker, afterwards Locker-Lampson (1821–9j), whose *London Lyrics,* first printed in 1857 and constantly modified until 1893, is in some respects a typical example of pure *vers de société.* Numerous others attempted to carry on the tradition in English. Superior to all of them was Austin Dobson (1840–1921), who was. however, more than a writer of *vers de socie'te'.*

VERSE. Verse is metrical language; that is, language in continuous rhythm. The smallest possible section of rhythmic language is called a foot; it is a group of syllables completely expressing a rhythmical relation, yet incapable, by itself, of producing metre. Thus the syllables in "again" constitute an iambic foot (∪ –), but do not produce iambic metre until they are succeeded by at least one more iambic foot. A succession of feet completely expressing a given metre is called a verse, or, since it is usually written as a single line, a line. A succession of feet incompletely expressing a given metre is called a *caesural division* or a line section; it is usually set off by a caesura or pause within the line. When foot rhythm is present, the metre is measured by the number of feet contained within the line or verse, and is called monometer, dimeter, trimeter, tetrameter, pentameter, hexameter, etc., accordingly as the verse contains one, two, three, four, five, six or more feet. Lines or verses ordered into a complete group are called a stanza; stanzas are described, according to the number of lines they include, as couplets, tercets, quatrains, sestets, octaves, etc., according to the rhythm and metre of the lines; *e.g.*, iambic pentameter; and according to the rhyme scheme, if rhymes are employed. A complete group of stanzas is called a verse form. Thus the sonnet is a verse form; and the sonnet form employed by Shakespeare is that of three quatrains rhyming a b *a* b, c d *c* d, e *f e f*, followed by a rhymed couplet (g g), all in iambic pentameter.

The study of versification seems to have been brought to early perfection by the Greeks. The rapid development of Greek poetry and music and the importance of these arts in Greek education had such effect that by the 4th century B.C. an adequate phonetics had been established, the basic principles of rhythm discovered, the types of quantitative metre analyzed and assigned to their appropriate literary species, and the psychological and mathematical bases of verse and music explored.

Plato and Aristotle, cautious as they were in accepting the scientific and artistic theories of their predecessors, seem content with the state of musical and prosodic knowledge in their day: the former holds up the method of phonetics as a model of dialectical procedure (*Philebus* 17 A ff.), and the latter, even in dealing with poetry, is content to refer questions of versification to the metrists. Unfortunately, early Greek musical and prosodic theories have been handed down only in fragments, the most extensive and important of which are the works of Aristoxenus, a pupil of Aristotle, on harmonies and rhythms.

The Alexandrian grammarians wrote voluminously on prosody; a surviving work, the *Encheiridion* of Hephaestion (2nd century A.D.), suggests that the broad philosophical principles of older theory had long been supplanted by academic rules and formulas. Latin verse in its maturity was modelled on the quantitative measures of the Greeks, but the Romans, little given to speculative thought and interested in prosody chiefly as it bore on rhetoric, made no important contributions to the subject. During the middle ages the Byzantine grammarians, influenced by Hephaestion, continued the Alexandrian tradition, while Latin literary theory, usually in corrupt and garbled form, reigned in the west; such notable figures as St. Augustine (354–430), Boethius (*c.* 480–525), Aldhelm (c. 640–709) and Bede (673–735) touched upon the subject without substantially advancing it. As the Latin language fell into decay, quantitative distinctions among syllables disappeared, and from the 4th century accent became increasingly the basis of Latin verse. The Romance languages, developing out of popular Latin, produced verses based upon syllable counting; early Teutonic versification depended not upon foot construction, but upon the counting of alliterated or accented syllables; and, in brief, as the modern languages developed, poets constructed verses of such variety and upon such a diversity of bases that the induction and generalization requisite for philosophical analysis became ever more difficult and dangerous.

"Rules of versification," advanced in great number by European theorists from the 16th century onward, were no sooner stated than they were violated, and such violations seldom impaired the beauty and effectiveness of the verse. Classical prosody, even as rehabilitated by Richard Bentley (1662–1742), was too narrow to explain the vast diversity of structures; and the gradual increase of linguistic knowledge, bringing ever greater varieties of verse into the purview of the prosodist, complicated further the general problems of verse structure. In the 19th century and throughout the first half of the 20th, prosodic questions engaged the attention of physiologists, psychologists, phoneticists and acoustical physicists, without the discovery of any determinate principles. The modern state of the subject was in varying terms pronounced chaotic by such authorities as G. E. Saintsbury, Paul Verrier, T. S. Omond, W. P. Ker and E. W. Scripture.

Yet the principles laid down in antiquity are perfectly sound, and require only development and proper application to explain all verse. The solution to prosodic problems lies partly in the nature of rhythm, partly in the capacities of a given language, through determinations of its pronunciation, to satisfy the conditions of rhythm. The term "rhythm" is often applied figuratively to spatial proportions, such as those of landscapes, buildings and paintings; strictly, however, it applies only to such things as have successive existence in time, and possess order rather than position; for spatial objects, having coexistent parts, may have their parts viewed in any order without altering their proportions, whereas rhythm reversed or converted usually results in a different rhythm. Again, rhythm is not every proportion, but only such as are perceptible to sense, and capable of retention in the memory. Rhythm may therefore be defined as a numerical proportion, perceptible to sense, of things occurring in different intervals of time. Thus even prose may be rhythmic, in the sense that certain parts of it may be predominantly of this or that rhythmic character; *e.g.*, iambic or trochaic, but the consistent use of the same rhythmic ratio, however constituted, invariably produces metre, or verse.

Rhythms differ as to their form and matter. The form of a rhythm is the numerical proportion, based on some unit, constituting the rhythmic ratio; the matter is the sounds or movements entering into the ratio. All rhythm derives from number; hence, although rhythmical kinds are very numerous, all ultimately depend upon two possibilities of numbering: measurement in terms of some sound or movement taken as a unit, or measurement of sounds and motions in terms of their multitude merely. For example, the classical iamb (∪ –) is a three-count rhythm, the unit of measurement being the short syllable, the long syllable being equal to two of these, so that the ratio is 1:2; and rhythms may also be constructed by counting the number of syllables merely, without regard to any unit of time value, as in French syllabic verses.

In language the simplest rhythmic construction is the foot, which, like its analogue the musical measure, is based upon equal or proportional intervals of time measured by the length of the short syllable as unit. Every simple foot is a ratio between its two constituent parts, arsis and thesis, in terms of the time units or counts comprised in each part. The thesis is distinguished from the arsis by emphasis achieved by the use of certain characteristics of the syllable, such as accent or loudness, quantity or duration, etc., which will be discussed below. Foot rhythms differ formally according to the relative order of thesis and arsis and according to the difference of the ratio constructed. There are four possible orders: arsis as a whole may precede thesis as a whole, as in the iamb (∪ –); thesis as a whole may precede arsis as a whole, as in the trochee (– ◡); half of the arsis may precede, and half of it succeed, the whole thesis, as in the amphibrach (◡ – ◡); or half of the thesis may precede, and half succeed, the whole arsis, as in the cretic (– ◡ –). Since rhythm is temporal proportion, order is important; the ratio of 1:2, for example, is not the same as the ratio of 2:1. The common numerical ratios on which feet are based are 1:1, 1½:1, 2:1 and 3:1; thus the English iamb and trochee are both in the ratio of 1:1, difference in the quantity or duration of the syllables being disregarded; the classical iamb and trochee, in which the long syllable is given twice the value of the short, present the ratios of 1:2 and 2:1 respectively; the classical first paeon, composed of a three-count arsis and a two-count thesis (– ◡ ◡ ◡), is in the ratio of 1:1½; and the English paeon, a four-count measure, is in the ratio of 1:3. Two simple feet may be combined to form one compound foot; thus trochee and iamb combine to form the choriamb (– ◡ ◡ –) or the antispastic (◡ – – ◡), two trochees combine to form the ditrochee, two iambs make a diiamb, etc.

The material structure of the foot—the sounds and silence entering into proportion--can be described in terms of the kind of emphasis involved and in terms of the *rhythmical figuration.* All languages construct syllables out of vowels and consonants and determine the pronunciation of these, as they enter into discourse, according to accent, pitch, or quantity; syllables therefore are characterized in general by entity (their consonantal and vocalic construction), accent, pitch and quantity. These characteristics, as determined by the pronunciation of a particular language, are used to achieve emphasis in footed verse; unless they are determinate, construction of foot rhythm is impossible, and verse must be constructed on other bases. For example, since the Greeks and Romans pronounced syllables with attention to quantity, classical verse could be based upon quantity, the long syllable generally marking the thesis of the foot; as the sense of quantity disappeared, a new basis for versification had to be found. Similarly, English accentual verse was not possible until accentuation became determinate, and English quantitative verse has always remained only an artificial possibility because the syllables have no "natural quantity." Entity gives emphasis by alliteration, assonance, or rhyme, and pitch can create emphasis in languages with fixed pitches or intonations. Once rhythm has been established, it is possible in some verse to shift the principle of emphasis; *e.g.*, from accent to quantity, or from quantity to entity; or several of the characteristics of the syllable can be combined to create special emphasis, as in

> Stigma, signal, cinquefoil token
> For lettering of the lamb's fleece, ruddying of the rose-flake.[1]

Rhythmical figuration results from the number of sounds and silences and from their disposition within the foot. Thus, in a two-count foot, two syllables concurrent with the "counts," and disposed in the order of arsis and thesis requisite for a given rhythm, produce *strict representation,* and any variation from strict representation is variation in rhythmical figure. Strict representation, if continued at any length, produces monotony and fails to express emotion, character and even meaning adequately, since it restricts the possibility of inflections and nuances of the voice; hence poets utilize different rhythmical figures while maintaining the same formal rhythmical proportion, *i e.,* rhythm, just as composers use different numbers of notes differently disposed while keeping to the same musical measure. Thus, in a given verse foot, arsis or thesis may have its syllables doubled or tripled, sharing the allotted counts among them, even as in music two eighth notes or a triplet of eighth notes may be substituted for a quarter note; the arsis, or even in certain cases the thesis, may be suppressed, a silence taking its place in the rhythm; and the speech sound of arsis or thesis may be prolonged throughout the whole foot, or from part of one foot into part of another, as for example, the word cold is prolonged in Shakespeare's

> Toad, that under cold stone
> Days and nights has thirty-one.

Since the days of the Alexandrian grammarians, prosodists have confused rhythm with rhythmic figure, and consequently troubled themselves over "irregularities" of rhpthm; but variations in rhythmic figure do not disrupt the rhythm, as the slightest reflection will show. All substitutions of rhythmic figure are based upon the principle that, in rhythmic as in other proportions, equals may be substituted for equals.

As observed earlier, rhythm may also be based upon the multitude of sounds, without reference to any unit of duration. Such rhythm may be called *demarcative rhythm.* Languages capable of foot rhythm combine both forms; all other languages are confined to the various kinds of demarcative rhythm. Demarcative rhythm consists of sections, measured either in terms of the number of syllables contained, or in terms of certain syllables only, distinguished from the rest by alliteration, accent, or some comparable device, or in terms oi certain speech groups, such as phrases, rhythmical figures and the like. Larger sections are measured either in terms of the number of smaller sections contained, or in terms of the number of syllables, differentiated or undifferentiated, contained in these. Since such rhythm is more difficult to apprehend than foot rhythm, demarcative verses tend to be governed by rigorous rules as to the place of caesurae or pauses; and the beginning or ending of a section is often signalized by alliteration, assonance or rhyme.

It will be observed that verse is hierarchical in structure: each part, that is, enters into a whole which is in turn part of yet another whole, until the final composite is reached; for example, the foot is part of a line section, that section is part of a line, which is in turn part of the stanza. A second kind of hierarchy is possible through the use of superimposed or *mounted rhythm.* For example, an iambic pentameter line may have the first, third and fifth of its theses much more strongly emphatic than the rest, *e.g.*, by alliteration, quantity, or grammatical or rhetorical accent, and the consistent use of such three-stress rhythm against the "ground rhythm" of iambic pentameter will obviously generate another rhythm; this in turn may have yet another superimposed upon it. Thus in "The King was in his counting-house,/Counting out his money;" the ground rhythm is iambic tetrameter in the first line, iambic trimeter in the second; but "King," the first syllables of "counting-house," "counting" and "money" receive special stress and set up a mounted rhythm of trochaic dimeter in both lines. Again, in Browning's "Kentish Sir Byng stood for his King,/ Bidding the crop-headed Parliament swing:" the ground rhythm is dactylic tetrameter; but "Byng," "King," "crop" and "swing" have special stress, and establish a mounted rhythm of iambic dimeter. Mounted rhythm is capable of imparting a brisk swing or a slow swaying motion to the verse; it is very common in folk poetry and folk music.

While continuation of the same proportions, whether of foot, line or stanza, results always in symmetrical verse, poets frequently abandon such symmetry in favour of the greater expressiveness or appropriateness which may sometimes be achieved by a change of rhythm. Such changes may be made without disruption of the rhythmic beat, by increasing or diminishing the counts of a foot, although retaining the order of thesis and arsis; thus trochaic measures easily augment to dactylic, or anapests diminish to iambics. Similarly, the counts of a section can be increased or diminished. Again, where there is mounted rhythm, the ground rhythm can be replaced by another, or the ground rhythm maintained while the mounted rhythm is shifted. The powerful effects of such rhythmical transitions can be observed in Dryden's "Alexander's Feast," Schiller's "Der Handschuh" and Hugo's "Les Djinns."

Anyone who has heard a piece of music played too slowly or too rapidly is aware of how tempo influences the character of rhythm; and in verse as well the effectiveness of rhythm is relative to the tempo of the verse. The tempo of verse, like that of piose, is partly dependent upon the grammatical construction and significance of the language, but it also depends upon certain devices of versification. All things being equal, short-count measures like iamb and trochee tend to be faster than long-count measures like paeon and epitritus (◡ – – –); falling rhythm, in which thesis precedes arsis, is faster than rising rhythm, in which arsis precedes thesis; rhythms in strict representation and regular figuration are faster than those which are not. Yet such is the relativity of verse that short feet can be slowed by the use of long and sonorous syllables, by rendering both thesis and arsis forceful, and by using detached sounds; *i.e.*, monosyllabic rather than polysyllabic words. Conversely, the longer measures can be accelerated by the use of light and brief syllables, by using composite (doubled or tripled) arses and theses, and by using connected sounds. Since tempo is a matter of the speed or slowness with which rhythmic intervals succeed each other, shortening of the duration of the unit of measurement, especially when coupled with the doubling or tripling of the syllables of each count, will increase the speed of foot rhythms; conversely, deceleration can be achieved by lengthening the unit and reducing the number of syllables, even to the extent of prolonging one syllable from thesis to arsis. Milton's "L'Allegro" and "Il Penseroso" provide many examples of these and similar devices.

In scanning foot rhythms, it must not be supposed that the rhythm of a word or phrase, taken by itself, is necessarily the same as that of the verse in which it is found; that, for example, a verse is necessarily trochaic because it contains trochaic words. This supposition—a stumblingblock even to so eminent a theorist as Robert Bridges—is quite unfounded; poets have repeatedly demonstrated the various effects achieved by the confinement or nonconfinement of grammatical units, whether words, phrases, or clauses, within the metrical interval. Analysis has also been hindered by another supposition: that the most strongly stressed syllables are always necessarily theses. This overlooks the fact that emphasis is, after all, relative and not absolute; a heavily marked syllable frequently turns out to be nonemphatic because it is coupled with one still more heavily marked, and conversely, the weak secondary or even the tertiary accent of a polysyllable may be emphatic; *cf.* T. S. Eliot's use of the word "polyphiloprogenitive" to fill out an entire iambic tetrameter line.

VERTEBRATE is the name given to the group of animals having vertebral columns or backbones. The vertebrates, which include the fishes, amphibians, reptiles, birds and mammals, are the predominant members of the Chordate (*q.v.*) phylum. In addition to the backbone from which they derive their name, the vertebrates are characterized by (1) a muscular system consisting primarily of bilaterally paired masses and (2) a central nervous system partly enclosed within the backbone. The heart and other visceral organs lie below the backbone.

Vertebrates are unique in possessing an internal skeleton. By its ability to provide support during growth, this skeleton allows vertebrates to achieve large size, so that most vertebrates are bigger than most invertebrates. Except in the most primitive forms, the skeleton consists of skull, vertebral column and two pairs of limb elements, although one or both pairs of limbs are absent from a few higher forms (*e.g.*, snakes, whales) that have lost limbs in the course of evolution. The skull, by providing a secure housing for brain, eyes, ears and olfactory organs, has facilitated the evolution of intelligence and a high degree of responsiveness to the environment.

The vertebral column and limb skeleton provide support for the body as a whole. Movement is effected by the action of muscles that are attached to the bones. The mass of musculature forms the contours of the body. The outer surface is covered by skin which protects the inner parts not only by providing a general covering, but also by forming structures of specific protective value, such as bony or horny scales, feathers and fur. Teeth have evolved from scalelike structures formed inside the mouth.

Internally the vertebrate trunk is a hollow cavity in which the visceral organs are suspended. The cavity is subdivided, the heart having a chamber to itself. Other organs occupy a common pleuroperitoneal cavity, except in the mammals, in which each lung has a separate chamber.

The heart and respiratory organs are closely associated. The heart lies just behind the gills or between the lungs; it sends impure blood directly into these organs for oxygenation and removal of carbon dioxide. The gills of fishes lie along the sides of the pharynx, a large chamber that is part of both respiratory and digestive tracts. In land-living forms the enlarged pharynx perforated by gill slits is repeated in early embryonic development but later regresses. The remainder of the digestive tract includes esophagus, stomach and intestine, and usually terminates in a cloaca, a chamber common to the digestive, genital and urinary systems. In mammals, however, the digestive tract acquires a separate terminal opening. The urinary and genital systems are closely associated, particularly in males, in part because the kidneys, which develop early, make contributions to the later-developing reproductive system.

The central nervous system consists of brain and spinal cord. Although both of these become very thick walled, they always retain a small central canal (*i.e.*, are hollow). The brain in lower vertebrates is devoted largely to serving the sense organs of the head. During the course of evolution, however, the brain has become much larger, relative to body size, through the development of association areas that permit more intensive interchange of information among the parts of the brain. The spinal cord, extending backwards from the base of the skull, gives off pairs of nerves at repeated intervals. These nerves run to the skin, muscles and internal organs. The brain also gives off a series of nerves, not regularly arranged, of which one passes through the neck to innervate the heart, lungs and other viscera.

Vertebrate history may be traced back to the Ordovician period, approximately 400,000,000 years ago. The primitive vertebrates existing at that time were the Ostracoderms, now totally extinct. These were small, armoured creatures lacking either jaws or fins.

The body form was, however, fishlike and their armour was made of true bone, a material found only in vertebrates. Their closest surviving relatives are the finless, jawless cyclostomes (lampreys, hagfishes). The later occurring Placoderms possessed jaws, which apparently evolved through shifting and conversion of the supports of the most anterior gills. The true fishes added the two pairs of appendages that have become part of the standard vertebrate pattern. Thus equipped with fins and jaws, the fishes have been able to flourish for more than 200,000,000 years.

Fishes breathe by means of gills, over which a continuous stream of water passes. Many fishes, however, also have lungs which supplement the action of the gills. The possession of lungs, plus thick fleshy fins that made waddling possible, enabled the ancient crossopterygian fishes to come out on land. These fishes gave rise to the first amphibians, in which the fins became transformed into walking legs. The gills disappear in most amphibians in the adult state. Correlated with this change is the appearance of a subdivision in the heart to receive pulmonary blood, since blood that has been refreshed in the lungs is returned to the heart rather than being distributed directly to the tissues, as is done in a gill system. Although amphibians were the first animals to live successfully on land, their expansion has been limited by the need to lay their eggs in wet places.

The reptiles, which evolved from the amphibia, were the first vertebrates to be able to live entirely out of water. This independence resulted partly from the formation of a horny skin covering that conserves body moisture, partly from the development of a large egg, laden with food and water, and encased in a leathery coating that protects against drying. Structurally and functionally the reptiles show numerous other advances beyond the amphibian stage, including a heart in which the freshly oxygenated blood that has circulated through the body is kept partly separate from the spent blood from the other organs. Body temperature, however, varies according to the ambient temperature, as in lower forms.

At the time of reptilian predominance, about 100,000,000 years ago, two groups of reptiles gave rise to the birds and mammals separately. In the birds, the skeleton has been greatly modified through elimination and fusion of elements and the bones have become very light. The heart is completely subdivided into right and left halves, so that there is no mixing of refreshed and spent blood. The supply of fully oxygenated blood that the tissues thus receive facilitates the maintenance of constant temperature and makes possible a sustained high level of bodily activity. A covering of feathers, evolved from reptilian scales, helps to retain body heat. Birds reproduce by laying large eggs, but unlike reptiles they tend the eggs and care for the young.

Mammals resemble birds physiologically in being able to maintain constant temperature and high activity. Mammals differ importantly in brain development and mode of reproduction The enlargement and elaboration of the brain permits more adaptable, less stereotyped behaviour patterns than occur in birds In all but the primitive monotremes, which lay eggs, mammalian reproduction involves the internal development of tiny eggs that derive oxygen, water and nutrients from the blood stream of the mother. Milk secreted by the mammary glands sustains the young after birth. All major vertebrate classes have shown striking ability to produce a great variety of species capable of exploiting every possibility for survival. This tendency is well illustrated by the mammals Beginning as rat-sized, ground-living animals, mammals have evolved into forms as small as the shrew and as huge as the whale, adapted to survive in swamps and jungles, on grassy plains or deserts, in burrows or tree tops, in fresh or salt water, on the arctic ice or under it. *See* FISHES; CHONDRICHTHYES; AMPHIBIA; REPTILES; MAMMALIA; EVOLUTION, ORGANIC; MONOTREMATA; *see* also references under "Vertebrate" in the Index volume.

VERTEBRATE EMBRYOLOGY. The science of embryology (*q.v.*) had its first beginnings in the study of the Vertebrate (*q.v.*), the group that includes those forms of life whose eggs and breeding habits naturally first attracted attention, and even today the mass of known embryological detail relating to vertebrates far exceeds that relating to any other phylum. Further there is no phylum of the animal kingdom which shows in so varying degrees the modifying influence of such factors as amount of yolk in the egg, external environmental conditions, etc.

The vertebrate animal, like most other animals, begins its existence as a single cell, the zygote or fertilized egg, formed by the fusion of two gametes, derived one from each parent. The zygote possesses in itself all the specific peculiarities of the complete individual of its species. To human observation, however, the zygotes of different animals do not exhibit any of the peculiarities differentiating the adults. Such peculiarities as they do present are in such comparatively trivial characters as size, shape, colour. Otherwise each zygote is to all appearance simply a typical cell with cytoplasm and nucleus. The superficial differences have to do mainly with adaptive features enabling the young individual to remain for a more or less prolonged period within the shelter of an egg shell. This is rendered possible in the first instance by the zygote possessing in its cytoplasm a store of yolk—highly concentrated food material—which provides it with subsistence. The greater the amount of this yolk capital stored away in the zygote, the greater its size: there is a rough proportion between size of egg and quantity of yolk. Thus in *Amphioxus* the zygote has a very minute trace of yolk in its cytoplasm and its diameter is about 0.1 mm.; in the extinct bird *Aepyornis* of Madagascar, judging from the size of the shell, the zygote may have been as much as 160 mm. in diameter.

In the Mammalia of the most ancient type (Monotremata, *q.v.*), which still lay their eggs, these are large and richly yolked (*Echidna* 3.5 mm., *Ornithorhynchus* 2.5 mm.), and the young pass through the early development within the egg shell.

In the ordinary modem mammal, on the other hand, the egg is not laid in the ordinary sense. The zygote is retained within the uterus and there proceeds with its development, absorbing such nourishment as it requires from the mother. The store of yolk, no longer necessary, has disappeared and the zygote has reverted to the small size of from 0.1 mm. to 0.3 mm. in diameter.

Embryology of a Typical Vertebrate.—The basic features of vertebrate development can best be illustrated by an account of the transformations of the salamander embryo during the earlier formative stages. The first step following fertilization is the cleavage, by cell division, of the egg into a greatly increased number of smaller cells, together constituting the spherical *blastula* (fig. 1). The latter develops a cavity, the *blastocoele,* which is eccentrically situated because of the large amount of nutritive yolk stored in the cells composing the lower half of the embryo (fig. 2). There now ensues a remarkable process termed *gastrulation,* during which the primitive gut cavity and the germ layers are established. The first indication of the onset of gastrulation is the appearance of a small transverse indentation on the surface of the embryo below the equator (fig. 2). This groove is called the *blastopore,* and the tissue bordering it above, its *dorsal lip. Lateral* and *ventral lips* are formed as the groove extends to become crescentic and finally circular in form (figs. 7 and 8).

Meanwhile the original pocket formed beneath the overhanging dorsal lip has pushed deeper internally, where it gradually displaces the blastocoele and expands to form the primitive gut cavity, or *archenteron* (figs. 3 to 5). The understanding of the manner in which the archenteron is established is due largely to the classical studies of Walther Vogt. Fig. 6 represents a blastula on which a meridional series of closely spaced spots have been "painted" by the application of harmless dyes. As gastrulation proceeds the spots nearest the blastopore gradually disappear from view, until at the stage shown in fig. 7 all of the tissue lying between marks No. 5 and 10 has moved into the interior, where dissection shows it to form the roof and floor of the gut cavity. Before the latter is finally completed, at the close of gastrulation, all of the tissue below mark No. 4 moves in to share in its formation.

This inrolling of surface material, although initiated first at the dorsal lip and proceeding here most actively, takes place around the entire circumference of the blastopore as the lateral and ventral lips are formed. By applying spots of colour at various points on the blastula, Vogt was able to map out the portions of the blastula which are thus tucked into the interior, and to foretell what these invaginated materials will form after they have reached their new position. Some of this information is represented in fig. 6, showing the blastula in surface view just before the onset of gastrulation. Except for the area labelled

Fig. 9.—Transverse section of embryo in advanced stage of gastrulation. The roof of the gut cavity *(arch.)* is formed by the mesoderm. Later the lateral margins of the endoderm will grow upward (note arrows) and fuse to form an intestinal tube lined entirely with endoderm (see fig. 11). Fig. 10.—Dorsal view of embryo showing primordium of central nervous system. The tissue bordered by the horseshoe-shaped ridge will later form the brain and spinal cord. ***nf.***, neural fold. Fig. 11.—Transverse section of embryo at stage shown in fig. 10. ***nf.***, neural fold; ***np.***, neural plate; ***not.***, notochord. Fig. 12.--Showing the beginning closure of the neural folds to form the tubular central nervous system. Compare with fig. 10.

ectoderm, all of the surface tissue passes to the interior, where the regions marked mesoderm and *endoderm* constitute the germ layers bearing these names. Meanwhile the ectoderm undergoes a process of stretching or expansion which enables it to envelop entirely the two internal germ layers.

The diagram in fig. g shows the relationships of all three layers as seen in a transverse section of the embryo toward the completion of gastrulation. The mesoderm, which has invaginated at the dorsal and lateral lips (fig. S), forms an arched mantle roofing the archenteron and extending ventrally on either side between the ectoderm and endoderm. Its original continuity with the endoderm along the line labelled vl. in fig. 6 has become interrupted during the process of invagination. The lateral margins of the trough-like endoderm are seen to be pushing upwards (note arrows) and will later meet to form the definitive roof of the alimentary tube.

First, however, attention may be called to an important development which now ensues in the dorsal ectoderm. As viewed externally (fig. 10), this consists of the appearance of a pair of longitudinal ridges, the neural folds, continuous with one another anteriorly and converging posteriorly toward the blastopore, which is now greatly reduced in aperture and constitutes the anus. The neural folds bound a large horseshoe-shaped area of ectoderm, the neural plate, which will subsequently differentiate as the brain and spinal cord. The neural plate in transverse section, as well as the condition of the internal germ layers at this stage are represented in fig. 11. The gut cavity is now completely enclosed within the endoderm, through fusion dorsally of the processes noted in fig. 9, and the axial portion of the mesoderm has constricted off as a rod-like structure, the notochord, or forerunner of the backbone.

The neural plate, which at this stage is broad and flat, gradually becomes narrower and more trough-like as the folds bordering it laterally become further elevated and move closer together (fig. 12). They finally meet and fuse along the mid-dorsal line of the embryo, and it is in this manner that the tubular central nervous system of the vertebrate embryo is characteristically formed. The anterior portion of the tube later differentiates as the brain and the remainder as the spinal cord.

Following closure of the neural folds and the increasing elongation of the embryo one can begin to recognize the emergence of several organ primordia (fig. 13). The eye is visible as a bulge on the side of the head, and immediately below it is a depression in the epidermis which will later form the nasal passage communicating with the mouth cavity. The pit noted higher on the head subsequently sinks to the interior and differentiates as the membranous labyrinth (semicircular canals, etc.) of the internal ear. Elevated ridges mark the beginning outgrowth of the external gills, and further back the embryonic kidney, or *pronephros*, is becoming visible as a swelling beneath the skin. The dorsal portion of the mesoderm has become divided by transverse furrows into a number of segments, or somites, visible through the semitransparent skin.

The internal relationships at this stage are seen in fig. 15, which will also serve as a basis for indicating the subsequent fate of the principal structures shown. The notochord, after a transitory existence, is replaced by the vertebral column, formed by adjacent portions (sclerotomes) of the somites. The remaining tissue of the somites differentiates principally into the segmented muscles (*myotomes*) of the back, and, by a process of downgrowth, those of the abdominal wall. Meanwhile the spinal nerves grow out from the spinal cord to supply the muscles and the skin. The individual fibres constituting these nerves represent greatly elongated processes of the cells of the spinal cord; the sensory fibres to the skin growing out from the cells of the *neural* crest, and the motor fibres to the muscles from cells in the ventral portion of the cord. The so-called "white-matter" which gradually envelops the embryonic cord consists principally of innumerable nerve fibres connecting with the brain and other levels of the central nervous system.

The coelom, or cavity housing the viscera, originates as paired clefts formed by a splitting into two sheets of the lateral layers of unsegmented mesoderm. At first small (fig. 16), these clefts gradually expand, as room is made by the increasing withdrawal

Figs. 15, 16 and 17.—Diagrams illustrating the formation of the coelom, mesenteries, musculature of the body wall (myotomes), and the vertebral column. The aggregations of cells labelled *sclerotome* in Fig. 16 are budded off from the somites and later (fig. 17) form the vertebral column. The *neural crest* (fig. 15), in addition to forming the nerves (not shown) to the skin, gives rise to wandering cells which differentiate into chromatophores (see fig. 14).

of yolk from the wall of the gut into the blood stream, and eventually the medial sheets from each side meet to form the *mesentery* supporting the intestine (fig. 17). It is during this period of coelom formation that the myotomes grow ventrally beneath the skin to complete the musculature of the body wall.

In its broad outlines the preceding account of the early development of the salamander is applicable to vertebrates in general. For example, if we ignore the inevitable differences imposed by variations in the amount of yolk stored in the egg, the processes of cleavage, gastrulation, coelom formation, etc., are remarkably similar in such widely related vertebrates as the amphibians, fish and birds. One of the most notable differences between the embryos of the lower and higher vertebrates is the development by the latter of the extra-embryonic membranes, an innovation essential to embryos developing within a shell on land (reptiles and birds), and inherited and adapted by the mammal for uterine life.

The remainder of the article will be devoted to special accounts of the development of the various *organ systems*.

The Skin.—The skin of vertebrates is formed by the ectoderm, with a backing of tough connective tissue traversed in all directions by fine intercellular fibres and constituting the dermis. In all members of the group the epidermis, by cell multiplication, loses its original condition of being only one cell thick. In fish numerous epidermal cells become glandular and secret slime. From the lungfish upwards, local aggregations of these cells form definite flask-shaped glands, opening by minute pores on the body surface. These epidermal glands undergo specialization in various directions—salivary glands, poison glands, sweat glands, milk glands, etc. In terrestrial vertebrates the superficial ectoderm cells become converted into keratin, forming a horny layer which obstructs evaporation, and these horny cells are shed from time to time as loose scurf, as coherent flakes, or as a continuous slough (*e.g.,* snakes). In reptiles they form a hard layer, covering underlying bony plates in tortoise shell or the surface of the head in reptiles generally, or forming, with a dense backing of connective tissue, the scales of ordinary reptiles. Innumerable special developments of the horny layer occur, some of which will be found described in other articles: such are claws, feathers, hair, hoofs, rhinoceros horn, whalebone, etc.

The Nervous System.—In most of the more primitive holoblastic vertebrates the brain first becomes differentiated into an anterior cerebrum and a posterior rhombencephalon, demarcated from one another by an upward fold of the brain floor. Of these the former becomes later differentiated into the thalamencephalon in front and the mesencephalon behind. The cerebral hemispheres, which in the higher mammals assume great importance, seem to arise primitively as paired outward bulgings of the side wall of the brain towards its front end—related to the sense of smell. The main part of the thalamencephalon undergoes thickening of its side walls (optic thalamus) while its roof becomes for the most part degenerate, forming a thin membrane in intimate contact with a network of blood vessels (choroid plexus) lying immediately outside it. At its hind end an outgrowth—the pineal body—develops which may remain a simple club-shaped or tubular structure, but in several cases becomes differentiated into two portions, the anterior of which (parapineal) develops into an eye *(Sphenodon,* various lizards).

In front of the fold of the brain floor already alluded to. the floor of the thalamencephalon dips down as the infundibulum, and this becomes in the course of development closely associated with an independent structure—the pituitary body. In the more typical vertebrates the two become inextricably involved with one another and it is customary to speak of the nervous part of the pituitary body. The pituitary ingrowth of the ectoderm is typically a hollow pocket and in the surviving crossopterygians it retains this form through life, forming a gland which opens into the buccal cavity. In those vertebrates in which yolk is present at the site of its formation, the pituitary ingrowth is, as in other such cases, solid, developing its cavity secondarily.

The *organs* of *special sense* arise as localized developments of the ectoderm. In the case of the olfactory organ and the auditory organ, the rudiment shows first as a localized thickening of the ectoderm, which then, through extension in area, becomes involuted below the surface of the skin as a saucer-like depression. Finally, the opening to the exterior becoming gradually constricted, the organ assumes the form of a more or less completely closed vesicle. In the case of the olfactory organ the closure is never complete, the function, that of chemical testing of the surrounding medium, necessitating free communication between its cavity, in the lining of which the sensory cells develop, and the outside. In the majority of vertebrates however partial closure takes place, to divide the opening into two—one at each end of the organ—and so render possible the drawing in of a current of the external medium through the organ. The first vertebrates that have this power of "sniffing" are the lungfishes and the origin of the arrangement which makes this possible is well seen in *Protopterus,* where the opening of the olfactory organ narrows, except at its two ends, so as to form a slit. The edges of the slit then undergo fusion and the original single opening is now represented by two separate openings a considerable distance apart. As the anterior boundary of the buccal cavity becomes delimited, one, the anterior or external naris, is left outside and the other, posterior or internal naris, is enclosed within the buccal cavity, perforating its roof. In terrestrial vertebrates in general the olfactory organ becomes similarly provided with external and internal nares, though the process of development shows various modifications in detail.

The early stages of development of the otocyst or rudiment of the auditory organ are similar to those of the olfactory organ, but the reduction of the external opening goes further: in fact in all vertebrates except elasmobranchs, it becomes completely closed. The peculiar feature which distinguishes the vertebrate is that the usually pyriform otocyst of early stages undergoes a complicated process of modelling, whereby its wall comes to project into three hollow ridges situated in planes perpendicular to one another. The basal or attached portion of each of these becoming obliterated except at its two ends, the ridge is converted into an arched tube — the semicircular canal — opening at each end into the cavity of the otocyst and filled, like the rest of the otocyst, with watery endolymph. In all except the most archaic vertebrates, the otocyst undergoes a still further process of modelling whereby its lower portion (saccule), which develops a special pocket-like outgrowth devoted to the sense of hearing, becomes more or less completely constricted off from the upper portion or utricle, carrying the semicircular canals.

The vertebrate eye differs from the other sense-organs in that its main portion — that containing the actual sensory cells — is developed, not from the external ectoderm, but from the involuted portion of the ectoderm which forms the brain. In a typical case, as in a bird embryo, the optic rudiment consists in its earliest stage simply of the lateral portion of the wall of the thalamencephalon, which here extends outwards on each side so as to give the brain a T-shape. As development proceeds the optic rudiment becomes narrowed at its base to form the optic stalk, which later will become the optic nerve. The distal dilated portion gives rise to the retina, while the region of external ectoderm in contact with its outer end gives rise to the lens. In a typical case, *e.g.*, a bird, the lens is at first simply a slight thickening of the ectoderm, but this soon sinks inwards to form a saucer-shaped depression of the surface, which, by a gradual narrowing of its opening, becomes converted into a closed vesicle. The deep wall of this becomes greatly thickened, its individual cells becoming tall and columnar, and gradually takes on the form of a biconvex lens, the outer wall forming a thin layer of epithelium covering its outer surface. As development goes on the cells of the lens become keratinized and transparent.

Meanwhile the original optic rudiment is undergoing differentiation. Its distal portion next the lens becomes involuted within the proximal portion, so that the whole rudiment now takes the form of a double-walled optic cup the mouth of which is blocked by the lens. The inner wall of the cup increases much in thickness and gradually assumes the immense complexity characteristic of the functional retina, of which the most striking peculiarity is that the visual cells are situated on its deep face, the sensory rods facing not towards the lens but away from it — so that rays of light have to traverse the whole thickness of the retina, which is therefore necessarily transparent. On the other hand, the nerve-fibres which pass from the retina to the brain emerge from the retina on its face next the lens, instead of from its deep face as one would expect. This extraordinary reversal of the vertebral retina is at once explained by the method of its development, the deep surface carrying the rods having been originally, before the involution of the brain rudiment took place, part of the outer surface of the head. The outer layer of the optic cup undergoes none of the complicated histogenesis seen in the retina. It persists as a single layer of polygonal cells within which there is deposition of granules of dark melanin pigment. They constitute what is termed the pigment layer of the retina.

The ectodermal lens and retina, which constitute the essential optical part of the eye, become ensheathed during development by a thick coating of connective tissue or mesenchyme. This, in its outer layers, becomes condensed into the tough protective wall of the eyeball, the part between the lens and the surface of the head becoming clear and transparent (cornea) while the remainder becomes white and opaque (sclerotic). Between the sclerotic and the pigment layer of the retina there is a rich development of blood spaces and of dark melanin, which gives its characteristic appearance to the choroid.

Alimentary Canal. — The alimentary canal of the vertebrate is in its early stages closed anteriorly, the mouth being a secondary perforation. As in many other animals, the portion of external surface in the region of the mouth becomes involuted to form the lining of the buccal cavity, so that the protective and glandular functions of the skin extend inwards into the first portion of the alimentary canal. The buccal cavity of the vertebrate is therefore morphologically a stomodaeum. For a time, in many vertebrate embryos, the stomodaeal involution remains isolated from the rest of the alimentary canal by a thin partition, covered on its buccal face by ectoderm, on its enteric face by endoderm. This partition eventually ruptures and disappears, although in *Amphioxus* it remains distinctly visible as the velum, perforated in its centre by a circular opening.

The most important features to note in the buccal cavity of the vertebrate are the organs in its lining which have been brought in from their original position on the outer surface of the head. Among these are glands which become of special importance in terrestrial vertebrates, where their watery secretion serves to keep moist the buccal lining, and in certain cases play a preliminary part in the digestive process, as the salivary glands. Still more conspicuous however are the placoid scales, which, in the primitive elasmobranch scattered all over the outer surface of the body, are also recognizable in the buccal lining. Around the margin of the jaw a series of these placoid scales become specially enlarged, forming the teeth of the adult. The embryology of the elasmobranch then demonstrates that the teeth of vertebrates are vestiges of the placoid scales on the surface of the body.

The buccal cavity is continued into the pharynx, characterized in all vertebrates by the development of (1) the gill clefts or pouches and (2) the thyroid. The gill clefts, normally six in number, arise as pocket-like extensions of the pharyngeal wall (visceral pouches), which at their tips undergo fusion with the external ectoderm and open to the exterior, the original visceral pouch becoming thus converted into a visceral cleft, lined with endoderm except towards its outer end, where the lining is ectodermal. The cleft lining, in view of its respiratory function, undergoes increase of area by growing out into folds (respiratory lamellae) and develops a rich blood supply.

Visceral cleft I develops in all gnathostomes characteristic differences from the others. In elasmobranchs its respiratory lamellae are reduced to the vestigial pseudobranch on its anterior wall, its function being, as in crossopterygians and sturgeons, that of a mere passage for the water of respiration. In Dipnoi its outer ectodermal end forms a sensory organ (organ of Pinkus) embedded in the side of the head. In these and in all terrestrial vertebrates, it has lost its communication with the exterior. In anurous amphibians and in all amniotes it expands towards its outer end into a wide tympanic cavity lying immediately under the skin so as to allow a wide flat area of the latter to vibrate freely (tympanic membrane or eardrum). The pharyngeal portion of the cleft remains as the narrow Eustachian tube, providing a means of keeping the air pressure equal on the two sides of the eardrum.

While the presence of pharyngeal visceral clefts constitutes one of the most striking vertebrate characteristics, the evidence of comparative anatomy clearly indicates that the series of clefts is undergoing a gradual process of reducticn. This is shown by the diminishing number of clefts present in the series *Amphioxus*—cyclostomes (up to 14 in *Bdellostoma*)—Gnathostomata. Embryology shows us this process of reduction actually at work. In various elasmobranch embryos vestigial pouches appear behind those which actually develop into clefts. In teleosts the vestigial spiracular rudiment flattens out while its pseudobranch remains visible on the inner surface of the operculum, thus appearing in the adult as if it belonged to visceral cleft II. The operculum of fishes above elasmobranchs is simply the exaggerated valvular flap formed by the outer edge of visceral arch II (hyoid) which grows back to cover the visceral clefts further back in the series.

The thyroid, an equally characteristic development of the vertebrate pharynx, arises as a mid-ventral downgrowth of the pharyngeal floor about the level of the hyoid arch. This rudiment, arising either as a hollow pouch or as a solid structure which develops a cavity secondarily, soon becomes isolated from the pharynx as a closed vesicle, and this in turn becomes subdivided into a multitude of little spherical sacs of endoderm separated by mesenchyme, in which there arises a rich network of blood spaces. The endodermal epithelium is glandular, producing a clear colloid secretion which distends the numerous rounded vesicles. In its later development the thyroid differs in different vertebrates. It may, as in teleostean fishes, become diffuse and no longer recognizable as a compact organ, while in tetrapods it retains its compact form but becomes more or less completely separated into a right and left lobe. The clue to the evolutionary history of the thyroid is given by the embryology of the lamprey (Petromyzon), in the larva of which it is recognizable as an endostyle, an organ known also in *Amphioxus* and Tunicates.

The lung, a characteristic feature in the main groups of Vertebrata above the elasmobranchs, arises normally from a rudiment very similar to that of the thyroid, only situated farther back, about the hinder limit of the pharynx. Normally unpaired at first, the rudiment soon divides into right and left branches. In simple urodeles each lung remains a thin-walled membranous sac, but in other tetrapods increase in area of the endodermal respiratory lining is brought about by its bulging out into more and more complicated recesses, culminating in large reptiles and in mammals in a spongy texture. In birds, the endoderm-lined cavities of the lung become converted into fine tubular channels (air capillaries) interwoven with the blood capillaries and constituting the most highly evolved respiratory organ known. To enable it to function, a bellowslike arrangement is formed by pocketlike outgrowths of the lung wall which become greatly dilated and constitute the air sacs. Portions of these grow out into the substance of the bones, replacing the bone marrow, while others extending in among the muscles of flight provide a mechanism whereby air is automatically passed in and out through the air capillaries during flight.

The postpharyngeal portion of the alimentary canal forms the digestive tube and in different vertebrates undergoes varying degrees of differentiation into distinct parts. The great glands of the intestine arise in the embryo as pocketlike diverticula of its wall. The pancreas is peculiar in that it arises normally from three distinct diverticula--a pair situated ventrally in the neighbourhood of the bile duct, and the third dorsal. The pancreas of the adult is formed by the fusion of these three rudiments and it may retain (birds) all three openings to the intestine; *i.e.,* three distinct pancreatic ducts.

Coelomic Organs.—The *coelom* or body cavity becomes normally subdivided into a smaller pericardiac and a larger peritoneal cavity. In some of the more archaic vertebrates (*e.g.,* elasmobranchs) the two cavities remain continuous through a narrow pericardioperitoneal canal.

The loss of the primitive coelomic segmentation has brought with it characteristic modifications in the development of the archinephros or series of nephridial tubes.

It is a normal characteristic of the embryo of metamerically segmented animals that the head end, with its special nerve centres and sense organs, develops first, the process of development spreading slowly tailward, and this principle applies to the nephridial tubes as to other organs. The disappearance of the coelomic septa in the Vertebrata has, however, eliminated the necessity of each segment having its independent pair of drainage tubes. There has accordingly come about a loss of the serial regularity in the development of the nephridial tubes and these tend to develop in three successive batches, known as pronephros, mesonephros and metanephros. Of these the pronephros is the functional kidney in the early stages of those vertebrates in which these stages are free living (larval). Where, on the other hand, early development is embryonic, it no longer becomes a functional organ, the excretory products presumably passing away by diffusion from the extensive network of blood vessels on the surface of the yolk. The pronephros is purely larval: eventually it atrophies, a pair of its nephrostomes, however, persisting in greatly enlarged form, at least in selachians, as the ostia of the oviducts. The excretory function is now carried out by the series of tubules extending back to the region of the cloaca and termed the opisthonephros. In the fishes and amphibians, this constitutes the kidney of the adult, though already in many of these (*e.g.,* elasmobranchs and urodeles) there is seen a tendency for the excretory function to become concentrated in the hind portion of the opisthonephros, its front portion remaining small and serving for the transmission of the spermatozoa. This condition foreshadows that of the Amniota in which the opisthonephros has become completely divided into mesonephros and metanephros. The former, representing the greater part of the opisthonephros, acts as the functional kidney during embryonic life but later becomes purely reproductive, forming the epididymis attached to the testis. The metanephros—the extreme hind end of the opisthonephros, in which the tubules become greatly increased in size and number—alone forms the kidney of the adult amniote.

The renal organs of vertebrates present many other features of embryological interest. In various of the more archaic types the rudiments of the first pronephric tubules, in the form of little outgrowths of the somatic mesoderm, bend backward at their outer ends and become joined together, forming in this way the rudiment of a longitudinal duct (archinephric duct) which gradually extends back, receiving the successive tubules which undergo fusion with it, and eventually opens into the cloaca. This opening of the tubules into a longitudinal duct instead of directly to the exterior constitutes one of the striking differences between the Vertebrata and the Annelida.

In elasmobranch fishes the archinephric duct becomes split longitudinally into two—a Mullerian duct, into which opens the persistent pronephric nephrostome, and a Wolffian duct, into which open the tubules of the opisthonephros. Functionally, the former becomes the oviduct. In the Amniota the functional tubules of the metanephros open into a third duct—the ureter—while the Wolffian duct now functions exclusively as a vas deferens or male genital duct.

The gonads—ovaries or testes—develop from a pair of elongated ridges, the genital ridges, which arise just mesial to the kidneys. In the female, the reproductive cells (eggs or macrogametes) are still shed into the coelom, finding an exit through the Mhllerian ducts. In the male, however, the testis is shut off as an isolated chamber into the cavity of which the reproductive cells (spermatozoa or microgametes) are shed. They eventually reach the vas deferens by way of fine tubular channels (vasa efferentia), which arise in the embryo as outgrowths from the wall of certain of the Malpighian bodies.

The mesenchyme cells, distributing themselves through the body of the embryo, settle down into spongy connective tissue which forms a support and backing to the various developments of ectoderm and endodern. As development proceeds, special tracts take on special characters—fatty tissue, tendon, ligament and so on—but there are two developments of the mesenchyme which are of special importance. These are the vascular and the skeletal systems.

Vascular System.—The blood vessels originate from condensations of mesenchyme cells which hollow out into channels containing the watery tissue fluid which bathes all the cells of the embryo The corpuscles may arise either *in situ,* by differentiation of central cells of the original mesenchyme aggregations, or may enter the blood stream from special centres of proliferation, ahich include, especially in later developmental stages, liver, bone marrow and lymphatic glands Detailed study of the later development of the blood system shows that it provides a most interesting chapter in vertebrate embryology The fundamental plan is seen to be that of two main longitudinal blood vessels, one ventral to the alimentary canal, in which the blood runs forward, and one dorsal (dorsal aorta), in which the blood streams in a tailaard direction, these two longitudinal vessels being connected by a series of hooplike aortic arches, situated between the gill clefts, in uhich the blood passes from the ventral vessel to the dorsal The vertebrate heart consists of the portion of the ventral vessel immediately behind the pharynx, in which contraction of the vessel wall, elsewhere comparatively inconspicuous, becomes greatly exaggerated and occurs rhythmically throughout life

The *heart or cardiac tube* is that part of the ventral vessel which is contained within the pericardiac chamber At first straight, its rapid increase in length, combined uith the fact that it is fixed at each end where it traverses the pericardiac wall, causes it to assume a characteristic S-shaped curvature As may be well seen in the embryo of a fowl during the third day of incubation, waves of contraction pass forward along the cardiac tube, propelling the blood in its interior forward toward the aortic arches. As development proceeds the originally uniform cardiac tube becomes at intervals relatively enlarged to iorm a series of four dilatations. demarcated from one another by relatively less dilated portions. These four dilatations become the sinus venosus, atrium, ventricle and conus arteriosus. With this morphological change in diameter comes a physiological change in that the originally uniform wave of contraction becomes replaced by serial contractions of each chamber in turn. As development proceeds further, the four chambers become compacted together and the original tubular shape of the heart is completely lost. The pumping activity of the heart becoming more and more concentrated in the ventricle, the muscular wall of this part becomes much more highly developed than that of the others.

To secure that the blood stream flows in the proper direction a valvular apparatus becomes developed in the interior of the heart and this, in its earliest stages, takes the form of longitudinal ridgelike thickenings oi the inner layer oi the heart wall. These are best seen in the conus arteriosus, where they are normally four in number and where they are jammed together when the conus contracts, obliterating its cavity and so preventing any backward suction when the ventricle dilates. These endocardiac ridges, dependent for their efficiency upon physiological activity, become in such relatively archaic vertebrates as elasmobranchs and ganoids converted into a purely mechanical apparatus which works automatically, each ridge becoming segmented into a row of valves shaped like match pockets, with their openings directed toward the head. These flatten against the wall when the blood streams forward, but open out and occlude the cavity by their edges coming in contact the moment the bloods tends to regurgitate. In the air-breathing vertebrates from lungfish upward, the conus with its valvular apparatus undergoes an extraordinarily interesting series of evolutionary changes. In the lungfish the conus is relatively long and is bent into a characteristic Z-iorm. Along its interior run the four endocardiac ridges. Two of these, the right and the left, project as thin bladelike structures more than haliway across the lumen, their free edges overlapping so that they subdivide the cavity into two portions, one dorsal and one ventral. The two cavities are continued forward into the ventral aorta by a horizontal partition which extends as far forward as the level of aortic arch V where it merges into the roof of the ventral aorta. Aortic arches V and VI take oripin irom the dorsal or pulmonary cavity, while the remaining aortic arches spring irom the continuation forward of the ventral cavity. The atrioventricular portion oi the heart also has its cavity divided, in this case by a vertical septum projecting forward from its posterior wall. This septum is incomplete, not extending completely across the atrioventricular cavity except when the wall of this part of the heart is contracted. Owing to the peculiar flexure of the conus, its incomplete septum — horizontal at its front end — becomes at its ventricular end vertical and in line with the atrioventricular septum. The result is that, in the contracted condition of the ventricle, the right hali of its cavity is continuous with the right half of the cavity of the conus and this cavity, owing to the peculiar flexure, ends off at its headward end by being dorsal, *i.e.,* continuous with the pulmonary cavity of the ventral aorta.

Correspondingly the leit ventricular cavity is continued through' the conus to the ventral or systemic cavity of the ventral aorta.

In the tetrapods the conus develops endocardiac ridges similar to those seen in lungfish, but the conus has now greatly shrunken in length, with the result, owing to its ends being fixed, that the Z-flexure is drawn out and replaced by a spiral twist. Further, in the Amniota, the two prominent ridges, which in the lungfish merely overlap, undergo complete fusion, so that the cavity of the conus, as of the ventral aorta, becomes divided completely into pulmonary and systemic cavities, continuous respectively with the right and left ventricles, which also become completely separated during development. In the higher Amniota the septum so iormed in the conus becomes itseli split, so that the conus comes to be represented by two separate vessels, pulmonary and systemic, spirally twisted round one another.

Of all features in the development of the blood system of vertebrates, perhaps the most interesting is that the great arteries of the higher amniotes repeat in the course of their development the series of aortic arches between the visceral clefts. Although the bird or human being will never use its gill clefts for breathing, yet it shows for a time the typical piscine arrangement of aortic arches. As development proceeds, large tracts of this primitive scheme disappear while others persist and become straightened out into the great arteries of the adult.

The *venous system* of the vertebrate shows also many features of interest in its embryology. Perhaps the most important of these is that the venous system of the higher vertebrates shows for a time in the embryo the same main trunks — duct of Cuvier, anterior and posterior cardinal veins — as those of an adult fish. The main new development in the venous system of tetrapods, the inferior or posterior vena cava, presents the striking peculiarity that it has a double origin in the embryo. its anterior portion being associated with the liver and its posterior portion with the posterior cardinal veins. This points to the posterior vena cava having originated in evolution from an arrangement similar to that of modern dinnoans. where the anterior end of the opisthonephros is fused with the tip of the liver, thus rendering possible the direct passage of blood from kidneys to heart through the liver substance.

The Skeletal System. — The vertebrae are formed from cells oi the segmented mesoderm (somites), and differentiate first as paired cartilaginous rudiments of the neural and haemal arches, two pairs of each in the lower types within the length of a single muscle segment. In two of the more archaic groups, Elasmobranchii and Dipnoi, cartilage cells from the arch-rudiment burrow through the primary sheath and colonize the secondary sheath of the notochord. The notochord thus becomes enclosed in a cylinder of cartilage, which in the elasmobranch becomes segmented into vertebral centra, each carrying two pairs oi neural and of haemal arches. In other vertebrates this invasion of the secondary sheath by cartilage cells does not take place, and the centra arise outside the primary sheath by expansion of the bases of the arches. In the head region traces of cartilaginous vertebrae can be traced in various archaic vertebrates as far forward as the tip of the iniundibulum, the hinder region of the cranium representing a part of the axial skeleton in which the vertebral segmentation has disappeared and the neural canal become greatly enlarged in correlation with the expansion of the central nervous system to form the brain. The olfactory organ and the otocyst each becomes enclosed in a capsule of cartilage and these become incorporated in the complete cranium. The anterior portion of the cartilaginous cranium, including the capsule of the olfactory organ, has been demonstrated to arise in large part from the cranial neural crest (see fig. 15). Most of the cartilaginous visceral skeleton has a similar origin. The principal elements of the limb skeleton are also preformed in cartilage. Later the cartilaginous skeleton of the embryo is largely replaced in the adults of most vertebrates by bony tissue.

In addition to those portions of the skeleton already mentioned, which appear first in cartilaginous form, there are many elements which develop directly into bone from membranous concentrations of mesenchyme. In the typical mammal these are confined principally to the skull, but in lower types such as the turtle, and in many extinct forms, they are often abundant in other portions of the body as variously sized plates situated in the deeper part of the skin. These are believed to have evolved irom enlarged or compound dermal scales. In the elasmobranch, the placoid scales of the skin extend into the buccal cavity, where some oi them enlarge to form the teeth. In other lower vertebrates, embryology demonstrates that the bones which underlie the base of the cartilaginous cranium and reinforce it are formed of originally separate denticles, which become united into a continuous plate by the spreading out and fusion of their basal portions. This origin through fusion of small scalelike elements is no longer evident in the embryonic development of the homologous dermal bones of the higher vertebrates, including man.

Adaptations to Environment. — In certain cases the environment and the young individual's relations to it present no special peculiarities. The young crossopterygian or lungfish or urodele leads a normal kind of aquatic existence and the strikingly uniform type of larva in these three relatively archaic vertebrates suggests strongly that it repeats an early stage of vertebrate evolution. In most vertebrates, however, development is either embryonic or secondarily larval. In elasmobranchs, in teleosts and in reptiles and birds, the early stages are passed within the shelter of egg envelopes and this involves the modifications associated with the storing up of a supply of yolk— modifications which still persist in cases such as the majority of teleosts, where a larval mode of development is re-acquired. Embryonic development is seen in its highest expression in the terrestrial vertebrates and these, in addition to the immense exaggeration of the ventral part of the endoderm to store up yolk (*yolk* sac), show two other striking peculiarities: (1) the body of the embryo becomes enclosed in a water jacket (*amnion*) in which it floats suspended and is thus protected from the sudden jars incidental to a terrestrial existence. and (2) the allantois (the pouchlike outgrowth from the hinder end of the alimentary canal which in the amphibian functions as a urinary bladder) becomes precociously enlarged and, spreading around the inner surface of the egg shell, constitutes the breathing organ during a large part of embryonic life. In ordinary mammals the allantois has developed a new function, that of absorbing nourishment from the uterine wall, and in correlation with this, the supply of yolk, which in the reptilian egg was so conspicuous, has now disappeared almost entirely.

VERTIGO AND DIZZINESS. Dizziness is a subjective symptom of disturbed stability. not a specific disease. In its mild form it may be a sensation of weakness, giddiness, confusion, insecurity or unsteadiness. Its severer form — properly designated as vertigo — is a feeling of whirling or propulsion, often accompanied by sweating, nausea. vomiting and inability to stand.

Normal stability (or the feeling of proper orientation in space) is controlled by a balanced interaction of three body mechanisms: (1) the muscles and joints of the body; (2) the muscles of the eyes; and (3) the end organ of equilibrium, situated in the internal ear and consisting of three small, extremely sensitive semicircular canals so related to each other that body motion in any direction stimulates one or more of them.

The motion that stimulates the semicircular canals, and to a lesser degree the other two mechanisms, may be voluntary or caused by an external force such as the rhythmic movement of a swing, an airplane or a ship. It sets up nervous impulses that are immediately transmitted to the brain. The brain, in turn, automatically (by reflex action) relays the message back to the muscles through an intricate pathway of nerves. The result is prompt adjustment of the body to changes of its position in space. If prompt adjustment cannot be made—either because the equilibrium system is not working properly or because of inability to compensate for abrupt or sustained unaccustomed motion—dizziness or vertigo will probably ensue. Ability to adapt to motion varies, which explains why some persons become sick and dizzy on a boat or on an airplane while others do not.

Mild forms of dizziness (without whirling) may result from causes other than motion. Commonest are eye-muscle or visual disturbances, chronic alcoholism, anemia. changes in blood supply to the brain when blood pressure falls, fainting, certain infections of the coverings of the brain, injury to the head, mild forms of epilepsy, lowering of blood sugar and, sometimes, tension.

Whirling vertigo is usually produced by disturbances of the ear and its pathways to the brain. Some of these are: infections of the middle and internal ear (including mastoid infection), toxicity from drugs. allergy, Ménière's disease, meningitis, brain tumours, strokes and certain neurological diseases such as multiple sclerosis. Vertigo may also follow head injuries, skull fractures or any conditions that produce bleeding into the internal ear or its nervous connections or that suddenly shut off the blood supply.

Because of the multiplicity of causes, of which those mentioned constitute only a partial list, it is often necessary to conduct detailed diagnostic studies before specific cause is determined.

VERTUE, GEORGE (1684–1756). English engraver and antiquary, who collected records of English art. was born in London, where he began to engrave portraits after Sir Godfrey Kneller about 1709. He soon acquired a large practice; among his chief works, besides his many portrait engravings. were the Oxford Almanac (1713–51) and the plates to Paul Rapin's History *of England* (1736).

In 1717 Vertue was made engraver to the Society of Antiquaries of London and elected a fellow. The plates of his "Historic Prints" from Tudor paintings are still owned by the society. Skilled though he was as an engraver, his notebooks. which provide a major primary source of information concerning art in England. add to his importance. These, mainly in the British museum. were used hy Horace Walpole as the foundation of his Anecdotes of *Painting* in England (4 vol., 1762–71), and have been published in full by the Walpole society. Vertue died in London. July 24, 1756, and was buried in the cloisters of Westminster abbey.

See *Walpole* Society, vol. xviii, including autobiography (1930), vol. xx (1932), vol. xxii (1934), vol. xxiv (1936), vol. xxvi (1938), vol. xxix (1942) and vol. xxx (1950). (M. D. WY.)

VERTUMNUS, in Roman cult, a god of uncertain functions and origin, although he probably was from Etruria (Volsinii). The Romans later connected his name with Lat, vertere ("turn." "change"). and thus he became a god of the changing year with its seasons, its flowers and its fruits. In the last connection he is found associated with Pomona (*q.v.*). Ovid records the story of his wooing of Pomona, which is brought to a successful conclusion by Vertumnus' power to change into any form he wishes (*Metamorphoses*, xiv, 641 ff.). He had a shrine and statue in the Vicus Tuscus marking the spot where. according to one tradition, the god turned back an inundation of the Tiber. The appropriate offerings here were the first fruits of the changing season. From the god's connection with this busy street he was regarded as having a special interest in trade and barter, also forms of exchange.

Vertumnus had in addition a temple on the Aventine, dedicated in 264 B.C., where an annual sacrifice was performed on Aug. 13, an appropriate time for ripening of fruit.

VERULAMIUM, a Romano-British town situated in the territory of the Catuvellauni, close to the modern St. Albans (Hertfordshire). Before the Roman conquest it was the capital of Tasciovanus, prince of the Catuvellauni, who issued coins inscribed with the name of the place, and of his son, Cunobelin; afterward it received the dignity of a municipium (implying municipal status and Roman citizenship). Tacitus tells us that the town was burned by Boadicea (*q.v.*), in A.D. 60 or 61, but it again rose to prosperity. The visit of Germanus to the tomb of St. Alban shows that it was still inhabited in 429. Its site is still easily recognizable. Its walls of flint rubble survive.

VERVAIN (Verbena *officinalis*), a plant of the family Verbenaceae (*q.v.*), native to Europe and Asia, common in the south of England and naturalized across the continent of North America. It is a smooth slender annual, one to three feet high, with opposite, deeply incised leaves and numerous very slender spikes of purplish or white flowers. In the U.S. the name vervain is applied to several native species of Verbena, as the white vervain (V. *urticifolia*), the blue vervain (P. hastataj, the hoary vervain (*V.* stricta), the bracted vervain (V. *bracteata*) and the spreading vervain (V. *prostrata*). Most of these interhybridize. To the vervain, which was held in superstitious veneration by the ancient peoples of Great Britain, were ascribed remarkable medicinal virtues, now wholly discredited. *See* also VERBENA.

VERVET, a Central and South African monkey. *Cercopithecus aethiops pygerythrus.* It is allied to the grivet (*q.v.*), but distinguished by the presence of a rusty patch at the root of the tail and by the black chin, hands and feet.

VERVIERS, a town, province of Liège, Belg. Pop. (1955 est.) 37.843. It is on the Vesdre, which flows into the Ourthe a few miles before its junction with the Meuse; and the water of that river is supposed to be especially good for dyeing purposes.

VERWEY, ALBERT (1865–1937), Dutch man of letters, was one of the leading figures of the revival of Dutch literature, called "the movement of 1880." He helped to found and from 1884 to 1889 was one of the editors of the *Nieuwe Gids;* from 1894 to 1904 of the Tweemaandelijksch *Tijdschrift* and De *XXe Eeuw,* and from 1905 to 1919 of De *Beweging*. In 1924 Verwey was appointed professor of Dutch literature in the University of Leyden. His anthology with commentaries of *Nederlandsche* Dichters *behalve Vondel* (1893, etc.) and his essay on Potgieter and his circle, Het *Testament* van Potgieter (1908), are works of lasting value. Verwey, who held an honorary doctor's degree from the University of Groningen, translated into Dutch Shelley's 4 *Defence* of Poetry, Sidney's *An* Apology for Poetry (1891) and Shelley's *Alastor* (1922j. In 1885 he issued an article on The Sonnet and the Sonnets of Shakespeare.

He published several volumes including *Inleiding tot* de *nieuwe Nederlandsche* dicht *Kunst, 1880–1900* (1914) ; *Proza* (1911, etc.); De *Maker* (1924); and *Rondom mijn Werk, 1890–1923* (1925).

VESALIUS, ANDREAS (1514–1564), founder of modern anatomy. was born in Brussels, son of a well-to-do court apothecary and educated at Louvain and afterward (1533–36) at the University of Paris. There he came under the influence of the great teachers of anatomy, Jacques Dubois (Sylvius) and Johann Guenther of Andernach. The latter's Latin translation (1531) of the *De anatomicis* administrandis of Galen deeply impressed him by its practical character. After a time spent in Louvain, where he reintroduced the study of human anatomy, Vesalius left for Padua in 1537 where he obtained his M.D. and was appointed lecturer in surgery and anatomy. His success was immediate. and in 1538 he published at Venice, in collaboration with his fellow countryman the artist Jan van Calcar, his Tabulae *anatomicae* sex.

These six very large plates are a landmark in the history of anatomical nomenclature, for they embody an attempt to standardize both the form and the meaning of anatomical terms, contrasting the newly interpreted Greek terms with those of the middle ages, many of which originate in Arabic and Hebrew. Modern anatomical nomenclature is directly descended from that adopted by Vesalius. The physiology he presents is largely that of Galen.

During 1539–42 Vesalius prepared his masterpiece, the *De humani corporis fabrica.* For this he had the help of artists, of whom one was of very great ability; it is likely that Calcar was responsible for some of the illustrations but was not the most significant artistically. The *Fabrica,* published in 1543 as an enormous folio at Basel by the printer Johannes Oporinus (Herbst), is beyond dispute one of the great books of the 16th century. Its figures introduced a new standard into illustrated works in general and medical works in particular. Despite its turgid and verbose character, the text is of great importance both as a clear statement of the need for introducing a scientific method into the study of anatomy and for the many important discoveries that are presented in its seven books: i and ii, on bones, ligaments and muscles, with figures of superlative excellence and accuracy; iii, on the blood vessels, probably partly illustrated by Vesalius himself and inferior to i and ii; iv, on the nerves, conservative and closely following Galen; v, on the abdominal viscera, a considerable advance on any previous work; vi, on the thoracic organs, too brief, sometimes confused and erroneous; vii, on the brain, a pioneer work of great importance. The *Fabrica* was an immediate success and was reprinted, pirated, abridged, copied and translated. It heralds the advent of biology as a science. At the same time, Vesalius issued what he miscalled an *Epitome* of it, a work for students of art rather than of medicine. In 1555 he produced a new edition of the *Fabrica* with a vast number of alterations of content and style of presentation. The typography and layout of the illustrations greatly surpass those of the first edition.

Vesalius' other works are of lesser scientific importance, and the rest of his life has little scientific interest. Leaving Padua, he accepted the position of physician to the imperial household of Charles V and in 1559 to the royal household of Philip II. In 1564 he undertook a pilgrimage to Jerusalem but died on his way back. Romantic stories and myths have accumulated round his career. Of his character little is known save that he had a mordant wit. *See* also ANATOMY, GROSS: *History of Anatomy.*

VESPASIAN, in full TITUS FLAVIUS VESPASIANUS, Roman emperor A.D. 70–79, was born on Nov. 18, A.D. 9, in the Sabine country near Reate. After having served with the army in Thrace and been quaestor in Crete and Cyrene, Vespasian rose to be aedile and praetor, having meanwhile married Flavia Domitilla, by whom he had two sons, Titus and Domitian, afterwards emperors. Having already served in Germany, in the years 43 and 44, in the reign of Claudius, he distinguished himself in command of the 2nd legion in Britain under Aulus Plautius. He reduced Vectis (Isle of Wight) and penetrated to the borders of Somersetshire. In 51 he was for a brief space consul; in 63 he went as governor to Africa, where, according to Tacitus (ii, 97), his rule was "infamous and odious"; according to Suetonius (*Vesp.* 4), "upright and highly honourable." He went with Nero's suite to Greece, and in 66 was appointed to conduct the war in Judaea.

On the first of July, 69, while he was at Caesarea, he was proclaimed emperor, first by the army in Egypt, and then by his troops in Judaea. The legions of the East at once took the customary oath of allegiance. Nevertheless, Vitellius, the occupant of the throne, had on his side the veteran legions of Gaul and Germany, Rome's best troops. But the feeling in Vespasian's favour quickly gathered strength, and the armies of Moesia, Pannonia and Illyricum soon declared for him, and made him in fact master of half of the Roman world. They entered Italy on the northeast under the leadership of Antonius Primus, defeated the army of Vitellius at Bedriacum (or Betriacum), sacked Cremona and advanced on Rome, which they entered after furious fighting, in which the Capitol was destroyed by fire. The new emperor received the tidings of his rival's defeat and death at Alexandria, whence he at once forwarded supplies of corn to Rome, which were urgently needed, along with an edict or a declaration of policy, in which he gave assurance of an entire reversal of the laws of Nero, especially those relating to treason.

Leaving the war in Judaea to his son Titus, he arrived at Rome in 70. He at once devoted his energies to repairing the evils caused by civil war. He restored discipline in the army, which under Vitellius had become utterly demoralized, and, with the cooperation of the senate, put the government and the finances on a sound footing. He renewed old taxes and instituted new, increased the tribute of the provinces, and kept a watchful eye upon the treasury officials. By his own example of simplicity of life, he put to shame the luxury and extravagance of the Roman nobles and initiated in many respects a marked improvement in the general tone of society. By taking over the censorship, the last of the republican magistracies, he gained complete control over the entry to the senate. He altered the constitution of the praetorian guard, in which only Italians, formed into nine cohorts, were enrolled, while Italians seem to have been excluded from the legions; he tended to assimilate the auxiliaries to the legions in personnel. The time-expired men, when they went back to their homes, he made use of to promote the urbanization and Romanization of the more backward and unorganized provinces. In 70 a formidable rising in Gaul, headed by Claudius Civilis, was suppressed and the German frontier made secure; the Jewish War was brought to a close by Titus's rapture of Jerusalem, and in the following year, after the joint triumph of Vespasian and Titus, the temple of Janus was closed, and the Roman world had rest for the remaining nine years of Vespasian's reign. In 78 Agricola went to Britain, and both extended and consolidated the Roman dominion in that province, pushing his arms into north Wales and the Isle of Anglesey. In the following year Vespasian died, on June 23.

The "avarice" of Tacitus and Suetonius seems to have been an enlightened economy, which, in the disordered state of the Roman finances, was an absolute necessity. Vespasian could be liberal when he chose, as Quintilian's pension shows. Pliny's great work, the *Natural History,* was written during Vespasian's reign and dedicated to his son Titus. Of the philosophers who encouraged conspiracy by republican theorizing only one, Helvidius Priscus, was put to death, and he had affronted the emperor by studied insults. "I will not kill a dog that barks at me," were words honestly expressing the temper of Vespasian.

Much money was spent on public works and the restoration and beautifying of Rome—a new forum, the splendid temple of peace, the public baths and the vast Colosseum being begun under Vespasian. The roads and aqueducts were repaired, and the limits of the *pomerium* extended.

The most important of his changes in the provinces was the reorganization of the eastern provinces, whereby Judaea became a province of its own, Syria absorbed the vassal kingdom of Commagene and had its legionary forces strengthened and centred at Samosata, and Cappadocia and lesser Armenia were absorbed in Galatia, whose governor also was given legionary troops to hold the upper river, stationed at Melitene; second to this comes the annexation of the *agri decumates,* the first step to cutting out the salient in the Rhine-Danube frontier. Mention may be made of his extension of Latin rights to Baetica.

To the last, Vespasian was a blunt soldier, with strength of character, and with a steady purpose to establish good order and secure the prosperity and welfare of his subjects. In his habits he was punctual and regular, transacting his business early in the morning, and enjoying his siesta after a drive. He was free in his conversation. and his humour was apt to take the form of coarse jokes. Characteristic is the exclamation he is said to have uttered in his last illness, "An emperor ought to die standing."

VESPERS, in the Roman Catholic liturgy, the seventh of the eight "hours" which make up the daily office. (*See* BREVIARY.)

VESPERS, SICILIAN, the revolution of the Sicilians against' Angevin domination. so called because it broke out at the hour of Vespers on Easter Tuesday, 1282. The government of Charles I of Anjou (see CHARLES I, king of Naples) was highly oppressive, and the people of Sicily were strongly attached to the house of Hohenstaufen. The actual outbreak was a purely unpremeditated popular movement. Charles at that time was making preparations for an attack on the East Roman empire, and heavily taxing the Sicilians in order to meet his expenses. Peter III, king of Aragon, wishing to assert the claims to Sicily which he possessed in right of his wife, Constanza, daughter of Manfred (*q.v.*), was negotiating with the enemies of Charles, when the people of Sicily, goaded beyond endurance, rose unexpectedly against their rulers. On March 31, 1282, a riot broke out in a church near Palermo, in consequence, according to tradition, of the insults of a French soldier toward a Sicilian woman, and a general massacre of the French began. The rising spread to the city, where a republic was proclaimed. and then through the rest of the island; thousands of French men, women and children were butchered (there may be some exaggeration in the wholesale character of the slaughter), and by the end of April the whole of Sicily was in the hands of the rebels. Charles at once led an expedition against the Sicilians and besieged Messina. The island mas saved from re-conquest by the intervention of Peter of Aragon, but this intervention changed the character of the movement, and the free communes which had been proclaimed throughout the island had to submit to royal authority and a revived feudalism. Peter. having reached Palermo in Sept. 1282, accepted the Sicilian crown, and declared war on Charles. (See NAPLES, KINGDOM OF; SICILY.)

BIBLIOGRAPHY.--The standard work on the subject is Michele Amari's *Guerra del Vespro* (2 vols 8th ed., Florence, 1876), which is based on a study of the original authorities. but is too strongly prejudiced against the French; *cf.* L. Cadier's *Essai sur l'administration du royaume de Sicile par Charles I. et Charles II. d'Anjou* (fasc. 59 of the *Bibliothèque des écoles françaises de Ronze et d'Athènes,* 1891) See also A de Saint-Priest, *Histoire de la conquête de Naples par Charles d'Anjou* (1847–49); A Cappelli's preface to the "Leggenda di Messer Giovanni da Procida," in *Miscellanea di opuscoli inediti o rari* **dei** *secoli XIV. XV.* (Turin, 1861); F. Lanzani, *Storia dei communi d'Italia,* lib. v. ch. 3 (Milan, 1882).

VESPUCCI, AMERIGO (1454–1512), Italian merchant and navigator whose traditional family name Amerigo was given to the continent of America, was born at Florence. the son of Nastagio, a notary. As a boy Vespucci was given a humanistic education by his uncle Giorgio Antonio. In 1479 he accompanied another relation, sent by the Medici family to be their spokesman to the king of France. On returning Vespucci entered the "bank" of Lorenzo and Giovanni di Pier Francesco de' Medici and gained the confidence of his employers. At the end of 1491 they sent him to Seville, where they had a business directed by a man named Giannotto Berardi who appears to have been engaged chiefly in fitting out ships and he was probably present when Columbus returned from his first expedition, which Berardi had assisted Later S'espucci was to collaborate, still with Berardi, in the preparation of a ship for Columbus' second expedition and of others for the third. On the last occasion Vespucci and Columbus became personally acquainted. When Berardi died. either at the end of 1495 or at the beginning of 1496, Vespucci became manager of the Seville agency.

The period during which Vespucci made his voyages falls between 1497 and 1504. At the beginning of 1505 he was summoned to the court of Spain for a private consultation, and as a man of experience was engaged to work for the famous Casa de Contratación de las Indias (Commercial House for the West Indies), which had been founded two years before at Seville. In 1508 the house appointed him chief navigator — a post of great responsibility, which included the examination of the pilots and ships' masters licences for voyages. He also had to prepare the official map of newly discovered lands and of the routes to them (for the royal survey), interpreting and co-ordinating all data which the captains were obliged to furnish. This position Vespucci, who had obtained Spanish citizenship, held until his death. His widow, Maria Cerezo. was granted a pension in recognition of her husband's great services.

Two series of documents on Vespucci's voyages are extant. The first consists of a letter from Vespucci himself dated from Lisbon, Sept. 4, 1504, written in Italian, perhaps to the gonfaloniere Pier Soderini and printed in Florence in 1505, and of two Latin versions of this letter printed under the titles of *Quatuor Americi* Navigationes and *Mundus Novus*, or *Epistola* Alberici de *Novo* Mundo. The second series consists of three private letters (*i.e.*, letters not intended for publication) addressed to the Medici. In the first series of documents four voyages by Vespucci are mentioned; in the second, only tno. Until the 1930s the documents of the first series were considered from the point of view of the order of the four voyages. According to a theory of A. Magnaghi, on the contrary. these documents are to be regarded as the result of skillful manipulations and the sole authentic papers would be the private letters, so that the verified voyages would be reduced to two. The question is fundamental for the evaluation of Vespucci's work, and has given rise to fierce controversy which had not ended by the late 1950s, and attempts to reconcile the two series of documents cannot generally be considered to be successful.

The voyage completed by Vespucci between May 1499 and June 1500 as navigator of an expedition of four ships sent from Spain under the command of Alonso de Ojeda is certainly authentic. (This is the second expedition of the traditional series.) Since Vespucci took part as navigator. he certainly cannot have been inexperienced; but it does not seem possible to accept as having really taken place in this area a previous voyage (1497–98), believed to have been made around the Gulf of Mexico and the Atlantic coasts from Florida to Chesapeake bay.

In the voyage of 1499–1500, Vespucci would seem to have left Ojeda after reaching the coast of what is now Guiana. Turning south, he is believed to have discovered the mouth of the Amazon and to have gone as far as the Cape of La Consolación or São Agostinho (about 6° lat. S.). On the way back he reached Trinidad, sighted the mouth of the Orinoco and then made for Haiti. Vespucci thought he had sailed along the coasts of the extreme easterly peninsula of Asia, where Ptolemy believed the market of Kattigara to be; so he looked for the tip of this peninsula calling it Cape Kattigara. He supposed that the ships, once past this point, emerged into the seas of southern Asia. As soon as he was back in Spain he equipped a fresh expedition with the aim of reaching the Indian ocean, the Gulf of the Ganges and the island of Taprobane (Ceylon). But the Spanish government did not welcome his proposals, and at the end of 1500 Vespucci went into the service of Portugal. Under Portuguese auspices he completed a second expedition which set off from Lisbon on May 13, 1501. After a halt at the Cape Verde Islands the expedition traveled southwestward. reached the coast of Brazil toward Cape São Agostinho, discovered (Jan. 1502) Rio de Janeiro bay and certainly sailed as far as the Plate river, which Vespucci was the first to discover. In all probability the ships took a quick run still farther south, along the coast of Patagonia to the Gulf of San Julian or beyond. The return route is unknown. The ships anchored at Lisbon on July 22, 1502.

This voyage is of fundamental importance in the history of geographical discovery in that Vespucci, himself, and scholars as well, became convinced that the newly discovered lands were not part of Asia, but a "New World." In 1507 a humanist, M. Waldseemuller, reprinted at St. Die in Lorraine the *Quatuor Americi Vesputii* Navigationes preceded by a pamphlet of his own entitled Cosmographiae *Introductio*, and he suggested that the newly discovered world be named "ab Americo Inventore . . . Amerigen quasi Americi terram sive Americam" The proposal is perpetuated in a large planisphere of Waldseemüller's, in which the name America appears for the first time, although applied only to South America. The suggestion caught on; the extension of the name to North America, however, came later. On the upper part of the map. with the hemisphere comprising the old world, appears the picture of Ptolemy; with the new world hemisphere is the picture of Vespucci.

It is uncertain whether Vespucci took part in yet another expedition (1503–04) for the Portuguese government (it is said that he may have been with one under G. Coelho). In any case this expedition contributed no fresh knowledge. Subsequently Vespucci returned to the service of Spain and certainly, in the capacity of *piloto* mayor, helped to prepare other expeditions, but never again joined one in person. Some scholars have held Vespucci to be an ignorant usurper of the merits of others. The fact that Spain entrusted him, a foreigner, with the office of chief navigator is sufficient to dispose of these accusations. The Spaniards saw that he possessed an outstanding knowledge of the theory and practice of nautical science and that he was an upright and scrupulous person to whom confidential matters could be entrusted. As a seaman and navigator he may be said to stand comparison with Columbus, though the latter became the more famous.

BIBLIOGRAPHY.—Vespucci charted the coast line he had discovered and mapped it, but his map is lost, as also are his logbooks. A few maps, however, survive (apart from Waldseemiiller's already mentioned) which originate directly or indirectly from Vespucci, but see *Amerigo Vespucci y el Nuevo Mundo: Cartas relativas a sus viajes y descubrimentos* (1951). *See* also: Alexander von Humboldt, *Examen critique d l'histoire de la géographie du nouveau continent,* vol. iv (1837); F. (1949); "Amerigo Vespucci nel V centenario della nascita," numero speciale della *Rivista Geografica Italiana* (1954). Articles by various scholars have appeared in *Revista de Historia* (1954 *et seq.)* (R. Aà.)

VESTA, the Roman goddess of the hearth. The name probably is etymologically identical with the Greek Hestia (*q.v.*), and the two deities are of similar cult. Vesta's worship, if not primitive, is very ancient. The lack of an easy source of fire in the early community placed a special premium on the ever-burning hearth fire, both publicly and privately maintained, and thus from the earliest times Vesta is assured a prominent place in both family and state worship. The private worship of Vesta, as deity of the family hearth, was observed in every household along with that of the Penates and the Lares, and her image is sometimes encountered in the household shrine (lararium). A wreath was placed on the family hearth by the chief female slave (*vilica*) on the Kalends, Nones and Ides of each month (Cato, De agricultura, 143, 2).

The state worship was much more elaborate. The sanctuary of Vesta was traditionally a circular building, in imitation of the early Italian round hut. Symbolic of the public hearth, it was not strictly speaking a temple, although popularly called such. The shrine of Vesta in the Roman forum was of great antiquity, traditionally going back to Romulus or Numa, although it should be remembered that the forum area was not a part of the earliest Rome. The structure underwent many restorations and rebuilding in both republican and imperial times. There burned the perpetual fire of the public hearth attended by the vestal virgins and renewed annually on March 1 (the Roman new year). The innermost sanctuary (*penus;* cf. PENATES) was not open to the public, and only the vestals might enter it. Once a year, however, on the occasion of the Vestalia (June 7–15), it was opened to matrons who visited it barefooted. The days of the festival were unlucky. On the final day occurred the ceremonial sweeping out of the building, and the period of ill omen did not end until the sweepings were officially disposed of by placing them in a particular spot along the Clivus Capitolinus or by throwing them into the Tiber.

The public worship of Vesta was in the care of the vestal virgins. If the state cult is merely the extension of the worship in the king's household (a questioned viewpoint), these priestesses originally were the king's daughters who, ceremonially at least, attended the hearth. They were two or four in number at first, entering service when they were from six to ten years old and continuing as vestals for five years; *i.e.,* until they were old enough for marriage or at least betrothal. In historical times they were six in number, chosen by the pontifex *maximus* (who assumes the religious functions of the king), and they served for 30 years under a vow of chastity. There was nothing that forbade marriage after that, but by custom and superstition they rarely married. Those chosen had to be of the required age, freeborn of freeborn and respectable parents (although later daughters of freedmen were eligible), having both parents alive (patrimae et *matrimae*) and free from physical and mental defects. The pontifex took the candidate by the hand, pronouncing the formula of admission, te, Amata, capio. Her hair was cut and the cuttings hung on a certain tree and she was dressed in an ancient costume identical with that of a bride (not that the maiden became the bride of some deity, as many suppose; rather both the bride and the vestal wore garments symbolic of virginity). The vestals enjoyed many honours and privileges not accorded other Roman women. They were, for example, free from the tutelage (*manus*) of either a father or a husband, although they were in the charge of the pontifex *maximus,* who could punish them if they were remiss in their duties.

Their obligations involved keeping the sacred fire (the punishment for letting it go out was a beating) and maintaining their vow of chastity (breaking this was a capital offense, punishable with burial alive). Other duties included fetching water from a sacred spring (Vesta would have no water from the city system); the preparation of sacred foodstuffs (*muries* or brine, and mola salsa, coarse meal mixed with salt) for ritual purposes; and custody of the sacred objects of the *penus*. These last were a secret, but there was much conjecture as to what the *penus* contained; *e.g.,* the sacred objects brought by Aeneas, the Palladium (*q v.*).

In addition to the shrine itself and between it and the Velia stood the magnificent Atrium Vestae, a name which originally related to the whole sacred area comprising the shrine, a sacred grove, the Regia (headquarters of the pontifex *maximus*) and the house of the vestals, but ordinarily designates the home or palace of the vestals. This was an elaborate structure of two or three stories built around an open peristyle lined with statues of former vestals. The extensive remains, excavated in modern times, date for the most part from the empire, and the fragments of the numerous statues of the vestals belong largely to the 3rd century A.D. When Augustus became pontifex *maximus* he transferred his headquarters to his own home on the Palatine, turning over the Regia to the vestals. He also constructed a second shrine of Vesta either within or close to his palace.

As the shrine of Vesta contained no cult statue, it is perhaps not surprising that images of Vesta are rare. When she appears, however, she is a fully draped woman, sometimes accompanied by her favourite animal, an ass. As goddess of the hearth fire, Vesta was the patron deity of bakers. hence her connection with the ass, usually used for turning the millstone, and her association with Fornax, spirit of the baker's oven. She is found also allied with the primitive fire deities Cacus and Caca, whose worship goes back to the time of the Palatine settlement.

VESTINI, an ancient Sabine tribe which occupied the eastern and northern bank of the Aternus in central Italy. It entered into the Roman alliance, retaining its own independence, in 304 B.C. A northerly section around Amiternum near the passes into Sabine country probably received the Caerite franchise soon after. The local dialect, which belongs to the north Oscan group, survived certainly to the middle of the 2nd century B.C. (see LATIN LANGUAGE). The Latin first spoken by the Vestini was not that of Rome but that of their neighbours the Marsi and Aequi (*qq.v.*). See also PAELIGNI; SABINI.

VESTMENTS, ECCLESIASTICAL, are ceremonial garments worn by bishops, priests, deacons, ministers and others in performing the offices of religion, as distinct from clerical clothing worn in everyday life. This article, dealing with Christian and Jewish liturgical dress, is organized as follows:

I. EVOLUTION OF CHRISTIAN ECCLESIASTICAL VESTMENTS

The liturgical vestments of the Christian Church, as modern archaeological research has shown, are not derived from the sacerdotal ornaments of the Jewish ritual, as was once thought; rather, they developed from articles of dress worn in the Roman empire, the basic forms being inspired by classical Greek attire. Christian archaeology indicates conclusively that ecclesiastical apparel from the 1st century onward consistently follows the Greco-Roman pattern and manner of wearing the tunic and the mantle.

1. Greco-Roman Origins.--Since ecclesiastical attire is based ultimately on clothing forms developed in classical Greece. understanding of the Greek attitude toward clothing is basic to a study of vestments. This closely resembled their attitude toward and understanding of architecture. Solid forms are produced either about a point or about a line. In architecture a building may either centre about a single pivotal point, such as a dome, or may be developed from two points that are tied together by a beam. In clothing, the body may be encircled horizontally with the head as pivotal point, or it may be draped vertically from the shoulders. The Greeks perceived that the tunic, like all form-fitting types of clothing that drape from the shoulders, was essentially expressive of the body and its movements; while the enveloping cloak, draped around the body with the head as centre, expressed spiritual and intellectual perfection. In the Greco-Roman world of the 1st century A.D., then, there were two fundamental types of clothing: (1) the tunic (Greek *chiton;* Latin *tunica*), adapted to the body by clasps at the shoulders and held at the waist by a cord or belt; and (2) the mantle or cloak (Greek *chlamys* or *himation;* Latin *palla* or *pallium*), a rectangular piece of cloth of varying length and width, wrapped around the body. The tunic was essentially an undergarment, the mantle an outer garment. (For descriptions, see DRESS: Mediterranean World.) Some customs connected with the wearing of these that particularly affected ecclesiastical vesture are discussed below.

A man at work wore only a tunic, but no Roman of any standing appeared in public without a toga, the more elaborate Roman form of the *pallium* or mantle. Even when the tunic was hidden by the toga, ho ever, good form required it to be belted. The tunic of the ordinary citizen was made of plain white wool. On the tunics of knights and senators stripes of garnet colour (perhaps woven into the material) descended, one from each shoulder, to the bottom of the tunic, both front and back. The mantle of the poorer classes, the *byrrhus,* was gradually supplanted by the *paenula*, or casula ("little house"), a semicircular piece of cloth whose ends were brought together and sewn partially up the front, allowing enough room for the passage of the head, forming a conical or bell-shaped garment. Originally worn only by slaves, soldiers and others of low station, it was adopted during the 3rd century by persons of fashion as a convenient riding or traveling cloak, and finally. by a sumptuary law of the emperor Theodosius in 382. it was prescribed as the proper everyday mantle of senators, the toga being reserved for state occasions.

Another garment that was to affect ecclesiastical usage came into fashion in the Roman world during the 2nd century. This was the dalmatic, a loose, unbelted tunic. with very wide sleeves, worn as an outer garment over the long white tunic (tzmica alba) now worn by the better class of citizens. The bands or stripes that were found on the tunics of knights and senators were transferred to the dalmatic, frequently being given greater importance on the latter.

The *lacerna,* introduced into the Roman army by Lucullus as an article of luxury worn only by the higher officers, was another mantle. fastened in front by a *fibula* ("pin" or "brooch"). It was often described by the generic name *amictus,* "wrapped around," but is distinct from and not to be confused with the neckcloth also called *amictus,* which has survived as the amice. The *lacerna* was used by early Christian artists, aptly enough, in depicting Melchizedek and the Jewish high priests (as in the apsidal mosaics of SS. Cosmas and Damian in Rome and of San Vitale in Ravenna), and according to the Vulgate (Ecclus. 1, 12) the high priest Simon, son of Onias, wore the *amictus.* Jewish priests of the New Testament were also depicted as wearing it, as is the high priest at the judgment of Christ before Pilate in the nave mosaic of San Apollinare Nuovo in Ravenna. As a military costume the *lacerna* is worn by the emperor and his attendants in the superb offertory mosaic at San Vitale in Ravenna.

2. Development of Ecclesiastical Vesture: 6th to 13th Centuries. — As late as the 6th century the under tunic (*linea*), the upper tunic (tunica dalmatica) and the chasuble (paenula, casula) were common to both clergy and laity. and were used both in the liturgy and in everyday life. By the 4th century, however, the garments worn at liturgical functions had been separated from those in ordinary use, though they were still identical in form. The major development of specifically ecclesiastical vestments took place between the 6th and 9th centuries. Secular fashions altered with changes of taste and because of the barbarian invasions; the church retained the dress of the Roman empire of the 4th century, which still conserved the modified classicism of a vertically draping undergarment (indutus) in the tunic, and an enveloping outer garment (amictus) in the chasuble.

One of the most important questions concerning ecclesiastical vestments is why the church chose to retain these modsfied forms rather than the more perfect garments of classical Greek times. The early Christian writers approached the subject of clothing by referring to the book of Ecclesiasticus, which, speaking of the creation of man, declares that God clothed him with divine power (Ecclus. xvii, 2). Understanding this literally, they considered the attributes of the state of innocence to be the "clothing" of the first parents. Since they consistently tried to clarify the Old Testament by comparison with the New, they related these words of the Ecclesiast with those of St. Matthew, which refer to the vestments of Jesus as becoming white as snow on Mt Tabor (Matt. xvii. 2), or with those of St. Luke, which describe the angels of the resurrection clothed "in dazzling apparel" (Luke xxiv. 4). In this dazzling apparel was seen a replica, so to speak, of the garment of glory with which Adam was clothed at creation. St. Basil approached the problem from a more positive point of view by noting that man should receive more fitting gifts than natural clothing because of the love he bears to God. Thus Jesus recalled the life of Paradise when he said, "Do not be anxious about your life, what you shall eat or what you shall drink, nor about your body what you shall put on" (Matt. vi. 25). Man should not have possessed clothing, either natural or fabricated. Should he give proof of his virtue, another clothing mas reserved for him. the splendour of the gift of God, the robe of light similar to that of the angels.

For this reason, perhaps, the early church chose to temper the intellectual perfectionism of Greek classicism in clothing, leaving room for the eternal "robe of glory," and chose the chasuble of the peasant instead of the toga or *pallium* of the free Roman citizen. That this was done intentionally, not as a result of mere historical accident, is indicated by the fact that in all iconography, from the early Christian centuries till modern times, Jesus himself is invariably clothed in tunic and toga or *pallium*, never in a chasuble. Very often the saints in early frescoes and mosaics, as well as in medieval manuscripts, are also so portrayed. On the other hand, living churchmen of priestly rank are invariably clothed in tunic and chasuble. The church chose to accept the inspiration of classical Greece without being bound by its proud rigour or intellectual formalism The tunic or alb continued to express the bodily nature of man, and the enveloping, circular chasuble continued to express the fallen spirit of man healed by redemption but not yet in possession of the robe of glory. In this respect it is interesting to note that in the full liturgy of the Western rites only the celebrant is perfectly clothed, up to and including the encircling chasuble: he is the complete man.

During the 4th and 5th centuries the first distinctive vestments, the sacred pallium and stole, made their appearance as ensigns of office or dignity. It was the period between the 9th and 13th centuries, however, that marked the final development of eucharistic vestments in the West. Since by this time the clothing worn in the liturgy was almost completely distinguished from secular dress, vestments came to symbolize a special dignity. In the second quarter of the 9th century bishops, when fully vested wore a *camisia* or shirt, girdled; a neck cloth or amice (analolaium); an alb (linea), girdled; a tunicle (*dalmatica* minor); a dalmatic (dalmatzca *major*); stole (*orarium*); chasuble (*planeta* or *casula*); and the sacred pallium. This is especially observable on the ivory covers of a 9th-century missal, preserved at Frankfurt am Main.

In an age when costume was becoming a symbol of the status of the wearer, it was natural that in the church official vestments should undergo a similar process. Canonical legislation began to prescribe as a rule many actions that had previously been hallowed by custom and religious association, and also put a check upon the discretion or caprice of individuals. Until this time, the ancient garments had no significance beyond the meaning that had been attributed to them from the time of classical Greece and the early Christian writers; by the 11th century, symbolic meanings and prayers were attached to all major garments used in the liturgy.

In the 9th century appeared the pontifical gloves; in the 10th, the mitre; in the 11th, the use of liturgical shoes and stockings was reserved to cardinals and bishops. By the 12th century, mitre and gloves were worn by all bishops. Until the 9th century vestments had been very plain; what splendour they had was the result of material and colour and the ample folds of their drapery. But from this time onward they tended to become more and more elaborately decorated.

3. Final Determination of Ecclesiastical Usage: **13th** to **16th** Centuries. — The only significant development of the late middle ages and the Renaissance was the extension of various forms of choir habit. The eucharistic vestments became more ornate and colourful, with the addition of apparels and brocades; they also deteriorated in form. The black choir cape or cope developed into various types of cloaks, ornamental copes, gowns and hoods; the white rochet and surplice came to the fore in noneucharistic usage. These developments are treated in detail below.

II. VESTMENTS IN THE WEST

A. Four Major Vestments

Four types of vestments, three of which are eucharistic (alb, dalmatic and chasuble) and one noneucharistic (cope), constitute the basic forms of Christian ecclesiastical vesture. These vestments are treated here as structural or architectural, as distinguished from derivative forms and secondary and symbolic items of apparel. The dalmatic, however, proper to deacons in Western rites, must be designated as a major Christian vestment because of its usage rather than its structure; in form it is similar to the alb, in usage it is employed as an outer robe rather than an undervestment.

1. Alb.—The alb derived from the white linen tunic (*tunica alba*), especially those forms that were sewn up the sides and provided with sleeves. In its modern form it is a sacklike, full-length, white, usually linen garment with long, narrow sleeves, secured at the waist by a cincture (*cingulum*) or girdle of white linen. silk or cotton cord. Albs were originally plain. but about the 10th century the custom arose of ornamenting the hem and cuffs with embroidery, and this became common in the 12th century. Such ornamentation at first encircled the whole hem and cuff, but soon it became customary to substitute rectangular patches of embroidery or fabric. These "parures," "apparels" or "orphreys" were usually four in number, one being sewn on the back and another on the front just above the hem, and one on each cuff. A fifth was occasionally added just below the neck opening. Apparels fell into disuse during the 16th century, although they are retained in the Roman Catholic Church in certain localities and according to wish, and they are favoured by many Anglican authors. The use of lace, prevalent since the 16th century. denoted a marked decadence, at times virtually destroying the character of the alb. The vestment symbolizes purity.

2. Dalmatic.—This is a more elaborate tunic (colour and fabric the same as those of the vestments of the officiating priest) whose form has remained almost identical to the original, with open sides, wide sleeves with bands about the cuffs, and *clavi* or coloured bands descending from the shoulders. As in early Christian times, it is worn without cincture or girdle. The dalmatic became the distinctive garment of the deacons of the city of Rome during the 5th century, and it has been retained as the diaconal vestment in the Roman Catholic and Anglican churches. By extension, a shorter dalmatic with narrower sleeves, called the tunic, or tunicle, has become the characteristic vestment of the subdeacon. Dalmatic and tunicle are never worn by priests, except when officiating as deacons (*e.g.*, as deacon and subdeacon assisting at Mass). but both are worn, under the name of tunicles, by bishops under the chasuble (never under the cope) on certain occasions. A silk dalmatic forms one of the English coronation robes.

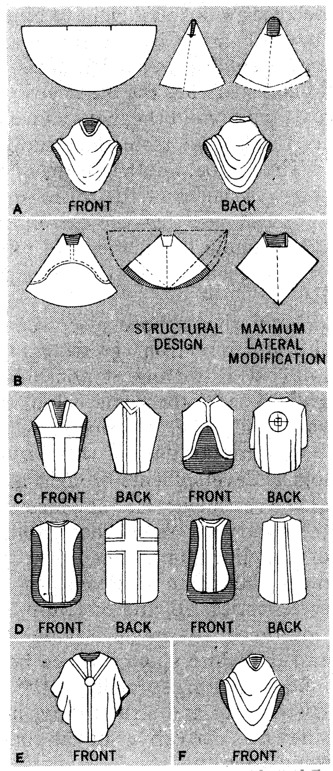
3. Chasuble. — The chasuble, the outermost eucharistic vestment, is the distinctive priestly garment and the Mass vestment par excellence. It retained for hundreds of years in both East (as the phelonion) and West the classical form of its ancestor, the Roman *paenula*. But in modern times no vestment is so difficult to recognize as descending from the earlier Christian centuries.

The early chasuble was worn in three ways: (1) The right side was elevated over the shoulder in order to free the right arm, as in classical Roman times and as shown in the great majority of mosaics and frescoes of the 5th to 9th centuries (2) Both sides were elevated equally, leaving the forearms moderately free; this style was exceptional at the beginning, but became common during the 9th century and throughout the middle ages. (3) The front of the chasuble was gradually elevated over the forearms and chest, a usage which became typical of the Byzantine and Russian churches after the 14th century. These various ways of draping the chasuble did not greatly affect its structure until motives of convenience began to affect usage from the 15th to the 19th centuries, during which period the vestment underwent drastic structural violations.

Ornamentation was the first element that began to alter the appearance of the chasuble. In order to strengthen the single front seam, it was covered by a band, as seen in the 13th-century sculptures at Chartres; the neck opening was also strengthened, and a transverse band became common. This "T" form led to the placing of crosses on the chasuble. The medieval custom was to add oblique side bands to the central column, forming a "Y" or fork; this is typical of chasubles from the 13th to the 16th centuries. As the sides of the chasuble came to be cut down in later centuries, the fork was correspondingly squared off to form the Latin cross, which for the sake of symbolism was transferred to the back of the vestment. Even today, however, there is no requirement for the placing of a cross or any other decoration on the chasuble.

The conical form of the chasuble does not permit lateral diminution over the arms beyond the 90° angle without destroying its essential structure. Beyond this point the front and back become panels draping from the shoulders in the manner of the alb or tunic, rather than retaining the architectural quality of an enveloping garment centring about the head and drawn around the body. This development occurred at the end of the medieval period and during the Renaissance, when the use of brocades and other heavy, stiff materials caused the vestment to hang badly and led to the gradual reduction of the material that extended over the arms; eventually front and back became panel surfaces for weighty baroque decoration. This occurred little by little, without the support of any text and by tolerance of the authorities. St. Charles Borromeo did his best to stem the tide during the high Renaissance, but in spite of his efforts the original structure of the chasuble disintegrated beyond recognition until by the end of the 18th century there existed so-called national models—the French or Gallican, Spanish and Italian chasubles.

The 19th-century renewal of interest in the medieval period, which was felt in both the Roman Catholic and Anglican churches, led to efforts to restore the chasuble to its traditional form. Working on the French side of the Alps, the neo-Gothic reformers adopted as their fundamental model the style that may be called Gallican or French (though the same type was used in Germany), and contented themselves with loosening and enlarging this style in the hope of recovering the medieval or "Gothic" model. They neglected the form known as the Italian model, and, unfortunately, the Gallican chasuble was not a diminution of the medieval chasuble but rather a deformation of the Italian; the latter is truly a reduction of the traditional chasuble and has retained its fundamental structure. This error of the Gothic revivalists has produced indescribable confusion and has delayed the restoration of the true chasuble even in the 20th century.



DEVELOPMENT OF THE CHASUBLE
(A) Ancient model, a semicircle sewn in the form of a cone and modified at the collar and base; (B) Eastern-rite frontal modification after the 16th century; (C, left) Italian model after the 16th century; (C, right) Eastern-rite model frequently used in recent centuries; (D, left) French or Gallican model, (D, right) Spanish model; (E) Neo-Gothic model, a false amplification of French or Gallican model, resulting in two amplified panels rather than a cone; (F) amplification of Italian model (C, left), or Eastern rite frontal modification (B, left) resulting in a vestment similar to the ancient chasuble

In the matter of usage, the chasuble was originally worn by all ranks of clergy. The first Roman *ordo* (an 8th-century document which describes the liturgy of 6th-century Rome) notes that the clergy wore the chasuble over their other garments as they entered the stational church. Only the pontiff, however, retained his chasuble throughout the whole rite of which he was celebrant. On the occasion of his visit to Rome in 831, Amalarius of Metz notes that the deacon who read the Gospel retained his chasuble until the *Alleluia* verse just before his reading. At that moment he removed his chasuble, rolled it on his left shoulder, passed its two ends together with the stole, across and under his right arm and fastened them there. This was done to free the arms. The custom of the deacon wearing a folded chasuble in this fashion during Lent and Advent continued until the usage became obsolete by a new code of rubrics promulgated on July 26, 1960, although in most instances the so-called "broad stole" was unfortunately substituted for the folded chasuble. The clergy are also shown wearing the chasuble on the covers of the 9th-century Frankfurt missal. As late as the 17th century the Ceremonial of Bishops published by Pope Clement VIII directs that presbyters who assist the bishop at solemn vespers wear the chasuble; and even today the priests who assist the bishop of the Roman rite on Maundy Thursday, when the oils for the anointing of the sick and other sacramental uses are blessed, are vested in chasubles. The chasuble symbolizes Christ's love.

In the Eastern churches the equivalent of the chasuble is the phelonion, or phenolion, reserved exclusively to priests; the sakkos is substituted by the higher clergy (see below, Eastern Orthodox *Church*).

4. Cope.—The cope (Med. Lat. *cappa*) is a mantle reaching the heels and worn when the chasuble is not used. The word was in its origin identical with cape; the garment was a hooded outdoor cloak worn by both men and women. *Pluviale* ("rain cape"), the Latin name for the cope in the Roman Catholic Church, is parallel in meaning. When spread out the cope forms a semicircle. Along the straight edge there is usually a broad band or orphrey, and at the neck is attached the hood or cowl. The usage of an actual hood attachment is being restored; in the past four centuries it was replaced by a shield-shaped piece of material (*clypeus*) that was sewn onto the back or attached as an appendage, often rounded or fringed. The cope is secured in front by a broad tab sewn onto one side and fastened to the other with hooks, or by means of a brooch (morse, or fibula).

The use of the cope as a liturgical vestment can be traced to the end of the 8th century. Before this time the so-called *cappa choralis* ("choir mantle"), a black, hooded vestment with no special liturgical significance, had been worn by the secular and religious clergy at choir services and processions. In the Anglican Church it is still worn as the "cloth cope" or *cappa* nigra ("black cope") for funerals in bad weather, when taking communion to the sick and sometimes for general use. In reality, the choir mantle is identical with the cowl, such as was prescribed by St. Benedict (c. 530) for his monks. In the 10th century, partly under the influence of the community of Cluny, the use of an ornamental choir mantle or cope became widespread, and by the 11th century it was universally worn. By the 13th century the cope, as an ornamental, coloured garment of finer material, had supplanted the chasuble in all noneucharistic functions. It came to be used for choral and processional services not only by bishops and priests but also by cantors and others.

In form the original chasuble and cope have remained identical, with the major exception that the cope is open at the front and the chasuble is sewn; this front seam, of course, produces an entirely different appearance (see fig. [A]).

B. Secondary, Derivative and Symbolic Vestments

1. Amice.—The amice (*amictus*, "wrapped around") may have originated in a scarf wrapped around the neck and shoulders to protect the outer garments from soil. It was not strictly a part of ancient Roman dress, and like the loincloth (which served a similar purpose) was scarcely considered a real garment. The medieval amice, similar to the cowl, was simply a hood to cover the head and ears when the church was cold, and this hood form became the basis for the amice's development as a distinctly ecclesiastical vestment in the West. The hood form is retained by monks of various religious communities (*e.g.*, the Benedictine), but among the secular clergy, more in accord with ancient usage, the amice is a rectangular piece of linen cloth, about 24 by 36 in., secured about the neck and shoulders by two long narrow bands. In correlation with the apparels used upon albs, the upper border of the amice was often appareled during the late middle ages, and the practice continues in many instances. The amice symbolizes the helmet of salvation.

2. Pallium.—The pallium (or pall), which symbolizes the fullness of the pontifical power, belongs to the pope but is conferred by him on archbishops (and occasionally other bishops) to indicate their participation in this authority. Since the 9th century no archbishop may exercise his metropolitan jurisdiction until he has received the pallium. He must apply for it, personally or by deputy, within three months after his consecration, and it is buried with him at his death. Though the pallium is thus a vestment distinctive of bishops having metropolitan jurisdiction, it may be worn by them only within their jurisdiction, on certain solemn occasions The pope alone has the right to wear it everywhere and at all times.

Early Christian art, following an invariable convention, clothed Jesus and the apostles in a pallium. and this tradition prevailed even when the pallium in its original form of a long, rectangular cloth. wrapped around the body as a mantle. had ceased to he a cominon article of dress. In ancient times, the pallium was often folded up and thrown over the shoulder when not needed for warmth. By this process (contabulatio, "folding") the sacred pallium was also folded into a band, which finally appeared only as an ornamental scarf of white wool, morn on the shoulders over the chasuble; in this form it is seen in mosaics of the 6th to 12th centuries. Later it gained its present form of a yoke. made of white lamb's wool, with ends hanging down before and behind. so that when seen from either front or back it resembles the letter "Y." It is decorated with six crosses, one on each pendant and four on the loop.

The Eastern equivalent of the pallium is the bishop's omophorion. a long, white, embroidered scarf of silk or velvet, about ten inches wide. worn over the shoulders at celebration of the Holy Liturgy.

3. Stole.—This ensign began to enter into liturgical usage as early as the 4th or 5th century. Its origin is obscure. The word stola did not appear until the Carolingian period, and until that time all Christian writers used the word *orarium* to designate this vestment, indicating that the stole was originally intended for wiping the mouth (os, *oris*). It was morn about the neck and is frequently seen on pagan monuments and in the catacombs. As a vestment, however, it may have originated from the consular toga (the only form that survived the 4th century), a sumptuous garment so heavily embroidered in gold that it had to be folded in broad bands that showed only the ornament; after it had been drawn around the body in the usual manner of the toga, it was passed around again with the decorative pattern fully displayed, the end resting on the left arm. This article survived in the Byzantine court as an ensign of imperial dignity, but by that time it had become a mere scarf.

In its present form it is a relatively narrow (two to four inches) band of silk, about eight feet in length, harmonizing in colour with the major vestments. It is the distinctive diaconal vestment but is also a regular vestment of the priest. The deacon wears it over the left shoulder with the ends joined under the right arm; the priest wears it around the neck, the ends crossed (if worn over the alb) or hanging down It symbolizes immortality.

The counterparts of the stole in the Orthodox Church are the epitrachelion (peritrachelion) of the priests and the orarion of the deacons.

4. Maniple.—This ensign (Lat. *manipulus,* "handful"), which assumed its present general form and purely ceremonial character about the 11th century, is a narrow (about two to four inches) strip of silk, three to five feet in length, worn over the left forearm with the ends hanging down on either side. It corresponds in colour with the major vestments and is ornamented with three crosses, one in the centre and one at each end, that in the centre being obligatory; it is often elaborately embroidered. The maniple is the special ensign of the office of subdeacon (though proper to all orders above). It is worn only at Mass, by the celebrant and the ministers assisting.

The maniple may have originated in a cloth in practical use as a napkin during the liturgy, or it may have been a diminutive stole proper to the subdeacon. The earliest extant specimen of the bandlike maniple is that found in the grave of St. Cuthbert (early 10th century). It was carried originally in the left hand or hung over the left arm near the wrist, and it is represented this way in the iconography of the 9th. 10th and 11th centuries. By the 12th century the rule according to which it is worn over the left arm had been universally accepted. The maniple symbolizes work and service.

5. **Humeral** Veil.—The humeral veil is mentioned, under the name of *sindon,* in the 8th-century Roman *ordo,* when it was worn by acolytes who had charge of the sacred vessels. It was used as a shoulder (*humerus*) support to lighten the burden of the heavy chalices. The humeral veil did not make its appearance in the Rituale Romanum until the latter part of the middle ages, when it was used principally by the subdeacon at high Mass; general adoption for other uses came in the 19th century. It has become a silk scarf, eight to nine feet in length by two to three feet in width, worn by the priest at benediction and processions and by the subdeacon at high Mass. Its normal colour is white, but at Mass it matches the other vestments. The ends (usually fringed) are used to hold the monstrance or paten; thus the veil still retains its function of a shoulder support.

The vimpa, another form of veil, ordinarily white in colour, is worn by clerks of the mitre and crosier at pontifical ceremonies. It is believed that the extremities of the surplice were formerly used to hold the crosier and mitre, and that the vimpa came into existence only when the surplice was reduced in size (see Cotta, below).

Latin rite bishops also wear a form of apron or veil, called the gremial (from *gremium,* "lap"), which is placed over the knees while sitting at pontifical Mass or when anointing. The gremial is of the same colour as the vestments and ornamented with gold or silver fringe.

6. Derivatives of the Cope.—With the Reformation, theological developments brought about a reaction against the wearing of the vestments used at Mass, such as the alb and chasuble. Contemporary excess in ornamentation also led to a reaction in favour of simplification. The cope, as the original black choir vestment, thus came to serve as the principal noneucharistic model for ecclesiastical apparel of late medieval, Renaissance and Reformation times. As modifications of the choir mantle, the black gown and the white choir surplice became major religious garments in modern times. especially in the Protestant and Anglican churches. Historically and structurally. however, all of these must be considered as derivatives of the cope and of choir costume used in the middle ages.

Chimere, Mantelletta and Mantellone.—The chimere, worn as part of the ceremonial dress of Anglican bishops, has as its counterpart in the Roman Catholic Church the mantelletta ("little mantle"), worn by cardinals, bishops, abbots and other prelates of rank. Both vestments are long. sleeveless mantles of silk or satin, open at the front but fastened at the neck, worn over the rochet (see below) as a cape. The chimere was more immediately derived from the medieval tabard, an upper garment worn in civil life by all classes of people, including the clergy. In the Anglican form for the consecration of bishops the newly consecrated prelate, hitherto vested in rochet, is directed to put on "the rest of the episcopal habit"; *i.e.,* the chimere. The robe has thus become in the Church of England symbolic of the episcopal office and is in effect a liturgical vestment. The mantellone (of purple silk or wool). worn by lesser prelates at the papal court. and the academic robe of the master's degree closely resemble the chimere, except that the streamers pendant from the shoulders of these garments indicate vestigial remnants of former sleeves.

Cappa Magnu.—At what date the choir mantle developed into the cappa magna, a nonliturgical garment of state peculiar to the pope, cardinals, bishops and certain privileged prelates. is not known, but mention of it is found as early as the 15th century. This vestment is a loose mantle, with a large hood lined with fur in winter and silk in summer, and a long train. Its colour varies with the hierarchical rank of the wearer.

Mozzetta—The name is derived from the Italian *mozzare,* "to cut off," which points to its being an abbreviated *cappa* It is a short cape of silk or wool with a miniature hood, fastened down the front with buttons. It is worn over the rochet by the pope (red), cardinals (red), bishops (purple) in their dioceses, abbots (colour according to habit) in their abbeys and certain privileged prelates.

Black Gown—For the sake of convenience in freeing the forearms, the ancient black choir mantle was somewhat modified in the middle ages, but its basic copelike form was retained The first modification was the opening of slits at the sides for passage of the arms, as seen in the chimere. A fundamental structural change, however, consisted in the addition of sleeves. long and either flowing or tucked in at the wrists. In this manner, the original enveloping quality of the cope was altered into that of an open-fronted dalmatic or kimono, architecturally becoming an under-garment or tunic. The gown is worn by both civil and ecclesiastical magistrates: as academic apparel, as formal costume for judges and lawyers, as preaching gown for ministers and as costume for vergers and other functionaries. Coloured bands, similar to those on copes, sometimes enliven the otherwise sombre black gown, and at court and academic functions coloured gowns may be worn (See also ROBES: Academical Dress.)

Almuce.—From the hood of the *cappa* was developed the almuce, a hooded cape of fur, or fur-lined, worn occasionally as a choir vestment, although almost superseded by the mozzetta. In the late 13th century two types of almuce were distinguished. (1) a cap coming donn just over the ears; (2) a hoodlike cape falling over the back and shoulders, reserved to more important canons and worn over surplice or rochet in choir. The square cap and biretta. in common use by the 16th and 17th centuries, tended to replace the almuce as a head covering. Its hood then became smaller. and the cape was enlarged and the fur lining introduced. In England the almuce was known as "gray amice" (from the colour of the fur; the word amice, or amess, in this connection is derived independently from the eucharistic vestment called amice). By the 16th century the almuce had become definitely established as the distinctive choir vestment of canons; but it had ceased to have any practical use, and was only carried over the left arm as a symbol of office. A form of almuce survives among the canons of some churches in Rome and elsewhere.

Academic Hood and Black Tippet.—The choir habit peculiar to the Anglican Church consists of a long surplice (see below), the academic hood (according to the wearer's degree) and the black scarf or tippet. The short cape vith hood. structurally identical with the full cape or rain cape. was worn by all classes during the middle ages and developed into various styles, among them the academic hood. Until the 17th century this was a real hood attached to a shoulder cape, but the fashion for large wigs made it necessary to enlarge the neck opening. so that. by the reign of George III, the hood became a rather shapeless garment, hanging down very far at the back and almost completely cut away in front and over the shoulders. Use of the original type of academic hood with cape is encouraged in modern times.

The black scarf or tippet developed out of the liripipe, a piece of fabric attached to the point of the hood. The liripipe gradually grew longer until it could be wrapped around the throat. Eventually it mas separated from the hood and worn by itself around the shoulders, becoming a scarf.

Hood and tippet are worn over the surplice for matins and evensong and other nonsacramental services, and the tippet is also worn with cassock and gown as the formal dress of the Anglican clergy. The tippet is a wide piece of black cloth (silk for doctors and masters. stuff for others), gathered together about the neck and worn in the manner of a priest's stole.

7. White Choir **Vestments.**—*Surplice.*—The most commonly used choir vestment in the Roman Catholic Church (in which it is proper to all clerics) is the surplice (Lat, *superpellicium*, "over the fur coat"); in the Anglican Church it is the normal eucharistic vestment in parish churches, and it is worn by the ministers of some Lutheran and Free churches. But the surplice does not possess an ancient and venerable tradition. Until as late as the middle of the 13th century the alb was not only the undervestment of the priest at the altar but also the proper choir attire of all clerics. The first use of the surplice seems to have occurred in England or France about the 11th century, and it is mentioned in an ordinance of King Edward the Confessor; its adoption in Rome was delayed until the 13th century. Its Latin name derives from its use over fur-lined tunics during the cold winter months in order to give the choirs a more uniform appearance. and this likewise accounts for the ampleness and the full sleeves of this garment Such an outer garment should traditionally be an enveloping one, like the chasuble or cope. Though the surplice, in white linen, is used in place of the alb in choir and at other functions, its classical structure is indeed almost identical with that of the chasuble, with the major exception that it is provided with sleeves, which alters the draping and destroys the effect of the encircling folds. The surplice reached the apex of its development during the 14th and 15th centuries, when it is depicted by the artists of the Florentine and Sienese schools. It has no counterpart in the Eastern churches.

Cotta—The mistaken notion that the surplice was derived from the alb led to the introduction of a diminutive, jacketlike garment named the cotta, which even today is used and named indiscriminately as a surplice. The cotta is a square-necked chemise, often pleated about the shoulders and descending to the waist or a little lower; its shoulder draping places it beyond all question in the category of the tunic. This article of clothing is a most unhappy development, since it partakes of the qualities of neither the alb nor the surplice.

Rochet.—This garment is in reality a substitute for the alb or surplice; in form it is more closely related to the alb. The alb requires the use of an amice and cincture, and thus involves some care in vesting; the rochet, which may be sleeveless or tight-sleeved, can be put on and carried about easily. It is usually made of linen and falls to within a foot to six inches of the ground. The rochet, with wide lawn sleeves, is worn under the chimere by Anglican bishops; in the Roman Catholic Church it is worn under the mozzetta by bishops, abbots and occasionally other dignitaries.

8. Head Coverings.—The most important liturgical head covering is the bishop's headdress, the mitre. which, in its customary form, is a sort of folding cap consisting of two halves, which. when not worn, lie flat upon each other, and. when worn, rise in front and in back into pointed arches. (See MITRE.)

The square cap which is used in various forms in many of the Christian churches was originally the medieval "barret cap." When the word *biretum* was first used in the 13th century. it meant little more than the pileum (pileolus) or skullcap, used as a protection against the cold and by clerics to cover the tonsure. By the 16th century it had developed through various forms and mas the common headgear of all people of substance. The academic cap is a direct descendant of its form as a "square cap" (see ROBES: *Academical* Dress). One of the most attractive forms is found during the reign of Edward VI, depicted in the famous portrait of Archbishop Thomas Cranmer in the National Portrait gallery, London. This is one of the forms preferred by the Anglican clergy. The pileum, later designated by the diminutive form pileolus, became a round skullcap of silk, lined with red leather. called the zucchetto, worn by bishops under biretta or mitre. By a brief of June 17, 1868, Pope Pius IX granted to all patriarchs. archbishops and bishops the privilege of wearing this skullcap at home. in church and even when celebrating Mass. except from the Sanctzrs until after communion. The biretta, whose form is peculiar to the Roman Catholic Church. was devised in the 17th century, and its liturgical usage, strictly post-Reformation. is quite limited (see BIRETTA). From the point of view of both history and appearance, the episcopal usage of both pileum and biretta at the same time is anomalous.

III. USAGE IN THE CHRISTIAN CHURCHES

A. ROMAN CATHOLIC CHURCH

Ecclesiastical vestments may be divided into two categories. liturgical and nonliturgical. Liturgical vestments are again divided into three classes: (1) those worn at the celebration of Mass; (2) those never worn at Mass, but worn at other liturgical functions; (3) those used at both Nonliturgical vestments are those (*e.g.*, cappa magna, rochet) that have no sacred character but have come into use from motives of convenience or as ensigns of dignity and are worn at secular as well as ecclesiastical functions

1. Eucharistic Vestments.—As the sacrifice of the Mass is the central mystery of the Catholic faith, the vestments worn by the priest when celebrating Mass are the most important. The cassock. which must always be worn under the vestments, is not itself a liturgical garment (see CASSOCK). Over this the priest, robing for Mass, puts on, in order, the amice, alb, cincture, maniple, stole and chasuble. Deacons wear amice. alb, cincture, maniple, stole and dalmatic; subdeacons wear amice, alb, cincture, maniple and tunicle. The vestment proper to the minor orders, formerly the alb with amice and cincture, is now the surplice. The pontificating bishop, as belonging to the order of the fullness of the priesthood, wears the same vestments as the priest. with the addition of the pectoral cross, pontifical gloves and ring, liturgical sandals and stockings, tunicles which replace and symbolize the dalmatic and tunicle and which are worn over the stole and under the chasuble, and the mitre. Archbishops. on solemn occasions, wear the pallium over the chasuble. Bishops also carry a pastoral staff as a symbol of their office as shepherd (see CROSIER). Finally, the pope, when celebrating Mass, wears the same vestments as an ordinary bishop, with the exception of the *fanon* or *orale,* a specially designed and ornamented cloak which, put on after the alb and then placed over his head, is allowed to fall over the chasuble like a cape, and the *subcinctorium,* an ornament that is the Western version of the epigonation (see below, Eastern *Orthodox* Church). The liturgical headdress of the pope is the mitre, not the tiara. which is the symbol of his supreme office and jurisdiction (see TIARA).

2. Others.—Of the liturgical vestments not immediately or exclusively associated with the sacrifice of the Mass, the most conspicuous are the cope and the surplice. In addition to the strictly liturgical vestments there are also numerous articles of costume worn at choir services, in processions or on ceremonial occasions in everyday life, which have no sacral character; such are the almuce. the cappa magna, the mozzetta, the mantelletta, the mantellone, the rochet and the pileum or small skullcap, worn under mitre and tiara.

3. Colour.—The custom of marking the seasons of the ecclesiastical pear and the more important feasts by the colour of the vestments dates approximately from the 12th century. Certain rules, already established by Pope Innocent III (c. 1200), are still in effect. Late medieval and Renaissance paintings and tapestries show that a wide profusion of colours was used in the liturgy, so much so that a need for simplification and systematization of some sort became apparent.

In modern times five liturgical colours are used in the Roman rite, together with two alternate colours. (1) White is used at Christmas. Epiphany, Easter, most of the feasts of Christ and the Blessed Virgin, and at other feasts and name days of virgins and confessors. (2) Red is used for Pentecost, or Whitsuntide. feasts of martyrs and on certain other occasions. (3) Green is used for ordinary Sundays from Epiphany to Septuagesima, and after Pentecost. (4) Violet is the distinctive colour of Advent and Lent; a violet stole is also worn by the priest in the administration of the sacraments of penance and extreme unction or anointing. (5) Black is used at Masses for the dead and for funeral ceremonies of adults. as well as on Good Friday. (6) On two Sundays of the year—Gaudete. the third Sunday in Advent, and Laetare, the fourth Sunday in Lent—rose-coloured vestments may be substituted for violet. (7) Gold is tolerated as a substitute, particularly in churches which are unable to afford complete wardrobes, for white, red and green. In Spanish countries blue or azure is used for certain feasts of the Virgin Mary.

B. EASTERN ORTHODOX CHURCH

The vestments of the great historical churches of the East are derived from the same Greco-Roman originals as those of the West. Between the patriarch Germanus of Constantinople in the 8th century and Simeon, archbishop of Thessalonica in the 15th century, there is scarcely any essential distinction between Eastern and Western liturgical clothing. All colours may be used, the differentiation lying only in the fact that dark colours characterize the penitential seasons! light colours the festive seasons. Black is used in many churches at Masses for the dead and on Good Friday, but this has been borrowed from the Latin Church through Poland. A tendency toward the use of heavy ornamentation has prevailed during the past few centuries.

The phelonion (phenolion), or chasuble. the outermost and chief vestment of the priest, suffered the most serious alteration of all the vestments after the 16th century. The entire front of the cone-shaped garment was cut out in the form of an ellipse, so that the phelonion as it is used in certain rites now resembles a *cappa* and no longer encircles the body with horizontal folds. A reaction to this alteration has occurred: however, and a return is being made to the encircling form. The phelonion is not so specifically a eucharistic vestment as the chasuble is in the West, but is worn at solemn functions other than the Liturgy—*e.g.,* at marriages and processions.

The sakkos, a short, tight-fitting tunic with half-sleeves, similar in form to the dalmatic, was adopted by Greek metropolitans in 1433 and by all Russian bishops from the time of Peter the Great. It is widely believed that this was the tunic of the Byzantine emperors, who conceded its use first to the patriarchs, then to bishops whom they wished to honour in a special manner. It may, however, be a vestige of the deacon's dalmatic, over which the bishop assumed the phelonion; and it may have been influenced by the sleeveless tunic (*me'il*) of the Jewish high priest. The wearing of the sakkos (which substitutes for the phelonion) is unfortunate, since it is not an enveloping outer vestment and the ancient classical relationship of under and outer garments is lost.

The amice, maniple and cope are not employed in the Eastern churches.

1. Episcopal Vestments.—An Orthodox bishop, vested for the Holy Liturgy, wears over his cassock: (1) the sticharion; (2) the epitrachelion (peritrachelion), or stole; (3) the zone, which fastens the sticharion about the waist as the cincture fastens the alb; (4) epimanikia or liturgical cuffs, which fasten the sticharion at the wrists (originally, perhaps, like the maniple, a napkin worn on the arm); (5) the epigonation, a lozenge-shaped piece of stiff material about 12 by 10 in. and embroidered, hanging at the right side from the zone or shoulders, to the level of the knee; (6) the sakkos; and (7) the omophorion, or pallium.

In addition to these, the bishop wears one or two enkolpia, images of Christ or of the Virgin, suspended from the neck; a pectoral cross; and carries the bakteria (dikankion) or crosier, which ends in two serpents facing one another, symbolizing prudence in guiding the flock. (Archimandrites and higumens having actual jurisdiction in a monastery are also entitled to use a crosier, of which the upper endings are not turned upward—as is the case with bishops' crosiers—but downward.) For blessings he holds the dikerotrikera, a double candelabrum, one of two branches (dikerion) representing the two natures in Christ, the other of three branches (*trikerion*) representing the three Persons of the Trinity. The mitra, or mitre, is believed to be a copy of the imperial crown of the Byzantine emperors, with a cross on top and adorned with various religious emblems, though it may owe some derivation to the Jewish mitre. (See MITRE.) In Russia archimandrites and higumens by right and certain secular clerics by special favour wear a mitre.

Two other garments are worn before formal vesting for the Holy Liturgy: (1) the epikalymmauchion (or epanokalymmauchon), a black veil of monastic origin worn over the kamelavkion, or ordinary round black headdress of the priest or monk; and (2) the mandyas, also of monastic origin and assumed at the threshold of the church, is likewise worn on less solemn occasions. The mandyas is a long, full cloak, blue or purple in colour and open down the front, its edges caught together under the chin and at the bottom by hooks or small bells. At these points the cloak is adorned with squares of some richly embroidered material, called pomata ("beverages"), from which issue red and white stripes, called potamoi ("rivers"). The pomata typify the Old and the New Testaments, the sources whence the bishop should draw the doctrine he pours out upon his flock. Neither of these is a distinctive episcopal garment—bishops wear the epikalymmauchion because they are monks, and the mandyas is also worn by archimandrites and higumens, though without the potamoi.

2. Priests' and Deacons' Vestments.—The vestments of the priest are the sticharion, epitrachelion, zone, epimanikia and phelonion. He wears all of these only at the celebration of the Eucharist and on other very solemn occasions. A dignitary in priests' orders is distinguished by wearing the epigonation; and in

Russia the use of the mitra was formerly sometimes conceded to distinguished priests by the tsar.

The deacon wears the sticharion without zone, the epimanikia and the orarion (deacon's stole, counterpart of the priest's epitrachelion) hanging over his left shoulder. The deacon's epimanikia cover the sleeves of the cassock rather than the sticharion, which in tlie case of the deacon does not reach the wrists. Acolytes wear a shorter sticharion and a tunicle. The phelonion has only in modern times come to be reserved exclusively to priests. It is still conferred on deacons and lectors at their ordination, but once the ordination ceremony is over, the lower orders may not wear this vestment. During the 10th century it was worn by cantors at Hagia Sophia, and even in the late middle ages was worn by deacons.

C. Protestant Churches

In the Protestant churches custom in regard to vestments differs widely. corresponding to a similar divergence in tradition and teaching. At the Reformation two tendencies became apparent. Luther and his followers regarded vestments among the adiaphora — matters of indifference, that might be either retained or abolished—and in the churches that afterward came to be known as Lutheran many of the traditional vestments were retained. Calvin, on the other hand, laid stress on the principle of the utmost simplicity in public worship. At Geneva the traditional vestments were absolutely abolished, and the Genevan model was followed by the Calvinistic or Reformed churches throughout Europe.

In modern times the Lutheran churches of Denmark and Scandinavia retain the use of alb and chasuble in the celebration of the Eucharist (stole, amice, cincture and maniple were not used after the Reformation), and bishops retain the cope and mitre. The surplice is not used, the ministers conducting the ordinary services and preaching in a black gown, of the 16th-century type, with white bands or ruff.

In the United States, Lutheran pastors are under no obligation in the matter of vestments. The custom of wearing a plain black gown is gradually diminishing in favour of cassock, surplice and stole. This tendency, however, is disapproved by many leading American Lutheran scholars for Holy Communion, matins, vespers, "preaching services," processions and noneucharistic devotions, although the stole may properly be worn by ordained clergymen in the administration of baptism, matrimony, orders and penance.

> Official pronouncements of other Lutheran bodies in this country notwithstanding, the present widespread vogue among us of surplice plus stole . . . is an ill-considered importation into the Lutheran Church of an Anglican compromise that even Anglican liturgiologists disapprove and that is without real warrant in historic Lutheran practice . . . The next step for a Lutheran parish beyond the simple white vestment is not surplice and stole, but the combination of surplice (or sleeveless rochet) and chasuble . . . The acquisition of a chasuble as the next step after the surplice thus has a number of advantages. It is simple and convenient. It adds the specifically Eucharistic vestment, the chasuble, to the general service vestment, the alb (A. C. Piepkorn. "What About Vestments for Pastors?", in *Concordia Theological Monthly,* vol. xxx, no. 8, pp. 587–588, 591; Aug. 1959).

The fullest Lutheran usage would include eucharistic vestments for Holy Communion, cope for processions and solemn offices, surplice and stole for noneucharistic services and surplice for choir offices. There is also no reason why dalmatics and tunicles should not be revived; they were in actual use in the church of the Augsburg Confession at least until the end of the 18th century.

The Evangelical Church in Germany has, in general, discarded the old vestments. In isolated instances the surplice is still worn, but pastors now wear a barret cap, a black gown of the type worn by Luther himself, and white bands. Superintendents in Prussia wear the pectoral cross.

In the Reformed churches the minister wears the black Geneva gown with bands. This use has been largely discontinued in the modern Free churches, but some of these have in comparatively recent times adopted the surplice, and in the Irvingite or Catholic Apostolic Church the traditional vestments have been revived. In the United States, a tendency toward changes in worship and liturgy frequently affects the wearing of vestments at services. For instance, the Book of Worship (1948) of the Congregational Christian churches indicates that the vestments worn by the minister include a cassock, surplice and stole, which "is the sign of an ordained clergyman" and may be of various colours. (E. J. Su.)

D. Anglican Church

In the matter of vestments the Reformation in England passed through several stages. Under Henry VIII no alterations were made. In the first Prayer Book of Edward VI (1549) the priest at Holy Communion is directed to wear "a white alb plain with a vestment or cope," while the assisting priests or deacons are to wear "albs with tunicles." In the medieval period the word vestment was generally used as a collective noun to cover what is now called "a set of vestments." Elsewhere there are directions for the wearing of surplice and hood at choir services in cathedrals and collegiate churches, and bishops are directed to wear, besides a rochet, a surplice or alb and a cope or vestment, with a pastoral staff.

The intention of the framers of this book, among whom was Bishop Nicholas Ridley, was to substitute the Holy Communion for the Mass as a sacrifice as this had been understood in the middle ages. It was soon found. however, that the conservative clergy took advantage of the retention of so much of the old liturgy to celebrate it as "a verie niasse." To guard against this the second Prayer Book of Edward VI (1552), in addition to changing the phraseology and order of the prayers, prescribed as the sole vestment of the minister the surplice, which had previously been associated with the daily prayer offices and sacramental administration but which was free of association with the sacrifice of the Mass. They did this against the Puritan wish to reject all ecclesiastical vestments and to wear lay dress, generally in some academic form, to conduct all services of the church. The Prayer Book of 1552 was of course suppressed during the reign of Queen Mary, but in 1559, after the accession of Elizabeth I, parliament once more adopted it, and passed the Act of Uniformity, which made its use obligatory on all.

In the Prayer Book ordered by the Act of Uniformity of 1559, no explicit directions were given as to the vestments to be worn, but the act ended with a section directing that the ornaments of the church and its ministers were to be "retained and had in use" as they were "by authority of Parliament in the second year of the reign of King Edward VI." An act of parliament is dated from the day it is introduced, not the day it is passed. Although the Prayer Book of 1549 was not issued until the third year of the king's reign. the act imposing it would be referred to as of the second year. Lawyers would naturally read that the Act of Uniformity imposed the "ornaments" ordered by that book, in which at least the most conspicuous of the Mass vestments had been retained. Nothing is historically clearer, however, than the fact that these vestments were not retained long after 1559. The "Reformation Settlement" of the 16th century attempted to settle on an ecclesiastical vesture acceptable to both traditionalists and to the Puritans. The difficulty seems to have been not to suppress the chasuble, which fell into almost complete disuse after 1559, but to save the surplice, which the more zealous Puritans looked on with scarcely less disfavour. More practical directions had been put out by the archbishop of Canterbury, Matthew Parker, in the *Interpretations* of 1560 and the *Advertisements* of 1566. The latter required the clergy to wear "a four-cornered cap, a scholar's gown priestly and in the church a linen surplice." It was impractical to order the use of the chasuble as most of them had been destroyed and contention was too strong, but the cope was ordered as the normal eucharistic vestment for cathedrals and collegiate churches. In practice copes came to be used only on occasions of high ceremony such as the coronation or funeral of the sovereign. The instructions of the *Advertisements* on clerical garments were incorporated into the fully authorized Canons of 1604. Despite this, the Ornaments Rubric, with minor verbal changes, was repeated in the 1662 book. These formularies still govern the Church of England in the matter of vestments. The ordinary costume of the bishop consists of rochet, chimere and square cap, which formerly had been the "undress" uniform of the bishop when going about his business outside the church building. Great liberty with regard to the colour of vestments is also legitimate under the strictest interpretation of the Ornaments Rubric.

With the revival in the 19th century of high sacramental doctrine and of belief in the sacrifice of the Mass, there was a natural tendency to restore the usage of the vestments that symbolized these doctrines (see ENGLAND, CHURCH OF: 20th-Century History *and* Development: Anglo-Catlzolicism). Opposition was aroused, and the judicial committee of the privy council in two cases (1870 and 1877) decided that the usage of the Advertisemeats overruled what seemed to many the natural interpretation of the rubric. This judgment did not at all settle the question. The "ritualistic" clergy refused to obey it on the ground that it was not delivered by a spiritual court, and after 1877 usage became varied even according to parishes. A subcommittee of five bishops was finally appointed to investigate the matter, and their report—"On the Ornaments of the Church and Its Ministers"—was presented in 1908. This document concluded that under the Ornaments Rubric the vestments prescribed in the first Prayer Book of Edward VI are permitted, if not enjoined.

Parliament, by the Enabling act of 1919 (officially Church of England Assembly [Powers] act), gave the Church of England powers of self-government; measures passed by the convocations and the newly established church assembly were subject only to the veto of parliament. Early in 1927 an alternative Prayer Book, drawn up by a committee of bishops and intended, among other things, to regularize practices of doubtful legality under the old book, was adopted by both convocations and by the church assembly; but it was rejected by the house of commons later that year.

The rubrics contained in the new Prayer Book directed that the minister at Holy Communion is to wear either a surplice with stole or scarf, or "an alb plain with a vestment [i.e., chasuble] or cope." The former directive is followed among strong Evangelicals in England and in Canada; the latter is freely interpreted to permit the entire gamut of eucharistic vestments in the liturgy. (W. A. P.; B. G. F. M.)

IV. JEWISH VESTMENTS

1. Old Testament **Priests.**—According to the Pentateuch God commanded Moses to prepare special garments for Aaron and his sons to be worn by them during their services in the Tabernacle. One set of vestments was prescribed for the common priests and two sets for the high priest. These were considered obligatory for the priests of all future generations (cf. Mishnah Yoma 7, 5).

Common Priests.—The vestments of the common priests consisted of four pieces: coat, girdle, cap and breeches. The coat and cap were made of fine linen, the breeches of fine twined linen and the girdle of fine twined linen and of blue, purple and scarlet stuff, embroidered with needlework (Ex. xxviii, 40, 42; xxxix, 27–29).

High *Priest.*—The vestments of the high priest consisted of eight pieces. In addition to the four pieces of the common priest, the high priest had to wear during the services at the Tabernacle: (1) a coat called ephod (*q.v.*); (2) a breastpiece called *hoshen* or *hoshen ha-mishpat;* (3) a *me'il* or robe of blue; and (4) a *ziz* or diadem.

The *hoshen,* in the form of a pouch, was adorned with precious stones. It was "square and double, a span its length and a span its breadth." Four rows of stones were set in it: a row of sardius, topaz and carbuncle; a row of emerald, sapphire and diamond; a row of jacinth, agate and amethyst; and a row of beryl, onyx and jasper. They were enclosed in settings of gold filigree. There were 12 stones "with their names according to the names of the sons of Israel: they shall be like signets, each engraved with its name, for the twelve tribes" (Ex. xxviii, 16–21; xxxix, 8–14). The breastpiece contained the divine oracle called Urim and Thummim (q.v.).

The *me'il,* woven all of blue, is described as follows:

> The opening of the robe in it was like the opening in a garment, with a binding around the opening, that it might not be torn. On the skirts of the robe they made pomegranates of blue and purple and scarlet stuff and fine twined linen. They also made bells of pure gold, and put the bells between the pomegranates upon the skirts of the robe round about, between the pomegranates; a bell and a pomegranate, a bell and a pomegranate round about upon the skirts of the robe for ministering (Ex. xxxix, *22–26; cf.* xxviii, 31–35).

The *ziz,* or diadem of gold, worn by the priest on his forehead, was inscribed. "like the engraving of a signet, 'Holy to the Lord.' And they tied to it a lace of blue. to fasten it on the turban above" (Ex. xxxix, 30–31; cf. xxviii, 36–37). The headgear of the high priest, or his mitre (*miznefet*), was different in form from the cap (*migba'at*) of the common priest, but no description is given in the Pentateuch.

On the Day of Atonement, the most solemn day in the Jewish calendar, the high priest was dressed in pure white from head to foot. These were the "holy vestments;" and before putting them on he had to bathe in water. The ritual bath was repeated when, after his dismissal of the goat (the scapegoat) which was sent away into the wilderness to Azazel, he laid the vestments aside. After the subsequent sacrifices of the day, the high priest resumed his sacerdotal vestments (Lev. xvi).

Levites.—The Levites, who performed various services and were the hymn singers of the Temple, were also dressed in distinctive robes (I Chron. xv, 27; II Chron. v, 12). Flavius Josephus, the Jewish historian of the 1st century A.D., relates that the Levites, who during the time of the Second Commonwealth were degraded by the priests to the position of lower servants (c. 200 B.C.), persuaded King Herod Agrippa II in A.D. 63 to convene the supreme religious council, the Sanhedrin, and to seek from it permission for the Levites to wear linen garinents; the permission was granted (*Antiquities* xx, 9. 6).

2. Second Commonwealth.— In the literature of the time of the Second Commonwealth the vestments of the high priest are described by some authors with great pride (*see* Ecclus. [Sirach] xlv, 6–24; l, 11; Letter of Aristeas, 96–99). The Hellenistic Jewish philosopher Philo of Alexandria (*Vita Mosis* ii, 109–135; De *specialibus legibus* i, 82–97) interpreted the vestments symbolically, as representing the world and its parts: the robe is an image of the air, the ephod a symbol of heaven, the stones at the breast signify the zodiac cycle, and so on. Josephus (*Antiquities* iii, 179–187; *The* Jewish *War* v, 231–237) gives a similar though independent allegorical interpretation of the vestments: The high priest's tunic signifies the earth. being of linen; its blue represents the arch of heaven, its pomegranates the lightning, the sound of its bells the thunder. His upper garments, too, denote universal nature, the breastpiece being set in the midst of the garments after the manner of the earth. Sun and moon are indicated by the two sardonyxes with which the high priest's robe is pinned. The talmudic scholars emphasized the power of the priestly garments to procure forgiveness of sins.

3. Roman **Period.**—In the Roman period of Jewish history, the vestments of the high priest, as symbols of political power. became involved in the struggle between Jewish and Roman authorities. During A.D. 6–36 the vestments were held all year in custody of the Roman authorities and were given out to the high priest only before a holiday, but in 36 the Roman legate Vitellius returned them to the custody of the high priests. In A.D. 44 the procurator Fadus demanded that the vestments be placed under his control, but the emperor Claudius decided against him and they remained in the custody of the high priests until the destruction of the Temple in A.D. 70. After this, animal sacrifices ceased, the high priesthood was abolished and there were no more sacerdotal vestments in Judaism.

4. Nonpriestly **Vestments.**—The synagogue (q.v.) antedates the destruction of the Temple by many centuries, but the scholar, the predecessor of the rabbi, is not the historic heir of the priest and his garments have not the holiness of the high priest's garments. The scholar in the house of learning or in the synagogue wore the same garments as other people. The only demand put on him was that his garments be clean and neat and that all his body be covered by them; it was expected, however, that he would observe the commandment of the fringes, or tassels (*zizit;* Num. xv, 37–40). All Jews, however, endeavoured to reserve a special suit for use in the synagogue, particularly on the Sabbath and holidays.

In course of time. however, a class of scholars developed, and the scholar and later the rabbi could be recognized by his outward appearance. The Talmud already mentions "the overcoat of the scholar" (Baba Batra, 57b), and it prohibits a nonscholar from dressing in the manner of a scholar (*ibid,* 98a). In the middle ages it became customary for a rabbi to wear black velvet or silk, even on weekdays. Rabbis were also exempted from the sumptuary laws in order to add to and strengthen their dignity. Some scholars with mystic inclinations preferred white for their garments. because white symbolizes forgiveness of sins (cf. Isaiah i. 18: Eccles. ix, 8). As early as Josephus (*The Jewish War* iii, 123) the Essenes made a point of always being dressed in white. and in the middle ages even nonscholars dressed in white on the high holidays. A survival of the medieval mystical movements in Judaism, which penetrated deep into Jewish life and left an indelible imprint, is the *kittel* (called *sargeness* by German Jews), the white robe worn by many Jews on the high holidays, on Passover eve at the Seder. and by ultra-Orthodox Jews at the wedding ceremony.

Mysticism became the dominant spiritual power in Judaism with the rise of Hasidism in the 18th century. The *zaddik* ("righteous one") in Hasidism was considered as the sacrificing priest; hence his garb had to be white, like the clothing of the high priest on the Day of Atonement. The conception of the *zaddik* as a surrogate for the high priest. rooted in the cabalistic literature of the middle ages could be traced to some statements in the Talmud The hasidic *zaddikim* dressed in white silk or velvet garments They also wore a distinctive headgear, a round fur cap nith tails, called the *shtreimel* (of Tatar origin). which became the characteristic part of hasidic attire in eastern Europe and was worn not only by the *zaddikim* but also by many of their adherents, especially on the Sabbath and holidays.

In the middle ages certain rabbis wore special kinds of overcoats, but alnays in the style of the country in which they lived. Generally speaking in the early middle ages, as in ancient times, the Jews did not wear distinctive Jewish garments. The fact that the Christian church in the 13th century had to resort to special signs. as the yellow badge and the "Jew hat." imposed upon the Jews by the fourth Lateran council (1215). prove that at that time there was no distinctive Jewish dress. A study of Jewish garments mentioned in the Talmud shows that all their names are of Greek or Latin origin. The *tallit* (prayer shawl) worn by men in the synagogue during the morning service is not of sacred origin. It is an outgrowth from the desire to fulfil the commandment of the fringes To the same category belongs the *arba kanfot*, or small *tallit*, worn by Orthodox Jews under the upper garment all day. Not until later times did the *tallzt* come to be considered as a liturgical garment for the divine service.

A part of Jewish religious attire in modern times is the *yarmulke* or skullcap, which is worn by Orthodox and Conservative male Jews in the synagogue; Reform Jews. however. pray with uncovered heads. The *yarmulke*, like the *shtreimel*, is of non-Jewish origin.

The modern rabbi of all denominations in Judaism adapts his official attire to his environment—in Protestant countries his vestments resemble those of the Protestant clergy, in Catholic countries those of the Catholic clergy. Even the most Orthodox rabbis in western Europe and America, who at the beginning of the 19th century opposed all innovations on principle. have yielded to the natural processes of acculturation and adopted the clerical garments of the Christian clergy. The first Jew to officiate in Protestant clerical garb was Israel Jacobson at the dedication service of the temple in Seesen am Harz. Ger.. in 1810. Only the ultra-Orthodox rabbis and hasidic *zaddikim* remain loyal to the rabbinic attire of the late middle ages. (J. M. RL.)

VESTRIS, AUGUSTE (MARIE JEAN AUGUSTIN) (1760–1842), French virtuoso dancer of unusual brilliance, was a star of the Paris Opéra from his debut in 1772 until his retirement in 1816. Born in Paris on March 27, 1760. he was the son of Marie Allard and Gaetan Vestris (*q.v.*), and was sometimes called Vestr'Allard. Vestris, who inherited the vivacity of his ballerina mother and the technical aptitude of his father. was especially noted for his prodigious leaps. His greatest roles were in *Télémaque* and as Amour in Pierre Gardel's *Psychk*.

His later years mere devoted to teaching, his pupils including Auguste Bournonville, Fanny Elssler (*qq.v.*) and his son Armand Vestris. In 1835 he reappeared for one performance. dancing a minuet with Marie Taglioni. He died in Paris on Dec. 5, 1542. (LN. ME.)

VESTRIS, GAETAN (GAETANO) (1729–1808), French dancer who was the finest male dancer of his time. was noted for his lightness. precision, strength and versatility, Born in Florence, Italy, April 18, 1729. he entered the Paris Opéra ballet school at the age of 19 and studied under Louis Dupré. He danced briefly in the ensemble. was appointed soloist in 1751 and for the next 30 years enjoyed a succession of triumphs in the ballets of Jean Barthélemy Lany, Pierre Gardel and Jean Georges Noverre. He died in Paris. Sept. 23. 1808. Enormously conceited. Vestris declared that the century had produced only three great men: Voltaire, Frederick the Great and himself. He was called. half ironically. "the god of the dance." (LN. ME.)

VESTRIS, MADAME (LUCIA ELIZABETH MATHEWS, née BARTOLOZZI) (1797–1856). English actress and opera singer. was born in London on Jan. 3. 1797, the daughter of Gaetano Stefano Bartolozzi and granddaughter of Francesco Bartolozzi. both engravers. In 1813 she married Auguste Armand Vestris, who deserted her four years later. Madame Vestris made her first appearance in Italian opera in the title role of Peter Winter's *Il ratto di Proserpina* at the King's theatre in 1815. She had an immediate success in both London and Paris, where she played Camille to F. J. Talma's Horace in *Horace*. Her first hit in English was at Drury Lane in James Cobb's *Siege* of *Belgrade* (1820). Because of her beautiful figure, she was a particular favourite in "breeches parts," like Cherubino in *The Marriage of Figaro*, and in *Giovanni in London*. In 1831 she became lessee of the Olympic theatre, and began the presentation of a series of burlesques and extravaganzas for which she made that house famous. She was the first to inaugurate tasteful and beautiful stage décor and to set a standard in stage costumes. She married Charles James Mathews (*q.v.*) in 1838. accompanying him to the United States and aiding him in his subsequent managerial ventures. She died in London on Aug. 8. 1856.

VESUVIANITE: *see* IDOCRASE.

VESUVIUS, a volcano rising from the eastern margin of the Ray of Naples in Italy about 7 m. E S E. of Naples The height of the mountain varies from time to time within limits of several hundred feet. but averages about 4.000 ft above sea-level (in June 1900, 4.275 ft., but after the eruption of 1906

3.668 ft., 4,190 ft. in the 1950s). Vesuvius consists of two distinct portions. On the northern side a lofty semicircular cliff, reaching a height of 3,858 ft., half encircles the present active cone, and descends in long slopes to the plains. This precipice, Monte Somma, forms the wall of a vastly greater prehistoric crater.

At the beginning of the Christian era, and for many previous centuries, no eruption had been known. Strabo, however, detected the probable volcanic origin of the cone and drew attention to its fire-eaten rocks. The sides of the mountain were richly cultivated, as they are still, the vineyards being of extraordinary fertility. Pompeian wine jars are frequently marked with the name *Vesuvinum* (*vinum*). (The wine is now known as *Lacrima Christi.*) On the barren summit lay a wide flat depression, walled by rugged rock festooned with wild vines. The present crater-wall of Monte Somma is doubtless a relic of that time. It was in this lofty rock-girt hollow that the gladiator Spartacus was besieged by the praetor Claudius Pulcher (73 B.C.): he escaped by twisting ropes of vine branches and descending through unguarded fissures in the crater-rim. A painting discovered when excavating in Pompeii in 1879 represents Vesuvius before the eruption (*Notizie degli scavi*, 1880, pl. vii.).

After centuries of quiescence the volcanic energy began again to manifest itself in a succession of earthquakes, which spread alarm through Campania. For some sixteen years after 63 these convulsions did much damage to the surrounding towns. On Xug. 24, 79, the earthquakes, which had been growing more violent, culminated in a tremendous explosion of Vesuvius. A contemporary account of this event has been preserved in two letters of the younger Pliny (Epist. vi. 16, 20) to the historian Tacitus. He was staying at Misenum with his uncle, the elder Pliny, who was in command of the fleet. The latter set out on the afternoon of the 24th to attempt to rescue people at Herculaneum, but came too late, and went to Stabiae, where he spent the night, and died the following morning, suffocated by the poisonous fumes. Three towns are known to have been destroyed — Herculaneum at the western base of the volcano, Pompeii on the south-east side, and Stabiae, which was situated farther south on the site of the modern Castellamare.

For nearly fifteen hundred years after the catastrophe of 79 Vesuvius remained in a condition of less activity. Occasional eruptions are mentioned, in A.D. 202, 472, 512, 685, 993, 1036, 1049, 1139. At length, after a series of earthquakes lasting for six months and gradually increasing in violence, the volcano burst into renewed paroxysmal activity on Dec. 16, 1631. So swiftly did destruction come upon them that 18,000 people are said to have lost their lives.

Since this great convulsion, which emptied the crater, Vesuvius has never again relapsed into a condition of total quiescence. At intervals, varying from a few weeks or months to a few years, it has broken out into eruption, sometimes emitting only steam, dust and scoriae, but frequently also streams of lava. The years 1766–67, 1779, 1794, 1822, 1872, 1906 and 1929 were marked by special activity. The extensive eruption of 1906 completely altered the cone, considerably reducing its height.

The modern cone of the mountain has been built up by successive discharges of lava and fragmentary materials round a vent of eruption, which lies a little south of the centre of the prehistoric crater. The southern segment of the ancient cone has been almost concealed, but is still traceable among the younger accumulations. The numerous deep ravines which indented the sides of the prehistoric volcano have on the south side served as channels to guide the currents of lava from the younger cone. On one of the ridges between these radiating valleys an observatory for watching the progress of the volcano was established by the Neapolitan government (1844). Since 1880 a funicular railway has carried tourists almost to the crater's mouth.

(A. GEI.; T. A.)

VETCH (*Vicia*), a genus of leguminous (pod-bearing) herbs widely distributed in temperate regions of North America and Eurasia. Of approximately 150 known species, a few are cultivated as important food, fodder and cover crops and green manure. Like other legumes, they add nitrogen, by means of nitrogen-fixing bacteria, to the soil and thus are particularly valuable as a soil-enriching crop. The plants are from one to four feet high with trailing or climbing stems. compound leaves with several pairs of leaflets and magenta, bluish-white, white and yellow flowers borne singly, in clusters and in racemes. There are from two to ten smooth, usually varicoloured seeds in a pod.

Species and Distribution. — Most perennial vetches are wild. The wild annual form, sometimes regarded as a distinct form of *Vicia angustifolia*, is common in dry soils. Bitter vetch (*V. ervilia*) and wood vetch (V. *sylvatica*) are indigenous British species. The name vetch is applied to plants of a few genera other than *Vicia* of the family Leguminosae, including kidney vetch (*Anthyllis vulneraria*); the yellow-blossomed horseshoe vetch (*Hippocrepis*) with its characteristically shaped curved pods; milk vetch (*Astragalus*); and crown vetch (*Coronilla*).

Common or spring vetch (*V. sativa*). a winter annual also known as tares, is native to Eurasia and naturalized in North America, where it is cultivated in the northern and Pacific states of the U.S. and in southern Canada. Hairy or winter vetch (V. *villosa*), also introduced from Eurasia, is grown in states along the southeastern seaboard and the Gulf of Mexico. inland in Oklahoma, Arkansas, Missouri and Nebraska, and in Oregon and Washington. Common vetch, while widely used as a soil-improving crop, is grown in western Oregon and Washington for hay, silage, green feed, pasture and seed; hairy vetch is utilized mainly for seed and green manure. Other species grown to a limited extent are Hungarian vetch (*V. pannonica*) and purple vetch (*V. atropurpurea*), in the Pacific coast states; monantha (*V. monantha*), in the Gulf states; and smooth vetch, a less downy variety of the hairy species, grown in both regions and gradually replacing the pubescent variety. Seeds of the hairy and smooth varieties often are mixed and sold as hairy vetch. Woollypod (*V. dasycarpa*),, similar to smooth vetch, is of increasing importance in southern states, but seed supplies are limited.

In Britain, spring varieties do best; they are cultivated for fodder, silage or seed, or plowed under as green manure. The pod of V. *faba*, known as Windsor, horse or broad bean, is the bean grown for human and animal consumption since early times; it remains an important crop in Europe and southeast Asia.

Cultivation. — Vetches are adaptable to a wide range of soil conditions but yield the greatest bulk of forage on fertile. heavy, well-drained soil. Barnyard or artificial manure should he supplied where the soil is in poor physical condition. Like other legumes, vetches require the presence of certain symbiotic bacteria for successful development; such bacteria must be introduced when planting the crop for the first time.

By alternating winter and spring varieties of vetch with clover or grass, each crop of vetch can be utilized as cattle food when at its peak. When used for forage the crop generally is cut in the flowering or early-seeding stage. For seed it generally is mowed and swathed when the majority of pods are mature, and threshed when dry. Shattering varieties should be cut earlier to reduce seed losses. Vetches may be cultivated with rye for early spring grazing; grown in association with oats, they form a useful mixture for hay, silage or green fodder. When winter vetch is required it is important to obtain seed from a crop sown in the autumn.

When intended for seed production, vetches commonly are grown in association with companion crops that will reduce lodging. For silage, typical mixtures for, autumn sowing on light lands are two bushels of tares and one-half bushel of rye per acre; and on heavy lands, two bushels of tares, one-half bushel of beans and one-half bushel of winter oats. On rich lands lighter seedings of tares are required to avoid lodging, the difference being made up by increased quantities of beans and oats. Lighter seedings of tares are required in the U.S. than in Europe, especially when grown for hay or seed. Vetch seed in demand in the southern states, primarily for cover-crop and green-manure purposes, formerly was imported from Europe. By the late 1950s, however, the seed was supplied largely from states of the Pacific northwest and from Texas, Arkansas and Oklahoma.

In Britain about. 60% of the crop is cut for green fodder or silage, about 25% harvested ripe for seed and about 15% cut for hay. The amount of hay and green fodder sold to horse and cow owners in towns is small. About 70% of the seed is used for reseeding or for feeding of stock; the remainder is sold. usually for pigeon and poultry mixtures.

VETERANS ADMINISTRATION, U.S. The Veterans administration (VA), an independent agency of the United States government charged with administering benefits created by law for U.S. veterans and their families, was created by executive order no. 5398, dated July 21, 1930, issued under authority of a law enacted on July 3, 1930.

The purpose of the VA, as stated in that law, was to "consolidate and coordinate Governmental activities affecting war veterans," which, up to that time, had been carried on by three separate agencies: the veterans bureau, the pension bureau of the interior department and the national home for disabled volunteer soldiers.

The VA, headed by an administrator of veterans affairs, maintains a central office in Washington, D.C., as well as regional offices, hospitals, domiciliary homes and district offices located in various parts of the United States and its possessions.

By the end of Aug. 1958 there were more than 22,700,000 veterans of all wars in the United States. Together with their families, they made up two fifths of the nation. Of the veterans. 67%, or more than 15,308,000, served in World War II. About 5,300,000 saw service following the outbreak of hostilities in Korea in June 1950. Of these, 917,000 were World War II veterans who had gone back on active duty during the Korean conflict.

Early History.—Veterans' benefits first took the form in Europe of war pensions (*q.v.*) in the late 16th century; the concept of community responsibility for those who served in battle was brought over to the American colonies by the Pilgrims. Early medical benefits were provided by such military hospitals as the Kilmainham hospital in Dublin (1679), the Invalides in Paris (1670) and the Royal hospital at Chelsea, Eng. (1692). (*See* CHELSEA, THE ROYAL HOSPITAL.)

The United States took its first steps in caring for ill and disabled ex-servicemen in 1811. when congress authorized the secretary of navy to build a permanent naval home for disabled and decrepit officers, seamen and marines. The home, built in Philadelphia, was not occupied until 1831. The National Home for Disabled Volunteer Soldiers was established after the Civil War, and its first branch at Togus, Me., opened in 1867. Others later were established for domiciliary care of veterans! and all became part of the VA when that agency was formed in 1930.

With World War I came a new concept of benefits for veterans in the U.S., encompassed in an amendment of Oct. 6, 1917, to the War Risk Insurance act. The program included compensation for injuries received in military service; allotments for the support of close dependents; a system of life insurance; medical, surgical and hospital treatment; and vocational rehabilitation for the service disabled. Administration of the first four benefits was assigned to the bureau of war risk insurance; the fifth was given to the federal board for vocational education. Functions of the two agencies were consolidated with the establishment of the veterans bureau on Aug. 9, 1921. The veterans bureau became part of VA in 1930.

World War II Veterans' Benefits.—World War II was in progress in Europe, but had not pet involved the United States. when two laws were enacted which were to affect U.S. veterans. The first, the Selective Training and Service act of Sept. 16, 1940, provided for the draft as well as for benefits after discharge, such as re-employment rights. The second, passed Oct. 8, 1940, established a low-cost system of National Service life insurance for servicemen and veterans. At the end of 1958 nearly 5,400,000 World War II veterans were holding $35,400,000,000 worth of National Service life insurance. At the same time there were approximately 351,000 veterans of World War I who held insurance policies valued at $1,500,000,000.

When the war was at its height two more veterans' measures came into being. One was the Vocational Rehabilitation act of March 24, 1943 (public law 16, 78th congress), furnishing training to veterans who needed it to overcome the handicap of service-connected disabilities. By the time this program ended for virtually all veterans on July 25, 1956, more than 610,000 disabled World War II veterans had received training.

The other law mas the far-reaching G.I. Bill of Rights (public law 346. 78th congress) of June 22, 1944. Under this lam, eligible veterans could receive education and training at government expense, readjustment allowances for unemployment and guaranteed or insured loans for homes, farms and businesses.

The G.I. bill benefited millions of veterans in their efforts to readjust successfully to postwar living. Under the readjustment allowance program, which ended for most veterans in July 1949, nearly 9,000,000 veterans received a grand total of $3,800,000,000, which they used to tide them over during periods when they were looking for work. Only one out of ten of the veterans stayed on the allowance rolls for the maximum period of 52 weeks.

The education and training program, in turn, reached its end for nearly all World War II veterans on July 25, 1956. Under this program, a World War II veteran could go to school or college! or obtain on-the-job or on-the-farm training, with the government paying all his training expenses and in addition paying him a living allowance of up to $120 a month.

More than half of the nation's World War II veterans, or 7,800,000, availed themselves of the educational opportunities of the G.I. bill during the 12 years the program was in effect. Of these, 2,300,000 attended college; 3,400,000 attended schools below the college level; 1,400,000 received on-the-job training and 700.000 had taken on-the-farm training. The program cost $14,500,000,000. Only five cents out of every dollar was spent for administration.

By 1957 the guaranteed and insured loan program of the G.I. bill was the only one of the "big three" G.I. benefits still in force. World War II veterans then had until July 25, 1958. to apply for loans and up to a year later to complete the transaction. By later legislation. however. World War II veterans had until July 25, 1960, to apply for G.I. loans and up to a full year after that to close the transaction.

Under the G.I. loan program, the veteran usually made his own arrangements for a loan through such lending channels as banks. building and loan associations or builders. Then. VA was empowered to guarantee home loans up to 60% of the amount, with a top guaranty of $7.500. Other real estate loans were guaranteed up to 50%, with a $4,000 top. Nonreal estate loans. such as business loans, could be guaranteed for 50%, with a $2,000 guaranty ceiling.

About 5,395,000 veterans had obtained G.I. loans, valued at nearly $43,800,000,000, by the end oi Feb. 1958. About 95% of the loans were for homes. Veterans proved to be excellent loan risks, for it was found that less than 1% of the total defaulted on their payments to the point where VA had to pay lenders the guaranteed portions of the loans.

Benefits for Korea Veterans.—On June 27. 1950, the president ordered U S. troops into action in Korea. Men nere subsequently called into service in increasing numbers. At first. the veterans' benefits to which this new group of servicemen would be entitled were limited to those that any peacetime veteran could get—disability compensation at peacetime rates, hospitalization under certain limited conditions and a few others. Wartime benefits could not be authorized because the United States was not officially at war.

On Dec 27, 1950, vocational rehabilitation training was extended to disabled Korea veterans—the first of a stream of benefits designed to assist Korea veterans in readjusting to civil life. While in training and for two months afterward. the veterans received a subsistence allowance from the government, in addition to their monthly disability compensation payments. About 56,000 disabled Korea veterans had received vocational rehabilitation training by the end of 1958.

On April 25, 1951, a new system of G.I. insurance was created for Korea veterans under the Servicemen's Indemnity and Insurance acts. Without cost, U.S. Korea veterans were insured against death in service and for 120 days after discharge. They also were given the right to apply for low-cost nonparticipating (nondividend paying) G.I. policies after they left service. The free coverage, as well as the right to apply for G.I. insurance. ended for Korea veterans on Dec. 31, 1956. At that time there went into effect the Servicemen's and Veterans' Survivor Benefits act (public law 881, 84th congress); which generally increased benefits to widows and children of deceased servicemen and veterans who died of service-connected causes by partially relating benefits to the military pay of the deceased. It also placed the armed forces under social security, on a contributory basis, and revised the six-month death gratuity paid to veterans' survivors by the armed forces. so that payments ranged from $800 to $3,000. Death payments to widows and children of veterans who died of non-service-connected causes were not changed by the act.

By the end of 1958 about 685,000 Korea veterans had G.I. term insurance totaling $6,200,000,000. Under a law passed in 1958, these veterans obtained the right to convert their term insurance to permanent plans beginning Jan. 1. 1959.

On July 16, 1952, a new Korean G.I. bill was enacted, providing five benefits for veterans who served in the armed forces during the Korean conflict. The benefits included education and training, G.I. loans. unemployment compensation, mustering-out pay and job-finding assistance.

Under this G.I. training program, a veteran is entitled to one and one-half days of education or training for each day spent in service during the Korean conflict period, with a maximum of 36 months. While in training, he is entitled to receive an allowance from the government of up to $160 a month, to help meet the cost of his studies. By the end of 1958 more than 2,000,000 veterans had taken training under the Korean G.I. bill: half had attended college; one third had gone to schools below the college level, and the rest had received on-the-job or on-the-farm training.

In 1958 VA regulations were liberalized to permit many veterans who had been obliged to drop out of training to resume their education. This program was to remain in effect through Jan. 31, 1965.

The Korean G.I. loan program operates in exactly the same manner as the program for World War II veterans. About 550,000 Korea veterans obtained G.I. loans by the end of Feb. 1958; the program extends until 1965. VA administers both the training and loan provisions of the Korean G.I. bill.

Unemployment compensation for Korea veterans—$26 a week for a maximum of 26 weeks—is handled through the individual state governments by the U.S. department of labour. The mustering-out program administered by the armed forces provides payments. at time of discharge, ranging from $100 to $300. depending on length and type of military service. Another G.I. bill program consists of job counseling and placement services offered by the U.S. employment service. Under a law passed in 1958 unemployment compensation was made available to servicemen released from the armed forces after Oct. 27. 1958.

Other Veterans Benefits.—At the close of 1958, VA operated a network of 171 hospitals for the treatment of ill and disabled veterans of all wars and the peacetime service. It also used beds in civil. state and other federal hospitals on a contract basis. Veterans with service-connected disabilities received first call for VA hospitalization. Then came war veterans and those with post-Korean service, who needed treatment for conditions having nothing to do with their military service. Veterans in this latter class were required to state that they were unable to pay for private hospital care. and to wait until a bed became available.

VA administers programs of compensation and pensions for veterans and the families of deceased veterans. Compensation is payable to those with service-connected disabilities resulting either from war or peacetime service. Wartime rates—also paid to disabled Korea veterans—range from $19 to $225 a month, depending upon the severity of the disability. Peacetime rates are 80% of the wartime scale. Pensions are paid to World War I, World War II and Korea veterans. who are totally and permanently disabled for reasons not traceable to service. and whose income falls below certain levels. Rates are $66.15 a month. increased to $78.75 after 10 years or when the veteran reaches the age of 65.

More than 3.700.000 veterans and dependents of deceased veterans were on VA's pension and compensation rolls in Feb. 1958. Nearly 900,000 were drawing payments as a result of the Korean conflict.

VA administers a number of other benefits. mostly designed to help disabled veterans readjust successfully to peacetime living despite their handicaps. A grant of $1.600 toward the purchase of an automobile may be provided to those who lost, or lost the use of. one or both hands or feet, or who were blinded. The disabilities must have resulted either from World War II service or from service after the Korean conflict began.

Also, VA may furnish a grant of up to $10,000 toward the purchase of a specially-equipped "wheelchair home" to veterans of either war or peacetime service who were entitled to VA compensation because of the loss, or loss of use of, both of their legs. The disability must be so severe that the veteran cannot get about without the aid of crutches. cane or a wheelchair.

War Orphans Education.— In June 1956 congress enacted a War Orphans Education program for the sons and daughters of World War I. World War II and Korea veterans who died as a result of service-connected conditions. Veterans' children. generally between 18 and 23 years of age, may receive up to 36 months of schooling. with VA paying them an allowance of up to $110 a month for those enrolled full time.

Approximately 150.000 young men and women were eligible for the educational grants. Some still were expected to be in school when the 20th century drew to an end. (S. G. W.)

VETERANS DAY (Armistice Day), the anniversary of the cessation of hostilities in World War I (Nov. 11, 1918) and of the signing of an armistice between the Allies and Germany. Immediately after the war, Nov. 11 was set aside in the U.S., Great Britain and France as a day of remembrance for those who had given their lives in the war and was generally called Armistice day. After World War II the day was recognized as a day of tribute to the dead of that conflict as well as of World War I. In Canada it came to be known as Remembrance day. In Great Britain the Sunday nearest Nov. 11 was proclaimed as Remembrance Sunday and was devoted to honouring the dead of both world wars. After the Korean war the president of the U.S. signed a bill (June 1, 1954) designating Nov. 11 as Veterans day and proclaiming it as an occasion for honouring veterans of all mars. The day is usually observed with parades, speeches and the placing of floral tributes on the graves of servicemen. In the U.S., group naturalization ceremonies have come to be an important part of the day's activities. Special services are held at the Tomb of the Unknowns in Arlington National cemetery, Arlington, Va., and at similar shrines in other countries.

VETERANS OF FOREIGN WARS, a U.S. organization created in 1913–14 by the merger of three national societies of overseas war veterans that were founded shortly following the close of the Spanish-American War in 1899. These societies were the American Veterans of Foreign Service, chartered by the state of Ohio on Oct. 11, 1899; the Colorado Society of the Army of the Philippines, organized in Denver: Colo., Dec. 1, 1899; and another society also known as the American Veterans of Foreign Service, formed in Altoona, Pa. These organizations merged in a convention in Pittsburgh, Pa., to become the single nationwide association that has been known since then as the Veterans of Foreign Wars of the United States (V.F.W.). The organization received a congressional charter in 1936.

Membership in the V.F.W. is restricted to "Any male officer or enlisted man, or any honorably discharged male officer or enlisted man, who is a citizen of the United States of America and who has 'served' in the Military or Naval Service of the United States of America in any foreign war, insurrection or expedition, which service shall be recognized by the authorization of the issuance of a campaign medal by the Military or Naval Service of the United States of America."

The basic aims of the V.F.W. are as follows: to ensure the national security through maximum military strength; to speed the rehabilitation of the nation's disabled and needy veterans; to assist the widows, orphans and other dependents of disabled and needy veterans; to promote Americanism through education in patriotism and constructive service to individual communities.

The V.F.W. legislative service maintains its office in the V.F.W. Memorial building in Washington, D.C., dedicated Feb. 1, 1960, by Pres. Dwight D. Eisenhower. The V.F.W. also maintains the central office of its national rehabilitation service in Washington, D.C. This nationwide program serves all disabled veterans of all wars, members and nonmembers alike, in matters of government compensation and pension claims: hospitalization, civil service employment preference, etc. Another important function of the organization is the community-service and youth-activities programs. The organization annually completes more than 500.000 individual community service projects through its 10,000 individual units, known as "posts." The V.F.W. also supports a youth program in which about 5,000,000 youths annually participate in events such as bowling tournaments, rifle meets, marble tournaments and baseball tournaments.

At Eaton Rapids: Mich., the V.F.W. maintains a national home for orphans of deceased or totally disabled overseas veterans. The home campus includes more than 30 family-size dwellings, each housing a typical family group of children under the care of a trained housemother.

In addition to its Washington office! the V.F.W. maintains its national headquarters in Kansas City, Mo. From this office the 50 state departments of the organization and the department of the Panama Canal Zone are serviced. (J. L. SM.)

VETERINARY SCIENCE deals with the anatomy, physiology and pathology of animals other than man. It includes the diagnosis, prophylaxis and treatment of their diseases and infirmities; their relationship to man with regard to intercommunicable diseases and to the use of their flesh and other products; and their scientific breeding, feeding and handling. In North America and to a lesser extent in Europe, however, the breeding, feeding and handling of normal animals is largely in the hands of persons trained in the field of animal husbandry.

This article surveys the general field of veterinary science, while the following articles discuss specific aspects: ANIMAL BREEDING; ANIMAL HEAT; FEEDS, ANIMAL; POULTRY AKD POULTRY FARMING. *See* also CAT; CATTLE; DOG; HORSE; PIG; SHEEP; and other articles on various animals.

Many specific diseases are treated in individual articles, as ANTHRAX; BACTERIAL AND INFECTIOUS DISEASES; BRUCELLOSIS; CANCER; DISTEMPER, CANINE; ENCEPHALITIS; FOOT-AND-MOUTH DISEASE; GLANDERS; IMMUNITY; PATHOLOGY; PLEUROPNEUMONIA; PSITTACOSIS; RABIES; RINDERPEST; SWIKE FEVER; TULAREMIA; VACCINE THERAPY; VIRUSES.

HISTORY

Persons known as animal doctors have existed since earliest times. Veterinary science flourished in ancient India, where separate treatises on the diseases of horses and elephants were written, and there were hospitals for various species of animals. The legal code of the Babylonian king Hammurabi (c. 1800 B.C.) prescribed the fees for "doctors of asses and oxen," and the Egyptian papyrus of Kahun (c. 1900 B.C.) gave prescriptions for diseases of dogs and cattle. The ancient Greeks had a class of *hippiatroi* (literally, "horse-doctors"), and a number of writers (Hippocrates, b. 460 B.c.; Xenophon, b. c. 430 B.C.; Aristotle, b. 384 B.c.) gave consideration to the treatment of animal diseases. The Romans took little interest in medicine, leaving this to the Greek physicians in Rome, but several writers on husbandry (Cato, b. 234 B.C.; Varro, b. 116 B.C.; Columella, fl. A.D. 60), gave good descriptions of animal disease and treatment. The word veterinary comes from the Latin *veterinarius,* "pertaining to beasts of burden," and the armies of the later Roman empire had a *veterinarium* or "hospital for sick and wounded horses." The physician, Galen (c. A.D. 130–c. 200), wrote on animal physiology.

The Greek veterinarians of the Roman armies during the Byzantine period demonstrated a high level of proficiency! superior in some respects to that of medical practitioners. Chief among these Byzantine veterinarians was Xpsyrtus (fl. A.D. 330), whose writings mark him as the "father" of veterinary medicine. The *Hippiatrika,* compiled in the 10th century under the direction of Constantine Porphrygenitus from these Byzantine writings, has preserved the best account of veterinary practice prior to the fall of the eastern empire. Better known is the *Artis Veterinariae* of the Roman, Vegetius (fl. A.D. 450), the last important veterinary writing for nearly 1,000 years and the first influential veterinary work to be printed (Basel, 1528). Vegetius demonstrated an understanding of the importance of segregating sick animals as well as other principles of hygiene and preventive medicine. He also deplored the already lowered status of the veterinary art and ridiculed the tendency to attribute animal disease to supernatural influences. However, this superstition long remained a deterrent to the development of animal medicine.

From the middle ages until modern times, persons called farriers, who in Roman times were merely horseshoers, were attached to the cavalry of most countries to treat sick and wounded horses. Practice upon the animals of the civilian population also became firmly entrenched in their hands. However, they contributed little to the general knowledge of animal diseases, and their mean status was a factor in deterring educated persons from taking up the profession. Practitioners upon cattle, called cow leeches, were even more ignorant in their methods, and were looked down upon even by farriers. A standstill in veterinary knowledge extended from late Roman times to the 18th century. A major exception. however. was Carlo Ruini's excellent treatise. *Anatomia del Cavallo* ("Anatomy of the Horse." 1598), the first completely original work on the horse in more than 1.000 years, which included a section on diseases.

The depredations caused by animal plagues during the 18th century in Europe forced a reappraisal of the methods of dealing nith animal disease. Most significant was the establishment of veterinary schools throughout Europe in the late 18th and early 19th centuries. With veterinary medicine once again in the hands of educated men, the profession rapidly regained its lost status and its development closely paralleled that of medicine. The methods and techniques of one were readily adapted to the other, and with the recognition of the close interrelationship of many human and animal diseases. human and animal medicine came to be regarded as complementary.

In the Cnited States and Canada. because of the scarcity and isolation of domestic animals during the colonial period. which was thus characterized by a relative freedom from major animal diseases. veterinary science as a profession developed somewhat belatedly.

ECONOMIC ASPECTS

Preventive veterinary medicine and control measures are of great economic importance to animal breeders, farmers and the general populace. A precise figure for the losses from animal disease cannot be given, but conservative estimates place this at about $2,000,000,000 annually in the U.S., or about 10% of the total value of livestock. The major causes of loss are parasitism of all species. and the complex of conditions resulting in impaired fertility of cattle, which probably account for about half the total. All poultry diseases, together with mastitis and brucellosis of cattle. account for about 25%. Other diseases of major importance are: swine fever (hog cholera), tuberculosis of cattle and swine. swine erysipelas and anthrax and leptospirosis in all species. Losses from diseases of dogs and cats cannot be determined reliably. The loss of animals from rabies is not great. but the cost of rabies control is high.

Methods of control include rigid sanitation and the segregation of sick animals to prevent the spread of disease, and optimal nutrition to increase natural resistance of animals to disease and to parasites. Vaccination is employed'to create an artificial immunity against such infectious diseases as anthrax, brucellosis. canine distemper, rabies and swine fever. Quarantine is imposed to prevent spread of highly contagious diseases once their presence is known. Imported animals are regularly quarantined to prevent introduction of disease. X regular program of testing cattle for tuberculosis and brucellosis is carried out nationally. and infected animals are slaughtered. The addition of antibiotic substances to feedstuffs has markedly decreased losses from swine and poultry diseases.

PUBLIC HEALTH ASPECTS

This discipline requires the attention of many veterinary and medical practitioners, research workers and administrators. Traditionally it has included eradication and control of the zoonoses (diseases communicable betaeen animals and man) and food hygiene — primarily the inspection of food products of animal origin. To these have been added industrial hygiene, including prevention of air and water pollution and occupational diseases of handlers of animal products; radiological health, concerned with the biological effects of radiation; space medicine. involving research on the effects of high altitudes on the animal body; and animal cancer research as a means of attacking the problem of cancer in man and animals.

Of the more than 80 animal diseases transmissible between animals and man. the more common include: tuberculosis. brucellosis, anthrax, rabies. psittacosis, encephalomyelitis (several kinds), typhus, plague, Q fever, trypanosomiasis, amoebic dysentery. leptospirosis and salmonellosis. In the U.S. bovine tuberculosis in man has been virtually eliminated by the work of veterinarians in the eradication of the disease in cattle, and much progress has been made in the eradication of brucellosis. In many countries of the world the zoonoses are a major deterrent to economic development.

In the U.S , nations of the British Commonwealth and most of continental Europe veterinary inspection of foods of animal origin is a major safeguard to consumers of these products. In most countries the various aspects of veterinary public health are administered on local and state levels as well as by national governments.

VETERINARY SCIENCE AS A PROFESSION

In the United States persons trained in veterinary science are usually known as veterinarians; in British Commonwealth nations the usual designation is veterinary surgeon. To qualify for membership in the profession in many parts of the world, candidates must complete an educational program of from five to six or more years of work at the university level, after which they must obtain a licence to practise the profession from some duly constituted governmental authority. In Great Britain this authority is invested in the Royal College of Veterinary Surgeons. In the United States a licensing board consisting of veterinarians appointed by the government of each state examines the credentials of graduates, gives examinations and recommends those to be licensed.

About 1950 a national board of veterinary examiners was set up, and a number of states accepted the examinations of this board in lieu of their own. In both the U.S. and Britain. the qualifications for the profession are set and maintained by the profession itself.

Schools. — Formal veterinary education had its beginnings in France. The first school was organized at Lyon in 1762 and the second at Maisons-Alfort. a suburb of Paris, in 1765. During the half-century following 1765, schools were established in Berlin, Copenhagen and London and eventually in nearly every important city of Europe. The veterinary schools of other parts of the world appeared considerably later. The veterinary schools of Great Britain were established in London (1792), Edinburgh (1823), Glasgow (1863), Dublin (1900), Liverpool (1904), Bristol (1949) and Cambridge (1949). Each is affiliated with the university of the city where it is located. Those of the G.S. are affiliated with Iowa State college (veterinary school established 18793, University of Pennsylvania (1884), Ohio State university (1885), Cornell university (1896), Washington State college (1899), Kansas State college (1905), Alabama Polytechnic institute (1907), Colorado State university (1907), Michigan State university (1909), Texas Agricultural and Mechanical college (1916), Tuskegee institute (1945). University of Georgia (1946), University of Missouri (1946). University of Minnesota (1947), Oklahoma Agricultural and Mechanical college (1947), University of California (1948), Cniversity of Illinois (1948) and Purdue university (1958).

There are tno veterinary colleges in Canada: the Ontario Veterinary college (1862), affiliated with the University of Toronto. and the École de Mkdecine Vétérinaire (1894). affiliated with the University of Montreal. Instruction in the latter is in French. Veterinary schools in other English-speaking countries include Makerere, in British East Africa; Onderstepoort, affiliated with the University of Pretoria, Union of South Africa; and those affiliated with the Universities of Queensland and of Sydney, in Australia, and with the University of the Philippines. By the second half of the 20th century there were about 180 veterinary schools in the world.

In the U S and some European countries the veterinary schools award the degree of Doctor of Veterinary Medicine (D V.M.). Graduates of veterinary colleges in Great Britain do not receive the doctor's degree, but upon admittance to membership in the Royal College of Veterinary Surgeons are entitled to append the letters M.R C.V.S. to their names.

Curriculum.—The fundamental disciplines common to most veterinary schools require preliminary training in chemistry, physics, zoology, animal husbandry, botany and languages, as in premedical education. The preclinical subjects include: anatomy, the study of the normal structure of domestic animals, and histology, the microscopic anatomy of tissues; physiology, the study of function of organs and systems of the body; pharmacology, the study of drugs and their actions; microbiology. including bacteriology and virology, the study of bacteria and viruses and their immunological reactions, and parasitology, pertaining to both ecto- and endoparasites and the means of their control; and pathology, the study of the effects of disease upon the body.

The clinical subjects can be divided broadly into: medicine, surgery, preventive medicine and clinical practice. Internal medicine includes the diagnosis, treatment and prophylaxis of diseases as they affect animals. Preventive medicine and public health concern the broader aspects of disease prevention and control, especially of diseases transmissible between animals and man or affecting human welfare, like the contagious diseases of food-producing animals. Surgery includes wound treatment, fracture repair, the excision of body parts and the related techniques of radiology, anesthesiology, obstetrics and treatment of lamenesses. A clinic is operated to enable students to observe and assist with actual cases of disease or other conditions requiring attention. In both medical and surgical treatment the same techniques are employed as in human practice.

Growth of Profession. — In the late 1950s the Directory of the American Veterinary Medical association listed more than 19,000 veterinarians in the United States and more than 1,400 in Canada. The Register of the Royal College of Veterinary Surgeons listed about 6.300 members, of which more than 4.000 were working in the British Isles. The world supply of veterinarians in the late 1950s was in excess of 90,000, about one-third of them in western Europe. The remainder of the world was generally undersupplied.

In both Great Britain and North America the veterinary population rose steadily from late in the 19th century until the end of World War I. During this time a large part of the profession had been concerned primarily with horses. There followed a period of readjustment to the mechanization of transportation and agriculture in which pessimism about the future of the profession was reflected in declining numbers of practitioners and of students entering veterinary schools.

After 1935, however, a decided upturn was noted; schools were forced to limit enrollments, and after World War II several new schools were established to accommodate the pressures for admission. Growth of the veterinary profession was a reflection of increasing demand.

Vocational Trends. — Graduates in the 1950s who had a broad cultural and scientific education found many outlets for their talents. Surveys showed that only about 60% of graduates in the U.S. and 50% in Canada went into private practice; the rest were employed in salaried positions. A substantial proportion of those who chose to enter practice did so as specialists in one or more species, or in such subspecialties as the breeding diseases of cattle. In the U.S. the federal department of agriculture was the largest single employer of veterinarians. Of these, many were engaged in meat inspection; others were in various field activities such as enforcing quarantine laws and regulations designed to prevent importation of diseased animals and disease-harbouring materials from abroad, the enforcing of interstate shipping laws and the supervision of production of serums, vaccines and other biological products. Many were engaged in research and diagnostic work. All of the state governments employed veterinarians for similar duties. Others were in the federal public health service and the food and drug administration, or the armed services. Some were employed as teachers in veterinary and agricultural schools. Many others were privately employed in zoological parks, food processing concerns, large dairy companies, pharmaceutical and biological manufacturing companies and animal feed manufacturers.

VETERINARY ORGANIZATIONS

Veterinary associations exist in practically all countries, their purpose being to advance the standards and improve the services of the profession.

The *Veterinary Record* is a weekly publication of the British Veterinary association; the *Journal of the American Veterinary Medical Association,* a biweekly, and the *American Journal of Veterinary Research,* a quarterly, are publications of the American Veterinary Medical association. The International Veterinary congress is organized at approximately four-year intervals, with about 60 countries sending delegates.

TRENDS IN VETERINARY SCIENCE

An increased emphasis on public health and animal disease research is evinced by the increasing number of graduates entering these areas. Specialization in practice, alnays more or less characteristic, is increasingly evident. In the U.S. many small-animal practitioners own hospitals comparable in many respects to hospitals for humans. The extension of contract farming to livestock raising. whereby individual stock owners are affiliated with a marketing corporation, has placed increased emphasis upon maintenance of herd or flock health, and proportionately less on the treatment of individual sick animals.

A major challenge to veterinary science is the supplying of adequate service to underdeveloped areas of the world. The plains of Africa, for example. could produce vast quantities of much needed meat once the problems of animal diseases, such as tsetse fly infection, peculiar to this region have been mastered. Except for most of the countries of western Europe, the supply of veterinarians has not been adequate to meet the demand. To meet these needs, a greatly increased output of broadly trained veterinarians by existing or new schools will be required.

VETO, a negative upon a course of action, preventing or impeding its execution. (Latin. *veto,* "I forbid"). A veto is a means of self-protection exercised by a unit of government against encroachment by other units of government. A veto may be absolute, in which case it cannot be reversed by other governmental units; or it may be qualified, or subject to being overriden, under certain conditions, by other units.

The president of the United States is given a strong veto power by the constitution (art. i, sec. 7). All bills, passed by both houses of congress, must be submitted to the president. To veto a bill, he declines to sign it and returns it to the house of origin with his objections. The bill is then of no effect unless each house votes by a two-thirds majority to pass it over his veto. In such case, the bill becomes law without presidential approval. Under the constitution. if the president does not return a bill within ten days. excluding Sundays, it becomes law without his signature. If, however, congress adjourns before the ten days have elapsed, the president may kill the bill simply by failing to act upon it. This is the pocket veto, and it is absolute.

Early presidents employed the veto chiefly to object to legislation which they considered unconstitutional. Andrew Jackson was the first president to use the veto as a means of appealing to the public on matters of general policy. Jackson's veto of legislation to recharter the second Bank of the United States was in effect a campaign document which figured prominently in the presidential election of 1832. Of all presidents. Franklin D. Roosevelt vetoed the most bills, 584 in all. His closest competitor was Harry S. Truman, who vetoed 101 bills. The overriding of vetoes is highly infrequent.

American governors are given the veto power in every state except North Carolina. Governors in 38 states are empowered to exercise the item veto in respect to appropriation bills, but the president does not possess this power. The item veto gives the executive power to strike out specific sections while signing the remainder of the bill.

The striking down by courts of statutes on constitutional grounds is sometimes termed the judicial veto. *(See* JUDICIAL REVIEW).

The veto is also important in the United Nations. The UN charter requires that votes on nonprocedural matters be taken in the Security council by concurrence of 7 of the 11 members, provided that all 5 of the permanent members of the council be among the 7. The charter provision has the effect of granting a veto on UN action to each of the five permanent members — the Soviet Union, the United States, Great Britain, France and China. Serious dissatisfaction has been expressed with the arrangement. (See UNITED NATIONS.)

For a discussion of the Polish *liberum veto,* an absolute power of veto enjoyed by individual members of the Polish diet in the 17th and 18th centuries, *see* POLAND: *History.*

BIBLIOGRAPHY.—Edward C. Mason, *The Veto Power* (1891); Edward S. Corwin, *The President: Office and Powers, 1787–1948,* 3rd ed. rev. (1948); Eugene P. Chase, *The United Nations in Action* (1950); Edward S. Corwin and Louis W. Koenig, *The Presidency Today* (19j6). (L. W. K.)

VETTER, a lake of south Sweden, 81 mi. long and 19 mi. in extreme breadth, 733 sq.mi. in area, 420 ft. maximum depth and at an elevation above sea level of 289 ft. It drains by the Motala river to the Baltic. Its waters are transparent and blue, its shores picturesque and steep on the east side, where the Omberg (863 ft.) rises abruptly, with furrowed flanks pierced by caves. The lake is subject to sudden storms. Its northern part is crossed from Karlsborg to Motala by the Gota canal route. At the southern end is the important manufacturing town of Jonkoping.

VETULONIA, an ancient town of Etruria, Italy. It lies 1,130 ft. above sea level, about 10 mi. directly northwest of Grosseto, on the northeast side of the hills which project from the flat Maremma and form the promontory of Castiglione. In Etruscan times there was a bav there. Silius Italicus tells us that it was hence that the Romans took their magisterial insignia (fasces, curule chair, purple toga and brazen trumpets), and it was undoubtedly one of the 12 cities of Etruria. There are remains of the acropolis walls and also of houses and a street of the Roman period. The earliest tombs found belong to the Villanovan period (First Benacci to late Second Benacci stage). Next come transitional tombs (in some of which hut urns are foundj surrounded by a ring of stones, and a few graves which are very early Etruscan: and then a group of important palaeo-Etruscan tombs (850–700 B.C.), most of them circle graves.

VEUILLOT, LOUIS (1813–1883), French journalist and leader of the extreme conservative wing of French Roman Catholicism, was born of poor parents at Boynes, near Orléans, Oct. 11, 1813. He had little schooling and at 13 was working as a clerk in a Paris law firm. An incessant reader, he began to write for periodicals at 18 and developed his talents in provincial journalism. Without interest in religion until 1838. he was converted on a visit to Rome and immediately became involved in polemics. He violently attacked the July monarchy on the school issue. Quickly disillusioned with the Republic in 1848, he mas a champion of Louis Napoleon until the emperor threatened the papal temporal sovereignty by his Italian campaign (1859). In 1870. at the peak of his influence from his support of the doctrine of papal infallibility during the Vatican council, Veuillot turned to the Bourbon restoration as the hope of the church. His health failed in 1878, but his influence persisted in the French Church. He died in Paris on March 7, 1883

Veuillot was an enemy of all conciliation and accommodation Pessimistic about human progress, filled with hatred for bourgeois institutions and all that stemmed from the Revolution, despising industrialism and its agents Veuillot wrote precisely, popularly and satirically. He knew the poner of public opinion and was adroit in its manipulation. Merciless toward opponents, including all he chose to call liberal Catholics, he finally drew a rebuke from his admirer, Pope Pius IX, for his "bitter zeal." His collected works, *Oeuvres Complètes* (1927–38), comprise 38 volumes one of poetry, 11 of correspondence, 12 of short pieces and 13 of full-length books. (J. N. M.)

VEVEY, a small town in the Swiss canton of Vaud near the eastern extremity of Lake Geneva. Population (1960) 16.269, of whom most were French-speaking and Protestant. Vevey was a Roman settlement (Viviscus) and later formed part of the barony of Vaud, that was held by the counts and dukes of Savoy till 1536 when it was conquered by Berne. In 1798 it was freed from Bernese rule and became part of the canton du Léman (renamed canton de Vaud in 1803) of the Helvetic republic. Vevey is 12 mi. S E. of Lausanne at the mouth of the Veveyse and commands fine views of the mountains. The surrounding country is covered with vineyards. Every 20 years or so the *Fête des Vignerons* is held here by an ancient guild of vinedressers.

VÉZELAY, a village of France, in the *département* of Yonne, 10 mi. W.S.W. of Avallon by road. Its population, which was over 10,000 in the middle ages, was 412 in 1954. The history of Vézelay is bound up with its Benedictine abbey, which was founded in the 9th century under the influence of the abbey of Cluny. The acquisition of the relics of St. Magdalen, soon after its foundation, began to attract crowds of pilgrims, whose presence enriched both the monks and the town which had grown up round the abbey and acknowledged its supremacy. In the 12th century the exactions of the abbot Artaud and the refusal of the monks to grant political independence to the citizens resulted in an insurrection in which the abbey was burned and the abbot murdered. During the 12th century Vézelay was the scene of the preaching of the second crusade in 1146 and of the assumption of the cross in 1190 by Richard Coeur de Lion and Philip Augustus.

Vézelay stands on a hill on the left bank of the Cure and still preserves most of its ancient ramparts, notably the Porte Neuve. consisting of two massive towers flanking a gateway. The church of La Madeleine dates from the 12th century.

VIANNEY, SAINT JEAN BAPTISTE MARIE (1786–1859). known as the CURÉ D'ARS and famous for the supernatural powers ascribed to him, was born on May 8, 1786, at Dardilly, near Lyons. Though not without talent, he encountered almost insuperable difficulties when at the age of 18 he started to learn Latin. for he had received only the most elementary education. When scarcely begun, his studies were interrupted for two years while he went into hiding to avoid conscription. After some private coaching in theology he was ordained in 1815 and was made assistant priest at Écully. In 1818 he became parish priest of Ars, 22 mi. from Lyons. Religion was at a low ebb in the village, but by his prudence and gentleness, his daily catechizing and the example of his life, the cur6 made it a model parish. Reports of his holiness and his supernatural powers soon spread abroad. Nocturnal molestations by the devil (le *grappin*) often troubled him. By 1827 people flocked to Xrs from every part of France. Every year from 1845 until his death in Ars on Aug. 4, 1859, some 20,000 persons of every age and condition visited Ars to see a saint, to speak to him, to ask his prayers, but above all to make their confession to him, so that the holy curé daily spent as many as 12 or even 15 hours in his confessional at all seasons of the year.

The curé d'Ars was canonized in 1925 and his feast day falls on Aug. 9.

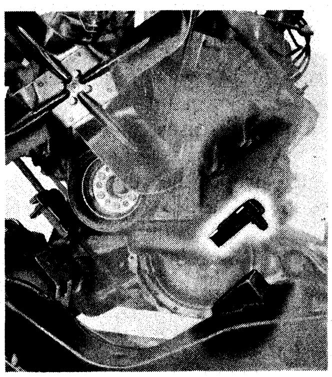
BIBLIOGRAPHY.—His sermons were ed. by M. A. Delaroche, 4 vol. (1928). *See* also F. Trochu, The *Cure' d'Ars,* Eng. trans. by E. E. Graf (1927); L C Sheppard, *Portrait of a Parish Priest* (1958). (ER G.)

VIAREGGIO, a maritime town and sea-bathing resort of Toscana, Italy, in the province of Lucca, on the Mediterranean. 13 mi N W of Pisa by rail. 7 ft above sea level. Pop. (1957 est.) 45,134 (commune). Being sheltered by dense pine-woods on the north, it is frequented as a winter resort, and in summer by some thousands for its sea bathing. In 1740 the population was only 300, and in 1841. 6,549. The body of Shelley was burned on the shore near Viareggio after his death by drowning in 1822. At Varignano near Viareggio is a large oil refinery.

VIATICUM, a Latin word meaning "provision for a journey" (Gr. τὰ ἐφόδια), is used by early Christian writers to denote anything that gave spiritual comfort to the dying. Ultimately it came to be restricted to the last communion given to the dying. In extreme cases the viaticum may be given to persons not fasting. and the same person may receive it frequently if his illness be prolonged. The ritual administration is that prescribed for the communion of the sick, except in the formula "Accipe, frater (soror), viaticum corporis Domini nostri Jesu Christi, qui te custodiat ab hoste maligno, et perducat in vitam aeternam. Amen." The viaticum is given before extreme unction, a reversal of the medieval practice due to the importance of receiving the Eucharist while the mind is still clear.

VIBORG, a town of Denmark, capital of the amt (county) of its name, in the district of Jutland, on Viborg lake. Pop. (1960) 23,253. The most notable building is the cathedral (1130–69. restored 1864–76). It has paintings by Joachim Skovgaard. The Black Friars' church is of the 13th century, and the museum has specimens of the Stone, Bronze and Iron Ages. The industries embrace distilleries, iron foundries and manufactures of cloth.

VIBRATION CONTROL. The study of mechanical vibrations is the study of the oscillatory motion of a mechanical part about some equilibrium, or neutral, position. Every structure or machine exhibits this phenomenon to some extent when subjected to a shock or an oscillating force. There are some cases where the vibration is essential to the operation of machines; examples are musical instruments, vibratory grain separators and vibrating conveyor belts. Often, however, vibration produces undesirable effects and must be reduced. For example, vibration may produce structural failures, excessive wear of rubbing surfaces, disturbances of delicate instruments and noise or other discomforts. This' article will discuss only cases involving undesirable vibrations. Thus vibration control will mean vibration reduction.



BY COURTESY OF BUICK MOTOR DIV., GENERAL MOTORS CORP

FIG. 1.—VIBRATION ISOLATOR FOR AUTOMOBILE ENGINE: ISOLATOR (OUTLINED IN WHITE) AND ENGINE ARE SHOWN LIFTED AWAY FROM CHASSIS

Good examples of vibration-control methods are found in automobiles. Without proper design of the suspension system, shocks and vibration caused by road irregularities would be transmitted directly from the wheel and axle assemblies to the chassis. Automobile suspension systems comprise two primary components—an elastic member, consisting of a steel or air spring, and a shock absorber, to damp out the motion of the elastic member.

(See SHOCK ABSORBER.)

Vibration in automobiles is caused also by unbalance in the engines. For this reason, engines are elastically mounted on the automobile chassis (see fig. 1). Used in this way. the elastic members are called vibration isolators. Their purpose is to insure that only a minimal part of the unbalanced forces in the engine are transmitted to the frame of the automobile.

Principles of Vibration Isolation.—The choice of vibration-isolation systems depends upon the mass of the part to be isolated and the character of the shock or oscillating force. Fig. 2 indicates the essential parts of a simple vibrating system under the influence of an oscillating force. This system approximates that of the automobile engine supported on the chassis by vibration isolators. The force is a result of the unbalance in the engine and is represented by Fsinwt. This force, the maximum value of which is indicated by F, varies in magnitude with time t at a frequency of ω radians per second (depending on the speed of the engine). If the engine were bolted directly to the frame, the entire force would be transmitted to the chassis.

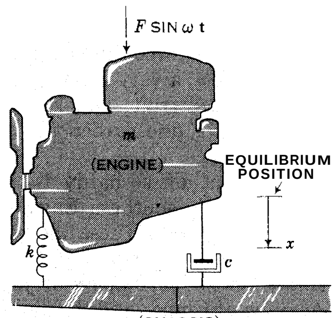


FIG. 2—SCHEMATIC DRAWING OF ESSENTIAL COMPONENTS OF AUTOMOTIVE ENGINE ISOLATED FROM CHASSIS

The purpose of the isolators is to diminish the force that is transmitted to the frame.

The isolators have two functions—to act as springs supporting the mass m of the engine and to dissipate energy as dampers and thereby restrict the magnitude of the vibration.. In the case of the automobile wheel-suspension system these two functions are performed separately by two components, springs and shock absorbers. However, in the engine suspension, these two functions are performed by single units, usually made of rubber. The springs exert a force on the engine and the chassis which is proportional to their deformation. This force will always tend to return the engine to its nonvibrating (equilibrium) position. The stiffness of the springs is indicated as k pounds per inch of deformation. Dampers exert a force on the engine and the chassis which is dependent on the speed of the relative motion of the engine with respect to the frame. Since this force is always opposite to the motion, it dissipates energy, and its magnitude is determined by multiplying the velocity by the damping coefficient c.

FIG. 3.— AMPLITUDE OF VIBRATION AS RELATED TO VIBRATION FREQUENCY FOR VARIOUS AMOUNTS OF DAMPING

(Natural frequency $= \omega_n = \sqrt{k/m}$)

In terms of the displacement x from the equilibrium position (see fig. 2), the differential equation describing the motion of the engine with respect to the frame of the automobile is

$$m\frac{d^2x}{dt^2} + c\frac{dx}{dt} + kx = F\sin\omega t \qquad (1)$$

The solution of this equation indicates that, after transient vibrations caused by starting die out, the engine will vibrate with a frequency equal to the exciting frequency (frequency of the force Fsinwt) and with an amplitude A (maximum displacement from the equilibrium position) given by the expression

$$A = \frac{F}{\sqrt{(k - m\omega^2)^2 + (c\omega)^2}} \qquad (2)$$

A plot of this amplitude in relation to frequency appears in fig. 3, when the exciting frequency equals the value given by

$$\omega_n = \sqrt{k/m} \qquad (3)$$

the amplitude approaches a large value. This condition is known as resonance, and the frequency ω_n is called the natural frequency or resonant frequency.

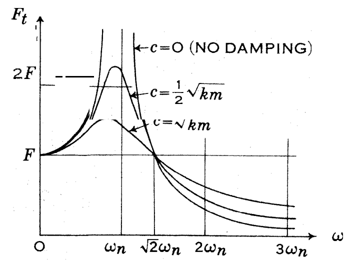
It is apparent also from fig. 3 that increased damping (shown by increased values of c for two of the curves) reduces the amplitude of vibration of the engine.

The force transmitted to the chassis through the isolators, F_t, is equal to the sum of the spring force and the damping force, and it also will vary with a frequency equal to the exciting frequency.

The maximum value of this force can be shown to be

$$F_t = \frac{F\sqrt{k^2 + (c\omega)^2}}{\sqrt{(k - m\omega^2)^2 + (c\omega)^2}} \qquad (4)$$

A plot of transmitted force in relation to frequency (see fig. 4) shows that this force is large in the vicinity of resonance. In fact, it is apparent that only when the exciting frequency is larger than the natural frequency ω_n by a factor of at least $\sqrt{2}$ times is the transmitted force less than F (that is, less than what it would be if no isolators were used at all). It is also apparent that using no isolators at all nould be better than using isolators that give a natural frequency so high that the exciting frequency can not exceed it by at least $\sqrt{2}$ times. In general, then, isolators must be chosen so that, when applied to a particular mass, they produce a natural frequency $\omega_n = \sqrt{k/m}$) which is substantially lower than the frequencv of the vibration to be 'isolated. Since the mass of the machinery usually cannot be increased, the isolators must be chosen so that their stiffness k is low.



FROM J. P. DEN HARTOG, "MECHANICAL VIBRATIONS 4TH ED (1956) MCGRAW HILL BOOK CO, INC

FIG 4.—TRANSMITTED FORCE IN RELATION TO VIBRATION FREQUENCY FOR VARIOUS AMOUNTS OF DAMPING

(Natural frequency $= \omega_n = \sqrt{k/m}$)

Another conclusion to be drann from fig 4 concerns the proper amount of damping It can be seen that in the region where the isolators are effective (*i.e.*, for an exciting frequency greater than $\sqrt{2}\omega_n$), damping increases the magnitude of the transmitted force. It might appear, therefore, that the best situation would be to have no damping at all. However, this is not true, for in most practical cases the applied force must be brought up from zero speed to the operating speed, and during this time the system will be operating in the resonant region. In this region damping is desirable.

Therefore, it may properly be concluded that for these conditions the isolators should have as little damping as possible but not so little that excessive vibration will result when the machinery is brought up through resonance to operating speed.

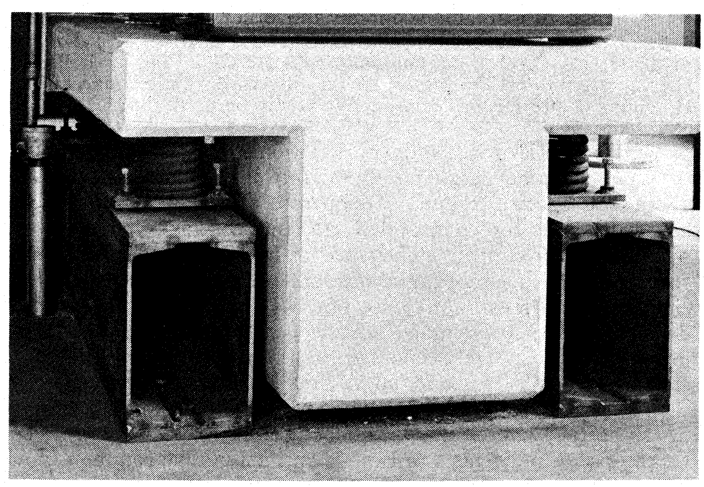


FIG. 5.— MACHINERY SUPPORT WITH COIL-SPRING VIBRATION ISOLATORS. T-SHAPED CONCRETE BLOCK INCREASES THE MACHINE MASS, REDUCING NATURAL VIBRATION FREQUENCY

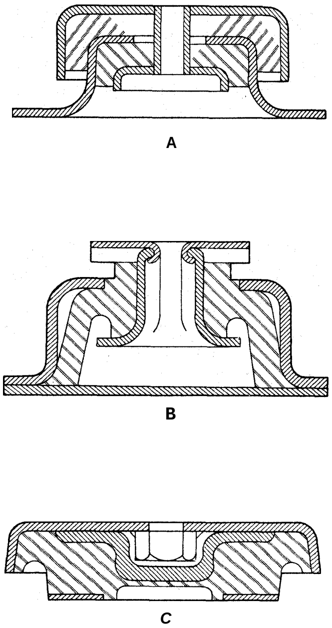
In the case just cited and in all cases of isolation from steady vibration, the effectiveness of the isolators does not depend primarily on their damping characteristics; rather, it depends upon their ability to produce a low natural frequency which allows the equipment to move in a natural way in response to the applied exciting forces and its own inertia.

The case of isolation from shocks is more difficult to discuss, partly because the term shock encompasses many different kinds of phenomena. However, any use of the term shock implies a sudden force or motion. For this reason isolation from shock requires suspension systems which store energy rapidly and then release it slowly or dissipate it quickly in the form of heat. In either case, the damping characteristics usually play a more important part in the isolation systems than they do in the case of isolation from steady vibration. This is the reason for the special shock absorbers on the automobile wheel-suspension system in addition to the suspension springs.



FROM "MACHINE DESIGN," VOL. 26, AUG. 1954

FIG. 6.— SELF-CONTAINED RUBBER ISOLATORS FOR VARIED MOUNTING CONDITIONS AND SPRING RATES

Vibration **Isolators.**—Vibration isolators are made up of many different materials and in many shapes and sizes. They may be classified in three general categories: (1) self-contained isolators; (2) metallic springs; and (3) resilient pads.

Self-contained rubber isolators are made of natural or synthetic rubber bonded to metal parts with appropriate mounting holes or other means of attachment. Cross-sectional views of some of the common types are shown in fig. 6.

Metallic springs, in either leaf or coil form, are often used as isolators by attaching them directly to the machinery, and coil springs are also used in self-contained vibration isolators in place of rubber.

When the latter is done, additional damping devices are often provided in the isolators because of the small damping characteristic of the coil springs.

Resilient pads, often used under the bases of heavy machinery. are available in a variety of materials and in many shapes and sizes. Some of the more common materials are cork, glass fibre. felt, sponge rubber and neoprene and other synthetic materials.

(RA. C.)

VIBURNUM, a genus of handsome shrubs (rarely small trees) of the honeysuckle family (Caprifoliaceae, *q.v.*), comprising about 120 species, found in temperate and subtropical regions, especially in eastern Asia and North America, many of which are planted for ornament. They are usually upright, rather large shrubs with opposite, simple, medium-sized leaves and numerous small flowers, mostly in large umbellike clusters, the marginal Bowers often showy, much enlarged and sterile. The fruit (a drupe), is often highly coloured, with a single, usually flattened stone. Two species are found in Great Britain: V. *lantana* (wayfaring tree), found widely also in Europe and Asia, and naturalized in the eastern United States; and V. *opulus* (cranberry tree; *see* CRANBERRY), indigenous to Europe and Asia. The common snowball of the gardens is a floral variant of the latter (*see* GUELDER-ROSE), while the Japanese snowbali is V. *tomentosum sterile* (or *V. t. plicatum).* In the United States and Canada 15 or more species occur, several of which are widely distributed. Four species attain the size of small trees: V. *lentago* (nanny berry; *q.v.*), V. *prunifolium* (black haw; *q.v.*), V. *rufidulum* (southern black haw) and V. *obovatum* (small viburnum). Well-known shrubby species are V. *trilobum* (high-bush cranberry), *V. alnifolium* (hobblebush), *V. dentatum* (arrowwood) and *V. acerifolium* (dockmackie). Beside the foregoing many other species are cultivated for ornament, and several American species yield medicines. The finest cultivated sorts comprise V. *carlesi* of Korea, grown both outdoors and forced in the greenhouse for its fragrant bloom; V. *carlcephalum,* a very fragrant hybrid; V. *dilatatum* of Japan, with persistent red fruit; and V. *burkwoodi,* a semi-evergreen hybrid. All these are fine garden plants, hardy in regions of reasonably mild winters.

Finer, but not so hardy as the above species, are the evergreen sorts hardy in southern England and northwestern and southeastern coastal U.S. These include the laurestinus (*q.v.*), V. *tinus,* with white, winter-blooming flowers; the fragrant V. *odoratissimum* and *V. japonicum* of Japan; the large-flowered V. *rhytidophyllum* of China; and the pinkish-flowered V. *suspensum* of Hong Kong. Viburnums may be propagated by seed or by cuttings.

(N. TR.)

VICAR, a title, more especially ecclesiastical, describing various officials acting in some special way for a superior. Cicero uses *vicarius* to describe an under-slave kept by another slave as part of his private property. The *vicarius* was an important official in the reorganized empire of Diocletian. It remained as a title of secular officials in the middle ages, being applied to persons appointed by the Roman emperor to judge cases in distant parts of the empire or to wield power in certain districts or, in the absence of the emperor, over all the empire. In the early middle ages the term was applied to representatives of a count administering justice for him in the country or small towns and dealing with unimportant cases, levying taxes, etc. Monasteries and religious houses often employed a vicar to answer to their feudal lords for those of their lands which did not pass into mortmain.

The title of "vicar of Jesus Christ," borne by the popes, was introduced as their special designation during the 8th century, in place of the older style of "vicar of St. Peter" (or *vicarius principis apostolorum*).

All bishops were looked upon as in some sort vicars of the pope, but the title *vicarius sedis apostolicae* came especially to be applied as an alternative to *legatus sedis apostolicae* to describe papal legates to whom in certain places the pope delegated a portion of his authority. Pope Benedict XIV tells us in his treatise *De synodo dioecesana* that the pope often names vicars-apostolic for the government of a particular diocese because the episcopal see is vacant or, being filled, the titular bishop cannot fulfil his functions. The Roman Catholic Church in England was governed by vicars-apostolic from 168j until **1850,** when Pope Pius IX re-established the hierarchy. Vicars-apostolic at the present day are nearly always titular bishops taking their titles from places not acknowledging allegiance to the Roman Catholic Church.

Sometimes the pope appointed a neighbouring bishop as the vicar of a church which happened to be without a pastor. A special vicar was appointed by the pope to superintend the spiritual affairs of Rome and its suburbs, to visit its churches, monasteries, etc., and to correct abuses. It became early a custom for the prebendaries and canons of a cathedral to employ "priest-vicars" or "vicars-choral" as their substitutes when it was their turn as hebdomadary to sing High Mass and conduct divine office. In the English Church these priest-vicars remain in the cathedrals of the old foundations as beneficed clergy on the foundation; in the cathedrals of the new foundation they are paid by the chapters. "Lay vicars" also were and are employed to sing those parts of the office which can be sung by laymen. The incumbent of a parish where the tithes are impropriate is entitled vicar.

In the Anglican Church a vicar-general is employed by the archbishop of Canterbury and some other bishops to assist in such matters as ecclesiastical visitations. In the Roman Catholic Church bishops sometimes appoint lesser vicars to exercise a more limited authority over a limited district. They are called "vicars-forane" or rural deans. They are entrusted especially with the surveillance of the parish priests and other priests of their districts, and with matters of ecclesiastical discipline. They are charged especially with the care of sick priests and in case of death with the celebration of their funerals and the charge of their vacant parishes. In canon law priests doing work in place of the parish priest are called vicars. Thus in France the *curé* or head priest in a parish church is assisted by several *vicaires*.

VICENTE, GIL (c. 1465–1536?), sometimes called the Portuguese Shakespeare, was born in the latter part of the reign of King Alphonso V. The first half of his life is vague. He was of humble birth and almost certainly spent his boyhood in some mountain village of the north of Portugal. He was perhaps apprenticed later to his father or uncle, Martim Vicente, goldsmith of Guimarães, and first came to the court at Evora, with many other provincials, on the occasion of the marriage of King João II.'s young son and heir to a daughter of the Catholic king in 1490. His work as goldsmith attracted the attention of Queen Lianor, and after the death of her son in 1491, and her husband four years later and the accession of her brother Manuel, Vicente retained her favour. It was at her request that he contributed (in 1509) a few verses to a poetical contest printed in the *Cancioneiro Geral* (1516). On the evening of June 7, 1502, the day after the birth of King Manuel's heir, the future João III., Vicente with a few others, dressed as herdsmen, entered the queen's chamber and recited a rustic monologue of 114 lines in Spanish. This primitive *Auto da Visitaçam* pleased Queen Lianor, and for the following Christmas Vicente had ready a longer but equally simple *Auto Pastoril Castelhano*.

For the next 34 years he was a kind of poet laureate, accompanying the court from Lisbon to Almeirim, Thomar, Coimbra or Evora and staging his plays to celebrate great events and the solemn occasions of Christmas, Easter and Maundy Thursday. The departure of a Portuguese fleet on the expedition against Azamor in 1513 turned his attention to more national themes, and in the *Exhortação da Guerra* (1513) and *Auto da Fama* (1515), inspired by the splendid victories of Albuquerque in the East, he wrote fervent patriotic verse which still stirs the hearts of his countrymen. Vicente's first wife, Branca Bezerra, may have died at about this time, and it seems that he was a widower when in 1514 he produced the charming *Comedia do Viuvo*.

His career as goldsmith kept pace with his growing success as dramatist. In 1509 he was appointed overseer of works in gold and silver at Thomar and elsewhere; in 1512 he was elected to the Lisbon Guild of Goldsmiths, and in Oct. 1513 he became one of their four representatives on the Lisbon town council. On Feb. 4 of this y'ear he was appointed master of the Lisbon mint. a post which he resigned on Aug. 6, 1517, in favour of Diogo Rodriguez, whose sister Melicia he married, perhaps in the same year. After the death of King Manuel in 1521 and of Queen Lianor four years later, Vicente frequently complains of poverty, but he received various pensions in the new reign; his accomplished daughter Paula won the favour of Princess Maria (1521–77); and he enjoyed the personal friendship of King Joio III.

On the occasion of the departure by sea of King Manuel's daughter Beatriz to wed the duke of Savoy in Aug. 1521, Vicente's *Cortes de Jupiter* was acted in a large room "adorned with tapestry of gold," a fact chronicled by his friend, the poet Resende. The *Fragoa de Amor* (1524) was also written for a court occasion, the betrothal of King João III. to the. sister of the Emperor Charles V. In the *Auto Pastoril Portugues* (1523), the farce *O Juiz da Beira* (1525), the *Tragi-comedia da Serra da Estrella* (1527) and the satirical *O Clerigo da Beira* (1529–30) he returned to the people, to the peasants and shepherds of the Beira mountain country which he knew so intimately.

He devoted himself more and more to the stage and multiplied himself in answer to the critics of Sá de Miranda's school. In 1526 came the *Templo de Apolo,* followed in rapid succession by the biblical play *Sumario da Historia de Deus,* the *Nao de Amores,* the *Divisa da Cidade de Coimbra,* and the *Farsa dos Almocreves*. These last three plays, with the *Serra da Estrella,* were all produced before the court in 1527 at Lisbon and Coimbra. On the other hand the *Auto da Festa* appears to have been acted in a private house at Evora. The elaborate *Auto da Feira* (1528), with its living popular types, contains some exceedingly caustic satire against Rome (personified on the stage): "You remit the sins of the whole world and forget to shrive yourself." It must be remembered that this was not a question of religion but of national politics: the relations of the devout João III. with the Vatican were often as troubled as those of his equally pious and even more regalist nephew Philip II. of Spain.

Vicente was now over 60, but he retained his vigour and versatility. The brilliant scenes of two of his last plays, the *Romagem de Agravados* (1533) and the *Floresta de Enganos* (1536), are loosely put together, and may well be earlier work; but the lyrical power of the *Triunfo do Inverno* (1529) and the long, compact *Amadis de Gaula* (1532) prove that his hand had lost none of its cunning and that his mind remained alert and young. The *Auto da Mofina Mendes* (1534), partly a religious allegory, partly a version of "Pierrette et son pot au lait," shows his old lightness of touch and penetrating charm. The *Auto da Lusitania,* which was acted in the presence of the court in 1532, may with some plausibility be identified with the *Caça de Segredos* at which Vicente tells us he was at work in 1525. It was the last of his plays to be staged at Lisbon in his lifetime; in Lent of 1534, by request of the abbess of the neighbouring convent of Odivelas, he produced there his religious *Auto da Cananea,* but the remainder of his plays were acted before the king and court at Evora; and it was probably at Evora that Vicente died in the year of his last play (1536).

Vicente's 44 plays admirably reflect the tragi-comedy of his age of change and upheaval in all its splendour and its squalor. Eleven are written exclusively in Spanish, 14 in Portuguese; the rest are bilingual; scraps of church or medical or law Latin, of French and Italian, of the dialect or slang of peasants, gipsies, sailors, fairies and devils frequently occur. His drama may be divided into religious plays, foreshadowing the Calderon *autos*, court plays, pastoral plays, popular farces and romantic comedy. They were often elaborately staged: a ship was rowed on the scene, or a tower opened to display some splendid allegory; here too he forestalled the later Spanish drama.

The various plays of the years 1513–19, composed when he was about 50, show Vicente at the height of his genius. He possessed a genuine comic vein, an incomparable lyric gift, and the power of seizing touches of life or literature and transforming them into something new by the magic of his phrase and his satiric force, under which lay a strong moral and patriotic purpose.

A far-sighted patriot and imperialist, and intensely national, he was also a devout son of the church; but he belonged to the more outspoken days before the Reformation, and his satire of priests and of the abuses of Rome was frank and merciless; so that when in 1531 one of his plays, the *Jubileu de Amores* (which some critics would identify with the *Auto da Feira)* was acted at Brussels, the papal nuncio, Cardinal Aleandro, who was present, felt "as if I were in mid-Saxony listening to Luther or in the horrors of the sack of Rome." As a lyric poet Vicente is first seen at his best in the wonderful poems of the *Auto da Sibila Cassandra* (1513?) in Spanish. This poet, who goes to the very heart of the Portuguese people, can as a lyric poet occasionally rival and even excel Camões, who, as Prof. W. P. Ker remarked, is "less of a miracle than Vicente" and owed more to the Renaissance. Vicente was over 50 when Sá de Miranda brought the new forms and metres from Italy; in their rivalry Vicente remained faithful to the indigenous octosyllabic verse. He had to meet growing criticism, and, in answer to the taunts of pedants, borrowed from Gomez Manrique the proverb, "Better an ass that carries me than a horse that throws me," and, building on it the *Farsa de Ines Pereira,* turned the tables on the "men of good learning."

It is Vicente's originality that he is an artist of the Renaissance untainted by its pedantry. He is at once the most imitative and the most original of poets; we continually find him working up his borrowed material, like gold in the hands of an artist of genius, into concrete figures; and his rapidly sketched portraits of peasant, priest and courtier will last as long as literature. Even in his rudest plays, and when the execution is at its roughest, his bold plastic genius makes itself felt. His plays are rich in folklore, and in his love of all that was popular and indigenous he seized on the essential and eternal elements of art. His knowledge of the French language was small, the influence of France came to him through Spain, and his *Barcas* were inspired by the Spanish version of the Dance of Death. The Spanish influence is always strong in this most national poet; he even quotes from the Book of Job, not direct but through Garci Sanchez de Badajoz. He had studied very carefully the work of the early Spanish playwrights Gomez Manrique and Encina, although he soon surpassed them. No other country produced so inspired a dramatic poet before the second hali of the 16th century. Actor, stage manager and author, Vicente was also a goldsmith and musician; he wrote the settings for some of his own lyrics, delightful popular romances and *cossantes* interspersed in his plays, which often end and open with a song, and are sometimes, as in the *Auto da Alma,* one long lyric.

Vicente is no exception to the general rule that Portuguese literature is mainly lyrical, in prose and verse; but in his many-sidedness he delineated life in its various aspects with the skill of a master, and he is the true forerunner of writers so different as Molière, Lope de Vega, Calderon and Shakespeare.

BIBLIOGRAPHY.—The only collected editions of Vicente's plays, a few of which were printed separately in his lifetime (seven of these were placed on the Portuguese Index of 1551), are the folios of Lisbon (1562, 1j86); 3 vol. of Hamburg (1834) and Lisbon (18jz); and the modern edition by Mendes dos Remedios, 3 vol. (1907–14). The critical edition of the 1562 text prepared by Michaelis de Vasconcellos immediately before her death has not yet seen the light. The only English translations are A. F. G. Bell, *Lyrics of Gil Vicente* (1914; 3rd ed. 1921) and *Four Plays of Gil Vicente* (1920). *See E*. Prestage, "The Portuguese Drama in the 16th Century; Gil Vicente," in the *Manchester Quarterly* (July, Oct. 1897); M. Menéndez y Pelayo, *Antologia de Poetas Liricos,* vol. vii; *T*. Braga, *Gil Vicente e as origens do theatro nacional* (1898); J. I. de Brito Rebello, *Gil Vicente* (1902, 1912); C. Michaelis de Vasconcellos. *Notas Vicentinas,* 4 vol. (Coimhra, 1912–22); A. Braamcamp Freire, *Vida e Obras de Gil Vicente* (Porto, 1919); and A. F. G. Bell. *Gil Vicentr* (1921).

For a fuller bibliography see *Four Plays of Gil Vicente* (1920). *A* new Vicente play, the *Auto da Festa,* was published from his library in 1906 by the Conde de Sabugosa. (A. B.)

VICENTE LÓPEZ, Argentine city and suburb of greater Buenos Aires, is 8 mi. N.W. of the federal district on the estuary of the Rio de la Plata. Pop. (1960) 250,823. Its name commemorates the author of the Argentinian national anthem, Vicente López y Planes. Vicente López was incorporated as a city in 1905. Engulfed by the growth of the capital in the 20th century, it still has many attractive homes which dominate the bank of the Rio de la Plata. During and after World War II numerous industrial enterprises were established in the city. (Js. R. S.)

VICENZA (anc. VICETIA), a town and episcopal see of Veneto, Italy, capital of the province of Vicenza, 42 mi. W. of Venice. Pop. (1957 est.) 87,856 (commune).

It lies at the northern base of the Monti Berici, on both sides of the Bacchiglione, at its confluence with the Retrone. It was surrounded by 13th-century walls, mostly demolished. The town has many buildings by Andrea Palladio (*q.v.*). The best is the basilica (1549–1614), one of the finest works of the Renaissance, replacing the exterior of the Palazzo della Ragione, a Gothic building (1444–77), which the colonnades of the basilica enclose. Close by is the Torre di Piazza (12th–15th century) 270 ft. high, the Loggia del Capitanio, by Palladio (1571) and the long Lombardesque Monte di Pietà (16th century). He also designed many of the fine palaces which give Vicenza its individuality; only two, the Porto Barbaran and Chiericati palaces (the latter containing the picture gallery), have two orders of architecture, the rest having a heavy rustica basis with only one order above it. Many palaces attributed to him are really the work of Scamozzi (the architect of the fine Palazzo del Municipio, 1588) and others of his successors. The famous Teatro Olimpico begun by him, but finished in 1583, is a remarkable attempt to construct a theatre in the ancient style. and the stage, with the representation of streets ascending at the back, is curious.

The Italian Gothic cathedral (mainly 13th century), consists of a nave with eight chapels on each side, and a very high Renaissance domed choir. The churches of S. Lorenzo (1280–1344) and S. Corona (1260–1300), both .of brick, are better examples of Gothic; both contain interesting works of art — the latter a very fine "Baptism of Christ," by Giovanni Bellini. The church of SS. Felice e Fortunato was restored in 975, but has been much altered, and was transformed in 1613. The portal is from 1154, and the Lombardesque square brick tower from 1166. Under it lies a mosaic pavement with the names of the donors, belonging to the original church of the Lombard period (?). Of the Palladian villas in the neighbourhood, La Rotonda, 1½ mi. S.E., is a square building with Ionic colonnades and a central dome which has been more than once copied in England and France. Nearby is the Villa Valmarana, with fine frescoes by G. B. Tiepolo (1737), and the new Piazzale della Vittoria, behind which is the baroque church of Monte Berico, with good works of art, from which porticoes lead down to the tower. Vicenza also has Venetian Gothic palaces.

The ancient Vicetia was of less importance than Verona and Patavium. It was for some time during the middle ages an independent republic, but was subdued by the Venetians in 1405. Toward the end of the 15th century it became the seat of a school of painting strongly influenced by Mantegna, of which the principal representatives were Bartolomeo Montagna, its founder, his son Benedetto Montagna, more important as an engraver, Giovanni Speranza and Giovanni Buonconsiglio. Andrea Palladio (1518–1580) was a native of Vicenza, as was also a contemporary, Vincenzo Scamozzi (1552–1616), who was largely dependent on him, but is better known for his work on architecture (Architettura *universale,* 1615). Palladio inaugurated a school of followers who continued to erect similar buildings in Vicenza even down to the French Revolution. Other natives of Vicenza were Giangiorgio Trissino (1478–1553) (see ITALIAN LITERATURE; PALLADIO, ANDREA), Antonio Pigafetta (1491–1534) and Antonio Fogazzaro (1842–1911) (*q.v.*). (T. A.)

VICHY, the chief spa of France, lies on the east bank of the Allier river (there nearly 1.000 ft. wide) in the Allier *département*, 365 km. (227 mi.) S.S.E. of Paris and 174 km. (108 mi) W.N.W. of Lyons by rail. Pop. (1954) 30.099. The town. largely modern and with a profusion of hotels, is separated from the river by gardens surrounding the extensive bathing establishments. Known to the Romans as Vicus Calidus, Vichy acquired fame for its hot and cold alkaline springs in the 17th century and was patronized by the families of successive French sovereigns, and notably by Napoleon III himself. The waters have a high reputation for alleviating liver and stomach complaints and are bottled for export. With more than 130,000 visitors annually, Vichy has extensive recreational amenities (casino, theatres, golf, lawn tennis, regattas and horse racing) and its airport at Charmeil provides links with London and Lyons. Following the Franco-German armistice of 1940, the collaborationist government under Marshal Pétain was established at Vichy until 1944.

VICIA: see VETCH.

VICKERY, HOWARD LEROY (1892–1946), U.S. naval officer and outstanding merchant shipbuilder of World War II, was born in Bellevue, O., April 20, 1892. He graduated from the U.S. Naval academy, Annapolis, Md.. in 1915 and later took graduate work in naval architecture. From 1921 to 1937 he served in various technical posts in the U.S. navy and, in 1937, was a technical adviser to a senate technical committee on safety of life at sea.

In 1937 he was selected as assistant to the chairman of the U.S. maritime commission, in full charge of the shipbuilding program under the Merchant Marine act of 1936; was appointed a commissioner in 1940; and vice-chairman of the commission in 1942, in which year he became a rear admiral. Vickery was a vigorous and unswerving administrator who demanded full performance and set an indefatigable example. Under his leadership more than 5,500 ocean-going ships were built — an unprecedented production record and a contributing factor in winning the war in spite of shipping losses inflicted by German U-boats. In 1944 he was made a vice-admiral. Among many awards, he received the army distinguished service medal; in 1948, posthumously, he was made, by King George VI, a knight commander of the Order of the British Empire. Vickery died at Palm Springs, Calif., March 21, 1946. (E. L. C.)

VICKSBURG, a city of the state of Mississippi situated about halfway between Memphis and New Orleans on the Mississippi river. It is historically famous as the site of one of the most decisive campaigns of the American Civil War (see below). On the landward side the city is almost completely surrounded by the 1,323-ac. Vicksburg National Military park and the Vicksburg National cemetery to the north fronting on the river where lie the graves of 16,653 Union soldiers, three-fourths of them marked "unknown." The park includes the battle lines of the opposing armies during the siege of the city. May 18 to July 4. 1863. Hundreds of bronze markers tell the story and observation towers afford comprehensive views of the field: Scores of busts and statues. state memorials and a bronze statue of Jefferson Davis are all further testimony of its historic importance.

Geography- *and History.*— Vicksburg owes its importance in peace and war to its geographic location. For miles above the city the Mississippi river meanders through an alluvial plain many miles wide. bounded on the east by a range of high land rising in some places more than 200 ft. The city was established at a point where a hairpin-shaped bend carried the river to the base of a 230-ft. bluff and then abruptly turned away, leaving a narrow peninsula of land across the river. Eight miles upstream the Tazoo river flowed into the Mississippi.

BRONZE STATUE OF JEFFERSON DAVIS BY HENRY KITSON, IN THE VICKSBURG NATIONAL MILITARY PARK

In 1718 a few Frenchmen settled on the bluff and the next year built Ft. St. Pierre, but the settlement was wiped out by Indians ten years later. In 1790 Spaniards established an outpost there and in 1791 built Ft. Nogales on the highest hill. naming it for the many walnut trees growing there. Flatboatmen and other voyagers later called the place Walnut Hills

The Rev. Nenitt Vick, a Methodist minister from Virginia. established a mission in a clearing 6 mi. E. of the present city in 1811. Foreseeing the coming of settlers and river traffic, he then acquired a tract of land on the river front and prepared to lay out a town. Yellow fever killed him and his nife in 1819, but his son-in-law. John Lane. established the town, which was incorporated in 1825 as Vicksburg It was a lusty frontier river town, warring with river gamblers and claiming five heroic and individualistic newspaper editors dead by violence in a period of 22 years. It rapidly became the commercial centre of a cotton-groaing region with gins, compresses and warehouses dominating the business scene.

Commercial activity ceased and the city became an armed camp during the American Civil War. In 1876, before it had recovered from the effects of the war, another disaster struck. The Mississippi river broke through the narrow peninsula in front of the city making a new channel and leaving Vicksburg high and dry. But by closing the mouth of the Yazoo and diverting its waters through a canal past the bluffs the city lived again to become a great river port. Competition of railroads reduced river traffic to a mere trickle, but it revived in 1917 when the U.S. government started a barge line to relieve the wartime pressure on the railroads. This line was so successful that private enterprise started other lines. Harbour improvements later made it a growing centre of transportation and water-integrated industries. About 140,000 freight cars a year pass over its railroad bridge, the only such bridge spanning the Mississippi between Memphis and Baton Rouge. Cattle, livestock, lumber and cotton come to Vicksburg from the surrounding countryside. The U.S. government maintains at this strategic location the river fleet and general headquarters for flood-control research and for work on the blississippi and its tributaries.

The seat of Warren county, Vicksburg has a commission form of government and owns and operates an airport, a gas system and a waterworks. Sixty-two churches representing 16 denominations serve the community. The Illinois Central railroad, river craft and a highway system that includes a bridge across the Mississippi bring people and goods to the city. An estimated one-third of a million tourists visit the city and the national military park each year. For comparative population figures ***see*** table in MISSISSIPPI: *Population.*

Military Campaigns, 1862–63.—Vicksburg became a key point in the defense of the Confederacy in the spring of 1862. The fall of Forts Henry and Donelson in Tennessee in February and of New Orleans in April. meant further Union action from above and below the city to clear the river and cut the Confederacy in half. Vicksburg was ideally situated for defense purposes. Beyond the point where the Yazoo entered the Mississippi just above the city was a maze of swampy bayous, backwaters and side channels. Thus the only approach on high land was from the east or south.

The Confederates moved immediately to take advantage of these natural features. They laid out and constructed batteries to command the river approaches and fortified the river front. They were none too soon, for before the end of June. Adm. David G. Farragut's fleet arrived from New Orleans to be joined shortly by the upper fleet under flag officer C. H. Davis. Naval bombardment proved futile. The ironclads could run the batteries but could do no damage to the city. After a month they withdrew.

Anticipating attack by land the Confederates began the construction of a line of defenses in the rear using mostly Negro labour hired or impressed from nearby plantations. They also fortified Haynes's bluff, 11 mi. N. on the Yazoo, and Warrenton, 6 mi. below the city, and prepared to face attack from any or all quarters. On Oct 14, Gen. John C. Pemberton assumed command of the Department of Mississippi and East Louisiana and established headquarters at Jackson, 50 mi. to the east, and connecte l to Haynes's bluff by railroad. During the winter the Confederates also fortified Grand Gulf, the first bluff south of Vicksburg on the east side of the river about 50 mi. below the city, and Port Gibson several miles east of the river, the starting point of roads to Grand Gulf. Vicksburg and Jackson.

The winter witnessed a series of movements, usually remote from Vicksburg and none of them successful, to reach the high ground north of the city. The first of these was made at the end of November when Grant sought to move from Memphis and Grand Junction on Grenada. The outnumbered Confederates fell back without fighting but their cavalry under Maj. Gen. Earl Van Dorn and blaj Gen. Sterling Price destroyed most of Grant's supplies and communications and forced him to abandon the effort. Meanwhile Maj. Gen. William T Sherman had come downriver with a flotilla and about 30,000 men to attack Vicksburg simultaneously from the water side. Sherman attacked the Yazoo bluffs above Vicksburg. unaware that Grant had been turned back by the same troops now aiding the defenders, and met with defeat. Retreating from the upland. Grant sailed down the river and joined Maj Gen. John A. McClernand and Sherman at Milliken's bend above Vicksburg, with Maj. Gen. James B. McPherson's making three corps at Grant's disposal. Three other efforts followed. He attempted to cut a channel across the narrow neck of land in front of Vicksburg, hoping to isolate the fortress. to gain a water connection nith the lower river and to land an army on the bluffs beyond Pemberton's left flank. Kext he tried to make a channel from the Mississippi to the upper Yazoo and so to turn Pemberton's right flank, but the Confederates erected a fort where Grant's force had to emerge from the bayous and thwarted him in the effort.

Grant was about to lose his reputation for effectiveness. Several months and a half-dozen futile tries had brought him no nearer to Vicksburg Criticism and doubts of his leadership were freely expressed. Finally. not to be outdone and showing some of that doggedness and resourcefulness that was to make him famous. Grant decided on a bold move that succeeded probably beyond his wildest expectations. On April 16, 1863, a part of the upper fleet non commanded by flag officer David D. Porter ran the batteries at Vicksburg. JJ'hereas ironclads had previously run back and forth many times, this was the first time that ordinary steamers had done so Two nights later four more boats towing barges of large capacity passed down the river. Meanwhile Grant had crossed the river at Milliken's bend and made his way southward across the peninsula to meet the fleet at Bruinsburg. He had abandoned his line of communications by rail or river and had even sent his wagon train by a somewhat safer route. The fleet on the 29th unsuccessfully attacked Grand Gulf, but that night ran past the batteries for the rendezvous with Grant and put the army across 10 mi. below. At the time Grant was greatly outnumbered by the Confederates around Vicksburg, principally at Grand Gulf, Haynes's bluff and Jackson. He had to move rapidly to beat the enemy in detail outside the fortifications of Vicksburg before they could concentrate their forces. On the 30th Grant reached the high ground 2 mi. from Bruinsburg and moved quickly toward Port Gibson where roads led to Grand Gulf, Vicksburg and Jackson. He took Port Gibson on May 2 and moved toward Grand Gulf. Since his wagon train had not yet caught up with him, he had collected a motley train from the countryside and moved ahead. On May 3, Grant reached Grand Gulf abandoned by Confederates withdrawing to Vicksburg to await attack there. Whereupon Grant decided to abandon the idea of using Grand Gulf for a base and to hurry to Jackson before reinforcements could arrive for Gen. Joseph E. Johnston there and before they could join Pemberton who had gone to see to the defenses of Vicksburg. On May 12 McPherson took Raymond and two days later Grant drove Johnston from Jackson where he had arrived the night before to take command.

At this point the Confederate high command made fateful contradictory decisions. President Davis had wired Pemberton to hold Vicksburg at all costs. Johnston, on the other hand, favoured abandoning the city until the Confederate forces could be concentrated and then attack Grant there. Pemberton came out of Vicksburg on the way to Johnston's aid. but met Grant moving westward at Champion's hill and was forced back into the city. Thus on May 18 Grant was in the rear of Richmond, having meanwhile brought up more men and supplies, and Pemberton was isolated in the city. When assault proved futile, Grant settled down to siege tactics. By July 3 the besiegers were close to the Confederate lines, and Johnston had been prevented from coming to Pemberton's relief, nor could the latter escape across the river to Louisiana. Short of ammunition, almost completely without food and with his limited manpower approaching exhaustion, Pemberton surrendered on July 4, with approximately 30,000 men. The Mississippi river was open; the Confederacy was divided. A turning point had been reached, and Lincoln had found a new general. See also AMERICAN CIVIL WAR.

VICO, GIAMBATTISTA (1668–1744), Italian philosopher of law and of cultural history, renowned as the exponent of a "new science of humanity," was born in Naples on June 23, 1668. The son of a poor bookseller, he attended various schools for short periods but was largely self-taught. For nine years he was tutor to the nephews of the bishop of Ischia, in the castle of Vatolla in the Cilento, south of Salerno. He received his law degree from the University of Naples in 1694 and was professor of rhetoric there from 1699 until 1741, when he was succeeded by his son Gennaro. He had aspired to a chair of law, but made no further attempt after an unsuccessful candidacy in 1723. He was appointed royal historiographer in 1735. He died in Naples in the night of Jan. 22–23, 1744.

One of the duties of the professor of rhetoric was to open the academic year with a Latin oration, and Vico's first professional publication. "On the Method of the Studies of Our Time" (De nostri *temporis* studiorum ratione, 1709), was expanded from such an inaugural oration. Six of his earlier orations, concerned with the several ends of university studies, he revised to form a companion volume but did not publish.

After a metaphysical essay "On the Ancient Wisdom of the Italians" (De *antiquissima Italorum* sapientia, 1710) and a biography of Marshal Antonio Carafa (De *rebus gestis A.* Caraphaei, 1716), he published in the three volumes of his "Universal Law" (De uno *universi iuris principio* et fine uno, etc.. 1720–22) a first version, or more precisely the first three versions, of his "new science of the common nature of nations" or "principles of humanity" as he later called it. All the works so far mentioned were in Latin, but from then on he wrote in Italian. After an unpublished intermediate version "in negative form," there appeared in 1725 the first published version to bear the name Scienza *nuova* in its title. A completely rewritten second edition appeared in 1730, and a much revised third edition in 1744, after his death.

Among disciplines familiar to the 20th century, perhaps the nearest in intent to Vico's new science is the history of civilization. But what he laboured to bring about may be more accurately described as the convergence of history from the one side and the more systematic social sciences from the other and their interpenetration to form a single science of humanity. In language closer to his own, the new science unites philology as ascertainment of particular historic fact and philosophy as demonstration of general truth.

Vico approached his new science through a new theory of knowledge, announced in his publications of 1709 and 1710. We know in mathematics because. by abstraction and definition, me have made the objects of our knowledge. We have a quasi-knowledge of the world of nature just so far as we are able to carry the experimental method by which, as it were, we make what we know; but, to speak more strictly and as a whole, the world of nature is known only by God, who made it. On the other hand, we can know the civil world or world of nations, the institutions of human culture, because we have made that world and "its principles are therefore to be found within the modifications of our own human mind."

The root formula for these modifications is not far to seek. "Men at first feel without observing; then they observe with a troubled and agitated spirit; finally they reflect with a clear mind." The recovery of the origins of civilization from the surviving fragments of antiquity by a new critical art guided by this formula is a more difficult matter, and it cost Vico "the research of a good twenty years." The best examples of this research are (1) his critique of "the fiction that the law of the Twelve Tables came to Rome from Greece" and (2) his "discovery of the true Homer" as the Greek people of the heroic or poetic age, mythological in thought, barbaric in manners and completely ignorant of the "recondite wisdom" of later philosophers.

The principal aspects of the new science, as formulated in the edition of 1744, are: (1) a rational civil theology of divine providence; (2) a philosophy of authority; (3) a history of human ideas; (4) a philosophical criticism; (5) an ideal eternal history; (6) a system of the natural law of nations; and (7) the principles of universal history.

VICQ-D'AZYR, FÉLIX (1748–1794), French physiologist and pioneer in comparative anatomy, was born at Valognes, Normandy, on April 23, 1748, the son of a physician. He went to Paris in 1765 to study medicine and from 1773 gave courses at the Jardin des Plantes that opened up an entirely new approach to the study of anatomy. He compared the structures of the arms and legs in man with the limbs of other vertebrates, and demonstrated the similarity of the muscular systems and their function. His description of the structure of the brain was the most exact up to that time. In 1774 he was elected a member of the Académie des Sciences. The following year he was appointed to study an epizootic in the south of France, and partly as a result of his experiences during that investigation, encouraged the creation of a new society for the study of epidemic diseases: La Société Royale de Medicine, founded in 1776 with Vicq-d'Azyr as permanent secretary. He became consulting physician to the queen and on the death of G. Buffon in 1788 was elected to his seat in the Académie Française.

His many studies dealing with vertebrate comparative anatomy and physiology were published in the *Mémoires de l'Académie des Sciences* and other scientific journals. An annotated edition containing most of these memoirs was prepared by Moreau: *Oeuvres complètes de Vicq-d'Azyr,* 6 vol. (1805). Besides these he wrote La *Médicine des bêtes à cornes* (1781). He died at Paris on June 6, 1794. His *Système anatomique des quadrupèdes* was left unfinished, but was completed by Hippolyte Cloquet and published in the *Encyclopédie me'thodique,* vol. 3 (1819). (ED. HE.)

VICTOR, the name of three popes and two antipopes.

VICTOR I. SAINT, pope in the last decade of the 2nd century, an African. succeeded Eleutherius in 189. His pontificate. which lasted 10 years. is memorable for a great enhancement of Rome's authority in the church. He treated the Quartodecimans harshly in the controversy about fixing the date of Easter.

VICTOR II (Gebhard), pope from 1055 to 1057, was the son of the Swabian count Hartwig of Calw (Kalw). At the instance of Gebhard. bishop of Regensburg. a relative of the emperor Henry III, he was appointed bishop of Eichstadt in 1042, when he was still very young. His talents soon enabled him to render important services to the emperor. whose chief adviser he eventually became. His nomination to the papacy. in succession to Leo IX. by the emperor at Mainz in the autumn of 1054, was made on the demand of the Roman deputation headed by Hildebrand (the future Gregory 1-11). After his consecration at St. Peter's (April 13. 1055) Victor rejoined the emperor at Florence in May. There, in June, they held a council which again condemned clerical marriages, simony and the alienation of the estates of the church. In the following year he was summoned to Germany to the side of the emperor and was with him when he died at Botfeld in the Harz on Oct. 5, 1056. As guardian of the infant Henry IV and adviser of the empress regent Agnes, Victor now wielded enormous power, which he began to use with much tact for the maintenance of peace throughout the empire and for strengthening the papacy against the aggressions of the barons. He died shortly after his return to Italy, at Arezzo, on July 28,.1057.

VICTOR III (Dauferius), pope from 1086 to 1087, was born in 1027, a member of the ducal house of Benevento. After studying in various monasteries he entered the cloister at Monte Cassino, where his name was changed to Desiderius. In 1058. on the death of Pope Stephen X (who had retained the abbacy of Monte Cassino throughout his pontificate). Desiderius succeeded him as abbot. His rule there marks the golden age of that great monastery: he promoted literary activity and established an important school of mosaic. Desiderius was created cardinal priest of Sta. Cecilia by Nicholas II in 1059 and as papal vicar in southern Italy conducted frequent negotiations between the Normans and the pope. Among the three or four men suggested by Gregory VII on his deathbed as most worthy to succeed him was Desiderius, who was favoured by the cardinals because of his learning, his connection with the Normans and his diplomatic ability. The abbot, however, declined the papal crown. and the year 1085 passed without an election. The cardinals at length proclaimed him pope against his will on May 24. 1086. but he was driven from Rome by supporters of the emperor Henry IV before his consecration was complete. Laying aside the papal insignia at Terracina. he retired to his beloved Monte Cassino. In 1087, as vicar of the Holy See he convened a synod at Capua early in March, resumed the papal insignia on March 21 and received tardy consecration in St. Peter's on May 9; but imperial support for the antipope Clement III (Guibert of Ravenna) made it impossible for Victor to spend more than a few weeks in Rome. He sent to Tunis an army that defeated the Saracens and compelled them to pay tribute to the papal see. In Aug. 1087 he held a synod at Benevento, which renewed the excommunication of Guibert; banned Archbishop Hugo of Lyons and Abbot Richard of Marseilles as schismatics; and confirmed the prohibition of lay investiture. Falling ill at the synod. Victor returned to Monte Cassino. where he died on Sept. 16. 1087.

While abbot of Monte Cassino, Victor III contributed personally to the literary activity of the monastery. His *Dialogi de miraculis S. Benedicti* and his *Epistolae* were printed by J. P. Migne (ed.), in *Patrologia latina,* vol. cxlix (Paris, 1853); his short account of two miracles of Leo IX is in the Bollandist *Acta Sanctorum,* under April 19 (Paris, Rome, 1866).

VICTOR IV (Gregory, sometimes surnamed Conti), the first antipope to take the name. had since 1122 been cardinal priest of SS. Dodici Apostoli when he was chosen by a party opposed to Innocent II in succession to the antipope Anacletus II. about March 1j, 1138. St. Bernard of Clairvaux. however. prevailed on him to make his submission to Innocent on May 29.

VICTOR IV (Octavian of Monticelli), second antipope of the name, had since 1138 been cardinal priest of Sta. Cecilia when he was elected successor to Adrian IV by a minority of cardinals in the course of a series of indecisive scrutinies in the three days following Sept. 4, 1159. He was put up in opposition to Alexander III by those who desired a *rapprochement* with the emperor Frederick I Barbarossa and was the first of the series of antipopes that Barbarossa was to support in his struggle against Alexander. After a scandalous scene in which Octavian snatched the scarlet mantle from his rival. his armed supporters burst into St. Peter's and enthroned him. forcing Alexander to withdraw. Victor was consecrated at Farfa by Imarus, cardinal bishop of Tusculum, on Oct. 4. Despite Frederick's diplomatic efforts and his attempt at the council of Pavia (Feb. 1160) to consolidate ecclesiastical opinion on Victor's behalf, the rest of Europe had no desire to see a revival of imperial control over the papacy. and even in Germany a section of the clergy remained loyal to Alexander. Victor died on April 20, 1164, at Lucca. whither he had been conducted by the imperial arch-chancellor, Rainald of Dassel. He was succeeded by the antipope Paschal III. Pope Gregory VIII had his hones disinterred in 1187.

VICTOR, SEXTUS AURELIUS, prefect of Pannonia about 360 (Amm. Marc., xxi, 10), possibly the same as the consul (jointly with Valentinianj in 373.and as the prefect of the city who is mentioned in an inscription of the time of Theodosius. Four small historical works have been ascribed to him on more or less doubtful grounds: (1) *Origo Gentis Romanae,* (2) *De Viribus Illustribus Romae,* (3j *De Caesaribus,* (4) *De Vita et Moribus Imperatorum Romanorum excerpta ex Libris Sex. Aur. Victoris* The four have generally been published together under the name *Historia Romana,* but the fourth is a *réchauffé* of the third.

The first edition oi all four was that of A. Schottus (Antwerp, 1579). A good modern edition of the De *Caesaribus* is by F. Pichlmayr (Munich, 1892).

NICTOR AMADEUS II (1666–1732), duke of Savoy and king first of Sicily and then of Sardinia: is famous for his aggrandizement of the house of Savoy as a European power and also for his astute changes of alliance in wartime. He was born at Turin on May 14. 1666. the son of Charles Emmanuel II of Savoy. His mother. Marie Jeanne Baptiste of Savoy-Nemours. became regent for him on his father's death in 1675 and pursued a pro-French policy: and in 1684. when \-ictor Amadeus began to rule in person. he married Anne Marie of Orléans (1669–1728), niece of Louis XIV of France. In 1687. however. he went to Venice for a secret conference with representatives of the German powers then coalescing against Louis. When the War of the Grand Alliance (*q.v.*) broke out. the French tried to ensure that he would not be against them. but in 1690 he settled terms with the .Austrian and Spanish Habsburgs. refused to allow the French to garrison Turin and entered the war on the side of the allies. England and Holland ratified the terms accorded to him by the Habsburgs. while insisting on guarantees for his Waldensian subjects. As the war went against him (battles of Staffarda [1690] and Marsaglia

[1693]), he demanded the government of Milan from his Spanish ally and. on being refused this, negotiated for a separate peace with France. The treaty of Turin (1696) gave Savoy very favourable terms and increased territory; and it stipulated the neutrality of Italy for the rest of the war, which ended with the peace of Ryswick (169;). His daughter Marie-Adelaide was married to the French dauphin's eldest son.

In the War of the Spanish Succession (*q.v.*) Victor Amadeus allied himself first with the French (1701). Then, in 1702 he began negotiations with the Holy Roman emperor; and late in 1703 he finally changed sides, after the suspicious French had disarmed a contingent of his troops. The French defeat at Turin (1706) secured his position in Italy; and the treaties of Utrecht and Rastatt (1713–14) gave him the royal title as king of Sicily. The quadruple alliance of 1720 made Victor Amadeus take Sardinia instead of Sicily, which he had lost to the Spaniards in 1718, though he would have preferred a state on the Italian mainland, such as Parma.

In 1730 Victor Amadeus abdicated his crown in favour of his son, Charles Emmanuel III, and retired to Chambéry with his newly married second wife, Anna, the nidowed contessa di San Sebastiano. When he tried to revoke his abdication, Charles Emmanuel eventually had him arrested (1731) and confined first at Rivoli and then at Moncalieri, where, on Oct 31, 1732, Victor Amadeus died.

VICTOR **EMMANUEL II** (1820–1878), king of Sardinia and first king of Italy, was born at Turin on March 14, 1820, and was the son of Charles Albert, prince of Savoy-Carignano. Brought up in the bigoted and chilling atmosphere of the Piedmontese court, he received a rigid military and religious training, but little intellectual education. In 1842 he married Adelaide, daughter of the Austrian Archduke Rainer. Victor Emmanuel played no part in politics during his father's lifetime, but took an active interest in military matters. When the war with Austria broke out in 1848, he was delighted at the prospect of distinguishing himself, and was given the command of a division. At Goito he was slightly nounded and displayed great bravery, and after Custozza defended the rearguard to the last (July 25, 1848). After the defeat at Novara on March 23, Charles Albert, having rejected the peace terms offered by the Austrian field-marshal Radetzky, abdicated in favour of his son. Victor Emmanuel was received by Radetzky with every sign of respect and the field-marshal offered not only to waive the claim that Austria should occupy a part of Piedmont, but to give him an extension of territory, provided he revoked the new Piedmontese constitution granted by Charles Albert in March 1848, and substituted the old blue Piedmontese flag for the Italian tricolour, which savoured too much of revolution. But the young king rejected the offer, and had to agree to the temporary Austrian occupation of part of his territories and of half the citadel of Alessandria, to disband his Lombard, Polish and Hungarian volunteers, and to withdraw his fleet from the Adriatic; but he secured an amnesty for all the Lombards compromised in the recent revolution, having even threatened to go to war again if it were not granted. It was the maintenance of the constitution in the face of the overwhelming tide of reaction that established his position as the champion of Italian freedom and earned him the sobriquet of *Rè Galantuomo* (the honest king). But the task entrusted to him was a most difficult one. Parliament having rejected the peace treaty, the king dissolved the assembly; in the famous proclamation from Moncalieri he appealed to the people's loyalty, and the new Chamber ratified the treaty (Jan. 9, 1850). This same year, Cavour (q *v.*) was appointed minister of agriculture in D'Azeglio's cabinet, and in 1852 became prime minister.

In having Cavour as his chief adviser Victor Emmanuel was most fortunate, and but for that statesman's astounding diplomatic genius the liberation of Italy would have been impossible. The years from 18jo to 1859 were devoted to restoring the shattered finances of Sardinia, reorganizing the army and modernizing the antiquated institutions of the kingdom. Among other reforms the abolition of the *foro ecclesiastico* (privileged ecclesiastical courts) brought down a storm of hostility from the Church both on the king and on Cavour, but both remained firm in sustaining the prerogatives of the civil power. When the Crimean War broke out, the king strongly supported Cavour in the proposal that Sardinia should join France and England against Russia so as to secure a place in the councils of the great powers and establish a claim on them for eventual assistance in Italian affairs (1854). In 1855, while the allied troops were still in the East, Victor Emmanuel visited Paris and London, where he was warmly welcomed by the Emperor Napoleon III and by Queen Victoria, as well as by the peoples of the two countries.

Victor Emmanuel's object now was the expulsion of the Austrians from Italy and the expansion of Sardinia into a North Italian kingdom, but he did not regard the idea of Italian unity as coming within the sphere of practical politics for the time being, although a movement to that end was already beginning to gain ground. With this end in view he entered into communication with some of the conspirators, especially with La Farina, the leader of the *Società Nazionale,* and even communicated with Mazzini and the republicans. In 1859 Cavour's diplomacy succeeded in drawing Napoleon III into an alliance against Austria, although the king had to agree to the cession of Savoy and possibly of Nice and to the marriage of his daughter Clothilde to the emperor's cousin Prince Napoleon. These conditions were very painful to him, but he was always ready to sacrifice his own personal feelings for the good of his country. He had an interview with Garibaldi and appointed him commander of the newly raised volunteer corps, the *Cacciatori delle Alpi.* Even then Napoleon would not decide on immediate hostilities, and it required all Cavour's genius to bring him to the point and lead Austria into a declaration of war (April 1859). Although the Franco-Sardinian forces were successful in the field, Napoleon, fearing an attack by Prussia and disliking the idea of a too powerful Italian kingdom on the frontiers of France, insisted on making peace with Austria, while Venetia still remained to be freed. Victor Emmanuel, realizing that he could not continue the campaign alone, agreed to the armistice of Villafranca. When Cavour heard the news he hurried to the king's headquarters at Monzambano, and in violent, almost disrespectful language implored him to continue the campaign at all hazards. But the king on this occasion showed great political insight and saw that by adopting the heroic course proposed by the latter he ran the risk of finding Napoleon on the side of the enemy, whereas by waiting all might be gained. Cavour resigned office, and by the peace of Ziirich (Nov. 10, 1859) Austria ceded Lombardy to Sardinia, but retained Venetia; the central Italian princes who had been deposed by the revolution were to be reinstated, and Italy formed into a confederation of independent states. But this solution was most unacceptable to Italian public opinion, and both the king and Cavour determined to assist the people in preventing its realization, and consequently entered into relations with the revolutionary governments of Tuscany, the duchies and of Romagna. As a result of the events of 1859–60, those provinces were all annexed to Piedmont, and when Garibaldi decided on the Sicilian expedition Victor Emmanuel secretly assisted him. He had considerable influence over Garibaldi, who, although in theory a republican, was greatly attached to the bluff soldier-king. When Garibaldi having conquered Sicily was determined to invade the mainland possessions of Francis II. of Naples, Victor Emmanuel, foreseeing international difficulties, wrote to the chief of the red shirts asking him not to cross the straits; but Garibaldi, although acting throughout in the name of his majesty, refused to obey and continued his victorious march, for he knew that the king's letter was dictated by diplomatic considerations rather than by his own personal desire. Then, on Cavour's advice, King Victor decided to participate himself in the occupation of Neapolitan territory, lest Garibaldi's doubtful entourage should proclaim the republic or create anarchy. When he accepted the annexation of Romagna offered by the inhabitants themselves the pope excommunicated him, but, although a devout Catholic, he continued in his course undeterred by ecclesiastical thunders, and led his army in person through the Papal States, occupying the Marches and Umbria, to Naples. On Oct. 29 he met Garibaldi, who handed over his conquests to the king. On Feb. 18, 1861, the parliament proclaimed him king of united Italy.

The next few years were occupied with preparations for the liberation of Venice, and the king corresponded with Mazzini, Klapka, Türr and other conspirators against Austria in Venetia itself, Hungary, Poland and elsewhere, keeping his activity secret even from his own ministers. The alliance with Prussia and the war with Austria of 1566, although fortune did not favour Italian arms, added Venetia to his dominions.

The Roman question yet remained unsolved, for Napoleon, although he had assisted Piedmont in 1859 and had reluctantly consented to the annexation of the central and southern provinces, and of part of the Papal States, would not permit Rome to be occupied, lest he should lose the support of the French clericals, and maintained a French garrison there to protect the pope. When war with Prussia appeared imminent Victor Emmanuel was anxious to assist the man who had helped him to expel the Austrians from Italy, but he could not do so unless Napoleon gave him a free hand in Rome. This the emperor refused to do until it was too late. Even after the first French defeats the chivalrous king, in spite of the advice of his more prudent councillors, wished to go to the rescue, and asked Thiers, the French representative who was imploring him for help, if with 100,000 Italian troops France could be saved, but Thiers could give no such assurance and Italy remained neutral. On Sept. 20, 1870, the French troops having been withdrawn, the Italian army entered Rome, and on July 2, 1871, Victor Emmanuel made his solemn entry into the Eternal City, which then became the capital of Italy.

The pope refused to recognize the new kingdom even before the occupation of Rome and the latter event rendered relations between church and state for many years extremely delicate. The king himself was anxious to be reconciled with the Vatican, but the pope, or rather his entourage, rejected all overtures, and the two sovereigns dwelt side by side in Rome until death without ever meeting. Victor Emmanuel devoted himself to his duties as a constitutional king with great conscientiousness, but he took more interest in foreign than in domestic politics and contributed not a little to improving Italy's international position. On Jan. 9, 1878, Victor Emmanuel died of fever in Rome, and was buried in the Pantheon.

Bluff, hearty, good-natured and simple in his habits, he always had a high idea of his own kingly dignity, and his really statesmanlike qualities often surprised foreign diplomats, who were deceived by his homely exterior. As a soldier he was very brave, but he did not show great qualities as a military leader. He had a great weakness for female society, and kept several mistresses; one of them, the beautiful Rosa Vercellone, he created Countess Mirafiori e Fontanafredda and married morganatically in 1869; she bore him one son.

VICTOR EMMANUEL III (1869–1947), king of Italy, son of King Humbert I and Margherita of Savoy-Genoa, was born at Naples on Nov. 11, 1869. He entered the army and soon after attaining his majority, was appointed to the command of the Florence Army Corps, and in 1896 to that of the Naples Army Corps. His formal accession to the throne took place on Aug. g and 11, 1900, after the assassination of his father (July 29).

When in 1915 Italy declared war on Austria, the king at once went to the war zone, remaining there until the armistice, appointing his uncle Ferdinand, duke of Genoa, regent of the kingdom to act in his stead. At the front he lived in a most unassuming manner at the "Villa Italia" near Udine, and after Caporetto near Padua, constantly visiting the trenches and the most exposed positions, as well as the military hospitals, and leading to a very large extent the life of the soldiers. Although nominally commander-in-chief he never interfered with the conduct of operations, or in the matter of appointments.

After Caporetto he multiplied his activities a thousand-fold, and his proclamation of Nov. 19, 1917, sounded like a trumpet-call to the whole people. After the armistice, King Victor Emmanuel returned to Rome on Nov. 14, 1918.

On the night preceding the fascist "march on Rome" (Oct. 28, 1922) the cabinet had decided unanimously to proclaim martial law, of which Marshal Badoglio said in those days that the simple fact of its proclamation would have been sufficient to disperse at once the rabble of the so-called "march." The prime minister, Facta, went with the decree at midnight to the villa Savoia, out of Rome, to have it signed by the king. At two in the morning back he went with the decree not signed by the king. Official fascist propagandists wrote later on that the king had "nobly" refused to sign. Others, the first of whom was Count Sforza in his *Makers of Modern* Europe, asserted that Facta had accepted reluctantly the decision of the cabinet; that he had been induced by Mussolini into believing that a new Facta-Mussolini cabinet might be formed; and that he secretly suggested that the king not sign the decree. The fact is that the king's rule had always been to obey the prime minister in any political matters. He went too far with this rule under fascism, because he signed and welcomed, or feigned to nelcome, decrees which violated his oath as a constitutional king, as when he ratified the complete suppression of the freedom of the press, the suppression of the chamber of deputies, etc. Under Mussolini's rule, the king's prerogatives existed nominally but not in fact, so that by the time of World War II he was taking a small part indeed in the Italian affairs of state. On June 5, 1944, the day after the Allies entered Rome, he named his son, Crown Prince Humbert, lieutenant general of the realm, relinquishing all power for himself but retaining his title of king. On May 9, 1946, he abdicated in favour of Kumbert. On June 2, 1946, however, the Italian people voted to end the monarchy and to set up a republic. Victor Emmanuel died Dec. 28, 1947, in Alexandria, Egypt.

Victor Emmanuel married Princess Elena Petrovich-Niegosh, daughter of the first and last king of Montenegro; she bore him four daughters: Yolanda Margherita (June 1, 1901), Mafalda (Nov. 19. 1902), Giovanna (Nov. 13, 1907) and Maria (Dec. 26, 1914); and a son and heir, Humbert, prince of Piedmont (Sept. 15, 1904). Princess Yolanda was married in 1923 to Count Giorgio Calvi of Bergolo, Mafalda in 1925 to Prince Philip of Hessen and Giovanna in 1930 to King Boris of Bulgaria.

VICTORIA (1819–1901), queen of the United Kingdom of Great Britain and Ireland, and from 1876 empress of India, was born at Kensington palace on May 24, 1819, the only child of Edward, duke of Kent, fourth son of King George III. With the death in 1817 of the prince regent's daughter. Princess Charlotte, there was no surviving legitimate offspring of George III's 15 children. In 1818, therefore, three of his sons, the dukes of Clarence, Kent and Cambridge, married to provide for the succession. The duke of Kent's wife was Princess Mary Louisa Victoria of Saxe-Coburg-Gotha, the widow of Prince Ernest Charles of Leiningen. The duke of Kent died when his daughter (who was christened Alexandrina Victoria) was eight months old; accordingly, on George IV's accession she became heir to the throne next after the duke of Clarence (subsequently William IV) whose own children died in infancy.

Victoria, by her own account, "was brought up very simply," principally at Kensington palace where her closest companions, other than her homely and impoverished mother, were her half-sister Féodore and her governess Louise (afterward the Baroness) Lehzen, a native of Coburg. Her mother's nearest adviser was her brother, Victoria's uncle Leopold, widower of Princess Charlotte. Until he became the first king of the Belgians in 1831 he lived at Claremont, near Esher, Surrey, where Victoria would visit him. From her father's family she was virtually isolated, growing up to regard herself as a Coburg rather than as a member of the house of Hanover. Her mother's morbid fear of Victoria's uncle, the duke of Cumberland, and after the death of George IV, her pretentiousness on her daughter's behalf, led to an estrangement from Victoria herself and to friction with William IV. Early in life Victoria learned caution in her friendships; she also revealed a liking for her own way; nor did her retentive memory allow her to forgive readily.

The legend (upon which the queen herself was to cast some doubt) ran that she was unaware until she was 12 that she would one day succeed to the throne. "I will be good" she is reported to have responded to the news. Not long afterward she began the detailed and highly characteristic Journal which she kept throughout her life.

If in Great Britain at mid-20th century the crown is at the centre of society and but rarely concerned with political decisions, at Victoria's accession in 1837 it was almost the reverse. Society in the conventional sense revolved not so much around the court as around the great houses whose owners might still look down upon, or at least askance at, the palace. Politics, however, still revolved around the throne. As recently as 1834 the Melbourne ministry had been dismissed by the crown, and prime ministers such as Sir Robert Peel who had served their political apprenticeship before the Reform act of 1832 were still likely to hold "the confidence of the crown" to be a political necessity to an administration. The political role of the crown when Victoria first came to wear it was thus by no means clear; neither was the permanence of the throne itself. When she died and the new king moved from Marlborough house to Buckingham palace the change was one of social rather than of political focus: nor was there any doubt of the monarchy's continuance. That was the measure of her long reign.

Accession.—In the early hours of June 20, 1837, Victoria received the archbishop of Canterbury and the lord chamberlain to learn of William IV's death. Later that morning the privy council was impressed by the graceful assurance of the new queen's demeanour. The accession of a young woman was romantically popular; moreover. because of the so-called Salic law, which prevented succession by a woman, it entailed the separation of the crowns of Great Britain and Hanover, the latter of which passed to William IV's surviving brother, Ernest, the unpopular duke of Cumberland.

The new queen, who had never before had a room to herself, exiled her mother to a distant set of apartments when they moved into Buckingham palace. Sir John Conroy, her mother's major-domo. was pensioned off; only Lehzen, of whom she was still in awe, remained close to the queen. Even her beloved uncle Leopold was politely warned off discussions of English politics. "Alone" at last, she enjoyed her new-found freedom. "Victoria," wrote her cousin, Prince Albert (*q.v.*) who was later to marry her, "is said to be incredibly stubborn and her extreme obstinacy to be constantly at war with her good nature; she delights in Court ceremonies, etiquette and trivial formalities . . . She is said not to take the slightest pleasure in nature and to enjoy sitting up at night and sleeping late into the day." It was, in retrospect, "the least sensible and satisfactory time in her whole life"; but at the time it was exciting and enjoyable, the more so because of her romantic friendship with Lord Melbourne, the prime minister.

Together with the threat of Cumberland as heir apparent, two episodes in 1839, revealing that if she had too little in her head she had perhaps too little in her heart also, may explain why "those who had her welfare most at heart were anxious," as she wrote long afterward, "to secure for her without delay a husband's guidance and support." Lady Flora Hastings, a maid of honour with Tory connections, was forced to undergo a medical examination for suspected pregnancy. The gossip, when it was discovered that the queen had been mistaken, became the more damaging when later in the year Lady Flora died of a disease not diagnosed by the physician whom the queen had thrust upon her earlier. The brief enthusiasm of the populace over the coronation (June 28, 1838) swiftly dissipated.

Between the two phases of the Hastings case "the bedchamber crisis" intervened. Lord Melbourne had proved a delightful and devoted mentor to the young queen; but, by surrounding the queen with Whig ladies, he had allowed her to become a Whig partisan. When he resigned in May 1839 Sir Robert Peel, the Conservative leader, stipulated that the Whig ladies of the bedchamber should be removed. The queen imperiously refused, not without Melbourne's encouragement. "The Queen of England will not submit to such trickery," she said. Peel therefore declined to take office which Melbourne rather weakly resumed. "I was very young then," wrote the queen long afterward "and perhaps I should act differently if it was all to be done again." Denunciation of her conduct became a popular item in Chartist propaganda.

For a short time after Albert's arrival at Windsor the queen wrestled with her desire for continued and enjoyable independence until on Oct. 15, 1839, she proposed to him. Her letters became ecstatic; his were more circumspect. They were married on Feb. 10, 1840, the queen dressed entirely in articles of British manufacture.

The "Albertine Monarchy."—At first the queen was insistent that her husband should have no share in the government of the country. Within six months, on Melbourne's repeated suggestion, the prince was allowed to start seeing the despatches, then to be present when the queen saw her ministers. The concession became a routine and, during her first pregnancy, the prince received a "key to the secret boxes." Quickly, too, she learned from her husband to dislike London and to abandon late parties. His was the stronger personality. It was the "Prince who insisted on spotless character, the Queen not caring a straw about it," the duke of Wellington (*q.v.*) told Charles Greville, the diarist—the prince was "extremely strait-laced and a great stickler for morality whereas she was rather the other way." The royal dinner parties became a conspicuous model of decorum: and not very amusing.

Blissfully happy herself, the queen settled down to have children while the prince busied himself with the administration of the royal properties. The "mere amusement" of the gossipy days with Melbourne was past. Later she recorded talking them over with her husband and of her "unbounded affection and admiration for Lord Melbourne which I said to Albert I hardly knew from what it arose excepting the fact that I clung to someone and having very warm feelings. Albert thinks I worked myself up to what really became rather foolish."

It is convenient to summarize here the growth of the royal family. The princess royal (the "Vicky" of the *Letters)* was born in Nov. 1840; in 1858 she married the crown prince of Prussia and later became the mother of the emperor William II. The prince of Wales (Edward VII) was born in 1841. Then followed Princess Alice, afterward grand duchess of Hesse, 1843; Prince Alfred. afterward duke of Edinburgh and duke of Saxe-Coburg-Gotha, 1844; Princess Helena (Princess Christian), 1846; Princess Louise (duchess of Argyll), 1848; Prince Arthur (duke of Connaught). 1850; Prince Leopold (duke of Albany), 1853; Princess Beatrice (Princess Henry of Battenberg), 1857. The queen's first grandchild was born in 1859, her first great-grandchild in 1879. There mere 37 great-grandchildren alive at her death.

The prince came into his own to negotiate a compromise on the bedchamber question with Peel after the Melbourne government had been defeated in the general election of 1841. The queen's first interview with Peel went well, eased by Melbourne's advice to his successor: "the Queen is not conceited—she is aware there are many things she cannot understand and she likes to have them explained to her elementarily—not at length and in detail but shortly and clearly." If, as Lady Lyon once noted, "there was 'a vein of iron' which ran through the Queen's extraordinary character," her personal happiness as wife and mother evoked a less willful humility. Peel's very real distress when in the summer of 1842 an attempt was made to assassinate the queen—together with the affinity between the prince and the new prime minister—soon converted the "cold odd man" of the queen's earlier comment into "a great statesman, a man who thinks but little of party and never of himself." Lord Aberdeen, the foreign secretary, also became a great favourite. "We felt so safe with them both," she told King Leopold. It was under Albert's influence that she came to adopt what she later called "the obvious but up to that time much neglected doctrine that it is the paramount duty of a constitutional monarch to maintain a position of neutrality towards the leaders of party on both sides." At' the election of 1841 the queen had subscribed, through Lehzen, £15,000 to the Whig cause.

By the autumn of 1842 Lehzen had left for Germany forever and the prince could reorganize the palace. He became effectively the queen's private secretary: according to himself. "her permanent minister": using his own staff. George Anson and Gen. Charles Grey, for the purpose. There are. perhaps, three significant aspects of what has been called the "Albertine monarchy": apart from the intense happiness in which it enclosed the queen. In 1842 she had made her first railway journey. Railway travel made an important contribution to the queen's contentment, for it enabled her to spend much of the year in the Isle of Wight and in Scotland, ministers taking turn in "doing service" (as Lord Palmerston came to call it). by residing in attendance. An estate at Osborne in the Isle of Wight was purchased on Peel's advice, and the residence — "our island home" — built in 1846 out of the queen's savings from her income once the prince had got her properties into shape. She had already paid off her father's debts. The lease of the original Balmoral house near Ballater was taken in 1848 after three previous visits to Scotland. In 1852 the estate was bought and in 1855 a great castle in "Scotch baronial" was almost completed. At Balmoral she was happiest: there it was possible to form a new establishment without the difficulties which the prince had encountered in organizing the palace or Windsor castle. In Scotland. moreover, he did not have to face the unpopularity so frequently his experience in England. At Balmoral the royal pair and their family were able to live "with the greatest simplicity and ease." wrote Greville. The queen soon came to hold the Highlanders in more esteem than any other of her subjects. She liked the simpler life of the Highlands, as her published *Journal* was to reveal: she came to make the most of the thin stream of Scottish blood in her veins; also, so long as the sermons were short enough, to prefer the Scottish form of service. "You know," she was to tell Gladstone, "I am not much of an Episcopalian": and she developed a comfort in the consolations of the Rev. Norman MacLeod. as also a delight in the plain speech of John Brown, the Highland servant who stalked with Albert.

The political circumstances within which the monarchy operated in the prince's lifetime are peculiarly worth remarking. After the repeal of the corn laws there was a period not ending until the election of 1568 when politics tended to consist of a series of temporary alliances between splinter groups and no single group (one may perhaps hardly use the word "party" in the modern sense so early) could guarantee its extended control over the house of commons: a condition rendering active political intervention by the crown not only possible but sometimes even necessary. There was a role for the cabinet maker: especially in helping to compose coalitions. Its significance must not, however, be overemphasized, since (as C. H. Stuart reminds us: *Trans. Roy. Hist. Soc., Fifth Series,* vol. 4 [London, 1954]) "the initiative in politics in the twilight years between the decline of royal government and the dawn of purely parliamentary rule still lay mith the official men of ministerial standing or ambition." 'and the queen's share "though substantial was always secondary." It may be doubted. however, whether she herself saw matters in this light.

Again. the tradition persisted that in foreign affairs the crown had a special part to play, and could continue to "do it alone with a Secretary of State." Victoria and Albert had relatives throughout Europe and were to have more. Moreover, they visited and were visited by other monarchs: the tsar. Nicholas I, and Louis Philippe, for example, and later by Napoleon III. Albert was determined that this personal intelligence should not be disregarded and that the queen should never become (as his own mentor the Baron Stockmar had indicated) "a mandarin figure which has to nod its head in assent or shake it in denial as its Minister pleases." The result was a clash mith Lord Palmerston who could look back on a career of high office beginning before the royal couple mas born. Confident in his parliamentary skill and in his capacity to solve every problem of foreign policy on the spur of the moment, shrewd, bold, instinctive, contemptuous of foreign potentates, diplomatic amenities or his ministerial colleagues, in every respect save industry he was Albert's antithesis. The prince distrusted Palmerston's character, disapproved of his methods, thought his policy shallow, and. prompted by Stockmar, disagreed with his concept of the constitution.

In the ensuing contests Victoria, as Albert's disciple, outran her lord and master in her vehemence and in 18jo thought "it right in order to avoid any mistakes for the future. to explain what it is she expects from the foreign secretary. She requires: (1) that he distinctly state what he proposes in a given case in order that the Queen may know as distinctly to what she has given her royal sanction; (2) having once given her sanction to a measure, that it be not arbitrarily altered or modified by the minister." Palmerston's habits did not change and n-hen without consultation he expressed his approval of Louis Napoleon's *coup d'état* in 1851, Lord John Russell at once dismissed him. using the occasion to make public the queen's memorandum just quoted. Within a few months Palmerston was back in office. however, as home secretary. and on the eve of the Crimean War the royal pair encountered a wave of unpopularity such as they had endured in 1846–47. There was however a marked revival of royal sentiment as the war wore on. The queen personally superintended the committees of ladies who organized relief for the wounded and eagerly seconded the efforts of Florence Nightingale: she visited crippled soldiers in the hospitals, and instituted the Victoria Cross for gallantry.

Widowhood. — The importance of the Albert period lay in the training the queen received: in orderly ways of business, in hard work (which she certainly never learned from Melbourne). in the expectation of royal intervention in ministry-making at home; and in the establishment of a private (because royal) intelligence service abroad. The English monarchy had changed. "In place of a definite but brittle prerogative it had acquired an undefinable but potent influence." (G. M. Young, *Victorian England,* 2nd ed., Oxford University Press. London, 1953.)

The queen had played with Albert a "substantial" (if "secondary") part in choosing and putting into office Aberdeen's ministry when Derby resigned in Dec. 1852. The habit died hard, for after the nervous breakdown—the "two dreadful first years of loneliness" — after the prince consort's death (Dec. 1861), she sought, on her recovery, to behave as he would have ordained. Her testing point was, then, her "dear one's" point of view; and this she had known at a particular and thereafter not necessarily relevant period in English political life. Her training and his influence were ill suited to the "swing of the pendulum" politics which better party organization and a wider electorate enjoined after the Reform bill of 1867. She was a widow of 42 with nine children when Albert died. And since she blamed her son and heir for his death — the prince consort had come back ill from clearing up an indiscretion of Albert Edward's at Cambridge— she did not hesitate to vent her loneliness upon him. "It quite irritates me to see him in the room." she startled Lord Clarendon by saying. The breach was never really healed. The Hanoverians —and in this, at least, she was a Hanoverian—were never able to get on to terms with their heirs. Hating ceremonial herself, although she had much talent for it, as time went on the queen was clearly envious of the popularity of the prince and princess of Wales. She liked to be, but she took little trouble to see that she was, popular.

To Balmoral (to which telegraphic communication with London was established in the 1860s) and to Osborne, for four months in the year. she came to retreat in turn. giving the impression to shrewd observers like Walter Bagehot (whose *English Constitution* was published in 1867) that she was "a retired widow" because he could not read her *Letters;* and. although his division between the dignified or "theatrical" and the efficient or "business" parts of the constitution. came to grow truer in her case, the *Letters* exist to reveal that, so far as she was concerned, she mas determined to remain, as Albert had taught her, very much one of the efficient parts of the constitution: although, from the point of view of the populace and those tradespeople who needed a more splendid court, carrying into effect all too few of the "theatrical" aspects of the task. She had been an adoring wife and, if Albert had left her prejudices less narrow, he had not, of course, been able to alter her temperament: as she herself realized. "My nature is too passionate," she told an old friend, "my emotions are too fervent; he guided and protected me, he comforted and encouraged me." Not only was Albert gone but the advisers of earlier days were dead too — Melbourne. Peel, Wellington and Aberdeen — and Stockmar had retired in Coburg. "Uncle Leopold" died not long afterward. And the old men who survived. she had never liked: Palmerston, Derby or Russell to whom there soon came a black-edged reproach from Osborne warning him not to take up Palmerston's habit of sending off drafts "without the Queen's having first seen them." (Jan. 14, 1862). Moreover, there were to be changes, because of retirement, in the next few years, in the household, and one of them was of some moment. "Good, excellent General Grey." who had been Albert's secretary, stoutly resisted her attempt to make herself a recluse. It was he who urged ministers to press her to appear in public. He realized what an infliction it was to ministers that she stayed so long at Balmoral and Osborne nursing her grief; he advised "a strong — even a *peremptory* tone." Grey had been prepared to lose his temper with her — and survive. After he retired nobody dared, except, till 1883. John Brown. Henry (later Sir Henry) Ponsonby. Grey's successor, mas too young to try. He might soften her asperities, or take the blame on her behalf, but he could not, indeed (despite his wife's prompting) did not try to, stand up to her prejudices as Grey had done. No longer restrained. her *Letters* became more forcefully characteristic, and, as Lady Ponsonby told Sir Henry, "When she is disagreed with. even slightly, she thinks nothing too bad to say of the culprit."

It was despite, yet because of, Albert that she succumbed to Disraeli. Albert had thought him insufficiently a gentleman and remembered what he had done to Peel; the prince had approved of Gladstone. Yet Disraeli was able to enter into the queen's grief. flatter her, restore her self-confidence and make the lonely crown an easier burden. Behind all the calculated attack on her affections there was a bond of mutual loneliness, a note of mystery (which she had already found of interest in Napoleon III): and the return to good gossip. Moreover, Disraeli told the queen in 1868 that it would be "his delight and duty, to render the transaction of affairs as easy to your Majesty, as possible." Since the queen was only too ready to consider herself overworked, this approach was especially successful. Gladstone, on the other hand. would never acknowledge that she was, as she put it, "dead beat": perhaps because he never was himself; whereas Disraeli tired easily. The contrast between Disraeli's gay. often malicious, gossipy letters and Gladstone's 40 sides of foolscap is obvious. And there was no Albert to give her a neat précis. Moreover, Gladstone held the throne as an institution in such awe that it affected his relations with its essentially feminine occupant. His "feeling" for the crown, said Lady Ponsonby. was "always snubbed." There was a lack of personal understanding between the queen and Gladstone fairly early which was accentuated by Disraeli's willingness that such should be so. Later, this was to grow into political differences; but they began, it would seem, on the psychological and personal level. Dean Wellesley, her favourite cleric, took considerable trouble to warn Gladstone in 1868 before he took office, that "everything depends upon your manner of approaching the Queen. Her nervous susceptibility has much increased since you had to do with her before and you cannot show too much-regard, gentleness, I might even say tenderness, towards Her."

Gladstone took the advice to heart, and although they might differ on a particular issue, such as the disestablishment of the Irish church in 1869, it did not prevent the queen's active co-operation: in that particular issue, certainly. when her intervention with the bishops was decisive, to avoid clashes between the two houses. Friction began in 1871 when Gladstone, alarmed at the wave of republican feeling, tried to persuade the queen to reappear in public and postpone her departure to Balmoral. She threatened abdication, and Disraeli made matters worse for Gladstone by defending the queen's seclusion in a speech savouring of what Gladstone called his "usual flunkeyism." When Gladstone subsequently appeared at Balmoral he noted "the repellent power which she so well knows how to use has been put in action towards me . . . I have felt myself on a new and different footing with her."

Over Ireland. their paths separated ever more widely. Whereas "to pacify Ireland" had become the "mission" of Gladstone's life, the queen (like the majority of her subjects) had little understanding of, or sympathy for, Irish grievances. She disliked disorder and regarded the suggestion of Irish Home Rule as sheer disloyalty. The proposal of an Irish "Balmoral" was repugnant to her, especially when it mas suggested that the prince of Wales might go in her place. To avoid the Irish sea, she claimed to be a bad sailor; yet she was willing in her later years to cross the English channel almost every year. In all, she made but four visits to Ireland, the last in 1900 being provoked by her appreciation of the gallantry of the Irish regiments in the South African War; she never forgot that she was herself a soldier's daughter.

Constitutional **Position.**—News of Gladstone's defeat in 1874 found the queen in delight. "What an important turn the elections have taken." she wrote to Sir Theodore Martin (Albert's biographer). "It shows that the country is not *Radical.* What a triumph, too, Mr. Disraeli has obtained and what a good sign this large Conservative majority is of the state of the country, which really required (as formerly) a strong Conservative party!" If. years before. Melbourne, almost despite himself. had made her a good little Whig: if Albert had left her, in general, a Peelite, temperamental and subsequently doctrinal differences with Gladstone made it easy for Disraeli to turn her into a stout supporter of the Conservative party. And he took an artist's pleasure in doing so (as his *Letters to Lady Bradford and Lady Chesterfield* make evident). By 1878 we find Lady Ponsonby writing to her husband "I *do* think Dizzy has worked the idea of personal government to its logical conclusion and the seed mas sown by Stockmar and the Prince. While they lived, the current of public opinion, especially among the Ministers, kept the thing between bounds, but they established the superstition in the Queen's mind about her own prerogative. and we who know her, know also perfectly how that superstition. devoid as it is of even a shadow of real political value, can be uorked by an unscrupulous Minister to his own advantage."

Lady Ponsonby went on to hint at a future clash with Gladstone. When in Sept. 1879 a dissolution seemed imminent, the queen wrote to the marchioness of Ely (who was, after the duchess of Argyll. perhaps her most intimate friend):

Dear Janie,—I wish it were possible for Sir Henry Ponsonby to *get at some* of the Opposition and to point *out* the *extreme* danger of binding themselves by foolish, violent declarations about their policy beforehand I hope and trust the Government will be able to go on after the Election, as change is so disagreeable and so bad for the country; but, if it should *not,* I wish the *prtnctpal* people of the Opposition should *know* there *are certain* things which I *never can* consent to.

1. Any lowering of the position of this country by letting Russia have her way in the East, or by letting down our Empire in India and in the Colonies. This *was* done under Mr. Gladstone, quite *contravy* to Lord Palmerston's *policy,* which, whatever faults he had, *was always* for *keeping up England* which of late years had *quite* gone down, so that we were *despised* abroad.
2. That I would never give way about the *Scotch Church* which is the real and true stronghold of Protestantism.

These are points which I *never* could *allow* to be *trifled with,* and *I* could have *no* confidence in any men who attempted this. Our position in India, and in the Colonies, *must* be *upheld.* I wish to *trust my* Government w-hoever it is, but they should be *well aware* beforehand I never could if they intended to *try* and *undo* what has been done.

In the same way I never could take Mr. Gladstone or Mr. Lome as my Minister again, for I never could have the slightest *particle* of confidence in Mr. Gladstone *after* his violent, mischievous and dangerous conduct for the last three years, nor could I take the *latter* after the very offensive language he used three years ago against *me.*

Sir Henry Ponsonby has so many Whig friends that he might easily *get* these things *known.* In former days much good was done by Baron Stockmar and Mr. Anson paving the way *for* future arrangements and *preventing* complications at the moment. like Sir Robert Peel's failure in 1839 about the Ladies. Ever yours affectionately, V.R. and I. I never *could* take Sir C. Dilke as a *Minister.*

After the blow fell with the Conservative party's defeat in 1880 she sent for Lord Hartington. "Mr. Gladstone *she* could have nothing to do with, for she considers his whole conduct since '76 to have been one series of violent, passionate invective against and abuse of Lord Beaconsfield and that *he caused* the Russian war." Nevertheless, as Hartington pointed out, it was Gladstone whom she had to have. She made no secret of her hostility, she hoped he would retire, and she remained in correspondence with Lord Beaconsfield (as Disraeli had become). Gladstone. indeed, said he himself "would never be surprised to see her turn the Government out, after the manner of her uncles." Over the abandonment of Kandahar, in 1881, for example, Ponsonby had never seen her so angry: "The Queen has never before been treated." she told him, "with such u-ant of respect and consideration in the forty three and a half years she has worn her thorny crown . . . ." Over the Franchise bill of 1884 she nas able to intervene usefully, and it would seem that it was Lord Salisbury who was the more difficult; nevertheless she blamed Gladstone. "The Lords." she said, "are *not* in disharmony with the people, but unfortunately Mr. Gladstone's government leans so much to the extreme Radical side, instead of to the sound and moderate portion of his following. that measures are presented to the House of Lords which the Conservatives and moderate Liberals do not feel they can with safety agree to. No one is more truly Liberal in her heart than the Queen, but she has aluays strongly deprecated the great tendency of the present Government to encourage instead of checking the stream of destructive democracy which has become so alarming. This it is that. she must sap justly, alarms the House of Lords and all moderate people. And to threaten the House of Lords that they will bring destruction on themselves is in fact, to threaten the Monarchy itself Another Sovereign but herself must acquiesce in any alteration of the House of Lords. She will not be a Sovereign of a Democratic Monarchy." She "was under the impression," said Ponsonby's son, that "she was holding the scales evenly between the two parties."

Of the three great rights (to be consulted. to encourage and to warn) which Walter Bagehot had awarded the crown in his *English Constitution* she had come to make partisan use. Nothing escaped her "drill eye." She insisted on consultation whoever was in power—and over the most trivial details. As time went on, she came, to encourage the Conservatives and to warn the Liberals. The considered view of the Radical Joseph Chamberlain, not notably a friend of royalty, is of interest: "The Queen does interfere constantly," he wrote; "more, however. when Liberal Ministers are in power than when she has a Conservative Cabinet, because the Conservatives on the whole do what she likes, as she is a Conservative; whereas the Liberals are continually doing and indeed exist for the purpose of doing the things she does not like. But it is very doubtful how far her interference is unconstitutional. and it would be quite impossible to prove it . . . The Queen is a woman of great ability . she writes to the Prime Minister about everything she does not like, which when he is a Liberal means almost everything that he says or does . . . she insists that administrative acts should not be done nithout delay for the purpose of consulting with regard to them persons whose opinions she knows will be unfavourable . . . her action to my mind is strictly speaking constitutional . . . it would be difficult to maintain that uith her immense experience the Queen is not justified in asking for time in order that men of distinction should be consulted upon various acts." Her warnings in 1884 about General Gordon passed unheeded. and when he was killed at Khartoum she sent her reproof (Feb. 5. 1885) *en clair.*

"The lengthening experience of the Queen. laid up in the most retentive and faithful memory, was making her an excellent person to talk things over with; if she had mastered the nervous horror of London which drove her to Balmoral or Osborne, and had kept her Ministers under the charm at Buckingham Palace, her influence would have groan with her experience. . . . On three occasions after the Prince's death she intervened with decisive effect: in checking the hysterical fussiness with which Palmerston and Russell were behaving over Schleswig-Holstein under the grim contemptuous eyes of Bismarck; in promoting the passage of the Reform Bill of 1867; in releasing the deadlock of the Houses over Reform and Redistribution in 1884. But Disraeli had made her a partisan: the hoarded experience which might have been freely at the disposal of all her Ministers was reserved for such favourites as Salisbury and Rosebery, and the influence was dissipated in reprimands and injunctions, often shrend, always vigorous, but sometimes petulant and sometimes petty. . . . Now that her relations with her ministers are known with some degree of intimacy, it is permissible to say that if she never overstepped the limits of her admitted powers, she did not alnays behave well within them: she did her duty but often with a reluctance and temper which in a more critical age might have been even dangerously resented." (G. M. Young, *Victorian England,* and ed., Oxford University Press, London, 1953.) She never acclimatized herself to the effects of the new electorate on party organization. No longer was the monarchy normally necessary as cabinet maker—but she still had an obscure desire to have a coalition (Aberdeen had become her favourite minister in Albert's day) and she had been brooding, since 1880, over getting "the moderate men of both parties," as she called them, into a coalition together as an anti-Radical bloc. Irish Home Rule provided her with a solution.

In 1885 Ponsonby explained to Sir William Harcourt that "her idea was that 'extremes' (meaning Gladstone and R. Churchill) should be got rid of, that Hartington should be Prime Minister and Salisbury Foreign Secretary under him, the whole of the rest of the Cabinet being Liberal and Whig." She had already sounded the duke of Argyll in the matter and she pressed G. J. (afterward Lord) Goschen to act as go-between. "Out of this," she said. "might grow a Coalition in time." In this she was right: and in the Salisbury administration (1895–1902) with which her long reign ended she was eventually to find not only the sort of ministry with which she felt comfortable. but one which lent a last ray of colour to her closing years by its alliance, through Joseph Chamberlain, with the mounting imperialism which she had so greatly enjoyed in Disraeli's day when he had made her empress of India. Before that, however. she mas to have two more rounds of bickering with Gladstone and the shortlived administration of Lord Rosebery whom she herself chose unadvised in 1894 as her prime minister.

Last Years.—Victoria absorbed a great deal of the time of her ministers, especially Gladstone's, but after 1868 it may be doubted whether, save in rare instances, in the longer run it made a great deal of effective difference, politically. She may have postponed an occasional evil day; she certainly hampered an occasional career. And sometimes. that "continuous political experience" which Bagehot remarked as a long-lived monarch's greatest asset, was invaluable: in stopping "red tapings," as the queen called them, or in breaking a log jam. Meanwhile—"a comparatively late growth"—she had gained the affection of her subjects. Lord Salisbury observed in the lords (Jan. 25, 1901) after her death that: "She had an extraordinary knowledge of what her people would think—extraordinary, because it could not come from any personal intercourse. I have said for years that I have always felt that when I knew what the Queen thought, I knew pretty certainly what views her subjects would take, and especially the middle class of her subjects." Bagehot had emphasized the fact that the court stood aloof from the rest of the London world and had "but slender relations with the more amusing part of it." The court, was, then, unfashionable: but the queen herself, as the two Jubilees of 1887 and 1897 showed. was popular. Gone were the days when pamphlets were circulated asking what she did with her money. More and more fully with advancing years. she was able to satisfy the imagination of the middle class—and the poorer class—of her subjects.

Many of the movements of the day passed the aged queen by, many irritated her. but the stupendous hard work which Albert had taught her went on—the meticulous examination of the boxes, the regular signature of the papers. "Wiggings" (as her scoldings of family and ministers were familiarly called) grew more infrequent. When in 1896 the prince of Wales wanted her to give the kaiser a "good snubbing," she replied, "Those sharp answers and remarks only irritate and do harm and in Sovereigns and Princes should be most carefully guarded against. William's faults come from impetuousness (as well as conceit); and calmness and firmness are the most powerful weapons in such cases." She had mellowed. She had come into calmer, if lonely, waters. Those who were nearest to her came completely under her spell; yet all from the prince of Wales down stood in considerable awe. A breach of the rules could still make a fearsome change in the kindly, managing great-grandmother, in black silk dress and white cap. The eyes began to protrude, the mouth to go down at the corners. Those who suffered her displeasure never forgot it; nor did she. She lived surrounded by mementoes, photographs, miniatures, busts and souvenirs: at the end of long corridors down which one tiptoed past Indian attendants to the presence. Nobody knocked; a gentle scratching on the door was all that she permitted. Every night at Windsor Albert's clothes were laid out on the bed, every morning fresh water was put in the basin in his room. She slept with a photograph--over her head—taken of his head and shoulders as he lay dead.

Queen Victoria had fought a long rearguard action against the growth of "democratic monarchy": yet, in some ways, she had done more than anyone else to create it. She had made the monarchy respectable and had thereby guaranteed its continuance: not as a political power but as a political institution. Her long reign had woven a legend and, as her political power ebbed away. her political value grew. It lay, perhaps, more in what the electorate thought of her, indeed felt about her, than in what she ever was or certainly ever believed herself to be. Paradoxically enough, her principal contribution to the British monarchy and her political importance lay in regard to those "dignified" functions which she was accused of neglecting rather than to the "business" functions which, perhaps, sometimes, she did not neglect enough.

The queen died at Osborne on Jan. 22, 1901, after a short and painless illness. She was buried beside Prince Albert in the mausoleum at Frogmore near Windsor. Her essential achievement was simple. By the length of her reign, the longest in English history, she had restored both dignity and popularity to a tarnished crown: an achievement of character, as well as of longevity. Historians may differ in their assessment of her political acumen, her political importance or her role as a constitutional monarch. None will question her high sense of duty as wife, mother and queen, or the transparent honesty, the massive simplicity, of her royal character.

BIBLIOGRAPHY.—The most important authority for the queen's life is the *Letters of Queen Victoria,* in 3 series, *1837–61,* 3 vol. (London, 1907); *1862–85,* 3 vol. (London, New York, 1926–28); *1886–1901,* 3 vol. (London, New York, 1930–32). *Further Letters of Queen Victoria* were edited (London, New Haven, Conn., 1938) by Hector Bolitho, who also consolidated his own several studies of the queen and her family in *The Reign of Queen Victoria* (New York, 1948; London, 1949). Her letters to Gladstone were edited, with commentary, by Philip Guedalla, *The Queen and Mr. Gladstone,* 2 vol. (London, 1933). *Leaves* from her *Journal of Our Life in the Highlands . . . 1848–61,* Sir A. Helps (ed.) (London, 1868) and *More Leaves . . . 1862–82* (London, 1884) were published in the queen's lifetime and played their part in securing the eventual public affection. Besides publications already cited in the text, and in the article ALBERT, PRINCE CONSORT OF ENGLAND, there should be noted Sir Sidney Lee's article in the *Dictionary of National Biography,* vol. xii, suppl. (London, 1921–22); Arthur Ponsonby's *Queen Victoria* (London, New York, 1933) and *Henry Ponsonby* (London, 1942); Sir Frederick Ponsonby's *Side Lights on Queen Victoria* (London, New York, 1930) and *Recollections of Three Reigns* (London, 1951); and Lord David Cecil's *Lord* M (London, Toronto, 1954). Lytton Strachey's well-known biography, *Queen Victoria* (London, 1921; New York, 1924) was written before the second and third series of her *Letters* had been published. Frank Hardie, *The Political* Influence *of Queen Victoria, 1861–1901,* 2nd ed. (London, 1938), without which it would have been far more difficult to deal here with the period after 1861, takes a different view from that expressed here. *See* also *English Historical Documents, 1833–1874, G. M.* Young and W. D. Handcock (eds.) (London, New York, 1956). (E. T. Ws.)

VICTORIA, TOMAS LUIS DE (TOMMASO LUDOVICO DA VITTORIA) (*c.* 1540–1611), Spanish composer. was born at Avila. He was ordained and in 1571 was appointed choirmaster to the Collegium Germanicum at Rome. In 1578 he became chaplain to the empress Maria, sister of Philip II of Spain, and probably returned to his native country in 1583. From 1586 he was choirmaster to the convent of the Descalzas Reales. In 1603 he composed for the funeral of the empress Maria the greatest requiem of the golden age of vocal polyphony. This *Officium defunctorum* (published 1605) is his last-known work. He died in Madrid on Aug. 27, 1611.

Victoria was not ostensibly Palestrina's pupil, but Palestrina had the main influence upon his art, and alike personally and artistically the relations of the two were close. The work begun by Christobal Morales and perfected by Palestrina left no stumbling blocks in Victoria's path, and he was able from the outset to express the purity of his ideals of religious music without having to sift the good from the bad in that Flemish tradition which had entangled Palestrina's path while it enlarged his style. From Victoria's first publication in 1572 to his last requiem there is practically no change of style, all being pure church music of unswerving loftiness and showing no inequality except in concentration of thought. Like his countryman and predecessor Morales. he devoted himself entirely to sacred music; yet he differs from Morales, perhaps more than can be accounted for by his later date, in that his devotional spirit is impulsive rather than ascetic. He strikes the note of aspiration rather than that of renunciation.

Victoria's work is the crown of Spanish music: music which has been regarded as not constituting a special school, since it absorbed itself so thoroughly in the Rome of Palestrina. In any extensive anthology of liturgical polyphony, such as the *Musica* Divina of Karl Proske, his work stands out as impressively as Palestrina's and Orlando Lasso's; and the style, in spite of a resemblance to Palestrina which amounts to imitation. is as individual as only a successful imitator of Palestrina can be. That is to say, Victoria's individuality is strong enough to assert itself by the very act of following Palestrina's path. When he is below his best his style does not become crabbed or harsh, but overfacile and thin, though never failing in euphony. If he seldom displays an elaborate technique it is not because he conceals or lacks it. His mastery is unfailing, but his methods are those of direct emotional effect; and the intellectual qualities that strengthen and deepen this emotion are themselves innate and not sought out. The emotion is reasonable and lofty, not because he has trained himself to think correctly, but because he does not know that anyone can think otherwise. (See also MASS; MOTET; ORATORIO.)

(D. F. T.; X.)

VICTORIA, a state of the commonwealth of Australia occupying a triangular area of 87,884 sq.mi. in the extreme southeast of the continent. After Tasmania it is the smallest Australian state, with an area only 2.96% of that of the commonwealth.

Victoria is marked off from New South Wales by the river Murray from near its source to the South Australian border and by a straight boundary line from Forest Hill near the Murray source east-southeast to Cape Howe. On the west the border with South Australia extends from Discovery bay about 2jo mi. N.. running about 2 mi. W. of the meridian 141° E. which had been designated the boundary but was not correctly located when the boundary was marked in 1847. The coast line, about 680 mi. in length, extends in a generally east-west direction from 141° E. to 150° E. The most northerly corner of the state is at latitude 34° S. and the most southerly, Wilson's promontory. which is also the most southerly point of the Australian mainland, extends to 39° 8' S.

PHYSIOGRAPHY

For the main divisions of the state see map in Fig. r.

Central Highlands.—Official maps of Victoria still apply the name "Great Dividing range" to the main water-parting dividing north-flowing from south-flowing rivers and often represent it in a way suggesting a sharp-crested ridge. The highlands of Victoria in no way justify the term "range" and in parts of them the water-parting traverses level upland surfaces. The eastern highlands may be taken as extending from the border of New South Wales to a north-south line through hlelbourne. In this extensive area considerable diversity of structure and rock types occurs and distinctive subregions may be distinguished. The eastern highlands as a whole form part of the main eastern highland belt of Australia and are a complex of blocks bounded by intersecting fractures and flexures. The eastern section includes massive plateau areas from which peaks such as Mounts Cobboras. Feathertop. Hotham, Bogong, Fainter and Cope rise to over 6,000 ft. as blunted elevations. The area is strongly dissected and many of the valleys cut as much as 3.000 ft. below the intervening plateau surfaces, locally known as "high plains." The Bogong high plains, an extensive plateau at 5,500 ft between Mounts Bogong and Hotham. are the site of an extensive construction program for storages for the Kiewa hydroelectric scheme. Somewhat to the west Mounts Buffalo, Hoaitt and Buller exceed 5,500 ft. Still farther west the highlands become lower and narrower. The highest point within 50 mi. of Melbourne is Mt. Donna Buang (4,077 ft.). The southwestern corner of the eastern highlands includes the Dandenong ranges. The maximum elevation is only 2,078 ft. but since these hills lie less than 20 mi. from the centre of Melbourne and are, for census purposes, actually included in the metropolitan area. they provide a recreation area of great local importance. North of Melbourne, along the junction between the eastern and western highlands, the main route to the north and northeast crosses through the Kilmore gap at only 1,145 ft. No railways cross the highlands east of this line.

Western Highlands.—These are of generally lower elevation. only a few points attaining 3,000 ft. Toward the western end are

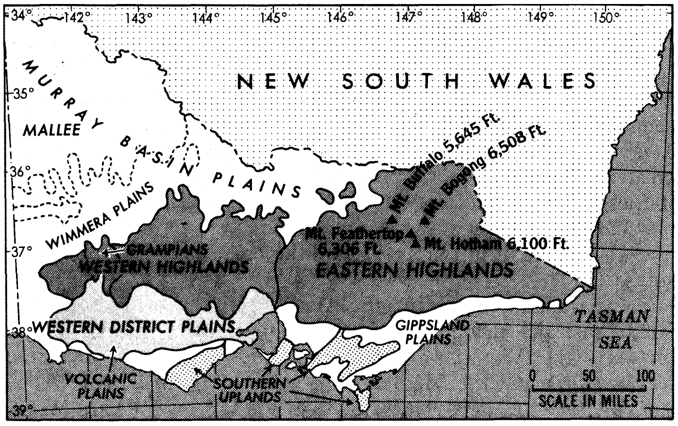

FIG. I. —VICTORIA: PHYSIOGRAPHIC DIVISIONS

the Grampians, prominent ridges of Upper Palaeozoic sandstone (Mt. William 3.828 ft.). Between these and the Kilmore gap the highlands form a rough upland zone from which rise peaks, including domes of Palaeozoic igneous rocks, such as Mounts Lar Ne Gerin. Buangor and Macedon, all of which exceed 3,000 ft., ridges of older Palaeozoic sediments and Tertiary volcanic cones. Within this zone occurred much of Victoria's gold mining and the relief is such that only in a few places was serious difficulty encountered in developing routes in and through the area.

Southern *Uplands.*—In the south lies a discontinuous series of higher areas reaching maximum heights of about 2,000 ft. The Otway ranges and the South Gippsland hills consist of Jurassic sandstones and mudstones overlain by Tertiary sands, the ranges being due to faulting and flexuring along lines with a generally northeast trend. With this group may be included the Mornington peninsula between Port Phillip and Westernport bays and Wilson's promontory, a granitic mass rising to 2,475 ft.

Southern Plains.—Between the central highlands and the southern uplands extends east-west a series of lowlands for which J. W. Gregory popularized the graphic term "great valley." While this term is useful in emphasizing the fact that one may move east or west from Port Phillip bay without encountering obstruction, the term "valley" strictly applies only to the east Gippsland plains where the Latrobe valley lies between the central and southern highlands. This section is reached from the low land at the head of Westernport bay across a low divide (500 ft.). To the west of Port Phillip bay extend the Western district plains. of which large tracts are covered by lava flows of late Tertiary to recent age. Around the western end of the highlands these plains join with the plains of the Murray basin.

Murray Basin Plains.—These include the plains of the Wimmera, Mallee and Northern districts. The map in Fig. 3 shows the boundaries of these districts as adopted for many official purposes, but these boundaries do not follow precisely the limit of the characteristic Mallee type of soil (alkaline sandy loam) and vegetation (see below). The surface is undulating and bears sand in east-west ridges or irregular dunes. The Wimmera and Northern district plains are both built up of the flood-plains of streams flowing to the Murray. They are flat except where occasional residuals of bedrock rise through the alluvium.

Climate.—Since Victoria extends through only 5° of latitude the differences in climate between districts depend principally on relief and distance from the sea. The highlands form a considerable area cooler and wetter than the rest of the state and only in the higher parts of the eastern highlands is winter snow regularly received. The highlands also form a climatic divide between the coastal zone and the interior plains, and the rainfall decreases toward the interior. It is also less reliable and, at irregular and unpredictable intervals: years with rainfall far below average have occurred. The droughts of 1902, 1914, 1927, 1938 and 1945 were among the most disastrous. Within the higher rainfall areas of the south occur two dry strips—one across the Western district to Port Phillip bay and the other around Sale in Gippsland. The seasonal distribution of rainfall reflects the position of Victoria at the southeastern corner of the continent. Toward the west there is a clear winter maximum of rainfall. This becomes less marked toward the east and at Melbourne the monthly rainfall figures are nearly uniform. Since, however. the winter rainfall is more frequent and gentle and the summer rainfall more intense and erratic. with falls on about half as many days as in winter, and since the higher summer temperatures reduce the effectiveness of the rainfall, it can be said that Melbourne has a dry summer. Toward the east there is a less distinct dry season. Average annual temperatures fall below 45° F. only on the higher parts of the eastern highlands and exceed 60° F. only in the northern parts of the Mallee and Northern districts. Except in the highlands the mean temperatures of the winter months show general uniformity throughout the state (July av.: Melbourne, 48.8° F.; Mildura 49.5° F.) though daily range and frost risk are greater in the interior. The higher annual means of the north are due to the higher temperature of the summer months. The hot spells characteristic of the Victorian summer are more severe and more prolonged in the interior. During a typical hot spell in the south the temperature reached on several successive days will rise to values nearing or exceeding 100° F. (absolute maximum, Melbourne: 114° F.). The spell is ended by the arrival of a southerly change. The effect of such a change may stop at the divide or it may extend over the whole state.

Water Supply.—Compared with the other mainland states Victoria is fortunate in the small proportion of its area which receives deficient rainfall. Nevertheless there are considerable areas in which settlement depends on the provision of water for domestic supply and for cattle and where intensive agricultural development is possible only with irrigation. The main source of water for irrigation is the Murray system. This is by far the largest river system in Australia, but the main stream and many of its major tributaries show great variations of flow from season to season and from year to year. Thus in the drought of 1914 the discharge of the river Goulburn fell to one-quarter of the average and three years later it rose to three times the average value. Obviously no large-scale development in. the use of this water could succeed without the provision of extensive storage. The Irrigation act of 1886 vested in the crown the right to the use of all water in any stream, lake or swamp, provided for the extinction of riparian rights which might prevent this and authorized the construction of national works. Even these revolutionary provisions proved inadequate since expansion under local irrigation trusts tended to be unregulated and outstripped the provision of storage. By 1905 it became necessary to abolish all but one of the trusts and to vest the state-wide control of irrigation in the State Rivers and Water Supply commission. Since the Murray itself forms the boundary between two states and then flows into a third, agreement on the use of its waters was reached only after prolonged negotiation. In 191j legislation by the interested states and the commonwealth incorporated an agreement about Murray waters and created a commission to give it effect. Subject to a specified delivery to South Australia. Victoria controls its own tributaries and shares equally

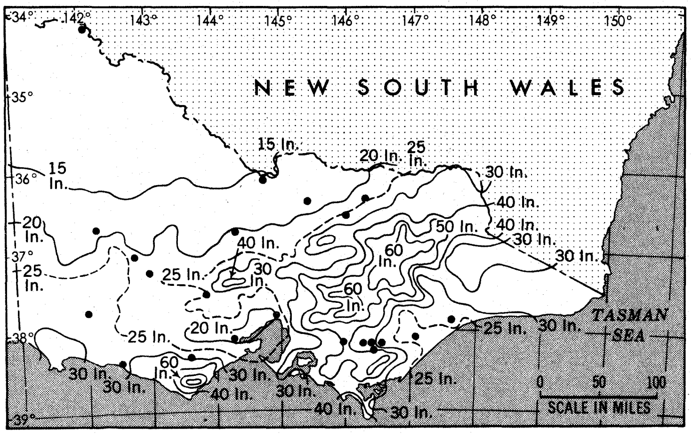

FIG. 2.— AVERAGE ANNUAL RAINFALL IN VICTORIA. PRINCIPAL CITIES ARE SHOWN WITH LARGE DOTS; FOR IDENTIFICATION SEE FIG. 3

with New South Wales the flow of the Murray. In 195j the total storage available to Victoria was 5,500,000 ac.-ft. (1 ac.-ft. = 272,-250 gal.j. The largest single contribution to this total is that of the Big Eildon storage (2,750,000 ac.-ft., completed 195j; cf. 310,000 ac.-ft. of the earlier dam on the same site). At the Goulburn weir 1jo mi. downstream from the Eildon reservoir water is diverted, the main channel to the northeast supplying irrigation districts around the town of Shepparton and the main western channel supplying other irrigation and filling the Waranga reservoir (330,000 ac.-ft.). This serves irrigation districts in the north of the state and contributes, through a long western channel, to the extensive Wimmera-Mallee domestic and stock supply. This system, which fills farmers' storages and provides town supply over an area of 11,000 sq.mi., also receives water from storages in the Grampians to which was added in 1953 water diverted from the south-flowing river Glenelg by the Rocklands reservoir (270,000 ac.-ft.). This is the first diversion of a coastal river for inland supply to be completed in Australia. On the river Murray itself the works constructed under the River Murray agreement include the Hume reservoir at Albury which. under an amendment to the agreement in 1954, is to be enlarged to 2,500,000 ac.-ft., and a series of weirs along the river (Yarrawonga, Torrumbarry, Euston, Mildura, Wentworth) which increase storage and permit diversion to irrigation districts along the river. Enormous works in progress in 19j6 in the Snowy mountains of New South Wales were planned to divert to the Murray system water from the headwaters of the Snowy river. While irrigation in the south of Victoria is obviously less widely needed than in the interior, the dry area of Gippsland mentioned above is irrigated with water from the Glenmaggie reservoir on the Macallister river. Town supply for Melbourne and a few of the other cities is still controlled separately from the state system. Storages on tributaries of the river Yarra supply Melbourne. Storage construction on its headwaters undertaken after World War II was designed to treble the capacity of the reservoirs and maintain for an increasing population the advantages of an unusually good metropolitan supply from strictly controlled catchments.

Flora and Fauna. — Both the central highlands and the southern uplands were originally mostly forested. The plains on either side of the central highlands included considerable areas of native grassland. The Mallee district includes wide tracts of scrub composed of small eucalypts to whose characteristic habit of growth the name mallee originally referred. It also contains considerable tracts of heathland and, in the area subject to flooding by the river Murray, red gum occurs as a fringing forest.

The forests proper lie chiefly on the highlands. On the high plains (see above) trees are sparse or absent. At lower elevations snow gums occur. Between 3,500 ft. and 4,500 ft. alpine ash (*Eucalyptus* gigantea) extends as pure forest. At still lower elevations on those parts of the southern slopes of the main highlands and in the southern uplands where the rainfall exceeds 40 in. a year. *Eucalyptus regnans* forms extensive stands of pure forest. These mountain forests are exceeded in area by the drier forest (25 in.–40 in. a year) which extends across the state and includes various associations of eucalypts. notably of species covered by the popular names stringybark. messmate. peppermint, box and gum. These forests are best developed at elevations of 500 ft. to 2.000 ft. above sea level and! with the mountain forests; they form the principal sources of commercial timber. On the lower rainfall areas on the inland foothills of the highlands and the northern plains the forests tend to be open and the trees smaller. Eucalypts of various species (ironbarks and boxes) are the principal trees. The control of forests was made the responsibility of a state department in 1907 and in 1919 the department was reconstituted as the Forests commission. Increasing private investment in the establishment of softwood plantations, principally of *Pinus radiata,* had led to the establishment of more than 20,000 ac. by 1956. Sawn hardwood remains the principal product.

Of the two mammals found only in Victoria, Leadbeater's possum may be now extinct and the smoky mouse is very rare. The smallest carnivorous marsupial in Victoria is the fat-tailed pouched mouse, found in the open plains, and the largest is the tiger cat, re-established recently in the east and south. Many once-common small marsupials have become extinct and the dark rat-kangaroo is now only found locally, but the gray kangaroo is common in the open forest of the coastal belt and a variety of it is found in the Mallee. The largest gliding possum is the greater glider; there are echidnas. platypuses, bandicoots, one species of wombat, the gray-headed fruit bat (a visitor). other bats, rats and mice. Deer were introduced in 1870–73, the fox and hare in 1870, the rabbit in 1840. Around the coast are whales, dolphins and seals.

The peculiar avifauna of the Mallee country of Victoria and South Australia includes the eastern mallee fowl (*Leipoa* ocellutu *rosinae*), the Victorian coachwhip bird (Psophodes *olivaceus* seryncgeourij and the Victoria emu wren (*Stipiturus malachurus mallee*). (A. A. W.)

HISTORY

The Victorian community was founded by groups of pastoral pioneers who crossed Bass strait from Launceston in the 1830s in search of fertile grazing land. The occupation of the area was made in defiance of a British government edict forbidding settlement in the territory, which was then part of the colony of New South Wales.

In Nov. 1834 the Henty brothers landed stock and stores at Portland, on the south coast. and established the first settlement. In 1835, John Batman, backed by a Launceston syndicate. landed at Port Phillip. Batman's venture led the way to the pastoral occupation of Victoria. In the same year John Pascoe Fawkner established a small colony of settlers on the banks of the river Yarra. From Batman's colony grew Victoria's capital city, Melbourne.

The Port Phillip settlement developed rapidly. In 1836 the British government authorized the settlers, but gave them no title to their land. In Dec. 1836 the New South Wales governor sent Capt. William Lonsdale to act as resident magistrate in the new settlement.

Before its pastoral settlement in the 1830s Victoria had been sketchily explored by sea and land and unsuccessfully occupied by several groups. Capt. James Cook sighted the coast at Cape Everard on April 19, 1770, shortly before his landing at Botany bay. In Dec. 1797 George Bass, naval surgeon, sailed a whaleboat south from Botany bay and explored Western Port. In 1798, accompanied by Matthew Flinders, he circumnavigated Van Diemen's Land (now Tasmania), and established its identity as a separate island. In 1802, Lieut. John Murray sailed into Port Phillip.

Two abortive attempts were made at founding convict settlements in the area in the early years of the 19th century. The first, in 1803, near Sorrento, on Port Phillip, lasted seven months. The second was in 1826, at Settlement point on the coast of Western Port. It was abandoned after two years.

The extent and nature of Victoria's hinterland was revealed in a series of probing expeditions in the 1820s and 1830s. In 1824, Hamilton Hume and W. H. Hovell led a party south from Lake George to reach the south coast on the western arm of Port Phillip. In 1829 Charles Sturt explored the full reach of the Murray river. In 1836 an expedition led by hlaj. Thomas L. Mitchell opened up a large area of western and central Victoria. and between 1834 and 1840 a number of parties penetrated the eastern portion of the territory, the mountainous Gippsland district.

During the 1840s and 1850s Victoria became a prosperous pastoral community. The squatters extended their grazing runs to the boundaries of the territory. The population rose rapidly as British migrants arrived and more settlers crossed from Van Diemen's Land or drove their flocks and herds south from New South Wales. By 1850 Victoria had 76,000 people and 6,000,000 sheep. Melbourne (pop. 23,000), Geelong and Portland were its main urban centres.

Dissatisfied with their limited representation on the legislative council of New South Wales. the Port Phillip pastoralists agitated for separation. In 1851 Victoria became a separate colony. with an executive council appointed by the crown and a legislative council, partly elected and partly nominated, effectively dominated by conservative landed interests.

Victoria's establishment as a separate colony coincided with the discovery of gold. An early find at Warrandyte, 16 mi. from Melbourne, led to a dramatic rush. By the end of 1851 half the men of the colony were working on the gold fields. In ten years, more than £105,000,000 worth of gold was won from these fields. For five years gold-seeking migrants poured into the colony. Over 200,000 came from Britain and 25,000 from China. By 1860 the population of Victoria had passed the 500,000 mark.

The gold rushes produced a spectacular, but short-lived, boom. By 1854 Melbourne was suffering from a severe depression and the treasury faced a deficit of £1,000,000 sterling. Financial stringency aggravated discontent on the gold fields. The miners strongly resented the fee demanded for a mining licence and the brutal fashion in which it was collected by the gold fields' police. This discontent culminated in a minor rebellion at Eureka, near Ballarat. Mining licences were burned and a republican flag hoisted. On Sunday, Dec. 3, 1854, police and troopers stormed the rebels' stockade. In a brief battle the miners were overwhelmed. Thirty miners and five soldiers were killed. But the incident hastened the redress of the miners' grievances and the movement for democratic reforms in the colony.

Victoria, along with New South Wales, attained self-government in 18jj. The new constitution set up two houses of parliament—a legislative council of 34 members, elected on a limited property franchise. and a legislative assembly, elected on a wider property and income franchise. The assembly was entrusted with exclusive powers of initiating all money bills. In 1856 an act providing for secret ballots was passed. In 1857 manhood suffrage was introduced for elections to the legislative assembly, and the property qualifications for membership of the assembly were reduced. The payment of members of the legislative assembly was first introduced in 1870.

The legislative council remained the stronghold of the rich, conservative landowners; throughout the 19th century it was a major obstacle to radical demands for effective land reform. Until the late 1850s Victoria depended on imports of flour from South Australia, California and Chile. During the 1860s the grazing leases of the pastoralists were thrown open to agriculture. In keeping with a policy designed to "unlock" the land, a series of land acts was passed to encourage the development of small freeholds. These opened up the Mallee and Wimmera to the small wheat farmers. and by the end of the century Victoria was Australia's largest wheat producer. But in other districts the wealthy pastoralists managed by guile and financial manipulation to evade the acts. And very many of them acquired freeholds to large estates at low prices, especially in the fertile Western district.

The period between 1860 and 1890 was one of general prosperity and economic progress. Significant industrial development occurred, partly under the stimulus of high protective tariffs. Between 1855 and 1880 the number of factory hands employed in Melbourne rose from 4,000 to 40,000. During the 1860s and 1870s the population of the state steadily increased. There was a considerable expansion in public works. By 188;. 20,000 ac. of land had been irrigated, mostly in wheat areas. And between 1870 and 1890, 3,000 mi. of railways were laid down.

Responsible government, mounting industrialization, growing prosperity and population and the rapid expansion of trade unionism produced a period of economic, social and political reform, despite the political dominance of the legislative council. The growing conflict between the assembly and the council over questions affecting protection. taxation, land policy and the reform of the constitution reached a climax. Although the upper house retained its basic powers, a number of significant reforms were secured.

In 1871 the property qualification for the council was reduced and the tenure of seats shortened. In 1888 further electoral reforms for both houses were passed. With a few exceptions, single-member constituencies became the rule for the assembly. In 1899 plural voting for the assembly was abolished and in 1900 postal voting introduced. Significant progress was also made in the field of social and industrial reform. An act of 1872 introduced a system of free, compulsory and secular primary education. The successful fight of the Melbourne stonemasons for the eight-hour day in 1856 heralded a series of industrial reforms, culminating in the factory acts of 189j–96, which laid down standards for hours and conditions in shops and factories, and set up tribunals to fix minimum wages.

By the end of the 1880s the state's growing prosperity had expanded into a speculative boom. The crash came in 1891 and was considerably aggravated by a sharp fall in the prices of Victoria's main exports, wool and wheat. In 1891–92 21 finance societies and land banks collapsed and in 1893 all but 3 of the trading banks closed their doors. Most resumed payment, but three were liquidated. The depression which followed was marked by high levels of unemployment and considerable industrial unrest. It took almost 20 years to work itself out.

In 2891 the first Australian national convention met in Sydney to consider proposals for the creation of an Australian federation (see also AUSTRALIA). Ten years later, on May 9, 1901, the first commonwealth parliament mas opened in Melbourne. The federal parliament continued to sit in Melbourne till 1927, when it moved to Canberra, the new commonwealth capital.

Following federation there was an immediate need to rationalize the constitutional structure of the states. In Victoria, an act of 1903 provided for a reduction in the number of members of both houses. The franchise for the legislative council was further liberalized and the property qualifications for membership extended. Adult suffrage was introduced in 1908, when women were given full voting rights for the assembly and equal voting rights with men for the council. In 1923 women candidates were admitted for election to both houses. Preferential voting was introduced for the assembly in 1923 and for the council ten years later. Voting was made compulsory for the assembly in 1926 and for the council in 193j. The upper house was gradually reformed over the years until full adult suffrage was finally introduced in 1950.

Political developments in Victoria in the first 50 years after federation were marked by the rise of the Labour and Country parties. leading to the creation of a three-party pattern in place of the former Liberal-Conservative two-party system. The existence of three political parties partly accounts for the instability of Victorian government. Between 1901 and 1950 there were 27 different ministries. Many of these were composite governments, or ministries based on minority support. Labour first won office, as a minority government, under G. A. Elmslie in 1913. It formed minority governments on five subsequent occasions. and only succeeded in winning effective political power in 1952, when it gained an electoral majority under the leadership of John Cain.

In 1914 the Victorian Farmers' union was founded. Three years later four of its members were elected to parliament and in 1926 it formally changed its name to the United Country party. From 193j the Country party. led by Albert Dunstan, governed for eight years with the support of the Labour party, and again from 1943 to 1945.

The Country party's influential role in Victorian politics is partly explained by the unequal size of rural and urban electoral districts. The original design of the legislative assembly provided for electoral equality, but subsequent redistributions considerably reduced the value of an urban vote. Between 1924 and 1945 the unequal size of electorates meant each rural vote mas worth more than twice an urban vote. In 1953–54 an electoral redistribution, planned by a section of the Liberal party and carried through by a Labour government. restored comparative parity between rural and urban electorates.

Successive Victorian governments in the first half of the 20th century were mainly concerned with the problems of administering those functions retained by the state under the distribution of powers involved in the creation of a federal system. These functions included the administration of the police force and of justice, education. health services. agriculture (including marketing boards), transport and the utility and development services associated with electricity, irrigation and water supply, ports and harbours. sewerage, forestry and country roads. A distinctive feature of this period was the development and application of a policy of state socialism, begun in 1902 by a Liberal government, and adopted and extended by all subsequent governments, regardless of party. Government departments or agencies have been vested with responsibility for the regulation of primary production. industry and commerce. labour, professional and occupational standards, education. social welfare and public health. The most significant developments in public enterprise were associated with the conservation and development of community resources.

The development of Victoria during this period was marked by two main trends. First. an increasing proportion of the population became urbanized. At the beginning of the century only 58 out of every 100 persons in Victoria lived in urban areas. By 1947 the percentage had risen to 70, of which 60 lived in or around the capital city. Melbourne. Second. Victoria became increasingly industrialized. In just under jo years the proportion of the total work force of the state engaged in primary industry dropped from 30% to 14%, while that engaged in secondary industry rose from 27% to 37%, and in tertiary industry from 43% to 49%. In 1901 Victoria had 66,000 factory workers. In 1951 there were five times as many, and they produced more wealth than wool. agriculture, mining and forestry combined. (C. L. Bs.)

POPULATION

At the census of June 1954 the population of Victoria was 2,452,341 (males 1,231,099, females 1,221,242), forming 27.29% of the population of the commonwealth. The average density, 27.90 persons per sq.mi., is higher than that of any other state in Australia. Since first settlement the people of Victoria have been nearly all of British stock. Australian-born persons formed more than half the population by the 1870s and more than 90% by World War II; then a vigorous immigration policy led to a rapid increase in the numbers born elsewhere. Between the censuses of 1947 and 1954 the number of overseas-born more than doubled, the principal increases in such numbers being Italians (34,124), English (33,485), Germans (17,465) and Polish (17,396). These additions reduced the Australian-born part of the population to 85% by mid-1954. Of the other 15% born outside Australia, about half were born in Great Britain and many were residents of long standing. The new feature of the postwar migration was the great increase in numbers from continental Europe. By mid-1954 this had brought the European-born proportion to 6.6% of the Victorian population and the Victorian community faced, for the first time in its history, the problem of assimilating a rapidly increasing population element which was not dominantly British.

The outstanding feature of the distribution of Victoria's people is the concentration in the metropolitan area. At the 1954 census the population of metropolitan Melbourne, defined for census purposes as an area of 27; sq.mi. embracing the city and its suburbs, was 1,524,111; *i.e.*, 62.15% of the population of Victoria. The city itself has a population of 93,172. Each phase in Victoria's development has tended to increase Melbourne's lead. Pastoral occupation

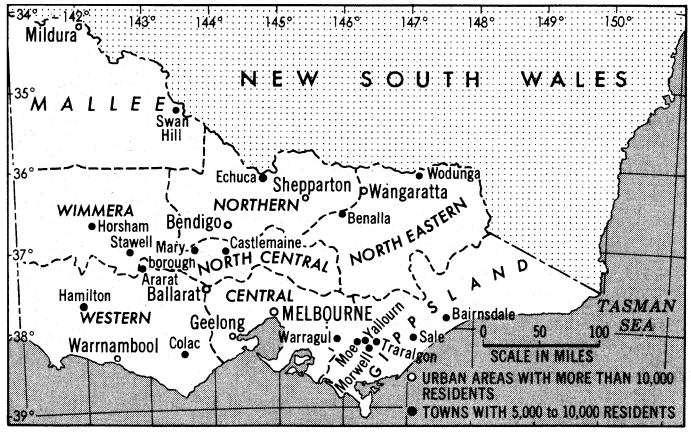

FIG. 3.—STATISTICAL DISTRICTS AND PRINCIPAL CITIES OF VICTORIA

(183j on) rapidly produced a wide sparse spread and tended to support towns at the ports rather than in the interior. Of these Melbourne was best placed to serve, and profit by. the pastoral expansion. It was the inevitable choice as capital. The discovery of gold in 1851 led to a rapid influx of people. largely through the colony's best port, and the road. and later the rail, pattern was focused on Port Phillip. With the decline of gold began the rise of manufactures, aided to an extent which cannot be precisely determined by Victoria's tax policy and protective tarifi. No coal field offered any inducement to establish them away from the labour. the market and the port which Melbourne offered. % further factor favouring metropolitan concentration was a tradition of centralized administration. Partly because of the smallness of provincial populations, many activities elsewhere carried on by private enterprise or by local government have in Victoria fallen to the central government. The financial and administrative strength of hlelbourne may also have been increased by its position as temporary federal capital (1901–27).

Of the 37.85% of the population not resident in Melbourne in 1954 slightly more than half were classed as urban. Only three cities exceeded 15,000 in population and the total number in all three was just over one-tenth of Melbourne's. The largest. Geelong (1954: city 20,034; urban area 72,595), as a port of Port Phillip bay shared some of the advantages of position noted for Melbourne but was too close to Melbourne to profit by them when the railway (1857) permitted the use of Melbourne's port and business facilities rather than encouraged the development of its,own. Its present growth is aided by the availability of port facilities and industrial sites. Ballarat (city 39,945; urban area 48,050) and Bendigo (city 28.726; urban area 36,918) were founded by the discovery of gold and in 1954 contained as many people as in the 1870s and 1880s. Four other cities exceeded 10,000 in 1954. Mildura and Shepparton are centres of irrigation districts. The other two are Warrnambool. long established as an important centre in the Western district, and Rangaratta, a district centre and the see of an Anglican bishop, in the northeast which passed 10,000 between the censuses of 1947 and 1954 with the assistance of a rayon-spinning factory established there. In the postwar years government encouragement was offered to the establishment of industries away from Melbourne and some success in decentralizing industry was claimed. The most significant change in Victoria's urban pattern is in the Latrobe valley. There, because of development based on brown coal. town populations greatly increased.

Education. — Attendance at school is compulsory for all children between the ages of 6 and 14. Of the 382,000 children attending in 1952, 73% were in government schools. Other schools, without state aid. included the system under the Roman Catholic Church (19.3% of pupils! and other nongovernment schools, the majority under the sponsorship of Protestant churches, with 7.7%

of all pupils but a much higher percentage of the secondary pupils.

Government and Administration. — The Victorian legislative council consists of 34 members and the legislative assembly of 65 members. The state is represented in the federal parliament by 10 senators and sends 33 members to the house of representatives.

ECONOMICS

Agriculture. — At the census of 1954 the working population of Victoria mas just over 1,000,000. Of these 111,300 were engaged in agriculture, grazing and dairying. This may be contrasted with the number engaged in manufacturing—341,400. These numbers reflect not only the great expansion of secondary industry but also the extent to which farming in Victoria is a mechanized undertaking with high output per man. The subdivision of this 111,300 between agriculture (52,690), grazing (23,060) and dairying (35,-550) follows a traditional distinction very important in Victorian social history, but tends to obscure the fact that nearly all cereal farms carry sheep and on some the flock returns a larger income than the crops. In 1953–54 there were 4,400,000 ac. under crop and 2,200,000 ac. in fallow, making a total cultivated area of 6,600,-000 ac.

Wheat has always been the principal crop and the area sown to it first passed 1,000,000 ac. in the season 1883–84. After that the area fluctuated. reaching a maximum of 4,600,000 ac. in 1930–31 when an unsuccessful attempt was made to counter economic depression by expansion in production. By the end of the 19th century the practice of fallowing was universal, the use of artificial fertilizers mas established and the breeding of wheat varieties suited to local conditions was in progress. All these features of the industry are still evident. In 1954–5j, 2,390,000 ac. were sown to locally developed wheat varieties. 78,000 tons of superphosphate were used on the crop and most of the fallow was in the wheat-growing districts. The yield of 20.3 bu. per acre mas very good but not exceptional. Generalizations about yield are made difficult by extreme fluctuations from year to year. Average yields for the whole state have been as low as 1.3 bu. per acre in the drought of 1902–03, and as recently as 1944–45 drought reduced the average to 1.63 bu. per acre. There is, however, no doubt about the general increase in yield. A more recent advance has been an increase in lea farming. The introduction of a year or two of grazing on clover benefits the soil and the yield of the crop which follows and permits an increase in the number of sheep carried.

Of the wheatlands of Victoria 95% lie in the Wimmera, Mallee and Northern districts. These three divisions contain between them over 85% of the cultivated land of the state and wheat occupies most of the cropped land in each. Most of the wheat is produced within a triangle bounded on the west by a line from Mildura to Horsham, on the north by the Murray and on the south by a line from about Horsham to Corowa. In the Northern district the expansion of irrigation has led to the subdivision of some holdings formerly devoted to wheat. The wheat acreage in 1954–55 was divided between districts thus: Mallee 46% of Victorian acreage, Wimmera 32% and Northern 17.5%; but the higher yields of the Wimmera enable this smaller area to produce almost the same contribution to the total crop, nearly 40%. In the ten years following the drought of 1944–45 the total Victorian wheat crop exceeded 50,000,000 bu. in four seasons and 45,000,000 bu. in five others. This decade included an exceptional run of good seasons and the crop of 3,498,000 bu. in 1944–45 stands as a reminder that, despite all improvements, Australian wheat farming still' depends on the seasons. The rail pattern of the northern wheat areas was designed to open them to cultivation and a series of almost parallel lines extended across them in successive advances between 1890 and 1925. Bulk handling of wheat began in 1938–39 and by 1955 just over 200 railway stations in the wheat belt had structures (153 of them concrete silos) for receiving and loading wheat. For the export crop the terminal silos and other storage are at Geelong.

Other Crops. — The areas sown to oats show less concentration in the three northwestern districts than the wheat areas do, though the largest acreages are in these districts. The total area varies from year to year and in the decade after the end of World War II ranged between 454,000 ac. and 676,500 ac. Hay has always ranked among the principal arable crops of Victoria. Because of the unsuitability of native grasses for hay the practice early developed of sowing cereal crops and cutting them as hay. In the year of greatest production (191j–16) almost 1,000,000 ac. of oats and one-third of this area of wheat were cut for hay. With increase in the use of auperphosphate as top dressing came changes in the species composing pastures and the possibility of cutting meadow hay. Oaten hay fell to about 220.000 ac. with smaller areas of other cereals and lucerne. and meadow hay rose (1953–54: 476,600 ac.). The two remaining principal arable crops are barley (1954–55: 280,000 ac.) and potatoes (45,000 ac.). Potatoes are grown mainly on the volcanic soils of the Central district (45% of total crop), North Central (17%) and Western (20%). Victoria is the chief potato-producing state, though the yields per acre are not as high as those of Tasmania. Victorian maize production has never been comparable with that of the other eastern states and the acreage (about 5,000 ac.) in eastern Gippsland is only about 3% of the Australian maize acreage. Grass grown for seed by specialized suppliers occupies an area which in 1954–5j reached 11,700 ac. Other minor crops are tobacco and flax. Fruit growing is widely distributed and its diversity gives an indication of the range of Victorian climates. In the Murray valley, particularly toward the west, grapes, principally for drying, and oranges are important. The irrigation areas of the Goulburn valley produce peaches and apricots. Pears are grown both there and east of Melbourne. East and southeast of Melbourne and at Harcourt, south of Bendigo, apples are grown. For the whole state vineyards occupy about 46,-000 ac. and orchards nearly 68,000 ac. (apples. 20.000; peaches 14,000; pears 12,000). Vegetables other than potatoes accounted for 36,000 ac. in 1954–5j.

Irrigation. — Reference has been made above to water supply and to fruit growing under irrigation. Considerably greater areas are occupied by other forms of irrigated production but, since the intensity of watering differs in different districts, acreage alone provides an incomplete comparison. In 1953–54 the irrigated area was 821,000 ac., of which 81.7% was in pasture or fodder crops compared with 5.4% in vineyards and 4.4% in orchards. In value, the aggregate production from the livestock carried on the much greater area of irrigated farm exceeds, though by a much smaller margin. the production from the horticultural holdings; *e.g.* (1952–53) livestock total £19,600,000, including milk and milk products (£9,100,000), wool, lamb and mutton (F5,800,000). Production from orchards and vineyards was valued at £9,200,000; including dried vine fruits (£5,600,000), canning fruits (£1,900,000). Vegetables contributed £3,900,000.

Pastoral Industries. — Sheep remain the principal form of livestock. In 1955 Victoria's total number exceeded 22,000,000 for the first time. The number first reached 20,000,000 in 1941 and was sharply reduced by the drought of 1944–45. The rebuilding of the flocks after this was encouraged by high wool prices and by 1951 the total again passed 20,000,000. The Western district with 32.7% (1955) continues in its traditional role as the principal Victorian producer of fine-woolled sheep. The Wimmera (15.2% of total sheep) and Northern (15.5%) have similar sheep populations but more attention is given in the Wimmera to fine-woolled breeds and in the Northern district a much higher proportion of ewes are mated to rams of British breeds for the production of fat lambs. The three districts named account for more than 63% of Victoria's sheep. The smallest district totals are found in the North Eastern (7.8%), Gippsland (5.8%) and Mallee (5.7%). In much of the two former districts rugged topography or excessive rainfall exclude sheep raising. The lower number in the Mallee reflects the larger size and lower carrying capacity of the Mallee farms. In wool production Victoria stands second to New South Wales which usually produces more than twice as much, but in lamb and mutton production Victoria is the leading state. The total number of cattle in Victoria in 1955 was 2,456,000; only in the first year of the previous decade had it been below 2,000,000. In the second half of this period the proportion of beei cattle rose somewhat to just over one-third of the total number. If the districts are arranged in order according to the number of beef and dairy cattle, the first four districts in each class are found to aggregate more than 80% of the state total, three districts figuring in the first four of both lists. Dairy cattle (1955). 1.613 000; Gippsland 25.6%, Western 23 8%, Central 18 1% arid Northern 15.7%. Beef cattle. 843,000; Western 25.9%, North Eastern 21 8%, Gippsland 18.5% and Central 15.1%. Dairying in the irrigation areas of the Northern district contrasts with the importance of beef cattle in the adjacent North Eastern district where many of the cattle. like some of those in Gippsland. spend part of the year on upland grazings. In dairying Victoria is the leading state. producing about 40% of Australia's milk and a somewhat higher proportion of product manufactured from milk. Progress in the pastoral industries is indicated by the fact that in 1955 more than 8.200.000 ac. were under sown pasture and nearly six times as much superphosphate was used on pasture as on the wheat crop.

Mining and **Industries.**—The gron·th oi population in Victoria and the establishment oi several of its more important provincial cities was largely the result of the discovery of gold. After 1851 more than 75,000,000 oz. of gold (£333,000,000) were won but production declined (1954: 52,665 oz.; £820.179) and the most valuable mineral product of the state became brown coal. of which over 9,000,000 tons were produced in 1954. Even black coal. with which the state is poorly endowed. exceeded in value the gold produced. After gold come, in order of value. limestone (1954: 694,684 tons; £464.833) and clay. The black coal is mined in Gippsland where the state mines at Wonthaggi produce small quantities (141,000 tons in 1954). The main seam has an average thickness of about 4 it. and the area is extensively faulted. Black coal is largely used by Victorian government railways. The great. and expanding. mineral resource of Victoria is brown coal. The most extensive deposits lie in the Latrobe valley in Gippsland. There are smaller basins west of Melbourne. Reserves are enormous. From Yallourn eastward the belt is practically continuous for 40 mi. and ior much of the distance it is irom 4 to 10 mi. wide. Boring has revealed, at one point. a seam 757 ft. thick lying only 89 ft. below the surface. The proved reserves suitable for open-cut working exceed 20,000,000,000 tons. In extent. thickness and shallowness of overburden the deposits are admirably suited to large-scale working by specialized machinery for cutting and handling. Thirty years of mining at Yallourn have produced an open cut already about $1\frac{3}{4}$ sq.mi. in area and about 200 ft. deep.

Manufacturing in Victoria greatly increased and diversified during and after R'orld War II. In 1938–39 an average of 201.800 persons were engaged in manufactures in 9,250 iactories. By 1953–54 the numbers had increased to 331,300 persons in 15,533 factories. Roughly three times as many Yictorians work in factories as on iarms and in mines and forests. In the following paragraphs the numbers cited are taken from the census of 1954 and give the number of persons, including working proprietors. engaged in the industrial groups mentioned. Certain groups require little comment. The processing of local raw materials — bricks. cement. timber, flour, butter and soap manuiacture — is to be expected. A somenhat higher degree of industrial development is implied by the existence of woollen mills. with Geelong as an important centre. supplying about half Australia's needs. The manufacture of clothing was established earlier than in the other states and in some parts of the field Victoria (with 56,000 engaged) retains a lead; e.g., in the case of boots and shoes. hosiery and knitwear. and women's outer clothing. The largest industrial group is classified as founding, engineering and metal working with 75,200 workers (*cf.* agriculture and grazing, total 75,700). The manufacture. assembly and repair of ships. vehicle parts and accessories engaged 43,200 (cf. dairying, 35.600). Since Yictoria has no industrial metals thic growth rests entirely on imported raw materials. The trend has been from repair and assembly to the construction of completed machines. In some types of agriculturul machinery. design and construction were entirely local as early as 1890. Motor-car assembly plants were established in the 1920s and the first mass production oi an Australian car began in 1948. World War II stimulated great expanaion in heavy general engineering and electrical engineering. The manufacture of chemicals. dyes, explosives, paints, etc. (14,300), began in the 19th century n·ith sulphuric acid and superphosphate. The manufacture of explosives was begun during World War I. The range of fine chemicals made increased during World War II.

Electricity Supply.—The main producing authority is the State Electricity commission which generates about 99% of the electricity used. transmits it over two-thirds of the area of the state and thereby caters ior four-fifths of the population. At Yallourn a generating station using raw brown coal generates about 40% of the electricity produced in Victoria. Yallourn is the base-load station of an interconnected system comprising three steam stations in Melbourne. two in Ballarat. two in Geelong, several hydro stations and three provincial diesel stations. Brown coal, either raw or briquetted at the commission's Yallourn iactory (producing 630,000 tons a year). provides a subctantial part of the fuel for the steam stations so that about three-quarters of all the electricity produced in Victoria is derived from brown coal. After World War II a vigorous construction program trebled electricity production in a decade. At S-allourn the addition of two 100-megawatt extensions. one completed in 1955. the second planned for 1957–58, represented a doubling of capacity. At Morwell, six miles away, construction aimed at the installation by 1960 of a 91-megawatt power station and two briquette factories with a combined capacity of 1,500,000 tons a year. As well as meeting Victoria's need for solid fuel these briquettes are used in a gas-making plant which began production in 1956 using the Lurgi process and supplying gas to Melbourne through a 102-mi. pipeline. Victoria's hydroelectric potential is relatively small. At the Big Eildon reservoir a 135-megawatt station was nearing completion in 1956. The largest hydro del-elopment is on the Kiewa river. 160 mi. S.E. of Melbourne, where the first of a series of stations began operation in 1944. The total installation planned exceeds 300 megawatts. By 1955 generators with a capacity of 80 megawatts were in service.

Communications. — In the development of railways private companies played a brief and insignificant part. The construction and operation of railways has always fallen to the government and the strict economics of operation have always been modified by public policy. As elsewhere. railways sutiered from road competition and the route mileage open in 1954, 4.482 mi.. represented a reduction of about 300 mi. on the 1939 figure. Post-World War II re-equipment included an increased use of diesel traction and electrification of the line between Melbourne and the brown-coal centres in Gippsland. The gauge is 5 ft. 3 in. and the break to "standard" gauge at the New South Wales border is a major source of inefficiency. The rail pattern is largely radial from Melbourne. The Melbourne suburban lines (174 route mi.) are electrified.

In 1913 the country roads board was constituted to construct and maintain main country roads. A system of state highways exists. but martime deterioration and the increasing size of road transport pose problems. In particular. interstate road transport makes heavy demands on the roads and the problem of ensuring that it makes. as the government railways must. a fair contribution to the maintenance of the roadway it uses is complicated by constitutional difficulties.

Melbourne is outstandingly the most important port in Victoria. From the point of view oi port construction its site offered little beyond shelter. The port in 1956 had 20 berths at piers on Hobson's bay, 63 at wharves along the Yarra river and 24 in Victoria dock excavated alongside the river. Xbout four-fifths of the seaborne commerce of Victoria and a greater proportion of passenger traffic pass through the port. Geelong ranks second and Portland handles minor amounts of the trade of the Western district.

(X. A. W.)

VICTORIA, Brazil: see VITÓRIA.

VICTORIA, capital and second largest city of the province of British Columbia. Can., is situated on the southeastern tip of Vancouver Island. One of the oldest centres in the province, Victoria was founded in 1843 as a nen- fur-trading headquarters for the western department. Hudson's Bay company. In anticipation of the Oregon boundary settlement of 1846, Ft. Victoria was located well to the north of the former headquurters near Vancouver. Wash.. U.S.

In 1849 Victoria became capital of the new crown colony of Vancouver Island and in 1868 was made capital of the united colony of British Columbia. It remained the largest business and commercial centre in the province until about 1900 when rapidly growing Vancouver, about 70 mi. N., on British Columbia's mainland. eclipsed the older city. The pleasant climate and attractive surroundings continue to draw people and Victoria has become primarily an administrative, residential and tourist centre noted for its fine homes and beautiful gardens. Public buildings include an imposing provincial legislative building, a large federal astrophysical observatory, United Services college (Royal Roads), which trains cadets for the army, navy and air force, and Victoria college, nhich is affiliated with the University of British Columbia. The port is small but well equipped and is important in both coastwise and deep-sea traffic. Victoria has the main Vancouver Island termini and repair yards for the Canadian Pacific and Canadian National railways and is the island terminus of Trans-Canada Air Lines. Manufacturing is mainly sawmilling, other wood processing and shipbuilding and repair. The federal government dry dock at Esquimalt is capable of holding the largest vessels afloat. Since earliest times Esquimalt has been linked with the navy and is Pacific coast headquarters of the Royal Canadian navy. The population of Victoria in 1961 was 54,941, that of the metropolitan area, including Oak Bay, Esquimalt, Saanich and Central Saanich, was 154,152. (A. L. Fy.)

VICTORIA, LAKE (Victoria Nyanza), the largest lake in Africa and chief reservoir of the Nile. lies mainly in Tanganyika and Uganda but borders on Kenya. The quest for the Nile sources led to the discovery of the lake by J. H. Speke in 1858. Formerly known to the Arabs as Ukerewe, the lake was named Victoria by Speke, in honour of the queen of England. He. with A. J. Grant, visited it again a few years later and mapped part of it. It was more thoroughly explored by H. hi. Stanley in 1875. A detailed survey was made of the lake by Sir William Garstin in 1901 and the possibility of using the lake as a vast reservoir for Egypt was considered for many years. Plans for the gradual raising of the level of its waters were completed in 1954. An associated project was the building of the Owen Falls dam on the Nile at Jinja, to provide electricity on a large scale.

Among the fresh-water lakes of the world it is exceeded in size by Lake Superior only and has an area of 26,828 sq.mi. In shape it is an irregular quadrilateral but its shores, save on the west, are deeply indented. Its greatest length from north to south is 200 mi., its greatest breadth 150 mi. Its coast line exceeds 2,000 mi. It fills a shallow depression in the central part of the great plateau which stretches between the western and eastern rift valleys *(see* Africa: *Physical Geography),* and has an elevation of 3,717 ft. above the sea. Its greatest ascertained depth is 270 ft. It contains many archipelagoes, the majority being near the coast line.

The lake is full of reefs, many just below the surface of the clear water. It is abundantly stocked with fish. The land surrounding the lake consists of gneiss, quartz and schistose rocks, covered with marl and red clay and in the valleys with loam. The basin area covers 92,240 sq.mi.

Shores and Islands.—The shores of the lake present varied aspects. The western coast, which contains no large indentations, is, in the south, backed by precipices 300 ft. high, behind which uplands rise to three times the height of the cliffs. To the north the hills give way to papyrus and ambach swamps, which mark the delta of the Kagera. Beyond the delta the hills reappear, and increase in height, till at the northwest corner they rise about 500 ft. above the water. This western shore is marked by north to south faults which run parallel to the lake at a short distance inland. The northern coast is deeply indented and is marked by rocky headlands jutting into the waters. There is a rim of high land near the shore, and streams which rise on its northern face drain north away from the lake. On a promontory about 30 mi. E. of the Katonga is Entebbe *(q.v.),* a port and the administrative centre of the Uganda protectorate. At Jinja is the outlet of the Nile. the water there forcing its way over the Ripon falls through the rock-bound shore of the lake. The northeast corner of the lake is flat and bare. A narrow channel leads into Kavirondo gulf, which, with an average width of 16 mi.. extends for 45 mi. to Kisumu. the terminus of the railway from Mombasa on the east coast of Africa. Hills dominate the south shore of the gulf and behind them are the Kisii highlands. To the south the shore trends generally southwest and is marked by many deep inlets with bold bluffs. At the southeast corner is Speke gulf, and at the southwest corner Emin Pasha gulf. There the coast is barren and hilly, while long ridges of rock run into the lake.

Ukerewe, north of Speke gulf, is the largest island—almost a peninsula. Its wooded hills rise 650 ft. above the lake. It is densely populated. At the northwest corner of the lake is the Sese archipelago, consisting of 62 islands. The largest island in the group is Bugala. Most of these islands are forested, and some of them attain considerable elevation. Their scenery is of striking beauty. Buvuma Island is at the entrance to the channel leading to Jinja. There are numerous other islands: most being of ironstone formation overlying quartzite and crystalline schists.

Rivers.—The Kagera *(q.v.),* the largest and most important of the lake affluents, rises east of Lake Kivu, and enters the west side of the lake just north of lat. 1° S. It is the most remote headstream of the Nile *(q.v.)* and is navigable for 80 mi. The only other river of note entering Lake Victoria from the west is the Katonga, north of the Kagera. Between the Katonga and the Nile outlet: the rivers which rise near the lake drain away northward, the watershed being close to the lake shore. On the northeast several streams reach the lake—notably the Sio, Nzoia and Yala. On the east the Mara enters the lake between lat. 1° and 2° S. It is, next to the Kagera, the largest of the lake tributaries. On the southern shores a number of short rivers drain into the lake. The only outlet of the lake is the Nile.

Population.—The Lake Victoria region is one of the most densely populated in Africa and within 50 mi. of its shores live several million people. These are nearly all of the Bantu race, the better-known tribes being the Ganda in Buganda, the Kavirondo in Kenya and the Sukuma and Haya in Tanganyika. Other tribes, some of which are not Bantu in origin, are the Soga in Uganda, the Luo and Tende or Kuria in both Kenya and Tanganyika, and the Girango, Kerewe and Zinza in Tanganyika. Considerable anthropological study, organized by the East African Institute for Social Research, was done in that area, which was the scene. of much tribal change and movement with pronounced Hamitic, Nilo-Hamitic and Nilotic intrusions.

Fishing.—Most of the tribes living on the shores are skilled fishermen and adept at handling canoes. The importance attached to the fishing industry is shown by the establishment of the East Africa Fisheries Research organization at Jinja, where, under the aegis of the East Africa high commission, research is conducted into the habits and distribution of the fish in the lake (there are more than 200 varieties) and into the economic and other problems connected with the industry.

At Kisumu are the headquarters of another high commission service, the Lake Victoria Fisheries board, with branches at Entebbe and Mwanza. The board has made a survey of fishing in the lake to determine the best methods of developing and controlling it.

Steamer Services.—The East Africa Railways and Harbours administration runs weekly steamer services round the lake from Kisumu in both directions, calling at Port Bell, Entebbe, Bukakata, Busungwe, Bukoba, Mwanza and Musoma. There are weekly services to the Sese Islands, a tug and lighter service round the Kavirondo gulf ports, and local services from Mwanza to Nansio, Karumo, Katunguru, Nyamirembe, Buchenzi and Nyamtukusa. The lake is connected with Mombasa by rail from Kisumu, with Dar es Salaam by rail from Mwanza and with the Nile steamer service by rail from Jinja to Namasagali, thence by steamer to Masindi Port, and from there by road to Butiaba on Lake Albert.

VICTORIA FALLS, on the boundary betneen Southern and Sorthern Rhodesia, form the most remarkable feature of the Zambezi river. central Africa. The falls are about midway in the course of the Zambezi in 17° 51′ S. ,25° 41′ E. For a considerable distance above the falls the river flows over a level sheet of basalt. its valley bounded by low and distant sandstone hills. Its clear blue uaters are dotted with numerous tree-clad islands. These

CENTRAL AFRICAN PRESS FROM BLACK STAR

VICTORIA FALLS SEEN FROM THE AIR

islands increase in number as the river, without quickening its current. approaches the falls. whose nearness is indicated only by a veil of spray. At the spot where the Zambezi is at its widest—more than 1,500 yd.—it falls abruptly over the edge of an almost vertical chasm with a mighty roar and a cloud of sunlit spray. From 4,000,000 to 75,000,000 gal. a minute fall over the edge (minimum flow, April-May; maximum, Tovember-December). The mist that rises hundreds of feet gave the falls their native name of *Mosi-oa-tunya* ("the smoke that thunders").

The chasm, extending over the whole breadth of the river, is wider than Niagara, though broken, and it is more than twice the depth, a measurement varying somewhat, but attaining 35j ft. in the centre. Unlike Niagara the water does not fall into an open basin but is arrested at a distance of from 80 to 240 ft. by the opposite wall of the chasm. Both walls are of the same height, so that the falls appear to be formed by a huge crack in the bed of the river. The only outlet is a narrow channel cut in the barrier wall at a point about three-fifths from the western end of the chasm, and through this gorge, not more than 100 ft. wide, the whole volume of the river pours for 130 yd.—the Boiling Pot—before emerging into an enormous zigzag trough (the Second, Third, Fourth and Fifth gorges) which conducts the river past the basalt plateau.

The fall is broken by islands on the lip of the precipice into four parts. Close to the right bank is a sloping cataract 36 yd. wide, called the Leaping Water; beyond Cataract (formerly Boaruka) Island is the Main fall in two parts, 1,719 and 975 ft. wide, beyond which is Livingstone Island and the Rainbow falls, 1,800 ft. wide. At both these falls the rock is sharp cut and the river maintains its level to the edge of the precipice. At the left bank of the river is the Eastern Cataract, a millrace resembling the Leaping Water. From opposite the western end of the falls to Danger point, which overlooks the entrance of the gorge, the escarpment of the chasm is covered with great trees known as the Rain forest; looking across the gorge the eastern part of the wall (the Knife Edge) is less densely wooded. At the end of the gorge the river has hollowed out a deep pool, named the Boiling Pot. It is about 500 ft. across; its surface, smooth at low water, is at floodtime troubled by slow, enormous swirls and heavy boilings. Thence. the channel turns sharply westward. beginning the great zigzag mentioned. This grand and gloomy series of gorges is more than 40 mi long. Its almost perpendicular walls are more than 400 ft. high, the level of the escarpment being that of the lip of the falls. A little below the Boiling Pot, and almost at right angles to the falls. the gorge is spanned by a rail and road bridge (completed in April 1905). This bridge. 657 ft. long, with a main arch of 500 ft. span, is slightly below the top of the gorge. The height from low-water level to the rails is 420 ft.

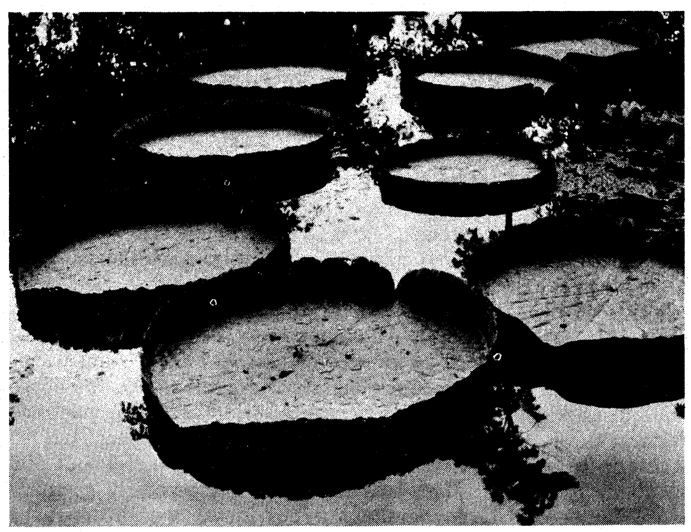
The volume of water borne over the falls varies greatly. The maximum flow is 12.000.000 cu.ft. a minute. the minimum 594,000 cu.ft. a minute. Every foot rise in the river above the rapids gives a 6-ft. rise in the gorge. The highest known rise of water in the gorge is j6 ft.

The falls were discovered by David Livingstone on Nov. 16, 18jj, and by him named after Queen Victoria of England. Livingstone approached them from above and gained his first view of the falls from the island on the lip now named after him. In 1860 Livingstone, with Dr. (afterward Sir John) Kirk, made a careful investigation of the falls, but until the opening of the railway from Bulauayo (Sept. 12, 1905) there were few visitors. The land in the vicinity of the falls was made a public park by the Rhodesian government.

Livingstone's theory of the origin of the falls (that they were the result of volcanic action) was disputed by later geographers, who claimed that they were caused by the check to erosion of the bed of the river by the resisting sheet of basalt over which they flow. The latter claim has been accepted.

Bibliography.—See Livingstone's *Missionary Travels and Researches in South Africa* (London, 1857) for the story of the discovery of the falls, and the *Popular Account of Dr. Livingstone's Expedition to the Zambesi and its Tributaries 1858–1864* (London, 1894). *See* also E. Mohr, *To the Victoria Falls of the Zambesi* (London, 1876). In the *Geographical Journal*, Jan. 1905, A. J. C. Molyneux on "The Physical History of the Victoria Falls" gives photographs and bibliography. Consult also "The Gorge and Basin of the Zambesi Below the Victoria Falls," by G. W. Lamplugh in the *Geog. Jour.*, vol. xxxi (London, 1908).

VICTORIA REGIA, a giant, showy water lily, native to British Guiana and the Amazon region of Brazil, hence the oldest scientific name, *Victoria amazonica*. It is a perennial with a thick, erect rhizome, usually growing in four to six feet of water. The huge. peltate leaves are from four to seven feet across, with upturned margins three to eight inches high. The leaves are green above but usually purple underneath, with veins bearing



EDGAR AUBERT DE LA RUE

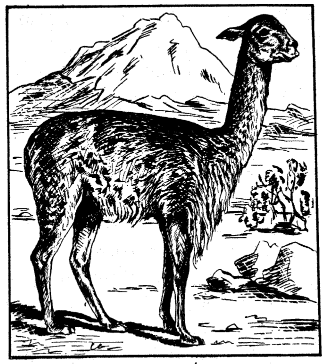
GIANT WATER LILIES (VICTORIA REGIA) OF THE AMAZON

horny prickles.

The fragrant, floating blossoms measure from 6 to 18 in. across and bear numerous white, pink or red petals. When cultivated in temperate regions the plant is treated like an annual and raised from seed.

See also WATER LILY. (T. K. J.)

VICUÑA (VICUGNA), one of the two wild South American representatives of the camel family still surviving (*see* TYLOPODA). From its relative the guanaco (*q.v.*), the vicuña (Lama *vicugna*) differs by its inferior stature, more slender build, shorter head, and the absence of bare callosities on the hind limbs. The colour is orange-red. Vicuñas live in herds on the bleak and elevated parts of the mountain range bordering the region of perpetual snow, in various parts of Peru, Ecuador, and Bolivia. Its fine, silky wool is highly valued for weaving.



CABRERA AND YEPES, MAMÍFEROS SUD-AMERICANOS

VICUÑA (LAMA VICUGNA)

VICUÑA, a term applied both to a distinctive variety of wool, and also to a special kind of "finish" given to certain varieties of woolen textures.

Vicuña wool is the fleece obtained from the vicuña (*q.v.*), a wild relative of the llama (*q.v.*) inhabiting the mountainous districts of Bolivia, Chile and Peru. This type of wool is distinguished for its remarkably long, fine, soft and lustrous character for which it is greatly prized. These properties adapt it eminently for the production of woolen and worsted textures that require a soft and full "handle" or "feel," and also for the development of "nap."

Vicuña fabrics comprise several varieties of woolen and worsted textures, which are of the character of serge (*q.v.*), excepting that they are more supple, softer and fuller and of a more subdued lustre than true serge textures. These qualities partly result from the different character of wool employed in their manufacture and partly from the method of finishing. Like serges, also, vicuña fabrics are usually based on the simple twill weave structures and employed as dress and costume materials and suitings.

Vicuña fabrics comprise two distinct types of textures: (1) simple structures for the lighter and medium textures suitable for women's wear and light suitings and coatings for men's summer wear; and (2) double-cloth structures for the heavier and stronger textures suitable for men's overcoatings. (H. N.)

VIDAL DE LA BLACHE, PAUL (1845–1918), founder of the French school of human geography, was born in Pézenas, Hérault, on Jan. 22, 1845. He was educated at the Ecole Normale Supérieure in Paris and entered upon the study of geography by way of that of history. He made a life study of the interrelations of the terrestrial environment and the activities of man.

Rejecting the theory of absolute geographical "control," Vidal de la Blache held that man's role is not passive, since he can within limits modify his environment to advance his own ends. His interpretation of the geographical personality of France in his *Tableau de la géographie de la France* prefixed to E. Lavisse's Histoise de *France* (1903) is a notable exposition of his approach. Vidal de la Blache joined the French school at Athens in 1867. From 1898 to 1909 he held the chair of geography in the Faculté des Lettres at Paris. He died at Tamaris-sur-Mer, Var, on April 5, 1918.

BIBLIOGRAPHY.—He founded in 1891 and edited until his death the periodical *Annales de Géographie*. His *Atlas général; histoire et géographie* was first published in 1894, and his uncompleted work *Principes de géographie humaine* appeared posthumously in 1922 (Eng. trans. reprinted 1950). *See* also biographical notice by L. Gallois in *Ann. Géogr.* 23:*161–73* (1918). (G. R. CE.)

VIDAME, a French feudal title. Originally, like the *avoué*, the vidame (*vice-dominus*) was a layman charged with representing an ecclesiastical institution in the domain of temporal affairs (war, money, etc.), which clerics were forbidden by the canon law to handle. The office applied in particular to the abbeys and sees to which the king had granted immunity and in which the vidame used to deal with questions that elsewhere would devolve upon the count.

When feudalism had attained its full growth and ecclesiastical seigniories were created, the vidame came to represent the bishop as a vassal, the *avoué* assuming the same office in the abbeys whose protector he was. In the 12th century the office of vidame had become an hereditary fief. As a title, however, it was less common and less dignified than that of *avoué*. The *advocati* were often great barons; the vidames were usually petty nobles, who exercised their office in strict subordination to the bishop. Their chief functions were: to protect the temporalities of the see, to represent the bishop at the count's court of justice, to exercise the bishop's temporal jurisdiction in his name and to lead the episcopal levies to war.

See A. Luchaire, *Manuel des institutions françaises* (Paris, 1892); A. Villien, *Dictionnaire de droit canonique* (Paris, 1924), *s.v.* "Avoué."

VIDIN (formerly written WIDIN or WIDDIN), a fortified river port and capital of Vidin district in the extreme northwest of Bulgaria; on the right bank of the Danube, near the Yugoslav frontier. Population (1956) 23,932, including descendants of refugees who fled thither from the Inquisition in the 16th century.

Vidin is an episcopal see and the headquarters of a brigade. A steam ferry connects it with Calafat, on the Rumanian bank of the Danube, and there is a branch railway to the main line Sofia-Lom. The old town, containing several mosques and synagogues and a bazaar, preserves its oriental appearance. There is a modern cathedral, a school of viticulture and a high school, besides an ancient clock-tower and the palace (*Konak*) formerly occupied by the Turkish pashas. Vidin exports cereals and fruit, and is locally celebrated for its gold and silver filigree. It has important fisheries and manufactories of spirits, beer and tobacco.

Vidin stands on the site of the Roman town of Bononia in Moesia Superior. It is a fortress of great natural strength owing to the marshes which surround it. In the 14th century it was the seat of an independent tsardom, which was overthrown by the Turks in 1396. Under the Turks it was the seat of a pashalik, which under Pasvanoglu (1794–1807) was practically independent.

VIDOCQ, FRANÇOIS EUGENE (1775–1857), French detective, was born at Arras in 1775 (or possibly 1773). After an adventurous youth he joined the French army, where he rose to be lieutenant. At Lille he was sentenced to eight years' hard labour, and sent to the galleys at Brest, whence he escaped twice but was recaptured. For the third time he escaped, and lived for some time in the company of thieves and other criminals in Paris and elsewhere, making a careful study of their methods. He then offered his services as a spy to the Paris police (1809). Eventually Vidocq was made chief of the reorganized detective department of the Paris police, with a body of ex-convicts under his immediate command. Vidocq possessed unbounded energy and a real genius for hunting down criminals. In 1827 he retired and started a paper-mill, the work-people in which were drawn entirely from ex-convicts. The venture was a failure, and in 1832 Vidocq re-entered the police service and was employed mainly in political work. Anxious to get back to his old detective post he himself foolishly organized a daring theft. His real part in the matter became known, however, and he was dismissed from service. He died in poverty. Several volumes have been published under his name, the best known of which is *Mémoires de Vidocq* (1828). It is, however, extremely doubtful whether he wrote any of them.

See Charles Ledru, La Vie, la mort et *les* derniers moments de *Vidocq (1857)*.

VIDYASAGAR, ISWAR CHANDRA (1820–1891), writer and social reformer of Bengal, was born at Birsinha in the Midnapur district in 1820, of a Kulin Brahman family. He was removed to Calcutta at the age of nine, was admitted into the Sanskrit College, and carried on his studies in the midst of privations and extreme poverty. In 1839 he obtained the title of *Vidyasagar* (="Ocean of learning") after passing a brilliant examination, and in 1850 was appointed head pundit of Fort William College. In 1846 appeared his first work in Bengali prose, The Twenty-Five Tales *of* a *Betal*. This was succeeded by his *Sakuntala*, 1855, and by his great work, The Exile of Site, 1862.

As a social reformer and educationist, too. Iswar Chandra made his mark. He associated himself with Drinkwater Bethune in the cause of female education; and the management of the girls' school, called after Bethune, was entrusted to him in 1851. And when Rosomoy Datta resigned the post of secretary to the Sanskrit College of Calcutta, a new post of principal was created. and Iswar Chandra mas appointed to it. He simplified the method of learning Sanskrit; and thus rendered a great service to Sanskrit learning of that ancient tongue among his countrymen. Under the education scheme of 1854 he established aided schools in Bengal. In 1858 he resigned his appointment under government and became manager of a private college at Calcutta.

But he then turned to practical reform. He had discovered that the ancient Hindu scriptures did not enjoin perpetual widowhood. and in 1855 he startled the Hindu world by his work on the *Remarriage of Hindu Widows*. Such a work, from a learned and presumably orthodox Brahman, aroused a storm of indignation. He appealed to the British government to declare that the sons of remarried Hindu widows should be considered legitimate heirs. The act was passed in 1856. and some years after, Iswar Chandra's own son was married to a widow. In the last years of his life Iswar Chandra wrote works against Hindu polygamy. He was as well known for his lavish charity and wide philanthropy as for his educational and social reforms. He was appointed companion of the Order of the Indian Empire in 1880. He died on July 29, 1891. (R. C. D.)

VIEIRA, ANTÓNIO (1608–1697), Portuguese Jesuit. diplomat, writer and orator, a great master of classical Portuguese prose. Born at Lisbon on Feb. 6, 1608, his life span coincided with a critical period in the history of Portugal and Brazil, and he played an active and at times a leading role on both sides of the Atlantic. His sermons, letters and state papers form the best collective source for the understanding of the climate of opinion in 17th-century Portugal and Brazil. In an age when the pulpit had great power in forming public opinion, Vieira's sermons were among the most famous and influential, "being bought up as fast as they are printed, and sent for out of all parts of Spain. Italy and France," as a contemporary Englishman noted. He was a prolific letter writer, and his correspondence is the more valuable in that he was a well-placed, intelligent and critical observer who frequently wrote at white heat and without reserve. His state papers on such varied subjects as diplomatic negotiations with the Dutch. Portugal's economic ills and their remedies, toleration for the crypto-Jews, or "New Christians," and freedom for the Indians of Brazil are models of clear and incisive reasoning and exercised great influence in the councils of the crown. A great historical as well as a great literary figure, Vieira may be considered the most remarkable man in the 17th-century Luso-Brazilian world.

Vieira went with his parents to Brazil in 1614. He was educated by the Jesuits at Bahia and entered the Society in 1623, being ordained as a priest in 1634. He became the most popular and influential preacher in the colony. Many of his sermons were calls to battle against the Dutch invaders who occupied northeast Brazil from 1630 to 1654, and others contained devastating criticisms of the colonial authorities. He also worked among the Amerindians and the Negro slaves. though he was not allowed by his superiors to devote his whole life to ministering to them as he had hoped to do. He returned to Portugal in 1641, as a member of a Brazilian mission sent to congratulate King John IV on his accession. The king fell under the spell of Vieira's self-assured and magnetic personality, and soon came to regard the tall, lean, dynamic Jesuit as "the greatest man with the world." Vieira repaid him with a passionate devotion which, after John's death (1656), became a hallucination that he would rise from the dead to inaugurate the fifth biblical universal monarchy under Portuguese leadership.

Between 1646 and 1650, Vieira was employed on confidential diplomatic missions to Holland, France and Italy, but none of them was successful, and he made himself unpopular with many Portuguese by his outspoken advocacy of toleration for the persecuted crypto-Jews and of peace at any price with the Dutch. The Jesuit general at Rome, embarrassed by Vieira's multifarious activities, resolved to dismiss him from the Society. but the king intervened and the matter was dropped. At the end of 1652 he was sent to the Maranhão and the Amazon delta mission fields, where he remained for the next nine years, except for a brief visit to Portugal (1654–55). During this time he displayed as much energy and ardour in work among the savages of the South American rivers and jungles, as he had shown in his political activities in the European capitals and courts. He learned several of the local languages of the Amazon delta, in addition to the Tupí-Guarani, or lingua franca, of the Brazilian littoral and the Kimbundu of the Negro slaves from Angola. His caustic criticism of the colonists' enslavement of the Indians led to his expulsion and deportation to Portugal in Sept. 1661. He was first received sympathetically by the court, but a palace revolution in June 1662 brought his enemies to power, and the Inquisition. which had long disliked him. arrested and tried him for his messianic beliefs concerning the future of Portugal and the resurrection of Ring John IV. Luckily for him, his sentence coincided with another palace revolution which brought the prince regent Dom Pedro and his own friends to power, and he was released in 1668. But his old influence at court was gone, and he spent the years from 1669 to 167j at Rome trying to secure the annulment of his sentence and a degree of toleration for the crypto-Jews. He did secure the partial revision of his sentence, and a papal brief exempting him from any further molestation by the Portuguese Inquisition, but he ultimately failed to attain his second object, though securing the suspension of the Inquisition's anti-Jewish activities for five years (1676–81).

He returned to Bahia in 1681 with the intention of ending his days in Brazil, and there he died on July 18, 1697, a paralyzed physical wreck. but mentally active and a fighter for the freedom of the Indians to the last.

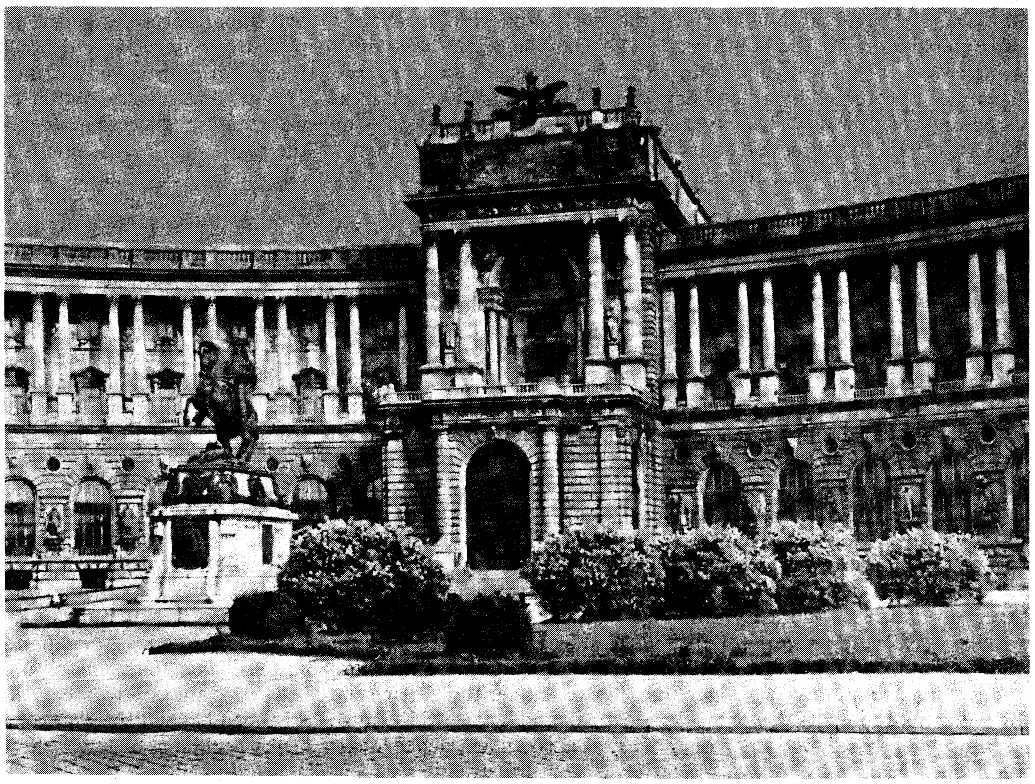
VIENNA (German WIEN, Czech VIDEŇ, Hungarian BÉCS), the capital and a *Bundesland* (federal state) of Austria, extends from the eastern slopes of the Wienerwald (Vienna woods) in the west and northwest to the plains of the Danube basin in the east and south. It lies mainly on the right bank of the Danube, with only 2 of its 23 districts on the left bank. It is situated between 515 ft. and 790 ft. above sea level and has a changeable climate liable to rapid falls of temperature and gusty winds. The mean annual temperature is 49° F. and the mean rainfall 27 in. a year. Area 160 sq.mi. Pop. (1961) 1,619,668.

The layout of Vienna resembles a star. While many of its main streets, extending radially from the centre, follow the courses of covered brooks where once the old villages stood, the inner city itself is encompassed by the beltlike wide boulevard, the Ringstrasse, built in 1858–60, around which are inner districts encircled by the Giirtel, built in 1894. Both these circular road systems replace the old fortifications.

The very centre of the city is the Stephansplatz with the cathedral of St. Stephen. measuring 361 ft. in length and with a nave 114 ft. wide and 95 ft. high. The cathedral is one of the chief Gothic buildings in Europe, incorporating remnants of the original Romanesque edifice, probably built between 1137 and 1147, but soon destroyed by fire. The choir and nave were built between 1304 and 1450, simultaneously with the southern tower (446 It.). while the northern tower, never finished; was finally completed with a Renaissance spire in 1578. Burned out during the battle of Vienna in April 1945, its reconstruction was completed by 1952; and even the 20-ton bell, founded from captured Turkish cannons in 1711, was recast. Other Gothic churches include the Augustinerkirche, the Maria am Gestade church and the Church of the Friars Minor, all dating from the 14th century. St. Ruprecht, dating from the 13th century with parts from the 11th century, is

Vienna's oldest church and is believed to have been originally built in 740. St. Peter's, standing on the site of a church allegedly founded by Charlemagne in 792, was built chiefly by J. L. von Hildebrandt in 1702–33. Other fine examples of baroque art are the richly frescoed University church (1627–31) and the Capuchin church (1622–32), the latter containing the imperial crypt, the vault in nhich 140 members of the house of Hapsburg. 12 emperors and 1j empresses among them, repose. The Church of the Scots, founded in 11jj. together with a monastery of Scottish and Irish monks, was rebuilt in late Italian Renaissance style in 1638–48. Most of the noteworthy secular buildings are baroque, for example the Harrach and Kinsky palaces and the Winter palace of Prince Eugene of Savoy (now the ministry of finance).



BY COURTESY OF THE AUSTRIAN INFORMATION SERVICE, N.Y.

THE HOFBURG, VIENNA. FORMERLY THE IMPERIAL PALACE

Thoroughfares of the city are the Graben, nith the magnificent Plague of Trinity column (1682–86), and the Karntnerstrasse, both of which issue from the Stephansplatz and are lined with Vienna's most fashionable shops. The vast complex of the imperial palace. the Hofburg, adjoins the Ring. It consists of a number of buildings of various periods and styles, enclosing several courtyards. the oldest part dating from the 13th, the latest from the end of the 19th century. It abounds in magnificently appointed private and state apartments, and also houses the imperial treasury of the Holy Roman and Austrian empires; the National library containing about 1,620.000 volumes, 35,000 manuscripts, 85,000 autographs. 125,000 maps, 100.000 papyri, etc.; the Albertina and several other museums; and the Spanish Riding school. founded in the 16th century. The state apartments of the Hofburg wing adjoining the Ballhausplatz are now the offices of the president of the republic of Austria. Opposite is the edifice of the federal chancellery, built in 1717–19, where the congress of Vienna took place in 1814–1j and where Chancellor Engelbert Dollfuss was assassinated in 1934. The magnificent Ringstrasse, 2 mi. long and 160 ft. wide, is planted with four rows of trees. It is lined with splendid buildings, monuments and parks.

Facing the Hofburg to the southwest are the museums of natural history and fine arts, two domed Renaissance-style buildings dating from 1872–81, identical in construction but separated by gardens containing the Maria Theresa monument. Adjoining the museums to the west is the palace of justice (1881), burned during riots in 1927, and the houses of parliament (1883) in modified Grecian style. Beyond these, to the north. stands the new Rathaus (city hall. 1872–83), a very large and lavishly decorated building in modern Gothic style. Farther to the north stands the university, an imposing building of Neo-Renaissance style (1873–83). It is the oldest German university in existence. Founded in 1365, it has contributed much to building up Vienna's high cultural reputation in Europe. Its library contains 1,463,000 volumes.

Other important buildings are, opposite the Rathaus. the Burgtheater. built in 1874–88. and the Opera (1861–69) at the intersection of Ring and Karntnerstrasse. both in Neo-Renaissance style. Heavily damaged by bombs and fire in 1945, these two largest theatres of Vienna were reopened in 1955. On the eastern side of the inner town lies the Stadtpark, rich in monuments. The inner town with its immediate neighbourhood is still, unlike the older parts of most European towns, the fashionable quarter, containing the government offices. the principal hotels, embassies and legations and many handsome buildings. Located at some distance outside the Ring to the south are the beautiful baroque Charles church (begun in 1716 by Johann Fischer von Erlach the Elder, completed in 1739) and, farther to the south, the Belvedere palace (1714–23), a perfect example of secular baroque style. Here the state treaty of Austria was signed in 19j;. The imperial summer palace of Schonbrunn with splendid rooms in rococo taste, and its large park of 18th-century style, lie to the southwest in the suburb of Hietzing.

The town as a whole has preserved its general character of the period prior to 1914, although in World War II it suffered heavy damage. The Southern and Eastern Railway stations near the Belvedere, and the Western station adjoining the Mariahilferstrasse. were rebuilt in modern style after their wartime destruction. Some residential areas are dominated by large new buildings containing workers' flats, many of them built with the aid of public funds; these social housing schemes were first introduced in 1923. On the contrary, some of the outer districts, such as Grinzing or Sievering, still keep their picturesque 18th- or early 19th-century village atmosphere.

Vienna is rich in museums, art collections and libraries. It possesses two big concert halls and 10 major theatres. In addition to the University of Vienna, there are technical, commercial, veterinary and agricultural colleges and three art academies. Vienna also possesses a great number of monasteries and convents.

Vienna is a city of open green spaces and parks. The largest ones are the Prater (2,000 ac.), situated between the Danube river and the Danube canal, and the spacious Lainzer Tiergarten (a zoological garden) at the western end of the town. Most of the industrial plants are situated in the southern and eastern precincts.

Communications and Industry.— Vienna has been a centre of cominunications since its foundation and many roads intersect there, linking north and south. east and west. Five main railway lines link the city to nearly all European capitals. From the main airport of Schwechat. 10½ mi. from the city, there are air services to most of the major towns of the world.

The northeastern limit of the inner town is not the Danube proper but the Danube canal. It is 10.7 mi. long; it branches from the Danube river at Nussdorf to the north and rejoins it near Kaiserebersdorf to the southeast. The Danube itself flows in a course 866 ft. wide regulated in 1870–84. The left bank of the Danube is protected by a flood dam built behind a high-water area, about 1,500 ft. wide. The river is navigable for 340–350 days of the year. In the three harbours (Freudenau, Albern and Lobauj almost 2,000,000 metric tons of goods were loaded or unloaded in 1956.

In spite of losses in population and trade during World Wars I and II, Vienna remained the focus of industrial life in Austria. The most important branches of industry are the manufacture of foodstuffs. the electrical and chemical industries, machine manufacture, the making of iron and metal goods, clothing and textiles.

The Vienna fair, founded in 1921, is one of the most popular trade exhibitions in central Europe.

History. — Vienna's position in central Europe is marked by the crossing of two immemorial routes of trade and migrations: the waterway of the Danube river, linking the west with the east, and the road from the Adriatic to the Baltic, connecting south and north. Thus the city's geographical situation has enabled it to rise from the nucleus of a nameless settlement in the mists of prehistory to the rank of an imperial capital.

Traces have been found in Vienna of the Neolithic and Bronze Ages, and more of the early Iron Age. In the later Iron Age the dwellings of Veneto-Illyrian tribes in this area were superseded, in successive Celtic inroads. by the first organized settlement. When the Romans advanced to the Danube, they took over the Celtic settlement, retaining its name of Vindobona, and enlarged it into a frontier station (*castrum*) bounded. on a small eminence near the Hoher Markt. by today's Salzgries. Rotenturmstrasse. Graben and Tiefer Graben. Soon public life developed in connection with the rising importance of the fortress. which temporarily served as the command post of Marcus Aurelius (who died there in A.D. 180).

In the middle of the 5th century Vindobona was raided by Attila, moving westward with his Huns, and tradition relates a conquest at the end of the 8th century by Charlemagne. A definite mention occurs only later, in annals of 881. under the heading *Primum bellum* cum *Ungaris* ad *Weniam* ("first war with the Hungarians at Vienna"), and in annals of 1030, in connection with the ill-fated Hungarian campaign of the Frankish emperor Conrad II, whose army was captured in "Viennis." After the battle on the Lechfeld (955), in which Otto the Great decisively defeated the Hungarians, the Vienna area was settled from the west, and the margraves of Babenberg, originating' from Franconia, set up an effective administration, expanding Ostarrichi, the core of the future Austria (see AUSTRIA, EMPIRE OF), as far as the March and Leitha rivers. Shortly before the House of Babenberg moved its residence to Vienna, Wienne is referred to for the first time as a *civitas* (city) in a document of 1137. With Duke Henry II Jasomirgott establishing his court at the square today called Am Hof. and the foundation of St. Stephen's cathedral, ever since known as the city's symbol. Vienna began to grow. At about 1200, already ranking among the major German cities. it expanded beyond its original boundaries and was surrounded by a system of ramparts which determined its size for nearly six centuries and is still reflected in the beltlike shape of the Ringstrasse. A decree of Duke Leopold VI, of 1221, conferred municipal privileges on the city. Further legislation, of the Emperor Frederick II in 1237 and the Babenberg Duke Frederick II in 1244, defined and secured the status of the prospering city in which also the Jewish population was granted special privileges by both the emperor and the duke in relevant decrees of 1238 and 1244. With Duke Frederick, the last of the Babenberg dynasty, killed in action against the Hungarians in 1246, and the death of Emperor Frederick II in 1250, a period of chaos followed. The city had temporarily to accept the reign of King Ottokar (Otakar) II of Bohemia (1251) until in 1278 the victor in the fateful battle on the Marchfeld. Rudolf I of Hapsburg (German king from 1273), established the new ruling house of Austria with its seat in Vienna.

In the 14th century, after the city had struggled through critical epochs under the new dynasty but continued to enlarge its wealth and importance, the generous activities of Rudolf IV initiated a period of enterprise and prosperity in Vienna, marked by his extension of St. Stephen's cathedral, his foundation of the university (1365), and his promotion and organization of many municipal institutions. Increasing social tensions between the patriciate and the craftsmen led to serious rifts in the political structure of the city under the reign of Frederick III (crowned as emperor in 1452), when Vienna was torn between weakened imperial authority and ambitious moves for power of Archduke Albert (Albrecht) VI. In the outcome of the strifes, the craftsmen obtained a share in the civil government. At the end of the century; troubled times recurred in the conquest of the city by the Hungarian king Matthias Corvinus (1485–90).

The independence and determination of the citizens, which had overcome political setbacks as well as continual afflictions by devastating epidemics of plague and conflagrations, stood its historical test on the European scene in the Ottoman invasion marked by the two sieges of Vienna under Suleiman II in 1529 and Mohammed IV in 1683. Between the two Turkish inroads, continental political developments, reflected in the religious struggles of the 17th century, brought insecurity and distress to Vienna: for the Thirty Years' War broke the imperial power and initiated the rise of France at the expense of Austria and Spain. But a century later, the statesmanship of Emperor Charles VI (1711–40) and the fortunate reign of his daughter Maria Theresa (1740–80) gave new brilliance to the metropolis.

Toward the end of the 17th century, the suburbs of Vienna had expanded beyond the ramparts protecting the city in the past, and in the beginning of the 18th century new fortified walls were constructed to enclose the built-up area which today is marked by the Gürtel. In 1754 the population amounted to 1 j5,400. The new spirit in public activities and imperial promotion attracted artists, scholars, architects and musicians as well as patrons. Adding to the mainly ecclesiastical buildings of the 17th century. palaces, governmental edifices, academies. richly decorated cathedrals, festival halls and theatres. magnificent squares and streets mere built. Treasures of art accumulated in the imperial collections! and operatic and theatrical tradition gained national importance. Even today the Viennese baroque has retained its specific appeal in the architectural appearance of the city centre.

At the dawn of the 19th century, the reign of Francis I was troubled by the Napoleonic wars, during which the French twice seized the capital. But the city soon revived to witness the congress of Vienna (1814–15). The revolution of 1848 finally destroyed the ancient "rock of order" of Metternich's conservative state. The accession of Emperor Francis Joseph I (1848–1916) inaugurated a new period, with the right of self-government by elective bodies, and the advancing middle class eventually achieved permanent successes under the determined leadership of the great mayor of Vienna of the "Christian Social era," Karl Lueger (1897–1910). The development of the city. whose population had nearly quadrupled within half a century (reaching 2,031,498 in 1910), was marked by the razing of the old ramparts in 1858 and the subsequent reconstruction of the inner centre, while the outskirts freely extended into the green belt and the surrounding vineyards, blending the urban area with the open landscape.

Vienna emerged from World War I as the capital of a federal state of nine provinces. It covered one two-hundredth part of the new Austrian territory while containing more than one-fourth of its total population (1,841,326 in 1920). But Vienna surmounted the difficulties caused by this unbalanced situation which were partly alleviated by the aid of foreign relief organizations. The city's initiative. guided by a Socialist majority in the municipal administration. became visible in modern building projects, social housing settlements, effective welfare institutions. well-planned highways and industrial expansion. The achievements of this period are inseparably linked with the untiring efforts of mayor Karl Seitz (1923–34), the outstanding counterpart to Lueger in this decade.

Developments were interrupted by repercussions of Hitler's rise to power which culminated in March 1938 in the invasion by the German *Reich,* known as the *Anschluss*. Essential elements of

SCENES IN VIENNA

1. The centre of the city — Kartnerstrasse at the corner of Ringstrasse
2. General view of the Ring, showing the old Parliament building at the left, the Rathaus with the high tower, the Votive church with twin towers in the distance, and the Hofburg theatre (right) with part of the Volksgarten in front
3. A section of the Parliament building, facing the Ring
4. The Opera house, built during 1861 and 1869
5. View of the Graben and Stefansplatz
6. The Votive church
7. Spire of St. Stephen's cathedral, 450 ft. high, regarded as one of the finest of Gothic spires. It was rebuilt in 1860–64. The roof was completely destroyed and the vaulting of the apse partially destroyed in World War II

Viennese' life were stamped out not only by the Nazi system, but also by the hail of bombs and shells at the end of World War II which severed Austria's connection with Germany.

Vienna's faculty of combining conservative and creative power once again proved a vital factor in the postwar years, which were to begin with a ten-year quadripartite occupation. Careful planning and imaginative improvisation made it possible to overcome the first difficulties of reconstruction which was soon substantially helped, especially by the U.S. Three symbols of Vienna, St. Stephen's cathedral, the opera house and the Burgtheater, all seriously damaged during World War II, rose again to testify to the joint determination of the Viennese population to revive and maintain the city's famous tradition.

Vienna still retains the stamp of its multiple development, the traces of the Latin, Slavonic, German and Magyar elements that have intermixed to form this metropolitan centre.

VIENNA, CONGRESS OF (1814–1815). The fall of Napoleon left the disposition of his empire to the four powers who had overthrown him—Austria, Prussia. Russia and Great Britain. Other countries, of which Spain, Portugal and Sweden were the most important had shared in this task and had signed the treaties of Paris (*q.v.*) in 1814, but the four greater powers were bound together by a special alliance (treaty of Chaumont. March 1. 1814) Thus. though the treaties with France stipulated that all countries that had taken part in the war should send plenipotentiaries to a congress at Vienna, the four powers meant to make the decisions themselves, and, as they could not agree at Paris. bound France by a secret article of the treaties to recognize these decisions at a future date.

The Delegates.—Thus the meeting at Vienna, where representatives began to arrive toward the end of September, was meant to be merely a convenient assembly to ratify the decisions of the "four." Nevertheless, all Europe sent its most important statesmen. Metternich, principal minister of Austria since 1809, naturally represented his Emperor Francis II. a stubborn man who sometimes had a policy of his own. The brilliant, but wayward and emotional, Alexander I of Russia directed his own diplomacy. The weak Frederick William III of Prussia had as his principal minister Prince von Hardenberg. who had lost credit owing to physical infirmities. Great Britain was represented by the foreign minister, Lord Castlereagh, the creator of the alliance of Chaumont. When Castlereagh had to return to his parliamentary duties the duke of Wellington replaced him and Lord Clancarty was principal representative after the duke's departure. The restored Louis XVIII sent the astute diplomatist. Prince Talleyrand. Spain, Portugal and Sweden had only men of moderate parts to represent them, in Don Pedro Gomez Labrador, the duke of Palmella and Count von Lovenheilm. Count Miinster, who represented the British prince regent as ruler of Hanover, had much influence on German questions. Many of the rulers of the minor states of Europe put in an appearance. With them came a host of courtiers, secretaries and ladies to enjoy the magnificent hospitality of the almost bankrupt Austrian court. The social side of the congress made a great impression on the age, and on history. It was one of the causes of the long and unexpected delay in producing a result, for Metternich at least sometimes subordinated business to pleasure.

Procedure of the Congress.—This was determined by the difficulty and complexity of the problems to be solved. First there was the problem of the organization of the congress. for which there was no precedent. The "four" were determined to keep the management of the main problems entirely in their own hands; but since they had rather rashly summoned a congress they had to pay some attention to it. The ministers of the "four" assembled early to discuss this problem, and finally agreed on Sept. 22 that the "four" should have the "initiative." by which they meant the "decision" of the future of all the conquered territories. They were then to "communicate" with France and Spain. The "congress" was to be summoned only when all was ready.

This was the situation which Talleyrand found when he arrived on Sept. 24. He refused to accept it and was supported by Labrador. He denied that either the "four" or the "six" were legally constituted bodies, and desired that the congress should be summoned to elect a directing committee. If there was any other body which had any rights it was the "eight" powers who had signed the Paris treaties. The "four" were much disturbed, for they knew that all the smaller powers would support Talleyrand if they gave him the chance of appealing to them. But they had no intention of giving way, and refused to summon a meeting of all the plenipotentiaries. A notice was issued that the opening of the congress was postponed till Nov. 1. No solution could be found, however, and after a meeting of the "eight" on Oct. 30 the opening was again postponed.

Meanwhile the work of the congress proceeded without the sanction of the main body of plenipotentiaries. The "four" discussed the main territorial problems informally among themselves. The "eight" assumed the formal direction of the congress; a committee of German states met to draw up a constitution for Germany, and a special committee on Switzerland was appointed by the "four." Talleyrand was thus excluded from the main work of the congress. but his protests on behalf of the smaller powers grew fainter as he realized that the "four" were not in agreement, Castlereagh and Metternich gradually won his confidence and at last insisted on France being admitted to the "four." The "four" thus became the "five" and it was this committee of five which was the real Congress of Vienna. Between Jan. 7 and Feb. 13 it settled the frontiers of all territories north of the Alps and laid the foundations for the settlement of Italy. Meanwhile the committee of "eight" dealt with more general matters. The congress as a representative body of all Europe never met.

Poland and Saxony.—The great difficulty which nearly produced war was the disposition of Poland and Saxony. By treaties signed in 1813 Alexander had promised that the sovereigns of Prussia and Austria should rule over as many subjects as they had done before they were reduced in size by Napoleon. He had also promised that the duchy of Warsaw. which Napoleon had constituted out of the Prussian and Austrian shares of the Polish partitions, should be divided among the three powers. After the battle of Leipzig, however, he claimed practically all Poland for Russia, and suggested that Austria could find compensation in Italy, and Prussia by annexing all Saxony, whose king had been the most faithful of Napoleon's vassals. In this plan he was moved by a sincere wish to give the Poles an opportunity for the expression of their nationality; but. of course, he intended to keep Russian sovereignty over all Poland. Metternich was much alarmed. and Hardenberg, while very desirous of Saxony, was not anxious to see Russia's frontier extended so far. Castlereagh was also, as a true disciple of Pitt. afraid of Russian expansion. Accordingly Castlereagh encouraged Austria to agree to the sacrifice of Saxony to Prussia so that the three powers could oppose Russia's demands on Poland. With great difficulty he eventually succeeded in so doing. But the plan. which included an offer of constituting an entirely independent Poland, which it was known Alexander must reject, failed because Frederick William III. who was grateful to the tsar for his help in the overthrow of Napoleon, refused to support Hardenberg when the crisis came. Metternich and Hardenberg were, therefore, estranged, and the former withdrew his consent to Prussia's absorption of all Saxony. Prussia then went altogether on to Russia's side. and a complete deadlock resulted. Meanwhile Talleyrand had been advocating the principle of "legitimacy" which had brought Louis XVIII back to France, so as to support the king of Saxony and the return of the Bourbons to Naples.

Castlereagh's Diplomacy.—Castlereagh had been much chagrined at the failure of his first plan. Moreover. his cabinet were alarmed at his activity in European matters. and he was warned against going too far. The difficult negotiations with the United States, with whom Britain was still at war! also made caution necessary. Nevertheless, Castlereagh saw that if a European war broke out both France and Britain would certainly be involved before it was over. He had already prepared the way with Talleyrand, and in December both he and Metternich promised Talleyrand that the Bourbon house should be re-established in Naples instead of Joachim Murat (*q.v.*). Secure of Talleyrand's support they insisted that France should be admitted to the committee of the "four." When Hardenberg threatened war, Castlereagh drew up a secret treaty of defensive alliance which Talleyrand and Metternich signed on Jan. 3, 1815. For a few days the issue was doubtful, but the tsar, who had already obtained most of Russia's demands, inclined to peace, and eventually Prussia gave way. With Castlereagh acting as mediator, a compromise was arranged on the question of Saxony, and then the rest of the territorial settlement was comparatively easy, especially as Castlereagh reduced the demands of both Hanover and the Netherlands, whose policy was ultimately controlled by Britain.

Decisions of the Congress.—Alexander gave back Galicia to Austria. Thorn and a region round it to Prussia, while Cracow was made a free town. The rest of the duchy of Warsaw was incorporated as a separate kingdom under the tsar's sovereignty. Prussia got two-fifths of Saxony, and was compensated by extensive additions in Westphalia and on the left bank of the Rhine. It was Castlereagh who insisted on Prussian acceptance of this latter territory, with which it was suggested the king of Saxony should be compensated, for he wanted Prussia to guard the Rhine against France and act as a buttress to the new kingdom of the Netherlands, which Holland had formed by incorporating Belgium. Austria was compensated by Lombardy and Yenice, and also got back most of the Tyrol. The south German states on the whole did well. Hanover was also enlarged. The outline of a constitution, a loose confederation, was drawn up for Germany. It was a triumph for Metternich and a defeat for the Prussiaa statesman, Baron von Stein. Denmark lost Norway to Sweden hut got Lnuenberg, while Smedish Pomerania went to Prussia. In Italy, Piedrnont absorbed Genoa; Tuscany and Modena went to an Austrian archduke; Parma was given to Marie Louise, though the young Napoleon's claims to succeed failed to win British and French approval. The papal territory was restored to the pope. Murat's fate was decided even before his rash attempt after Napoleon's return from Elba, and the Sicilian Bourbons restored to Naples. Switzerland was given a new constitution. Valuable articles were included on the free navigation of international rivers and diplomatic precedence. (*See* DIPLOMACY.) Castlereagh's great efforts on behalf of the abolition of the slave trade were only rewarded by a pious declaration.

The final act, which included all these agreements in one great instrument, signed on June 9, 1815, by the "eight" (except Spain, who refused as a protest against the Italian settlement) was afterwards acceded to by all the other Powers, and was the most comprehensive treaty which Europe had ever possessed.

As a result the lines laid down by the Congress of Vienna lasted, except for one or two changes, for over 40 years. The statesmen had successfully worked out the principle of a balance of power. But the idea of nationality had been almost entirely ignored—necessarily so because it was not yet ready for expression. Territories had been bartered about without much reierence to the wishes of their inhabitants. Until an even greater settlement took place at Versailles after World War I it was customary for historians to condemn the statesmen of Vienna. It is now realized how difficult their task was, and the fact that they secured for Europe a period of peace, which was its cardinal need, is fully recognized. But the statesmen failed to give to international relations any organ by which their work could be adapted to the new forces of the 19th century, and it was ultimately doomed to destruction.

BIBLIOGRAPHY.—Treaties and acts of the congress may be consulted in J. L. Klüber, *Acten des Wiener Congresses*, 9 vol. (Erlangen, 1817–35); Comte d'Angeberg (J. L. Chodzko), *Le Congrès de Vienne* (Paris, 1863); *British and Foreign State Papers*, vol. ii, gives some of the documents in English, and the final act is found in many collections. VIENNE, a department of west-central France, formed in 1790 out of Poitou (four-fifths of its present area), Touraine (one-seventh), and Berry, and bounded by Deux-Sèvres on the west, Charente on the south, Haute-Vienne on the southeast, Indre on the east, Indre-et-Loire on the northeast and north and Maine-et-Loire on the northwest. Pop. (1946) 313,932. Area 2,720 sq.mi. The department includes the basin of the Vienne from the point at which it emerges from the Plateau Central down to its junction with the Creuse, while its extreme southwest corner includes a small part of the course of the Charente. It contains the famous gate of Poitou (Seuil du Poitou) between the Plateau Central and the Gâtine, the historic southwest entry into the Paris basin. The winter average temperature is 39° to 41° F., the summer average temperature being 66° to 68° F. The prevailing winds are from the southwest and west. The annual rainfall is 24 in. in the north to 32 in. in the south.

Wheat, oats and barley are the principal cereals grown, other important crops being lucerne, sainfoin, clover, mangel-wurzels and potatoes with some colza and hemp. The district of Poitiers produces good red wine, and the white wine of Trois-Moutiers near Loudun is well known. The breeding of livestock is fairly active. Poitou is famous for its mules, and the geese and turkeys of the department are highly esteemed. Among the fruit trees are the chestnut, walnut and almond. In the forests a small number of wild boars and other wild game survives. Freestone is quarried. There are mineral springs at La Roche-Posay. The most important industrial establishments are the national arms manufactory at Châtellerault and the cutlery works near that town. The capital of Vienne is Poitiers, and the department is divided into 3 arrondissements (Poitiers, Châtellerault, Montmorillon), 31 cantons and 298 communes. The chief towns are Poitiers, Châtellerault, Loudun, Chauvigny (*qq.v.*) and Montmorillon. Sanxay has ruins of a theatre and other Gallo-Roman remains nearby. Vienne is rich in megalithic monuments.

VIENNE, the chief town of an arrondissement of the department of the Isère, France. Pop. (1946) 23,519. Vienne stands on the left bank of the Rhône just below the junction of the Gère with the Rhône, between the river and low hills, and about 20 mi. by rail S. of Lyons. Its site is an immense mass of ancient *débris*, which is constantly yielding interesting antiquities. On the bank of the Gère are traces of the ramparts of the old Roman city, and on the Mont Pipet (E. of the town) are the remains of an amphitheatre, while the ruined castle there was built in the 13th century on Roman substructures. Several of the ancient aqueducts (one only is now actually in use) are still to be seen.

Vienne, originally the capital of the Allobroges, became a Roman colony about 47 B.C. under Caesar, who embellished and fortified it. A little later these colonists were expelled by the Allobroges; the exiles then founded the colony of Lyons (Lugdunum). It was not till the days of Augustus and Tiberius that Vienne regained all its former privileges as a Roman colony. Later it became the capital of the Provincia Viennensis. In 257 Postumus was proclaimed emperor here, and for a few years Vienne was the capital of a short-lived provincial empire. It is said to have been converted to Christianity by Crescens, the disciple of St. Paul. There were Christians here in 177, as in the Greek letter (preserved to us by Eusebius) addressed at that date by the churches of Yienne and Lyons to those of Asia and Phrygia mention is made of "the" deacori of Yienne. The first bishop certainly known is Verus, who was present at the Council of Arles in 314.

About 450 Vienne became an archbishopric and continued one till 1790, when the see was suppressed. The archbishops disputed with those of Lyons the title of "Primate of all the Gauls." Vienne was conquered by the Burgundians in 438, and in 534 was taken by the Franks. Sacked in 558 by the Lombards and in 737 by the Saracens, the government of the district was given by Charles the Bald in 869 to a Count Boso, who in 879 was proclaimed king of Provcnce, and was buried in 887 in the cathedral church oi St. Maurice. Vienne then continued to form part of the kingdom of Provence or Arles till in 1032 it reverted to the Holy Roman empire. Vienne was sacked in 1562 by the Protestants under the Baron dcs Adrets, and was held for the Ligue 1590–95, when it was taken by Montmorency. The fortifications were demolished between 1589 and 1636. In 1790 the archbishopric was abolished, the title "Primate of all the Gauls" being attributed to the archbishops of Lyons.

Ancient Monuments.— The town possesses two fine Roman monuments. One is the temple of Augusta and Livia, a building of the Corinthian order, built by the emperor Claudius, and inierior only to the Maison Carrée at Nîmes. From the 5th century to 1793 it was a church (Notre-Dame-de-Vie), and the "festival of reason" was celebrated in it at the time of the Revolution. The other is the Plan de *l'Aiguille,* a truncated quadrangular pyramid, about 52 ft. in height, resting on a portico with four arches; it is now generally believed to have been part of the *spina* of a large circus, the outlines of which have been traced. The church of St. Peter belonged to an ancient Benedictine abbey and was rebuilt in the 9th century. in the earliest Romanesque style. It has of late years been completely restored, and shelters the magnificent *Musée Lapidaire.* The former cathedral church of St. Maurice (11th to 16th centuries) has three aisles, but no apse or transepts. The most striking portion is the west front (1533), which rises irom a terrace overhanging the Rhône.

There are very important cloth factories and also distilleries, iron foundries, refining furnaces, etc. Vienne is the seat of a subprcfect, of a tribunal of commerce, a chamber of commerce and a board of trade arbitrators.

VIENNE, a river of central France, 217 mi. long, a left-hand tributary of the Loire. Rising on the plateau of Millevaches at a height of 2,789 ft., the Vienne flows westward through the hilly country of the crystalline rocks of the central plateau of France. The first large town on its banks is Limoges. below its confluence with the Taurion (right). The river next reaches St. Junien, turns abruptly northward to Confolens and passes on to the Jurassic rocks to flow through a picturesque and wider valley. Passing Chauvigny. it proceeds to the confluence of the Clain (left). on which stands Poitiers, just above Chhtellerault. Below that town it receives the Creuse (right). which rises on the Millevaches plateau and is 158 mi. long. From near Châtellerault, past Chinon, to its junction with the Loire the Vienne flows across Cretaceous strata. There is little river traffic on the Vienne below its confluence with the Creuse (30 mi.). (See LOIRE.)

VIENNE, COUNCIL OF, an ecclesiastical council, which in the Roman Catholic Church ranks as the 15th ecumenical synod. It met from Oct. 16, 1311, to May 6. 1312, under the presidency of Pope Clement V. The transference of the Curia from Rome to Avignon (1309) had brought the papacy under the influence of the French crown: and this position Philip the Fair of France now endeavoured to utilize by demanding from the pope the dissolution of the powerful and wealthy order of the Temple. together with the introduction of a trial for heresy against the late Pope Boniface VIII. To evade the second claim. Clement gave way on the first (see TEMPLARS). On the 22nd of March the order of the Temple was suppressed by the bull *Vox clamantis,* while further decisions as to the treatment of the order and its possessions followed later. Additional decisions were necessitated by the violent disputes which raged within the Franciscan order as to the observance of the rules of St. Francis of Xssisi.

See Mansi, Collectio Conciliorum, vol. xxv; Hefele, *Conciliengeschichte,* vol. vi, pp. 532–534.

VIERKANDT, ALFRED FERDINAND (1867–1953), German sociologist. who conceived of sociology as the study of human interactions, was born in Potsdam, June 4. 1867. He taught at the University of Berlin throughout most of his career. An early work. Die Stetigkeit im Kulturwandel (1908), anticipated many of the conclusions of F. Boas, A. Kroeber and W. Ogburn on the processes of culture change. Yierkandt was first greatly influenced by the phenomenology (*q.v.*) of E. Husserl and the instinct theory of W. McDougall. He later put greater emphasis on group function and structure in his *Familie,*. Volk, und Staat in *ihren gesellschaftlichen* Lebensvorgangen (1936; new ed., 1949). This work, appearing when National Socialism had virtually smothered sociology. gained little notice. but his *Kleine Gesellschaftslehre* (1949) made an impression after World War II.

Vierkandt edited a massive Handworterbuch der *Soziologie* (1931) to which most of the leading German sociologists contributed. He died in Berlin on April 24, 1953. (HD. BR.)

VIERSEN, a town in North Rhine-Westphalia, Ger., 11 mi. S.W. of Crefeld, at the junction of lines to München-Gladbach, Venlo, etc. Pop. (1950) 36,974. Viersen is one of the chief seats in the lower Rhine country for the manufacture of velvets, silks and plush, cotton, paper, boots and cement.

VIERZON, a town of central France, in the *département* of Cher, zo mi. N.W. of Bourges by rail. Pop. (1954) 26.808. The Cher and the Yèvre unite at the foot of the hill on which lies the greater part of Vierzon into which were incorporated Vierzon-Villages, Vierzon-Bourgneuf and Vierzon-Forges in 1937. The town has a port on the canal of Berry and is an important junction on the Orléans railway; there are several large manufactories for the production of agricultural machines, also foundries, porcelain, brick and tile works and glass works.

VIETA (VIÈTE), **FRANÇOIS,** SEIGNEUR DE LA BIGOTIÈRE (1540–1603), more generally known as FRANCISCUS VIETA, French mathematician, was born at Fontenay-le-Comte, in Poitou. On the completion of his studies in law at Poitiers, Vieta became an advocate in his native town, and later councilor of the *parlement* of Brittany. Rohan, the well-known chief of the Huguenots. took Vieta under his special protection. After the accession of Henry IV, Vieta became in 1589 councilor of the parlement at Tours, and subsequently a royal privy councilor.

While at Tours he discovered the key to a Spanish cipher consisting of more than 500 characters, so that all the dispatches in that language which fell into the hands of the French could easily be read. Philip II was so convinced that his cipher was a safe one that when he found the French were aware of the contents of his letters he complained to the pope that the French were using sorcery against him. Vieta printed numerous papers on various branches of this science, and distributed them to scholars in almost every country of Europe. Vieta has been called the father of modern algebraic notation. All that is nanting in his writings, especially in his *Isagoge* in *artem* analyticam (1591), in order to make them look like a modern school algebra is merely the sign of equality. His *Recensio canonica effectianum geometricarum* was what is now called an algebraic geometry. He conceived methods for the general resolution of equations of the second, third and fourth degrees different from those of L Ferrari, with which, however, it is difficult to believe him to have been unacquainted. He knew the connection existing between the positive roots of an equation (which, in his day. were alone thought of as roots) and the coefficients of the different powers of the unknown quantity. He found out the formula for deriving the sine of a multiple angle. In his *Apollonius Gallus* (1600) Vieta made use of the centre of similitude of two circles.

Vieta's collected works were issued under the title of *Opera Mathematica* by F. van Schooten at Leiden in 1646. (O OE.)

VIETNAM, a country of Indochina. bounded on the north by China, on the east and on the south by the Gulf of Tongking and by the South China sea and on the west by Cambodia and by Laos. It extends from lat 8° 33' to lat 23° 2′ N and from long. 102° 11′ to long. 109° 28' E. While the northern and southern extremities of Vietnam are more than 1,000 mi. apart, the maximum east-west extension is about 330 mi. (in the north) and the minimum less than 40 mi. (in the centre). From July 21, 1954, Vietnam was de facto partitioned in two independent republics: the Democratic (Communist) Republic of Vietnam in the north (area: 60,1j6 sq.mi.; pop. [1957 est.] 14,900,000) and the Republic of Vietnam (area: 65,948 sq.mi.; pop. [1958 est.] 12,366,291) in the south.

Physiography.— The geography of Vietnam is best considered zone by zone.

Northern Vietnam.—Northern Vietnam comprises two distinct regions: the delta. 5,670 sq.mi.; and the mountains. 39,330 sq.mi. The mountains represent the end of the southern Chinese foldings: granitic and calcareous formations alternate. the latter having been so much eroded. north of Red river. that they stand out in intricate and striking relief. South of the river, the folds have a northwest-southeast direction. which the rivers follow. The highest peak is Fan Si Pan (11,191 ft.).

The Red river has its source in Yunnan and a course of 745 mi.. with a discharge of nearly 25,000 cu.ft. per second at low water and of nearly 1,060.000 cu.ft. at flood. Its alluvial deposits have formed the delta. over which it flows at high water. often threatening to burst the dykes and flood the rice fields. The delta of the Song Thai Binh, on which the port of Haiphong stands, is merged with that of the Red river. The coast is muddy. apart from the fine bay of Along and the eastern extremity. which is bordered with islands.

Central *Vietnam.*—The long coast line of central Vietnam is backed by a series of alluvial plains in front of the rocky bastions of the Annamite chain of mountains. The most important of these little plains are those of Thanh Hoa and of Vinh in the north. of Hué in the middle and of Qui Nhon in the south. The coast line itself consists of a succession of dunes and promontories. The Annamite mountains are in some places more than 70 mi. from the coast. though in others they approach within 30 mi. from it.

In the south the Moi plateaus are more extensive, reaching their highest point in the peak of the Mother-and-Child (6.634 ft.) near Cape Varella. Passes across the chain connect central Vietnam with Laos. The streams are torrential, except where they cross the plains.

Southern Vietnam. — In Quaternary times a gulf of the sea was silted up by alluvial deposits of the Mekong (*q.v.*) to form the southern part of what is now Vietnam; some areas were later solidified, others remained marshy. In the east the Rivière de Saïgon and its tributaries drain a group of hills and constitute a system distinct from that of the Mekong. which enters the sea in several branches. The coast is flat and muddy. The little island of Poulo Condore lies about 60 mi. offshore.

Climate, Vegetation and *Animal* Life. — The climate of Vietnam is that of tropical monsoon Asia: equatorial in the south, somewhat milder in the north. At Saigon. in the south, the annual variation of temperature is very slight. averages being 26° C. in January and 29° C. in April. At Hanoi in the north the average temperature is 28° C. for June but only 1 j° C. for January; and the minimum can be as low as 6° C. The summer monsoon, coming from the Pacific. brings rain from May to October (a little later in central Vietnam). Rainfall. which amounts to 58 in. at Saigon and at Hanoi. reaches its maximum in central Vietnam, where Hué gets 116 in. and the mountains even more.

The forests of the north resemble those of southern China, with many species of deciduous trees and an undergrowth of rattans and bamboos. In the south are tropical evergreen forests containing numerous economically valuable species (such as the "sao," the "dan" and the "ban lang") and many palms (*e.g.*, the *Latania* and the coconut palm). In the hills pines (*Pinus* merkusii and P. *khassya*) form almost continuous cover.

Deer. buffaloes. wild oxen. elephants, tigers and panthers are plentiful in the mountainous areas (especially in the south). as fish are on the seaboard. Fish and crustaceans are also abundant in the rivers. in the streams, in the lakes and even in the paddy fields.

History. — Excavations in the caves of Pho-Binh-Gia and of Luang-Com in the north and in those of Minh-Cam in central Vietnam have revealed skulls of a Negrito type in the lower strata and skulls of an Indonesian type. to be assigned to an early Neolithic period, in the upper strata. The Bronze-Age culture. represented by extant specimens of work testifying to a high degree of artistry (notably those of Dong-Son). belongs to the time when Mongoloid peoples from China entered the country and mingled with the Indonesians to form the Vietnamese. Iron seems not to have been worked before the first centuries of the Christian era.

The Vietnamese people had their origin in the delta of the Red river, where. by turning the marshes into paddy fields, a steady gron·th of population was made possible. The adjacent mountains, however. remained occupied by Indonesians until the latter had to retreat before new invasions from China (the Thai from the 13th century onward. the Man and the Meo from the 16th).

Champa.—Throughout the middle ages the greater part of the coast south of the delta of the Red river and north of that of the Mekong was held by the Chams, an Indonesian people to whom a Hindu civilization had been brought from India late in the 2nd century A.D. Seafarers, the Chams traded in spices. in aloes wood and in ivory; their monumental art resembles that of the Khmers. Their kingdom. Champa. which had its capital first at Indrapura (near Touranej. then at Vijaya (near Qui Nhon). lasted for more than 1.200 years but was continually engaged in warfare against Cambodia. with great vicissitudes of fortune. In 1470. however. the Vietnamese (see below). who in the previous century had already advanced their frontier to a line south of Indrapura. won a decisive victory over the Chams. Thereafter Champa disintegrated, till by the end of the 17th century it no longer existed as a political entity.

The Mekong delta itself was part of the Khmer kingdom in the middle ages (see CAMBODIA). The mountains. meanwhile, mere occupied by primitive tribes of Indonesians (called Moi).

Nam-Viet, Annam.—In 207 B.C. a Chinese general who had been appointed governor of the southern province of the empire set up the kingdom of Nam-Viet on the Red river. This kingdom, however, was overthrown by the Chinese under the Han dynasty in the year 111 B.C., whereupon the country became a Chinese province under the name of Giao-Chi, which was later changed to Annam ("Dominion of the South"). Thus Chinese civilization came to mold the lives of the Vietnamese. There were occasional revolts (one. in A.D. 43, was led by two sisters), but these met with no success. The T'ang emperors ruled very oppressively; but their successors in the 10th century weakened their hold on the "land of the south" (Yietnam), which recovered its independence, though theoretically acknon·ledging Chinese overlordship.

After a period of anarchic feudalism, the country was unified by the Li dynasty (11th–13th centuries). The next dynasty. that of the Tran (13th–14th centuries), both repelled the Mongol invasion sent by Kublai Khan and also conducted a successful campaign against Champa (*see* above). Early in the 15th century the country was again under Chinese control for a few years; then a new dynasty. that of the Lê, expelled the Chinese. Le-Thanh-Ton, a great ruler (1466–97), won the victory of 1470 over the Chams; he also established an effective system of administration.

The Vietnamese planted military colonies throughout the former Cham territories. From these, they next began to spread into the hlekong delta, displacing or subduing the few Khmers who were holding it (17th century onward). By the beginning of the 19th century they had overrun the whole delta.

Though the emperors of the Lê dynasty were still theoretically supreme, real power, from the middle of the 16th century. was shared between two families. the Trinh in the north and the Nguyen. with their capital at Hué. to the south. The expansion of the empire over the Cham and Khmer lands was the work of the house of Kguyen; and this family, as its power increased, came more and more into conflict with its northern rivals, the Trinh, particularly in the course of the 18th century.

European contacts began with the visits of Portuguese ships in the 16th century. In the 17th century Dutch and English merchants established counters at Hanoi and Catholic missionaries went to work throughout Annam. It is to one of these missionaries, Alexandre de Rhodes. a Frenchman. that the credit for inventing the *quoc-ngu* (*i.e.*, the adaptation of the Roman alphabet to the Vietnamese language) chiefly belongs.

The insurrection of the Tay-Son (1773) overthrew both the Trinh and the Nguyen; but a IS-year-old member of the latter family, Kguyen Anh (1762–1820) succeeded in organizing a counterrevolution in the south and, with the help of a French bishop, P. J. G. Pigneau de Behaine, and a number of French officers, defeated the Tay-Son, advanced northward, entered Hanoi and, in 1802, under the name of Gia-Long, became emperor of a unified Vietnam (Annam). Gia-Long's policy of friendship with France, however, was abandoned by his successors Minh-Mang (1820–41) and Tu-Duc (1848–83), who began a terrible persecution of the Christians. This led to intervention and eventually to conquest by France in the latter half of the 19th century and thus to a long period of French rule before Vietnam recovered its independence after World War II.

For this French period, for the Indo-Chinese War and for the Geneva convention of 1954, which cut Vietnam in half, see INDO-CHINA.

Partition.— Pierre Mendes-France. who became French premier in june 1954, decided to put an end to the war in Indochina. As there was no hope to maintain French rule there he proposed to negotiate an armistice. This was signed on July 21 at the Geneva conference at which France, the United Kingdom, the United States, the C.S.S.R., Communist China: the two de *facto* states of Vietnam. Laos and Cambodia participated. The armistice ended the seven years' war in Indochina and. among other things. "provisionally" partitioned Vietnam into a Communist state on the north and a national one on the south. divided by the Ben-Hoi river. near the 17th parallel. Elections in both parts of Vietnam were to be held within two years, with the aim of recreating a unified government.

The Democratic Republic of Vietnam. with its capital at Hanoi, was organized on Communist lines. Ho Chi Minh became the president. and Pham Van Dong the chairman of the council of ministers. On Oct. 29. 1956, the central committee of the Lao Dong (Workers' or Communist) party dismissed Truong Chinh, the party first secretary, as responsible for the excesses of the land reform program; Ho Chi Minh succeeded him without ceasing to be head of state. The three-year plan of rehabilitation was said to have been successfully fulfilled in July 1957. About 80 big and medium industrial enterprises had been built and 240 rebuilt with Chinese. Soviet. Polish and Czechoslovak aid.

The National state, with its capital at Saigon, had Bao Dai, the former emperor of Annam, as chief of state, but on Oct. 23, 1955, over 98% out of an electorate of 5,000,000 deposed Bao Dai and declared that Ngo Dinh Diem, the prime minister. was to be head of state. Three days later Ngo proclaimed himself president of the republic under a provisional constitution. The following year Ngo withdrew his country's representatives from the assembly of the French union. On July 21, 1956, the post of French high commissioner was abolished and an ambassador was accredited instead.

A constituent assembly of 123 members (with 66 representing Ngo's National Revolution movement) was elected on March 4, 1956, and a new constitution was adopted on July 7. .The president of the republic, elected by direct popular vote for six years, was to be the head of government. The armed bands of the sects were defeated and strong measures were taken against Communist agitation. An agreement signed on May 8. 1956, between the United Kingdom and the U.S.S.R., the co-chairmen of the 1954 Geneva conference, postponed the general elections that were to reunify the two Vietnams.

Population.— In 1957 the total population of Vietnam was estimated at 27,200,000. Density of population is greatest in the Tongking delta. where it is more than 1,000 per square mile, with the result that famine is chronic and emigration considerable. The little plains of the central zone are also densely populated (more than 200 per square mile).

The Vietnamese. who occupy the plains, number more than 22,000,000. Other peoples include the Cambodians in the south (300,000), the Moi in the Xnnamite chain of mountains (720,000), and the Thai (700,000), the Muong (200,000), the Man (90,000) and the Meo (80,000) in the northern mountains. To these must be added the 400.000 Chinese tradesmen of the towns and 40,000 people of European or partly European descent.

The Vietnamese belong to a southern branch of the Mongoloid races. They are, on an average, a little taller in the north than in the south, where there is a stronger admixture of Indonesian blood. Their language is monosyllabic and can be written either in Chinese characters or in the quoc-ngu alphabet, which is based on the Roman. Chinese civilization has had a great influence on their way of life.

There are many towns with more than 20.000 inhabitants and five large towns: Saigon (1958 est.) 1,219,500. including the port of Cholon; Tourane (1958 est.) 100,978; and Hué (1958 est.) 90.682 in the Republic of Vietnam; Hanoi (1955 est.) 274.000, and the port of Haiphong (1954 est.) 217,000 in the Democratic Republic of Vietnam. Most of the people live in villages, each within its bamboo pale, constituting a largely self-governing commune under the administration of a council of notables.

Religion is mainly ancestor-worship, influenced by Confucianism. by Taoism and by Chinese Buddhism: but more than 2,000,000 Vietnamese are Roman Catholics; and large numbers adhere to modern sects, for instance to Cao-Dai (a syncretism of Christianity and Buddhism) and to Hoa-Hao (a prophetic faith developed from Buddhism).

The Thai. who are racially akin to the Laotians. and the Muong. who are closer to the Vietnamese, have their paddy fields in the valleys but also use the *ray* (terrace) method of growing rice and tubers in the mountains. where the forests on the slopes have to be burned down first; their social structure is quasi-feudal. The Rlan and the Meo occupy the highest ground, where they raise livestock and grow maize and opium.

The Moi (*i.e.*, "savages." so called by the Vietnamese) are the descendants of Indonesians driven into the mountains by invaders. There are several difierent groups of them: some (the Sedang and the Bahnar) speak Mon-Khmer languages, others (the Jarai and the Rhadé) various Indonesian dialects. They live by the *ray* method of agriculture, by fruit picking. by fishing or by hunting. Their clothing consists of a loincloth, their houses are built on piles. Some of them have a matrilineal system of family-reckoning. Social organization goes no farther than the confines of the villages; and ritual is limited to the family circle, within which it is mainly a matter of ancestor worship and of fertility ceremonies.

Economy.— Rice is the principal export oi Vietnam, representing more than one-third of the total value of the country's exports: beiore World War II only two countries in the world exported more rice. Other principal exports are coal (irom Hongay, on the Tongking coal field), rubber and maize. The tea and coffee plantations suffered considerable damage in the course of the war. Forestry, fishing and stock raising (oxen, buffaloes, pigs and chickens) are mainly concerned with supplying the local markets; and the principal industries (cement, textiles and fish curing) also serve local needs. Imports consist for the most part of manufactured goods, machinery, automobiles and textiles.

The major ports are Cholon and Haiphong. The railway along the coast (1,073 mi.) and the road network (15,500 mi.) were largely disorganized by the war. In the late 1950s the Hanoi-Yunnan railway was rebuilt.

The unit of currency is the piastre. That of the Republic of Vietnam has a value of 35 piastres to the U.S. dollar.

(HU. DE.; X.)

VIETNAMESE LANGUAGE is spoken by over 20,000-000 people in Vietnam and Vietminh, the two sections of what nas called Annam in Indochina. The area occupied by speakers of the language is the Tongkinese delta in the north. the plain of Cochin-China in the south, and the long, narrow coast line betneen. There are a number of dialects. Those of the Tongkinese delta are very similar to one another. Those of Cochin-China, of which that of Saigon is typical, differ somewhat from the northern dialects in pronunciation and vocabulary, but these two groups are mutually intelligible. Many of the dialects of the central coast line differ considerably irom those of north and south.

The language is a typical monosyllabic, nonlnflecting, tonal language The grammar is marked by rigid rules of word order. The major parts of speech, which are distinguished by the positions they occupy in the sentence. include nouns and verbs of several kinds. One class of nouns is the classifiers which are used when nouns are numerated. An interesting feature of the noun system is the use of kinship terms as pronouns. Minor parts of speech include conjunctions and sentence-ending particles: the latter mark sentences as questions, expressions of doubt and the like.

Indochina came under Chinese political influence at least as early as 2,000 years ago. Beginning from that period speakers of Vietnamese have continually borrowed Chinese words. At present the vocabulary of the everyday language contains about 50% Chinese loanwords and that of literature more, sometimes up to 90%. This vocabulary abounds in compounds which were first coined in Chinese.

The first writing known in Indochina was Chinese, and down to the last century all literary and official writing was done in Chinese. A system was evolved of writing Vietnamese with Chinese characters adapted to show Vietnamese pronunciation; it was called *chữ' nôm* "the vulgar writing." The earliest known document is dated A.D. 1343. It was used chiefly for writing popular literature which had no connection with official matters. In the 17th century Catholic missionaries invented a roman transcription for the language, complete with indications of all phonemic distinctions, including the tones. The system is called *quô'c ngữ'* "the national language." The earliest printing using it seems to have been done in 1649. It was adopted by the French for official use as early as 1910. At present it is used for all purposes, and is well adapted to popular education.

In Tongkin are spoken dialects called *Mu'o'ng,* which are closely allied to Vietnamese. The group has variously been held to belong to the Thai family with borrowed Khmer vocabulary, or to the Khmer family with borrowed Thai vocabulary.

VIGANO, SALVATORE (1769–1821), Italian dancer and choreographer noted for the stirring realism of his dramatic ballets. such as *La Vestale, Otello* and *I Titani.*

Born March 25, 1769, in Naples, he made his debut in Rome. During an engagement in Madrid: he married the dancer Maria Medina. There he also met Jean Dauberval, pupil of Jean Georges Noverre, who strongly influenced his choreography.

With his beautiful. accomplished wife. Viganò toured Italy and Germany. In Vienna he created several ballets, including *Prometheus* (1801), on which he collaborated with Beethoven. In 1811 he became choreographer of La Scala, Milan, where his finest works were produced. He died in Milan Aug. 10, 1821. (LN. ME.)

VIGEE-LEBRUN, MARIE ANNE ELISABETH (1755–1842), French portrait painter, a general favourite at the courts of Europe, was born in Paris on April 16, 1755. the daughter of a painter, from whom she received her first instruction. though she benefited more by the advice of Gabriel François Doyen. Jean Baptiste Greuze, Joseph Vernet and others. When only about 20 years of age she had made her name by her portraits of Count Orloff and the duchess of Orleans. In 1776 she married the painter and art critic Jean Eaptiste Pierre Lebrun, and in 1783 her picture of "Peace Bringing Back Abundance" (Louvre) gained her membership in the French Academy. When the Revolution broke out in 1789 she escaped first to Italy, where she worked in Rome and Naples. In Rome she painted the princesses Adelaide and Victoria. and at Naples "Lady Hamilton as a Bacchante." She then visited Vienna, Berlin and St. Petersburg, returning to Paris in 1802. In April 1802 she went to London, where she painted Byron and the prince of Wales. She was a great traveler, and her portraits are to be found in the collections of many countries. She died in Paris on March 30, 1842, at the age of 87, having been widowed for 29 years.

Among her many sitters was Marie Antoinette, of whom she painted over 20 portraits between 1779 and 1789. A portrait of the artist is in the hall of the painters at the Uffizi gallery, Florence, and another at the National gallery, London. The Louvre owns two portraits of Mme. Lebrun and her daughter. besides five other portraits. A full account of her eventful life is given in her *Souvenirs* (1835–37), which was translated by Lionel Strachey, *Memoirs of Madame Vigée-Lebrun* (1903).

VIGELAND, ADOLF GUSTAV (1869–1943), Norwegian sculptor, was born at Mandal in southern Norway on April 11, 1869. Vigeland studied in Oslo. Copenhagen. Paris, Berlin, Rome and Florence. He created the Frogner park in Oslo, where most of his major works are displayed around a bridge. fountain and monolith. The massive, nude figures of more than 100 men, women and children in granite and bronze were powerfully yet sensitively executed. After Yigeland's death at Oslo on March 12, 1943, his studio was opened as a Vigeland museum. Yigeland also achieved a wide reputation as a portrait sculptor. His imaginative study (1905) of N. H. Abel, considered among his finest works. shows the influence of Auguste Rodin. Later he adopted a more classic style.

VIGEVANO, a town and episcopal see of Lombardia. Italy, in the province of Pavia, on the right hank of the Ticino, 24 mi. S.W. from Milan by rail on the line to Mortara, 381 ft. above sea level. Pop. (1951) 37,101. It is a medieval walled town, with an arcaded market place and a castle of the Sforza family, dating from the 14th century and adorned with a loggia by Bramante and a tower imitating that of Filarete in the Castello Sforzesco at Milan.

VÍGFÚSSON, GÚDBRANDR (1828–1889), the foremost Scandinavian scholar of the 19th century, was born of a good Icelandic family in Breiðafjord. In 1849 he came to Copenhagen university as a *bursarius* in the Regense college. He was, after his student course, appointed *stipendiarius* by the Arna-Magnaean trustees, and worked for 14 years in the Arna-Magnaean library till, as he said, he knew every scrap of old vellum and of Icelandic written paper in that whole collection. During his Danish life he twice revisited Iceland (last in 1858), and made short tours in Norway and south Germany with friends. In 1866, after some months in London, he settled down in Oxford, which he made his home for the rest of his life. He held the office of reader in Scandinavian at the University of Oxford (a post created for him) from 1884 till his death. He was a jubilee doctor of Upsala, 1877, and received the Danish order of the Dannebrog in 1885. Vígfússon died of cancer and was buried in St. Sepulchre's cemetery, Oxford. His memory was remarkable; if the whole of the Eddic poems had been lost he could have written them down from memory.

By his *Túnatál* (written between Oct. 1854 and April 1855) he laid the foundations for the chronology of Icelandic history, in a series of conclusions that have not been displaced (save by his own additions and corrections), and that justly earned the praise of Jacob Grimm. His editions of Icelandic classics (1858–68), *Biskopa Sögur, Bardar Saga, Forn Sögur* (with Mobius), *Eyrbyggia Saga* and *Flatcyar-bdk* (with Unger) opened a new era of Icelandic scholarship, and can only fitly be compared to the Rolls Series editions of chronicles by Dr. Stubbs for the interest and value of their prefaces and texts. Seven years of constant and severe toil (1866–73) were given to the Oxford Icelandic-English dictionary, incomparably the best guide to classic Icelandic, and a monumental example of single-handed work. His later series of editions (1874–85) included *Orkneyinga* and *Háconar Saga,* the great and complex mass of Icelandic historical *sagas,* known as *Sturlunga* and the *Corpus Poeticurn Boreale,* in which he edited the whole body of classic Scandinavian poetry.

VIGIL, in the Christian Church, the eve of a festival. The *vigiliae* (*pernoctationes, παννυχίδες*) were originally the services celebrated during the night preceding the feast. The abuses connected with nocturnal vigils led to their being attacked, especially by Vigilantius of Barcelona (c. 400), against whom Jerome fulminated in this as in other matters. The custom, however, persisted until the middle ages, when the nocturnal *vigiliae* were, except in the monasteries, gradually discontinued, the vigil services, with the term itself, being transferred to the day preceding the feast. The only surviving relic of the older custom, in the Roman Catholic Church, is the midnight mass at Christmas.

The Church of England has a special collect, gospel and epistle for "Easter Even" only. For the other vigils recognized, the rubric directs that the collect appointed for the feast "shall be said at the Evening Service next before."

VIGILANCE COMMITTEE, in the United States, a self-constituted judicial body, occasionally organized in the western frontier districts for the protection of life and property. The first committee of prominence bearing the name was organized in San Francisco in June 1851, when the crimes of desperadoes who had immigrated to the gold fields were rapidly increasing in number and it was said that there were venal judges, packed juries and false witnesses. At first this committee was composed of about zoo members; afterwards it was much larger. The general committee was governed by an executive committee and the city was policed by sub-committees. Within about 30 days four desperadoes were arrested, tried by the executive committee and hanged, and about 30 others were banished. Satisfied with the results, the committee then quietly adjourned. but it was revived five years later. Similar committees were common in other parts of California and in the mining districts of Idaho and Montana. That in Montana exterminated in 1863–64 a band of outlaws organized under Henry Plummer, the sheriff of Montana City; 24 of the outlaws were hanged within a few months. Committees or societies of somewhat the same nature were formed in the Southern States during the Reconstruction period (1865–72) to protect white families from Negroes and "carpetbaggers," and besides these there were the Ku Klux Klan *(q.v.)* and its branches. the Knights of the White Camelia, the Pale Faces and the Invisible Empire of the South. the principal object of which was to control the Negroes by striking them with terror.

See T. J. Dimsdale, *The Vigilantes of Montana* (Virginia City, 1866); H. H. Bancroft, *Popular Tribunals* (San Francisco, 1887); P. Garnett, ed., *Papers of the San Francisco Committee of Vigilance of 1851* (Berkeley, Calif., 1910–19); Mary Floyd Williams, ed., *Papers of the San Francisco Committee of Vigilance of 1851* (Berkeley, 1919); Mary Floyd Williams, *History of the San Francisco Committee of Vigilance of 1851* (Berkeley, 1921); and William John McConnell, *Frontier Law* (Yonkess-on-Hudson, N.Y., 1924).

VIGILANTIUS (*fl.* c. 400), the presbyter, celebrated as the author of a work, no longer extant, against superstitious practices, which called forth one of the most violent and scurrilous of Jerome's polemical treatises, was born about 370 at Calagurris (Cazères or perhaps Saint Bertrand de Comminges, Haute-Garonne), where his father kept a "statio" or inn on the great Roman road from Aquitania to Spain. Sulpicius Severus sent him in 395 with letters to Paulinus of Nola. On his return to Severus in Gaul he was ordained, and set out for Palestine, where he was received by Jerome at Bethlehem. Vigilantius was dragqed into the dispute then raging about Origen, in which he did not see eye to eye with Jerome. About 403, some years after his return from the East, Vigilantius wrote his work against superstitious practices, in which he argued against relic worship, as also against the vigils in the basilicas of the martyrs, the rejection of earthly goods and the attribution of special virtue to the unmarried state, especially in the case of the clergy. All that is knomn of the work is through Jerome's treatise *Contra Vigilantium,* or, as that controversialist would seem to prefer saying, "Contra Dormitantium." 'ihe influence of Vigilantius long remained potent both in France and Spain, as is proved by the polemical tract of Faustus of Rhegium (d. c. 490).

VIGILIUS, pope from 537 to 555, succeeded Silverius *(q.v.)*. having been elected and consecrated pope by order of Belisarius in March 537 while Silverius was still alive. His elevation was due to the empress Theodora. who had induced him to promise to disallow the council of Chalcedon. in connection rvith the "Three 'Chapters" controversy. Failing to fulfil his promise, he was summoned to Constantinople. which he reached in 547. There he issued a document known as his *Judicatum* (548), in which he condemned indeed the "Three Chúpters" but expressly disavowed any intentions thereby to disparage the council of Chalcedon. After some trimming, he prepared another document, the *Constitutum* cd *Imperatorem,* which was laid before the second council of Constantinople (553) and led to his condemnation by the majority of that body. some say even to his banishment. Ultimately, however. he was induced to confirm the decrees of the council and was allowed after an enforced absence of seven years to set out for Rome. He died at Syracuse, before he reached his destination, on June 7, 555.

VIGLIUS, the name taken by WIGLE VAN AYTTA VAN ZUICHEM (1507–1577), Dutch statesman and jurist, a Frisian by birth. who was born on Oct. 19, 1507. Having lectured on law at the universities of Bourges and Padua, he accepted a judicial position under the bishop of Munster which he resigned in 1535 to become assessor of the imperial court of justice (*Reichskammergericht*). In 1542 he became a member of the council of Mechlin, and some years later president of that body. He was soon one of the most trusted of the ministers of Charles V. He was generally regarded as the author of the edict against toleration issued in 1550; a charge which he denied. When the emperor abdicated in 1555 Viglius was anxious to retire also. but at the instance of King Philip II he remained at his post and was rewarded by being made coadjutor abbot of St. Bavon. and in other ways. In 1559, when Margaret, duchess of Parma, became regent of the Netherlands, Viglius was an important member of the small circle who assisted her in the work of government. He was president of the privy council, member, and subsequently president, of the state council, and a member of the committee of the state council called the *consulta.* In 1565 he was allowed to give up the presidency of the state council! but was persuaded to retain his other posts.

However, Viglius had lost favour with Margaret, who accused him to Philip of dishonesty and simony, while his orthodoxy was suspected. When the duke of Alva arrived in the Netherlands Viglius at first assisted him; but he subsequently opposed the duke's scheme of extortion.

Viglius died at Brussels on May 5, 1577.

He wrote a *Tagebuch des Schmalkaldischen Donaukriegs,* edited by A. von Druffel (1877), and some of his lectures were published under the title *Commentarii in decem Institutionum titulos* (1564). His *Vita et opera historica* are given in the *Analecta Belgica* of C. P. Hoynck van Papendrecht (1743).

VIGNOLA, GIACOMO DA (GIACOMO BAROZZI or BAROCCHIO) (1507–1j73j. with Andrea Palladio *(q.v.)* the most important Italian architect- of the later 16th century. He was bom at Vignola. between Modena and Bologna. on Oct. 1,.1507, and, after studying in Bologna, he went to Rome in the 1530s and made drawings of the antiquities for a projected edition of Vitruvius' treatise. In 1541–43 he spent 18 months at the court of Francis I at Fontainebleau and in Paris, and there he must have met his fellow Bolognese Sebastiano Seriio. On his return to Italy he built the Bocchi palace at Bologna and then went to Rome (c. 1550) where he was appointed architect to Pope Julius III, for whom he built the Villa Giulia (now the Etruscan museum) in collaboration with Giorgio Vasari and Bartolommeo Ammanati, between 1551 and 15jj. This was a summer villa, based on ancient villa types as drscribed by Pliriy the Younger, with a small house and an elaborate garden. In 1554 he built the church of S. Andrea in the nearby Via Flaminia, the first church to have an oval dome, although the ground plan is rectangular. In his church of Sta. Anna dei Palafrenieri (begun c. 1572) Vignola extended this idea to include an oval in the ground plan. and this oval theme became a favourite of 17th-century architects. Vignola's most important church was. however, the Gesu in Rome, headquarters of the Society of Jesus, which he began in 1568. It was completed after his death. and not according to his design, but he established the plan, which is of the older cruciform type with side chapels and a broad nave adapted to the new importance attached to preaching. All over Europe there are versions of the Gesu, many by Jesuit architects.

After the death of his patron Julius III in 15jj, Vignola worked mainly for the Farnese family, for whom he completed the huge Villa Farnese at Caprarola, near Viterbo, the plan of which had been established earlier by Antonio da Sangallo and Baldassare Peruzzi. Vignola died at Rome on July 7. 1573.

The academic tendency of Vignola's mind is epitomized in his *Regola delli cinque ordini d'nrchitettura* of 1562, which remained a standard textbook on the architectural orders for three centuries. He also wrote on perspective—Dus *regole della prospettiva pratica,* published posthumously (1583) with a short life.

See J. Coolidge, "The Villa Giulia," *Art Bulletin,* vol. xxv, pp. 177–225 (1943). (P. J. My.)

VIGNY, ALFRED DE (1797–1863), French poet, was born at Loches (Indre-et-Loire) on March 27, 1797. For generations the ancestors of Alfred de Vigny had been soldiers, and he himself joined the army, with a commission in the Household Troops. at the age of sixteen. But the Revolutionary and Napoleonic wars were over. and after twelve years of life in barracks he retired. While still serving he had made his mark, if as yet unrecognized, by the publication in 1822 of a volume of poems, and in 1826 by another, together with the famous prose romance of *Cinq-Mars*, which derived some of its popularity from the enormous vogue of the novels of Scott. Some of his most celebrated pieces — Elon, *Dolorida, Moïse*—appeared (1822–23) before the work of younger members of the Romantic school whose productions strongly resemble these poems. Nor is this originality limited to the point which he himself claimed in the Preface to his collected *Poems* in 183; — that they were "the first of their kind in France, in which philosophic thought is clothed in epic or dramatic form." Indeed this claim is disputable in itself; it is in *poetic*, not *philosophic* quality. that his idiosyncrasy and precursorship are most remarkable. It is quite certain that the other Alfred — Alfred de Musset—felt the influence of his elder namesake. and the verses of Hugo, and even of Lamartine, considerably his elder, owe something to him. His poetry, written for the most part in the earlier part of his life, is small in volume. but it forms probably his chief title to fame.

Alfred de Vigny, though he belonged to no *cénacle,* but shut himself up, as the saying went, in a *tour d'ivoire,* belonged to the Romantic movement of the thirties, and was stimulated by it to drama and to novel writing. In the ·ear before the revolution of July he produced at the Théâtre Français a translation, or rather paraphrase, of *Othello,* and an original piece. *La Maréchale d'Ancre*. In 1832 he published the curious book *Stello,* containing studies of unlucky youthful poets—Gilbert. Chatterton. Chénier—and in 1835 he brought out his drama of *Chatterton,* which, by the hero's suicide, shocked French taste even after five years of Romantic education, but had a considerable success. The same year saw the publication of *Servitude et grandeur militaires,* a collection of sketches rather than a connected work in which Vigny's military experience, his idea of the soltlier's duties, and his rather poetical views of history were all worked in. The subjects of *Chatterton* and *Othello,* were. of course, drawn from English sources, and in fact Alfred de Vigny knew English well, lived in England for some time and married in 1828 an Englishwoman, Lydia Bunbury.

In 1845 Alfred de Vigny was elected to the Academy, but made no compromise in his "discourse of reception," which was unflinchingly Romantic. Still, he produced nothing save a few scraps: antl, beyond the work already enumerated, little has to be added except his *Journal d'un poète* and the poems called *Les Destinies*. Vigny died at Paris on Sept. 17, 1863.

Estève for the Soc. dcs Textes français modcrnes.

VIGO, a seaport and naval station of northwestern Spain. in the province of Pontevedra; on Vigo bay (Ria de Vigo) and on a branch of the railway from Tuy to Corunna. The population in 1950 was 51,636. Vigo was attacked by Sir Francis Drake in 1585 and 1589. In 1702 a combined British and Dutch fleet under Sir George Rooke and the duke of Ormonde destroyed a Franco-Spanish feet in the bay. and captured treasure of about £1,000,000. In 1719 Vigo was captured by the British: in 1936 by Spanish Nationalists. Vigo bay, one of the finest of the Galician fjords, extends inland for 19 mi., and is sheltered by low mountains and by the islands (Islas de Cies, ancient *Insulae Sic-cae)* at its mouth. The ton-n is built on the southeastern shore. and occupies a hilly site dominated by two obsolete forts. Vigo owes its importance to its deep and spacious harbour. and to its fisheries. It is a port of call for many lines trading between Western Europe and South America. The town contains flour. paper and sawmills, sugar and petroleum refineries. tanneries. distilleries and soap works.

VIIPURI, or VYBORG. U.S.S.R., formerly a seaport and summer resort of Finland in 60" 43' N., 28° 3j' E., at the mouth of the Saima canal on the Bay of Viipuri in the Gulf of Finland. Pop. (1959) 51,000. The canal links it with a series of lakes. Its exports are timber, timber products, cement and farm produce, and its imports coal. fertilizers, foodstuffs and manufactured goods. It is on glaciated granite hills surrounding the bay, guarded by the naval station of Björkö. Its castle. built in 1293 by Marshal Torkel Knutson. was the first centre for the spread of Christianity in Karelia. It was the chief loss to Russia in the winter war of 1940–41, was regained in 1941 after Finland entered World War II and was lost again to Russia in 1944.

VIJAYANAGAR ("the city of victory"), an ancient Hindu kingdom and ruined city of southern India. The kingdom lasted from about 1336 to 1565, forming during all that period a bulwark against the hlohammedan invasion from the north. The great part of its history is obscure: but its power and wealth are attested by more than one European traveller and also by the character of the existing ruins. At the beginning of the 14th century Mohammedan raiders had effectually destroyed every Hindu principality throughout southern India, but did not attempt to occupy the country permanently. In this state of desolation Hindu nationality rose again under two brothers. named Harihara and Bukka. of whom little more can be said than that they were Kanarese by race. The kingdom reached its greatest extent under Krishna Deva Raya (1509–29). In 1565, on the downfall of the kingdom, the confederate sultans of Bijapur, Ahmednagar and Golconda overwhelmed the Vijayanagar army in the plain of Talikota and sacked the defenceless city. The city has ever since remained a wilderness of immense ruins. which are now conserved by the government.

See R. Sewell, *A Forgotten Empire, Vijayanagar* (London, 1900; new ed., 1924); and B. A. Saletore, *Social and Political Life in the Vijayanagara Empire,* 2 vol. (Madras, 1934).

VIKING. A word *wicing,* "warrior," corresponding to the O. Norse *vikingr* and the modern *viking,* was current in England at least a century before the earliest recorded Scandinavian descents upon the West. Its Scandinavian equivalent early acquired the more specialized sense of "sea-warrior." and the modern term "Viking age" is a convenient designation of the phase of Scandinavian history which produced the incessant raiding expeditions characteristic of the 9th and early 10th centuries. Most of our evidence as to the Vikings of this period is derived from the literature of the lands which they visited. and is therefore essentially hostile. To contemporary chroniclers they were utterly hateful, faithless. cruel and enemies of civilization and the arts of peaceful life. Their own side of the story is untold. for the men who created the great literature of western Scandinavia had no certain memory of events or personalities in the true Viking age. Their character can only be inferred from the scale upon which their raids were planned, the forms of society which arose in the different lands of their settlement, and the archaeological evidence which reveals something of their culture. Judged in this way they cease to appear as a mere blind force of destruction. It becomes clear that they possessed their own culture. though it was not the culture of the Christian West. Long before the end of the 9th century they had learned to penetrate all the greater waterways of Europe. And the raids through which they gained this knowledge were only preliminary to wider voyages through which at last even the New World became known for a moment to men of Scandinavian birth.

The Viking Raids. — The Vikings began by more or less desultory raids. in the course of which they seized upon some island, which they generally used as an arsenal for attacks on the mainland. At first the raids were made in the summer, and the *first wintering* in any new scene of plunder meant settlement in the country, and some sort of division of territory. After that the northerners assimilated themselves more or less to the natives of the country. This course was followed in the history of the Viking attacks on Ireland, the earliest of their continuous series of attacks. Thus they began by seizing the island of Rechru (now Lambay) north of Dublin bay (A.D. 795) and in 20 years were on the northern. western and southern coasts; by A.D. 825 they ventured a considerable distance inland. In A.D. 832 came a large fleet under Turgesius (Thorgestr). The new invader extended his conquests till. in A.D. 832. one-half of Ireland (called Lethcuinn or Con's Half) had submitted; he established his wife: Ota, as a sort of *völva,* or priestess, in what had been one of Ireland's most famous literary monasteries, Clonmacnoise. Turgesius was killed soon after. in 845; and though in A.D. 853 Glaf the White was over-king of Ireland, the Vikings' power diminished. In the end, territory was—if by no formal treaty—ceded to their influence; and the (Irish) kingdoms of Dublin and Waterford were established on the island.

This sketch may be taken as the prototype of Viking invasion of any region of Western Christendom which was continuously attacked. Almost simultaneously with the attacks on Ireland came others, probably also from Norway, on the western coasts and islands of Scotland. Plunderings of Iona are mentioned in A.D. 802. 806, and in the course of a generation almost all the monastic communities in western Scotland had been destroyed. Gn the Continent there were three distinct regions of attack. The Danes early settled on the island of Walcheren, which had, in fact. been given by the emperor Louis the Pious to a fugitive Danish king. Harald by name, who sought the help of Louis and adopted Christianity. From the island the raids extended on either side: sometimes eastward as far as the Rhine. and so into Germany proper; at other times westward to the Somme. and thus into the territory of Charles the Bald, the future kingdom of France. Toward the end of the 9th century all Frisia between Walcheren and the German ocean seems to have been possessed by the invaders. The serious attacks of the pirates in any part of the empire distant from their own lands began about. the middle of the century. when they first wintered in the Seine territory. Their first attack on Paris was in A.D. 845: in A.D. 885–887 a much more important but unsuccessful one took place. the invaders receiving an indemnity for raising the siege and leave to pass beyond Paris into Burgundy. The settlement of Danes under Rollo on the lower Seine, *i.e.,* in Normandy, belongs to the next century.

The third region is the mouth of the Loire, where the island *point d'appui* was Noirmoutier. The Northmen wintered there in A.D. 843. No region was more oiten ravaged than that of the lower Loire, so rich in abbeys—St. Martin of Tours, Marmoutiers, St. Benedict, etc. But the country ceded to the Vikings under Hasting at the Loire mouth was insignificant and not in permanent occupation.

Near the end of the 9th century, however, the plundering expeditions which emanated from these three sources became so incessant and so widespread that we can signalize no part of west France as free from them, and at the same time much mischief was wrought in the Rhine country and in Burgundy. Unfortunately, at this point our best authority ceases; and me cannot well explain the changes which brought about the Christianization of the Normans and their settlement in Normandy as vassals of the West Frankish kings.

For the Viking attacks in the British Isles, the course of events is clearer. In its general features it follows the normal course. The Vikings had begun to visit the English coast about the end oi the 8th century, but their serious attacks do not begin till 838. Their first wintering was on the contiguous island of Thanet in A.D. 851. In 865 England was visited by a "great army," which overthrew the ancient kingdoms of Northumbria, Mercia and East Anglia. Wessex was saved only by Alfred's victory at Edington, after which Guthrum, the Danish leader, accepted baptism and settled with his men in East Anglia. But the forces defeated at Edington represented but half oi the Viking army in England at the time. The other half had already settled in Korthumbria, and the region between Humber and Welland.

The six territories which we have signalized—Ireland, Western Scotland, England, the three in West Francia which merged into each other by the end oi the 9th century—do not comprise the whole field of Viking invasion. To the east they twice sailed up the Elbe (A.D. 851, 880) arid burned Hamburg. Southwards they plundered iar up the Garonne, and in the north of Spain; and one fleet sailed round Spain, plundering, but attempting in vain to establish themselves in this Arab caliphate. They plundered on the opposite African coast, and got as far as the mouth of the Rhone. and thence to Luna in Italy.

In the third quarter of the 9th century two distinct tendencies appeared among the Vikings in the West. One section was ready to settle down and receive territory at the hands of the Christian rulers; the other section adhered to a life of adventure and of plunder. A large portion of the great army, unable to obtain settlement in England, sailed to the Continent and spread devastation far and wide. Under command of two Danish "kings." Godfred and Siegfried, they mere first in the country of the Rhinemouth or the Lower Scheldt; afterwards dividing their iorces, some devastated iar into Germany, others extended their ravages on every side in northern France down to the Loire. 'Ihe whole of these vast countries, Northern Francia and part of Burgundy and the Rhineland, were as much at their mercy as England before the battle of Edington, or Ireland before the death of Turgesius. But in every country alike the wave of Viking conquest now began to recede. The settlement of Normandy was the only permanent outcome of the ?-iking age in France. In England, under Edward the Elder and Aethelflaed, Mercia recovered a great portion of what had been ceded to the Danes. In Ireland a great expulsion of the invaders took place in the beginning of the 10th century. In the following generations the kingdoms of Denmark and Sweden became consolidated, and the energy of the Norwegian peoples found vent in the settlement of Iceland.

Severe as were the raids in Europe, and great as was the suffering —on account of which a special prayer, *A furore Normannorum libera nos* was inserted in some of the litanies of the West—if the Vikings had been nothing more than pirates their place in history would be insignificant. But the Viking outbreak has to some extent the character of a national movement. While some were harrying in the West others were founding Garðaríki (Russia) in the East; others were pressing farther south till they reached the eastern empire in Constantinople, so that when Hasting and Björn had sailed to Luna in the Gulf of Genoa the northern folk had almost put a girdle around the Christian world. There is every evidence that they were not a mere lawless iolk, but under suitable conditions, as in their 10th century colony of Jomborg, could develop an elaborate discipline and a strict code of honour. They mere not entirely unlettered, for the use of runes dates back considerably earlier than the Viking age.

The **Viking** Ships.—In certain material possessions—those belonging to war and naval adventure—the Vikings were ahead of the Christian nations. There is certainly a historical connection betn-een the ships which the tribes on the Baltic possessed in the days of Tacitus and the Viking ships, a fact which would lead us to believe that the art of shipbuilding had been better preserved there than elsewhere in northern Europe. Merchant vessels must, of course, have plied between England and France or Frisia. But it is certain that even Charlemagne possessed no adequate navy. Nor was any English king before Alfred stirred up to undertake the same task. The Viking ships had a character apart. They may have owed their origin to the Roman galleys; they did without doubt owe their sails to them. Their structure was adapted to short voyages in a sea not exposed to the most violent storms or dangerous tides. They were shallow, narrow in the beam, pointed at both ends, and so eminently suitable for manoeuvring (with oars) in creeks and hays. The Viking ship had but one large and heavy square sail, and when a naval battle was in progress it mould depend for its manoeuvring on the rowers. In saga literature we read of craft (of "long ships") with 20 to 30 benches of rowers, which would mean 40 to 60 oars. It is not probable that the largest viking ships had more than ten oars a side. As these ships must often, against a contrary wind, have had to row both day and night, it seems reasonable to imagine the crew divided into three shiits which would give twice as many men available to fight on any occasion as to row. Thus a zo oared vessel mould carry 60 men. Rut some 40 men per ship seems, for this period, nearer the average. In 896, it is incidentally mentioned in one place that five vessels carried 200 Vikings, an average of 40 per ship. Elsewhere about the same time we read of 12,000 men carried in 250 ships, an average of 48.

The round and painted shields of the warriors hung outside along the bulwarks; the vessel was steered by an oar at the right side. Prow and stern rose high; and the former was carved most often as a snake's or dragon's head. The warriors were well armed. The *byrnie,* a mail-shirt, is oiten mentioned in Eddic songs; so are the axe, spear, javelin, bow and arrows and the sword. An immense joy in battle breathes through the earliest Korse literature, which has scarce its like in any other literature; and we know that the language recognized a peculiar battle fury, a madness by which men were seized and which went by the name of "berserk's way" (*berserksgangr*). The courage of the Viking was proof against anything, even as a rule against superstitious terrors. He was unfortunately hardly less marked for cruelty and iaithlessness. It is also true, however, that they showed a capacity for government, and in times oi peace for peaceiul organization. Normandy was the best-governed part of France in the 11th century: and the Danes in East Anglia and the Five Boruughs developed a iorm of society remarkable ior its stability amid changing political conditions. Nevertheless, the significance of the Vikings in the history of western Europe lies less in the communities which they founded than in the stimulus given by their raids to the new military organization oi society out of which feudalism was presently to arise.

Steenstrup, *Normannerne,* 4 vol. (1876–82); C. F. Keary, *The Vikings in Western Europe* (1891); A. Bugge, *Vikingerne* (1904–06) and A. Mawer, *The Vikings* (1913).

VIKRAMADITYA, a legendary Hindu king of Uzjain, who is supposed to have given his name to the Vikram Samvat. the era which is used all over northern India. except in Bengal, and at whose court the "nine gems" of Sanskrit literature are also supposed to have flourished. The Vikram era is reckoned from the vernal equinox of the year 57 B.C.. but there is no evidence that that date corresponds with any event in the life of an actual king. As a matter of fact, all dates in this era down to the 10th century never use the mord Vikram, but that of Malava instead that being the tribe that gives its name to Malwa.

VILE, WILLIAM (d. 1767), English cabinetmaker and upholsterer, mas partner with John Cobb (q *v.*) from about 1750 to 1765. Vile appears to have been the senior member of the firm whose name appears in the royal accounts only during the period of the partnership. Vile worked for George III both before and after his accession to the throne. Existing accounts show that he supplied furniture also to Strawberry Hill (Middlesex), Longford castle (Wiltshire), and Came house (Dorset). A considerable quantity of superb furniture in the rococo style has been identified as Vile's and has established him as the leading cabinetmaker of the period. Pieces still in the royal collection. such as the jewel cabinet and the *secretaire* made for Queen Charlotte, are characteristic of Vile's best work, both for their imposing design and for the magnificent quality of detail, and rank among the finest pieces of furniture made in England He died in Sept. 1767.

See R. Edwards and M. Jourdain, *Georgian Cabinet-Makeus,* 3rd ed. (1955). (J. E. LE.)

VILL, the Anglicized form of the word *villa,* used in Latin documents to translate the Anglo-Saxon *tun,* "township." Ultimately vill and township became regarded as equivalent terms, and so remained in legal use until the ecclesiastical parish became regarded as the normal unit of local administration. In classical Latin *villa* had meant "country house." "farm," "villa" *(see* VILLA) ; but even by the 3rd century it had acquired the sense of village. Later it even displaced *civitas,* for city. In the Frankish empire *villa* was also used of the royal and imperial palaces or seats with their appurtenances.

VILLA, PANCHO (FRANCISCO) (1878–1923), Mexican revolutionary general, was born in the municipality of San Juan del Río. Durango, on June 5, 1878. At the age of 16 he killed a man for molesting his younger sister and then fled to the mountains. For the next 15 years he lived as a cattle rustler and bandit, meanwhile changing his name from Doroteo Arango to Francisco Villa, and came to be known as "Pancho." Occasionally he worked as a labourer, and on one of these occasions he was persuaded to join the Madero revolution against Pres. Porfirio Diaz in 1910. After Madero's victory, Villa remained in the irregular army. During the campaign against Pascual Orozco in 1912. Gen. Victoriano Huerta condemned Villa to death for insubordination, but Madero ordered a stay of execution and sent Villa to prison. Villa escaped from prison in Nov. 1912 and fled to the United States.

Soon after Madero's assassination in 1913 Villa returned to Mexico and joined Venustiano Carranza against Huerta; his cavalry became the most famous force in the revolutionary armies. After Carranza's victory. he and Villa split as a result of mutual distrust. They renewed the civil war and Villa was defeated in a series of battles. By late 1915, when the United States recognized Carranza, Villa was no longer a serious contender for power; but, in order to demonstrate that Carranza did not control northern Mexico, Villa executed 16 U.S. citizens at Santa Isabel in early 1916 and soon thereafter attacked Columbus. N.M. Pres. Woodrow Wilson then sent an expedition led by Brig. Gen. John J. Pershing to Mexico to capture Villa, but Carranza's unco-operativeness and Villa's popularity among the people of Chihuahua prevented Pershing from fulfilling his mission.

Villa continued his bandit-rebel activities as long as Carranza remained in power, at times capturing some of the larger northern cities, but as soon as Carranza was overthrown in 1920 Villa made peace with the government. In return for agreeing to retire from politics he was given a large ranch in Durango. There he lived until he was assassinated in nearby Parral, Chihuahua, on July 20, 1923. *See* also MEXICO: *Independent Mexico.* (C. C. CU.)

VILLA, the Latin word (diminutive of *vicus,* "a village") for a country house and its appurtenances. In Great Britain the word has come to mean a small detached or semidetached suburban home and has lost much of its original significance. In the United States the mord has been used to mean a real estate development or tract? though generally it refers to a sumptuous suburban or country residence.

References to villas are constantly made by Roman writers, especially Cicero who had seven villas. and Pliny who described his villas in Tuscany and near Laurentum at great length in his letters. The Roman countryside is dotted with ruins of innumerable villas. The most famous of these is the villa of Hadrian at Tivoli which covered an area about two miles in length and in which were reproductions of celebrated buildings he had seen in his travels. Many villas existed throughout the Roman empire.

The villas were frequently asymmetrical in plan (the 4th-century imperial hunting lodge-villa near Piazza Armerina in Sicily is an excellent example), often built with elaborate terracing on hillsides, especially around Tivoli and Frascati, and had long colonnades, towers, fine water gardens with reflecting pools and fountains, and extensive reservoirs for the water supply. According to Pliny there were two kinds of villas. the *villa urbana,* which was a countryseat (with city comforts), and the *villa rustica,* the farmhouse. A villa at Boscoreale near Pompeii, excavated in 1893–94, is an example of a *villa rustica* in which the principal room was the kitchen! with the bakery and stables beyond and room for wine presses, oil presses, hand mill, etc.

During the middle ages the villas were abandoned and in some places castles and monasteries (*e.g.,* the Basilian monastery at Grottaferrata) built in and on top of them. The great Renaissance villas were occasionally built on their ruins and frequently used some of the better preserved remains as models. This influence is especially evident in such early examples as the Villa Madama (1520) just outside Rome, originally designed by Raphael. and Pirro Ligorio's Casino of Pius IV (1558–62) in the Vatican gardens. The Renaissance villas sought, however, for greater symmetry and the houses were less rambling (frequently being remodeled castles, especially in Tuscany), though the gardens were often even more elaborate. In fact, the garden often became the principal element in the 16th and 17th century. as in the Villa d'Este in Tivoli (1549), also designed by Ligorio, and the Villa Lante in Bagnaia and the Villa Orsini at Bomarzo, both near Viterbo. Other important examples are the Villa di Papa Giulio (1550) in Rome and the Villa Farnese at Caprarola, both by

G E KIDDER SMITH

THE VILLA BARBARO (1560) BY ANDREA PALLADIO. AT MASER IN THE VENETO, ITALY

Vignola, the villas Aldobrandini (1598–1603), Falconieri (1546) and Mondragone (1573–75) at Frascati, the Villa Barberini at Castel Gandolfo (on the site of a villa of the emperor Domitian), the Boboli gardens in Florence, the Villa Barbaro at Maser in the Veneto and La Rotonda near Vicenza by Palladio. and the villas Borghese. Medici (1540) and Doria Pamphili (1650) in Rome By the 18th and 19th century villas in Italy were less extensive. though fine ones were built in Piedmont (Villa Stupinigi near Turin) and Lombardy, especially on the lakes, in the Veneto (Villa dei Pisani at Stra), in Rome (Villa Albani and Villa Torlonia), on the slopes of Vesuvius near Naples (La Favorita at Portici) and at Bagheria near Palermo (Villa Palagonia). The Italian villa had much influence in France and England. See also HOUSE; ROMAN ARCHITECTURE.

VILLACH, an old Austrian town in the Bundesland of Carinthia (*q.v.*) on the Drava at the western end of the basin of Klagenfurt. It is a timber centre and manufactures lead wares. The 15th-century church of St. Jacob in Gothic style has a tower about 315 ft. high. Pop. (1951) 30,069. Warmbad Villach, with hot sulfur baths, and Mittewald, whence the ascent of the Dobratsch can be made, are near Villach. Some of the prettiest Carinthian lakes are to be found near Villach.

VILLAGE COMMUNITIES. The study of village communities has become one of the fundamental methods of discussing the ancient history of institutions. This article covers countries such as England, Germany and the U.S.S.R. and those of the Balkan peninsula because these nations have gone through all sorts of experiences and the historical data can be tolerably well ascertained. The best way seems to be to select some typical examples, chiefly from the domain of Celtic, Slavonic and Germanic social history, and to try to interpret them in regard to the general conditions in which communal institutions originate, grow and decay. As the principal problem will consist in ascertaining how far land was held in common instead of by individuals, it is advisable to look out for instances in which this element of holding in common is very clearly expressed. We ought to get, as it were, acclimatized to the mental atmosphere of such social arrangements in order to counteract a very natural but most pernicious bent prompting one to apply to the conditions of the past the key of our modern views and habitual notions. A certain acquaintance with the structure of Celtic society, more especially the society of ancient Wales, is likely to make clear from the outset to what extent the husbandry and law of an Aryan race may depend on institutions in which the individual factor is greatly reduced, while the union first of kinsmen and then of neighbours plays a most decisive part.

Seebohm called our attention to the interesting surveys of Welsh tracts of country made in the 14th century, soon after these regions passed into the hands of English lords. The fragments of these surveys published by him and his commentary on them are very illuminating, but further study of the documents themselves discloses many important details and helps to correct some theories propounded on the subject. Let us take up a concrete and simple case, *e.g.,* the description of Astret Canon, a trev or township (villata) of the honour of Denbigh, surveyed in 1334. In the time of the native Welsh princes it was occupied entirely by a kindred (progenies) of free tribesmen descended from a certain Canon, the son of Lawaurgh. The kindred was subdivided into four gavells or bodies of joint-tenants. On the half-gavell of Monryk ap Canon, *e.g.,* there are no less than 16 coparceners, of whom eight possess houses. The peculiarity of this system of land tenure consists in the fact that all the tenants of these gavells derive their position on the land from the occupation of the township by their kindred, and have to trace their rights to shares in the original unit. Although the village of Astret Canon was occupied by something like 54 male tenants, the majority of whom were settled in houses of their own, it continued to form a unit both in regard to the payment of land tax and other services and payments, and also in respect of the possession and usage of the soil. On the other hand, movable property is owned in severalty. Services have to be apportioned among the members of the kindreds according to the number of heads of cattle owned by them. From the description of another township—Pireyon—we hear that gavells ought to be considered as equal shares in respect of the arable, the wood and the waste of the township. If the shares were reduced into acres there would have fallen to each of the eight gavells of Pireyon 91ac., one rood and a half and six perches of arable and woodland, and 53⅓ac. and half a rood of waste land. But as a matter of fact the rights of the tenants of the gavell were realized not through the appropriation of definite acres, but as proportionate opportunities in regard to tillage and as to usages in pasture, wood and waste. Pastoral habits must have greatly contributed to give the system of landholding its peculiar character. It was not necessary, it would have been even harmful, to subdivide sharply the area on which the herds of cows and the flocks of sheep and goats were grazing.

We do not notice any systematic equalization between members of the tribal communities of the trevs. In fact, both differences in the ownership of cattle and differences of tribal standing, established by complex reckonings of pedigree and of social rank, led to marked inequalities. But there was also the notion of birthright, and we find in the laws that every free tribesman considered himself entitled to claim from his kindred grazing facilities and five erws for tillage. Such a claim could be made unconditionally only at a time when there was a superabundance of land to dispose of. In the 14th century, to which our typical descriptions refer, this state of things had ceased to be universal. Although great tracts of Welsh land were undoubtedly still in a state of wilderness, the soil in more conveniently situated regions was beginning to be scarce, and considerable pressure of population was already felt, with a consequent transition from pastoral pursuits to agriculture.

Although there are no rearrangements or redivision within the tribe as a whole, inside every gavell, representing more narrow circles of kinsmen, usually the descendants of one great-grandfather, *i.e.,* second cousins, the shares are shifted and readjusted according to one of two systems. In one case, that of the trevcyvriv or joint-account village, every man receives "as much as another yet not of equal value"—which means, of course, that the members of such communities were provided with equal allotments, but left to make the best of them, each according to chance and ability. This practice of reallotment was, however, restricted in the 14th century to taeog trevs, to villages occupied by half-free settlers. The free tribesmen, the priodarii of Wales, held by daddenhud, were reallotted shares within the trev on the coming of each new generation or, conversely, on the going out, the dying out, of each older generation. In other words: at the demise of the last of the grandfathers in a gavell, all the fathers took equal rank and claimed equal shares, although formerly some of the portions had been distributed equally only between the grandfathers or their offspring (stirps). The right to claim redivision held good only within the circle of second cousins.

Another fact which is brought out with complete evidence by the Welsh Surveys is that the tenure is ascribed to communities of kinsmen and not to chiefs or headmen. The latter certainly existed and had exerted a powerful influence on the disposal of common land as well as on government and justice. But in the view of the 14th-century surveys each township is owned not by this or the other elder, but by numerous bodies of coparceners. In this way there is a clear attribution of rights of communal ownership, and not merely of rights of maintenance.

Let us now compare this description of Celtic tribal tenure with Slavonic institutions. The most striking modern examples of tribal communities settled on a territorial basis are presented by the history of the Southern Slavs in the Balkan Peninsula and in Austria, of Slovenes, Croats, Serbs and Bulgarians, but it is easy to trace customs of the same kind in the memories of Western Slavs conquered by Germans, of the Poles and of the different subdivisions of the Russians. A good clue to the subject is provided by a Serb proverb which says that a man by himself is bound to be a martyr. The Slavs of the mountainous regions of the Balkans and of the Alps in their stubborn struggle with nature and with human enemies have clustered and still cluster to some extent in closely united and widely spreading brotherhoods (bratstva) and tribes (plemena). Some of these brotherhoods derive their names from a real or supposed common ancestor, and are composed of relatives as well as of affiliated strangers. They number sometimes hundreds of members, of guns, as the fighting males are characteristically called. Such are the

Vuktići, Kovacevići,—as one might say in Old English the Vukotings or Kovachevings,—of Montenegro. The dwellings, fields, and pasturages of these brotherhoods or kindreds are scattered over the country. But there was the closest union in war, revenge, funeral rites, marriage arrangements, provision for the poor and for those who stood in need of special help, as in case of fires, inundations and the like. And corresponding to this union there existed a strong feeling of unity in regard to property, especially property in land. Although ownership was divided among the different families, a kind of superior or eminent domain stretched over the whole of the bratstvo, and was expressed in the participation in common in pasture and wood, in the right to control alienations of land and to exercise pre-emption.

As the Welsh kindreds were subdivided into gavells formed of extended family communities, even so the Bosnian, Montenegrin, Serbian and Slovene tribes fell into house communities, *Kućas,* Zadrugas, which were built up on the principle of keeping blood-relatives and their property together as long as possible. They consisted generally of some 15 to 20 grown-up persons, some six or seven first and second cousins with their wives and children, living in a hamlet around the central house of the *domaćin,* the house leader. In some instances the number of coparceners increased to 50 or even to 70. The members of the united house community, which in fact is a small village or hamlet, joined in meals and work. Their rights in the undivided household of the hamlet were apportioned according to the pedigree, *i.e.,* this apportionment took account first of the stirpes or extant descendants of former scions of the family, so that, say, the offspring of each of two grandfathers who had been brothers were considered as equal sharers although the stirps, the stock, of one was represented only by one person, while the stirps of the other had grown to consist of two uncles and of three nephews all alive. There was no resettlement of shares, as in the case of Wales, but the life of the house community while it existed unbroken led to work in common, the contributions to which were regulated by common consent and supervised by the leader. Grounds, houses, implements of agriculture (ploughs, oxen, carts) and of viniculture — casks, cauldrons for the making of brandy, etc.— were considered to be common capital and ought not to be sold unless by common consent. Divisions were not prohibited. Naturally a family had to divide sooner or later, and the shares had to be made real, to be converted into fields and vineyards. But this was an event which marked, as it were, the close of the regular existence of one union and the birth of similar unions derived from it. As a rule, the *kuća* kept together as long as it could, because co-operation was needed and isolation dangerous — for economic considerations as well as for the sake of defence.

Attention, however, should be called more particularly to the parallel phenomena in the social history of the Russians, where the conditions seem to stand out in specially strong contrast with those prevailing among the mountain Slavs of the Balkans and of the Alps In the enormous extent of Russia we have to reckon with widely different geographical and racial areas, among others, with the Steppe settlements of the so-called Little Russians in the Ukraine, and the forest settlements of the Great Russians in the north. In spite of great divergencies the economic history of all these branches of Slavonic stock gravitates towards one main type, viz , towards rural unions of kinsmen, on the basis of enlarged households. In the south the typical village settlement is the dvoris'te, the big court or hamlet consisting of some four to eight related families holding together; in the north it is the *pećišće,* the big oven, a hamlet of somewhat smaller size in which three to five families are closely united for purposes of common husbandry.

Another fact to be noticed is the tendency to form artificial associations on the pattern of the prevailing unions of kinsmen. People who have no blood-relations to appeal to for clearing the waste, for providing the necessary capital in the way of cattle and plough implements, for raising and fitting out buildings, join in order to carry on these economic undertakings, and also to help each other against aggressors. The members of these voluntary associations, which at once call to mind German, Norse and English gilds, are called "siabri," "skladniki," and the gilds themselves "spólkíe," in south Russia. In a district of the Ukraine called the "Ratensky Sharostvo" there were no fewer than 278 such gilds interchanging with natural kindreds. The organization of all these unions could in no way be called patriarchal. Even in cases when there is a definite elder or headman (bolshoy), he was only the first among equals and exercised only a limited authority over his fellows: all the important decisions had to be taken by the council of the community.

In Great Russia, in the districts gathered under the sway of the Moscow tsars, the basis of the household community and of the rural settlements which sprang from it was modified in another direction. The entire agricultural population was subjected to strict supervision and coercive measures for purposes of military organization and taxation. Society was drilled into uniformity and service on the principle that every man has to serve the tsar, the upper class in war and civil administration, the lower class by agricultural labour. **A** consequence of the heavy burden laid on the land and of the growth of a landed aristocracy was a change in the management of land allotments. They became as much a badge of service and a basis for fiscal requirements as a means of livelihood. The result was the practice of reallotments according to the strength and the needs of different families. The shifting of arable (peredel) was not in this case a reapportionment of rights, but a consequence of the correspondence between rights and obligations.

Let us now pass to village communities in Teutonic countries, including England. A convenient starting-point is afforded by the social and economic conditions of the southern part of Jutland. The Saxon or Dithmarschen portion of this region gives us an opportunity of observing the effects of an extended and highly systematized tribal organization on Germanic soil. The independence of this northern peasant republic, which reminds one of the Swiss cantons, lasted until the time of the Reformation. We find the Dithmarschen organized in the 15th, as they had been in the 10th century, in a number of large kindreds, partly composed of relatives by blood and partly of "cousins" who had joined them. The membership of these kindreds is based on agnatic ties — that is, on relationship through males — or on affiliation as a substitute for such agnatic kinship. The families or households are grouped into brotherhoods, and these again to clans or "Schlachten" (Geschlechter), corresponding to Roman gentes. Some of them could put as many as 500 warriors in the field. They took their names from ancestors and chieftains: the Wollersmannen, Hennemannen, Jerremannen, etc.—*i.e.,* the men of Woll, the men of Henne, the men of Jerre. In spite of these personal names the organization of the clans was by no means a monarchical one: it was based on the participation of the full-grown fighting men in the government of each clan and on a council of co-opted elders at the head of the entire federation.

Let us notice the influence of this tribal organization on husbandry and property. The regular economic arrangement was an open-field one based on a three-field and similar systems. The furlongs were divided into intermixed strips with compulsory rotation on the usual pattern. And it is interesting to notice that in these economic surroundings indivisible holdings corresponding to the organic unities required for efficient agriculture arose of themselves. In spite of the equal right of all coheirs to an estate, this estate does not get divided according to their numbers, but either remains undivided or else falls into such fractions, halves or fourths, as will enable the farming to be carried on successfully. The Hufe or Hof goes mostly to the eldest son, but also sometimes to the youngest, while the brothers of the heir either remain in the same household with him, generally unmarried, or leave the house after having settled with their heir, who takes charge of the holding, as to an indemnity for their relinquished claims.

This evidence is of decisive importance in regard to the formation of unified holdings; we are on entirely free soil, with no vestige whatever of manorial organization or of coercion of tenants by the lord. The Hufe, the normal holding, is preserved intact in order to secure agricultural efficiency. This "Anerben" system is widely spread all through Germany. The question whether the eldest or the youngest succeeds is a subordinate one. In any case, manorial authority is not necessary to produce the limitation of the rights of succession to land and the creation of the system of holdings. although this has been often asserted, and one of the arguments for a servile origin of village communities turns on a supposed incompatibility between the unified succession and the equal rights of free coheirs.

We need not speak at any length about other parts of Germany, as space does not permit of a description of the innumerable combinations of communal and individual elements in German law, but we must point out some facts from the range of Scandinavian customs. In the mountainous districts of Norway we notice the same tendency toward the unification of holdings as in the plains and hills of Schleswig and Holstein. The bondrr of Gudbrandsdal and Telemark, the free peasantry tilling the soil and pasturing herds on the slopes of the hills from the days of Harald Haarfager to modern times, sit in *Ødalgaards*, or freehold estates, from which supernumerary heirs are removed on receiving some indemnity. and which are protected from alienation into strange hands by the privilege of pre-emption exercised by relatives of the seller. Equally suggestive are some facts on the Danish side of the straits: viz.. the arrangements of the bols which correspond to the hides and virgates of England and to the *Hufen* of Germany. Here again we have to do with normal holdings independent of the number of coheirs but dependent on the requirements of agriculture—on the plough and oxen, on certain constant relations betn-een the arable of an estate and its outlying commons. meadows and woods. The bol does not stand by itself like the Norwegian *gaard,* but is fitted into a very close union with neighbouring bols of the same kind. Practices of coaration, of open-field intermixture, of compulsory rotation of lot meadows, of stinting the commons, arise of themselves in the villages of Denmark and Sweden.

We catch a glimpse. to begin with, of a method of dividing fields which was considered archaic even in those early times, the so-called *forniskift* and *hamarskift.* The two principal features of this method are the irregularity of the resulting shapes of plots and the temporary character of their occupation. The first observation may be substantiated by a description such as that of Laasby in Jutland: "These lands are to that extent scattered and intermixed by the joint owners that it cannot be said for certain what (or how much) they are." Swedish documents, on the other hand. speak expressly of practices of shifting arable and meadows periodically. sometimes year by year.

Now the uncertainty of these practices based on occupation became in process of time a most inconvenient feature of the situation and evidently led to constant wrangling as to rights and boundaries. The description of Laasby quoted above ends with the significant remark: "They should be compelled to make allotment by the cord." This making of allotments by the cord is the process of *rebning,* from *reb,* the surveyor's cord. and the juridical procedure necessary for it was called solskift—because it was a division following the course of the sun.

The two fundamental positions from which this form of allotment proceeds are: (1) that the whole area of the village is common land (*faellesjord*), which has to be lotted out to the single householders; (2) that the partition should result in the creation of equal holdings of normal size (*bols*). In some cases we can actually recognize the effect of these allotments by ancient solskift in the 18th century. at a time when the Danish enclosure acts produced a second general revolution in land tenure.

The 12 oldest inhabitants, elected as sworn arbitrators for effecting the allotment, begin their work by throwing together into one mass all the grounds on-ned by the members of the community, including dwellings and farm buildings, with the exception of some privileged plots. There is a close correspondence between the sites of houses and the shares in the field. The first operation of the surveyors consists in marking out a village green for the night rest and pasture of the cattle employed in the tillage (*forta*), and assigning sites to the houses of the coparceners with orchards appendant to them (tofts), every householder getting exactly as much as his neighbour. From the tofts they proceed to the fields on the customary notion that the toft is the mother of the field. The fields are disposed into furlongs and shots. as they were called in England. and divided among the members of the village with the strictest possible equality. This is effected by assigning to every householder a strip in every one of the furlongs constituting the arable of the village. Meadows were often treated as lot meadows in the same way as in England. After such a solskift the peasants held their tenements in undisturbed ownership, but the eminent demesne of the village was recognized and a revision of the allotment mas possible.

After having said so much about different types of village communities which occur in Europe it will be easier to analyze the incidents of English land tenure which disclose the working of similar conceptions and arrangements. Features which have been very prominent in the case of the Welsh, Slavs, Germans or Scandinavians recur in the English instances sometimes with equal force and at other times in a mitigated shape.

There are some vestiges of the purely tribal form of community on English soil. Many Saxon and Anglian place names are derived from personal names, followed by the suffix ing, and closely resemble the common patronymics of Saxon and German families and kindreds. It is most probable, as Kemble supposed, that we have to do in most of these instances with tribal and family settlements, although the mere fact of belonging to a great landowner may have been at the root of some cases.

A very noticeable consequence of tribal habits in regard to landownership is presented by the difficulties which stood in the way of alienation of land by the occupiers of it. The Old English legal system did not originally admit of any alienation of folkland, land held by folkright, or, in other words. of the estates owned under the ordinary customary law of the people. Such land could not be bequeathed out of the kindred and could not be sold without the consent of the kinsmen. Such complete disabilities could not be upheld indefinitely, however, in a growing and progressive community. and we find the ancient folkright assailed from different points of view. The church insists on the right of individual possessors to give away land for the sake of their souls; the kings grant exemption from folkright and constitute privileged estates held by charter and following in the main the rules of individualized Roman law; the wish of private persons to make provision for daughters and to deal with land as with other commodities produces constant collisions with the customary tribal views. Already. by the end of the Saxon period, transfer and alienation of land make their way everywhere, and the Norman conquest brings these features to a head by substituting the notion of tenure—*i.e.*, of an estate burdened with service to a superior—for the ancient notion of tribal folkland.

But although the tribal basis of communal arrangements was shaken and removed in England in comparatively early times. it had influenced the practices of rural husbandry and landholding, and in the modified form of the village community it survived right through the feudal period, leaving characteristic and material traces of its existence down to modern times.

To begin with. the open-field system with intermixture of strips and common rights in pasture and wood was the prevailing system in England for more than 1.000 years. Under the name of champion farming it existed everywhere in the country until the Enclosure acts of the 18th and 19th centuries put an end to it; it could be found in operation even in modern times in some of its features in backward districts. It would have been absurd to build up these practices of compulsory rotation of crops. of a temporary relapse of plots into common pasture between harvest and ploughing time, of the interdependence of thrifty and negligent husbandmen, from the point of view of individual appropriation. On the other hand. it was the natural system for the apportionment of claims to the shareholders of an organic and perpetual joint-stock company.

Practices of shifting arable are seldom reported in English evidence. There are some traces of periodical redivisions of arable land in Northumberland: under the name of "runrig" such practices seem to have been not uncommon in the outer fields, the nonmanured portions, of townships in Scotland, both among the

Saxon inhabitants of the lowlands and the Celtic population of the highlands. The joining of small tenants for the purpose of coaration. for the formation of the big, heavy ploughs, drawn by eight oxen, sometimes caused a shifting in the possession of strips between the coparceners of the undertaking. But, as a rule, the arable was held in severalty by the different members of the township.

On the other hand, meadows were constantly owned by entire townships and distributed between the tenements entitled to shares from year to year by lot or according to definite order.

Let us, however, return for a moment to the arable. Although held in severalty by different owners it was subjected to all sorts of interference on the part of the village union as represented in later ages by the manorial court framing by-laws and settling the course of cultivation. It might also happen that in consequence of encroachments. disputes and general uncertainty as to possession and boundaries, the whole distribution of the strips of arable in the various fields had to be gone over and regulated anew. In such cases the strips were apportioned. not to single owners, but to the normal holdings, the hides, and the actual owners had to take them in proportion to their several rights in the hides. This point is very important. It gives the English village community its peculiar stamp. It is a community not between single members or casual households, but between definite holdings constructed on a proportional scale. Each hide or ploughland of a township took as much as every other hide, each virgate or yardland as every other yardland, each bovate or oxgang as every other oxgang. The yardland was almost everywhere one-fourth of the hide or ploughland, and corresponded to the share of two oxen in an eight-oxen plough; the oxgang was reckoned at one-half of the yardland, and corresponded to the share of one ox in the same unit of work.

The natural composition of the holdings has its counterpart, as in Schleswig-Holstein and as in the rest of Germany, in the custom of unified succession. The English peasantry worked out customary rules of primogeniture or of so-called Borough English or claim of the youngest to the land held by his father. The German examples already adduced teach us that the device is not suggested primarily by the interest of the landlord. Unified succession takes the place of the equal rights of sons. because it is the better method for preserving the economic efficiency of the household and of the tenement corresponding to it.

One more feature of the situation remains to be noticed, that is the *commons* which have survived the wholesale process of enclosure. They were an integral part of the ancient village community from the first, because there existed the most intimate connection between the agricultural and pastoral part of husbandry in the time of the open-field system. Pasture was not treated as a commodity by itself but was mostly considered as an adjunct, as appendant to the arable, and so was the use of woods and of turf. The problem of admeasurement of pasture was regulated by a reference to the proportional holdings, the hides. yardlands and oxgangs of the township, and the only question to be decided was how many heads of cattle and how many sheep each hide and yardland had the right to send to the common pasturage grounds.

When in course of time the open-field system and the tenure of arable according to holdings were given up, the right of freeholders and copyholders of the old manors in which the ancient townships were, as it were, encased, still held good, but it became much more difficult to estimate and to apportion such rights.

We may, in conclusion, summarize very briefly the principal results of our inquiry as to the history of European village communities. It seems that they may be stated under the following heads: (1) Primitive stages of civilization disclose in human society a strong tendency towards mutual support in economic matters as well as for the sake of defence. (2) The most natural form assumed by such unions for defence and co-operation is that of kinship. (3) In epochs of pastoral husbandry and of the beginnings of agriculture land is mainly owned by tribes, kindreds and enlarged households, while individuals enjoy only rights of usage and possession. (4) In course of time unions of neighbours are substituted for unions of kinsmen. (5) In Germanic societies the community of the township rests on the foundation of efficient holdings—bóls, hides, hufen—kept together as far as possible by rules of united or single succession. (6) The open-field system, nhich prevailed in the whole of Northern Europe for nearly a thousand years. was closely dependent on the customs of tribal and neighbourly unions. (7) The treatment of commons represents the last manifestations of ancient communal arrangements and it can only be reasonably and justly interpreted by reference to the law and practice of former times. (P. Vi.)

VILLAMEDIANA, COUNT DE (1580–1622), Spanish poet, was born at Lisbon, the son of a diplomatist He acquired a bad reputation as a gambler and was banished from court in 1608. On his return to Spain (1617) he proved himself a fearless, pungent satirist So great was the resentment caused by his envenomed attacks that he was once more ordered to withdraw from court in 1618 Appointed gentleman in waiting (1621) to Philip IV's young wife, Isabel de Bourbon, daughter of Henri IV, his ostentatious attentions to the queen supplied his numerous foes with a weapon which was destined to destroy him. A fire broke out while hii masque. La *Gloria* de *Niquea,* was being acted before the court on May 15, 1622, and Villamediana carried the queen to a place of safety. Suspicion deepened and on Xug. 21 he was murdered as he stepped out of his coach. The responsibility for his death aas divided between Philip IV and Olivares, and naturally the crime remained unpunished.

Villamediana's works contain not only the nervous, blighting verses which made him widely feared and hated, but a number of more serious poems embodying the most exaggerated conceits of gongorism But. even when adopting the perverse conventions of the hour. he remains a poet of high distinction, and his satirical verses. more perfect in form, are instinct with a cold, concentrated scorn which has never been surpassed.

VILLANELLE, in Italy nhere the term originated (Ital. *villanella* from *villano,* "peasant"), a rustic song; the term was used in France to designate a short poem of popular character favoured by poets in the late 16th century. Du Bellay's "Vanneur de Blé" and Philippe Desportes' "Rozette" are excellent examples of this early type of villanelle, unrestricted in form. Jean Passerat (d. 1602) left several villanelles, one of which became so popular that it set the pattern for later poets and, accidentally, imposed a rigorous and somewhat monotonous form: seven-syllable lines on two rhymes (the first feminine). distributed in (normally) five tercets and a final quatrain with line repetitions (indicated by numbered capitals and lines printed in italics below).

J'ai perdu ma tourterelle:	A^1
Est-ce point celle que j'oy?	b
Je veux aller après elle.	A^2
Tu regrètes ta femelle?	a
Helas! aussi fais-je moy:	b
J'ai perdu ma tourterelle.	A^1
Si ton amour est fidelle,	a
Aussi est ferme ma foy:	b
Je veux aller aprds elle.	A^2
Ta plainte se renouvelle?	a
Tousjours plaindre je me doy:	b
J'ai perdu ma tourterelle.	A'
En ne voyant plus la belle,	a
Plus rien de beau je ne voy;	b
Je veux aller après elle.	A^2
Mort que tant de fois j'appelle,	a
Pren ce qui se donne à toy:	b
J'ai perdu ma tourterelle,	A^1
Je veux aller après elle.	A^2

A villanelle double, composed of *sixains* with a final *huitain,* has also been used.

The villanelle was revived in the 19th century by Philoxène Boyer and J. Boulmier; the latter published collections in 1878 and 1879 and, at his death in 1881, left a third collection unfinished.

Théodore de Banville, Leconte de Lisle (two examples only) and, later, Maurice Rollinat also wrote villanelles. In England the revival of interest in French verse forms about *1877* attracted attention to the villanelle and it was cultivated by W. E. Henley, Austin Dobson. Andrew Lang and Edmund Gosse. Among Henley's numerous villanelles is "A dainty thing's the Villanelle," itself descriptive of the form. He and Dobson were also foremost in the writing of humorous villanelles.

See Théodore de Banville, *Petit traité de versification française* (1872) ; J. Boulmier, *Villanelles, . . . précedées d'une notice historique et critique* (1878). (F. J. WE.)

VILLANI, GIOVANNI (*c.* 1275–1348), Florentine chronicler, mas born at Florence of a mercantile family. and spent much of his early manhood in traveling on business in Italy. France and the Netherlands. He returned definitely to Florence before *1312.* and from *1316* onward held many important offices in his native city, and was employed on various diplomatic missions.

In his last years Villani was involved in the bankruptcy of the Bonaccorsi. and fell into poverty. He died in *1348* in the plague epidemic described by Boccaccio.

His *Historie Fiorentine,* or *Cronica universale,* begins with Biblical times and comes down to *1348.* The ground covered by the narrative, especially in the times near Villani's own, bears witness to the author's extensive travels and to the breadth of his mind. It is the cornerstone of the early medieval history of Florence. Villani was Guelph, but without passion; and his book is more taken up with an enquiry into what is useful and true than with party considerations. He is a chronicler, not a historian, and has but little method in his narrative. He provides information on the constitution of Florence, its customs. industries. commerce and arts; and of the chroniclers of his day he is perhaps unequaled for the value of his statistical data. The *Chronicle* has been printed by L. A. Muratori in tome xiii of the *Rerum Italicarum Scriptores* (Milan, 1728) and has been edited by I. Moutier and F. G. Dragomanni (Florence. *1844).*

Other editions appeared at Trieste (1857) and at Turin in *1879.* Selections have been translated into English by R. E. Selfe (2nd ed. *1906).*

VILLANOVANS, the name applied to the founders of an early Iron Age civilization in Italy, from the village of Villanova near Bologna. where in *1853* a typical cemetery was first discovered. The Villanovans branched from the cremating urn-field cultures of northern Europe and appeared in Italy, perhaps about 1000 B.C. Their characteristic cemeteries have been found in the Po valley from Bologna to Rimini, in Tuscany and. with certain differences. in northern Latium.

(See also ARCHAEOLOGY: *The Iron Age in Europe.)*

The cemeteries contain cremation burials almost exclusively, the ashes of the dead being normally deposited in a large jar of coarse. handmade pottery (*impasto),* which was placed in a round hole in the ground, sometimes enclosed in a rectangular cist of unhewn slabs. In the Po valley and in most of Tuscany the urn is almost universally of the distinctive biconical. or two storied, form, decorated with incised geometric patterns and covered with a shallow. single-handled bowl; in Tuscany the urn is occasionally covered with a bronze helmet with a high triangular crest or a pottery imitation of a helmet; in Villanovan cemeteries in Latium the biconical urn does not occur. but Latium shares with a feu- cemeteries of Tuscany the use of the terracotta hut urn, whose oval shape and pitched roof reproduce a primitive hut of wattle and daub over a frame of poles. The hut urn is characteristic of northern European urn fields, the helmet of western Europe; the two-storied urn may be related to similar types found in Hungary and Rumania.

FIG. 2.—LATE VILLANOVAN TRIPOD, WITH BRONZE HORSEMEN FORMING THE BASE: VETULONIA

The cremation burials of Latium (the Alban hills and the Roman forum) seem to be the earliest; very little metal of any kind was found in the graves. and only an occasional glass or amber bead. In Tuscany metalworking became a fine art; helmets, shields. swords of northern European and Greek types, belts and vessels of many shapes, all decorated with *repoussé* bosses and incision in geometric designs have been found in quantity. In the second half of the 8th century the Villanovans of Tuscany were strongly influenced by Greece: wheel-made painted pottery in imitation of Greek Geometric wares and cast-bronze figures in a style recalling that of Geometric Greece suggest the actual presence of Greek settlers in Tuscany. In this period inhumation became the predominant burial rite. as it did during the same period in Greece.

During the first quarter of the 7th century an orientalizing civilization, presumably introduced by the Etruscans, mas superimposed on the Villanovan in Tuscany and the amalgamation of this and the Villanovan produced, by the end of the 7th century, the Etruscan culture of historic times. The northern Villanovans of the Po valley, however, continued to produce a geometric art closely related to that of pre-Etruscan Tuscany as late as the last quarter of the 6th century, when Etruscan expansion into the Po valley obliterated their civilization.

VILLANUEVA Y GELTRÚ, a seaport of northeast Spain. in Barcelona province: on the Barcelona-Tarragona section of the coast railway. Pop. (1950) *19.555* (mun.). It is a modern town, with manufactures of cotton, woolen and linen goods, and of paper. It has also iron foundries and an important agricultural trade. The harbour affords safe and deep anchorage; it is a lifeboat station and the headquarters of a large fishing fleet. The coasting trade is also considerable. Villanueva has a museum. founded by the Catalan poet and historian, Yictor Balaguer (1824–1901), which contains a large library, including not only numerous historical works but also many valuable mss.

VILLARD, HENRY (1835–1900), American journalist and financier, was born in Speyer, Rhenish Bavaria, Apr. 10, 1835 He emigrated to America in 1853 end engaged in journalistic work for German-American newspapers and later for leading American dailies. He reported the Lincoln-Douglas debates for eastern newspapers, the Pikes Peak gold rush for the Cincinnati *Daily Commercial* and the Civil War from the field of action for the New York *Herald* and New Tork *Tribune*. In 1881 he purchased the *Nation* and the New York *Evening Post*.

Through acting as agent for German bondholders he became interested in railway finance. In 1875 he aided in reorganizing the Oregon and California Railroad and the Oregon Steamship company and in 1876 became president of both companies. He was receiver of the Kansas Pacific Railroad in 1876–78. In 1879 he organized the Oregon Railway and Navigation Company which built a line along the Columbia river from Portland to Wallula. In 1881 Villard secured control of the Northern Pacific and became its president. Its transcontinental line was completed under his management but the costs so far exceeded the estimate that both Villard and the road became insolvent in 1883 and Villard was removed from the presidency. He later recouped his losses so that from 1889–1893 he served as chairman of the board of directors of the same company. In 1890 he bought the Edison Lamp Co. at Newark, N.J., and the Edison Machine Works at Schenectady, N Y., and formed them into the Edison General Electric Co. of which he was president until its reorganization in 1893 as the General Electric Co. He died at Dobbs Ferry, N.Y., Nov. 12, 1900.

See *Memoirs of Henry Villard* (2 vols., 1904).

VILLARD DE HONNECOURT, French architect of the first half of the 13th century, whose architectural drawings give a clear insight into the working processes of a medieval workshop, was a native of Honnecourt. in Picardie. Villard's only documentary work is his sketchbook—preserved in the Bibliotheque Nationale, Paris—a fragment of 33 folios with about 325 drawings. It contains a treatise on different subjects, a "livre de portraiture" ("book of portraiture") as Villard himself calls it. Planned partly as a modelbook and partly as lodgebook for construction, it employs geometrical schemes as guiding lines instead of arithmetical measurement. In it Honnecourt demonstrates how to construct ground plans and elevations of Gothic buildings, church furniture, ornaments and ehgines, and depicts human and animal bodies by applying geometrical forms such as the pentagram, quadrangle, triangle and circle "for easy enlargement." As an architect of his time Villard had to combine the skill of a mason and draftsman and a knowledge of engineering with extensive architectural training.

Commissions and journeys led him into Switzerland and Hungary. The places he visited are recorded in the drawings and their explanatory notes: Vaucelle, Cambrai, Meaux, Laon, Reims, Chartres and Lausanne.

See H. R. Hahnloser, *Villard de Honnecourt, kritische Gesamtausgabe des Bauhüttenbuches* (1935) ; P. Frankl, *The Gothic: Literary Sources and Interpretations* (1959). (JA. W.-F.)

VILLARI, PASQUALE (1827–1917), Italian historian and statesman, born at Naples, Oct. 3, 1827, studied with Luigi la Vista under, Francesco de Sanctis. Implicated in the riots of May 15. 1848, at Naples, against the Bourbon government, he took refuge in Florence where he published his *Storia di Girolamo Savonarola e de' suoi tempi* (2 vol., 1859–61). It was followed by a work of even greater critical value, *Niccolò Machiavelli e i suoi tempi* (1877–82). Both these works have been through many editions, the latest in 1927. Meanwhile Villari had been professor of history at Pisa, and then obtained the chair of philosophy of history at the Institute of Studii Superiori in Florence. He was also a member of the council of education (1862), and in 1869 was made undersecretary of state for education. In 1884 he was nominated senator, and in 1891–92 minister of education. His collected essays on Florentine history were published as *I primi due secoli della storia di Firenze* (1893–94), and in 1901 his *Le invasioni barbariche in Italia,* a popular account of the events following the dissolution of the Roman empire. All these works have been translated into English by his wife. Villari died at Florence on Dec. 5, 1917. Villari's historical, political and social writings exercised a deep influence on his generation, and most of the Italian historians of today have been his pupils.

His other works include: *Saggi critici* (1868) ; *Arte, storia, e filosofia* (1884); *Scritti varii* (1894); another volume of *Saggi critici* (1896) ; *Discussioni critiche e discorsi* (190j), containing his speeches as president of the Dante Alighieri society; *Lettere meridionali* containing the first exposure of conditions in south Italy (1885); *Scritti sulla questzone sociale in Italia* (1902); *L'Italia da Carlo Magno alla morte di Arrigo VII* (1910; Eng. trs. 1910) ; and *Storia, politica e istruzione* (1914).

See F. Baldasseroni, *Pasquale Villari* (1907).

VILLARREAL, a town of eastern Spain, in the province of Castellón de la Plana; 4 mi. from the Mediterranean sea, near the right bank of the river Mijares. Pop. (1950) 20,871 (mun.). Under Moorish rule, and up to the expulsion of the Moriscoes in 1609, it was the headquarters of a flourishing trade. There are extensive orange groves, watered by the irrigation canal of Castellón. which is a good example of Moorish engineering skill. There are manufactures of paper, woolen goods and spirits.

VILLARRICA, a city of Paraguay. Population (1950) 14,680 It is the capital of the department of Guairá (pop. 90,308). Villarrica is situated on the Paraguay Central railway 90 mi. east of the capital; it is also connected with Asunción by the highway known as the Mariscal Estigarribia route. The city is in a fertile agricultural region, surrounded by wooded mountains. Principal products of this area are yerba mate, sugar cane, cotton and tobacco (W. Ft.)

VILLARS, CLAUDE LOUIS HECTOR DE, Prince de Martignes, Marquis and Duc de Villars and Vicomte de Melun (1653–1734), marshal of France, one of the greatest generals of French history, was born at Moulins on May 8, 1653, and entered the army through the corps of pages in 1671. He served in the light cavalry in the Dutch wars, and distinguished himself by his daring and resourcefulness. But in spite of a long record of excellent service under Turenne, Condé and Luxembourg, and of his aristocratic birth, his promotion was but slow, for he had incurred the enmity of the powerful Louvois, and although he had been proprietary colonel *(mestre de camp)* of a cavalry regiment since 1674, thirteen years elapsed before he was made a *maréchal de camp*. In the interval between the Dutch wars and the formation of the League of Augsburg, Villars was employed in an unofficial mission to the court of Bavaria, and there became the constant companion of the elector, with whom he took the field against the Turks and fought at Mohacs. He returned to France in 1690 and was given a command in the cavalry of the army in Flanders, but towards the end of the Grand Alliance War he went to Vienna as ambassador. His part in the next war *(see* Spanish Succession, War of the), beginning with Friedlingen (1702) and Hochstett (1703) and ending with Denain (1712), has made him immortal. For Friedlingen he received the marshalate, for the pacification of the insurgent Cévennes the Saint-Esprit order and the title of duke. Friedlingen and Hochstett were barren victories, and the campaigns of which they formed a part, records of lost opportunities. Villars's glory thus begins with the year 1709 when France, apparently helpless, was roused to a great effort of self-defence by the exorbitant demands of the Coalition. In that year he was called to command the main army opposing Eugene and Marlborough on the northern frontier. During the famine of the winter he shared the soldiers' miserable rations. When the campaign. opened the old Marshal Boufflers volunteered to serve under him, and after the terrible battle of Malplaquet (*q.v.*), in which he was gravely wounded, he was able to tell the king: "If it please God to give your majesty's enemies another such victory, they are ruined." Two more campaigns passed without a battle and with scarcely any advance on the part of the invaders, but at last Marlborough manoeuvred Villars out of the famous Ne *plus ultra* lines, and the power of the defence seemed to be broken. But Louis made a last effort, the English contingent and its great leader were withdrawn from the enemy's camp, and Villars, though still suffering from his Malplaquet wounds, outmanoeuvred and decisively defeated Eugene in the battle of Denain. This victory saved France, though the war dragged on for another year on the Rhine, where Villars took Landau, led the stormers at Freiburg and negotiated the peace of Rastatt with Prince Eugene.

He played a conspicuous part in the politics of the Regency period as the principal opponent of Cardinal Dubois, and only the memories of hlontmorency's rebellion prevented his being made constable of France. He took the field for the last time in the War of the Polish Succession (1734), with the title "marshal-general of the king's armies," that Turenne alone had held before him But he was now over eighty years of age, and the war was more diplomatic than earnest, and after opening the campaign with all the fire and restless energy of his youth he died at Turin on June 17, 1734.

Villars' memoirs show us a "fanfaron plein d'honneur," as Voltaire calls him. He was indeed boastful, with the gasconading habit of his native province, and also covetous of honours and wealth. But he was an honourable man of high courage, moral and physical, and a soldier who stands above all his contemporaries and successors in the 18th century, on the same height as Marlborough and Frederick.

The memoirs, part of which was published in 1734 and afterwards several times republished in untrustworthy versions, were for the first time completely edited by the Marquis de Vogue in 1884–92.

VILLARS (VILLARS-SUR-OLLON), a Swiss winter sports centre, frequented in summer also, situated at over 4,100ft. above sea-level, on a narrow gauge railway that branches from the Lausanne-Brig main line at Bex, about 8½m. beyond the point at which the railway leaves the Lake of Geneva. It is some distance above Gryon and commands a fine view of the Dent du Midi and the western Alps, and the Grand Muveran (3,061 metres) nearby. The railway runs on to Chesières, another resort which, in its turn, has road vehicles to Ollon, a station on the light railway from Monthey, which joins the Lausanne-Brig main line at Aigle.

VILLAVICIOSA, a seaport of northern Spain, in the province of Oviedo; on the Rio de Villaviciosa, an estuary formed by the small river Villaviciosa which here enters the Bay of Biscay. Pop. (1940) 2,219 (mun., 22,029). The town is the headquarters of a large fishery, and has some coasting trade. Its exports are chiefly agricultural produce.

VILLEFRANCHE, a manufacturing town of east-central France, capital of an arrondissement in the department of Rhône, on the Morgon river near its junction with the Saône, 21 mi. N. by W. of Lyons by rail. Population (1936) 18,603. Founded in 1212 by Guichard IV, count of Beaujeu, Villefranche became in the 14th century capital of the Beaujolais. Edward II was forced to surrender the Beaujolais to the duke of Bourbon. Among its industries the chief are the manufacture of working clothes, the manufacture, dyeing and finishing of cotton fabrics, including surgical dressings, linings, the spinning of cotton thread, copper founding and the manufacture of machinery and agricultural implements. The wines of Beaujolais, hemp, cotton cloth, linen, cotton thread, drapery goods and cattle are the principal articles of trade. An old Renaissance house is used as the town hall. The 15th century church of Notre-Dame des Marais has a 16th century tower and spire (rebuilt in 1862), standing to the right of the façade. Villefranche is the seat of a sub-prefect and has a tribunal of commerce and a chamber of commerce.

VILLEFRANCHE-DE-ROUERGUE, a town of France, capital of an arrondissement in the department of Aveyron, 36 mi. W. of Rodez by road. Pop. (1936) 6,852. Villefranche, founded about 1252, owes its name to the numerous immunities granted by its founder Alphonse, count of Toulouse (d. 1271), and in 1348 it was so flourishing that sumptuary laws were passed. Soon afterwards the town fell into the hands of Edward, the Black Prince, but was the first place in Guienne to rise against the English. New privileges were granted to the town by King Charles V, but these were taken away by Louis XI. In 1588 the inhabitants repulsed the forces of the League. Villefranche, which has a station on the Orléans railway, lies among the hills on the right bank of the Aveyron at its junction with the Alzou. One of the three bridges that cross the river is of the 13th century, and there are many houses of the 13th and 14th centuries. The church of Notre-Dame is flanked by a massive tower, beneath the porch of which passes one of the chief streets. The fine woodwork in the choir dates from the 15th century. The 15th and 16th century buildings (notably the fine refectory and two cloisters, the smaller a gem of late Gothic work) of a Carthusian monastery stand above the town on the left bank of the Aveyron. Quarries of phosphates and mines of galena and blende are worked near Villefranche. Villefranche is an agricultural centre with minor industries, and is the seat of a sub-prefect.

VILLEHARDOUIN, GEOFFROY DE (*c.* 1160–*c.* 1213), the first vernacular historian of France, and perhaps of modern Europe, who possesses literary merit, is rather supposed than known to have been born at the chhteau from which he took his name, near Troyes, in Champagne, about the year 1160. Not merely his literary and historical importance, but almost all that is known about him, comes from his chronicle of the fourth crusade, or *Conquête de Constantinople.* He was one of a list of knights of Champagne who with their count, Thibault, took the cross at a tournament held at Escry-sur-Aisne in Advent 1199. The next year six deputies, two appointed by each of the three allied counts of Flanders, Champagne and Blois, were despatched to Venice to negotiate for ships. Of these deputies Villehardouin was one and Quesnes de Béthune, the poet, another. They concluded a bargain with the seigniory for transport and provisions at a fixed price. Villehardouin had hardly returned when Thibault fell sick and died. Villehardouin made another embassy into Italy to prevent if possible some of his fellow-pilgrims from breaking the treaty with the Venetians by embarking at their ports and employing other convoy.

Villehardouin does not tell us of any direct part taken by himself in the debates on the question of interfering or not in the disputed succession to the empire of the East—debates in which the chief ecclesiastics present strongly protested against the diversion of the enterprise from its proper goal. It is quite clear, however, that the marshal of Champagne, who was one of the leaders and inner counsellors of the expedition throughout, sympathized with the majority, and it is fair to point out that the temptation of chivalrous adventure was probably as great as that of gain. He narrates spiritedly enough the dissensions and discussions in the winter camp of Zara and at Corfu, but is evidently much more at ease when the voyage was again resumed, and, after a fair passage round Greece, the crusaders at last saw before them the great city of Constantinople which they had in mind to attack.

When the assault was decided upon, Villehardouin himself was in the fifth "battle," the leader of which was Mathieu de Montmorency. But he does not tell us anything of his own prowess. After the flight of the usurper Alexius, and when the blind Isaac, whose claims the crusaders were defending, had been taken by the Greeks from prison and placed on the throne, Villehardouin, with Montmorency and two Venetians, formed the embassy sent to arrange terms. He was again similarly distinguished when it became necessary to remonstrate with Alexius, the blind man's son and virtual successor, on the non-keeping of the terms. Indeed Villehardouin's talents as a diplomatist seem to have been held in very high esteem, for later, when the Latin empire had become a fact, he was charged with the delicate business of mediating between the emperor Baldwin and Boniface, marquis of Montferrat, in which task he had at least partial success. He was also appointed marshal of "Romanie"—a term very vaguely used, but apparently signifying the mainland of the Balkan Peninsula, while his nephew and namesake, afterwards prince of Achaia, took a great part in the Latin conquest of Peloponnesus.

Villehardouin himself before long received an important command against the Bulgarians. He was left to maintain the siege of Adrianople when Baldwin advanced to attack the relieving force, and with Dandolo had much to do in saving the defeated crusaders from utter destruction, and in conducting the retreat, in which he commanded the rearguard, and brought his troops in safety to the sea of Rodosto, and thence to the capital. As he occupied the post of honour in this disaster, so he had that (the command of the vanguard) in the expedition which the regent Henry made shortly afterwards to revenge his brother Baldwin's defeat and capture. And, when Henry had succeeded to the crown on the announcement of Baldwin's death, it was Villehardouin who fetched home his bride Agnes of Montferrat, and shortly afterwards commanded under him in a naval battle with the ships of Theodore Lascaris at the fortress of Cibotus. In the settlement of the Latin empire after the truce with Lascaris, Villehardouin received the fief of Messinople from Boniface of Montferrat, with the record of whose death the chronicle abruptly closes.

Villehardouin reappears for us once, but once only, in the chronicle of his continuator, Henri de Valenciennes. There is a great gap in style, though none in subject, between the really poetical prose of the first historian of the fifth crusade and the Latin empire and the awkward mannerism (so awkward that it has been taken to represent a "disrhymed" verse chronicle) of his follower. But the much greater length at which Villehardouin appears on this one occasion shows us the restraint which he must have exercised in the passages which deal with himself in his own work. He again led the vanguard in the emperor Henry's expedition against Burilas the Bulgarian, and he is represented by the Valenciennes scribe as encouraging his sovereign to the attack in a long speech. Then he disappears altogether, with the exception of some brief and chiefly diplomatic mentions. Du Cange discovered and quoted a deed of donation by him dated 1207, by which certain properties were devised to the churches of Notre Dame de Foissy and Notre Dame de Troyes, with the reservation of life interests to his daughters Alix and Damerones, and his sisters Emmeline and Haye, all of whom appear to have embraced a monastic life. A letter addressed from the East to Blanche of Champagne is cited, and a papal record of 1212 styles him stiil "marshal of Romania." The next year this title passed to his son Erard; and 1213 is accordingly given as the date of his death.

It would be out of place to attempt any further analysis of the *Conquête* here. But it is not impertinent, and is at the same time an excuse for what has been already said, to repeat that Villehardouin's book, brief as it is, is in reality one of the capital books of literature, not merely for its merit, but because it is the most authentic and the most striking embodiment in contemporary literature of the sentiments which determined the action of a great and important period of history. There are but very few books which hold this position, and Villehardouin's is one of them. If every other contemporary record of the crusades perished, we should still be able by aid of this to understand and realize what the mental attitude of crusaders, of Teutonic knights, and the rest was, and without this we should lack the earliest, the most undoubtedly genuine, and the most characteristic of all such records. The very inconsistency with which Villehardouin is chargeable, the absence of compunction with which he relates the changing of a sacred religious pilgrimage into something by no means unlike a mere filibustering raid on the great scale, add a charm.

The book appears to have been known in the ages immediately succeeding his own; and, though there is no contemporary manuscript in existence, there are some half-dozen which appear to date from the end of the 13th or the course of the 14th century, while one at least appears to be a copy made from his own work in that spirit of unintelligent faithfulness which is much more valuable to posterity than more pragmatical editing. The first printed edition of the book, by a certain Blaise de Vigenère, dates from 1585, is dedicated to the seigniory of Venice (Villehardouin, it should be said, has been accused of a rather unfair predilection for the Venetians), and speaks of either a part or the whole of the memoirs as having been printed twelve- years earlier. Of this earlier copy nothing seems to be known, A better edition, founded on a Netherlandish ms., appeared at Lyons in 1601. But both these were completely antiquated by the great edition of Du Cange in 1657, wherein that learned writer employed all his knowledge, never since equalled, of the subject, but added a translation, or rather paraphrase, into modern French which is scarcely worthy either of himself or his author. Dom Brial gave a new edition from different ms. sources in 1823, and the book figures with different degrees of dependence on Du Cange and Brial in the collections of Petitot, Buchon, and Michaud and Poujoulat.

All these, however, have been superseded for the modern student by the editions of Natalis de Wailly (1872 and 1874), in which the text is critically edited from all the available mss. and a new translation added, while there is a still later and rather handier one by E. Bouchet (2 vols., Paris, 1891), which, however, rests mainly on N. de Wailly for text. The charm of Villehardouin can escape no reader; but few readers will fail to derive some additional pleasure from the two essays which Sainte-Beuve devoted to him, reprinted in the ninth volume of the *Causeries du lundi*. *See* also A. Debidour, *Les Chroniqueurs* (1888). There are English translations by T. Smith (1829), and (more literally) Sir F. T. Marzials (Everyman's Library, 1908).

VILLEINAGE (Villainage, Villenage), a mediaeval term (from *villa, villanus*), pointing to serfdom, a condition of men fntermediate between freedom and slavery. It occurs in France as well as in England, and was certainly imported into English speech through the medium of Norman French.

The materials for the formation of the villein class were already in existence in the Anglo-Saxon period. On the one hand, the Saxon ceorls (*twihyndemen*), although considered as including the typical freemen in the earlier laws (Aethelberht, Hlothhere and Edric, Ine), gradually became differentiated through the action of political and economic causes, and many of them had to recognize the patronage of magnates or to seek livelihood as tenants on the estates of the latter. These ceorls, sitting on gafolland, were, though personally free, considered as a lower order of men, and lapsed gradually into more or less oppressive subjection to the lords of whom they held their land. It is characteristic in this connection that the West Saxon laws do not make any distinction between ceorls and laets or half-freemen as the Kentish laws had done: this means that the half-free people were, if not Welshmen, reckoned as members of the ceorl class. Another remarkable indication of the decay of the ceorl's estate is afforded by the fact that in the treaties with the Danes the twihynde ceorls are equated with the Danish leysings or freedmen. It does not mean, of course, that their condition was practically the same, but in any case the fact testifies to the gulf which had come to separate the two principal subdivisions of the free class —the ceorl and the thegn. The Latin version of the *Rectitudines Singularum Personarum*, a document compiled probably in the 11th century, renders *geneat* (a peasant tenant of a superior kind performing lighter services than the gebur, who was burdened with heavy week-work) by *villanus;* but the gebur came to be also considered as a *villanus* according to Anglo-Norman terminology. The group designated as *geburs* in Anglo-Saxon charters, though distinguished from mere slaves, undoubtedly included many freedmen who in point of services and economic subjection were not very much above the slaves. Both ceorls and geburs disappear as separate classes, and it is clear that the greater part of them must have passed into the rank of villeins.

In the terminology of the Domesday Inquest we find the villeins as the most numerous element of the English population. Out of about 240,000 households enumerated in Domesday 100,000 are marked as belonging to villeins. They are rustics performing, as a rule, work services for their lords. But not all the inhabitants of the villages were designated by that name. Villeins are opposed to socmen and freemen on one hand, to *bordarii*, cottagers and slaves on the other. The distinction in regard to the first two of these groups was evidently derived from their greater freedom, although the difference is only one in degree and not in kind. In fact, the villein is assumed to be a person free by birth, but holding land of which he cannot dispose freely. The distinction as against *bordarii* and cottagers is based on the size of the holding: the villeins are holders of regular shares in the village —that is, of the virgates, bovates or half-hides which constitute the principal subdivisions in the fields and contribute to form the plough-teams—whereas the *bordarii* hold smaller plots of some five acres, more or less, and *cottarii* are connected with mere cottages and crofts. Thus the terminology of Domesday takes note of two kinds of differences in the status of rustics: a legal one in connection with the right to dispose of property in land, and an economic one reflecting the opposition between the holders of shares in the fields and the holders of auxiliary tenements. The feature of personal serfdom is also noticeable, but it provides a basis only for the comparatively small group of *servi,* of whom only about 25,000 are enumerated in Domesday Book. The contrast between this exceptionally situated class and the rest of the population shows that personal slavery was rapidly disappearing in England about the time of the Conquest. It is also to be noticed that the Domesday Survey constantly mentions the *terra villanorum* as opposed to the lord's demesne, and that the land of the rustics is taxed separately for the geld, so that the distinction between the property of the lord and that of the peasant dependent on him is clearly marked.

The Domesday Survey puts before us the state of things in England as it was at the very beginning of the Norman and at the close of the Saxon period. The development of feudal society, of centralizing kingship and ultimately of a system of common law, brought about great changes which all hinge on the fundamental fact that the kings, while increasing the power of the State in other respects, surrendered it completely as regards the relations between the peasants and their lords. The protection of the assizes was tendered in civil matters to free tenants and refused to villeins. The royal courts refused to entertain suits of villeins against their lords, although there was a good deal of vacillation before this position was definitely taken up. Bracton speaks in his treatise of the possibility of interference by the courts against intolerable cruelty on the part of the lord involving the destruction of the villein's waynage, that is, of his tillage, and in the *Notebook* of Bracton may be found a couple of cases which prove that 13th century judges occasionally allowed themselves to entertain actions by persons holding in villeinage against their lords. Gradually, however, the exception of villeinage became firmly settled. As the historical and practical position was developing on these lines the lawyers who fashioned English common law in the 12th and 13th centuries did not hesitate to apply to it the teaching of Roman law on slavery. Bracton fits his definition of villeinage into the Romanesque scheme of Azo's *Summa* of the Institutes, and the judges of the royal courts made sweeping inferences from this general position. To begin with, the relation between the villein and his lord was regarded as a personal and not a praedial one. Everyone born of villein stock belonged to his master and was bound to undertake any service which might be imposed on him by the master's or the steward's command. The distinction between villeins in gross and villeins regardant, of which much is made by modern writers, was suggested by modes of pleading and does not make its appearance in the Year-Books before the 15th century. Secondly, all independent proprietary rights were denied to the villein as against his lord, and the legal rule "quicquid servo acquiritur domino acquiritur" was extended to villeins. The fact that a great number of these serfs had been enjoying protection as free ceorls in former ages made itself felt, however, in three directions. (1) In criminal matters the villein was treated by the King's Court irrespectively of any consideration as to his debased condition. More especially the police association, organized for the keeping of the peace and the presentation of criminals—the frankpledge groups—were formed of all "worthy of were and wite," villeins as well as freemen. (2) Politically the villeins were not eliminated from the body of citizens; they had to pay taxes, to serve in great emergencies in the militia, to serve on inquests, etc., and although there was a tendency to place them on a lower footing in all these respects yet the fact of their being lesser members of the commonwealth did not remove the fundamental qualification of citizenship. (3) Even in civil matters villeins were deemed free as regards third persons. They could sue and be sued in their own name, and although they were able to call in their lords as defendants when proceeded against, there was nothing in law to prevent them from appearing in their own right. The state even afforded them protection against extreme cruelty on the part of their masters in respect of life and limb, but in laying down this rule English lawyers were able to follow the precedents set by late Roman jurisprudence, especially by measures of Hadrian, Antonine and Constantine the Great.

There was one exception to this harsh treatment of villeins. The rustic tenantry in manors of *ancient demesne,* that is, in estates which had belonged to the crown before the Conquest. had a standing-ground even against their lords as regards the tenure of their plots and the fixity of their services. Technically this right was limited to the inhabitants of manors entered in the Domesday Survey as *terra regis* of Edward the Confessor. On the other hand the doctrine became effective if the manors in question had been granted by later kings to subjects, because if they remained in the hand of the king the only remedy against ejectment and exaction lay in petitioning for redress without any definite right to the latter. If, however, the two conditions mentioned were forthcoming, villeins, or, as they were technically called, villein socmen of ancient demesne manors, could resist any attempt of their lords to encroach on their rights by depriving them of their holdings or increasing the amount of their customary services. Their remedy was to apply for a little writ of right in the first case and for a writ of *monstraverunt* in the second. These writs entitled them to appear as plaintiffs against the lord in his own manorial court and, eventually, to have the question at issue examined by way of appeal, on a writ of error, or by reservation on some legal points in the upper courts of the king. A number of cases arising from these privileges of the men of ancient demesne are published in the *Notebook* of Bracton and in the *Abbreviatio placitorum.* This exceptional procedure does not simply go back to the rule that persons who had been tenants of the king ought not to have their condition altered for the worse in consequence of a royal grant. If this were the only doctrine applicable in the case there would be no reason why similar protection should be denied to all those who held under grantees of manors escheated after the Conquest. A material point for the application of the privilege consists in the fact that ancient demesne has to be proved from the time before the Conquest, and this shows clearly that the theory was partly derived from the recognition of tenant right in villeins of the Anglo-Saxon period who, as we have said above, were mostly ceorls, that is, freeborn men.

In view of the great difference in the legal position of the free man and of the villein in feudal common law, it became very important to define the exact nature of the conditions on which the status of a villein depended. The legal theory as to these conditions was somewhat complex. Of course, persons born from villein parents in lawful wedlock were villeins, but as to the condition of illegitimate children there was a good deal of hesitation. There was a tendency to apply the rule that a bastard follows the mother, especially in the case of a servile mother. In the case of mixed marriages, the condition of the child was determined by the free or villein condition of the tenement in which it was born. This notion of the influence of the tenement is in accord with feudal ideas and makes itself felt again in the case of the pursuit of a fugitive villein. He can be seized without further formalities if he is caught in his "nest," that is, in his native place. If not, the lord can follow him in fresh pursuit for four days; once these days are past, the fugitive is maintained provisionally in possession of his liberty, and the lord has to bring an action *de nativo habendo* and has to assume the burden of proof.

So much as to the proof of villeinage by birth or previous condition. But there were numbers of cases when the discussion as to servile status turned not on these formal points but on an examination of the services performed by the person claimed as a villein or challenged as holding in villeinage. In both cases the courts had often recourse to proof derived not from direct testimony but from indirect indications as to the kind of services that had been performed by the supposed villein. Certain services, especially the payment of *merchet*—the fine for marrying a daughter—were considered to be the badge of serfdom. Another service, the performance of which established a presumption as to villeinage, was compulsory service as a reeve. The courts also tried to draw a distinction from the amount and regularity of agricultural services to which a tenant was subjected. Bracton speaks of the contrast between the irregular services of a serf, "who could not know in the evening what he would have to do in the morning," and services agreed upon and definite in their amount. The customary arrangements of the work of villeins, however, render this contrast rather fictitious. The obligations of downright villeins became so far settled and regular that one of the ordinary designations of the class was *custumarii.* Therefore in most cases there were no arbitrary exactions to go by, except perhaps one or the other tallage imposed at the will of the lord. The original distinction seems to have been made not between arbitrary and agreed but between occasional services and regular agricultural week-work. While the occasional services, even when agricultural, in no way established a presumption of villeinage, and many socmen, freemen and holders by serjeanty submitted to them, agricultural week-work was primarily considered as a trait of villeinage and must have played an important part in the process of classification of early Norman society.

This point brings us to consider the matter-of-fact conditions of the villeins during the feudal period, especially in the 12th, 13th and 14th centuries. As is shown by the Hundred Rolls and countless other records of the same kind, the customary conditions of villeinage did not tally by any means with the identification of villeinage with slavery suggested by the jurists. It is true that in nomenclature the word *servi* is not infrequently used (*e.g.,* in the Hundred Rolls) where *villani* might have been mentioned, and the feminine *nief (nativa)* appears as the regular parallel to *villanus,* but in the descriptions of usages and services we find that the power of the lord loses its discretionary character and is in every respect moderated by custom. As personal dependents of the lord native villeins were liable to be sold, and we find actual sales recorded: Glastonbury Abbey, *e.g.,* sells a certain Philipp Hardyng for 20 shillings. But such transfers of human chattels occur seldom, and there is nothing during the English feudal period corresponding to the brisk trade in men characteristic of the ancient world. *Merchet* was regarded as a badge of serfdom in so far as it was said to imply a "buying of one's own blood" *(servus de sanguine suo emendo).* The explanation is even more characteristic than the custom itself, because fines on marriage might be levied and were actually levied on people of different condition, on the free as well as on the serf. Still the tendency to treat *nterchet* as a distinctive feature of serfdom has to be noted, and we find that the custom spread for this very reason in consequence of the encroachments of powerful lords; in the Hundred Rolls it is applied indiscriminately to the whole rustic population of certain hundreds in a way which can hardly be explained unless by artificial extension. *Heriot,* the surrender of the best horse or ox, is also regarded as the common incident of villein tenure, although, of course, its very name proves its intimate connection with the outfit of soldiers *(here-geatu).*

Economically the institution of villeinage was bound up with the manorial organization—that is, with the fact that the country was divided into a number of districts in which central home farms were cultivated by work supplied by villein households.

The most important of villein services is the *week-work* performed by the peasantry. Every virgater or holder of a bovate has to send a labourer to do work on the lord's farm for some days in the week. Three days is indeed the most common standard for service of this kind, though four or even five occur sometimes, as well as two. It must be borne in mind in the case of heavy charges, such as four or five days' week-work, that only one labourer from the whole holding is meant, while generally there were several men living on every holding—otherwise the service of five days would be impossible to perform. In the course of these three days, or whatever the number was, many requirements of the demesne had to be met. The principal of these was *ploughing the fields* belonging to the lord, and for such ploughing the peasant had not only to appear personally'as a labourer, but to bring his oxen and plough, or rather to join with his oxen and plough in the work imposed on the village; the heavy, costly plough with a team of eight oxen had to be made up by several peasants contributing their beasts and implements towards its composition. In the same way the villagers had to go through the work of harrowing with their harrows, and of removing the harvest in their vans and carts. *Carriage* duties in carts and on horseback were also apportioned according to the time they took as a part of the week-work. Then came innumerable varieties of manual work for the making and keeping up of hedges, the preservation of dykes, canals and ditches, the threshing and garnering of corn, the tending and shearing of sheep, and so forth. All this hand-work was reckoned according to customary standards as day-work and week-work. But besides all these services into which the regular week-work of the peasantry mas differentiated, there were some additional duties. The ploughing for the lord. for instance, was not only imposed in the shape of a certain number of days in the week, but took sometimes the shape of a certain number of acres which the village had to plough and to sow for the lord irrespectively of the time employed. This was sometimes termed *gafolearth.* Exceedingly burdensome services were required in the seasons when farming processes are at their height—in the seasons of mowing and reaping, when every day is of special value and the working power of the farm hands is strained to the utmost. At those times it was the custom to call up the whole able-bodied population of the manor, with the exception of the housewives, for two, three or more days of mowing and reaping on the lord's fields; to these *boon-works* the peasantry was asked or invited by special summons, and their value was so far appreciated that the villagers were usually treated to meals in cases where they were again and again called off from their own fields to the demesne. The liberality of the lord actually went so far, in exceptionally hard straits, that ale was served to the labourers.

By the 14th century this social arrangement, based primarily on natural economy, had given way; the time of *commercial, contractual, cash intercourse* was fast approaching.

If we now turn to the actual stages by which this momentous passage from the manorial to the commercial arrangement was achieved, we have to notice first of all a rapid *development of contractual relations.* We know that in feudal law there was a standing contrast between *tenure* by custom—villein tenure—and *tenure* by *contract—free* tenure. While the manorial system was in full force this contrast led to a classification of holdings and affected the whole position of people on the land. Still, even at that time it might happen that a freeholder owned some land in villeinage by the side of his free tenement, and that a villein held some land freely by agreement with his lord or with a third person. But these cases, though by no means infrequent, were still exceptional. As a rule people used land as holdings, and those were rigidly classified as villein or free tenements. The interesting point is that, without any formal break, *leasing land for life and for terms of years* is seen to be rapidly spreading during the 13th century, and many small tenancies are created which break up the disposition of the holdings. From the close of the 13th century countless transactions on the basis of leases for terms of years occur between the peasants themselves. Any suitably kept set of 14th century court rolls contains entries in which such and such a villein is said to appear in the *halimote* and to surrender for the use of another person named a piece of land belonging to the holding. The number of years and the conditions of payment are specified. Thus, behind the screen of the normal shares a number of small tenancies arise which run their economic concerns in independence of the cumbersome arrangements of tenure and service, and, needless to add, all these tenancies are burdened with money rents.

Another series of momentous changes took place in the *arrangement of services.* Even the manorial system admitted the buying off for money of particular dues in kind and of specific performance of work. A villein might be allowed to bring a penny instead of a chicken, or to pay a rent instead of appearing with his oxen three times a week on the lord's fields. Such rents were called *mal* or *mail* in contrast with the *gafol,* ancient rents which had been imposed independently, apart from any buying off of customary services. There were even whole bodies of peasants called *Molmen,* because they had bought off work from the lord by settling with him on the basis of money rents. As time went on these practices of *commutation* became more and more frequent. There were, for both sides, many advantages in arranging their mutual relations on this basis. The lord got clear money—a much-coveted means of satisfying needs and wishes of any kind—instead of cumbrous performances which did not come always at the proper moment, were carried out in a half-hearted manner, yielded no immediate results, and did not admit of convenient rearrangement. The peasant got rid of a hateful drudgery which not only took up his time and means in an unprofitnble manner, but placed him under the arbitrary control of stewards or reeves and gave occasion to all sorts of fines and extortions.

With the growth of intercourse and security money circulated more freely and the number of such transsctions increased in proportion. But it must be kept in mind that the conversion of services into rents went on very gradually, as a series of private agreements, and that it would be wrong to suppose, as some scholars have done, that it had led to a general commutation by the middle or even the end of the 14th century. The 14th century was marked by violent fluctuations in the demand and supply of labour, and particularly the tremendous loss in population caused in the middle of this century by the Black Death produced a most serious crisis. No wonder that many lords clung very tenaciously to customary services, and ecclesiastical institutions seem to have been especially backward in going over to the system of money rents. There is evidence to show, for instance, that the manors of the abbey of Ramsey were managed on the system of enforced labour right down to the middle of the 15th century, and, of course, survivals of these customs in the shape of scattered services lived on much longer. A second drawback from the point of view of the landlords was that commutation for fixed rents gradually lessened the value of the exactions to which they were entitled. Money not only became less scarce but it became cheaper, so that the couple of pence for which a day of manual work was bought off in the beginning of the 13th century did not fetch more than half of their former value at its end. As quit rents were customary and not rack rents, the successors of those who had redeemed their services were gaining the whole surplus in the value of goods and labour as against money, while the successors of those who had commuted their right to claim services for certain sums in money lost all the corresponding difference. These inevitable consequences came to be perceived in course of time and occasioned a tendency to revert to services in kind which could not prevail against the general movement from natural economy to money dealings, but was strong enough to produce social friction.

The economic crisis of the 14th century has its complement in the legal crisis of the 15th. At that time the courts of law began to do away with the denial of protection to villeins which, as we have seen, constituted the legal basis of villeinage. This is effected by the recognition of copyhold tenure (see COPYHOLD).

It is a fact of first-rate importance that in the 15th century customary relations on the one hand, and the power of government on the other, reached a stage of development at which the judges of the king began to take cognizance of the relations of the peasants to their lords. The first cases which occur in this sense are still treated not as a matter of common law, but as a manifestation of equity. As doubtful questions of trust, of wardship, of testamentary succession, they were taken up not in the strict course of justice. but as matters in which redress was sorely needed and could only be given by the exceptional power of the court of chancery. But this interference of 15th century chancellors paved the way towards one of the greatest revolutions in the law; without formally enfranchising villeins and villein tenure they created a legal basis for it in the law of the realm. In the formula of copyhold—tenement *held* at the will of the lord and by the custom of the manor—the first part lost its significance and the second prevailed, in downright contrast with former times when, on the contrary, the second part had no legal value and the first expressed the view of the courts. One may almost be tempted to say that these obscure decisions rendered unnecessary in England the work achieved with such a flourish of trumpets in France by the emancipating decree of Aug. 4, 1789.

The personal condition of villeinage did not, however, disappear at once with the rise of copyhold. It lingered through the 16th century and appears exceptionally even in the 17th. Deeds of emancipation and payments for personal enfranchisement are often noticed at that time. But these are only survivals of an arrangement which has been destroyed in its essence by a complete change of economic and oolitical conditions.

VILLELE, JEAN BAPTISTE GUILLAUME MARIE ANNE SERAPHIN, COMTE DE (1773–1854), French statesman, was born at Toulouse on April 14, 1773 and educated for the navy. He joined the "Bayonnaise" at Brest in July 1788 and served in the West and East Indies. Arrested in the Isle of Bourbon under the Terror, he was set free by the revolution of Thermidor (July 1794). He acquired some property in the island, and married in 1799 the daughter of a great proprietor, M. Desbassyns de Richemont, whose estates he had managed. The arrival of General Decaen, sent out by Bonaparte in 1802, restored security to the island, and five years later Villèle, who had now realized a large fortune, returned to France. He was mayor of his commune, and a member of the council of the Haute-Garonne under the Empire. At the restoration of 1814 he at once declared for royalist principles. He was mayor of Toulouse in 1814–15 and deputy for the Haute-Garonne in the "Chambre Introuvable" of 1815. Villèle, who before the promulgation of the charter had written some Observations *sur le projet* de *constitution* opposing it, as too democratic in character, naturally took his place on the extreme right with the ultra-royalists. In the new Chamber of 1816 Villèle found his party in a minority, but his personal authority nevertheless increased. He was looked on by the ministerialists as the least unreasonable of his party, and by the "ultras" as the safest of their leaders. Under the electoral law of 1817 the Abbé Grégoire, who was popularly supposed to have voted for the death of Louis XVI. in the Convention, was admitted to the Chamber of Deputies. The Conservative party gained strength from the alarm raised by this incident and still more from the shock caused by the assassination of the duc de Berri. The duc de Richelieu was compelled to admit to the cabinet two of the chiefs of the Left, Villèle and Corbière. Villèle resigned within a year, but on the fall of Richelieu at the end of 1821 he became the real chief of the new cabinet, in which he was minister of finance. Although not himself a courtier, he was backed at court by Sosthiines de la Rochefoucauld and Madame du Cayla, and in 1822 Louis XVIII. gave him the title of count and made him formally prime minister.

He immediately proceeded to muzzle opposition by stringent press laws, and the discovery of minor Liberal conspiracies afforded an excuse for further repression. Forced against his will into interference in Spain, he reaped some credit from the campaign of 1823. Meanwhile he had persuaded Louis XVIII. to swamp the Liberal majority in the upper house by the nomination of twenty-seven new peers; he availed himself of the temporary popularity of the monarchy after the Spanish campaign to summon a new Chamber of Deputies. This new and obedient legislature, to which only nineteen Liberals were returned, made itself into a septennial parliament, thus providing time, it was thought, to restore some part of the *ancien régime*. Villèle's plans were assisted by the death of Louis XVIII. and the accession of his bigoted brother. Prudent financial administration since 181j had made possible the conversion of the state bonds from 5 to 4%. It was proposed to utilize the money set free by this operation to indemnify by a milliard francs the *émigrés* for the loss of their lands at the Revolution; it was also proposed to restore their former privileges to the religious congregations. Both these propositions were, with some restrictions, secured. Sacrilege was made a crime punishable by death, and the ministry were preparing a law to alter the law of equal inheritance, and thus create anew the great estates. These measures roused violent opposition in the country, which a new and stringent press law, nicknamed the "law of justice and love," failed to put down. The peers rejected the law of inheritance and the press law; it was found necessary to disband the National Guard; and in Nov. 1827, 76 new peers were created, and recourse was had to a general election. The new Chamber proved hostile to Villèle, who resigned to make way for the short-lived moderate ministry of Martignac.

The new ministry made Villèle's removal to the upper house a condition of taking office, and he took no further part in public affairs. At the time of his death, on March 13, 1854, he had advanced as far as 1816 with his memoirs, which were completed from his correspondence by his family as *Mémoires et correspondance du comte de Villkle,* j vol. (1887–90).

VILLEMIN, JEAN ANTOINE (1827–1892), French physician noted for his early researches on tuberculosis, was born at Prey, in the Vosges mountains, France, in 1827. Receiving his medical degree in 1853, he served for many years with the French army, retiring in 1885 with the rank of medical inspector-general.

In 1865 Villemin showed that tuberculosis could be transmitted from diseased to healthy animals by inoculation, thus proving that the malady was due to an infecting agent. The actual agent, the tubercle bacillus, was discovered by Robert Koch in 1882. Villemin published *Etudes sur la tuberculose* (1868), in which he announced his findings. Other works by Villemin include *Du tubercule, au point de vue de son siège, de son évolution et de sa nature* (1861) and *Rôle de la lésion organique dans les maladies* (1862).

VILLENA, ENRIQUE DE *(c.* 1384–1434), Spanish writer with a lively interest in a variety of subjects, was born *c.* 1384, of a noble Aragonese family. About 1402 he married Maria de Castilla, who soon became the mistress of Henry III; the complaisant husband was rewarded with the mastership of Calatrava in 1404. He died at Madrid on Dec. 15, 1434.

Villena's works are medieval in theme but look forward to the Renaissance in their latinized language. They include *Los doce trabayos de Hércules* (1417); a culinary handbook, the *Arte cisoria* (1423); and the *Libro de aojamiento* (142j), a treatise on the evil eye, to which Villena's enduring reputation as a sorcerer—the church burned his library after his death—must be attributed. His prose translation of the *Aeneid* (1428) was the first ever made. His treatise on poetry. the *Arte de trobar* (1433), survives only in fragments. (C. C. SH.)

VILLENEUVE, PIERRE CHARLES JEAN BAPTISTE SILVESTRE DE (1763–1806), French admiral, who commanded the French fleet at the battle of Trafalgar, was born at Valensole, Provence, on Dec. 31, 1763. He entered the French royal navy and received rapid promotion, being named post captain in 1793, and rear admiral in 1796. At the close of the year he took part in the unsuccessful expedition to Ireland.

He accompanied the expedition to Egypt, with his flag in the "Guillaume Tell" (86 guns). She was the third ship from the rear of the French line at the battle of the Nile and escaped in company with the "Genereux" (78). Villeneuve reached Malta on Aug. 23. His conduct was severely blamed, and he defended himself by a specious letter to his colleague Blanquet-Duchayla on Nov. 12, 1800, from Paris. In a letter written to him on Aug. 21, 1798, Napoleon said that the only thing with which Villeneuve had to reproach himself was that he had not retreated sooner, since the position taken by the French commander in chief had been forced and surrounded. But, in dictating his account of the expedition to Egypt to General Bertrand at St. Helena, the former emperor attributed the defeat at the Nile largely to the "bad conduct of Admiral Villeneuve." Villeneuve failed in the execution of the scheme for the invasion of England in 1805.

Nevertheless, Napoleon selected him to succeed Latouche Tréville at Toulon on his death in Aug. 1804. The duty of the Toulon squadron was to draw Nelson to the West Indies, return rapidly and, in combination with other French and Spanish ships, to enter the channel with an overwhelming force. It is obvious that Villeneuve had no confidence in the success of the operation. It required a tart order from Napoleon to drive him out of Paris in Oct. 1804. He took the command in November. For the details of the campaign. *see* TRAFALGAR, THE BATTLE OF. Having undertaken to carry out a plan of which he disapproved, it was clearly his duty to execute the orders he received. But Villeneuve could not free himself from the conviction that it was his business to save his fleet even if he ruined the emperor's plan of invasion. Thus after he returned to Europe and fought his confused action with Sir R. Calder off El Ferrol on July 22. 1805, he first hesitated and then, in spite of vehement orders to come on, turned south to Cadiz.

His decision to leave Cadiz and give battle in Oct. 1805, which led directly to the battle of Trafalgar, has been severely criticized. Defeat seemed to be inevitable, and yet he went out after learning from the minister of marine that another officer had been sent to supersede him. At Trafalgar he showed personal courage, but the incapacity of the allies to maneuvre gave him no opportunity to influence the course of the battle. He was taken as a prisoner to England but was soon released. He committed suicide at Rennes, on April 22, 1806.

The correspondence of Napoleon contains many references to Villeneuve. Accounts of the naval operations in which he was concerned will be found in William James's *Naval History.* Troude, in his *Batailles navales de la France,* vol. iii, published several of his letters and orders of the day.

VILLENEUVE-LÈS-AVIGNON, a town of southeastern France, in the *de'partement* of Gard on the right bank of the Rhône opposite Avignon. Pop. (1954) 4,431. In the 6th century the Benedictine abbey of St. André was founded on Mont Andaon, and the village which grew up round it took its name. In the 13th century the monks, acting in concert with the crown, established a *bastide,* or "new town," which came to be called Villeneuve.

The town was the resort of the French cardinals during the sojourn of the popes at Avignon, and was important until the Revolution.

Villeneuve preserves many remains of its medieval importance. The hospice, once a Franciscan convent, and the church and other remains of the Carthusian monastery of Val-de-Bénédiction, founded in 1356 by Innocent VI, are notable. A 17th-century gateway and a rotunda, built as shelter for a fountain, are interesting.

On the Mont Andaon, a hill to the northeast of the town, stands the Fort of St. André (14th century), with a fortified entrance gateway and a Romanesque chapel and remains of the Abbey of St. André.

VILLENEUVE-SUR-LOT, a town of southwestern France, capital of an *arrondissement* in the *de'partement* of Lot-et-Garonne, 22 mi. N. E. of Agen on a branch line of the Orléans railway. Pop. (1954) 13,02j. Villeneuve was founded in 1254 by Alphonse, count of Poitiers, brother of Louis IX, on the site of the town of Gajac, which had been deserted during the Albigensian crusade.

The river Lot divides the town into two parts. The chief quarter stands on the right bank and is united to that on the left bank by a 13th-century bridge. On the left bank portions of the 13th-century ramparts, altered and surmounted by machicolations in the 15th century, remain, and high square towers rise above the gates to the northeast, the Porte de Paris, and southwest, the Porte de Pujols. Arcades of the 13th century surround the Place La Fayette, and there are old houses of the 13th, 14th and 15th centuries in various parts of the town. On the left bank of the Lot, 2 mi. S.S.W. of Villeneuve, are the 13th-century walls of Pujols. The buildings of the ancient Abbey of Eysses, about a mile to the N.E., mainly 17th century, remain. Villeneuve has a subprefecture and a tribunal of commerce. It is an important agricultural centre and has a very large trade in plums *(prunes d'ente)* and in the produce of the surrounding market gardens, as well as in cattle, horses and wine. Many people are engaged in the preparation of preserved plums and the tinning of peas and beans; there are also manufactures of shoes and tin boxes.

VILLEROI, FRANCOIS DE NEUFVILLE, Duc de (1644–1730), French soldier, came of a noble family which had risen into prominence in the reign of Charles IX. His father Nicolas de Neufville, Marquis de Villeroi, marshal of France (1598–1685), created a duke by Louis XIV, was the young king's governor, and the boy was thus brought up in close relations with Louis. An intimate of the king, a finished courtier and leader of society and a man of great personal gallantry, Villeroi was marked out for advancement in the army, which he loved, but which had always a juster appreciation of his incapacity than Louis. In 1693, without having exercised any really important and responsible command, he was made a marshal. In 1655, when Luxembourg died, he obtained the command of the army in Flanders, and William III found him a far more complaisant opponent than the "little hunchback." In 1701 he was sent to Italy to supersede Catinat and was soon beaten by the inferior army of Eugene at Chiari *(see* Spanish Succession War). In the winter of 1701 he was made prisoner at the surprise of Cremona, and the wits of the army made at his expense the famous rhyme:

Par la faveur de Bellone, et par un bonheur sans égal,
Nous avons conserte Crémone—et perdu notre général.

In the following years he was pitted against Marlborough in the Low Countries. Marlborough's own difficulties with the Dutch and other allied commissioners, rather than Villeroi's own skill, put off the inevitable disaster for some years, but in 1706 the duke attacked him and thoroughly defeated him at Ramillies (*q.v.*). Louis consoled his old friend with the remark, "At our age. one is no longer lucky," but superseded him in the command and henceforward Villeroi lived the life of a courtier, much busied with intrigues but retaining to the end the friendship of his master. He died on July 18, 1730, at Paris.

VILLERS LA VILLE, a village of Belgium in the province of Brabant. 2 mi. E. of Quatre Bras, with a station on the direct line from Louvain to Charleroi. Pop. (1939) 1,109. It is chiefly interesting on account of the fine ruins of the Cistercian abbey of Villers founded in 1147 and destroyed by the French in 1795.

VPLLETTE, CHARLES, Marquis de (1736–1793), French writer and politician, was born in Paris on Dec. 4, 1736. He became the *protégé* of Voltaire. who had known his mother. During the Revolution Villette publicly burned his letters of nobility, wrote revolutionary articles in the *Chronique de Paris,* and was elected deputy to the Convention by the department of Seine-et-Oise. He died in Paris on July 7, 1793.

VILLIERS, BARBARA: *see* Cleveland, Duchess of.

VILLIERS DE L'ISLE-ADAM, PHILIPPE AUGUSTE MATHIAS, Comte de (1838–1889), French poet, was born at St. Brieuc in Brittany and baptized on Nov. 28, 1838. He may be said to have inaugurated the Symbolist movement in French literature, and *Axël,* the play on which he was engaged during so much of his life, though it was only published after his death, is the typical Symbolist drama. He began with a volume of *Premières Poésies* (1856–58). This was followed by a wild romance of the supernatural, *Isis* (1862), and by two plays in prose, *Elën* (1866) and *Morgane* (1866). La *Révolte,* a play in nhich Ibsen's *Doll's House* seems to be anticipated, was represented at the Vaudeville in 1870; *Contes cruels,* his finest volume of short stories, in 1883, and a new series in 1889; *Le Nouveau Monde,* a drama in five acts, in 1880; *L'Ève future,* an amazing piece of buffoonery satirizing the pretensions of science, in 1886; *Tribulat Bonhomet* in 1887; *Le Secret de l'échafaud* in 1888; *Axël* in 1890. He died in Paris, under the care of the Frères Saint-Jean-de-Dieu, on Aug. 19, 1889.

Villiers has left behind him a legend probably not more fantastic than the truth. Sharing many of the opinions of Don Quixote, he shared also Don Quixote's life. He was the descendant of the Grand Master of the Knights of Malta, famous in history, and his pride as an aristocrat and as an idealist mere equal. He hated mediocrity, science, progress, the present age, money end "serious" people. He remains a remarkable poet and a remarkable satirist, imperfect as both. He improvised out of an abundant genius, but the greater part of his work was no more than improvisation. He was accustomed to talk his stories before he wrote them. Sometimes he talked them instead of writing them. But he has left, at all events, the *Contes cruels,* in which may be found every classic quality of the French *conte,* together with many of the qualities of Edgar Allan Poe and Ernst Hoffman; and the drama of *Axël,* in which the stage takes a new splendour and a new subtlety of meaning. Villiers's influence on the younger French writers was considerable. It was always an exaltation. No one in his time followed a literary ideal more romantically. **(A. Sy.)**

Villiers de l'Isle-Adam* (1892); *R.* Martineau, *Un vivant et deux morts* (1901), bibliography. *A* selection from his stories, *Histoires souvernines,* was made by his friends (Brussels, 1899); there is a translation of the *Contes cruels* by Hamish Miles *(Sardonic Tales,* 1927).

VILLON, FRANCOIS (1431–*c.* 1463), French poet, was born in 1431, and, as it seems. certainly at Paris. He was entered on the books of the university of Paris as François de Montcorbier, but was always known by the name of his patron, Guillaume de Villon. It appears that he was born of poor folk, that his father died in his youth, but that his mother, for whom he wrote one of his most famous *ballades,* was alive when her son was 30 years old. Viilon was received into the house of Guillaume de Villon, chaplain in the collegiate church of Saint-Benoit-le-Bestourné, and a professor of canon law, who was probably a relative. The poet became a student in arts, no doubt early and took the degree of bachelor in 1449 and that of master in 1452.

On June 5, 1453, being in the company of a priest named Giles and a girl named Isabeau, he met, in the rue Saint-Jacques, a certain Breton, Jean le Hardi, a master of arts, who was nith a priest, Philippe Chermoye or Sermoise or Sermaise. A scuffle ensued; daggers mere drawn; and Sermaise, who started the broil, died of his wounds. Villon fled, and was sentenced to banishment—a sentence which was remitted in January 1456, the formal pardon being extant in two different documents, in one of which the culprit is described as "François des Loges, autrement dit Villon," in the other as "François de Montcorbier." By the end of 1456 he was again in trouble. In his first broil "la femme Isabeau" is only generally named, and it is impossible to say whether she had anything to do with the quarrel. In the second, Catherine de Vaucelles, of whom we hear not a little in the poems, is the declared cause of a scuffle in which Villon was so severely beaten that, to escape ridicule, he decided to flee to Angers, where he had an uncle who was a monk. As he was preparing to leave Paris he composed the *Petit Testament.* Hitherto Villon had been rather injured than guilty. But on the eve of leaving Paris he was concerned, just before Christmas 1456, in robbing the chapel of the college of Navarre from which five hundred gold crowns were stolen. The robbery was not discovered till March 1457, and in May the police came on the track of a gang of student-robbers owing to the indiscretion of one of thern, Guy Tabarie. A year more passed, when Tabarie. being arrested, turned king's evidence and accused Villon, who was then absent, of being the ringleader, and of having gone to Angers, partly at least, to arrange for similar burglaries there. Villon, for this or some other crime, was sentenced to banishment: and he did not attempt to return to Paris. For four years he was a wanderer, apparently a pedlar for some part of the time; and he may have been, as each of his friends Regnier de Montigny and Colin des Cayeux certainly was, a member of a wandering thieves' gang. It is certain that at one time (in the winter of 1457), and probable that at more times than one, he was in correspondence with Charles d'Orléans, and visited that prince's court at Blois. He made his way to Bourges where he was again in trouble, and had a taste of prison. From Bourges he went to the Bourbonnais, where he found shelter for a brief period with Jean II de Bourbon. Thence, if his own words are to be taken literally, he wandered to Dauphiné. He was in prison at Orleans, put to the question and under sentence of death, when he was released on the passage of the little princess of Orleans through the town on July 17, 1460. He had spent the summer of 1461 in the bishop's prison of Meung. Villon owed his release to Louis XI, who passed through Meung on a royal progress and freed prisoners on Oct. 2.

It was now that he wrote the *Grand Testament,* the work which has immortalized him. Although he was only 30 nothing appears to be left him but regret; his very spirit has been worn out by excesses or sufferings or both. In the autumn of 1462 we find him once more living in the cloisters of Saint-Benoit, and in November he was in the Châtelet for theft. In default of evidence the old charge of the college of Navarre mas revived, and even a royal pardon did not bar the demand for restitution. Bail was, however, accepted, but Villon was present at a street quarrel from which he hastily got away. Nevertheless he was arrested, tortured and condemned to be hanged, but the sentence was commuted to banishment (for ten years) by the parlement on Jan. 5, 1463. From this time he disappears from history.

Villon's two *Testaments* are made up of eight-line stanzas of eight-syllabled verses, varied in the case of the *Grand Testament* by the insertion of ballades and rondeaux. The sense of the vanity of human life pervades the whole of Villon's poetry. It is the very keynote of his most famous and beautiful piece, the *Ballade des dames du temps jadis,* with its refrain, "Mais où sont les neiges d'antan?", of the ballade of *La Grosse Margot,* with its burden of hopeless entanglement in shameless vice; and of the equally famous *Regrets de la Belle Heaulmière,* in which a woman, once young and beautiful, now old and withered, laments her lost charms. So it is almost throughout his poems, including the grim *Ballade des pendus,* and hardly excluding the very beautiful *Ballade que Villon feist a la requestc de sa mère, pour prier Nostre-Dame,* with its sincere and humble piety. In Villon's verse mediaeval Paris lives. Villon himself was beloved by the Paris of his day. His bright keen intellect, the exquisite polish of his verses and his realism, make him one of the great forces in French poetry. His influence on the moderns has been very great.

His certainly genuine poems consist of the two *Testaments* with their codicil (the latter containing the *Ballade des pendus,* or more properly *Épitaphe en forme de ballade,* and some other pieces of a similarly grim humour), a few miscellaneous poems, chiefly ballades, and an extraordinary collection (called *Le Jargon ou jobelin*) of poems in *argot,* the greater part of which is now totally unintelligible, if, which may perhaps be doubted, it ever was otherwise. Several poems usually printed with Villon's works are certainly, or almost certainly, not his. The chief are *Les Repues Franches,* a curious series of verse stories of cheating tavern-keepers, etc., having some resemblance to those told of George Peele. but of a broader and coarser humour. These, though in many cases "common form" of the broader tale-kind, are not much later than his time, and evidence to reputation if not to fact.

The first dated edition of Villon is of 1489. Before 1542 there were very numerous editions, the most famous being that (1533) of Clément Marot, one of whose most honourable distinctions is the care he took of his poetical predecessors. The Pléiade movement and the classicizing of the *grand siècle* put Villon rather out of favour, and he was not again reprinted till early in the 18th century, nhen he attracted the attention of students of old French like Le Duchat, Bernard de la Monnoye and Prosper Marchand.

The first critical edition in the modern sense—that is to say, an edition founded on mss. (of which there are in Villon's case several, chiefly at Paris and Stockholm)—was that of the Abbé J. H. R. Prompsault in 1832. The next was that of the "Bibliophile Jacob" (P. Lacroix) in the *Bibliotlzkque Elzévirienne* (Paris, 1854). The standard editions are *Oeuvres complètes de François Villon,* hy M. Auguste Longnon (1892), a revision of this text by Lucien Foulet, *François Villon: Oeuvres* (1923); and L. Thuasne, *François Villon; Oeuvres: édition critique* (1923), based on the Stockholm ms. of 1470, the ms. Fr. 20041 of the Bibliothèque Nationale, and Levet's text of 1489. M. Marcel Schwob discovered new documents relating to the poet, but died before he could complete his work, which was posthumously published in 1905. The researches of Schwob were completed by P. Champion in his *François Villon., sa vie et son temps* (1913). *See* also A. Lonpnon, *Étude biographique sur François Villon* (1877); Gaston Paris, *François Villon* (1901); D. B. Wyndham Lewis, *François Villon, A Documented Survey* (1928), with preface by H. Belloc, which contains renderings of the individual poems by Rossetti, Swinburne and Henley, and a full survey of the documents.

VILNIUS (WILNO, VILNA), former administrative district of soviet Lithuania, whose boundaries have shifted considerably with changes of political control. (*See* VILNIUS city.) As restored to Lithuania in 1939 the district was bounded by Latvia on the north, U.S.S.R. on the east, and the Byelorussian S.S.R. on the south, being about one-quarter the area and population of the former Polish province of Wilno (1920–39) and considerably smaller than the tsarist government of Vilna. The area forms an extension of the Baltic uplands and is drained in the north by the Disna and by the Neris (Vilija) in the south. Sand, numerous glacial lakes and marshes, some partially forested, cover large areas. The transportation is primitive except for a few railroads. The climate, slightly tempered by the Baltic sea, has a mean temperature of 43.7° F. and an average precipitation of 23.8 in. Agriculture is backnard, with rye, potatoes and flax the main crops grown on the badly eroded land. Timber and timber products are of considerable importance. The population, actually as well as in allegiance, has been unstable. Estimates of composition vary from 8.2% Poles (1897 Russian census) to 59.9% (1931 Polish census); from 50% Lithuanians (Lebedekin's 1861 estimate) to 10% in various Polish surveys. Statistics on Jewish (6% to 13%) and Russian (20% to 61%) groups are little more consistent, but the White Russians are generally considered the largest group. After the U.S S R. seized eastern Poland in Sept. 1939, it ceded parts of the Vilnius province to Lithuania. Chief city in this district is Vilnius (*q.v.*), but Trakai (Troki), Trumont, Dukszty, Nowoswieciany, and Podbrodzie are of some importance. The soviets absorbed the entire country in 1940, lost it to the German army in 1941, and regained it during the summer of 1944.

VILNIUS (Russian, VILNA; Polish, WILNO), capital of Lithuanian Soviet Socialist Republic, U S.S.R.. located 436 mi. S S.W. of Leningrad at the intersection of railways from Liepaja, Kaliningrad, Warsaw. the Ukraine, Gomel and Leningrad. Pop. (1959) 236.078. The city and its suburbs, Antokol, Lukiski, Pohulanka and Zarzecze, stand on and around an amphitheatre of wooded hills (2,450 ft.) which faces southeast at the confluence of the Neris and Vilejka. The old section of the city, resembling an overgrown village with its narrow winding streets, lies at the foot of Castle Hill on which the ruins of Gediminas' (Gedymin's) castle are still visible.

The newer areas, which spread up the hills and along the Neris, present a more modern aspect.

Situated between eastern and western Europe, Vilnius bears marks of many cultures. There are 28 Roman Catholic churches, 7 Orthodox, 2 Protestant, 1 Moslem mosque, and numerous synagogues. The public buildings show Byzantine, German, Latin, baroque, rococo and gothic influence. Most prominent is the Cathedral of St. Stanislas, built originally in 1387 and subsequently destroyed at least three times. The present neo-classical structure, designed by Gucewicz, was completed in 1801. There is a second cathedral, that of St. Nicholas, built in 1596–1604. Twelve of the city's churches were built in the 17th century by one Pac; one of these, the church of Sts. Peter and Paul, is a fine specimen of baroque style. The church of St. Martin was built on the site of the ancient pagan temple of Perkunas; while the small St. Anne's church, with its intricate gothic facade, so impressed Napoleon in 1812 that he wished he could take it with him to Paris. The Pointed Gate (Ostra Brama), with its venerated 16th century Madonna, is all that remains of the Jagellon wall of 1522.

The old university, in its neo-classical buildings, was originally founded as a Jesuit academy by Stephen Bathory in 1579. It uas re-estabhshed as the Superior school of the Lithuanian grand duchy in 1781, and toward the end of the 18th and early 19th centuries became an agitation centre of Polish culture. Political reasons caused the school to be closed in 1832 and, except for the faculties of astronomy and medicine, it remained inactive until 1919. In 1940, following the reoccupation of Vilnius by Lithuania, the school was reorganized, without most of the Polish staff, as the Lithuanian university. During the subsequent German occupation the school was closed and much of its equipment and archival collection destroyed.

The city possessed a Superior School of Political Science (est.

1930) as well as a college of dramatic art, academy of science, academy of art, academy of music, Roman Catholic and Orthodox seminaries, public library and botanical garden. It is a centre for timber, timber products, and furs, although the relative importance of the city declined between 1920 and 1939 because the city was separated from its natural economic hinterland. The German census of 1942 showed that in the city itself 53.2% of the population were Polish, 18.3% Lithuanian, 6.6% Jews, and 20.3% Russian groups. Heavy Polish refugee immigration and the German Jewish policy are reflected in these figures; the 1897 census reported 30.9% Poles and 40.3% Jews. The population composition of the Vilnius rural district is entirely different with a much stronger White Russian and Lithuanian proportion, fewer Jews, and probably not more than 15% Poles.

History. — Although it was founded in the 10th century, Vilnius was unimportant until Grand Duke Gediminas (Gedymin, *q.v.*) made it the capital of Lithuania (*q.v.*) in 1323. It was destroyed by Teutonic Knights in 1377 and was not completely restored until after the Union of Kreva of 1385. Two years later the first bishopric in Lithuania was established there. The city suffered bitterly in the two centuries following the Lithuanian-Polish Union of Lublin of 1569: the plague of 1588, a fire in 1610, Russian occupation from 1655–60, occupation by Charles XII during the Great Northern War in 1702 and again in 1706 when the city was burned, and a plague in 1710 which killed 35.000. Stanislas Augustus partially restored the city before it fell again to the Russians in 1788. Russian rule did not become permanent until 1795. The city and its Roman Catholic population suffered because of the abortive revolutions in 1831 and 1863.

Vilnius fell easily to the Germans on Sept. 19, 1915. At the end of the war Polish leaders sought to annex all Lithuania including Vilnius, demanding renewal of the ancient union. While the subsequent Polish-soviet frontier war was raging, the supreme allied command three times tried to draw a line of demarcation between Lithuania and Poland, each of which granted Vilnius to Lithuania, but Polish troops violated each one. Vilnius changed hands several times during the war, but the soviets turned over the city to Lithuanian troops on Aug. 24, 1920, according to the conditions of the Litho-soviet Moscow treaty of July 12.

Finally, on Oct. 7, the Polish and Lithuanian governments signed an armistice at Suwalki in the presence of the Allied control commission. Two days later, Gen. Lucien Zeligowski with a freebooting army recruited from the Polish forces and with the secret approval of Joseph Pilsudski, Polish chief of state, captured the city. The Council of the League of Nations immediately made plans for a plebiscite under the supervision of an international police force, but both the Poles and the Lithuanians refused. Paul Hymans, for the League council, then began, in May 1921, to mediate the dispute. His first proposal was to create two autonomous cantons in Lithuania, one centred at Vilnius and one at Kaunas, but with a joint Polish-Lithuanian foreign policy and military co-operation. Lithuania demanded reunion of Vilnius and a guarantee of her independence preliminary to all agreements, but Poland would not yield.

Meanwhile, on Jan. 8, 1922, Zeligowski held a plebiscite in "Central Lithuania." The Lithuanians and Jews boycotted the polls and the results called for union with Poland. In April the Polish Sejm voted to accept the offer and Vilnius was incorporated.

On Feb. 3, 1923, a month after the Lithuanian freebooting occupation of Memel, the League council decided to divide the neutral zone established by the military control commission, replacing it with a demarcation line granting Vilnius to Poland. But Poland and Lithuania remained in a state of war. The Litho-soviet treaty of 1926, stating that the Vilnius occupation was illegal, encouraged Lithuania. On Dec. 10, 1927, the League council forced a termination of the state of war, but the frontier remained closed. A World Court decision in 1931 sustained Lithuania's policy.

Polish suppression of Lithuanian-speaking individuals remained mild until 1937 when the Lithuanian daily papers were banned and Lithuanian leaders arrested. The Polish pretext was the closed frontier. Finally, on March 17, 1938, while the world's attention was distracted by the German occupation of Austria, the Polish government demanded the opening of the frontiers and the renunciation of Vilnius within 24 hours. Lithuania yielded.

The U.S.S.R. seized Vilnius along with eastern Poland in Sept. 1939, and shortly afterwards, on Oct. 10, ceded the city and adjoining areas to Lithuania. Soviet military occupation took place on June 15, 1940, and continued until the Red army was driven out by the German forces on June 22, 1941. The midsummer soviet offensive, 1944, shoved the Germans from the city.

VIMEIRO, BATTLE OF, 1808. Advancing upon Lisbon (see PENINSULAR WAR), Wellesley halted to cover the landing of reinforcements at the mouth of the Alcabrichella. Two miles from the sea this river cuts its may through a high ridge, which it divides into a western and an eastern section: at the southern entrance of the gorge thus formed lies the village of Vimeiro. Wellesley's force, 20.000 strong. was encamped upon the western ridge, with two brigades upon Vimeiro hill, a knoll just south of the village. On the morning of Aug. 21, 1808. Wellesley learned that Junot, with 13,000 men, was advancing to attack him. Junot, ignoring the western ridge, directed the brigades of Thomières and Charlot to attack Vimeiro hill, while Brennier mounted the eastern ridge and swept along it from the east. Wellesley at once sent five brigades on to the eastern ridge, two to overlook Vimeiro hill and three to stop Brennier's advance along its crest. The attack on Vimeiro hill followed a course that was to be the pattern for many such engagements throughout the war. The French advanced in solid columns on a narrow frontage, having thus little fire power; the British received them in line, wrapping themselves round the head and flanks of the columns, withered them with volleys of musketry, charged with the bayonet and swept them down the hill with heavy loss. A second attack by four battalions of grenadiers met with a similar fate, though two battalions did fight their way into Vimeiro village and were only dislodged after heavy hand-to-hand fighting. Meanwhile Brennier had lost himself among ravines north of the eastern ridge, but Solignac, who had been sent to reinforce him, struck correctly westwards along the ridge and blundered into three British hrigades in line. Within a few minutes Solignac's brigade had practically ceased to exist, but as the bulk of the British chased joyfully along the ridge in pursuit of the survivors Brennier's brigade came up from the valley behind them and roughly handled two battalions that had been left to guard Solignac's abandoned guns. Fortunately their comrades returned in time to scatter Brennier's men.

The moment was ripe for a general advance and pursuit of Junot's beaten army; but Sir Harry Burrard at this point arrived to take over command from Wellesley and timidly ordered hostilities to cease. Junot had lost half his guns and a quarter of his men. the British loss being only 750.

VIÑA DEL MAR, luxurious beach resort on the west coast of South America. just north of Valparaíso, Chile. A municipal gaming casino. attractive beaches and summer climate draw substantial numbers of national and foreign vacationers. Hotels, exclusive clubs, a race course, public gardens and plazas. handsome residential streets and a scenic coastal highway to Concón add to the city's charm. Situated within it are army and navy garrisons. petroleum depots and industries engaged in food. beverage, textile, glass. paint and metals processing or fabricating. Bus and rail communications with Valparaíso and Santiago are good. The population of Viña del Mar in 1952 was 84.471. (J. T.)

VINCENNES, a suburb $4\frac{1}{2}$ mi. E. of Notre Dame de Paris, in the *département* of Seine, on a wooded plateau. Pop. (1954) 50,316. Its celebrated castle. situated to the south of the town and on the northern border of the Bois de Vincennes, was formerly a royal residence, begun by Louis VII in 1164 and more than once rebuilt. It was frequently visited by Louis IS. The chapel, an imitation of the Ste. Chapelle at Paris! was begun by Charles V in 1379. continued by Charles VI and Francis I. consecrated in 13'3'2 and restored in modern times. In the sacristy is the monument erected in 1816 to the memory of the duke of Enghien, who was shot in the castle moat in 1804. Louis XI made the castle a state prison in which Henry of Navarre, the great Condé. hlirabeau and other distinguished persons were afterwards confined. Louis XVIII added an armoury. and under Louis Philippe numerous casemates and a new fort to the east of the dungeon were constructed.

Vincennes has a school of military administration and carries on horticulture and the manufacture of ironware, rubber goods, chemicals. etc.

VINCENNES, a city of southwestern Indiana. U.S., on the east bank of the Wabash river, 57 mi. S. of Terre Haute; the seat of Knox county. It is the centre of an agricultural region which produces apples, peaches. cantaloupes, watermelons. sweet potatoes and wheat. Manufactures include batteries, shoes. paper products. mirrors and window glass.

From the time of its first settlement by French traders on the site of an Indian village (c. 1702), it figured prominently in the colonial. Revolutionary and early national periods of American history. A fort. one of a chain from Quebec to New Orleans built by the French. was erected in 1732 and in 1736 the village was named for the fort's first commander. The French soldiers and *habitants* from Canada who settled there were accompanied by Jesuit missionaries who undertook to convert the Indian tribes of the area.

Ceded to the British at the end of the French and Indian War (1763), the settlement was virtually self-governing until the outbreak of the American Revolution. A British force occupied the fort for a brief period, but in 1779 it was taken by American forces under George Rogers Clark. Clark's dramatic victory at Vincennes, followed by the passage of the Northwest ordinance (1787), brought an influx of settlers from Kentucky. Virginia and Pennsylvania who soon challenged the city's domination by its French element.

Following the organization of the Northwest territory, Vincennes in 1790 became the seat of Knox county, an area then somewhat larger than the present state of Indiana. In 1800 the city was made the capital of the newly-created Indiana territory. which included the present states of Indiana. Illinois. Michigan and Wisconsin. Until the removal of the capital to Corydon in 1813.1-incennes. with a population of about 700. was the political, military and cultural centre of the Northwest frontier. At Vincennes. also; Gov. (later President) William Henry Harrison negotiated numerous land cession treaties with the Indians, bargained with their leader Tecumseh and launched the campaign which culminated in the battle of Tippecanoe (Nov. 1811). The city was incorporated in 1856.

The George Rogers Clark memorial. Grouseland (the Harrison mansion) and Vincennes university. a junior college founded in 1806. are reminders of the city's Iong history. For comparative population figures *see* table in INDIANA: *Population.* (J. *R.* C.)

VINCENT (or VINCENTIUS), **SAINT,** deacon and martyr. whose festival is celebrated on Jan. 22. In several of his discourses St. Augustine pronounces the eulogy of this martyr, and refers to *Acts* which were read in the church. It is doubtful whether the *Acts* that have come down to us (*Acta Sanctorum,* January, ii, 394–397) are those referred to by St. Augustine, since it is not certain that they are a contemporary document. According to this account. Vincent was born of noble parents in Spain, and was educated by Valerius, bishop of Saragossa. who ordained him to the diaconate. Under the persecution of Diocletian. Vincent was arrested and taken to Valencia. He was subjected to excruciating tortures and thrown into prison, where angels visited him. lighting his dungeon with celestial light and relieving his sufferings.

Vincent's warders, having seen these wonders through the chinks of the wall, forthwith became Christians. He died in an interval nhen nen torments were being prepared. His body. exposed to the wild beasts in vain, was thrown into the sea. but was recovered and buried outside Valencia.

See T Ruinart, *Acta martyrum sincera,* pp 364–366 (1713); Le Nain de Tillemont, *Mémoires pour servir* a *l'histoire eccle'siastique,* v, 215–225, 673–675 (1701 *et seq*).

VINCENT, SAINT, OF LÉRINS (d. *c.* 450), important to posterity for his *Commonitorium* (*i.e.,* "memoranda'!), was born perhaps at Toul, France, at an unknown date. After a secular career. he became, at some time before 425, a monk and later an ordained priest. His monastic life was spent at Lérins (in the Mediterranean. a few miles southeast of Cannes), where St. Honoratus had recently founded a community. Vincent wrote various works, most of them lost. The *Commonitorium,* for which he is remembered, attempts to reply to current heresies; it was written about 435 under the name of Peregrinus. It is not clear whether the work once consisted of two books, the second of which was lost but substituted by a résumé (ch. 29–33;) made by Vincent himself, or if the work is complete as it is known today. It is generally admitted now that the work is an indirect attack on Augustine. For the Semipelagians of whom Vincent was a spokesman, Augustine was a dangerous innovator teaching contrary to tradition. In the *Commonitorium* Vincent gives a theory and a norm for valid tradition, and from it is derived the classic formula for traditional doctrine: "What is believed everywhere, at all times, and by all." Vincent's feast day is May 24.

His surviving works are found in J. P. Migne, *Patrologia Latina,* vol. 50. Critical editions of the *Commonitorium* are those by G. Kauschen (1906), R. S. Moxon (1915) and A. Jülicher (1923'). An English translation. *Vincent of Lérins, the Commonitories,* by *R.* Morris is in *The Fathers of the Church,* vol. vii (1949).

See Cooper-Marsdin, *The History of the Islands of the Lérins* (1913). (G. WL.)

VINCENT, SAINT, DE PAUL (1581–1660), founder of the Lazarists and of the Confraternities of Charity, was born at Pouy in the Landes. France. on April 24, 1581. educated by the Franciscans at Dax. ordained priest. Sept. 23, 1600. and took his degree of B.D. at the University of Toulouse in 1604. Captured by Barbary pirates. he spent two years (1605–07) as a slave in Tunisia, whence he escaped to Aigues-Mortes and. after a year in Rome. went to Paris. where he remained for the rest of his life. He placed himself under the spiritual guidance of Pierre de Bérulle (*q.v.*), who directed him to take charge of the parish of Clichy, and, later, to act as tutor to the two sons of Philip Emanuel de Gondi, general of the galleys. of which Vincent became chaplain general in 1617. He subsequently had a hospital built at Marseilles for those wretched convicts.

In 1625 he founded the Congregation of the Mission (Lazarists or Vincentians) to evangelize neglected poor country folk and also to educate and train a pastoral clergy. He likewise established in I'aris and its environs Confraternities of Charity. associations of laywomen who visited, fed and nursed the sick poor in their homes. As these women were mostly members of noble and wealthy families, they enabled him to establish the Foundling and other hospitals and to relieve the distress occasioned by war in Picardy, Champagne and Lorraine. Vincent was the cofounder with Louise de Marillac (*q.v.*) of the Daughters of Charity. He died on Sept. 27, 1660. and was canonized in 1737. His feast day is July 19.

LD.)

VINCENT DE BEAUVAIS (VINCENTIUS BELLOVACENSIS) (*c.* 1190–c. 1264), the encyclopaedist of the middle ages, was probably a native of Beauvais, Normandy. The exact dates of his birth and death are unknown. A tradition preserved by Louis A. Valleoleti (c. 1413), gives the year of his death as 1264; but Tholomaeus de Luca, Vincent's younger contemporary id. 1.321), seems to reckon him as living during the pontificate of Gregory X (1271–76). If we assume that he died in 1264, the immense volume of his works forbids us to think he could have been born much later than 1190.

Very little is known of Vincent's career. He was a Dominican monk and it is certain that he was at one time reader at the monastery of Royaumont (Mons Regalis), not far from Paris: on the Oise.

The *Speculum Majus,* the great compendium of ail the knowledge of the middle ages. as it left the pen of Vincent, seems to have consisted of three parts only, viz.. the *Speculum Naturale, Doctrinale* and *Historiale.* Such, at least, is J. Échard's conclusion! derived from an examination of the earliest extant. manuscripts. All the printed editions. however. consist of four parts, the additional one being entitled *Speculum Morale.* This has been clearly shown to be the production of a later hand, and is ascribed by Échard to the period between 1310 and 1325.

The *Speculum Naturale* is divided into 32 books and 3.718 chapters. It is a vast summary of all the natural history known to western Europe toward the middle of the 13th century, copiously illustrated by passages from Latin, Greek, Arabic and Hebrew authors.

The *Speculum Doctrinale,* in 17 books and 2.374 chapters, is a summary of all the scholastic knowledge of the age. It is intended to be a practical manual for the student and the official alike. and treats of the mechanic arts of life as well as the subtleties of the scholar. the duties of the prince and the tactics of the general. It also treats of mathematics. under which head are included music, geometry. astronomy, astrology, weights and measures and metaphysics. It is noteworthy that in this book Vincent shows a knowledge of the Arabic numerals, though he does not call them by this name. The last book (xvii) treats of theology or mythology, and winds up with an account of the Holy Scriptures and of the church fathers, down to Bernard of Clairvaux and the brethren of St. Victor.

The *Speculum Historiale,* which is 31 books divided into 3,793 chapters, brings history down from the creation to the crusade of St. Louis.

Vincent has hardly any claim to be reckoned as an original writer. But it is difficult to speak too highly of his immense industry in collecting, classifying and arranging these three huge volumes of 80 books and 9,885 chapters. The undertaking to combine all human knowledge into a single whole was in itself a colossal one and could only have been born in a mind of no mean order. Indeed more than six centuries passed before the idea was again resuscitated by the encyclopaedists. and then it required a group of brilliant Frenchmen to do what the old Dominican did unaided.

Vincent's works, both manuscript and printed, are listed by P. C. F. Daunou in the *Histoire littéraire de la France,* vol. xviii (1733 *et seq.*), and by J. Échard in *Scriptores ordinis praedicatorum* (1719–21). The *Speculum Majus* with the *Speculum Morale* was printed by the Benedictines under the title. *Vincentii Burgundi ex ordine praedicatorum, venerabilis episcopi hellovacensis, speculum quadruplex, Naturale, Doctrinale, Morale, Historiale* (Douai, 1624). The *Tractatus consolatorius pro morte amici* and the *Liber de eruditione filiorum regalium* (dedicated to Queen Margaret) were printed at Basel in Dec. 1480. *See* also A. Steiner (ed.), *Vincent de Beauvais, De eruditione filiorum nobilium* (1938). (T. A. A.; F. J. WE.)

VINCENT (VICENTE) **FERRER, SAINT** (*c.* 1350–1419), Spanish Dominican friar, reputed the greatest preacher of his age, was born *c* 1350, in Valencia, where in 1367 he entered the Dominican order. In 1394. when he was professor of theology in his native city and already a noted preacher. the Avignon pope Benedict XIII summoned him to his court as his confessor and theologian. but five years later he resigned in order to set out on a long missionary enterprise that lasted until his death. Restricting himself to no plan, he wandered through Burgundy, southern France. Switzerland, northern Italy and Spain, recalling thousands to a better life and converting numberless heretics and Jews. Everywhere large crowds gathered to hear him, so that nearly always he was forced to preach in the open air. In 1412 he was one of the nine judges who elected Ferdinand I to the disputed throne of Aragon, and he prevailed on that prince to abandon the cause of Benedict XIII in order to assist in putting an end to the western schism. The last two years of his life he devoted to preaching in northern France, chiefly Britanny and Normandy. In May 1418 he acceded to the request of Henry V of England to preach before him and his court at Caen in Normandy. Vincent died at Vannes, April 5. 1419, and was canonized in 1455. His feast day is April 5. Some of his philosophical writings and several volumes of his sermons have been printed. Of his works, the *Tractatus de vita spirituali sive de interiori homine* is the best known.

VINCI, LEONARDO DA: *see* LEONARDO DA VINCI.

VINDELICIA, in ancient geography. a country bounded on the south by Rhaetia. on the north by the Danube and the Vallum Hadriani, on the east by the Oenus (Inn), on the west by the territory of the Helvetii. It thus corresponded to the northeastern portion of Switzerland. the southeast of Baden, and the south of Württemberg and Bavaria. Together with the neighbouring tribes it was subjugated by Tiberius in 15 B.C., and toward the end of the 1st century A.D. was made part of Rhaetia.

VINDHYA, a range of mountains in central India. They form a well-marked, though not continuous. chain with the river Narbada on the south. and separate the Ganges basin from the Deccan. Starting on the west in Gujarat, they cross the southern edge of the Malwa plateau and, continued by the Bhanrer and Kaimur ranges. abut on the Ganges valley near Varanasi. They have an elevation of 1.500 to 2.500 ft. and nowhere exceed 3.700 ft.

They are built of the "Vindhyan formation" (part of the Pre-Cambrian rocks of India). Traditionally they formed the boundary between the Madyadesha of the Sanskrit invaders and the non-Aryan Deccan.

VINE: *see* GRAPE.

VINEGAR. The term vinegar is applied to one of the most ancient of natural fermentations known to man, and has been closely associated with the human race throughout the ages. Biblical references to its uses can be found in the Book of Ruth and Proverbs; Caesar's armies drank diluted vinegar; and residues in an Egyptian vase dating to 3000 B.C. indicate that it had held vinegar.

Its principal use has been in foods as a flavouring and preservative agent. but throughout history it was believed to have considerable medicinal value as well. Hippocrates prescribed it for his patients and W. R. Fetzer reported that it was used with considerable success in the treatment of scurvy among soldiers during the American Civil War.

The intimate association of vinegar with man's daily life can be seen in a simple survey of newspaper columns devoted to cookery and home management in which such suggestions for its use as a substitute for eggs in baking, a gargle mixed with sugar or honey in relieving sore throat and a cleaning agent in furniture polish have been made. Thus. man has found mechanical. chemical and culinary virtues in vinegar, found in few other products.

Chemistry and Bacteriology.—Vinegar was undoubtedly first made by allowing fermented liquids to acetify naturally but wine was probably the first raw material used in its commercial manufacture. The word vinegar comes from two French words *vin* and *aigre* ("sour wine"), but the term vinegar applies to any product made by the acetous fermentation of a wide variety of materials. Actually, the manufacture of vinegar is a two-stage process (1) the conversion of sugars to alcohol by yeasts; and (2) the conversion of alcohol to acetic acid by bacteria. Thus. vinegar can be produced from any liquid capable of first being converted to alcohol.

There are many types of raw materials suitable for use in manufacturing vinegar, but those most widely used are apples and grapes in making cider and wine vinegars, malted barley and oats in making malt vinegar and industrial alcohol in making white distilled vinegar. Vinegars serve as seasoners for salads, sauces, stews, fish and meat dishes, and as preservatives of meat products, fish, fruit and vegetables, a process commonly termed pickling.

Chemically; vinegar is simply a dilute solution of acetic acid containing soluble substances of the source material. The chemical changes involved in converting sugar to vinegar can be shown by the following simplified formulas:

$$\text{(1)}\quad \underset{\text{Sugar}}{C_6H_{12}O_6} + \text{Yeast} \longrightarrow \underset{\text{Alcohol}}{2C_2H_5OH} + \underset{\text{Carbon Dioxide}}{CO_2}$$

$$\text{(2)}\quad \underset{\text{Alcohol}}{CH_3CH_2OH} + \underset{\text{Oxygen}}{O_2} + \text{Bacteria} \longrightarrow \underset{\text{Acetic Acid}}{CH_3COOH} + \underset{\text{Water}}{H_2O}$$

Theoretically 1.0 part of sugar will produce 0.5 part of alcohol, while 1.0 part of alcohol will theoretically produce 1.3 parts of acetic acid. Under actual conditions yields are somemhat lower because the microorganisms use some of the materials to support life processes and because of losses due to evaporation and to the bacterial conversion of some acetic acid to carbon dioxide and water (over-oxidation).

It was not until 1864 that Louis Pasteur, the French microbiologist, showed that the bacteria present in vinegar were directly responsible for converting alcohol to acetic acid. Since Pasteur's time a number of acid-producing organisms have been isolated from vinegar generators, and these have been given the genus name *Acetobacter*. The usual types of vinegar generators contain a number of strains of acid-producing bacteria and, in addition, the vinegar eel, *Anguilula aceti*, a nematode worm that apparently contributes to the normal bacterial processes within the generator. Vinegar generators, therefore, operate with a group of organisms working together symbiotically and producing sufficient acid to prevent invasion by other organisms.

Analysis.—Vinegars may contain several organic acids and esters derived from the source material and resulting from fermentation and acetification. These substances are responsible for flavour and aroma variations of different vinegars. The Orléans and Boerhaave slow processes of manufacturing are capable of producing vinegar of superior flavour and odour characteristics simply because the limited amounts of air used carry off little of the volatile esters of the mash.

Cider, nine and malt vinegar usually contain 5% to 6% total acid as acetic. Distilled vinegar may range in acid content from 5% to 12%, the snore concentrated types being preferred for commercial operations. The folio\\-ing table, compiled from various sources, shows typical analyses of the several vinegars.

	Cider	*Wine*	*Malt*	*Distilled*
Specific gravity	1.013–1.011	1.013–1.021	1.015–1.025	1.008–1.013
Acetic acid (in %)	4.84	6.55	4.23	6.34
Total solids (%)	2.49	1.93	2.60	0.35
Ash (%)	0.34	0.32	0.34	0.04
Sugar (%)	0.25	0.46	—	—

Processes.—Vinegar bacteria are aerobic types and require an abundant supply of air (oxygen) for proper growth and development. Vinegar can be produced in a small container but the bacteria are active only at the surface of the liquid where air is available. Under these conditions surface area in relation to total liquid volume is low and consequently aeration and the rate of acetification are also low. In spite of its ancient origin technological advances in the production of vinegar came slowly and consisted basically of improved methods of aeration. Starting with the primitive method of placing fruit or other juices in a container and allowing fermentation and acetification to proceed haphazardly the technology advanced through the old Orleans and Boerhaave slow processes to the modern quick vinegar methods of tremendous production capabilities.

The best known of the old acetification methods was the Orléans process in which vinegar was made in barrels of about 50 gal. capacity. In each barrel head one or two small air holes were drilled in such a position that when the barrel was laid on the side bung up and filled to ½ in. below the air holes it would be about three-quarters full, thus allowing exposure of the mash surface to aeration. A wooden spigot was installed close to the bottom in one of the heads to permit drawing off the finished vinegar. In general, the mash was prepared by mixing about 5 gal. of 5% vinegar with 30 gal, of wine or other alcoholic liquid containing 5% to 6% alcohol, the mixture then being poured into the barrel through the bung hole. A small volume of vinegar containing "mother of vinegar," a mass of vinegar bacteria, was then added to the mash in the barrel as a starter. The air holes were covered with screening to keep out insects and the barrel was stored at a temperature of 85° F. to permit acetification to proceed normally. During this period of the process a film, or mat, developed on the surface of the liquid, the film consisting of a mass of bacteria growing at the point of greatest air supply. When the acidity of the vinegar reached about 5% and the alcohol 0.25%, 30 gal. of vinegar were drawn off through the spigot leaving 5 gal. of vinegar in the barrel as an inoculant for the next batch, or charge, of mash. In refilling the barrel with the new charge, extreme care was necessary in order to avoid breaking up the surface film which would cause a setback in operations. Three or four months time was required to complete the acetification process which meant that each barrel acetifier was capable of producing but ¼ gal. of vinegar daily.

In the early part of the 18th century H. Boerhaave, a Dutch technologist, found that the rate of acid production in the vinegar process was directly proportional to the amount of surface exposed to air. He modified the Orlkans process by using large casks and loosely packing the casks with pomace, the residue from grape presses. Wine mash was allowed to trickle down and spread over the considerable area of the pomace thereby increasing the volume of mash exposed to aeration. While the Boerhaave method represented an improvement over the Orlkans method in convenience and in the amount of vinegar produced, it was still a slow method. In 1823, J. S. Schiitzenbach, a German chemist, drilled holes in the Boerhaave generator to permit entrance of abundant asnounts of air, and introduced more satisfactory types of porous materials. This method became known as the German process or quick vinegar process, and modern vinegar generators and methods are based on the principles developed by Schiitzenbach. The quick vinegar process reduced the time of acetification from months to days and brought the control of the acetification process to a great degree within the skill of the operator.

In the quick vinegar process wooden tanks, or generators, anywhere from 3 to 14 ft. in diameter and 6 to 16 ft. in height are used A perforated false bottom or grid is placed in the generator about two feet from the bottom The generator is then filled to about tno feet from the top nith loosely packed beechnood shavings or other suitable porous material. Holes are drilled around the generator to permit entrance of air and some means of mechanically distributing mash over the top of the shavings is installed

The generator is inoculated with fresh unfiltered, unpasteurized vinegar containing active vinegar bacteria, and the mash is then distributed evenly over the top of the shavings and allowed to dribble down through the shaving area, or the oxygen chamber where it comes in contact with the air. The mash is passed through the generator a number of times to complete the acetification and is then drawn off and a new charge added. Once the operation is started the process is continuous.

About 1952 a method of acetification called submerged fermentation was developed that proved capable of far higher production rates and efficiencies than any of the other systems described. Submerged fermentation differs from the usual quick vinegar process in that no wood shavings or other packing material is required. In this process air is supplied to the bacteria by continuously dispersing finely divided air bubbles throughout the mash: this action provides each bacterium with sufficient oxygen for maximum development, thereby increasing the efficiency and speed of acetification.

Considerable heat is produced in all quick vinegar processes and modern generators are equipped with cooling systems for maintaining generator temperatures at about 30" C.. the optimum growth point for vinegar bacteria.

See J. Schierbeck. *The Manufacture of Vinegar,* Technical Information Service report no. 117 (1951). (G. C. En.)

VINEGAR EEL: *see* NEMATODA.

VINET, ALEXANDRE RODOLPHE (1797–1847), French critic and theologian, of Swiss birth. was born near Lausanne on June 17, 1797. He was educated for the Protestant ministry. being ordained in 1819. when already teacher of French language and literature in the gymnasium at Basel; and during the whole of his life he was *littérateur* as well as theologian. His literary criticism brought him into contact with Sainte Beuve. who recognized his quality. Vinet's *Chrestomathie française* (1829), *Études sur la littérature française au XIXme siècle* (1849–51) and *Histoire de la littérature française au XVIIIme siècle,* together with his *Études sur Pascal, Études sur les moralistes aux XVIme et XVIIme siècles, Histoire de la prédication parmis les Réformés de France* and other works. show wide knowledge, moral seriousness and a fine faculty of appreciation.

As theologian he gave a fresh impulse to Protestantism especially in French-speaking lands. but also in England and elsewhere. Lord Acton classed him n·ith Rothe. He built all on conscience, as that wherein man stands in direct personal relation with God. and as the seat of a moral individuality which nothing can rightly infringe. Hence he advocated complete freedom of religious belief. and to this end the formal separation of church and state. in his *Mémoire en faveur de la liberté des cultes* (1826), *Essai sur la conscience* (1829), *Essai sur la manifestation des convictions religieuses* (1842). Accordingly. when in 1845 the civil pon·er in the canton of Vaud interfered with the church's autonomy. he led a secession which took the name of *L'Église libre.* A considerable part of his works was not printed till after his death at Clarens. May 4, 1847. They were re-edited with notes by P. Bridel in 1912.

BIBLIOGRAPHY.—Vinet's life was written in 1875 by Eugène Rambert, n·ho rc-edited the *Chrestomathie* in 1876. *See* also L. M. Lane. *Life and Writings of A. Vinet* (1890): L. Molines, *Études sur Alexandre Vinet* (1890); V. Rivet, *Études sur les origines de la pensée religieuse de Vinet* (1896); A. Schumann, *Alex. Vinet* (1907); E. A. L. Seillière, ?. *Vinet, historien dc la pensée française* (1925). A uniform edition of his works dates from 1903. (J. V. .

VINLAND or **WINELAND.** This was the southernmost of the countries discovered by Leif Ericsson (*q.v.*), the Scandinavian discoverer. on his voyage from Norway to Greenland in the year 1000. and it was later visited also by Thorfinn Karliefni (*q.v.*), probably in the year 1001. It derived its name from the wild grapes which the discoverer found there. It is first mentioned in writing by Adam of Bremen (*q.v.*) in his deicription of the northern countries. about 1075, his informant being King Svein Estridsson of Denmark. The fullest information about this country, as well as about these voyages in general is to be found in the *Sage of Eric the Red* and the *Tule of the Greenlanders.* All these sources agree as to the general characteristics of the country: wild grapes, self-sown wheat and very mild winter. In some Icelandic writings the name Vinland the Good occurs, and this led Dr. Fridtjof Nansen to assume that the story about Yinland was merely a transformation of the old legends about the Isles of the Blest (*q.v.*). His arguments have not been generally accepted, although it is possible that the epithet "the good" may have later been added under the influence of these legends. The historicity of the discovery can hardly be disputed. nor that Vinland was a part of the American continent, but more definite location is difficult. If we are to accept the account of the wild grapes as authentic. the location of Vinland must fall within the northern limits for this plant which, on the Atlantic coast, are generally put at Passamaquoddy bay. Of the principal writers who have dealt with the problem. C. C. Rafn placed Vinland round Mount Hope bay. in the state of Rhode Island. Gustav Storm in Nova Scotia. where the existence of wild grapes is. however. doubtful. W. H. Babcock and W. Hovgaard have practically reverted to Rain's view. while G. M. Gathorne-Hardy looks for it at the mouth of the Hudson river.

For bibliography of the subject see LEIF ERICSSON.

(H. HE.)

VINOGRADOFF, SIR PAUL GAVRILOVICH (1854–1925), Anglo-Russian legal scholar and medievalist noted for his study of the English medieval manor and village community, was born in Kostroma. near Moscow. Nov. 30. 1854. and educated at the University of Moscow. As a young man he traveled widely, and obtained a working knowledge of at least seven modern languages. before being appointed a professor in his own university. He then interested himself in the zemstvo (local self-government) movement and sought to improve the provision for the education of the Russian people. His activities, however. were displeasing to the authorities: consequently he resigned his professorship and in 1902 settled in England. where he had already made friends with many English scholars. In 1903 he was appointed Corpus professor of jurisprudence at Oxford and held this post until his death in Paris on Dec. 19. 1925.

An account of his life by H. A. L. Fisher is contained in his *Collected Papers* (1928). to which a complete bibliography is appended.

Vinogradoff's first book. *The Origin of Feudalism in Italy* (1887), was written in Russian, but his later works were appropriately nritten in English. and he became recognized as probably the first authority on the early laws and customs of England. His standard work is *Villeinage in England* (1892), in which he put forward the theory that the Anglo-Norman manor descended not from a condition of serfdom. but from a free village community. His article "Folkland." published in *The English Historical Review* in 1893, enunciated an entirely new theory on this subject. His other works include: *The Growth of the Manor* (1905); *English Society in the Eleventh Century* (1908): *Roman Law in Mediaeval Europe* (1909); *Self-Government in Russia* (1915); and *Outlines of Historical Jurisprudence* (1920–22). He also contributed to the *Encyclopædia Britannica* and the *Cambridge Medieval History.* (S. E. T.j

VINOGRADSKY (WINOGRADSKI), **SERGEI NIKOLAEVICH** (1856–1946), Russian biochemist. conducted epoch-making research in the fields of bacteriology (especially the bacteriology of soil) and the physiology of microorganisms. Born at Kiev on Sept. 1, 1856, he entered the University of Kiev in 1873 and later studied natural science at the University of St. Petersburg. n·here he continued his graduate studies until 1881, when he obtained the degree of M.S. He went to Strasbourg to work under A. de Bary and studied analytical chemistry. In 1888 he moved to Zürich. n·here he pursued his study of nitrification. He later returned to Russia to become head of the section of general microbiology of the Institute of Experimental Medicine. He was appointed director of the same institute in 1902 and held that position until 1905 when he resigned; although he was on the staff until 1912, he was practically inactive. He resumed his scientific activity only in 1922 when he accepted the position of head of the division of agricultural microbiology, Pasteur institute. Brie-Comte-Robert, near Paris. After the invasion of France in 1910 he again retired. He died Aug. 31, 1946.

Vinogradsky studied sulfur and iron bacteria and discovered that colourless sulfur bacteria in the absence of light can oxidize hydrogen sulfide and sulfur to sulfuric acid. Even more important were his investigations of nitrification (1888–90) and the role of bacteria in that process. In 1893 he discovered an anaerobic organism (*Clostridium pasteurianum*) and showed its ability to fix nitrogen from the atmosphere.

Vinogradsky later studied methods in soil microbiology and investigated the role of bacteria in the decomposition of cellulose and nitrogen fixation.

See Selman A. Waksman, "Sergei Nikolaevitch Winogradsky," *Soil Sci.,* vol. xlii (1946).

VINSON, FREDERICK MOORE (1890–1953), U.S. lawyer who, as 13th chief justice of the United States. was a vigorous supporter of a broad interpretation of federal governmental powers, was born in Louisa. Ky., on Jan. 22, 1890. Following completion of his legal studies at Centre college in 1911. he entered private practice of the law in Louisa and quickly assumed an active role in local political affairs. In 1923 he was appointed to fill a vacancy in the U.S. house of representatives. The following year he was elected to the seat as a Democrat and. except for one two-year period. served as a member of congress until 1938.

As congressman Vinson was recognized as an outstanding expert in tax and fiscal policy. From 1935 to 1943 he served as associate justice of the U.S. court of appeals for the District of Columbia. Between 1943 and 1945 he held a succession of high executive posts in emergency agencies of World War II and in 1945 he became secretary of the treasury in the cabinet of Pres. Harry S. Truman. In this office he helped inaugurate the International Bank for Reconstruction and Development and the International Monetary fund.

Upon appointment by President Truman he became chief justice on June 24, 1946. As a judge his interpretation of the powers of the federal government often led him to reject claims of individual right asserted in opposition to the exercise of governmental authority. Perhaps his best-known opinions, however, are those upholding the rights of members of racial minorities under the equal protection clause of the fourteenth amendment, such as that in *Shelley* v. *Kvaemer,* 334 U.S. 1 (1948). His opinion for the court in 1947 upheld the power of the federal courts to enjoin a strike in coal mines then under control of the federal government. He strongly dissented from the judgment of the court rendered in 1952 which held invalid Pres. Truman's "seizure" of the steel companies.

He died in Washington on Sept. 8, 1953. (F. A. A.)

VIOL, a generic term for the bowed precursors of the violin (*q.v.*), but in England more specially applied to those immediate predecessors of the violin which are distinguished in Italy and Germany as the *Gamba* family. The chief characteristics of the viols were a flat back, sloping shoulders, C-shaped sound holes and a short finger board with frets. All these features assumed different forms in the violin. which was derived rather from the guitar fiddle than from the viol, the back becoming delicately arched. the shoulders reverting to the rounded outline of the guitar, the shape of the sound holes changing from C to F and the finger board being carried considerably nearer the bridge. The viol family consisted of treble. alto, tenor and bass instruments, being further differentiated as *da braccio* or *da gamba* according to the positions in which they were held, against the arm or between the knees.

VIOLA: see VIOLIN FAMILY.

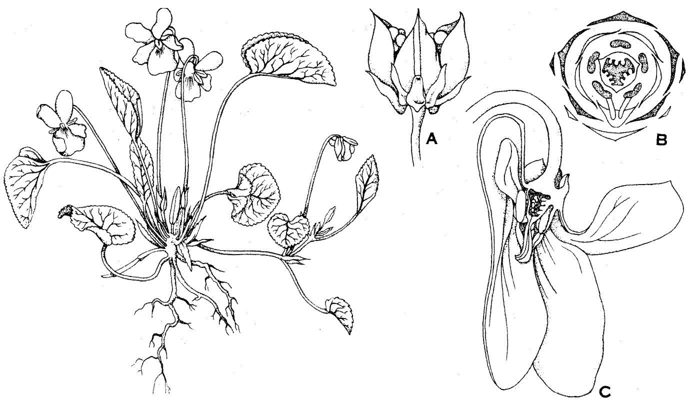
VIOLET (*Viola*) represents one of the larger genera of flowering plants. with approximately 400 species. They are found in both northern and southern hemispheres, most abundantly in temperate climates. The greatest variety is known from the Andes mountains of South America. the ancestral home of the genus. In the northern hemisphere the greatest number of species *(60)* is found in North America. where common species are the bird's foot violet (V. *pedata*), the bog blue violet *(V. cucullata*), the common blue violet *(V. affinis*), the woolly blue violet *(17. sororia*), the canada violet (*V. canadensis*), the mountain yellow violet (*V. rotundifolia*), the smooth yellow violet *(V. pensylvanica*), the dog violet *(V. conspersa*), the striped violet (*V. striata*) and the long-spurred violet (*V. rostvata).* In southeastern United States are also found *V. floridana,* V. *septemloba, V. esculenta* and the beautiful *V. walteri.*

In the great plains and the western mountains are found the prairie yellow violet (*V. nuttallii*), the pine violet (*V. lobata*), the yellow pansy violet (*V. pedunculata*), the western heartsease (*V. ocellata*) and the wood violet *(V. sempervirens*). Several species occur in Alaska and in Mexico. as well as in Australasia. In South America, some of the species attain the size of low shrubs and trees.

Several species of *Viola* grow in Great Britain. *Viola canina* is the European dog violet and is quite variable in appearance. *Viola odorata,* the sweet or fragrant violet, is known both in nature and in a variety of forms in cultivation. Other species grown in gardens are: *V. altaica,* flowers yellow or violet with yellow eye; *V. calcarata,* flowers light blue or white, or yellow in the variety *flava;* and *V. cornuta,* the tufted violet or bedding pansy, flowers blue, or white in one variety.

North temperate violets are all small, herbaceous plants with variously coloured, but characteristically shaped flowers. The species may be divided into those with leafy stems and those with underground rhizomes and no aerial stems. Though the most familiar forms have heart-shaped leaves, other species have leaves with different shapes. In some of them the leaves are cut into many linear segments. Large, leafy stipules subtend the leaves. Some species have stolons that root at the nodes and may form large clones.

Two kinds of flowers are produced by nearly all violets: the familiar open flowers in the spring (and sometimes in the fall), and the less familiar! but more abundant, closed flowers (cleistogenes), produced throughout the summer. The open flowers have five green sepals and five conspicuous petals. There are two upper petals, a pair of somewhat larger lateral petals, and a large, basal, spurred petal; nectiferous glands secrete nectar into this spur.



(LEFT) FROM CHURCH, "TYPES OF FLORAL MECHANISM" (CLARENDON PRESS); (A, B & C) BY COURTESY OF THE TRUSTEES OF THE BRITISH MUSEUM (NATURAL HISTORY)

SWEET VIOLET (VIOLA ODORATA)

(Left) Whole plant and (A) fruit; (B) floral diagram; (C) longitudinal section through flower

Two of the five stamens are also spurred. The pistil has a very short style and a peculiar stigma, the form of which is used in classification. The closed flowers, produced at the base of the plant, occur in abundance during the summer. They are completely enclosed by the sepals, the petals being aborted. Only two stamens are in each flower; from these the pollen tubes grow directly through the ovary wall, thus self-fertilizing the eggs. The seeds of violets are small, oval in shape, and often with a conspicuous caruncle. They are forcibly expelled from the drying capsules. (N. H. R.)

VIOLIN FAMILY, the group of bowed stringed musical instruments that includes the violin, viola, violoncello and double bass and forms the basis of the modern orchestra. The family takes its name from its smallest member, which is perhaps the best-known and most widely distributed musical instrument in the world.

The violin springs from different stock from the viol (*q.v.*). It is a descendant of the horizontally held arm viols of the middle ages by a process of evolution and metamorphosis. Its immediate precursor is the *lyra da braccio,* an elaborate instrument of the Renaissance, whose form foreshadows the physical essentials of the violin body: the arched modeling of the belly and back, and the shallow ribs. This shallow arched form probably encouraged or suggested another important detail: the use of a short vertical stick to prop the front and back apart and prevent the collapse of the belly arch under pressure of the strings. This device. the sound post, is peculiar to the violin; although it was later used on the viols, it is the acoustic effect of the sound post that imparts to the violin its lively response and generous singing tone, for it couples and co-ordinates the vibrations of the body as a whole, under the influence of the strings.

Although the generic name for the family is the Italian *viola* (whence vio*lino*, "small viola"; vio*lone*, "large viola"; violoncello, "small violone"). the treble instrument very soon became its most important member, from which the others took their main characteristics. Unlike the smaller viols. whose tone was reticent and impersonal. the violin was always recognized both for its superior cantabile and for its inherent sprightliness and smart attack. especially in Italy, its birthplace. where the earliest makers. Gasparo da Salò. Andrea Xmati and G. P. Maggini had settled its average proportions before the end of the 16th century. (*See* AMATI.) Thus the violin arrived at exactly the right time to lend impetus and conviction to the innovations of the Florentine school of composers. whose preoccupation with the expressive qualities of the solo voice marked a breakaway from the older polyphony. To this movement. the violin. the first treble instrument to achieve an innate lyricism. formed the perfect instrumental counterpart.

Two other features contributed to the character of the violin. the first heing the tuning of the strings in fifths and their numerical limitation to four. This wide regular tuning. typical of the rebecs (*cf.* the viols. whose six strings were tuned in a mixture of fourths and thirds). was ideal in furnishing a uniform diatonic fingering technique. reducing the amount of string-crossing the bow has to do, generally freeing the bridge from too many strings and permitting better clearance on each string for bowing. The second additional feature is the unfretted finger board, in which the violin followed the *lyra* da *braccio.* No doubt frets, if they were ever used. were removed from the arm viols because they impeded the use of the hand in supporting the instrument and in fingerinn. It is also true that the direct stopping of the strings by the fleshy part of the finger tips produces a tone quality that. although slightly damped. in consequence is more satisfying and easier to listen to than the pure open-string tone obtained from the use of frets. as on the viols. besides being more completely under the control of the player. Moreover. it leaves the player free to temper intonation as much as he pleases. since this is no longer dominated by the fixed tuning of the frets. It is perhaps this capacity for the mutual adjustment of intonation that led to the use of the violin family in a way that was entirely new in instrumental music: *i.e.,* as a massed "choir" in which the several parts were doubled at unison by instruments of like kind. This string ensemble. so different in its effect from the chamber music of the preceding "golden age." owes its first organization. if not its invention. to the French at the court of Louis XIV. whose *vingt-quatre violons du* Roi was the model for Europe of the embryo orchestra-to-be.

The four members of the group are tuned as follows:

violin

viola

violoncello

double **bass** sounding

(Note. the double bass always sounds one octave below the written notes. Observe that it is tuned in fourths not fifths. For a discussion of this matter and of five-stringed instruments, see *Double* Bass, below.)

It will be seen from the above tunings that the viola stands one fifth lower than the violin, its upper three strings being tuned to the same notes as the lower three of the smaller instrument. The tuning of the violoncello is one octave below the viola. while the normal double bass approximately covers the suboctave of the violoncello. There is some evidence for the former existence of a fifth member, the so-called true tenor violin, standing in pitch one octave below the treble instrument.

The violin and viola are the only members of the family that are played in the horizontal position. *i.e.,* "under the chin." The cello (this abbreviation of violoncello will be used in the rest of this article') and double bass both stand vertically on the floor. the first resting on a long steel rod—the end pin—with the player holding the instrument between his knees while seated. For the double bass the player stands. or rests on a high stool. As is done with every other necked stringed instrument, the player's left hand fingers the instrument. the bow being held in the right. The highest string is to the right. viewing the instrument from the front. the lowest to the left. Therefore. on the violin and viola. the bow attacks from the top-string side, and on the bass instruments from the bottom string side. This makes scarcely any difference to the bowing technique except perhaps to give freer control of the upper strings of the smaller instruments and lower strings of the larger. a useful bias in view of their respective functions. at least in earlier times.

Violin.—In structure and appearance, violins of all sizes are quite unmistakable. The body consists of a belly of pine and a back of sycamore, maple or a similar hardn-ood, spaced apart by shallow ribs (sides) of the same material. The arching of the belly and back. already mentioned, is both transverse and longitudinal, so that n-hen viewed from the side the effect is of a central bulge. flattening off in all directions to the edges. the undersides of which are plane where they meet the ribs. In most cases the "modeling" of the bulge changes from convexity to concavity as it approaches the edges. which are given a slight upward curl. The arching is worked from solid wood of suitable thickness, and the plate is dug out on its undersurface to a curve that follows the general contour of the outward modeling but not exactly. for the finished thickness is graduated in all directions. being thinnest in the margins of the outline just inside the ribs. The adjustment of these thicknesses is one of the prime skills in the craft of violinmaking. The wood used in both back and belly is usually, though not always. cut "on the quarter"; that is. in wedge-shaped segmental planks from the centre to the outside of the log. To form a plate. two wedges are glued "back to back" with the thin edges outward. This not only provides the basis for the tnodeling but also ensures that the annular rings of the tree are evenly disposed about the centre line of the plate, the oldest growth being on the outside edges.

The familiar. and deceptively simple. outline of the violin body is aesthetically satisfying. perhaps because its balance and proportion are largely functional. Its master makers have evolved a form based on an artistic unity of opposed curves that allows free play to individual nuance with scarcely any measurable deviation from the norm. The rounded ends of the body.—the upper and lower bouts—are separated by the indented waist. or middle bout, which provides clearance for the bow on the outer strings. The middle bout meets the upper and lower to form outturned corners: where the ribs are brought together and glued firmly to corner blocks within the instrument. Other blocks—the end blocks—are mounted top and bottom centre to provide firm bearings for the neck and end pin. which between them have to resist the tension of the strings. The ribs are slightly inset from the outline of the belly and back, so that the edge overhangs all round. The internal corners between the ribs and the plates are strengthened by a narrow fillet of pine. called the "linings." which runs between the blocks. Despite the very considerable stresses to which it is subject. the violin body is held together by simple flush glued joints. which can in emergency be opened up, without damaging the instrument, for repairs.

The arched belly or soundboard of the violin is supported in a curiously unorthodox and individual way, quite different from the regular barring of instruments with flat soundboards. The sound post has already been mentioned. It is a loose stick of pine. carefully cut to size, that is wedged between the plates of the finished instrument under. but a little behind, the top-string side of the bridge. It is not a fixture because its position is critical and must be adjusted with great care for the best tonal result. This adjustment is made through the sound holes in the belly. The other side of the bridge is supported by a bar glued under the belly and running lengthways along the grain of the wood. This bar, called the bass bar. is deepest under the bridge, but tapers to nothing at either end. since it fits into the internal curvature of the belly. Externally, the plates are finished off with a narrow inlay of laminated woods, the purfling, which follows the outline close to the edges. Even this, the only decoration normally permitted. has the function of preventing incipient splits from running.

The neck and head are cut from a solid block of sycamore wood. The lower end is formed into a shoulder that abuts against the ribs at the top of the body and, in fact, passes through them into a shallow mortise cut in the end block within. The back end of this shoulder is covered by a projection of the wood at the top of the back, known as the button. The head or pegbox carries the four tuning pegs, two on each side. It is slotted lo the front to receive the strings. The pegs are tapered and pass through two holes in the cheeks of the head. At the top of the head is the scroll, again a typical embellishment of the violin, its austere purity of line and curve being both the challenge and the sign manual of the master craftsman. The front face of the neck is flat. and to this is glued the finger board, which projects beyond the shoulder and over the belly toward the bridge. At the top of the neck is the nut, which is grooved to take the strings. keeping them correctly spaced apart and slightly raised over the finger board. The neck is raked back at an angle with the plane of the belly, so that the finger board rises with the strings toward the bridge. The bridge is high and arched because of the bowed technique. It is formed with two feet that are carefully cut to fit the transverse arch of the belly and is given a conventional perforated or fretted design, which is said to aid its free vibration. In section it is wedge-shaped, tapering to the thin, notched edge over which the strings pass. It is not a fixture but is kept in position only by the pressure of the strings. Its correct position is between the sound holes and just above the lower corners of the middle bout. The sound holes are of italic f form. sweeping outward and downward from the waist to the lower corners. A line joining the crosses of the *f*s marks the approximate position of the bridge. The lower ends of the strings are held by the long tailpiece below the bridge, whose function is to reduce the length of unused string behind the bridge and to keep the strings pulling radially inward on its top edge. The lower end of the tailpiece is anchored by a loop of gut to an end peg set in a hole in the lower end block. A small ebony button takes the pull of the tailgut off the edge of the belly.

During its history the violin has been subject to modifications that have progressively adapted it to its evolving musical functions. In general. the more primitive types have been more deeply arched in the plates, and the more modern, follo ing the innovations of **A.** Stradivari (*q.v.*) (1644–1737), have been shallower and more virile, which has affected the over-all tonal characteristics. The stresses to which the instrument is subjected under working conditions have increased not only because of the rise in pitch from the 17th century onward but also because of certain changes in physical design from about the beginning of the 19th century. Before that time the height of the bridge and its arching were lower, the neck thicker and wider and the bass bar shallower and shorter. These, with the type of bow then in use (*see* below) and the lower pitch, produced the small, delicate tone that served composers up to the time of Mozart. With the advent of larger auditoriums and the development of the violin virtuoso. however, greater power was demanded. and this demand was met by raising the height of the bridge., lengthening and slimming the neck slightly and setting it back at a greater angle, and putting in a stronger bass bar. The sum effect of these alterations mas to develop the optimuni sonority of which the instrument was capable. and the long experience of makers and players has shown that the Stradivari type with its shallower arching has stood up best to this metamorphosis. All fine violins now in use have been thus modified to bring them into line with modern technique and modern conditions.

Viola.—This instrument. standing a fifth lower than the violin. is similar to it in every essential, but, owing to its larger size. it has never been completely standardized in its main dimensions. since, whatever these are, they are bound to tax the human frame and fingers when the instrument is played. A compromise has to be effected between ideal size for the best tonal results and what is practicable to the player in handling, Too large an instrument is simply unplayable; too small an instruinent is weakest where it is most wanted—on the lower strings. The problem has never been solved to everyone's satisfaction, but it has produced a viola tone that is darker, more weighty and more sombre than the violin and without which the string ensemble cannot now be imagined. Violas have been made at various times with a body length (the most convenient measure of their maneuverability) of from 15 to 18 in.. and probably the majority of the most manageable and successful instruments are midway between these extremes. However desirable it may appear in theory. too big a body. whether in length or depth, is inclined to develop a "tubby," aggressive. unmanageable tone that lacks the blending qualities of the traditional instrument.

Violoncello.—The true bass of the violin, and the member of the family most nearly approaching it in character, is the violoncello. or cello. In build it differs somewhat, the ribs being proportionately much deeper and the much higher bridge standing on legs rather than feet. The neck is raked back at a sharper angle to allow for the height of the bridge. The instrument is held between the knees while it rests on an end pin, which is telescoped through the tailpin and can be clamped in any position to adjust the height of thc instrument above the floor. This playing position leaves both arms exceptionally free; in particular, the left-hand technique is more fluid and covers a wider range than in any other stringed instrument. This is strikingly shown by the ease with which a good cellist commands the brilliant solo register of the top (A) string! high above the normal *tessitura* of the instrument.

Double Bass.—Because of its great size. the double bass has always shown less regularity of form, stringing, tuning and technique than the other members of the violin family. Double basses have been in use for as long as the parent instrument. but they are not yet completely standardized in number of strings. tuning. shape or body size. The bass is sometimes made with the blunt corners and flat back of the viol and on that account has been called a hybrid instrument. But true double bass violins, with arched back and outturned corners. have existed since the early 17th century and are still in the majority. It is immaterial whether the back is flat or arched, except that the flat back is both more convenient for the player and more economical to make. It is the fitting and adjustment of the bass, which follows that of the cello. that makes it what it is—a double bass violin. The tuning in fourths. which is today almost universal, has been adopted on the bass owing to the great length of the strings ($42\frac{1}{2}$ in.), which makes the whole-tone interval in the fingering so large that it can be covered only by the span of the first and fourth fingers. The closer tuning therefore brings the technique of fingering more into line with what is possible on the smaller instruments, namely a scalewise or diatonic fingering that reduces hand movements to a minimum. The normal tuning, E-A-D-G, means that the bass cannot descend an octave below the cello's bottom string. and it is for this reason that the low fifth string is sometimes added. tuned to 16-ft. C. The note commonly occurs in symphonic works from the classical period onward and is being more specifically demanded by modern composers. Conversely, the high fifth C string, tuned a fourth above the normal top string. is occasionally used in dance bands, where it simplifies the fingering of high pizzicato (plucked) notes.

Another method of obtaining 16-ft. C is to fit an attachment mechanism that lengthens the existing E string (which is carried up to the top of the head on an extension bar) when these low notes are wanted. This has the advantage that it preserves the normal four strings and their normal tuning for all ordinary purposes and imposes no extra load on the bridge, as does the fifth string. On the double bass the pegs are replaced by a "machine head." such as is commonly used on guitars and other plucked instruments, each tuning peg being fitted with a worm-and-wheel screw adjuster. The pegs themselves are made of solid brass. The "tailgut" of the smaller instruments is also replaced by metal. usually a thick copper wire but preferably a stranded steel cable. An extending end pin, similar to the pin used on the cello. is now in universal use. On most basses the ribs are not of equal depth all round but are cut away at the top so that the back slants toward the shoulder of the neck in its upper part. This enables the player to bring the neck and upper portion of the hody closer to him and makes for ease of handling. The normal size of the bass. around six feet high. is about as large as the average person can manage for modern technical requirements. This size has been known since the early 17th century, but larger and smaller basses have been made at all times. without coming into general use.

The Violin Bow.—The bow consists of a strong, light flexible wooden stick. sprung so that a ribbon of horsehairs can be stretched between its ends. Powdered resin is applied to the hair (more properly. the hair is drawn across a solid cake of resin and rubs off a small quantity in powder form) and this supplies the frictional element that is necessary to make the string vibrate. Proper design is as important in a violin bow as in the violin itself. for it must give the player a feeling of complete control over the tone he is producing and must respond to every nuance of pressure and attack imposed upon it. The modern bow, which is really the culmination of a long line of evolution, was perfected late in the 18th century by François Tourte, of Paris. The light tapering stick now is made of Pernambuco wood (brazilwood) with a hatchet-shaped head formed at the thinner end. At the other end is a movable frog. which has a threaded eye projecting into a mortise or groove cut in the stick and runs on a screm that can be turned at the lower end of the stick. The hank of hair is stretched between the head and frog, and its tension is adjusted by the screm. The hair is retained as a flat ribbon by passing through a specially shaped ferrule and a shallow channel in the frog before it is wedged into a socket farther along. The hair is usually concealed in the channel by a small sliding panel of mother-of-pearl, The hair is similarly wedged in the head. the front of which is faced either with ivory or silver to protect it from damage. When the screw is slackened off, the stick curves toward the hair. When the hair is tightened, the stick straightens out. or rather, the curve flattens somewhat. It is the correct setting of this curve. which is put into the stick by bending under dry heat, and the exact shaping of the tapering section of the stick that give a good bow its desired qualities.

The earlier type of violin bow, which was used almost everywhere from the beginning of the 17th century until the end of the 18th century, was shorter and had a lighter head and a narrower ribbon of hair. Its chief characteristic, however. was the shape of the stick. which bent outward from the hair under working tension. This design would not stand up to modern ideas of bowing technique. where. on occasion, optimum sonority must be developed from the instrument. but it was admirably suited to the smaller scale and neat articulations of baroque and early classical violin music.

The larger instruments have followed the violin in bow design. adapting it to their special purposes by adjustments of dimension and weight. For a long time the double bass lagged behind and during the first half of the 19th century this instrument was still being played with a broad. heavy version of the earlier outcurved bow. This was supplanted in France. and in other countries under French influence, by the violin-type bow and in Austria and German-speaking countries generally. a little later. by the "Simandl" bow, named after a contemporary professor of the Vienna academy. The bow is really an adaptation of the older type but with an incurved stick, wide frog and narrow head.

See also STRINGED INSTRUMENTS. (E. HA.)

VIOLLET-LE-DUC, EUGÈNE EMMANUEL (1814–1879). French architect and writer on medieval architecture, was born in Paris on Jan. 27, 1814. and died at Lausanne, Switz., on Sept. 17, 1879. He was a pupil of Achille Leclère. but was inspired rather by Henri Labrouste. In 1836 he traveled to Italy where he spent 16 months studying architecture. Back in France he was drawn irrevocably to Gothic art.. In 1839 his friend, Prosper Mérimée, placed him in charge of the restoration of the abbey church at Vézelay, and in the following year he was appointed inspector, under F. L. J. Duban and J. B. A. Lassus, of the Sainte Chapelle. With Lassus he won a competition in 1843 for the restoration of Notre Dame in Paris. Soon he became a focal figure on the Commission des Monument Historiques, and, after 1848, the Service des Edifices Diocésains', supervising the restoration of numerous medieval buildings. the most important being the abbey of Saint Denis (1846), the cathedral of Amiens (1849), the synodal hall at Sens (1849). the fortifications of Carcassonne and. later. the Saint Sernin at Toulouse. For Louis Napoleon he reconstructed the chhteau of Pierrefonds (1859–70). His numerous written works, all finely illustrated, provide the foundation on which his distinction rests; his two dictionaries serve still as standard works of reference. But his special contribution to present-day thought is the *Entretiens sur l'Architecture,* a theory of modern architecture based on a scientific exposition of Gothic art.

Viollet-le-Duc's principal literary works are: *Dictionnaire raisonné de l'Architecture Française du XI au XV siècle* (1854–68); *Dictionnaire raisonnd du Mobilier Français de l'époque Carlovingienne à la Rénaissance* (1858–75); *Entretiens sur l'Architecture* (1860–72); *L'Art Russe* (1877); *De la Decoration appliquee aux edifices (1879).*

VIOLONCELLO: *see* VIOLIN FAMILY.

VIPER. In a broad sense vipers include the snakes of the family Viperidae, which is characterized by the presence of poison fangs on a movable upper jaw. The fangs are simply enlarged teeth perforated longitudinally for the passage of the venom and, like those of all other snakes. they are fused to the supporting bones. In this family, however. there are no other teeth on the maxillary bone. which is movable so that the fangs are folded down parallel with the roof of the mouth when not in use. The same mechanism is present in the pit vipers.

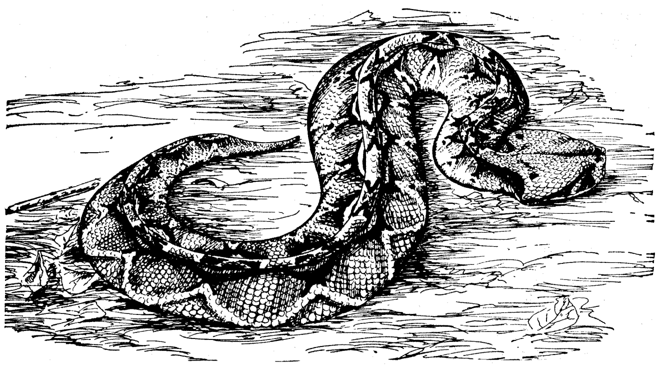
Venom is secreted by a pair of glands, situated behind the angle of the mouth. and is carried to the fangs by a short duct that opens close to their base inside a fold of skin (the *vagina dentis*) which surrounds them; within this fold of skin there is also a series of reserve fangs in different stages of development and, should one of the functional fangs be broken, the largest of these reserve teeth moves into its place and becomes fused to the jaw. Vipers, as a rule, are stout sluggish creatures with a broad. fattened head. and lack the large head shields so characteristic of the majority of other poisonous snakes; most of them are terrestrial, though there are aquatic, arboreal and burrowing species. A few lay eggs but the majority produce fully developed young.

All the Viperidae are very poisonous and the bite of most of them is dangerous to man; the toxicity of the venom varies with each species. and the virulence of any bite depends not only on the species of snake responsible for it but also on the amount of venom injected. the position of the bite and the physical condition of the snake. In composition viper venom resembles that of the back-fanged colubrids, rather than that of the cobras and their allies. and its action consists largely in the destruction of the blood corpuscles and vessels.

The family is closely allied to that of the pit vipers (Crotalidae), which have a similar venom-injecting apparatus. but are well distinguished by the presence of a sensory pit between the eye and the nostril.

The majority of the true vipers are terrestrial, though *Atractaspis* of tropical and South Africa is a genus of small burrowing creatures with enlarged shields on the head; the night adders (*Causus*) of the same region, have the head similarly covered. *Causus* is remarkable for greatly enlarged poison glands that extend into the neck. Arboreal forms are represented by *Atheris,* of the forests of tropical Africa, which is equipped with a prehensile tail and is usually green or olive in colour to harmonize with its

COMMON EUROPEAN VIPER (VIPERA BERUS) ABOVE; GABOON VIPER OF TROPICAL AFRICA (BITIS GABONICA) BELOW



surroundings. The colours of the terrestrial species, on the other hand, are more frequently shades of gray. brown or black to correspond to the rocky or sandy localities they frequent. The puff adder *(Bitis arietans)*, which occurs throughout the drier areas of Africa. is a sluggish. heavily built creature that may grow to a length of four or five feet; it is usually pale brown with a series of regular. dark, chevron-shaped crossbars along the back, a colouring that harmonizes so well with sandy soil that man:; accidents occur when people fail to notice the animal until they actually tread upon it. The Gaboon viper *(Bitis gabonica)*, and the nose-horned viper. *B. nasicornis,* unlike their relative, are inhabitants of the forested regions of Africa and exhibit a geometrical "camouflage" colour pattern of blues, reds and yellows. Many desert species show the ieature characteristic of desert-dwelling animals and plants, the development of spines; *Cerastes cornutus,* the horned viper of Egypt and northern Africa, has a prominent spine above each eye. *Cerastes* and *Echis,* the latter found through northern Africa and southern Asia, including India. exhibit a specialization for desert life not found elsewhere; the scales of the sides are small and have pronounced, serrated ridges which act, through lateral shoveling movements of the body, as scoops to dig up loose sand and throw it onto the creatures' backs: and so enable them to bury themselves completely. In Europe the family is represented by the genus *Vipera* of which the adder (*V. berus*) is the best-known species; it is an inhabitant of the northern countries and is the only venomous serpent in Great Britain.

In southern Europe an allied species *1'. aspis,* is more common, characterized by a "snub-nose." This feature is even more pronounced in *V. latastei* of the Iberian peninsula. while in *V. ammodytes* of southeastern Europe the tip of the snout is prolonged upward into a definite scaly appendage. In India the commonest and most dangerous viper is the handsomely coloured daboia or tic polonga *(V. russelli)*, which reaches a length of five feet.

The extensive parallelism between the genera of the viper family and those of the pit vipers well illustrates the principles of adaptive radiation in an evolutionarily successful group. The arboreal *Atheris,* with their green or mottled colors and prehensile tails are matched by the prehensile-tailed species of the pit viper genus *Trimeresurus* in the East Indies and in tropical America. "Desert coloration" reaches a high development in the vipers of the genera *Vipera* and *Bitis* and in the rattlesnakes of the southnestern deserts of Sorth America. (K. P. S.)

VIPER'S BUGLOSS (*Echium vulgare*); a hairy herb of the borage family (Boraginaceae). indigenous to Europe and western Asia. Also known as blue-weed. it is widely naturalized in the U.S. and Canada, from Nova Scotia to Ontario and Nebraska and southward to North Carolina; in some sections it is a troublesome weed. It prefers dry soil. The flowers are brilliant blue when expanded, but the buds are reddish. The genus *Echium* contains about 30 species, all found in Europe.

VIRCHOW, RUDOLF (1821–1902), German pathologist and politician, was born on Oct. 13, 1821. at Schivelbein, in Pomerania. In 1843 he received an appointment as assistant-surgeon at the Charité hospital, becoming pro-rector three years later. In 1847 he began to act as *Privatdozent* in the university, and founded with Reinhardt the *Archiv* fur *pathologische Anatomie und Physiologie,* which, after his collaborator's death in 1852, he carried on alone. In 1848 he went as a member of a government commission to investigate an outbreak of typhus in upper Silesia. About this time, having shown too open sympathy with the revolutionary or reforming tendencies. he was for political reasons obliged to leave Berlin and retire to the seclusion of Würzburg, the medical school of which profited enormously by his labours as professor of pathological anatomy. In 1856 he was recalled to Berlin as ordinary professor of pathological anatomy. As director of the pathological institute he formed a centre for research.

Pathology.—Wide as were Virchow's studies, yet the foremost place must be given to his achievements in pathology. In his book on *Cellular-pathologie* (1858), he established what Lord Lister described as the "true and fertile doctrine that every morbid structure consists of cells which have been derived from pre-existing cells as a progeny." Virchow made many important contributions to histology and morbid anatomy and to the study of particular diseases. The classification into epithelial organs, connective tissues, and the more specialized muscle and nerve. was largely due to him; and he proved the presence of neuroglia in the brain and spinal cord. discovered crystalline haematoidine. and made out the basic structure of the umbilical cord. Among the books he published on pathological and medical subjects may be mentioned *Vorlesungen über Pathologie,* the first volume of which was the *Cellular-pathologie* (1858), and the remaining three *Die Krankhaften Geschwülste* (1863–67); *Handbuch der speziellen Pathologie und Therapie,* 3 vol. (1854–62). in collaboration with other German surgeons; *Vier Reden über Leben und Kranksein* (1862); *Untersuchungen über die Entwicklung des Schädelgrundes* (18j7); *Lehre von den Trichinen* (1865); *Ueber den Hunger-typhus* (1368); and *Gesammelte Abhandlungen aus dem Gebiete dcr öffentlichen Medizin und der Seuchenlehre* (1879).

Anthropology.—Another science which Virchow cultivated with conspicuous success was anthropology. In ethnology he published a volume of essays on the physical anthropology of the Germans, with special reference to the Frisians; and at his instance a census, which yielded remarkable results, was carried out among school children throughout Germany, to determine the relative distribution of blondes and brunettes. His archaeological work included the investigation of lake dwellings and other prehistoric structures: he went with Schliemann to 'Troy in 1879, fruits of the expedition being two books. *Zur Landeskunde der Troas* (1880) and *Alt-trojanische Gräber und Schädel* (1882); in 1881 he visited the Caucasus, and on his return published *Das Gräberfeld von Koban im Lande der Osseten.*

Politics.— In 1862 Virchow was elected a member of the Prussian lower house. He was a founder and leader of the Fortschrittspartei, and the expression *Kulturkampf* had its origin in one of his electoral maniiestos. For many years he was chairman of the finance committee, and in that capacity was chief founder of the constitutional Prussian Budget system. In 1880 he entered the Reichstag as representative of a Berlin constituency, but was ousted in 1893 by a Social Democrat. In the Reichstag he became the leader of the Opposition, and a vigorous antagonist of Bismarck. In the local and municipal politics of Berlin again he took a leading part. and as a member of the municipal council was largely responsible for the transformation which came over the city in the last thirty years of the 19th century. It was his unceasing efforts that secured for its inhabitants the drainage system, sewage farms and good \\-ater-supply.

Of his writings on social and political questions may be mentioned *Die Erziehung des Weibes* (1865); *Ueber die nationale Entwicklung und Bedeutung der Naturwissenschaften* (1865); *Die Aufgaben der Naturwissenschaften in dem neuen nationalen Leben Deutschlands* (1871); *Die Freiheit der Wissenschaft im modernen Staat* (1877), in which he opposed the idea of Haeckel that the principles of evolution should be taught in elementary schools—on the ground that they were not as yet proved.

VIRELAY, the title applied to more than one fixed form of verse (*virer,* "to turn"). Its history and character are very obscure. It may be connected with the Provençal *ley.* Historians agree that it is a modification of the medieval *lai;* but no example of the *lai* is known except the following (first printed by Pere Mourgues in his *Traité de la Poésie*):

"Sur l'appui du monde Que faut-il qu'on fonde
D'espoir ?
Cette mer profonde Et débris féconde
Fait voir
Calme au matin l'onde Et l'orage gronde
Le Soir."

But this seems to be a mere fragment of a virelay, which proceeds by "veering" the two rhymes *ad libitum.* This is the *virelai ancien,* of which examples are rare in recent literature. There is also the *virelai nouveau,* which was used by Alain Chartier in the 15th century. In French the old and popular *Adieu vous dy triste Lyre* is a perfect example; and in English we have one admirable specimen in Austin Dobson's "Good-bye to the Town. good-bye." A so-called Virelay is found among Chaucer's spurious works (Skeat, vii, 448). The New Virelay is written on two rhymes, and begins with two lines that recur throughout as refrains, and (reversed in order) close the poem in a couplet. The Virelay is a vague and invertebrate form of verse. and one of little importance.

VIREO, the common name of birds of the American passerine family Vireonidae. There are about 50 species of these insectivorous birds. which have characteristic and often very musical songs. Twelve species inhabit the United States. all building deep, pendent, cup-shaped nests. usually hung between the forks of a branch. The red-eyed vireo (*Vireo olivaceus*) breeds from the Gulf states to Labrador and British Columbia, wintering in Central and South America. West of the Cascade mountains, it is replaced by Hutton's vireo (*V. huttoni*), with three subspecies, lacking the slate crown of *V. olivaceus.* The warbling vireo (*V. gilvus*) of eastern U.S. and Canada has a fine song.

VIRGIL (VERGIL; PUBLICS VERGILIUS MARO) (70–19 B.C.), author of the *Eclogues,* the *Georyics* and the *Aeneid,* was the greatest Roman poet. The Latin form of his name was undoubtedly Vergilius; in English Virgil has generally been the traditional form, but both spellings are current. Information about his life is derived partly from his own writings and partly from the ancient lives which have survived under the names of Probus, Aelius Donatus. Servius and others. Virgil was born of peasant stock on Oct. 1j. 70 B.C., at Andes near Mantua; his love of the Italian countryside and of the character of the people who cultivated it is one of the sources of inspiration for his poetry. He was educated at Cremona. Milan and, finally; at Rome. The education which he must have received involved a thorough study of Roman and Greek authors. especially the poets. and a detailed training in rhetoric and philosophy. One of his teachers was the Epicurean Siro. and it is interesting to see how Epicureanism figures largely in his poetry at first, but gradually gives way to an attitude more akin to Stoicism and neo-Pythagoreanism.

Virgil's life was devoted entirely to his poetry and his studies connected with it; his health was never robust, and he played no part in military or political life. It is said that he spoke once in the law courts without distinction, and that his shy and retiring nature caused him to give up any ideas he might have had of taking part in the world of affairs. But it should not be thought that he ever lost touch with current events; his iriends were men directing the movement of affairs. such as Octavian. Pollio. Gallus and Varus. and they must have influenced his thoughts and ideas as doubtless he influenced them. Thus his poetry is often concerned with the large aspect. the underlying significance. of contemporary Roman problems and hopes.

The *Eclogues,* the first of Virgil's certain works (the authenticity of the *Appendix Vergiliana* is discussed below), were composed betn-een 42 and 37 B.C. Two of these poems (the first and the ninth) refer to the confiscations of land in Virgil's own country near Mantua at the time of the resettlement of veteran soldiers after the battle of Philippi; it was widely believed in antiquity that Virgil's farm was among those confiscated (a belief which the poems support), and that it was restored to him on the intervention of friends (the support for this is much more controversial,). The publication of the *Eclogues* brought him recognition as one of the leading poets of Rome. and he became an important member of the literary court circle. under the patronage of Maecenas. to whom he dedicated the *Georgics.* At this time he was living in Rome. but he soon withdrew to Campania, where for the rest of his life he spent most of his time. at either Naples or Nola.

He spent the years 37–30 composing the *Georgics,* and the rest of his life on the *Aeneid.* In 19 B.C., when he planned to spend three more years perfecting the *Aeneid,* he set out on a voyage to Greece. doubtless to obtain the extra local knowledge and colour necessary for the revising and partial rewriting of sections of it, especially of book iii. But at Megara he caught a fever and, returning to Italy, died shortly after landing at Brundisium (Brindisi), on Sept. 21, 19 B.C. He left instructions that the *Aeneid* should be burned, but this was not permitted by Augustus, who ordered Varius and Tucca to publish the work with excisions where necessary. but without additions. A well-known example of such an excised passage which nevertheless survived is the Helen episode in Book ii, 567–588. Evidence of the unfinished state of the poem is to be found in certain relatively minor inconsistencies, in the presence of about 50 half lines and in the stopgap nature of some passages (*tibicines*); but there is no reason to think that Virgil intended any major alteration of scope or plan.

WORKS

Appendix **Vergiliana.**—There is extant a collection of poems said to be the work of Virgil's youth; the question of their authenticity has been much debated. but the evidence does not admit of conclusive proof. The indications suggest that most of them are not by Virgil. The poems generally included in this collection are *Culex, Ciris, Catalepton, Priapea, Copa, Dirae, Lydia. Moretum.* Servius gives all these as \-irgilian except *Lydia* (which is joined on to *Dirae* in the manuscripts) and *Moretum;* Donatus agrees with Servius except that he omits *Copa.* Both also attribute another poem, *Aetna,* to Virgil, but this attribution is extremely unlikely. The external evidence for *Culex* is particularly strong, as it is mentioned as a poem of Virgil's early youth by Lucan, Statius and Martial. It is a mock-heroic poem about the death of a gnat (*culex*), unkindly and too hastily killed by a 'shepherd whom the gnat awoke from sleep because of the approach of a dangerous snake. It contains phrases which occur also in Virgil's major works. but are sometimes not quite appropriate to the context in *Culex;* this suggests that a later author of *Culex* borrowed them not very successfully from Virgil (*see* E. Fraenkel. *Journal of Roman Studies,* 42:1–9, 1952), and the stylistic affinities of *Culex* with the late Augustan age point to the same conclusion. *Ciris* is a mythological poem of Alexandrian type. full of echoes of Catullus; like *Culex* it contains phrases (and indeed whole lines) which are found in Virgil's major poems. It was argued by F. Skutsch in *Aus Vergils Frühzeit* (1901–06) that Gallus wrote it and Virgil imitated it. This view has been widely accepted, but a post-Virgilian date for *Ciris* as well as for *Culex* cannot be ruled out. These two epyllia are the longest poems of the *Appendix*

Vergiliana, and it does not appear likely that Virgil wrote either. On the other hand, a few of the short poems of *Catalepton* (*e.g.,* v and viii) are probably Virgilian, and some of the other poems may be. It is reasonable to 'conclude that there existed a genuine collection of Virgilian *juvenilia* into which a number of non-Virgilian poems early found their way.

Eclogues.—The ten *Eclogues* ("Selections"), sometimes called *Bucolics* ("Pastoral Poems"), are modeled on the *Idylls* of the Greek poet Theocritus of Syracuse (fl. *c.* 310–250 B.C.), founder of pastoral poetry. Virgil several times explicitly acknowledges this debt, and there are many close parallels of diction. Most of the names of the shepherds and shepherdesses are taken from Theocritus, and the setting is a mixture of the Sicilian landscapes of Theocritus with Virgil's Italy. But Virgil does not attempt to imitate the lively realism characteristic of Theocritus' dialogue and situations; with him the pastoral becomes more literary and artificial. Persons of the contemporary literary world, like Gallus, appear in a pastoral setting, and the touches of allegory and topical allusion which are sometimes found in Theocritus (*e.g., Idyll* vii) become more frequent in Virgil. though it is a mistake to look for allegory everywhere.

The second and third eclogues. the earliest, are the closest to Theocritus: the second tells of Corydon lamenting his unhappy love, and the third is a singing match between two shepherds. The seventh and eighth are of this type too; so is the fifth, where Mopsus and Menalcas vie with each other in singing of their sorrow for the cruel death of Daphnis. Daphnis has often been thought to be allegorical, and many have equated him with Julius Caesar, but there are strong arguments against this, and it is wise to bear in mind the view expressed by Servius, that an allegorical interpretation of the shepherds' songs should not be accepted except in the eclogues dealing with the loss of Virgil's farm. These are the first and ninth: in the first Meliboeus laments for the loss of his farm while Tityrus rejoices that Octavian has restored his; in the ninth Menalcas is exiled from his farm—it had been hoped that his poetry would save him, but in vain. Clearly Virgil is here referring to personal experience. but it need not be assumed that he intended all the details to hear a precise allegorical significance.

The sixth eclogue, dedicated to the statesman Varus, is a song of the satyr Silenus about the origin of the world and about many mythological themes; the tenth tells of the unhappy love of Gallus. the fnmous poet and statesman, for Lycoris. This is the most artificial of all the poems. with its highly conventionalized pastoral setting for a subject which is not pastoral. It is a clear ancestor of Milton's *Lycidas.*

The fourth eclogue, perhaps the most discussed poem in Latin literature. prophesies in moving and exalted tones the birth of a child who will introduce a new Golden Age. It is dedicated to Pollio in his consulship, so that its date must be late 41 or 40 B.C. From early times it has often been regarded as prophetic of Christianity, and it is sometimes referred to as the Messianic Eclogue. It blends a mystic and oracular tone, influenced by sibylline prophecies. with the Golden Age motif of classical literature. The identity of the child remains mysterious. as Virgil probably intended; no historical child of this time is suitable, and it seems likely that Virgil was symbolizing the new generation in a way which could have been applied more specifically if a son had been born to Octavian.

The *Eclogues* generally have a gentle and polished charm reminiscent of some of the qualities of Alexandrian poetry and its followers in Rome, the *neoterici;* this is perhaps partly what Horace meant when he used the phrase *molle atyue fucetum* of the *Eclogues.* They foreshadow Virgil's later work in their sincere love of nature and the countryside, of peace and beauty; in their mellifluous control of the hexameter; and in their tender sympathy for suffering, shown especially in the laments for unhappy love and youthful death.

Georgics.—Virgil spent seven years on the composition of the four books of the *Georgics,* a didactic poem on farming which combines practical instruction with descriptive and imaginative passages in praise of Italy and the farmer's life. The first book is about tilling the land. the second about growing trees, especially the olive and the vine, the third about cattle and horses and the fourth about bees, ending with a fable or epyllion about Aristaeus and his bees, which includes the story of Orpheus and Eurydice.

The *Georgics* is clearly related to social and political conditions. The restoration of Italian agriculture, and with it of something of the old traditional way of life, was a matter of vital concern to the government, as well as a theme dear to Virgil's heart. There are enthusiastic references to the achievements of Augustus; the hopes which the Romans placed in their new emperor and their expectation of a stable order after generations of civil war are reflected in the poem. By writing about Italian farming, which he knew well and loved, and by setting it in the large context of a poet's vision. Virgil could contribute to the fulfillment of the Golden Age which he and his friends saw dawning for Rome.

Virgil's Greek model for the *Georgics* mas Hesiod. but the extent of his debt was not considerable. To the didactic poets of Hellenistic Greece he turned for some of his factual information but he owed most to Lucretius, who had shown that a didactic theme could be a subject for inspiring poetry, and had made great advances in the technique of the Latin hexameter.

The theme running through the *Georgics* is the joy of country life. It is a hard struggle which must be waged—Virgil often uses military metaphors—but the rewards are great. The moments of trouble or of triumph are vividly portrayed, and Virgil took advantage of and extended the personification of nature already existing in Roman agricultural terminology. The crops are joyful. the boughs are happy, the fruits of the self-seeded tree gradually forget their old flavour, the grafted tree is surprised when it grows fruit not its own. The animals of the countryside are described with knowledge and affection; they need man's help, and in return they give their service. Finally the bees reflect the organized existence of men, and their intricate arrangements for the well-being of their species serve to symbolize the essential oneness of nature.

Virgil wrote the *Georgics* slowly and with great care. The poem is organized with a harmony of structure which foreshadows the great achievement of the *Aeneid,* and in some ways (on a smaller scale) is more perfect. With the liquid cadences of the hexameter of the *Eclogues* Virgil now blends a more powerful element, able to express majesty as well as beauty, capable of sustained grandeur and unending variety. Here and in the *Aeneid* is the most successful sustained use in Latin literature of what Tennyson called "the stateliest measure ever moulded by the lips of man."

Aeneid.—As the *Georgics* is Virgil's poem of Italy. so the *Aeneid* is his poem of Rome. It tells in 12 books of the legendary foundation of Lavinium (parent town of Alba Longa and of Rome) by Aeneas, a Trojan who had left the burning ruins of Troy to found under divine guidance a new city with a glorious destiny in the west. The choice of subject gave Virgil scope for his poetic purposes; Aeneas, the son of Venus and Anchises, was an important but vaguely drawn character in Homer and in later authors, and the legend itself had many variations and was capable of modification. It thus allowed Virgil some freedom in the selection and treatment of the material, while having immediate and important points of relevance for his own time. By describing the time-honoured origins of contemporary customs and institutions Virgil was able to link the past with the present, and to enlarge the significance of events.

It is possible to distinguish two main sources of inspiration for Virgil's epic. One was the desire to give poetic expression to his conception of the achievements, ideals and destiny of Rome; to carry further the portrayal of Roman character which he had given in the *Georgics;* to show what virtues had made Rome great, and could in this era of new-dawning hopes make it greater still. This theme, which coloured such contemporary writings as Livy's history and some of Horace's odes, clearly captured Virgil's imagination, and throughout the *Aeneid,* particularly in the closing sections of the sixth book; it is given noble expression.

His second source of inspiration was the poetry of Homer. From early youth Virgil had been deeply influenced by the *Iliad* and the *Odyssey.* They had cast their spell upon him as poetic interpretations of the splendour and excitement of human activity, and he wanted to recreate for a later day and in a different idiom something of what these poems had meant to him. The Aeneid continues the story of the Iliad, and Homer's Greco-Trojan theme is completed from a Roman point of view as Aeneas, the new leader of Hector's race and founder of the Roman nation, reverses the defeat of Hector by Achilles when he himself prevails against his opponent, Turnus the Rutulian. The final scenes of Aeneid xii take the reader back again and again to Iliad xxii. Thus the Homeric background to Virgil's legend enriches and gives added significance to his narrative.

In structure and episode, in phraseology and imagery, the Aeneid often has close resemblances to Homer. The first six books, Aeneas' wanderings, are Virgil's Odyssey, and the last six, the battle scenes, his Iliad. Book vi has marked points of similarity with Odyssey xi, though it is entirely different in treatment; book v is based, but again with significant differences, on the funeral games in Iliad xxiii. In the battle scenes reminiscences of Homer are very frequent. Throughout the poem similes. descriptions, speeches, situations: have their Homeric counterparts. It is most important to understand the nature of this literary relationship. It should not be thought that Virgil went to Homer simply because he was his chosen model, and that he did so especially when he had nothing of his own to say. Rather it is that what Homer had said kindled Virgil's poetic imagination. and Homer's world was in a significant and permanent sense a part of Virgil's world.

In a way the Aeneid, is a synthesis of attitudes to human experience which Virgil had assimilated from the great literature of the past. The Greek tragedians had evoked a ready response in Virgil's poetic awareness; it has often been remarked that episodes of the *Aeneid* (*e.g.,* books ii, iv and xii) are closely akin to tragedy. The Alexandrian Greeks, who inherited and developed the intimate study of character which they found in Euripides, exercised a powerfui influence on Virgil: though one which he constantly sought to modify and control. The story of Dido and Aeneas in book iv owes much to the story of Medea and Jason in Apollonius Rhodius' *Argonautica;* but it goes far beyond it. Among the Romans, Ennius, Lucretius and Catullus all contributed largely to the Aeneid, not only verbally and in verse technique, but in attitudes to the different aspects of experience with which the Aeneid is concerned. By relating these interpretations of life to his own experience. Virgil sought to make his epic significant for the whole destiny of man.

The "architectural" structure of the Aeneid is most carefully organized with symmetries and variations of an intricate and aesthetically satisfying kind, both in subject matter and in tension and tone. After the invocation the narrative takes us immediately in medias res with the approach of the Trojans to Sicily; the storm caused by Juno drives them to Carthage, where Aeneas meets Dido. In the second and third books Aeneas describes to her the fall of Troy and his wanderings. and in the fourth Virgil returns to the narrative and to the tragic story of their love. The tension in the third book is at a lower pitch than in the books which precede and follow it, and in the same way the fifth book, mainly concerned with the anniversary games for Anchises, is a calm interlude after the intensity of the fourth and before the majesty of the sixth book, the pivot of the poem. In this book Aeneas descends to the underworld to learn from his father of the tasks and destiny which await him, and when he sees the great pageant of Roman heroes yet to be born he is given new strength to fulfill his mission. It is here, too, that Virgil's religious thought finds its fullest expression in a poetic vision of the world after death, with its atonements for sin and its rewards for virtue. The second half of the poem is concerned with the fighting in Italy before Lavinium can be founded, fighting that is necessary because of the hostility of Juno and of Turnus. her human agent. The numerous scenes of grim battle are diversified with passages of tender pathos; in the eighth book the tension is relieved by Aeneas' visit to the future site of Rome, and the description of the prophetic pictures on the shield which Vulcan made for Venus to give to her son. In the final denouement the action is resolved on the human plane when Xeneas kills Turnus in single combat, and on the divine plane when Juno is reconciled and accepts the common destiny of Italians and Trojans.

The Aeneid ends with the tragedy of Turnus, and one aspect of the inner cohesion of the poem is the tension and balance between the triumphant notes of Rome's heaven-sent destiny, and the feelings of pathos and sorrow which Virgil constantly expresses for the suffering which accompanies man's life on earth. This brooding note of sympathy in Virgil, this sense of the lacrimae *rerum,* is perhaps the feature of his poetry which leaves the deepest impression. The suffering of Dido is portrayed with a sympathy which has made Aeneid iv one of the most famous books of world literature; and our pity is powerfully evoked too for Turnus, for Euryalus, Pallas, Lausus, for the countless young warriors who die in battle. These two themes, Roman destiny and human suffering, are combined in the character of Aeneas himself, a lonely figure struggling against human frailty in order to fulfill a divine mission, and prevailing at last because of his devotion to his duty, his *pietas.* He has not the supreme self-sufficiency of a Homeric hero; he endures to the end to achieve a task which was almost beyond his strength. Tantae *molis* erat *Romanam* condere *gentem* ("So heavy was the task of founding the Roman nation").

Influence. — Virgil's poetry immediately became famous in Rome, and the Aeneid was always regarded by the Romans as their national epic. He was imitated by the writers of the Silver Age and their successors; the study of his works played an important part in Roman education, and many commentaries upon them were produced. Two from the late 4th century have survived, a rhetorical exposition by Tiberius Claudius Donatus. and the indispensable work by Servius. Allegorical interpretations of Virgil's poetry were common in late antiquity, and in the middle ages his popularity did not abate (see Virgil in the Middle Ages, below).

One result of Virgil's popularity is the excellence of his manuscript tradition. For most Latin authors the earliest manuscripts are Carolingian (9th, 10th or 11th century) or later, but for Virgil there are several written in the 4th and 5th centuries, and in addition there are the commentaries mentioned and many citations in early writers.

Virgil's influence on literature and thought has been greater than that of any other classical poet. Many reasons contribute to his continuing fame: his unsurpassed command of diction and rhythm and word music; his expression of the achievements and concepts which Rome has bequeathed to succeeding ages; his power of constructing an intricate work of art on the grand scale; his sense of pathos and sympathy for suffering; perhaps above all his universality, in that he symbolizes within the framework of a legendary story aspects of human experience which are of permanent significance.

BIBLIOGRAPHY.—Only a selection of the editions, translations and appreciations of Virgil can be mentioned here. For fuller bibliographical information see M. Schanz and C. Hosius, Geschichte der *römischen Literatur*, vol. 2, pp. 31–113 (1935); K. Büchner's article *Vergilius* in Pauly-Wissowa, Real-Encyclopiidie der classischen *Altertumswissenschajt*, 2nd series, vol. 8, col. 1021–1493 (1955–58); and the yearly lists in *L'Année* philologique, ed. by J. Marouzeau.

Texts: The foundation of modern texts was the edition (including Appendix *Vergiliana*) with detailed *Prolegomena* by O. Ribbeck (1859–68). Later editions include those by F. A. Hirtzel, Oxford classical texts (1900); G. Janell, "Teubner Series" (1930); R. Sabbadini (1930); and, with French trans. in the "Budé Series" by E. de Saint-Denis (Eclogues, 1942; Georgics, 19j6) and Goelzer-Durand-Bellessort (Aeneid, 2 vol., 1925–36). Editions with commentaries include those of Conington-Nettleship-Haverfield, 3 vol. (1858–98); T. E. Page. 3 vol. (1894–1900); and J. W. Mackail (Aeneid, 1930). See also the commentary by J. Henry, Aeneidea, 4 vol. (1873–92). Edition (including Appendix *Vergiliana*) by H. R. Fairclough, with Eng. trans., in the "Loeb Series," (1935). The Appendix I'ergiliana is also ed. by R. Ellis, Oxford classical texts (1907; reprinted with Vitae *Vergilianae* antiquae, ed. by C. Hardie, 1954), and by Vollmer-Morel, *Poetae Latini minores,* vol. 1, "Teubner Series" (1930).

Translations: Verse, Gavin Douglas (1553); Dryden (1697); C. Day Lewis (Georgics, 1940; Aeneid, 1952). Prose. J. W. Mackail (Aeneid, 1885; Eclogues and Georgics, 1889); W. F. Jackson Knight (Aeneid, 1956).

Servius' Commentary: edition by G. Thilo and H. Hagen, 3 vol. (1878–1902) and by E. K. Rand et *al.*, vol. 2 (1946. on Aeneid i and ii).

J. Rose. *The Eclogues of Vergil* (1942); R. Heinze, *Virgils epische Technik,* 3rd ed. (1928); *see* also H. J. Rose, *A Handbook of Latin Literature, pp.* 233–294 (1936). (R. D. Ws.)

VIRGIL IN THE MIDDLE AGES

Virgil's great popularity in the middle ages was due mainly to the fact that his works never ceased to be the chief textbook in the schools of grammar, which had no Christian writings of anything approaching equal literary reputation with which to replace them. In addition. Virgil's philosophy as revealed in his works, especially the Messianic Eclogue, led to the idea that he was an *anima naturaliter christiana* ("a soul Christian by nature'!), and thus one who, but for the accident of being born too soon, would readily have accepted Christ. It was this idea, together with deep appreciation of his poetic genius, that led Dante to take Virgil as his guide through Hell and Purgatory in the *Divina Commedia,* though as a pagan in fact Virgil could not of course enter Paradise, the subject of the third section of Dante's poem.

Virgil also plays a part in a variant of the story of the seven sages *(see* SEVEN WISE MASTERS, THE) entitled *Dolopathos,* by the late 12th-century monk Jean de Hauteseille. Dolopathos is a king of Sicily whose son Lucinius, educated in Rome by Virgil, is saved from his stepmother's wiles when he returns home by Virgil's advice and intervention.

Apart from his literary reputation, Virgil also became the central figure in a number of absurd but popular legends? the origin of which is obscure: about his magical powers. John of Salisbury, in the 12th century, is the source for the earliest of these, in which Virgil is said to have made a fly which exterminated all other flies in Naples. Later writers add further stories; as for example that Virgil built Naples on a foundation of eggs, and that he took a cruel revenge on a woman who left him hanging halfway up the wall for all to see in a basket in which he was coming by night to visit her in her closely guarded tower. By the early 16th century these scattered legends were collected into a romance entitled *Les Faicts merveilleux de Virgille,* which was soon translated into other languages including English. It relates that Virgil was born in the Ardennes soon after the foundation of Rome, studied at Toledo, exerted his magic art on the Roman emperor, fell in love with the sultan of Babylon's daughter, founded the city of Naples and finally disappeared in a violent storm at sea. Such stories, which are often confused with similar legends told about others. bear little relation to the known facts of Virgil's existence as a historical figure. It is difficult to discover what originally connected Virgil's name with them, but it was probably his early and deserved reputation for great learning, coupled with belief in his supernatural insight shown by his supposed prophesy of Christ.

See D. P. A. Comparetti, *Vergil in the Middle Ages,* Eng. trans.. 2nd ed. (1908); J. W. Spargo, *Virgil the Necromancer* (1934). (J. E. BH.)

VIRGIL, POLYDORE *(c.* 1470–1555), English historian, otherwise known as P. V. CASTELLENSIS, was a kinsman of Cardinal Hadrian Castellensis. Polydore was born at Urbino and was probably in the service of Guido Ubaldo, duke of Urbino, before 1495, as in the dedication of his first work. *Liber Proverbiorum* (April 1498), he styles himself this prince's client. Polydore's second book. *De Inventoribus Rerum,* is dedicated to Guido's tutor, Ludovicus Odaxius, from Urbino, in Aug. 1499. After being chamberlain to Alexander VI he came to England in 1501 as deputy collector of Peter's pence for the cardinal. As Hadrian's proxy, he was enthroned bishop of Bath and Wells in Oct. 1504. It was at Henry VII's instance that he commenced his *Historia Anglica* (1534), on which he had been engaged for nearly 30 years. A rash letter, reflecting severely on Henry VIII and Wolsey, was intercepted early in 1515, after which Polydore was cast into prison for several months. and supplanted in his collectorship (March and April). In 152j he published the first edition of *Gildas,* dedicating the work to Tunstall, bishop of London. Next year appeared his *Liber de Prodigiis,* dedicated from London (July) to Francesco Maria, duke of Urbino. Somewhere about 1538 he left England, and remained in Italy for some time. About the end of 1551 he went home to Urbino. where he appears to have died in 1555. He had been naturalized an Englishman in Oct. 1510, and had held several clerical appointments in England. In 1508 he was appointed archdeacon of Wells, and in 1513 prebendary of Oxgate in St. Paul's cathedral, both of which offices he held after his return to Urbino.

The first edition of the *Historia Anglica* (26 books) was printed at Basle in 1534; the 27th hook. dealing with the reign of Henry VIII down to the birth of Edward VI (Oct. 1536), mas added to the third edition of 1555. It is mainly from the time of Henry VI that Polydore's work is useful.

Polydore's *Adagia* (Venice. April 1498) was the first collection of Latin proverbs ever printed; it preceded Erasmus' by two years, and the slight misunderstanding that arose for the moment out of rival claims gave place to a sincere friendship. A second series of biblical proverbs (553 in numberj was dedicated to Cardinal Wolsey's follower, Richard Pace, and is preceded by an interesting letter (June 1519), which gives the names of many of Polydore's English friends, from Sir Thomas More and Archbishop William Warham to Thomas Linacre and Cuthbert Tunstall. The *Dc Inventoribus* treating of the origin of all things whether ecclesiastical or lay (Paris. 1499), originally consisted of only seven books, but was increased to eight in 1521. It was exceedingly popular. All editions. however, except those following the text sanctioned by Gregory XIII in 1756. are on the Index Expurgatorius. The *De Prodigiis* also achieved great popularity.

VIRGINAL or PAIR OF VIRGINALS, a name applied in England (and also recognized on the continent of Europe) to the spinet as being pre-eminently an instrument for girls. (For further particulars *see* PIANOFORTE.)

VIRGINIA or VERGINIA. in Koman legendary history, daughter of L. Virginius, a plebeian centurion. Her beauty attracted the notice of the decemvir Appius Claudius, who instructed Marcus Claudius, one of his clients, to claim her as his slave. Marcus accordingly brought her before Appius, and asserted that she was the daughter of one of his female slaves, who had been stolen and passed off by the wife of Virginius as her own child.

Appius declared Virginia a slave of Marcus. Virginius thereupon stabbed her to death. A storm of popular indignation arose and the decemvirs were forced to resign. The people for the second time "seceded" to the Sacred Mount. and refused to return to Rome until the old form of government was re-established.

VIRGINIA, officially designated the commonwealth of Virginia (after Elizabeth I, the "virgin queen") and familiarly known as the "Old Dominion," one of the 13 original states of the United States, being the 10th to ratify the constitution (1788). It is the southernmost of the middle Atlantic states, roughly triangular in shape, bounded on the north by West Virginia and Maryland, on the east by the Atlantic ocean and Chesapeake bay, on the south by North Carolina and on the west by Kentucky. Its total area is 40.815 sq.mi., of which 977 sq.mi. inland is water; in size it ranks 36th among the states. The state flag has a blue field in the centre of which the state coat of arms is represented. The flower is the dogwood *(Cornus florida)*; the bird, the cardinal *(Richmondena cardinalis)*; the song, "Carry Me Back to Old Virginia." The capital is Richmond.

PHYSICAL GEOGRAPHY

Physical Features. — Virginia (which lies between the extremes of 36° 32' and 39° 27′ N. latitude and 75° 15′ and 83° 41' W. longitude) before 1851 recognized officially, for statistical purposes, four "grand divisions": tidewater, piedmont, the valley and trans-Allegheny. Since the loss of West Virginia only southmest Virginia remains of the last division. Geographical differences in these divisions have profoundly influenced Virginia's life and history.

Tidewater.—Tidewater is a level plain of alluvial soil lying between the Atlantic ocean and the fall line (*q.v.*), the latter a distinct break in the crystalline rock formation of piedmont, a line where waterfalls furnish power for mills and act as a barrier to advancing tides. Running southwestwardly across tidewater are four great rivers, the lower Potomac, Rappahannock, York and James, the lower reaches of which form estuaries of Chesapeake bay into which they empty. At the fall line, which runs north and south, cities — Alexandria, Fredericksburg, Richmond and Petersburg — arose about trading posts at the head of navigation and on the mill sites at the falls.

Piedmont.—Piedmont, the largest of the geographical provinces, lies between the fall line and the Blue Ridge mountains (*q.v.*), extending in width 40 mi. at the north and 185 mi. along the southern border. It is a relatively low, rolling plateau region cut by many streams.

Valley. — The Valley of Virginia, or the Great valley, between the Blue Ridge mountains on the southeast and the Allegheny mountains (*q.v.*) on the northwest, consists of a number of valleys draining into a series of five rivers or their tributaries: the Shenandoah in the north, the James and Roanoke (*q.v.*) in the centre and the New and the Holston in the south. The waters of the first three flow through tidewater; those of the last two flow into the Ohio-Mississippi basin. The largest of the component valleys, the Shenandoah, is 95 mi. long, divided into two valleys by Massanutten mountain, and varies in width from 20 to 30 mi. (see SHENANDOAH VALLEY).

Mountains.—The Blue Ridge in the northern half of Virginia rises abruptly from piedmont. It is a distinct ridge having subordinate parallel ridges and providing many deep coves on each slope. In the north the Blue Ridge province is narrow, but in the south along the North Carolina and Tennessee borders it is a broad, rugged plateau with rolling upland, deep valleys and high mountains, the highest being Mt. Rogers (5,720 ft., the highest in Virginia) and Whitetop, both in the extreme southwest. The Allegheny mountains, forming the western wall of the Valley of Virginia and part of the great Appalachian plateau, are cut by streams into a maze of narrow valleys and irregular, winding ridges.

Climate. — The climate is mild and generally uniform throughout the state, with adequate rainfall. Snow seldom falls in southeastern tidewater, but occurs occasionally farther inland. The frost-free growing season is one to two months longer in lower tidewater than it is in southwest Virginia.

Soil. —A wide variety of soils is found in Virginia. The coastal plain, built of sedimentary deposits, is chiefly sandy; piedmont soil is the result of weathering of crystalline granite, gneiss and schists. the first two producing good soil. the third a poor soil; the floor of the Great valley, composed mostly of deposits rich in lime, is very fertile; much of the soil of western Virginia is of limestone origin: but a wide variety of soils is found in the region depending on the nature of the basic rock strata.

Vegetation. — The salt flats along the brackish rivers and creeks of tidewater are covered with marsh grass. On the uplands of tidewater and piedmont, crab grass and wire grass are native on arable land, and broom sedge takes over depleted land. Bluegrass is a thriving native of the Great valley and of limestone soils in the southwest. Among the many native Virginia wild flowers are blue lobelia, bluets, blue lupine, May apple, trumpet vine, morning-glory, violets and goldenrod. In the mountains and in the marl-rich woods of tidewater may be found trailing arbutus, laurel and rhododendron. More than half of Virginia is woodland, containing many varieties of trees, among them oak, pine, hickory, cedar, maple. birch, elm. walnut. locust, sweet gum, black gum, ash, persimmon, redbud, the Virginia magnolia and dogwood. Cypress, live oak and wax myrtle grow only in tidewater.

Animal Life. — Animal life is abundant and varied in the state. Some animals commonly found during the colonial period — among them beaver, timber wolf, southern fox, squirrel, panther, elk and bison — no longer occur in the area. Elk recently introduced are of a kind different from that once found in the state. Some animals, including black bear and wildcat, survive only in such primitive surroundings as the Dismal swamp (see DISMAL SWAMP) in southeastern Virginia and the mountains in the west. Mink and otter may be found along some isolated watercourses. Animals common in the state are deer (protected by game laws in Virginia as early as the 1ith century), squirrel, fox (red and gray), opossum, rabbit, raccoon, mole, rat and mouse.

Game birds (protected by law), songbirds and other birds are numerous. Many varieties of game and nongame waterfowl spend part or all of their time in the marshes and tidal waters. Throughout the state bobwhite, quail, wild turkey and, less common, mourriing dove and woodcock are found. The bald eagle and the golden eagle may be seen in a few coastal and mountain regions. Other birds are buzzard: many varieties of hawk and owl, mockingbird, wren, crow, blue jay, hummingbird, wood thrush, whippoorwill, cardinal and many others.

Many kinds of snakes live in the region, some harmless, such as the green snake and the black snake, some poisonous, such as the copperhead moccasin and water moccasin (rather widely distributed), the rattlesnake (found in the mountains and in some isloated eastern places) and the cottonmouth (in Dismal swamp). In addition there are varieties of turtle, terrapin, frog and lizard.

Among the fish of tidewater are the croaker, shad, spot, white perch, rock, menhaden, bluefish, gray trout and spotted trout. Oysters, scallops, clams, blue crabs and shrimp are found in abundance.

Parks, Historic Sites and Recreation. — Virginia is fortunate in the number, variety and interest of its national and state parks and historic shrines. It ranks third in the nation in the number of national park service areas located in the state. Among these are the Colonial parkway joining Jamestown, Williamsburg and Yorktown; the Blue Ridge parkway and the Shenandoah National park (*q.v.*), which includes the beautiful Skyline drive, a mountaintop highway running about 500 mi., from northern Virginia to North Carolina; and the 32-sq.mi. Cumberland Gap park. The national park service and the Association for the Preservation of Virginia Antiquities own and maintain Jamestown Island. The national park service also maintains the chief Civil War battlefields (Fredericksburg and Spotsylvania, Richmond, Petersburg, Manassas, etc.) and such historic places as the Custis-Lee mansion, George Washington's birthplace, Appomattox courthouse and the Moore house at Yorktown. The national and state governments and several private associations and foundations have acquired for preservation historic shrines, including the homesites and homes of Washington, Jefferson, George Mason, John Marshall, Booker T. Washington and other celebrated Virginians. The greatest private contribution to historical preservation is that of colonial Williamsburg, restored by John D. Rockefeller, Jr. (see WILLIAMSBURG).

Across the state are scattered nine state parks and three recreational areas with facilities for camping, fishing, boating. swimming and hiking. Excellent recreational facilities are furnished by three large lakes made by dams across the Roanoke river in Mecklenburg county and by dams on Smith river in Franklin, Patrick and Henry counties, and on the South Holston in Washington county.

HISTORY

Colonization. — After the failure of several attempts by Sir Humphrey Gilbert and Sir Walter Raleigh to plant a settlement in Virginia, Gilbert died. and Raleigh in 1606 transferred his interests to the Virginia Company of London, a group of merchants and others headed by Sir Thomas Smith. The first settlers, 144 in number, left England in Dec. 1606 in the "Susan Constant," the "Godspeed" and the "Discovery" and arrived at Jamestown on May 13, 1607. The aims of the Virginia company were to aid in building a strong merchant fleet (which served as part of the navy) and to train "able mariners" for England's protection; "to spread the gospel among the heathen people of Virginia"; to establish new areas for trade; to find precious metals; and to plant a Protestant English colony in a land threatened by Spain. The colony was kept alive during the first years mainly through the efforts of Capt. John Smith (*q.v.*), who secured food, made peace with the Indians, explored the country, wrote the first published book on Virginia (*A* True Relation, London, 1608) and drew a map of Virginia remarkable for its accuracy. After Smith left in 1609 the colonists experienced a year of great suffering, the "starving time."

In 1609 the company was reorganized, and almost absolute control over the colony was placed in the hands of the governor. The first governor was Sir Thomas West, Lord De la Warr, whose arrival in 1610 saved the colony from abandonment as a hopeless venture. Torn by strife within the company and within the colony, plagued by disease, hunger, lack of adequate shelter and clothing, polluted water, a climate to which they were unaccustomed, hostile Indians, homesickness and lack of experience in primitive surroundings. the colonists lived from one unfortunate experience to another. Among the evils endured were the failure of attempts to set up such industries as glassmaking. shipbuilding and the production of naval stores; the Indian massacre of 1622; and the plague that followed. The mortality rate reached about 75% during those years.

Yet the colony survived. Settlements spread beyond Jamestown. A headright system was established for land. In 1612 John Rolfe started the tobacco industry by introducing the seeds of two foreign varieties, Orinoco and Sweet Scented. of *Nicotiana tabacum,* exporting the first shipment in 1614. In 1618 instructions were given Gov. George Yeardley to call a representative assembly and once more to establish rule under laws to replace the autocratic administration set up in 1609. On July 30. 1619, the general assembly, consisting of the governor, councilors and 22 elected burgesses — the first English overseas representative body— met in the church at Jarnestown. In the same year the first Negro immigrants arrived as indentured servants and the Virginia company sent over 90 young women as wives for the colonists.

Royal Rule. — In 1624 the English government revoked the charter of the Virginia company and organized in Virginia its first royal colony. During the century and a half that followed, the two outstanding factors in the colony's history were the northern and western expansion of the population and a growing political maturity, which produced a strong representative lower house in the assembly, an able group of leaders and a spirit of independence. During Sir John Harvey's administration the first settlement on the York river was made (1630). and three years later a palisade, to provide protection from Indians as well as a large range for cattle, was built across the peninsula, and Middle Plantation (now Williamsburg) was founded. In 1634 a new system of local government began with the creation of the first eight counties, each with its sheriff, constable, justices, clerk and coroner. Church parishes already had been in existence.

First serious attempts to explore the trans-Allegheny region were made during Sir William Berkeley's administrations. The Indian massacre of 1644, in which at least 500 colonists perished, delayed exploration, but trading routes soon led from the sites of Richmond and Petersburg to the Indians in the southwest.

Virginians remained loyal to Charles I during his struggle with parliament, but in 1652 parliamentary commissioners with an overwhelming force assumed control of the colony. During the eight years of rule by parliament life in Virginia changed but little. The governors were only mildly Puritan, and the government in the colony was controlled by the house of burgesses — "representatives of the people." as its members often described themselves. After 1649 hundreds of Cavaliers fled to the colony, and from them were derived some of the leading families of Virginia.

Berkeley's second administration (1660–77) was marked by difficulties: the establishment of proprietorships in Virginia. human and cattle plagues, wars, hurricanes. oppressive trade laws, threats from the Indians who resented English encroachment, and, among the people, widespread discontent and growing distrust of those who governed the colony. The governor tried to prevent oppressive royal measures and to better economic conditions, but by the 1670s he had grown old, crabbed, autocratic, weak in body and inefficient. Yet he had assumed and continued to hold all authority in his own hands. and having secured a house of burgesses that suited him, refused for 14 years — until faced with rebellion — to call for new elections. The climax came when the Indians, made desperate by English encroachment, began war on the colonists. When in 1676 the people found Berkeley unable or, as they believed, unwilling to protect them, they chose young Nathaniel Bacon as their leader, compelled the governor to give him a commission, followed him against the Indians and forced reforms through the assembly. When the governor threatened to use military force against them, Bacon and his men defied him. On the death of Bacon, however, Berkeley soon ended the struggle with a series of hangings that shocked the home government and brought his recall.

From the end of Bacon's rebellion to the revolution of 1688 in England. Englishmen in Virginia, like their kinsmen in England! struggled to lessen the royal prerogative represented in the colony by a succession of autocratic governors.

During the remainder of the colonial period Virginia generally had able and conscientious governors. But conflicts inevitably arose when the mother country failed to realize the growing independence of the colony and refused, in such matters as the use of veto, trade regulations and taxation! to keep the promise of early charters that Virginians would "enjoy all liberties. franchises and immunities . . . to all intents and purposes as if they had been abiding and borne within this our realme of Englande. . . ."

During Francis Nicholson's administrations (1690–92 and 1698–99) the general assembly founded a college and a new capital. Under the leadership of Col. John Page it established the College of William and Mary and sent James Blair, president-elect, to England to secure a charter and endowments. The college received the charter in 1693, and in 1694 the College of Heralds granted it a coat of arms (see *Education,* below). In *1699* Middle Plantation became the capital of Virginia and was renamed Williamsburg; it was incorporated in 1722.

Alexander Spotswood, governor from 1710 to 1722 pursued an enlightened policy toward the Indians and in a famous journey with his "Knights of the Golden Horseshoe" (1716) blazed a trail over the Blue Ridge mountains for settlers in piedmont and the valley. Spotswood's skill as an architect is still seen in Williamsburg in the buildings he designed. In 1721 the first county beyond tidewater was created and named Spotsylvania for the governor.

William Gooch's administration (1727–49j was one of the most eventful periods in Virginia history. In 1730 the assembly passed Gooch's Tobacco act, which continued, with periodic renewals, to regulate the quality of the staple crop and medium of exchange until the Revolution. In 1736 the *Virginia Gazette* was founded. During King George's War Gooch commanded Virginia troops at Cartagena. By mid-18th century Scotch-Irish, Germans and tidewater Virginians had settled the valley and a few had entered trans-Allegheny at Draper's Meadows. The organization of the Ohio company in 1747 and its founding of a fort at the forks of the Ohio precipitated the French and Indian War, in which Virginia took a prominent part.

During the 1730s and 1740s Presbyterians gained a strong foothold in Virginia and organized Hanover presbytery, and in the 1750s the Separate Baptists from New England entered Virginia. Both denominations increased rapidly.

During the quarter-century before the Revolution, as Virginia grew in strength and political maturity, its house of burgesses became increasingly active in opposing the royal prerogative in such matters as the veto of the colony's laws, the Proclamation of 1i63 restricting westward expansion, and taxes imposed by parliament. Before 1776 such leaders as Richard Bland and Thomas Jefferson were formulating the constitutional and ethical bases for revolt, Patrick Henry was becoming an orator and George Washington mas acquiring military and political experience.

Virginia in 1763 had an estimated total population of 121,022 almost evenly divided between whites and Negroes. The population was rapidly increasing. The great planters were building substantial homes: the homes of lesser iarmers were neat and well built. Those who had the means enjoyed good books, music, the theatre and other forms of entertainment. An average of more than 50.000 hogsheads of tobacco, valued at £500,000 moved each year from Virginia to British ports.

Revolutionary Period. — Virginians took the lead in the constitutional crises preceding the Revolutionary War. They passed the Stamp Act resolutions of 1765; started in 1769 the boycott of British goods in order to cause the repeal of the Townshend acts; revived in 1773 the committee of correspondence of 1759 and brought about an intercolonial committee; called the first continental congress in 1774 and furnished its president, Peyton Randolph; set up a revolutionary committee of safety and armed for defense in 1775; called on congress on May 15, 1776, to declare independence; furnished the author, Thomas Jefferson, of the Declaration of Independence; and provided the leader of the Revolutionary army, George Washington. The May 1776 convention, in addition to proposing that congress declare independence, form a union and make foreign alliances; set up a commonwealth and chose Patrick Henry as its first governor. Meanwhile, in 1775, Governor Dunmore, fearful of the volunteer riflemen gathering in Williamsburg, had fled to the safety of the British fleet. On Nov. 7 he declared martial law and waged mar against Virginia until forced to leave the following July.

In 1778 George Rogers Clark led an army of Virginia and Kentucky riflemen in the conquest of the Northwest Territory: his campaign ended the Indian menace and brought that region into the area claimed and secured by the United States in the peace of 1783. Meanwhile, in 1781, Virginia gave up to the Cnited States its claim to the territory, based on its charter of 1609 and the more practical right of conquest, and in 1792 consented to the formation of Kentucky out of the state's westernmost counties.

During the Revolutionary War Virginia moved its capital from Williamsburg to Richmond (*qq.v.*) in 1780, reformed its code of laws in 1779, abolished the African slave trade in 1778 and set up 19 counties in the west (1776–82). The British captured Portsmouth (*q.v.*) in Oct. 1780. In Jan. 1781 Benedict Arnold sailed past Portsmouth, took Richmond and set up headquarters at Portsmouth. Cornwallis brought his army into Virginia from the south that spring, and Jefferson, governor of the state, with inadequate forces, was unable to stop him. Cornwallis, after marching his army through Richmond, Williamsburg (near which, at Green Spring, Lafayette attacked him) and Portsmouth, came to Yorktown and fortified the place. There, trapped by the American and French armies under Washington and Rochambeau and by the French navy under DeGrasse, he was forced to surrender on Oct. 19, 181. This practically ended the war (*see* also YORKTOWN).

Post-Revolutionary Period. — For almost half a century after the Revolution, Virginia, impoverished by two wars and their aftereffects and finding its soil depleted as a result of tobacco growing, suffered economically, and Virginians migrated to populate the west, northwest and southwest. But the foundations for future progress were being laid. The political philosopher John Taylor published a series of essays in 1803, collected in a book. *The Arator,* in which he advocated improved methods of agriculture. In 1818 Edmund Ruffin called attention to the benefit from the use of marl (lime) on acid soil, and his *Essay* on *Calcareous Manures* (1832) and articles in his journal, *Farmer's Register* (beginning June 1833), revolutionized agriculture in Virginia and elsewhere.

Virginia began an efficient system of chartered banks in 1804. The state undertook or aided in the building of roads, canals and railroads, and Virginians began direct trade with Europe and South America. By 1860 Virginia was the leading manufacturing state in the south. A state university and several colleges had been founded before 1850, public schools were being established by local option in 1846 and numerous private schools were flourishing. The constitution of 1851 provided white manhood suffrage, popular election of many officials. including the governor, and ended sectional inequalities in representation.

Slavery remained an unsolved evil. In Jan. 1832, after Nat Turner's slave insurrection in Southampton the previous year, the Virginia assembly tried in vain to find a solution; and abolitionists' indiscriminate abuse almost silenced native reformers.

Civil War and Reconstruction. — In 1861 Virginia seceded from the union. Richmond became the capital of the Confederacy, and Virginia was a battleground throughout the war that followed (*see* AMERICAN CIVIL *WAR*). In 1863 the state lost one-third of its territory to form West Virginia (*q.v.*). In 1867 congress placed the South under military rule. Virginia being Military District No. 1, with Gen. John M. Schofield in command.

Cnder the Reconstruction acts most Virginians with any experience in government were disfranchised. A constitutional convention made up largely of carpetbaggers and scalawags met and drew up a new constitution, which included articles that would have excluded thousands of whites from voting and disqualified almost every native white citizen from holding office. A committee of nine citizens headed by Alexander H. H. Stuart, however, secured permission from the federal authorities to vote separately on these articles, and they were rejected by the voters. The remainder of the constitution, including manhood suffrage, was adopted (1869), and congress readmitted the state to the union on Jan. 26, 1870.

Virginia escaped much of the punishment that Reconstruction inflicted on other states, but it had lost thousands of its young men and had been devastated by invading armies, its banks had been closed, its currency turned into worthless paper, its labour force demoralized and its territory occupied by its former enemy. It n-as also saddled with a prewar debt, made for internal improvements, amounting in April 1871 to over $45,000.000, more than one-third of which was interest accrued during the war and Reconstruction.

Strife over the state debt was the prominent feature of political life during the 1870s and '80s. When the pre-Reconstruction leaders regained control of the government, they provided for payment of the entire debt, designating one-third as West Virginia's share, for the payment of which Virginia assumed responsibility. The bankrupt state could not meet its obligations to its citizens and pay interest to its creditors, however, and the new system of public schools, organized in 1870. suffered accordingly. Then a group, the Readjusters, claiming that the debt and interest needed pruning and with aid of the Republicans: seized control of the government in 1882 and "readjusted" the debt, both principal and interest. Not until 1891–92 was a satisfactory compromise settlement reached with the creditors, and later West Virginia paid its share. The Democratic party was revived in 1883 and has controlled the state since then. In presidential elections the state supported the Republican candidate in 1928, 1952, 1956 and 1960.

Virginia adopted a new constitution in 1902.

20th Century. — In 1926 Harry Flood Byrd became governor of Virginia and within four years he had revolutionized the governmental machinery. During the first 60 days of his administration, the general assembly instituted a remarkable group of reforms through statutes or constitutional amendment. It revised the tax system; reformed the fee system; initiated constitutional amendments which greatly shortened the ballot, concentrating authority in the governor's hands; and encouraged industries to settle in Virginia. The years after World War I found the state's prosperity increasing as agriculture was diversified, manufacturing became more important in the economy and the tourist business became a major enterprise.

The depression of the 1930s was less severe in Virginia than in many other states. In the period before U.S. entry into World War II Virginia was the first state to set up a state defense system. The war brought tens of thousands of soldiers into the military camps of the state. The Hampton Roads area had a great boom with the expansion of the Norfolk naval base and the shipbuilding activities in Newport News.

GOVERNMENT

Alterations in the 1920s and later amendments have made a virtually new constitution from that of 1902. Qualifications for voting. also for office holding are: age. 21 years; residence in the state one year. county. city or town six months, precinct 30 days; payment of poll taxes for the preceding three years; and registration at least 30 days before election or primary election. The voters in state elections choose only the senators and delegates to the general assembly, the governor, lieutenant governor and attorney general.

Executive. — The governor chooses the heads of the 12 administrative departments of the government and is the business manager of the state. To aid the governor and general assembly are such agencies as the division of statutory research and drafting, the legislative advisory council and the state planning board.

Legislative. — The general assembly, which originated in 1619, consists of tn-o houses, the house of delegates, limited to 100 members elected for two years, and the senate, limited to 40 members elected for four years. It regularly meets at Richmond on the second Wednesday in January in even-numbered years.

Judiciary.— The administration of justice is vested in the supreme court of appeals, circuit courts. city courts and such other inferior courts as may be established by law. The seven justices of the supreme court are elected by a joint vote of the two houses of the general assembly for terms of 12 years. Each city of the first class (with at least 10,000 residents) and each county and city is included in a circuit court. These are grouped in 3i districts, each with its judge appointed by the general assembly. who sits in each court of his circuit. Each city of the first class may also have its corporation or hustings court. Each county has a trial justice: usually appointed by the judge of the circuit court. The judge of the juvenile and domestic relations court in each county and city (Norfolk excepted) is chosen by the circuit judge; and in each county the trial justice is appointed to that office.

Local **Government.**—Virginia's 98 counties and the 32 independent cities that have jurisdiction separate from the counties are agents of the state as well as units of local legislative and administrative bodies enjoying a large degree of autonomy. The counties are divided. into magisterial districts, from each of which a representative is elected to a county board of supervisors (Arlington county, however, elects them from the county at large). The board of supervisors is the governing body of the county, controlling taxation, the budget, borrowing and accounting. There are numerous other officers, about one-third elected by the people, others being appointed by the circuit court. This traditional form of government is expensive and inadequate. Yet, though the counties by popular vote may adopt one of three optional forms of county government, each designed to eliminate unnecessary offices and to concentrate county functions under a policy-forming board of supervisors, few counties have elected to do so. Within the old form, however, improvements are being made.

Cities, unlike towns, are independent of the counties in which they are located. The city-manager form of government in the United States originated in Staunton, Va., and 31 of the 32 independent cities in the state have that system.

Finance.—In finance, controlled by the general assembly, Virginia is notably conservative. Since the Readjuster period Virginians have been opposed to a state debt, and since the Budget act of 1918 and later fiscal reform acts the state budget has been balanced. The gross debt, of less than $10,000,000, is offset by sinking-fund assets of more than half that amount; hence the net state debt is negligible. To prevent overlapping taxation, taxable items in Virginia are separate for state and local governments. The state taxes all income, personal and corporate; local governments fix rates and tax real estate, tangible personal property, machinery and tools, and merchants' capital. The budget is prepared by the division of the budget of the governor's office from estimates furnished by the state agencies and after the governor, the director of the budget and members of the governor's advisory board on the budget have visited the state's agencies and institutions and held public hearings in Richmond.

POPULATION

The population of Virginia in 1790 was 747,610; in 1830 it was 1,211,405; in 1870, 1,225,163; in 1910, 2,061,612; in 1940, 2,677,-773; in 1950. 3,318,680; and in 1960. 3,966,949. This last figure represented an increase of 19.5% over the population in 1950. The population per square mile in 1960 was 97.2, as compared with 81.3 in 1950. 65.6 in 1930 and with 49.6 ior the U.S. in 1960.

Of the 1960 population 1,833,283 or 46.2% lived in incorporated places of 2,500 or more. as compared with 40.3% in 1950 and 35.3% in 19-10. The state has five standard metropolitan statistical areas. These areas had a total population of 1,481,008 or 37.3% of the total population of the state in 1960.

The number of households in 1950 was 845,932. as compared with 627,532 in 1940. The average population per household had declined from 4.3 in 19-10 to 3.9 in 1950.

The population of the state was distributed by colour and nativity in 1960 as follows: 78.1% native white; 1.1% foreign-born white; and 20.8% nonwhite, practically all Negro. These were 99.5 males per 100 females in the white population. and 98.1 in the nonwhite population; 7.3% of the population was 65 years old or over: and 55.7% of the population 14 years old and over was in the labour force. Of all employed males. 10.3% was engaged in agriculture. 9.8% in construction. 24.8% in manufacturing and 24.7% in transportation. public utilities and trade.

Very definite trends appear in population statistics: the increasing importance of federal employees to the population and economy. the declining relative importance of agriculture and the increasing importance of manufacturing and other services. the growth of health, medical and educational services, and the decreasing dependence of householders on domestic servants. In composition, in 1960 a larger percentage of Virginia-born whites were living in Virginia; on the other hand, the percentage of non-Virginia-born whites living in Virginia increased from 6% in 1870 to 30.3% in 1960. The proportion of Negroes has decreased steadily since 1830 (then 47.9%); in the 70 years before 1950 it decreased 20%, while the white population increased 19.5%.

*Populations are reported as constituted at date of each census. Excludes Arlington county (pop. [1960] 163,401) which was considered an urban area, †Name changed from Bedford City since 1910.

Note: Dash indicates place did not exist during reported census, or data not available.

EDUCATION

Public **Schools.**—Virginia replaced its local option system of public free schools of 1846 with a state-wide system in 1870. In the late 1950s there were more than 800.000 pupils of school age (7 to 19) and more than 30.000 teachers (including principals and supervisors). The state also supported two schools for the deaf and the blind.

Higher Education.— State *Institutions.*—The Virginia state board of education accredits 13 four-year colleges and universities and 2 junior colleges under state control. The leading Virginia university, indeed one of the leading southern universities, is the University of Virginia at Charlottesville, founded in 1519 and largely the creation of Thomas Jefferson, who left his mark on its beautiful buildings and grounds and on its academic traditions. Women are admitted only to the professional and graduate schools; its liberal arts college for women is the Mary Washington college of the University of Virginia at Fredericksburg, started in 1908. The university's schools and colleges include arts and sciences. architecture. business administration, commerce. education, engineering, law, medicine and nursing. It has several affiliated junior colleges. The university publishes The *Virginia Quarterly Review.*

Oldest of the institutions of higher education is the College of William and Mary at Williamsburg. chartered in 1693 by King William and Queen Mary, the second oldest college in the United States and pioneer in such fields as law, modern history, modern languages, lecture system, honour system and elective system. It is a coeducational college of liberal arts, with its associated Marshall-Wythe school of law. In co-operation with Colonial Williamsburg, Inc., the college conducts the Institute of Early American History and Culture and publishes the *William* and *Mary Quarterly*. Affiliated as the Colleges of William and Mary under one board are, in addition to the College of William and Mary, Norfolk college, the Richmond Professional institute, and two junior colleges—Christopher Newport at Newport News and Richard Bland at Petersburg.

Other state institutions are Longwood college at Farmville, a college for women, at which a few men are admitted as day students (founded 1884), and Madison college (1908) at Harrisonburg, coeducational but enrollment of men limited. The Medical College of Virginia was established in Richmond in 1837 as the Medical College of Hampden-Sydney and became independent of Hampden-Sydney in 1854. Virginia Military institute at Lexington, founded in 1839, is famous for the distinguished military leaders numbered among its graduates. Virginia Polytechnic institute at Blacksburg is a land-grant college established in 1872 under the Morrill act, specializing in agriculture, applied science, business administration, engineering and home economics; it has several branches for the first two years, and Radford college (1910) at Radford is the women's division. Virginia State college at Petersburg was established for Negroes in 1882; it offers a broad program and has a four-year affiliate college in Norfolk.

Private.—The state board of education accredits 18 four-year colleges and universities and 12 junior colleges under private control. Among these are Bridgewater college (Church of the Brethren; 1880) at Bridgewater; Emory and Henry college (Methodist; 1838) at Emory; Eastern Mennonite college (1917) at Harrisonburg; Hampden-Sydney college for men (Presbyterian; 1776) at Hampden-Sydney; Lynchburg college (Disciples of Christ; 1903) at Lynchburg; Mary Baldwin college for women (Presbyterian; 1842) at Staunton; Presbyterian School of Christian Education (1914) in Richmond, devoted chiefly to preparing women for positions in the mission fields and as directors of Christian education but offering also a regular liberal arts program; Randolph-Macon college for men (Methodist; 1830) at Ashland, the oldest Methodist college in the United States; Randolph-Macon Woman's college (Methodist; 1893) in Lynchburg; Roanoke college (Lutheran; 1842) in Salem; Shenandoah College and Conservatory of Music (1875) at Dayton; Sweet Briar college for women (1901) at Sweet Briar; the University of Richmond (Baptist; 1832); Washington and Lee university for men (1749) at Lexington, originating in a classical school and later named for a benefactor, George Washington, receiving its present name in 1870 after the death of Robert E Lee, its president from 1865 to 1870; Hollins college for women (1842) at Hollins.

Hampton institute at Hampton was founded in 1868 by Gen. Samuel Chapman Armstrong to bring education to recently freed Negroes. It is a nondenominational, nonprofit-making institution, incorporated by the state in 1870, that trains students in agriculture, building construction, architectural design and engineering, several trades, business, home economics, education and general studies St. Paul's college at Lawrenceville was founded for Negroes in 1888 primarily as an industrial school, but after 1941 offered a full college course. Virginia Union university at Richmond was organized in 1899 from two schools founded in 1865 for Negroes.

HEALTH AND WELFARE

Virginia established its state board of health in 1872. The commissioner of health formulates public health policies and programs and supervises all personnel and activities of the health department. The department has divisions of alcohol studies and rehabilitation, local health services, engineering and dental health.

The department of welfare and institutions is headed by a director, who is advised by a policy-making board of welfare and institutions. The department has four divisions: (1) division of general welfare, which administers aid to dependent children, old-age assistance, aid to the totally or permanently disabled and general relief; (2) division of corrections, which administers and supervises the six institutions for male and female offenders convicted on felony or misdemeanor charges, and inspects and supervises local jails and lockups in the state; (3) Virginia parole board, which sets the policy for and administers paroles; (4) division of youth services, which supervises the care and treatment of children committed to the board by the juvenile courts, is responsible for supervision and development of local detention and probation services for children, and administers two schools for boys and two for girls committed to the board of welfare and institutions by the courts.

The department of mental hygiene and hospitals controls the seven institutions that care for the mentally ill or deficient and the alcoholic. Virginia's Eastern State hospital at Williamsburg, established in 1773, is the oldest state-supported institution for the insane in the United States.

THE ECONOMY

Ten years of Civil War and Reconstruction and the social and economic troubles that followed during another quarter-century delayed economic development in Virginia for at least a generation, but beginning about 1930 such forces as improved agricultural methods, modern highways, the great increase in military and other federal installations, increased efficiency in government and the coming of industries to small towns and rural communities brought about an acceleration. The flow of native population from Virginia was reversed after 1930, and the increase in average per capita income surpassed that of the country at large. An interesting development of the second quarter of the century was the large number of industries near to and drawing their workers from small neighbouring farms. Automobiles, good country roads, higher incomes and government aid have enabled rural families to enjoy city conveniences: by 1950 four-fifths of farm families had electricity, about one-fourth had running water, one-half had automobiles and one-fourth had telephones. Although the mild climate and lack of population congestion make living conditions generally pleasant in Virginia. the average annual earning per worker is below the average for the nation.

Agriculture.—The average Virginia farm has about 110 ac.; tenancy is around 17%. In the decade 1940 to 1950 for the first time the number of persons employed in agriculture fell below the number employed in wholesale and retail trade and in manufacturing, but agriculture remained a major element in Virginia economy. In spite of a decline of about one-fourth in the number of farmers and the withdranal of 1,000,000 ac. from cultivation for purposes of reforestation. the total value of farm products greatly increased. More than half of Virginia's farm income is derived from livestock and poultry and their products. About one-fifth comes from tobacco, grown chiefly in the lower piedmont. The eastern counties grow truck vegetables, peanuts, potatoes, grains (especially corn) and hogs; peanut-fed hogs from this region, processed at Smithfield, furnish the famous Smithfield hams. Upper piedmont has many stock and dairy farms with crops of grain and hay. In the rich limestone soil of the valley-mountain counties are found large orchards of apple and other fruit trees, bluegrass and grains, as well as cattle, sheep and poultry farms.

Manufacturing.—Manufacturing is growing rapidly in Virginia, the five chief industries (in order of value added) being chemicals and chemical products, textile mill products, tobacco manufactures, food and kindred products, and pulp. paper and paper products. Virginia ranks third among the 11 southeastern states in value added by industry and fourth in numbers employed. Employment in textile manufacturing, though by the late 1950s still occupying the largest number of workers, was on the decline.

Minerals.—The most important of Virginia's mineral commodities in quantity and value is bituminous coal, found in seven counties of the Appalachian plateau region, the annual production over seven years in the 1950s ranging from 17,600,000 to 29,500,000 tons.

Tidewater furnishes sand, gravel, clay and marl. The sand and gravel combination used for building roads, third in importance among Virginia's mineral industries, conies mainly from this region. Clay from all sections of Virginia is used in'brick, tile and ceramic products. Virginia is the only producer of aplite in the United States; other minerals produced in the state for ceramics are kyanite, feldspar and silica sand. Underneath the piedmont and Blue Ridge regions are belts of crystalline rocks that furnish a great reserve of stone. Production of crushed stone and concrete aggregate is state-wide, ranking second in importance among mineral resources. Piedmont also furnishes soapstone and greenstone. Throughout the Appalachian Ridge and valley region are extensive beds of limestone. dolomite and shale. Pulverized limestone and dolomite. T'irginia's fourth-ranking mineral commodity, are valuable for agricultural. chemical, metallurgical and other specialized uses. The manufacture of cement from limestone and shale is an important and growing industry. Virginia's leading metallic mineral, zinc. is mined in the Blue Ridge and valley region.

Other minerals produced in commercial quantities are barite, calcareous marl, gypsum, manganese, mica, pyrites, ilmenite, slate and talc.

Fisheries. — Along Virginia's 1.280 mi. of tidal coast line (780 mi. mainland and 500 mi. island) on the Atlantic ocean, Chesapeake hay and the great tidal rivers, fisheries furnish part or full employment for 6,000 to 10.000 fishermen. Oysters contribute about one-half the value of the total catch. The chief edible fishes are sea bass. porgy. alewife, croaker, shad and spot. About two-thirds of the finfish caught in 1955 were menhaden, valuable for oil, meal and fertilizer. In the coastal counties are located many seafood plants and fertilizer factories.

Trade. — Virginia has four ports on the great Hampton Roads (*q.v.*) harbour — Sewport News, Norfolk. Portsmouth (*qq.v.*) and South Norfolk — and three river ports — Alexandria (*q.v.*) on the Potoniac and Hopewell and Richmond (*q.v.*) on the James. Of the exports from these ports (around 55,000,000 short tons annually) coal comprises 95% (by volume). the Hampton Roads ports being among the world's chief coal-exporting centres. Other products passing through the ports outward are iron. chrome and manganese ores and gypsum (totaling about 30% by volume), grain, soybeans, tobacco. and iron and steel scrap. Petroleum products make up about 60% of imports; also imported are newsprint, logs and lumber. fertilizers and fertilizer materials. and food products, especially sugar and fruits. Sine trunk-line railroads connecting with other railroads throughout the country converge on the Hampton Roads ports. Excellent piers, grain elevators and ore-handling facilities add to the ports' usefulness. More than 450 steamship owners or operators link these ports with about 300 world ports.

Transportation and Communication. — A letter from George Washington to Gov. Benjamin Harrison in 1784 recommended state aid for works of internal improvement connecting the James and the Potomac rivers with the Ohio in order to capture for the Virginia ports the trade of the west. This letter resulted in 1785 in the creation of the James River Co. and the Potomac River Co., starting a new era in constructing works of internal improvement in Virginia. Later the state built turnpikes connecting the Valley of Virginia with the Ohio, and financed other turnpikes. In 1827 Virginia chartered the horse-powered, later steam-polyered, railroad line connecting Winchester with the Baltimore and Ohio at Harper's Ferry. Between 1850 and 1860 Virginia extended its lines from 384 to 1,350 mi. By the second half of the 20th century there were 12 Class I railroads and several lesser roads, with more than 4,000 mi. of main-line track. The focal points of the railroads are Washington. Richmond and the ports of Hampton Roads. Few regions in the state are more than ten miles from a freight depot. but passenger service is limited, buses often furnishing cheaper and more convenient service.

There are about 50.000 mi. of state highways and several thousand more miles of municipal and federal roads. Virtually every part of the state is served by buses.

Interstate and intrastate water transportation, once of vital importance, has given place largely to land transportation systems, but large supplies of raw materials are carried by water to chemical and paper plants having their own piers. There are ferries across Chesapeake bay between the eastern and western shores, and an important amount of local traffic moves by water.

Four main airways enter or cross the state, placing some of the chief cities of I'irginia on air lines serving the chief centres of the north, south and west. The state is well supplied with radio stations and television facilities.

VIRGINIA, UNIVERSITY OF, a state institution of higher learning for men, founded in 1819 near Charlottesville, Pa.. hy Thomas Jefferson. Mary Washington college (I 908) at Fredericksburg, Va., in 1945 became the Women's College of the University of Virginia. See VIRGINIA: *Education.*

VIRGINIA CITY, county seat of Storey county. Nev., U.S., is situated 23 mi. S.E. of Reno. In June 1859, the fabulous gold and silver strike known as the Comstock lode turned the surrounding area into a booming mining camp overnight. When the Nevada territory was created by congress in 1861, Virginia City had more than three-fourths of the population of the new territory. In the 1870s it had a population of 30.000 persons; there were six churches and 100 saloons. The discovery of the "big bonanza" in 1873 led to a high point of $36,000,000 in mining production in 1878. A great fire in 1875 practically destroyed the town's buildings. with a loss estimated at $12,000,000. The ',bonanza barons" who made their millions in the mines proceeded to build Victorian-style mansions and even the public buildings were elaborately decorated. One of the reporters of the city's newspaper. the *Territorial Enterprise,* during its boom period was Samucl Clemens, who first signed his pen name Mark Twain to one of his newspaper stories.

Virginia City burned itself out in less than a quarter century of frantic mining activity. with the ore beginning to disappear in the 1880s. The population dwindled to less than 1.000 and it soon became a "ghost town," consisting of one main street. two or three parallel streets. and a few short cross-streets. The remaining business houses—mainly saloons and popular museums for the tourist trade––are clustered on the main street and there is only a scattering of buildings and homes in the rest of the city.

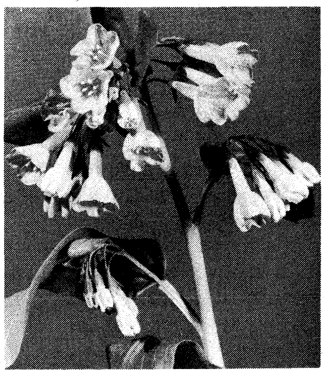
VIRGINIA COWSLIP (BLUEHELLS; *Mertensia virginica*), a North American plant of the borage family (Boraginaceae j. called also Roanoke bells or American lungwort. It grows in low meadows and in open woods along streams from New York and Ontario to Minnesota and south to Tennessee and Kansas



ROCHE

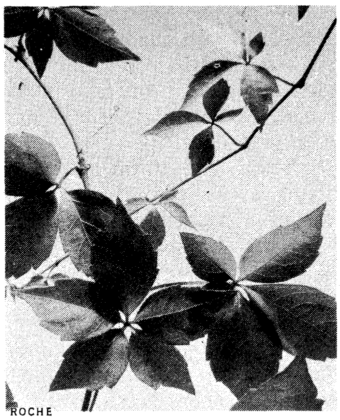
VIRGINIA COWSLIP (MERTENSIA VIRGINICA)

The Virginia cowslip is a smooth perennial, with a usually erect simple or somewhat branching stern, 1 to 2 ft. high, with large, oblong. long-stalked, veiny basal leaves.

In early spring it bears at the top of the stem showy clusters of biue-purple flowers. These are pink in the bud but when expanded are about 1 in, long and trumpet shaped, with a purple tube and a blue bell. This beautiful plant. one of the most popular wild flowers of the eastern states, transplants well and is often cultivated.

See BORAGINACEAE; MERTENSIA.

VIRGINIA CREEPER, a well-known woody vine (*Parthenocissus quinquefolia*) of eastern North America. sometimes cultivated for ornament. but not so well suited for this purpose as the related Boston ivy (P. *tricuspidata*), cultivated in the northeastern U.S. *Parthenocissus* belongs to the family Vitaceae and climbs by means of suckerlike tendrils. The leave? are split into leaflets. of which Virginia creeper has five. The reds and yellows of the leaves in autumn add to the attractiveness of this plant, ahich is sometimes confused with poison ivy (*q.v.*). See also VITACEAE.



ROCHE

VIRGINIA CREEPER (PARTHENOCISSUS QUINQUEFOLIA) LEAVES

VIRGINIA REEL, a lively American country dance. formerly popular in the United States. derived from the Sir Roger de Coverley. Originally intended for six couples only, in longways formation, it later became common practice to form in one long set. the men and women in seuarate lines facing each other. The steps include the usual country-dance, march and galop steps, best danced to the music of the violin, with the fiddler "calling" the figures. the partners advancing and swinging each other and other couples in turn, in a pattern in which the reel is most prominent.

VIRGIN ISLANDS, a group of about 100 small islands and islets: in the West Indies (*q.v.*), only 14 of which are inhabited. They lie about 40 mi. E. of Puerto Rico and extend for about 60 mi.. dominating the Anegada passage between the Atlantic ocean and the Caribbean sea, and covering a total area of 192 sq.mi. The islands are the peaks of submerged mountains that form the eastward extension of the submarine plateau constituting the base of the Greater Antilles. In general, elevations rise only a few score or a few hundred feet above the sea, but isolated peaks reach heights of 2,000 ft. The climate is agreeable and healthful, temperatures seldom going above 90° F. or falling below 65° F. Storms. though not common, are sometimes severe. Rainfall averages about 40 in. annually, a few high exposed slopes getting much more. sheltered spots getting much less; there is much variation from season to season and from year to year. Little ground water can be found in most parts of the islands, and the population depends largely upon cisterns for its water. The surface of the islands is generally rugged. with good soil decidedly lacking. outcrops of bare rock being common, as are also areas with coverings of coral sand or shallow loam derived from volcanic material. Before settlement, the land was largely covered with scant deciduous forest. but most of this has been cut for charcoal and to prepare the land for cultivation. The characteristic vegetation is scrub timber and Guinea grass. The main cultivated crops are sugar cane (used largely for making rum), cotton, tobacco. maize, yams, sweet potatoes and other vegetables for local use. Cattle, goats. sheep and swine are raised both for domestic consumption and for shipment to the larger urban centres such as those on St. Thomas.

Though otherwise closely related. the islands are divided into two political groups, the British Virgin Islands and the Virgin Islands of the United States.

History.—'She Virgin Islands were discovered by Columbus on his second voyage. in 1493, and named Las Virgenes, in honour of St. Ursula and her companions. The inhabitants were Carib and Arawak Indians. In 1666 the British occupied Tortola (previously settled by the Dutch in 1648) and have held it ever since. In the 17th century the islands were favourite resorts of the buccaneers. The islands of St. Thomas, St. John and St. Croix constituted a Danish colony from 1754 till 1917. with brief periods of capture by the British in 1801 and 1807–15.

British'Virgin Islands.—These consist of four larger and 32 smaller islands and tiny islets, with a total area of only 59 sq.mi. The principal islands are Tortola, Xnegada. Virgin Gorda and Jost Van Dyke. The inhabitants numbered 7,338 in 1960. most of them living on the island of Tortola. The chief town and the capital of the British group is Road Town (population in 1960 was 891) in a good harbour on the south side of Tortola Island.

The people are mainly small landowners who replaced the former British plantation owners; they give more attention to stock raising than to farming. A few are fishermen and boatmen, and a number of inhabitants depend upon employment in the U.S. islands. The small trade is mostly with St. Thomas and consists mainly of livestock.

These islands form a separate colony with a government consisting of an administrator who is subject to the governor, an executive council and a legislative council.

Virgin Islands of the United States.—These consist of St. Thomas, St. John and St. Croix or Santa Cruz (*qq.v.*), together with about 50 small islets and cays. The three larger islands of the group were bought from Denmark in 1917 for $25,000,000, mainly for their strategic importance in the Anegada passage and also because they lie about halfway between New York and Panamá. There is a U.S. air-base on St. Croix and a submarine base in St. Thomas harbour. These islands together with Culebra Island and Vieques or Crab Island (both of which are administered by Puerto Rico) constitute one of the most important keys to the defense of the Caribbean sea and the Panama canal. The city of Charlotte Amalie on St. Thomas has an excellent, spacious harbour; formerly an important port of call and coaling station, it more recently built oil reservoirs, shipyards, machine shops and floating docks.

There are commercial airports at St. Thomas and St. Croix and a regular transisland bus service.

The group has an area of 133 sq.mi and a population of 32,099 (1960), of which about 70% is of African descent. St. Thomas, second in area, has the largest population 116.201 in 1960), followed by St. Croix (14,973), the largest of the group, and by St. John (925). The capital. Charlotte Amalie, in 1960 had 12.880 inhabitants: the great majority of whom were engaged in the manufacture and shipping of bay rum and in service to the increasingly large tourist population. The people of St. Croix are occupied largely in raising cattle and sugar cane, making alcohol and in shipping these commodities to St. Thomas. Christiansted and Frederiksted on St. Croix are important ports and trading centres. The inhabitants of St. John raise cattle and collect bay leaves, both for shipment to St. Thomas.

Under the Revised Organic act of 1954, executive power is vested in the governor, who is appointed by the president of the United States for an indefinite term. The unicameral legislature is composed of 11 senators elected for two-year terms. The islands have the status of an organized but unincorporated territory under the jurisdiction of the U.S. department of the interior. Residents of the islands are United States citizens. but have no vote in U.S. presidential elections and are not represented in congress.

BIBLIOGRAPHY.—Annual reports, *The Governor of the virgin Islands to the Secretary of the Interior;* and the biennial *Colonial Office Report on the Leeward Islands.* (G. M. McB.; X.)

VIRGINIUS RUFUS, LUCIUS (A.D. 15–97), Roman soldier, three times consul (A.D. 63, 69, 97), was born near Comum. When governor of upper Germany under Kero (68), after he had put down the revolt of Iulius Vindex in Gaul, he was urged by his troops to assume the supreme power; but he refused, declaring that he would recognize no one as emperor who had not been chosen by the senate. Galba, on his accession, aware of the feelings of the German troops, induced Virginius to accompany him to Rome. After the death of Otho, the soldiers again offered the throne to S'irginius, but he again refused it. They then attacked him, and he had to escape through the back of his tent. Under Vitellius, one of Virginius' slaves was arrested and charged with the design of murdering the emperor. Virginius was accused of being implicated in the conspiracy, and his death was demanded by the soldiers.

Vitellius refused to sacrifice him to the army's resentment, and Virginius subsequently lived in retirement, chiefly in his villa at Alsium, on the coast of Etruria, till his death in 97, in which year he held the consulship, together with the emperor Nerva. At the public burial with which he was honoured, the historian Tacitus (then consul) delivered the funeral oration.

VIRGO ("the virgin"), in astronomy, the sixth sign of the zodiac. denoted by the symbol ♍. The Greeks represented this constellation as a virgin, but different fables are current as to the identity of the maid. She is variously considered to be: Iustitia, daughter of Astraeus and Ancora; according to Hesiod, the virgin is the daughter of Jupiter and Themis; others believe she is Erigone, daughter of Icarius, or Parthene, daughter of Apollo. The constellation contains a first magnitude star, Spica, which is a blue star, located at a distance of about 250 light years from the sun.

VIRTANEN, ARTTURI ILMARI (1895–), Finnish biochemist, was awarded the 1945 Nobel prize for chemistry ('for his researches and inventions in agricultural and nutritive chemistry, especially for his method of fodder preservation." He was born at Helsinki, Fin., on Jan. 15, 1895, and studied chemistry at the University of Helsinki. His doctoral thesis (1919) elucidated the composition of abietic acid, the principal constituent of pure rosin. After study in Switzerland, Germany and Sweden, he took up an appointment at the University of Helsinki in 1924. He became professor of biochemistry at the technical high school there in 1931 and at the university in 1939. He investigated the processes which occur during storage of green fodder, a subject of vital importance in countries where the winters are long and severe. Virtanen's researches from about 1920 showed that under ordinary conditions of storage green fodder is spoiled and its nutritive content reduced by fermentation processes. He further proved that addition of definite amounts of acids to the crops arrested the detrimental processes and ensured a constant supply of palatable and nutritious fodder. Extensive experiments carried out during 1928–29 showed that the taste, caloric value and vitamin content of treated fodder were entirely satisfactory and that cows fed on such fodder yielded milk of the highest quality. Virtanen also carried out important work on the bacterial and enzymatic processes concerned in the utilization of nitrogen and other nutritive materials by root crops. (W. J. Bp.)

VIRTUES, NATURAL AND THEOLOGICAL. Virtue is defined as "conformity of life and conduct with the principles of morality" (see ETHICS). The virtues are the practical attitudes adopted in obedience to those principles. They have been conventionally enumerated as seven because that number is supposed. when combined with its opposite number of seven deadly sins, to cover the whole range of human conduct (see SINS: SEVEN DEADLY). In Christian teaching. the seven virtues are divided into two groups, natural and theological, according as they spring from the common endo ment of humanity or as special gifts from God. Another way of explaining the difference would be to describe the natural virtues as those which were inculcated in the old pagan world, and the theological as those which are specifically prescribed in Christianity.

The natural virtues are sometimes known as the four cardinal virtues (Lat. *cardo,* "hinge") because on them all lesser attitudes hinge. They are prudence, temperance, fortitude and justice. Their enumeration is said to go back to Socrates and is certainly to be found in Plato and Aristotle. The Christian moralists, such as St. Ambrose, St. Augustine and St. Thomas Aquinas, took over the list as a convenient summary of the teaching of the ancient philosophers and of the highest excellence at which they aimed.

To these four the Christian teachers added the three theological virtues of faith, hope and charity or love. This classification is taken over directly from St. Paul, who in a famous passage (I Cor. xiii, 13) not only distinguished these three as the specifically Christian virtues but singled out love as the chief of the three. Thus in the Christian ethic, benevolence, which is omitted from the list of the pagan philosophers, becomes the ruling standard by which all else is to be judged and to which in the case of a conflict of duties must be yielded the prior claim. (See also FAITH.)

It is to be noted that according to Christian teaching the theological virtues are not originated by the natural man. They are imparted by God through Christ and are then exercised by the believer. (J. W. C. W.)

VIRTUS, a Roman deified abstraction not of Virtue in general but of prowess in battle. She is often associated with Honos, the deified abstraction of Honour. The earliest temple mentioned is one to Honos and Virtus, originally one of Honos alone. to which Marcellus added a shrine of Virtus (222 B.C.). She eventually attained an independent status. and in the empire the Virtus of a particular emperor is often commemorated. Virtus is at times associated with Bellona (*q.v.*). (R. B. LD.)

VIRUNGA or MFUMBIRO. also called Kirunga and Birunga, is a chain of volcanic mountains north of Lake Kivu in east central Africa. Noted for their scenic beauty, they stretch ior 50 mi. in a direction approximately east-west, perpendicular to the general direction of the rift valley in which lie lakes Kivu. Edward and Albert. The eastern cones (also called the Mfumbiro mountains) span the frontier between the Republic of The Congo and Ruanda, and that between Ruanda and Uganda. Many of the volcanoes and lava fields are within the former Albert national park. and are the habitat of the rare mountain gorilla. The Virunga ("smoking mountains") comprise eight great cones more than 10.000 ft. high. These are, from west to east, the Niarnlagira or Nyamuragira (10.056 ft.), Nyiragongo (11,381 ft.). Mikeno (14,437 ft.). Karisimbi (13,763 ft.). Vishoke (12,175 it.), Sabinyo (11,922 ft.), Gahinga (11,397 ft.) and Muhavura or Mfumbiro (13,537 ft.). Only the two western volcanoes are still active. The Nyamuragira is capped by lava and has a caldera at the summit. $1\frac{1}{2}$ mi. in diameter. The main crater of Nyiragongo is $\frac{3}{4}$ mi. across and contains a liquid lava pool. The other volcanoes are extinct. All are eroded, Sabinyo being the most dissected. The crater of Muhavura contains a lake. The highest cone of the chain is the Karisimbi, so called because of its irequent snow cover.

The volcanoes are of shield or Hawaiian type. In Quaternary times they emitted vast quantities of lava rich in alkalis (leucitite. mikenite. etc.). On their slopes and in the lava fields are many small volcanic cones (150–450 ft. in height) which are of Strombolian type. The lavas and the cones of the western volcanoes have blocked the rift valley in this section, thus forming Lake Kivu. To the east, lakes Bulero and Luhondo in the north of Ruanda have the same origin. Eruptions and lava flows in the western region are frequent (11 at least since 1900). Certain flows (in 1038 for example) descended as far as Lake Kivu. One of these barred the Bay of Sake which is now separated from the rest of the lake.

The peaks of Virunga were first seen by a European in 1861, when J. H. Speke obtained a distant view of the cones. which were also seen by H. M. Stanley in 1576. Their fine position was first ascertained by Franz Stuhlmann in 1891. In 1894 Count von Götzen traveled through the region which was subsequently explored by E. S. Grogan, Maj. St. Hill Gibbons. Capt. Herrmann. R. Kandt. Sir Alfred Sharpe (1912) and others, the chief heights being determined in 1903. In 1907–08 the range was geologically examined by the duke of Mecklenberg's expedition. By the Anglo-German agreement oi July 1. 1890, "Mount Mfumbiro" was included in the British sphere in East Africa.

VIRUSES, once usually referred to as filterable viruses, may be defined as self-reproducing agents smaller than the microscopically visible bacteria. multiplying only within living susceptible cells and responsible or potentially responsible for a wide range of infectious diseases.

There are virus diseases of man. domestic animals, insects. plants and bacteria. as well as an equally wide range of conditions in which viruses are present as virtually harmless minor parasites.

Historical Background. — In one sense, viruses were being scientifically studied well before the development of bacteriology as a science. In experiments on vaccination with cowpox, Edward Jenner used in crude form essentially the same general type of manipulation used in modern studies of viruses. The development of methods of growing bacteria in "pure culture" by Louis Pasteur. Robert Koch and their followers led for a time to the belief that eventually all agents of disease would be isolated and studied by such methods. The first hint that this was not the case was obtained by the Russian bacteriologist D. Ivanovski in 1892. Using the newly developed porcelain filter candles that were shown by Pasteur and C. Chamberland to stop the passage of bacteria. he found that a filtrate of the sap from tobacco plants infected with mosaic disease could be used to transfer infection to healthy plants. This observation was confirmed a few years later by M. W. Beijerinck. the first to recognize the scientific and philosophical importance of the discovery. The further finding in 1902 of F. Löffler and P. Frosch that the agent of foot-and-mouth disease oi cattle was also capable of passing a filter impermeable to bacteria made it clear that these filterable agents were not solely responsible for disease in plants. Finally, in the period 1915–17, F. W. Twort and F. H. d'Hérelle discovered the phenomenon of "bacteriophagia," now known to be caused by the activity of viruses parasitic on bacteria.

By 1930 it was becoming clear that a wide variety of agents would have to be included in the filter-passing group, some of them by no means easy to pass through the standard filter candles. For this and other reasons, the term "filter-passing" or "filterable" was gradually dropped and among inicrobiologists the term "virus" is now universally used without qualification.

After 1930 there was a steady development of new technical methods for the study of the physiochemical and biological properties \\-hich completely changed the outlook of biologists toward the viruses. Probably the most important single advance toward this new approach was W. J. Elford's development of "graded" filter membranes of known pore size. This allowed for the first time an opportunity of assessing the actual size of the particles responsible and so of replacing the vague idea of a *contagium vivum fluidum* with something much more precise. Thereafter all the apparatus of modern physics was brought to bear on the problem, with a rich harvest of results.

On the biological side an equally important advance was made at about the same time. when E. W. Goodpasture showed that the virus of fowl pox could be grown in the tissues of the developing chick embryo. This led to several important practical advances in the control of virus diseases of man and animals. Then in 1949 tissue culture methods long used in half-hearted fashion for the cultivation of viruses were shown by J. F. Enders and colleagues to be suitable for the growth of poliomyelitis viruses. This not only opened the way to immunization against polio. but supplied a method by which dozens of new types of virus were isolated. There is still controversy as to whether viruses represent a real biological group or a mere heterogeneous assemblage of agents with the single common quality of intracellular parasitism. All are agreed: however. that it is convenient to divide them into four major groups: (1) the animal viruses causing disease in man and other vertebrates; (2) the insect viruses; (3) plant viruses; and (4) bacterial viruses or bacteriophages,

Physical and Chemical Properties of Viruses. — The most obvious physical characteristics are size and shape and, particularly since the electron microscope became a practical laboratory tool, these are known for most of the viruses which are susceptible to experimental investigation. The most convenient unit oi length to express their sizes is the millimicron ($m\mu$) which is $\frac{1}{1,000,000}$ mm. ($\frac{1}{25,000,000}$ in.). On this scale the largest viruses, those of the psittacosis group, are about 300 $m\mu$ in diameter. while the smallest viruses responsible for disease in animals (foot-and-mouth disease virus') have a diameter of about 20 $m\mu$. There is a continuous range of size between these extremes.

Electron microscope pictures of animal viruses show considerable variations in structure, but in shape they are nearly all spherical or ovoid. Influenza viruses. honever. frequently appear in an alternative filamentous form, the threads being about 80 $m\mu$ in diameter and 100–200 times as long. The best-known plant virus. that of tobacco mosaic, is seen as slender rods 1; $m\mu$ by 300 $m\mu$.

Bacterial viruses show a considerable range of size, but all show a rounded or polygonal head and a tail usually several times the diameter of the head in length, but in a few forms very short.

Chemical studies of viruses have made rapid progress since 1946. It is known that the rods of tobacco mosaic virus are built up of a central core of nucleic acid, around which is a sheath of protein molecules, which seem to be related to one another in the form of a flat spiral. The nucleic acid is of the type containing ribose as its sugar component (RNA). There are regularities in such a structure that make it legitimate to speak of the virus rods as macromolecules. The small spherical plant viruses also appear to be built up of a nucleic acid core with an outer shell of protein.

A typical bacterial virus. the bacteriophage T_2 for example, is a highly organized structure composed of nucleic acid, in this case of deoxyribose (DNA) type surrounded by a sheath of protein. The DNA is concentrated in the head, but there is probably a core of nucleic acid running down the length of the tail. At the tip of the tail is a region of different protein adapted to make specific union with the surface of the host bacterium.

Influenza virus is a more complex but less highly organized unit than either the plant virus or the bacteriophage. It contains a relatively small amount of nucleic acid (RNA only) protein. a considerable proportion. 30%, of fatty material and complex carbohydrate. A variety of evidence suggests that much of the substance of the virus particle is almost unmodified material from the host cell. It is probable that the surface is largely composed of virus protein. carrying the specific qualities of the virus as manifested by its power to attach itself to susceptible cells and by its immune reactions.

Other animal viruses differ considerably in composition, vaccinia virus, for instance, containing nucleic acid of DNA type concentrated in a central nucleus. The small viruses. of which polio virus is typical. appear to be composed of protein and nucleic acid (RNA) only.

Biological Properties. — Most biologists would agree that in general all typical viruses behave like micro-organisms and that where the practical problems of control are involved, they must be handled in the same iashion as larger parasitic micro-organisms. There are three inter-related characteristics of living organisms which can be expressed only in the biological terms reproduction. variation and selective survival. Every type of virus that has been studied exemplifies these characteristics modified by the special circumstances of its existence.

There is much more controversy, however. about the evolutionary origin of viruses. Probably a majority would consider that the animal viruses have evolved by parasitic degeneration from larger forms; hut in a more sophisticated form the old speculation is reappearing that some viruses at least represent part of the genetic mechanism of the host species that has become freed from normal control. There are now many instances where an apparently normal plant or bacterium can be shown to carry a virus indefinitely. The multiplication of the virus keeps pace with the multiplication of host cells in so precise a fashion that some form of mutual co-ordination must be postulated. It may well be that viruses have arisen in many different ways and that the qualities that bring them under the definition must not he regarded as signifying that they have a common origin.

In 19jj the main academic interest in viruses was concentrated on the means by which they multiply in the infected cell. Again the iorms that had been most intensively studied as representatives of plant, bacterial and animal viruses were tobacco mosaic virus. the bacterial virus T_2 and influenza virus A. In all three it was evident that the nucleic acid. RNA in tobacco mosaic and influenza viruses. DNA in the bacteriophage. played a key role. There was almost unanimity that the nucleic acid carried the genetic "code" by which subsequent multiplication of the virus was controlled but most workers felt that until more was known of the mechanism of protein synthesis in general. little could be said about the chemical mechanisms by which viruses multiplied.

At a less fundamental level the situation was best known in the bacterial viruses. Here the process in outline is as follows. The virus attaches by the tip of the tail to certain chemical groupings on the bacterial surface. When contact has been completed. a series of reactions is initiated by which the D S A content of the virus particle is as it were injected into the bacterium. The sheath is left temporarily attached to the surface of the bacterium and has no further function. Once the virus D S A enters the cell it appears to take control of the metabolic processes. turning them to the synthesis of components of the virus. After about 12 min. under standnrd conditions, the first of the new brood of virus has made its appearance inside the cell and at 2j min. the bacterium bursts, liberating around 200 new virus particles. The essential features are the disappearance of virus as such as soon as infection is initiated (the eclipse phase) and the production of virus components before any new infectious virus is produced.

In animal viruses a somewhat similar process takes place. An eclipse phase is usually recognizable and in a number of instances, components or incomplete virus particles may be detected before any new complete virus is produced. Animal viruses differ from bacterial viruses in being liberated progressively from the infected cell instead of in a single explosive burst.

In general, the natural history of a virus is determined by the fundamental requirement that multiplication can take place only within the living cells of a susceptible host. For a virus species to survive there must be (1) a means by which virus units can reach susceptible cells; (2) multiplication within these cells; and (3) liberation of virus into the environment. The details of the means by which these requirements are fulfilled naturally vary widely from one virus to another. During an influenza epidemic. spread occurs directly from infected to uninfected persons by transfer of air-borne droplets. Multiplication occurs in the cells lining the air passages and reliberation into the environment is almost automatic. Polio virus is liberated in the intestine and its spread among children probably depends mainly on minor faecal contamination particularly of fingers. Yellow fever (*q.v.*) is spread in totally different fashion by the bite of certain mosquitos, especially *Aedes aegypti*. The virus passes in the blood to the liver and other susceptible tissues and, after multiplication, is reliberated into the blood. where it is available to infect fresh mosquitos. Inside the mosquito, multiplication in the insect's cells is necessary before the virus passes to the salivary glands. making the mosquito infectious for its next victim. Yellow fever persists in tropical America and Africa essentially because of the existence of a reservoir of infection in jungle monkeys. Examples could be multiplied indefinitely, but simple herpes of the lips may be taken as a final one. The virus of this trivial disease normally produces initial infection in children between one year and three years of age. giving rise to a vesicular affection of the mouth and lips of varying severity. The infection is apparently overcome within a week or two. but once it has been experienced the virus persists in the local tissues probably for life. Under various stimuli. particularly fever, it is activated, producing the well-known cold blister or cold sore on the lips: from the contents of these, virus is set frer and is available again for the infection of young children.

In the laboratory, viruses can produce a relatively wide range of mutant strains (with an inheritable variation in one or other property) and mutation is probably important in determining changes in the virulence of certain virus diseases over the years. The influenza viruses have been found to be undergoing continual change in their antigenic pattern in the 22 years since they were first isolated. The extreme virulence of influenza in the years 1918–19 was presumably due to the appearance at that time of a mutant or series of mutants.

Recently it has been shown that recombination of genetic characters can be demonstrated in a number of virus types. With bacterial viruses and influenza viruses double infections with two related but distinct strains can give rise to progeny showing some of the characters of each parent.

When a virus responsible for human disease has to be handled in the laboratory. it is usually necessary to adapt it to some convenient "host?"often to some type of tissue culture or to the chick embryo. By the time the virus has developed a high virulence for the new host it has often lost much of its virulence for its natural host. Such *attenuated* strains will often retain the power to immunize a man or animal against the natural disease and there are many practical applications in which these modified viruses are used as "living virus vaccines."

Human Virus Diseases.—The contribution of virus diseases to human misfortune is a large one. If one includes for practical purposes the diseases caused by rickettsiae the more important diseases may be arranged as follows:

1. Major epidemic diseases: smallpox. yellow fever and typhus.
2. The common specific infectious diseases: measles, German measles (rubella), mumps, chickenpox (with its variant form herpes zoster or shingles). infantile paralysis and, in tropical and subtropical countries. dengue.
3. Common minor infections: colds. influenza A and B and probably other mild or moderately severe respiratory infections such as atypical pneumonia and simple herpes.
4. Rarer infections. mostly derived from animals: rabies. psittacosis, several forms of encephalitis. Q fever and a variety of types of rickettsial diseases transmitted by fleas, ticks or mites, trachoma. the venereal disease lymphogranuloma and a number of less important diseases.

Two important new methods for the isolation of viruses responsible for human disease were developed after World War II, injection into new born mice and the use of tissue cultures of human or monkey cells. Both uncovered an unexpectedly large range of viruses. most of which produce only trivial or unrecognizable illness. The human intestine and the human respiratory tract are now known to harbour on occasion viruses almost as diverse as their bacterial inhabitants.

Although the agent or agents responsible for the common cold had not been effectively isolated by 1955 knowledge of the feverish colds and similar infections had been greatly advanced by the isolation and study of a group of interrelated viruses that produce characteristic effects in tissue cultures of human cells. The viruses of measles. chickenpox and probably rubella had also been cultivated in similar fashion.

Artificial Immunization Against Virus Diseases.—It has been common knowledge for centuries that second attacks of smallpox or measles are virtually unknown. These are typical virus diseases and there are many others which are also followed by a long lasting immunity. Since the days of Edward Jenner. attempts had been made to find a safe means of producing a similar effective immunity against the important infectious diseases. Jenner used cowpox virus (vaccinia) to protect against what is now known to be a closely related disease (smallpox) and his name for the process of artificial infection. vaccination. has come into general use for all processes of this type. A basically similar use of an attenuated living virus is seen in vaccination against yellow fever, developed about 1937 by Max Theiler and H. K. Smith in the Rockefeller Foundation laboratories. An injection of the vaccine provokes what is essentially a symptomless attack of yellow fever with subsequent immunity lasting several years.

A second method of artificial immunization depends on the use of killed vaccines in which the virus is grown in some suitable fashion, usually in chick embryos or in tissue culture. and then killed with formalin, ultraviolet light or some other agent. Such vaccines have been used successfully against typhus fever. and influenza. The most recent example of this type is the Salk vaccine against poliomyelitis (*see* below).

Virus diseases of domestic animals are common and of great economic importance. In recent years there has been great activity in the production of protective vaccines against animal virus diseases, the same principles being applicable as in human preventive medicine. Living virus vaccines were being extensively used in 1955 against the following diseases: rinderpest in cattle. swine fever (hog cholera), rabies and distemper of dogs. fowlpox, infectious laryngotracheitis and Newcastle disease of fowls. Killed vaccines against rabies and distemper were also in use.

Poliomyelitis and the Salk Vaccine.—By 1950 polio was almost the only infectious disease which had resisted preventive and curative measures. The discovery at this time by J. F. Enders and his group at Boston that polio viruses could be cultivated in tissues other than those of the nervous system, was immediately recognized as opening an important approach to prevention by immunization. It was clear from the epidemic behaviour of poliomyelitis that natural immunization by non-paralytic infection in childhood was extremely common and that an adequate method for imitating this process safely would almost certainly prevent polio. There were two possible ways of exploiting Enders' discovery. Virus could be grown in tissue culture, killed with formalin and injected under the skin as a killed vaccine; or an attenuated nonvirulent strain might be developed which could be administered by the natural method and produce a harmless but immunizing infection. To become practical methods in public health, both would of course need years of technical development. The first to reach that stage was the Salk vaccine (see INFANTILE PARALYSIS: The *Salk Vaccine*). first tested on a large scale during 1954 in the United States. The Salk vaccine is essentially a suspension of dead virus particles from the three antigenic types of polio. Briefly, each type of virus is grown on tissue culture till the largest possible amount of virus has been produced. The cells and tissue debris are removed by filtration and the virus killed by carefully controlled treatment with formalin. On the whole the development of the vaccine proceeded smoothly and the test in 1954 indicated that the Salk vaccine was "safe and effective." Comparison of vaccinated children with statistically adequate control groups of unvaccinated children showed that a protection of about 90% effectiveness could be expected against infection by types 2 and 3 virus. The protection against the most important variety of polio (type 1) was less complete, but there was evidence that the most technically satisfactory batches of vaccine were able to protect against type 1 to a much higher level than that given as an average for all the vaccines used. The vaccine was released for general use in April 1955. A serious setback was experienced by the occurence of some 40 cases of paralysis in inoculated children, which could be ascribed with reasonable certainty to the presence of living virus in some batches of vaccine. Requirements for testing vaccine before issue were immediately tightened and no further episodes of this type were reported. A considerable body of opinion regarded it as dangerous to use a highly virulent type 1 strain for the production of a killed vaccine and believed that this should be replaced by a less virulent strain. The vaccine would then have a "built-in" safety factor, which would make a disaster like that of early 1955 impossible, even if an unforeseeable accident occurred. During 1955–56 both the United Kingdom and Denmark developed vaccines of the Salk type in which less potentially dangerous type 1 strains were used.

Despite the considerable success of the Salk vaccine in the United States. it was by no means certain that it would remain the standard approach to the prevention of polio. There were good reasons for believing that use of non-paralytic strains of living virus would provide a more firmly based immunity. Unfortunately no one had yet solved the problem of testing the efficacy and safety of allegedly non-paralytic virus strains without exposing children to danger of paralysis. New technical methods might need to be discovered before it would be possible to exploit the theoretical advantages of a living vaccine against polio.

Plant Viruses.—Virus diseases of plants are widespread, many of them of great economic importance. It is hardly too much to say that the whole organization of the potato industry is conditioned by the necessity for minimizing virus diseases. For more than a century it has been known that if a farmer in England continued to use his own seed potatoes for successive crops, degeneration progressed gradually until the great majority of the plants were malformed and stunted. If. however. new seed was obtained every second or third year from certain Scottish regions, satisfactory crops resulted. Research showed that degeneration results from the accumulation of virus diseases, transmitted by aphides either from other potato plants or from associated plants of other species. In every potato-growing country, it is necessary to find areas for seed production where, because of climatic or other conditions. aphides are absent or ineffective in transmitting disease. Other important economic diseases of the group are spotted wilt of tomato. tobacco mosaic, leaf-crinkle of cotton in the Sudan and swollen shoot disease of cocoa.

Prevention of plant virus disease is based (a) on the development of resistant varieties and (b) on preventing infection. usually by an attack on the insects responsible for carriage of the virus. Different varieties of a given plant species often show sharp differences in their response to virus infection and it may be possible to breed resistant strains which maintain the economically valuable characters of the species. There is nothing in plants to correspond to immunity in animals. Laboratory experiments have shown that in some instances it is possible to protect a plant against severe virus disease by inducting a continuing infection with a mild strain of the same virus, but the principle has no practical application.

The most important approach to prevention depends on the fact that a large proportion of plant viruses are spread from infected to healthy plants by insects. Infection of cultivated plants can be prevented either by eliminating the plants that provide the source of infection, or by destroying the insect vectors. There are many instances where weeds or garden flowers have been shown to be carriers of a virus harmful to crop plants. In Australia, for instance: dahlias are important carriers of tomato spotted-wilt virus. Removal of such carrier plants from the vicinity of the crop may prevent the introduction of disease. Destruction of the insect transporter will of course serve equally effectively and, with the development of modern insecticides, this is becoming a more practical and effective procedure.

Bacterial Viruses (Bacteriophages).—Virus infection is extremely common among bacteria. Careful study will show that a large proportion of laboratory strains of intestinal bacteria and staphylococci carry low-grade viruses (first called by D'Hérelle "bacteriophages") which as a rule cause little visible effect. If a filtrate from sewage is mixed with a pure culture of a suitable dysentery bacillus. it is common to find that the bacterial viruses present will multiply actively at the expense of the dysentery bacilli. The initial turbid culture after a few hours becomes transparent and under the microscope the bacilli have vanished. In plate cultures of bacteria. virus action is shown by the appearance of clear areas (plaques). each of which really represents a localized "epidemic" of fatal disease.

Early hopes that bacterial infections might be cut short by the action of appropriate bacterial viruses have not been fulfilled and little research on such possibilities has been done since 1940. The bacterial viruses, however, are of particular interest to biologists on account of the technical facility with which their activities can be studied. Between 1945 and 1955 extensive investigations using all the newer physical and chemical techniques resulted in the acquisition of more detailed knowledge of the functioning of a bacterial virus than of any other biological unit.

The Relation of Viruses to Cancer. — Few pathologists doubt that eventually it will be found that malignant disease is based on some disorganization of cellular processes that is of the same general quality as that produced by certain viruses. Fewer still would venture to offer any specific estimate as to the part played by viruses in the causation of human cancer (*see* CANCER RESEARCH).

Viruses (or agents which in most essentials resemble independent viruses) can be obtained almost with regularity from many types of malignant tumour in domestic fowls. A virus of rabbits produces skin growths which when irritated by tar rapidly develop into true cancers. Mice of certain strains prone to mammary cancer secrete in their milk a viruslike agent which can confer the tendency to develop mammary cancer on suckling mice which would not otherwise become cancerous. These are the main experimentally verified facts which bear on the problem. None has any direct application to human conditions.

Ever since viruses were recognized as agents of disease, there has been speculation as to whether components of cells might not, under certain circumstances, take on anarchic activity free from the normal intracellular control. Nuclear genes or, later, plasmagenes were suggested as self-multiplying units within the cell which might take on such pathological activity. Once freed from control, such units would have all the characteristics of viruses. It is along such lines that most speculations about virus-cancer interrelationship have traveled.

VIS: *see* LISSA

VISAKHA, Buddhist laywoman whom Buddha called "chief of almsgivers." a distinction she shared with Anathapindika, a layman. She was disciple, friend and adviser of Buddha and the orders, and a loyal mother of the new creed. Visakha, the daughter and granddaughter of merchants of vast wealth in Bhaddiya, was directly converted by Buddha in her youth. Following her marriage at 16 to a son of the rich Migara .in Savatthi, she devoted her life and wealth to helping the Buddhist orders. Buddha granted her request for permission to bestow eight kinds of permanent alms: to provide robes for the rainy season. food for the incoming monks, for the departing monks, for the sick and their attendants, a supply of medicine, a permanent supply of gruel and bathing dresses for the almswomen, who were not to bathe nude.

Visakha, as well as Mahapajapati, was held to have reliable powers of discretion, and was equally familiar with the Dhamma. A conversation between Buddha and Visakha has survived in the *Anguttara-nikaya* as a talk to laywomen. The monastery that Visakha built in the Pubbarama was used as a retreat by Buddha after he settled permanently at Savatthi.

VISAYAN ISLANDS, the central group of seven large and several hundred small islands of the Philippines. Northernmost. the three small islands Tablas. Romblon and Sibuyan form the province of Romblon. Then, southward. come the islands of Panay with four provinces and Negros with two provinces. Eastward, are the island provinces of Cebu, Kohol. Masbate. Leyte and Samar. Pop. (1958 est.) 8.096.000; area about 22.000 sq.mi. Negros, Panay and the Romblon group sometimes are referred to as the Western Visayas, the others comprising the Eastern Visayas. Visayans all speak related dialects of the Visayan language. *See* also PHILIPPINES. REPUBLIC OF THE. (J. E. SR.)

VISBY, the capital of the Swedish island and administrative district (lan) of Gotland. in the Baltic sea. Pop. (1950) 14.740. The name Visby is derived from the old Norse ***ve*** ("sanctuary") and ***by*** ("town"). It was no doubt a place of religious sacrifice in heathen times. At any rate. it was a notable trading place and emporium as early as the end of the Stone Age, and long continued to enjoy its importance as such, as is proved by the large number of Arabic, Anglo-Saxon and other coins found.

In medieval times Visby was the centre of trade between Asia. Russia and Europe and grew to great wealth and power. It made its own maritime laws and coined its own money. The city was besieged in 1361 by King Valdemar IV of Denmark. who won it in a fierce battle. The defeated people of Gotland buried their warriors in one common grave. on which they placed a cross. This grave was opened by archaeologists shortly before World War II, and it revealed many articles of medieval warfare and art objects.

Visby is the seat of a bishop. the port of the island and a favourite resort. It is picturesquely situated on the west coast, 150 mi. S. by E. of Stockholm by sea. The houses cluster beneath and above a cliff (klint) 100 ft. high, and the town is thoroughly medieval in appearance. The remains from its period of extraordinary prosperity from the 11th to the 14th centuries are of the highest interest. Its walls date from the end of the 13th century, replacing earlier fortifications, arid enclose a space much larger than that now covered by the town.

Massive towers rise at close intervals along them, about 40 are in good preservation. Between them are traces of bartizans. The Cathedral Church of St. Mary dates from 1190–1225, hut was much altered in later times; it has a great square tower at the west end and two graceful octagonal towers at the east, and contains numerous memorials of the 17th century. There are ten other churches, in part ruin d. Among those of chief interest St. Nicholas', of the early part of the 13th century, formerly belonged to a Dominican monastery. It retains two beautiful rose windows in the west front. The Church of the Holy Ghost *(Helgeands-Kyrka)* in a late Komanesque style (*c.* 1250) is a remarkable structure with a nave of two stories. The

Romanesque St. Clement's has an ornate south portal, and the churches of St. Drotten and St. Lars, of the 12th century, are notable for their huge towers. St. Catherine's, of the middle of the 13th century, is Gothic, with a pentagonal apse. Galgberget, the place of execution, has tall stone pillars; and there is a stone labyrinth at Tröjeborg. Modern buildings include the Gotland Museum of Antiquities. The artificial harbour, somewhat exposed, lies south of the ancient Hanseatic harbour, now filled up.

See GOTLAND and MARITIME LAW.

VISCACHA (BISCACHA, VIZCACHA), a large South American burrowing rodent belonging to the family Chinchillidae. The viscacha (*Lagostomus*) is 20 in. long over-all, with an 8-in. tail; it is heavy set, with short ears and a massive head. The fur is short and soft, dark gray in colour, with black and white markings on the face. Viscachas inhabit the South American pampas between the Uruguay river and the Río Negro in Patagonia, where they dwell in warrens (*viscacheras*) covering from 100 to 200 sq.ft. and forming mounds penetrated by numerous burrows.

The ground around the *viscachera* is cleared from vegetation, the refuse of which is heaped upon the mound. Anything the rodents meet on their journeys, such as thistle stalks or bones, is deposited on the *viscachera*. In frequented districts the viscachas seldom emerge till evening. Their chief food is grass and seeds, but they also consume roots. The mountain viscachas, *Lagidium*, are built like the chinchillas, but have rabbitlike ears and yellowish-gray fur; they emerge in the day.

See RODENTIA. (J. E. HL.)

VISCHER, the name of a family of sculptors working in Nürnberg during the last half of the 15th and the first half of the 16th centuries.

1. HERMANN, the elder, was probably of north German origin but acquired citizenship in Nürnberg in 1453. A baptismal font in the Stadtkirche of Wittenberg (1457) is signed by him. He died in Jan. 1488.

2. His son, PETER, the elder, was born about 1460 in Niirnberg, where he died on Jan. 7, 1529. In 1494 he entered the service of Philip, the elector palatine, at Heidelberg but soon returned to Nürnberg, where he worked with the help of four of his sons, Hermann, Peter, Hans and Paul.

His principal works are the tomb of Archbishop Ernest in the cathedral of Magdeburg (1494–95); the tomb of Bishop John IV in the cathedral of Breslau (1496, signed); the shrine of St. Sebald in the Sebalduskirche at Niirnberg (between 1508 and 1519); a large grille ordered by the Fugger brothers in Augsburg. This last was not finished, and most of it was sold for metal in 1806, but four reliefs belonging to it are in the château of Montrottier near Annecy. The tombstone (1521) for Margareta Tucherin in the cathedral at Ratisbon (Regensburg) and that for Cardinal Albrecht of Brandenburg in the collegiate church at Aschaffenburg (1525) have been ascribed to Hans Vischer; that of the Eisen family in the Agidienkirche in Nürnberg to his brother Paul; and that of the electoral prince Frederick the Wise to Peter Vischer, the younger.

The style of Peter, the elder, is essentially Gothic but at the same time not without some Italian influence in detail. His is a case somewhat analogous to that of the painter Jacopo de Barbari, his contemporary.

The shrine of St. Sebald, his most remarkable work, is a tall canopied, bronze structure, lavishly decorated with reliefs and statuettes. Some of the statuettes of saints attached to the slender columns of the canopy are modeled with much grace and even dignity of form. A small portrait figure of Peter himself, introduced at one end of the base, is a marvel of clever realism: he represented himself as a stout, bearded man, wearing a large leathern apron and holding some of the tools of his craft. This shrine is a remarkable example of the uncommercial spirit which animated the artists of that time, and of the evident delight which they took in their work. Dragons, grotesques and little figures of boys, mixed with graceful scroll foliage, crowd every possible part of the canopy and its shafts, designed in the most free and unconventional way and executed with an utter disregard of the time and labour that were lavished on them. (A. K. McC.)

VISCHER, FRIEDRICH THEODOR (1807–1887), German writer and professor, whose Hegelian theories of aesthetics had great influence, was born at Ludwigsburg, June 30, 1807. After studying at Tübingen, he became a lecturer there in 1835 and was made professor in 1844 but was suspended for two years as a result of a characteristically outspoken inaugural address. During this time he began *Ästhetik oder Wissenschaft des Schönen,* finally completed in six volumes (1846–58), his most considerable work as philosopher and critic, which revealed industry and erudition rather than originality but contained much valuable material. In 1855 he became professor at Zürich but returned to Germany in 1866 and was again made professor at Tübingen. This was combined with a post at the Stuttgart polytechnic, which continued after the termination of his professorship in 1869. He died at Gmunden, Aus., Sept. 14, 1887.

As well as writings on aesthetics, and critical essays collected in *Kritische Gänge* (1844) and *Altes und Neues* (1881), Vischer wrote a popular novel, *Auch Einer* (1879; Eng. trans., *The Humour of Germany,* 1892), a satirical tragicomedy which reveals robust humour and interest in philosophy; a critical study of Goethe's *Faust* (1875); a parody of *Faust,* under the pseudonym Mystifizinski; and many poems.

VISCONTI, the name of a celebrated Italian family which long ruled Milan; members of the family claimed descent from King Desiderius, and in the 11th century possessed estates on Lakes Como and Maggiore.

A certain OTTONE, who distinguished himself in the First Crusade, is mentioned in 1078 as viscount of Milan. The real basis for the family's dominion was laid, however, by another OTTONE (d. 1295), a canon of Desio, appointed archbishop of Milan by Pope Urban IV in 1362 through the influence of Cardinal Ubaldini. The Della Torre family, who then controlled the city, opposed the appointment, and not until his victory at Desio in 1277 was Ottone able to take possession of his see. He imprisoned Napoleone Della Torre and five of his relatives.

His nephew, MATTEO, born at Invorio on Aug. 15, 1255, succeeded him as political leader of Milan, and although an uprising of the Della Torre in 1302 compelled him to take refuge at Verona, the emperor Henry VII, restored him to Milan in 1310 and made him imperial vicar of Lombardy. He brought under his rule Piacenza, Tortona, Pavia, Bergamo, Vercelli, Cremona and Alessandria.

An able general, he yet relied for his conquests more on diplomacy and bribery, and was esteemed as a model of the prudent Italian despot. Persevering in his Ghibelline policy, and quarrelling with Pope John XXII over an appointment to the archbishopric of Milan, he was excommunicated by the papal legate Bertrand du Puy in 1322. He at once abdicated in favour of his son Galeazzo, and died at Crescenzago on June 24.

GALEAZZO I (1277–1328), who ruled at Milan from 1322 to 1328, defeated the Holy Army which the pope had sent against the Visconti at Vaprio on the Adda (1324), with the aid of the emperor Louis the Bavarian. In 1327 he was imprisoned for a short time by the emperor at Monza because he was thought guilty of making peace with the church. By his wife Beatrice d'Este he had the son Azzo who succeeded him. His brother MARCO commanded a band of Germans, conquered Pisa and Lucca and died in 1329.

AZZO (1302–1339), who succeeded his father in 1328, bought the title of imperial vicar for 25,000 florins from the same Louis who had imprisoned Galeazzo I. He conquered ten towns, murdered his uncle Marco (1329), suppressed a revolt led by his cousin Lodrisio, reorganized the administration of his estates, built the octagonal tower of S. Gottardo, and was succeeded in turn by his uncles Lucchino and Giovanni. LUCCHINO made peace with the church in 1341, bought Parma from Obizzo d'Este and made Pisa dependent on Milan. He was poisoned in 1349 by his wife Isabella Fieschi.

GIOVANNI, brother of the preceding, archbishop of Milan and lord of the city from 1349 to 1354, was one of the most notable characters of his time. He befriended Petrarch, extended the Visconti sway over Bologna (1350), defied Pope Clement VI., annexed Genoa (1353), and died on Oct. 5, 1354, after having established the rule of his family over the whole of northern Italy except Piedmont, Verona, Mantua, Ferrara and Venice. The Visconti from the time of Archbishop Giovanni were no longer mere rivals of the Della Torre or dependants on imperial caprice, but real sovereigns with a recognized power over Milan and the surrounding territory. The State was partitioned on the death of Giovanni among his brother Stefano's three sons, Matteo II., Galeazzo II. and Bernabb. MATTEO II., who succeeded to Bologna, Lodi, Piacenza and Parma, abandoned himself to the most revolting immorality, and was assassinated in 13jj by direction of his brothers, who thenceforth governed the State jointly and with considerable ability. GALEAZZO II., who held his court at Pavia, was the patron of Petrarch, the founder of the University of Pavia, and a gifted diplomat. He married his daughter Violante to the duke of Clarence, son of Edward III. of England, giving a dowry of 200.000 gold florins; and his son Gian Galeazzo to Isabella, daughter of King John of France. He died in 1378. BERNABÒ, who held his court at Milan, was involved in constant warfare, to defray the expenses of which he instituted very oppressive taxes. He fought Popes Innocent VI. and Urban V., who proclaimed a crusade against him, and the emperor Charles IV., who declared the forfeiture of his fief. He endeavoured to exercise sole power in the State after the death of his brother, but his young nephew Gian Galeazzo put him to death (1385).

GIAN GALEAZZO, the most powerful of the Visconti, became joint ruler of the Milanese territories on the death of his father in 1378 and sole ruler on the death of his uncle seven years later. He founded the cathedral of Milan, built the Certosa and the bridge across the Ticino at Pavia, improved the University of Pavia and established the library there, and restored the university at Piacenza. He was an able and economical administrator, and was reputed to be one of the wealthiest princes of his time. Ambitious to reduce all Italy under the sway of the Visconti, he conquered Verona in 1387; and in the following year, with the aid of the Venetians, took Padua. He plotted successfully against the rulers of Mantua and Ferrara, and finally turned his attention to Tuscany. In 1399 he bought Pisa and seized Siena. The emperor Wenceslaus had already conferred on him the title of duke of Milan for 100,000 florins, reserving only Pisa, and refused to take arms against him. Gian Galeazzo took Perugia, Lucca and Bologna (1400–01), and was besieging Florence when he died of the plague (Sept. 3, 1402). His sons, Giovanni Maria and Filippo Maria, were mere boys at the time of his death, and were taken under the protection of the celebrated condottiere Facino Cane de Cesale; but most of Gian Galeazzo's conquests were lost.

GIOVANNI MARIA was proclaimed duke of Milan in 1402, displayed an insane cruelty, and was killed in 1412 by Ghibelline partisans. FILIPPO MARIA, who became nominal ruler of Pavia in 1402, succeeded his brother as duke of Milan. Cruel and extremely sensitive about his personal ugliness, he nevertheless was a great politician, and, by employing powerful condottieri, managed to recover the Lombard portion of his father's duchy. From his marriage with the unhappy widow of the above-mentioned Facino Cane he received a dowry of nearly half a million florins. He died in 1447, the last of the Visconti in direct male line, and was succeeded in the duchy, after the shortlived Ambrosian republic, by Francesco Sforza, who had married his daughter Bianca in 1441. (See SFORZA.)

BIBLIOGRAPHY.—A contemporary history of the principal members of the family by Paolo Giovio, bishop of Nocera, was published in several editions. *See* J. Burckhardt, *The Civilization of the Renaissance in Italy,* trans. *by* S. G. C. Middlemore (London, 1898); J. A. Symonds, *Age* of *the Despots* (New York, 1888); C. Magenta, *I Visconti e gli Sfovsa nel Castello di Pavia* (1883); A. Medin, *I Visconti nella poesia contentporanea* (Milan, 1891); F. Mupnier, "Lettres des Visconti de Milan" in *Mémoires et documents de la société savoisienne d'histoire et d'archéologie,* vol. x of the 2nd series (1896).

VISCONTI-VENOSTA, EMILIO, MARQUIS (1829–1914), Italian statesman. was born at Milan on Jan. 22, 1829. At first a disciple of Mazzini, he was later disillusioned by the ineffectual rising at Milan against the Austrians in 1853. Continuing. nevertheless. his anti-Austrian propaganda, he was obliged in 1859 to escape to Turin, and during the war with Austria of that year was appointed by Cavour royal commissioner with the Garibaldian forces. Elected deputy in 1860, he was sent on diplomatic missions to Modena and Naples. He was subsequently appointed undersecretary of state by Count Pasolini. Upon the latter's death he became minister of foreign affairs (March 24. 1863) in the Minghetti cabinet, in which capacity he negotiated the September convention for the evacuation of Rome by the French troops. Resigning office with Minghetti in the autumn of 1864, he was in March 1866 sent by La Marmora as minister to Constantinople. but was almost immediately recalled and reappointed foreign minister in a short-lived Ricasoli cabinet.

Out of office for two more years, he was again foreign minister under Lanza and Minghetti, 1869–76. During this long period he n-as called upon to conduct negotiations connected with the Franco-German War, the occupation of Rome and the consequent destruction of the temporal power of the pope. In 1894, after 18 years' absence from active political life, he was chosen Italian arbitrator in the Bering sea question, and in 1896 once more became foreign minister in the Rudini cabinet after the disastrous military defeat in Abyssinia. His first care was to improve Franco-Italian relations by recognizing the French position in Tunis. Over the Cretan question and the Graeco-Turkish War, he secured for Italy a worthy part in the European concert, and joined Lord Salisbury in saving Greece from the loss of Thessaly. Resigning office in May 1898, on a question of internal policy, he again assumed the management of foreign affairs in the second Pelloux cabinet in May 1899, and continued in the succeeding Saracco cabinet until its fall in Feb. 1901. During this period his attention was devoted chiefly to the Chinese problem and to the maintenance of equilibrium in the Mediterranean and in the Adriatic. For instance, he established an Italo-French agreement, by which France undertook to leave Italy a free hand in Tripoli. and Italy not to interfere with French policy in the interior of Morocco. In Feb. 1906 he was Italian delegate to the Morocco conference at Algeciras. Prudence and sagacity, coupled with unequaled experience of foreign policy, enabled him to assure to Italy its full portion of influence in international affairs.

VISCOSE RAYON: The process of making rayon from a viscose solution of cellulose was introduced commercially in 1905. It is the most widely used method. For particulars of the process see SYNTHETIC FIBRES.

VISCOSITY. When a fluid, which may be a liquid or a gas, is set in motion by any system of forces and then left to itself, it comes to rest by virtue of an internal friction. which tends to resist the sliding of one part of the fluid over another. This internal friction is known as viscosity. If a state of steady motion is maintained by any system of forces the viscosity of the fluid tends to oppose the motion and leads to the dissipation of energy as heat, just as does the friction between solid bodies.

The Coefficient of Viscosity.—The first stage in the study of any process in the physical sciences is to define a quantity which shall give a numerical measure of the property in question, which in this case is the resistance offered by a fluid to one layer sliding over another. Consider the movement of a fluid. for definiteness a liquid, between two parallel plates A and B (see fig. 1), at distance d apart, A being at rest while B is kept moving with a constant velocity v, which is communicated to the liquid in contact with it. With normal fluids the velocity of any given layer will be proportional to the distance from B, as indicated by the length of the arrows. and we speak of a velocity gradient v/d, which is the rate of change of the shear strain. A force, which is propor-

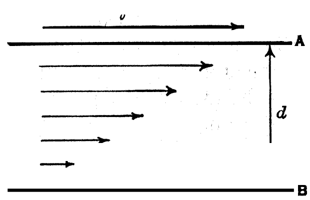

FIG 1 — SIMPLEST REPRESENTATION OF LAMINAR FLOW tional to the area of the plates, will be required to keep A in steady motion and with normal liquids this force is proportional to the velocity gradient. For a class of liquids known as lyophilic suspensions, which includes such substances as gelatin solutions. this proportionality to velocity gradient does not, in general, hold. Further, there are liquids, such as paints, whose flow properties depend upon their recent mechanical history, for instance! upon the time interval since they were stirred.

Normal liquids, such as water, alcohol and benzene, for which the shearing force is proportional to the velocity gradient, are known as Newtonian liquids, because Newton, in considering the behaviour of the imaginary fluid that? on the Cartesian world system, filled all space, assumed that it would have this property. He never considered the viscous properties of real liquids. The viscous behaviour of all gases is Newtonian. The exceptional liquids are called non-Newtonian. The flow of solids. in particular of metals, considered in the second part of this article. is. in general, non-Newtonian.

The constant that characterizes viscosity, known as the coefficient of viscosity. is defined as the shear stress—shearing force per unit area—which exists between parallel planes (as in fig. 1) when the velocity gradient is unity. It is thus a force divided by an area and by a velocity gradient, which gives it dimeniion $ML^{-1}T^{-1}$ (*see* DIMENSIONAL ANALYSIS). The unit of viscosity. when the centimetre-gram-second (c.g.s.) system is used. is called the poise. in honour of J. L. M. Poiseuille (*see* below). For such easily flowing liquids as mater this is rather a large unit, so a hundredth of it, called the centipoise. is often used. To give some notion of the significance of the unit, the viscosity of the very viscous fluid glycerin is about 1j poise (1.500 centipoise). of castor oil about 10 poise. of olive oil a little less than 1 poise, of water about 1 centipoise, of air 0.018 centipoise, all at 20° C. In the accompanying table are given the viscosities of some other well-known liquids.

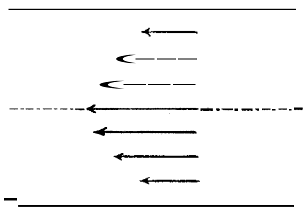

FIG. 2.— DISTRIBUTION OF VELOCITIES IN A TUBE OF CIRCULAR CROSS SECTION

TABLE.—*Viscosities of Pure Liquids in Centipoises at 20° C., Unless Otherwise Stated*

Water at 0°	1.7921	Ethyl alcohol	1.200
Water at 10°	1.3077	Carbon tetrachloride	0.969
Water at 20°	1.0050	Benzene	0.652
Water at so"	0.5494	Methyl alcohol	0.597
Water at roo°	0.2838	Toluene	0.590
Heavy water	1.2514	Carbon disulfide	0.363
Sulfuric acid, 100%	25.4	Ether	0.233
Aniline	4.40	Mercury	1.56

The fluidity, which is defined as the reciprocal of the viscosity, is sometimes used, the unit, a reciprocal poise, being called the rhe (from the Greek *rhein*, "flow"). When accelerated motion is in question on account of inertia the determining factor is the viscosity η divided by density ρ, which is called the kinematic viscosity, $\nu=\eta/\rho$. Thus, although the viscosity of air is less than that of water, stirred air comes to rest much sooner than water similarly stirred; the kinematic viscosities of air and water are, respectively, 0.162 and 0.0101 in c.g.s. units. In the same unit, which is called a stoke after George Gabriel Stokes, a pioneer in the theory of viscous flow, the kinematic viscosity of mercury is 0.00115. The critical velocity at which, with a given disposition, laminar flow breaks down and becomes turbulent is proportional to the kinematic viscosity.

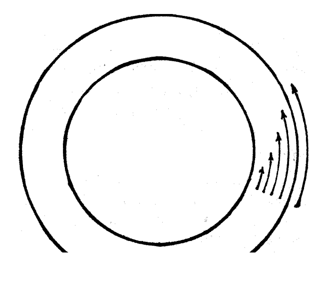

FIG. 3.— DISTRIBUTION OF VELOCITIES BETWEEN TWO CYLINDERS, THE INNER ONE FIXED. THE OUTER ROTATING ABOUT ITS AXIS

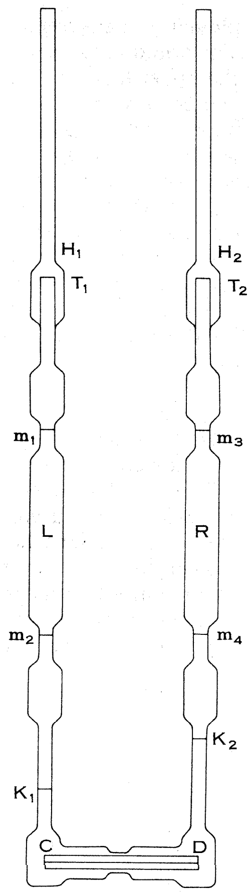
Measurement of Viscosity.—The motion contemplated in the definition of viscosity is laminar, that is, one in which the fluid moves in parallel planes gliding one over another. Other types of motion exist—in particular turbulent motion—but to derive simply the coefficient of viscosity laminar conditions are required. Such conditions exist in the not-too-rapid flow of a fluid through a capillary tube, in which the velocity of coaxial cylindrical sheets takes up a parabolic distribution, as shown in fig. 2, being zero at the wall; or in the motion between two coaxial metal cylinders. of which one rotates about the axis, relative to the other. In fig. 3 the inner cylinder is shown as being at rest and the outer rotating, the velocities being indicated by the lengths of the arrows.

The laws governing the flow of a viscous liquid through a fine tube were discovered experimentally by Poiseuille in a classical investigation published in 1842. He was a doctor of medicine and was led to undertake the work by his interest in the flow of blood through capillaries. He found that the volume V passing through the tube in unit time was proportional to (1) the difference of pressure at the two ends of the tube; (2) the fourth power of the radius of the tube: (3) the reciprocal of the length of the tube. E. Hagenbach, several years later, defined the coefficient of viscosity η and worked out the formula

$$V=\frac{\pi}{8\eta}\,\frac{a^4(p_1-p_2)}{l} \qquad (1)$$

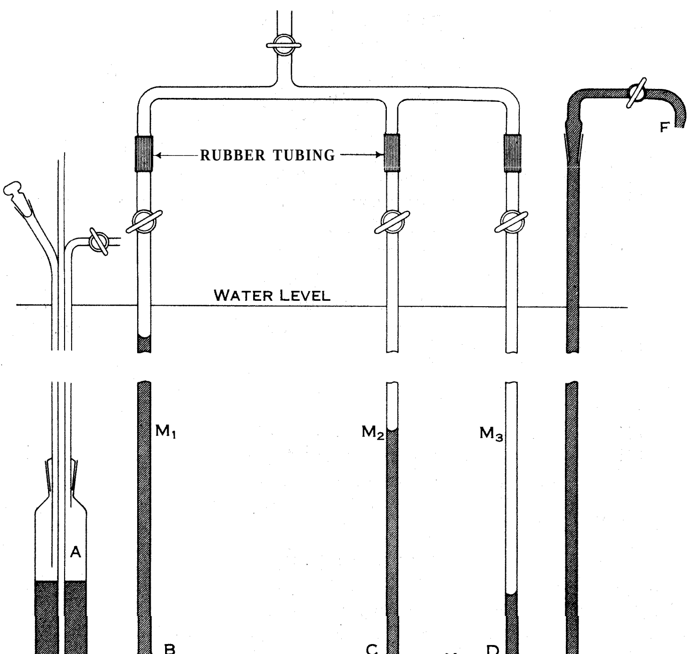
where a is the radius, l the length of the tube and p_1 and p_2 are the pressures at the two ends. This formula nas independently derived by G Wiedemann.



FROM THORPE & RODGER, IN "PHILOSOPHICAL TRANSACTIONS" (COUNCIL OF THE ROYAL SOCIETY)

FIG 4 —VISCOMETER OF THORPE AND RODGER, FOR STANDARD DETERMINATIONS

The capillary viscometer has many forms. The prototype of many used for precise determinations of viscosity was that of Sir Edward Thorpe and J. W. Rodger. em-



FROM GUY BARR, "A MONOGRAPH OF VISCOMETRY," OXFORD UNIVERSITY PRESS, 1931

FIG. 5.— VISCOMETER OF ERK, USED TO ELIMINATE END EFFECTS

ployed in measurements many of which are still standard (fig. 4). The liquid runs under a gravity difference of head, adjusted so that the upper level initially is at the top of the tube in bulb T_1 (or T_2) and the lower level at mark K_2 (or K_1). The time taken for the upper level to pass from m_1 to m_2, (or m_3 to m_4) is measured. Many precautions are taken with this type of viscometer to ensure accuracy. but there are inherent difficulties. The radius enters as r^4, so that any errors in r are multiplied by 4—available capillary tubes are neither exactly circular in cross section nor exactly uniform in bore. There are, further, troublesome end corrections, the formula (1) applying to a tube of infinite length.

To eliminate, as far as possible. the end corrections, S. Erk devised a viscometer (fig. 5) in which the liquid flows through two capillaries of different lengths, K_1 and K_2, cut from the same tube. The pressures at the ends of the tubes are measured by the three manometers M_1, M_2 and M_3. If the tubes were completely uniform in bore the differences in pressure would permit full allowance for end effects.

The capillary tube viscometer is extensively used for ordinary laboratory measurements of viscosity, being calibrated by the use of a standard liquid such as water or sucrose solution. A typical form is shown in fig. 6. A given volume of liquid is charged into the instrument and taken up until the upper meniscus is above A in the left-hand limb. The time for the meniscus to fall from A to B, under gravity. is measured. The viscosity and density of the calibrating liquid being η_0 and ρ_0, the viscosity η_1 of the liquid, density ρ_1, under test is given by

$$\eta_1 = \eta_0 \frac{\rho_1 t_1}{\rho_0 t_0}$$

where t_0, t_1 are the respective times of flow.

Instruments of this general type. in which the quantity to be measured is the time taken by a liquid flowing through a capillary to fall from a mark above a bulb to a mark below are generally known as Ostwald viscometers.

Another general type of instrument for measuring viscosity is the coaxial cylinder apparatus, originated by Maurice Frédéric Couette. In some the inner cylinder is at rest and the outer rotates steadily (schematically shown in fig. 3); in others the inner cylinder rotates while the outer cylinder is at rest. Typical of the former class is E. Hatschek's viscometer for liquids, which has been extensively used in the study of colloidal solutions (fig. 7). The inner cylinder. A, is suspended by a torsion wire; the angle through which it is turned, in consequence of the steady rotation of the outer cylinder, gives the moment M of the viscous forces. E and E' are fixed guard cylinders which eliminate end effects. Then

$$M = K\eta\Omega$$

where Ω is the constant angular velocity of the outer cylinder and K is an apparatus constant involving the radii of the cylinders and the height of the inner cylinder. The apparatus is calibrated by use of a standard liquid.

A similar type of apparatus, but with the outer cylinder suspended by a torsion wire and the inner cylinder maintained in steady rotation. was used by J. A. Bearden in his precision determination of the viscosity of air.

In a method which has been worked out practically and employed by E. N. da C. Andrade, the liquid is contained in a closed sphere which hangs by a bifilar suspension in a high vacuum. so that it can execute torsional vibrations about its vertical diameter. If it is set in motion by a twist and then left to itself, the effect of the enclosed liquid is to damp the vibrations and the viscosity can be calculated from the logarithmic decrement. that is, from the rate at which the angular amplitude diminishes. This method has the advantage that the liquid is sealed off and never comes in contact with air or other gas; it has therefore been extensively used for measurements on liquid metals which oxidize easily. The liquid is sometimes contained in a closed cylinder instead of a sphere.

FIG. 7.—THE HATSCHEK FORM OF COUETTE VISCOMETER

Quite a different method measures the viscosity of the fluid from the rate at which a small sphere, of known diameter and mass. falls through it. If the sphere is small enough, the suitable size depending upon the viscosity in question, it soon settles down to a uniform rate, as exemplified by a raindrop falling through the air. Stokes showed that the velocity v of steady fall was given by

$$v = \frac{2r^2(\rho-\rho')g}{9\eta} \qquad (2)$$

where r is the radius of the sphere, ρ and ρ' the densities of the substance of the sphere and of the fluid and g the gravitational acceleration. This formula enables η to be found from v. In the case of oils a small metal sphere can be used. The formula is also involved in the determination of the electronic charge, where the fluid is air and the liquid spheres used are about a thousandth of a millimetre in diameter. (*See* ELECTRON.)

For his measurements on the viscosity of liquids at high pressures. P. W. Bridgman used a tube of about 6 mm. internal diameter, in which slid a short hollow cylinder, with rounded ends, of slightly less diameter, kept central by small projections (fig. 8). The time of fall was measured. This gave relative viscosities under different conditions.

The Variation of the Viscosity of Liquids With Temperature.—The viscosity of liquids falls with rise of temperature. It would seem to be a general rule, pointed out by Andrade, that the more complex the liquid, the greater the influence of temperature. Thus, in the temperature range 0° to 30° C., with glycerin the viscosity falls to $\frac{1}{20}$; with water. which at the lower temperatures is heavily associated, it falls to $\frac{1}{2}$; with carbon tetrachloride, a straightforward liquid, to $\frac{2}{3}$;

and with monatomic mercury it falls to $\frac{5}{6}$—all values approximate.

For normal liquids the variation of viscosity with temperature is well represented by Andrade's formula:

$$\eta = Be^{b/T} \tag{3}$$

where B and b are constants; later modified to

$$\eta v^{\frac{1}{3}} = Ce^{c/vT} \tag{4}$$

where T is the absolute temperature. C and c are constants and v is the specific volume. This formula, with only two constants. agrees with observations over a wide range of temperatures. with normal liquids. It was derived by simple considerations which regarded the molecules as vibrating about slowly moving equilibrium positions and communicating momentum at every extreme libration at the temperature of melting. The temperature agitation was supposed to interfere with the communication of momentum, in accordance with L. Boltzmann's principle.

In formulas of type (3) and (4), when the exponential term is written $e^{E/kT}$, k being Boltzmann's constant. E represents an energy involved in the viscous process. Thus bk, or ck/v, represent such an energy and can be shown to be related to, for instance, the internal latent heat. H. Eyring and his colleagues have used consideration of reaction energy in elaborating a general analogy between the viscous process and rate of chemical reaction.

Water is in every way an anomalous liquid. as instanced by the variation of density with temperature, and the variation of its viscosity with temperature is not represented by formulas (3) or (4). There are certain other liquids. anomalous in other respects, such as the tertiary alcohols. whose viscous behaviour is likewise exceptional. For the majority of liquids, however, the formulas are in general use, especially the simpler one in the form

$$\log \eta = A + b/T$$

Andrade's theory, which connects the viscosity of the simplest class of liquids with the frequency of vibration of the molecules, allows an expression which does not contain any arbitrary constant to be worked out for the viscosity of the liquid at the melting point temperature. The frequency is derived from P. Debye's characteristic temperature or from F. A. Lindemann's constant. The absolute values calculated in this way agree well with experiment for liquid metals.

Viscosity and Pressure.—The work of Bridgman has shown that the viscosity of all liquids—water at lower temperatures. with its usual abnormality, excepted—increases steadily with pressure. For typical organic liquids the viscosity at 1.000 atm. is two or three times that at normal pressure, but the increase at the highest pressures is at a much greater rate—to take an extreme example, with isobutyl alcohol the viscosity is nearly 800 times as great at 12,000 atm. as at 1 atm. Bridgman has shown that viscosity is not a function of the volume alone, as certain theories put forward to account for the temperature variation had suggested. Xndrade's theory has given a rough representation of the variation of viscosity with pressure up to 3,000 atm. At higher pressures. where it fails, Bridgman has given clear evidence for supposing that the molecules themselves are deformed, which further complicates matters already complicated.

Viscosity and Chemical Constitution.—In the early attempts to relate viscosity to chemical constitution the viscosity at some particular temperature was selected as typical. Thorpe and Rodger: for instance, took the viscosity at the boiling point. which can have no fundamental significance, since at a pressure other than atmospheric the results would be different. Others have taken a fixed temperature for all liquids, when, again. the results will depend upon the temperature selected. The close fit afforded by formula (4) seems to offer a better opportunity of connecting viscosity and constitution, since the constant c is characteristic of the liquid and represents an energy which should vary systematically within homologous series of organic compounds. It has, in fact, been shown that in series for which figures are available, c varies regularly from member to member, and some connection between the viscosity constant and the intermolecular energy due to van der Waals forces has been indicated.

Viscosity of Suspensions, Sols and Solutions.—In the case of solutions and suspensions, use is often made of the term relative viscosity. defined as $\eta_r = \eta_c/\eta_0$, nhere the viscosities of solvent and solution are respectively η_0 and η_c. The relative or specific increase of viscosity is defined as

$$\eta_{sp} = \eta_r - 1 = \frac{\eta_c - \eta_0}{\eta_0}.$$

The simplest case is that of a suspension of solid spherical particles of microscopic or ultramicroscopic size. For such suspensions A. Einstein, on purely hydrodynamical grounds, derived the formula

$$\eta_c = \eta_0(1 + 2.5\,\phi) \text{ or } \eta_{sp} = 2.5\,\phi$$

where ϕ is the total volume of the solid spheres in unit volume of suspension. Thus only the aggregate volume of the spheres, not their size! comes into question. The formula has been tested with, for example, suspensions of gamboge containing globules of from 0.3 to 4μ in radius, and found to hold well as long as the concentration is not too high. For higher concentrations a term in ϕ^2 has to be added.

Suspensions of this class, which include gold and silver sols with particles whose diameter may be of the order 0.1μ, are known as lyophobic. or solution hating, because the solids are easily precipitated in a form which will not pass back into solution. They have normal Newtonian viscosity. Suspensions of minute rods. such as lengths of fine artificial silk fibre. likewise behave normally. except when the particles are so long as to interact.

With lyophilic or solution-loving sols small additions of the solid substance. *e.g.,* agar. to the solvent *e.g.,* water. cause a great increase of viscosity—even a few per cent may cause a hundredfold increase. Again, the increase of viscosity with concentrations is more rapid than would be indicated by a linear law. Ever?-thing points to the building up of a structure. The viscosity is non-Newtonian, the apparent viscosity at any particular shear stress, as measured by the velocity gradient produced, decreasing rapidly as the shear stress is increased. which would be in accord with the general picture of the breaking down of a structure. The results of the many investigations into the viscous behaviour of such gels are. from the nature of the subject: complicated.

Still more troublesome is the case of the colloidal suspensions whose behaviour depends upon their recent mechanical handling, suspensions which. otherwise expressed. slowly build up a structure which, when broken down. gradually restores itself. Thus paints, which in the simplest case consist of a suspension of a solid such as lithopone in a medium such as oil. flow comparatively freely if recently stirred. but on standing revert to a gellike state. Such behaviour—roughly speaking. a liquefaction on agitation—is known as thixotropy (from Greek *thixis,* "a touch." and *tropos,* "turning"—changing at a touch). The liquid form in some cases behaves in a Newtonian manner, in others not.

In the case of the viscosity of true solutions. such as sugar or salt in water, there is a lack of non-Ken-toninn complications and a simplicity might be expected which is. however. not evident. A distinction is usually made between electrolytes and nonelectrolytes. With electrolytes the relative increase of viscosity may be either positive or negati e: thus a concentration of 0.703 mols per litre of $LiNO_3$ in water at 18° C. gives $\eta_{sp} = 0.0737$, while a concentration of 0.732 mols per litre of $CsNO_3$ gives $\eta_{sp} = -0.0653$. It was at one time believed that only electrolytes could produce a decrease of relative viscosity. hut cases have been found where nonelectrolytes. which generally shon an increase. have such an effect, though small; *e.g.,* 0.25 mols per litre of *p*-nitrobenzene in alcohol give $\eta_{sp} = -0.0011$. The estabiished difference between electrolytes and nonelectrolytes is given by the response of η_r to change of temperature. For electrolytes it increases with temperature. for nonelectrolytes it decreases; in other words, for electrolytes the viscosity of the solution decreases less rapidly, for nonelectrolytes more rapidly. than that of the solvent.

Attempts have been made to connect the viscosity of electrolytes with the conductivity without any pronounced success. In general, while a great body of measurements exists for the viscosity of solutions of both kinds. no widely valid regularities have been revealed. Many empirical formulas have been shown to represent particular cases, but in the absence of either comprehensive empirical rules or approximate theory the subject is not ready for simple exposition. The same is true of the viscosity of liquid mixtures.

Effect of an Electric Field.—Early attempts. from 1885 onward. to detect the effect of an electric field on the viscosity of liquids led to very divergent results. In some cases large effects were found; Xndrade and Cyril Dodd showed that such results were spurious and established that with nonpolar liquids, such as benzene, no change to within 1 part in 100.000 took place even with a field of 42.000 v. per centimetre, but with polar liquids. such as monochlorbenzene, there was a small change of viscosity, $\Delta\eta$, given by

$$\frac{\Delta\eta}{\eta}=fF^2$$

where F is the field and f is the viscoelectric constant, which is around 2×10^{-7} if the field is measured in electrostatic units. This means that with practicable fields. $\Delta\eta/\eta$ does not exceed about 0.0012. so that very precise experimental methods and careful temperature control are necessary to detect it.

A general explanation of the effect can be given in that which polar molecules the field exercises an orienting effect which tends to hinder the rotation of the molecules. which is a consequence of laminar flow. The theory of the viscosity of polyatomic molecular liquids is not yet developed to a stage where a quantitative explanation of the effect can be worked out.

The Viscosity of Gases.—James Clerk Maxwell made his early determinations of the viscosity of air by measuring the damping of the torsional oscillations of a system of three parallel disks. mounted rigidly on an axis suspended by a torsion wire. which moved between four fixed disks (fig. 9). This arrangement made the frictional force produced by the viscosity of the air between the disks comparatively high. Later. the viscosity of gases was measured by methods similar to those used for liquids, in particular by the flow through capillary tubes and by concentric cylinder apparatus of the Couette type. suitably adapted. In particular. very great care was devoted to measuring the viscosity of air. since this enters into R. Millikan's method of measurement of that fundamental quantity, the electronic charge. (See ELECTRON.)

Viscosity measurements furnish strong support for the kinetic theory of gases. According to theory. as first worked out by Maxwell, the viscosity should be independent of the pressure. which at first appears an astonishing result. The reason for this independence can be seen in a general way without mathematics: when the pressure is halved the number of molecules crossing unit area of a given plane is halved, but the mean free path. which determines the momentum transfer from one plane of flow to a parallel plane. is doubled. The region where such considerations hold is limited at one end by densities sufficiently high to make the intermolecular. forces significant. which usually means several atmospheres pressure, and at the other end by pressures sufficiently low to make the mean free path comparable with linear dimensions of the gap used in the measurements. which usually means pressures much lower than a hundredth of an atmosphere.

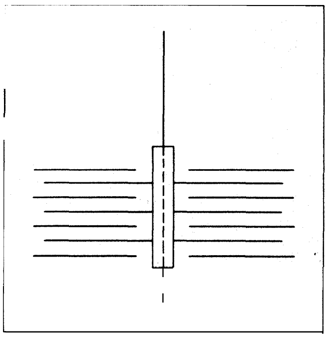

FIG. 9.—SCHEME OF MAXWELL'S VISCOMETER

The independence of the viscosity of gases of their pressure was verified by Maxwell in the experiments to which reference has been made and was later abundantly confirmed within the region indicated.

According to the kinetic theory, the viscosity of gases should increase with increasing temperature, in contrast with the behaviour of liquids. The elementary theory, which treats the molecules as ordinary elastic spheres, indicates that the viscosity should be proportional to the mean molecular velocity. which means to . Experimentally, however. it is found that the viscosity increases more rapidly with T than this law indicates. The reason for this departure is that the molecules do not behave as spheres of constant radius; but that as the temperature rises and the molecular impacts become more severe, the centres of the molecules approach. on the whole, more closely during collision. In consequence the molecules are, effectively. smaller at high temperatures than at low. The exact form of the more precise formula derived for the variation of η with T depends upon the assumption made as to the nay in nhich the repulsive force between close molecules varies with the distance. A successful and widely used formula is that of W. Sutherland:

$$\eta=\eta_0\frac{C+273}{C+T}\left(\frac{T}{273}\right)^{\frac{3}{2}}$$

where C is a constant (Sutherland's constant) pertaining to the gas in question.

At high pressures, in the neighbourhood of the critical point, when the liquid state is approached. matters naturally become very complicated and the viscosity behaviour begins to approach that of a liquid.

The Flow of Solids.—In general. solids. if subjected to stresses large enough, will flow progressively. In particular, there are many solids. of which pitch and sealing wax may be taken as typical, that, although they break with brittle fracture if suddenly stressed. will nevertheless flow under quite small sustained stresses. Pitch left in a funnel, for instance. will slowly creep out under its own weight. Again glass rods. supported horizontally at the two ends, will at ordinary temperature sag progressively under the force of gravity, and sticks of sealing wax flow comparatively quickly under like conditions. Metals. on the other hand. will not, in general, flow even very slowly unless subjected to considerable stress, but they too will creep, to use the term usually applied to their progressive movement, under sufficiently large sustained stresses.

Glass, an amorphous or noncrystalline substance, behaves approximately as a highly viscous liquid. Its flow properties have been measured, usually at temperatures of jooo C. and higher, by the progressive twist of a rod under a constant couple; by the extension of a rod or thread; by concentric cylinder methods; and, at high temperatures, by the slow fall of a sphere of platinum through the substance. Roughly speaking, the rate of flow is proportional to the stress, which enables an ordinary coefficient of viscosity to be calculated. The viscosity of glass at annealing temperature, when it must slowly yield under the internal stresses, is about 10^{13} poise; at the temperatures at which it is blown, about 10^7 poise, as compared with 1,400 poise for golden sirup (Lyle) at 12° C.

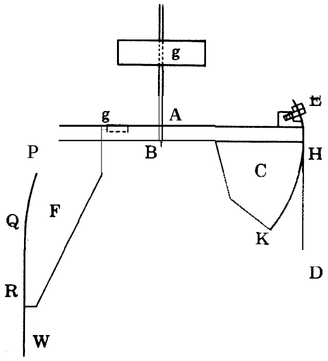
The pitchlike substance known as Chatterton compound is not quite so simple, because under constant stress it flows more rapidly at first: but ultimately reaches a stage at which the rate is constant. This final steady rate is proportional to the stress at higher temperatures, but not at the lower temperatures. Chatterton compound, then, behaves as a viscous liquid at higher temperatures, but at lower temperatures shows a double departure from Newtonian behaviour. Such departure is. in general, characteristic of solids. Clays, doughs. asphalts, and so on, have still more complex flow properties which make them troublesome substances to characterize quantitatively in the matter of flow.

In general, *solid* bodies do not begin to flow at a perceptible rate until a certain stress is exceeded. Bodies with this property are usually called plastic solids. E. C. Bingham imagined a substance which should be stable under stresses below a certain value and flow at a steady rate. connected linearly with the stress, for greater stresses. Such a body is called a Bingham solid or ideal plastic, but. like most ideals, it does not exist and is not closely approached in nature.

Since what is here in question is viscous flow, the discussion that follows will be confined to regions of stress where the flow is easily measurable and the elastic response negligible in comparison. The behaviour of metals, which are crystalline in structure, is in general more regular than that of amorphous bodies and will now be considered.

For many years the only method used for investigating the flow or creep of metals was by extension of a rod or wire under longitudinal stress. If a constant load be used to produce the extension then, as the length increases. the cross section diminishes and the stress increases, causing an additional complication. Andrade was the first to make use of devices which automatically so diminished the stretching force as to keep the stress constant. One such device which has, in various forms, been extensively used is the Andrade-Chalmers bar, or cam balance (fig. 10). The load is hung from the wire or metal tape which is attached at P and lies along the cam surface PQR, and an upward pull is applied to the metal wire under test by the wire or tape D. lying along a circular arc. As the test wire stretches and moves upward the bar tilts and the cam surface is so designed that the couple applied by W, and hence the tension in D, is reduced, in the way required to keep the stress in the test wire constant. The device can easily be modified so as to produce a downward pull. if required.

The form of the extension-time curve of a wire flowing under constant stress depends upon the metal and the temperatures. Fig. 11, 12 and 13 show the flow of lead at four different temperatures. The extension is in no case linear with time. At the lowest temperature, −180° C., the rate of flow is small for all stresses, but is much more rapid at the beginning than at a later time, when it is hardly distinguishable from zero. At −78° the rate of flow diminishes as time goes on, but is well marked throughout with the stresses in question. At 17° the rate likewise diminishes with time, but only slowly after some interval. At 160° C. the flow is a little more rapid at the beginning than later for all stresses. but is not far from linear with time.



FROM E. N. DA C. ANDRADE AND B. CHALMERS, "PROC. ROY. SOC. A.," VOL. 138, 1932

FIG. 10.—THE ANDRADE-CHALMERS BAR FOR ENSURING CONSTANT STRESS

These curves are typical of metals in general. the behaviour depending upon the temperature. Roughly speaking, the ratio $\theta = T/T_M$, where T, T_M are the absolute temperatures of the test and of the melting point of the metal respectively. determines the behaviour. Thus the flow behaviour of iron at 530° C. is similar to that of lead at 0° C. ($\theta = .45$ in each case) and that of copper at 15° C. to that of lead at −150° C. ($\theta = .21$).

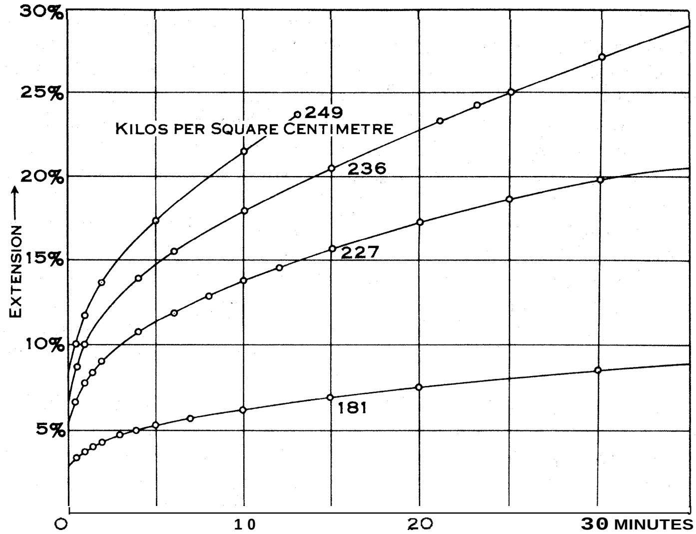
FIG. 11.—FLOW OF LEAD UNDER CONSTANT STRESS AT −180° C. (BROKEN LINES) AND AT −78° C.

The flow of pure metals and certain alloys was expressed by Andrade in the formula

$$l = l_0(1 + \beta t^{\frac{1}{3}})e^{\kappa t}$$



FROM E. N. DA C. ANDRADE. "PROC. ROY. SOC. A.," VOL. 90, 1914

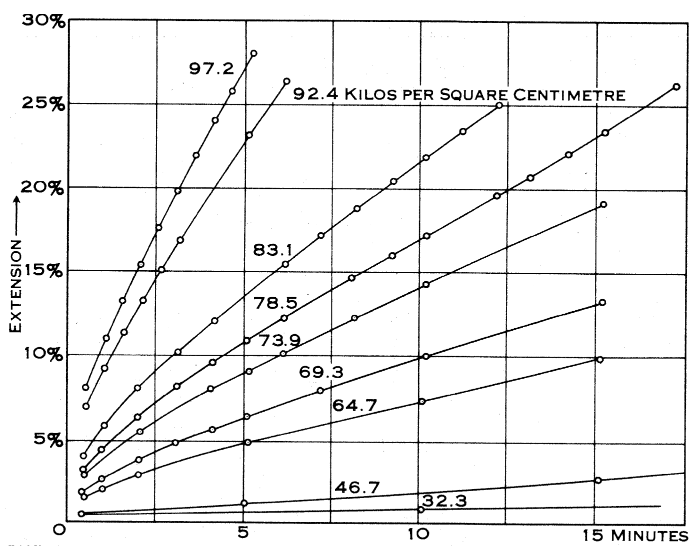
FIG. 12.—FLOW OF LEAD UNDER CONSTANT STRESS AT 17° C.

where l is the length at time t and l_0, β and κ are constants. The exponential term represents a constant rate of flow per unit length, since, if $\beta = 0$,

$$\frac{1}{l}\frac{dl}{dt} = \kappa.$$

Here the term in β represents a flow which progressively becomes slower and slower, which is alternatively called primary creep, transient creep or β flow (beta flow); the term in κ represents a flow which takes place at a constant rate and is called secondary creep, permanent creep, quasi-viscous creep or κ flow (kappa flow). There is much evidence for the physical distinction of the two types of flow, revealed by these analyses, the β flow being dominant at relatively low temperatures and the κ flow at relatively high temperatures. The $t^{\frac{1}{3}}$ law has been confirmed by many workers. Although other variations have been suggested for certain cases, this does not affect the existence of the two types of flow.

There is a large body of evidence for the view that transient creep is connected with processes taking place within the crystal grains which normally make up metals, while permanent creep pertains to processes taking place between the grains. Two experimental results bearing directly on this question may be cited. J. McKeown measured the creep of different specimens of lead varying only in the average size of the crystal grains, extreme values for mean cross-sectional areas being 0.84 and 0.01 mm^2. With the coarse-grained metal both β flow and κ flow were well marked at a given temperature and stress; as the grain size dimin-



FROM E. N. DA C. ANDRADE, "PROC. ROY. SOC. A.," VOL. 90, 1914

FIG. 13.—FLOW OF LEAD UNDER CONSTANT STRESS AT 160° C.

ished the κ flow became relatively more important until. with the finest grain metal, it markedly predominated. the flow being much more rapid than with specimens of coarser grain and nearly linear from the start. Andrade and B. Chalmers. by measuring the electrical resistance at various stages of the flow of different metals. showed that the β flow was connected with a rotation of the axes of the crystal grains, the direction of which was unaffected by the κ flow.

The work of D. Hanson and M. A. Wheeler likewise points to the physical distinctions between β and κ flow. They found a pronounced appearance of slip bands within aluminium crystal grains at low temperatures, n-here β flow was predominant, and absence of such slip bands at high temperatures, where κ flow prevailed, and. further. the crystal-grain boundaries were much emphasized in this latter case.

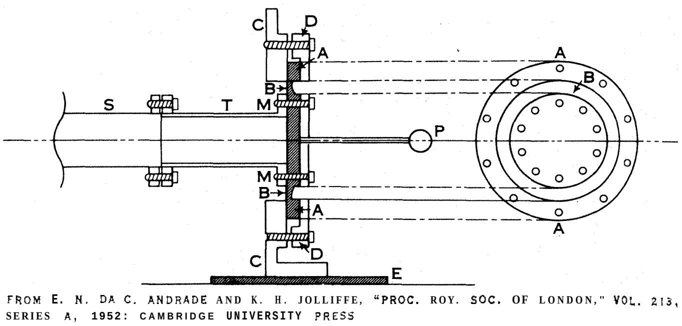
The slip within the crystal grains is a matter to which considerable attention has been devoted by W. Boas, H. Wilsdorf and D. Kühlmann-Wilsdorf. D. McLean and W. A. Wood. Besides the coarse slip. easily visible with a low magnification. which characterizes the β flo process and is accompanied by a rotation of the crystal axes, there is another finer slip process, revealed by such special means as the phase-contrast microscope or the electron microscope. and further a breakup of the grain into units which Wood calls "cells." These features have not been directly connected with flow processes; the fine slip is not, as is the coarse slip, associated with hardening. These processes are mentioned to indicate the complexity of the full problem of large deformations.

Great care should be taken in interpreting surface microphotographs in terms of creep processes. because crystal grains at the surface, whose movements normal to the surface are not constrained, clearly behave differently from grains in the interior, which are subject to stresses from all sides. With ordinary metallic specimens the majority of the grains suffering deformation are internal, and their typical deformations are not revealed by the ordinary methods of investigation.

The mechanism of creep, comprising glide on preferred planes within the crystal grain and relative movement at the boundaries of one grain with respect to others, makes it easy to understand the large effect which the addition of small quantities of foreign metal may have on the phenomena. Large foreign atoms within the crystal, producing local distortion, may tend to check the glide of one plane over another; similarly. foreign atoms in the disordered region between two crystal grains may produce a relatively large effect. In details of behaviour, much depends upon how the particular foreign atoms tend to distribute themselves in the metal.

A different method of studying creep, employed by Andrade and K. H. Jolliffe, is the investigation of behaviour under simple shear. The mechanical conditions are simpler than in the plastic. as against elastic, extension of rods. The experimental disposition is shown in fig. 14. The metal is in the form of a disk, shaded in the diagram, in which is cut an annulus B, B, constituting the metal flowing under stress. The outside part, A. A, of the disk is gripped so as to be held immovably; the inner part, M, M. is held between rigid disks subjected to a constant torque. With this disposition the flow can be observed first under torque in one, say clockwise, sense and then in the other, counter-clockwise, sense.

It was found that under these conditions, the flow under torque



FROM E. N. DA C. ANDRADE AND K. H. JOLLIFFE, "PROC. ROY. SOC. OF LONDON," VOL. 213, SERIES A, 1952: CAMBRIDGE UNIVERSITY PRESS

FIG. 14.— MEASUREMENT OF METALLIC CREEP UNDER SIMPLE SHEAR

in the initial direction followed the $t^{\frac{1}{3}}$ law, there being no permanent flow. This accords well with the geometry of the deformation, which would hinder intercrystalline movement. Under reversed flow a difference was found between the behaviour of lead. of cubic crystal structure, and cadmium. of hexagonal crystal structure. Cadmium behaves in much the same way under reversed flow as under forward flow; lead gives a reversed flow linear with the time, of κ character. This is satisfactorily explained by the fact that single lead crystals harden considerably under large shear strain; cadmium crystals do not. Therefore, lead crystal grains become too hard to be sensibly deformed under shear in the reversed move-, ment; but with the cadmium grains the deformations in forward and reversed movement are much the same.

In general, at no stage does a metal behave as a Newtonian viscous fluid. The transient creep does not have the characteristic of being linear with time. The permanent creep has this characteristic. so that, at a given stress, κ gives a measure of the apparent viscosity. In fact, if S be the longitudinal stress, approximately

$$\frac{S}{\kappa}=3\eta.$$

However, κ is not proportional to S, but increases much more rapidly: experimentally it is found that log κ is proportional to S. Hence. even at high temperatures. relative to the melting point, where the flow is mainly, if not entirely. of permanent type, the metal is behaving as a non-Newtonian liquid.

What is here effectively in question is a diminution of apparent viscosity with stress. Such behaviour is characteristic of most non-Newtonian liquids. such as solutions of cotton yellow or benzopurpurin. Speaking generally, we are confronted with a structure which breaks down, in the sense of allowing easier flow, as the stress is increased.

With transient creep we have what is effectively a hardening as flow under constant stress proceeds. This is a characteristic of a limited class of non-Newtonian liquids. the apparent viscosity of which increases with time, as can be shown with a Couette form of viscometer, in which the liquid lies between the two cylinders. If the outer cylinder is kept rotating at a steady rate, the deflection of the inner cylinder will increase as time goes on. There is a steady hardening or building up of a resistant structure. Speaking generally of non-Newtonian fluids. it is modifications of structure, affected either by time or by shear stress or both, that are the causes of the complications. These general wide resemblances between the flow of metals and of certain classes of non-Newtonian liquids do not imply that the mechanism is similar in detail in both cases for the internal structures are very different.

The constant β varies with stress in a sigmoid manner, increasing at first slowly, then rapidly and finally approaching a constant value.

There is no fully satisfactory theory of metal creep. The difficulties in the way of constructing such a theory are clear: the behaviour of a single metal crystal under a carefully specified stress system is a complicated matter; the behaviour of a crystal grain in a polycrystalline metal. where it is surrounded by other grains, each under the complicated stress system created by their preferential yields in certain directions. is clearly much more complicated. Crystal grains are known to contain inherent structural faults. It is the glide on preferred planes of a parallel system under inhomogeneous stresses that apparently gives rise to the β flow. As regards the κ flow, while the intergranular layer may be taken as homogeneous material of an unchanging thickness for very small stresses. as shown by C. Zener and T. Kê, it is improbable that this assumption can justifiably be made for the large stresses which produce progressive creep.

Besides the primary and secondary creep, a region of tertiary creep, in which the rate increases rapidly with time, is often recorded. Tertiary creep of n-hat would superficially appear to be much the same character, as judged by the form of the extension-time curves, may be due to various causes. In the old tests carried out on rods in tension under constant load, with final extensions of several per cent, it was usually a trivial phenomenon due to increase of stress, and not an intrinsic property of the material.

There are, however, many well-established cases of tertiary creep when the stress is approximately constant throughout the flow, due either to the final extension being very small or to the use of a constant stress device. In such cases it may be due to recrystallizations of various types, such as the migration of the crystal boundaries or the growth of new crystals under stress, any such internal movements leading to relative ease of local deformation. In the case of complicated alloys a phase change may take place, with a like result. Or transverse intercrystalline cracks, which effectively increase the local stress, may lead to increased rate of flow.

The creep of metals, a subject that before World War I attracted little attention, assumed great importance afterward because of its significance in such engines as the jet propulsion gas turbine, and gas turbines in general, in which the blades revolve at high speed, and so under considerable tension, in gas at temperatures of 800° C. or higher. There is the possibility of a slow progressive increase in length. which in view of the small clearances could seriously reduce engine life. Permanent, as distinct from transient, creep is particularly dangerous. There has been, therefore, intensive and successful research to evolve alloys free from pernicious creep.

Since the creep of simple metals is so difficult to explain in detail, it is easy to understand that there is no basic theory of the creep properties of the complicated alloys in question, usually containing two or more of the metals nickel, chromium. iron and cobalt, as well as small quantities of some or all of the elements carbon, silicon, titanium, aluminum, molybdenum, tungsten and niobium (often called columbium). There are, however, certain well recognized and approved lines of development; it is usual to start with a binary, ternary or even more complicated solid solution of the basic metals, to which elements judged likely to produce hardening by precipitation are added.

Viscosity and Elasticity.— A conception which was introduced by Clerk Maxwell is important as showing how the viscous behaviour of an ordinary liquid can be regarded as due to an evanescent elasticity, permanent elasticity being a characteristic of solid bodies. There is a certain mathematical similarity between viscosity and elasticity. In a Newtonian liquid the rate at which shear strain increases is proportional to the shear stress: in a perfect elastic solid it is the shear strain that is proportional to the stress. A viscous liquid may be regarded as an elastic substance which is unable to sustain a shearing stress; under the strain the elastic stress rapidly breaks down. Maxwell assumed that the stress decayed according to the exponential law that governs many such processes, for instance the decay of a radioactive body. If the stress be τ, then

$$\frac{d\tau}{dt} = -\frac{\tau}{\lambda}$$

where λ is a constant called the time of relaxation. If the elastic modulus in question be n, then it can be shown that $\eta = n\lambda$.

The time of relaxation for an ordinary liquid is probably of the order of a ten thousandth millionth (10^{-10}) of a second. which gives an elastic modulus of reasonable magnitude. This way of regarding viscosity may afford an approach to a general theory comprehending the behaviour of real solids and liquids in simple cases.

VISCOUNT, a title of nobility.

In the Carolingian period of European history the *vicecomites* or *missi comitis* were deputies, vicars or lieutenants of the counts (*see* COUNT; CHÂTELAIN), whose official powers they exercised by delegation. As the countships eventually became hereditary, the lieutenancies did so too: for instance, the viscounts in Narbonne, in Nîmes and in Albi appear to have made their office hereditary by the beginning of the 10th century. Even so, viscounts remained for some time with no other status than that of the count's officers, either styling themselves simply *vicecomites* or qualifying their title with the name of the countship whence they derived their powers. By the end of the 11th century, however, the universal tendency of feudalism to associate status with the possession of land caused the viscounts to qualiiy their title with the name of their own most important fief: thus the lords of Thouars, hereditary lieutenants of the counts of Poitiers. called themselves viscounts oi Thouars; and those of Bruniquel, lieutenants of the counts of Toulouse, viscounts of Bruniquel. In Aquitaine, of which the counts of Poitiers were dukes, and in the county of Toulouse the viscounts were great barons often able to assert themselves against their suzerain (*e.g.,* those of Limoges, of Turenne, of Béziers and of Carcassonne). In the Île de France, in Champagne and in parts of Burgundy, on the other hand, the viscounts by the end of the 12th century were surviving only as minor feudatories, having lost their special administrative functions to the *prévôts.*

In Normandy, however, the judicial functions of the viscounts as deputies of the duke remained important; by the middle of the 11th century most oi the country was administratively divided into *vicomtés* (this explains the Norman use of the name *viscounte* or *vicecomes* for the sheriff in England); and under Henry I the hereditary holders of the *vicomtés* were to a large extent replaced by ducal officials.

In England the viscountcy was not introduced into the peerage until nearly 400 years after the Norman conquest: John, Lord Beaumont, who had been created count of Boulogne in 1336, was on Feb. 12, 1440, created Viscount Beaumont in the peerage of England. with precedence over all barons. The oldest English viscountcy surviving in the second half of the 20th century was that of Hereford, created in 1550; the oldest Irish one, however, that of Gormanston, was considerably senior, having been created in 1478.

Viscounts had been set up in Catalonia by Charlemagne in the 8th century, whence the title had spread. with diminishing functions and increasing nobility, to Aragon and to Castile. Philip IV of Spain introduced the system of *vizcondados pvcvios* (regulations of 1631 and of 1664): under this, no one could proceed to the rank of *conde* or of *marqués* unless he had previously been *vizconde;* a fee of 750 ducats had to be paid for this habilitating title (except in the case of counts' sons); and a further iee of 750 ducats was required for the obligatory cancelation of the *vizcondado* when the time came for conferring the higher rank. The removal of the obligation to cancel, in 1846, led only to confusion, as numerous families began petitioning to have their already canceled titles revived; and in 1858 it mas declared that the *vizcondado previo* was no longer necessary for accession to the higher titles.

VISHNU [Sanskr. the "active one"], in the Indian Rig-Veda a minor deity. who takes three strides. *vi-kram*. the last and highest beyond mortal ken: these probably denote the three divisions of the universe. Closely allied with Indra in his fight with Vritra, the drought-dragon, and against the Dāsas. the dark aborigines, Vishnu in the Epic mythology developed into the Preserver god. one of the Hindu triad with Brahma, the creator; and Siva. the destroyer; and as such he has saved mankind in ten incarnations. His special devotees, the Vaishnavas, have evolved numerous sects.

VISIBILITY. In meteorology the word "visibility" has a technical significance entirely unlike its meaning in ordinary speech. Visibility on a given occasion in the daytime is the greatest distance at which an observer with normal eyesight can see a dark-coloured object which stands up against the horizon sky. It is the range of vision under the atmospheric conditions prevailing at the time. At night it is the greatest distance at which lights of certain standard candle powers can be seen. Its observation is of obvious importance to the aviator.

When the term is used without qualification the horizontal direction of view is always understood; the terms "vertical visibility" and "oblique visibility" are used to denote the range of vision (usually from an aircraft but sometimes from the ground) in the directions indicated. These latter concepts are not as clearly defined as is the horizontal visibility, nor are the techniques of observation as well standardized.

An atmosphere containing only permanent gases and uncondensed vapours is exceedingly transparent to visible light. In such an atmosphere it would be possible for an aviator to see a mountain at least 250 mi. away. The fact that such great values of the visibility seldom occur indicates that the air nearly always contains large numbers of particles of various sizes, but all considerably larger than the molecules of the atmospheric gases. The smallest among these particles are visible as haze. They consist of finely divided salt from sea spray, exceedingly fine dust. or (especially near cities) products of combustion. They are small enough to act differently on light of different colours, scattering the shorter waves of blue light more than the longer waves of red, and for this reason a haze seen against a dark background looks bluish. whereas a distant lamp or the setting sun seen through a haze looks redder than its normal hue.

Most haze particles are hygroscopic; *i.e.*, they attract water vapour. If there is enough water vapour present, some of it will condense on the particles and they will increase in size. When they reach a diameter of about half a micron (one micron = $\frac{1}{1,000}$ mm. = $\frac{1}{25,400}$ in.) they begin to act differently toward light, and by the time they are five microns in diameter they have become practically nonselective to light of different colours, appearing white to the eye; then we call them fog. At this stage they are almost entirely water, condensed on a very small nucleus of some other substance.

Under some circumstances the visibility can also be reduced by nonhygroscopic dusts (as in sandstorms). microorganisms. or even insects. It can of course be brought down to almost zero by snow or heavy rain. But generally it is the haze particles or fog droplets that determine how far one can see.

The theory of the phenomenon differs. depending on whether we have to look at lights at night, or ordinary objects in the daytime. The former case is the simpler. A distant lamp will emit a certain amount of light in the direction of the observer, some of which will travel within the narrow cone having the pupil of the eye as its base. Not all the light, emitted into this cone will reach the eye, some being absorbed by the particles in the intervening atmosphere: and some being scattered by them out of the cone, so that it proceeds in some other direction. If there is only a little light remaining to enter the pupil of the eye, the lamp will be only just perceptible; and the distance at which this occurs will be the visual range of the lamp. Should the lamp be of the standard candle power, this distance will be the visibility. The amount of light from the lamp that the eye needs in order to see it depends on many factors, of which the most important are: (1) the presence of other lights in the vicinity; (2) the brightness of the background against which the lamp is seen; and (3) the length of time the observer has been in comparative darkness. Unfortunately all these factors are variable under the conditions of observation usual at an airport.

The way in which the air obscures terrestrial objects in the daytime is quite different. An object which does not of itself emit light is distinguishable because of the contrast between the object and its background; for example, a wooded hill is seen against the horizon sky because the sky is much brighter than the hill. By scattering light into the eye of the observer, the atmosphere adds to the apparent brightness of all objects, making it approach more and more closely to that of the horizon sky as the observer gets farther away—an effect easily appreciated in mountainous country. and known to painters as "atmosphere." When the apparent brightness of two adjacent surfaces differs by less than about 2%, the eye cannot distinguish them and nothing is recognizable. Because the contrast at a given distance depends upon the colours of the objects, a standard pair of objects is used for the estimation of the visibility. A black object against the horizon sky affords the maximum contrast, and its visual range has been found to depend least upon the direction of the sun and the state of the sky, but any dark-coloured object is satisfactory as long as it is seen against the sky near the horizon.

Instruments are seldom used in observing the visibility, which is determined rather by simple estimation, the observer noting how many of a previously chosen series of objects or lamps can be seen from the observing station. The visibility is the distance of the farthest one distinguishable. It is reported directly in miles for airway purposes on the North American continent. For other meteorological purposes and elsewhere a two-digit code is employed. representing values from less than 20 m. (22 yd.) to the greatest possible. Ships and some other stations use an abbreviated code having only ten steps representing values from less than 50 m. (55 yd.) to 50 km. (31 mi.) and over.

See W. E. K. Middleton, *Vision Through the Atmosphere* (1952).

(W. E. K. M.)

VISION or **SIGHT**, the function in which the organ known as the eye, and its more immediate nervous connections in the brain. are crucially involved in a series of reactions to the form of radiant energy called light. Although the existence of an organ (the eye) which mill somehorv copy or report upon certain aspects of the organism's physical surroundings is indispensable in seeing, the behaviour of the eye is by no means sufficient to account for vision. The nervous system to which it is connected is also necessary, and it at the same time is receiving inputs from other sense organs which must be handled in the light of each other and the visual input. The central nervous system is a constantly active system. a going concern governed by principles of its own. and its activity is thus more than merely an end result of the combined peripheral sense-organ inputs. In seeing. the organism as a whole brings something to the occasion. Into this the ocular activity set up by physical stimulation must appropriately mix. The internal events of one moment determine in part those that occur later. The present is dependent upon the past.

The initial process in seeing is induced by the action of light on the retina, the photosensitive part of the eye. If light were to act uniformly over the entire retina there would be at any one time only a general awareness of light without reference to an external object. One of the essential conditions for vision as a guide to action is the formation of an image on the retina. Images are a kind of copy of external objects in terms of the distribution of light intensity resulting from nature's having placed refractive structures in the eye in front of the retina which properly bend the luminous rays so as to focus them on the retina.

PHYSICAL CONDITIONS FOR VISUAL STIMULATION

Radiant energy is dealt with not only in terms of magnitude of flux per unit area of object, but also in terms of the component wave lengths. The eye is selective, in the sense that only a restricted band of the full radiant spectrum is effective in eliciting experience. This band for daylight conditions lies roughly between 400 mμ and 700 mμ. The exact limits, however, are determined by intensity conditions. The eye is selective further in not responding equally to equal amounts of energy in all parts of the visible spectrum.

The Visibility Curve or Luminosity Curve of the Eye.— The relative sensitivity to various parts of the visible spectrum when measured and plotted in the usual way yields what is known as a visibility curve, or luminosity curve. For what is known as an equal-energy spectrum, the subjective brightness elicited by the constituent wave lengths of the spectrum is measured. the value being then converted to a common scale wherein the most effective wave length is given a value of 1.0. Luminosity curves for the human eye for two different conditions are shown in fig. 1. Curve *A* is for full daylight vision, the other for vision under definitely reduced illumination. It will be seen that a shift in the wave length which is maximally effective occurs from one set of conditions to the other. Not only does the maximum of the curve shift, but also the value of the other and less-effective wave lengths.

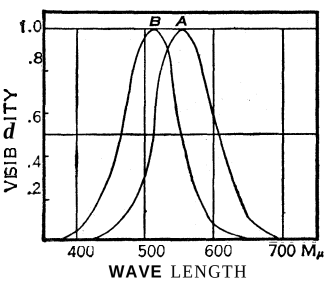

FIG. 1.—VISIBILITY CURVES OF THE HUMAN RETINA: *A*, PHOTOPIC; *B*, SCOTOPIC

At intensities corresponding to daylight, the maximum of the curve lies at about 554 mμ, but under twilight illumination, it shifts to the neighbourhood of 511 mμ. When a stimulus of fixed wave-length composition is varied in intensity, brightness is found to be a logarithmic function of the latter in the range of ordinary daylight intensities.

Minimal Energy Need for Vision.—There have been a number of studies on the question of the least amount of radiant energy required to elicit a reaction leading to the perception of light. The possibility of doing this developed when Samuel P. Langley, in the latter part of the 19th century, invented the bolometer, an instrument for measuring the energy distribution of the solar spectrum. Langley himself soon attempted to make the determination of the smallest amount of energy required to elicit visual sensation. He found it to be of the order of 3×10^{-9} ergs for light of 550 mμ. Between then and 1942, when Selig Hecht reported the investigation he and his colleagues. Simon Shlaer and M. H. Pirenne. had made, about a dozen other attempts to solve this problem had been made. Hecht reported that between 2.2 and 5.7×10^{-10} ergs at the cornea is required, this being from 58 to 148 quanta of blue-green light. A number of corrections had, of course, to be applied to arrive at a figure which would represent the number of quanta actually reaching the retina. The first of these corrections pertains to reflection from the cornea, a proportion which amounts to about 4%. The second correction has to do with loss in the ocular media between the outer corneal surface and the retina. Measurements made by others had found this loss to be 50% in young individuals and more in older persons. The third correction pertains to the amount of energy absorbed by the receptors themselves. Correction for this factor is considerably more difficult, but Hecht concluded that the upper limit of absorption is 20%. Taking into account the three corrections, it can be said that between 5 and 14 quanta are actually necessary at the retina. Since the probability that one single rod will absorb two quanta is only about 4%, it can be concluded that only one quantum of light need be absorbed by each of 5 to 14 rods in order for vision to be elicited. By a set of corollary experiments, Hecht obtained the value of between five and seven for the number of critical events to happen in order that a visual effect result. Hence it was concluded that between five and seven quanta is the actual number of quanta absorbed by the retina in threshold vision. Hecht, furthermore, believed he had shown that biological variation is of no great consequence in the threshold act. He believed he showed that in the threshold act, it is the stimulus rather than the observer which is critically variable.

LIGHT DISTRIBUTION AND IMAGE FORMATION ON THE RETINA

Kinds of Light-Sensitive Organs.—Light sensitive organs include three general kinds: (1) the sensitive light patch, activated more or less in accordance with average illumination; (2) the compound eye, which is made up of a number of cylindrical structures positioned side-by-side and directed more or less directly toward the light and (3) the complex eye, such as is illustrated by the human-eye form. In the first form, no redirection of the rays of light occurs. There are no structures for the purpose interposed between the light source and the sensitive area itself. In the second form, the light reaching each segment (ommatidium) falls on sensitive tissue at the opposite end, when its angle is such as nearly to parallel the long axis of the segment. Light falling on the cornea (the transparent structure in front of the ommatidia) is effective only so long as this is true. Oblique light is lost and so as an object passes this eye, light reflected from it reaches first one ommatidium and then another as the object becomes normal to the various ommatidia in succession. Motion differentiation is effected by the animal on this basis. The human eye represents another principle, that of refraction through a nodal point.

The Human Eye and Image Formation.—Before a ray of light can reach the human retina, it must pass through a number of transparent media and refractive surfaces. The eye is a nearly spherical organ, formed of transparent parts situated behind each other, and surrounded by various membranous structures, the anterior part of which is also transparent. The transparent parts are: (1) the cornea; (2) the aqueous humour, found in the anterior chamber of the eye; (3) the crystalline lens, formed by a transparent convex body, the anterior surface of which is less convex than the posterior and (4) the vitreous humour, filling the posterior chamber of the eye. The ray must therefore traverse the cornea, aqueous humour, lens and vitreous humour. Since the two surfaces of the cornea are parallel, the rays suffer practically no deviation in passing through that structure, but they are refracted during their transmission through the other media.

The action of a lens in forming an inverted image is illustrated by fig. 2, where the pencil of rays proceeding from a is brought to a focus at a′, and those from b at b′; consequently the image of ab is inverted at b′ a′. The three characteristic features of the retinal image are: (1) it is reversed; (2) it is sharp and well defined if it be accurately focused on the retina and (3) its size depends on the visual angle.

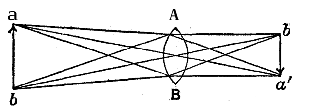

FIG. 2.—INVERSION BY ACTION OF A LENS

If we look at a distant object, a star for example, the rays reaching the eye are parallel, and in passing through the refractive media they are focused at the posterior focal point; that is, on the retina. A line from the luminous point on the retina passing through the nodal point is called the visual line. If the luminous object is not nearer than. say. 60 yd. the image is still brought to a focus on the retina without any effort on the part of the eye. Within this distance, supposing the condition of the eye to be the same as in looking at a star, the image would be formed somewhat behind the posterior focal point, and the effect would be an indistinct impression on the retina. To obviate this, for near distances, accommodation, so as to adjust the eye, is effected by a mechanism to be described later.

When rays, reflected from an object or coming from a luminous point. are not brought to an accurate focus on the retina, the image is not distinct in consequence of the formation of circles of diffusion, the production of which is illustrated in fig. 3. From the point A luminous rays enter the eye in the form of a cone, the kind of which will depend on the pupil. Thus it may be circular, or oval. or even triangular. If the pencil is focused in front of the retina, as at d, or behind it as at f, or, in other words, if the retina, in place of being at F, be in the positions G or H, there mill be a luminous circle or a luminous triangular space. and many elements of the retina will be affected.

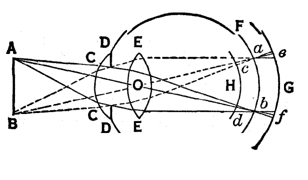

FIG. 3.—FORMATION OF CIRCLES OF DIFFUSION

The size of these diffusion circles depends on the distance from the retina of the point where the rays are focused: the greater the distance, the more extended mill be the diffusion circle. Its size will also be affected by the diameter of the pupil.

Light passing through all portions of the pupil are by no means equally effective in stimulating the retina. This inequality is known as the Stiles-Crawford effect, after the individuals who first gave the phenomenon considerable study.

Optical Defects of the Eye.—As an optical instrument the eye is defective. Because of optical conditions and defects of the eye, a mathematically punctuate image is never formed upon the retina even in a normal eye. The optical defects of the eye are primarily of two sorts: (1) those accruing from the curvature of the refractive surfaces and (2) those caused by the dispersion of the light by refractive media.

Spherical Aberration.—Suppose. as in fig. 4 *MAK* to be a refractive surface on which parallel rays from L to *S* impinge, it will be seen that those rays passing near the circumference are brought to a focus at F^1, and those passing near the centre at F^2, intermediate rays being focused between these tno positions. Consequently on the position of the axis betneen F^1 and F^2 there will be, in effect, a series of focal points and a surface interposed normal to F^2 will receive a blurred and distorted image. In the eye this defect is to a large degree corrected by the following arrangements: (1) the iris cuts off the outer and more strongly refracted rays; (2) the curvature of the cornea is flatter at the periphery and therefore those rays farthest from the axis are relatively least deviated; (3) the anterior and posterior curvatures of the lens are such that the one corrects to some extent the action of the other and (4) the structure of the lens is such that its power of refraction diminishes from the centre to the circumference. and therefore the rays farthest from the axis are relatively less refracted.

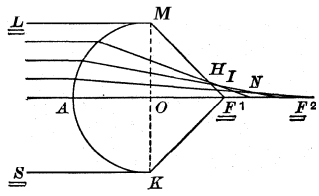

FIG. 4.— SPHERICAL ABERRATION

Astigmatism.—Another very common defect of the eye arises from different meridians of some of the media having different curvatures. This is known as astigmatism. The vertical meridian of the cornea generally has a shorter radius of curvature and is therefore more refractive than the horizontal. The meridians of the lens may also differ, but ordinarily the asymmetry of the cornea is the greater. The optical explanation of astigmatism can be gained from fig. 5. Suppose the vertical meridian CAD to be

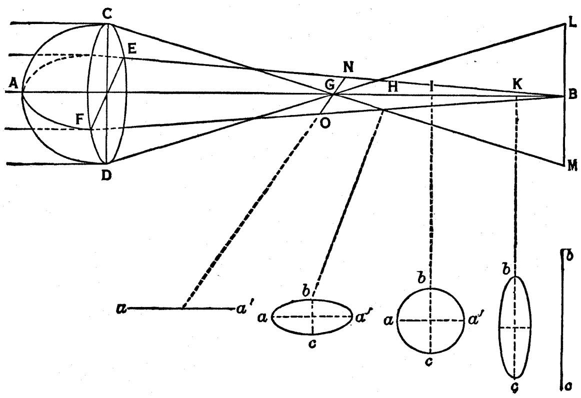

FIG. 5.— DIAGRAM ILLUSTRATING ASTIGMATISM

more strongly curved than the horizontal *FAE*, the rays which fall on CAD will come to a focus at *G*, and those that fall on *FAE* at B. If we divide the pencil of rays at successive points G, H, I, K, B by a section perpendicular to *dB*, the various forms it would present at these points are seen in the figures underneath, so that if the retina were placed at G, a horizontal line *aa'* would be seen, and if at *H* an ellipse with a long axis parallel to AB would he seen, etc. The degree of astigmatism is ascertained by measuring the difference of refraction in the two chief meridians. and the defect is corrected by the use of cylindrical glasses, the curvature of which added to that of the minimum meridian makes its focal length equal to that of the maximum meridian.

Chromatic *Aberration*—When a ray of white light passes through a lens the component rays, since they are unequally refrangible, are dispersed. The violet rays, the most refrangible, are brought to focus nearest the lens. and the red rays. the least refrangible, are brought to a focus somewhat farther away. If a lens uncorrected for chromatic aberration is used, a series of concentric circles will be formed wherever borders exist in the image which is formed. If the image is that of a so-called point or a disk, the near circle will be violet, and the outer a red colour, if the screen on nhich the image is formed is placed at the distance from the lens at nhich violet rays come to a focus. The reverse effect is produced if the screen is placed where the red rays come to a focus.

Diffraction.—Light at the edge of the pupil is broken into a series of concentric spectra contributing to the imperfection of the image. Diffraction is greatest with a small pupil, but is virtually negligible with a pupil three or more millimetres in diameter. Chromatic aberration and diffraction tend to counteract each other.

Defects Caused by Opacities, etc., in the Transparent Media.—Such opacities are termed entoptic and may be of two kinds: (1) extraretinal. those caused by opaque or translucent bodies in any of the refractive structures in front of the retina and presenting the appearance of drops, lines and bodies of unusual and grotesque shape and (2) intraretinal, those opacities in the layers of the retina in front of the rods and cones.

Entoptic Stray Light.—The light activating the retina is of two sorts: (1) the light entering the eye through the pupil and focused to form the retinal image; and (2) the light that reaches the retina otherwise. The latter is called entoptic stray light. Some of this stray light reaches the retina through the walls of the eyeball. and some is reflected from the media within the eye in the course of and after its transmission to the image. Most of the stray light in this category is reflected from the image itself, reaching the other parts of the retina by multiple reflection within the eye. the inner walls of the eye participating. Even when the eye is confronting a visual field, dark except for a single restricted target (stimulus) area, the retina must not be considered as containing an active and an inactive region, but as a system, all parts of which are stimulated to some extent or other. For most purposes, the veil of stray light thrown over the whole retina has been neglected, but in certain kinds of experimentation aimed at understanding retinal function, it has been taken into account.

The amount of entoptic stray light accruing from internal reflection from the retinal image is a function of both the intensity of light in the image and the size of the image. As the size of the image of a bright disk in a dark field is increased and covers a progressively greater fraction of the total retina, the smaller the ratio between the image intensity and the intensity of the light on the rest of the retina becomes. This ratio may be reduced to a much smaller fraction than is ordinarily supposed. It has been found, for example, that a test object (target) subtending a visual angle of 46° resulted in an intensity ratio between retinal image and the area outside of it, of 12 to 1. With a 7° stimulus, the ratio was 700 to 1. These figures were obtained by using excised albino rabbit eyes and microphotometry. The effective value of stray light within the eye may be ascertained by measuring the rise in the differential threshold at the fovea caused by the existence of a light in the periphery of the visual field. By this method it was found that the effect tapers as the peripheral light is placed at a progressively greater angle from the fovea. One of the indications in such an experiment, that it is the veiling effect of stray light and not merely some nervous interaction whose effects are being measured, is the folloning. When the peripheral object is made to cast its image on the optic disc (the insensitive part of the retina), the differential threshold at the fovea is somewhat greater than when the image of the peripheral object falls on retinal areas surrounding it. Since we should expect the less-pigmented optic disc to reflect more light than adjacent areas, the elevation of the differential threshold at the fovea would seem to be, in large part at least, a consequence of a greater amount (veil) of light reflected onto the fovea.

Beyond image formation, the problem of vision involves a number of aspects: (1) the photochemical processes which occur in the receptor cells directly affected by radiant energy; (2) nervous structures in the eye and optic pathway and **(3)** the introspective result called perception, and also the oculo- and other motor phenomena which form an integral part of the act of seeing. While sensation and perception are retained as somewhat separate concepts, modern studies of the manner of dependence of experience upon cerebral conditions have made rather free use of the concept of sensation. Whereas perception is the name for experience as it occurs, the term sensation varies from being a synonym of perception to a hypothetical ingredient of the perception complex, too elusive to extract satisfactorily from it.

THE STRUCTURE AND FUNCTIONS OF THE RETINA

The Structure of the Retina.—As already indicated. the light-sensitive layer of the retina is made up of a carpet of microscopic photosensitive elements, the photoreceptors. These form a mosaic, the fineness of grain of which is one factor in the smallness of object and the fineness of line which can be seen. In general, the retina consists of three main conducting elements lying end-to-end. The first is the receptor cell, the next is the bipolar cell and the third is the ganglion cell. Arborizations (branches) of these cells function for cross-connection and integration of the activities of individual parallel elements. Several other elements, among which are the transverse cells and the amacrine cells, also interconnect parallel elements. To simplify the description, lve may confine ourselves to the first three. The human retina contains two kinds of receptor cells which differ somewhat in their structures, anatomical interconnections, in their distributions in the retina, and in the kinds of sensations they mediate. First of all, the rods are sensitive to much weaker levels of stimulation than the cones and are spoken of as mediating scotopic vision. The cones mediate photopic vision. At very low levels of illumination. sensitivity to colour does not exist. The rods have been shown to be responsible for only the achromatic aspects of sensation. The complete set of differences in function between the two kinds of receptors has long been set forth in what is known as the duplicity theory, a combination of facts and deductions which came to form the basis for understanding human retinal function and human vision. The rods and cones are dissimilarly distributed across the retina. The very centre is rod-free. Beyond this both rods and cones are found, the latter diminishing disproportionately as the periphery of the retina is reached. In the rod-free area (1.5°) the connections of the cones to the bipolar cells and the connections of the bipolar cells to the ganglion cells differ from the connections between these elements toward the periphery. In the rod-free area there is a one-to-one relation between the cells in the three layers. Beyond this region, groups of several cones converge upon each bipolar cell. Convergence of rods occurs in all retinal regions and tends to overlap with that of the cones so that from the bipolars onward a mixed rod-and-cone system eventuates.

Aside from the cones being less sensitive than the rods and mediating vision only at higher levels of illumination, the cones mediate colour vision. This is evidenced by the fact that at very low levels of illumination all radiation, regardless of wave length dives rise to colourless sensations. The ordinary spectrum n-hen reduced in intensity becomes a neutral brand differing in brightness from one part to the other, the brightest part of which is at about 530 $m\mu$, a region which at ordinary levels of intensity would appear green. If the illumination level is raised, the brightest part of the spectrum becomes a region centring at j80 mp. or what is now yellow. That the cones mediate colour vision is also evidenced by the existence of concentric retinal colour zones.

The field of vision for colours is more restricted than for light itself. This is true for illumination of ordinary intensities: but the colour-sensitive held can be greatly expanded by increasing the intensity of illumination. In fact it may be made almost as extensive as that for white light. With ordinary intensities and with patches of coloured paper two centimetres square, the blue field is about 10° smaller than for white. yellow somewhat smaller than for blue and red about 20° smaller than for white. The zone sensitive to green is smaller still. Most colours change their hue as the stimulus object is moved from the fixation point outward toward the periphery. Some spectral colours, however, become merely paler or less and less saturated.

If instead of a spectral mixture monochromatic light is used, low intensities give rise to colourless or gray sensations. The interval measured by the absolute threshold for intensity and the colour threshold is called the photochromatic interval. This varies according to the wave length used. In case of those giving red, the interval is so small that its very existence is difficult to prove.

The shift in point of maximum brightness in the spectrum as intensity is lowered is shared to some degree by all parts of the spectrum, and is known as the Purkinje shift or Purkinje phenomenon. The shift is so marked that. for instance. a red of 670 $m\mu$ viewed under light adaptation at ordinary intensities may be ten times as bright as a blue of 480 $m\mu$, but only one-sixteenth as bright at decreased illumination and under dark adaptation.

The yellow spot or macula lutea in the centre of the retina is the area that is peculiarly sensitive to light. This area mediates the finest distinctions which are possible to perceive. Vision using this area is called direct vision.

The macula is oval. the vertical axis being about 1 mm. and the horizontal 3 mm. representing visual angle of about 3° and 12°. Within the macula is a 1" region.—a pit called the fovea, which is the part of the retina specialized for the most distinct vision.

The field of vision around the fixation point extends for more than go° horizontally outward, 70° downward, 60° inward. or nasally. and 50° upward.

There is one portion of the retina nhich is not excitable at all. This is the small region at which the fibres of the ganglion cells assemble and leave the eye to form the optic nerve. The area is called the optic papilla or optic disc. Distinguished from this, the area of the visual field within which stimuli cast light on the optic disc is called the blind spot. The diameter of the optic disc is about one and four-fifths millimetres, equivalent to a visual angle of about 6". The shape of the blind spot is generally somewhat ovoid with the centre lying somewhat below the visual fixation point and from 12° to 18° temporal to it.

If the visual field is unilluminated save for the test object whose image is made to fall on the optic disc. the sensory end result will vary in accordance with the intensity of the test object and its size in relation to the disc. Because of the fact that the light incident on the disc must reach sensitive elements on the retina around it to be effective, the threshold for obtaining any perceptual effect from optic-disc illumination is higher than for direct stimulation of other parts of the retina. The sensitive elements that surround the optic disc may be considered adjacent to each other as are two elements which lie close to each other in other regions of the retina. Light cast on the disc may be considered as cast between adjacent elements On other parts of the retina, were light to be precisely confined to the microscopically tiny space between adjacent cones or rods, it would not be expected to stimulate them, and no sensory end result mould occur. If, however, adjacent elements are stimulated the end effect is the impression of a single or continuous surface. This is why, when the sensitive border lying around the optic disc is illuminated, the subjective result is not that of a ring but of a patch or disk of light. If the image of the stimulus object is small and lies well within the optic disk, the stimulus must be rather intense to provide enough light to reach the borders of the optic disk. The phenomena arising from experimentation with optic-disk illumination are many because of the fact that many spatial and other arrangements of the stimuli have been studied.

Photoreception. — The initial visual activity is the photochemical processes in the eye. These possess characteristics which are reflected all the way from the retina through the neural elaborations which take place in the various parts of the nervous system, ultimately to consciousness itself. It has been pointed out that whatever the detailed processes may be, the photochemistry of the eye must possess three essentials: (1) there must be a sensitive substance which absorbs light and is transformed by it into one or more active products; (a) a supply of this substance must be maintained. or the activity would tenninate and vision would no longer be possible; these processes. (1) and (a), have customarily been called the primary light and primary dark reactions; (3) the active products of the primary light reaction must act in such a way that the end result is an impulse in the outgoing fibre of the receptor cell; this activity has been called the secondary dark reaction. The simplest photochemical postulates assume a photosensitive substance *S*. which, as a result of light shining on it, is broken into two other substances P and *A*. It is generally supposed that some of the photoproducts can reunite with or without the aid of additional substances or energy, to re-form the original sensitive material *S*. When such a chemical system of two opposing reactions (separation and recombination) is exposed to light, the two reactions proceed concomitantly until their rates become equal and the system reaches a pseudostationary state. The production of substances P and *A* of a given concentration at a given moment *t* reaches a velocity which is proportional to the light intensity I falling upon S, and to the difference between the original concentration a of S and its concentration at the moment x. Thus the equation may be written

$$dx/dt=k_1I(a-x)^m,$$

in which m is the order of the reaction and k_1, a velocity constant including the absorption coefficient. On the other hand, the velocity of the opposite reaction (dark reaction) is proportional to the concentrations x of the photoproducts. The equation for this is therefore

$$dx/dt=k_2x^n,$$

n being the order of the reaction and k_2 the velocity constant. Although this formulation of the processes may be too simple to account for all the facts, it has been found that the equations are so close to the data that the numerical values which represent the specific shapes and slopes of the curves representing certain visual functions can be determined.

The quantitative properties of several of these visual functions have been described faithfully in terms of the above-mentioned theoretical assumptions, apparently the siniplest which can be conceived to take place in the retinal elements. After the general acceptance of these assumptions and equations, there were occasional attempts to modify the equations so as to handle the visual phenomena which experimentation had brought to light but not yet explained at mid-20th century.

Since the photoreceptors of the eye are of two kinds (the rods and the cones). and functions somewhat differently, it might be expected that separate photosensitive pigments for the two would be detectable. Such has not been the case. No photosensitive substance characteristic of the cones had been discovered by mid-20th century although repeated efforts had been made. The visual purple found in the rods has manifested many properties which fit in well with visual information. It possesses an absorption spectrum with a maximum coinciding with the rod visibility curve. Likewise visual purple even in solution can undergo colour regeneration following bleaching. It has also long been known that visual purple may regenerate in two ways; (1) directly from its products and (2) from the proper materials supplied to the system.

The Retinoneural Events. — The retina, consisting, as already described, of a layer of photosensitive cells, is able to transmit to the brain a kind of complex set of signals regarding the outside world. Light acts on each of the individual cells making up the retinal mosaic in accordance with its intensity. Since all images consist of weak and intensely lighted parts, some cells transmit more activity than others. This activity is modified even before it leaves the retina, by the already described neural layers. The activity of the cells or units in each of the three layers of the retina consists in trains of very brief and tiny electrical impulses. Intense activity is represented by the occurrence of a very rapid series of impulses; weak activity is indicated by a slow series. There is not a one-to-one relation between the rate and number of impulses in the first, second and third layers of the retina; hence a modified version of the activity of the first or photoreceptor cell layer is transmitted along the optic nerve to the brain. Here, likewise, the pattern of activity reaching it is modified again and again as the input travels from the lower to the higher centres. Throughout the nervous system it is characteristic for the individual nerve cells, when set into action, to express something of their own properties in their discharge. This is manifest in impulse rate and the over-all duration of the impulse series. Modifications in impulse-discharge patterns are caused by (1) collateral impulses from other parts of the brain arriving in the same area along with the visual input, (2) the activity already in existence in the tissue in question as the visual input arrives, and (3) the basic principle already stated in regard to the retina; *i.e.*, that there is no one-to-one relation between reception of impulses in a complex nervous tissue (mass of cells) and the over-all distribution of impulses that is sent on to other regions.

The **Electroretinogram—The** Gross **Record of** Eye Activity. — Electrical effects can be detected if electrodes be placed, one upon the cornea, and the other either somewhere on the back of the eyeball or else on the tissue over the eye. The effects recorded are called electroretinograms and have most usually been investigated in animal forms rather than in man. In the former, the rear electrode can be placed near the optic nerve, and many other conditions can be obtained which are more conducive to good recording than in the human.

The electroretinogram is an over-all effect of the activity of the many receptors in the eye. For this reason it is not extremely definitive, but by the use of depressants, etc., the electroretinogram has been analyzed into three major components, *PI*, *PII* and *PIII*, which individually or in various combinations are responsible for the four waves, a, *b*, *c*, and *d*, which appear in the electroretinogram. The a wave is an initial slight negative deflection; the *b* wave, the large positive deflection which follows and declines often, but not always, to the base line before the *c* wave appears as a second positive wave, much longer and slower in its rise to maximum. If the flash producing the electroretinogram is quite long, a dip in the decline of the *c* wave to base line is known as the d wave. If the flash is very short the *c* wave is absent. It has been found that the many receptors aeakly stimulated by entoptic stray light contribute vastly more to the production of the recordable electroretinogram than do the intensely stimulated receptors which the image covers.

EVENTS IN THE OPTIC PATHWAY

Response of the Optic Nerve. — The long processes (axons) of the ganglion cells of the vertebrate retina form the fibres of the optic nerve. These number into the myriads, the actual number depending upon the animal form. The final pattern of events in the retina is transmitted to the brain in the form of groupings of impulses conducted along the optic-nerve fibres. These have been recorded by electrical methods in a few animal forms, such as the rabbit, cat and guinea pig. When a flash of light is presented to the eye, a burst of impulses is discharged into the optic nerve. The burst in some cases is not single but dual. Regardless of the duality, the result is taken together as the "on" response. If the flash is very short and quite weak, the response wave, if slightly above threshold, is quite simple and brief. Either lengthening the flash or strengthening it soon causes the response to contain a series of small sharp wavelets to follow the "on" response. Further increasing the stimulus in either respect results in the emergence of a single secondary wave which replaces the wavelet train. Still further stimulus increases results in the diminution of the secondary wave almost to a mere trace. If stimulation increase is brought about by lengthening the flash, a wave appears in the record to represent the flash's termination. However, by the time that this "off" response has reached a fair size, it is obvious that the remnant of the secondary wave has moved out later in the record and follows the "off" response. The use of the same stimulus setup for obtaining human sensory impressions has demonstrated that a flash of a given range of latency elicits a second visual impression. That is to say, a single flash (photic impulse) may appear to be a pair of flashes. If the stimulus is made still more potent, the second subjective impression disappears. A correlation between the sensory phenomena just described and the appearance and disappearance of the secondary wave in the optic-nerve discharge has been made. The second of the pair of sensory impressions is so timed as to appear to be one of the classical train of afterimages.

Response of the Optic Cortex. — The recordable response of the cortex is a complex wave whose major components have been analyzed by several methods including the local application of drugs to restricted areas of the cortical surface and by recording from the cortex at various depths below the surface. The usual response recorded at the surface consists of several parts. some tiny spikes which are not always detectable and two larger components, the earlier of which is augmented and made repetitive by strychnine locally applied, the later component being obliterated under the same conditions. The later component is assignable to certain cortical elements having to do with the continued spontaneous activity of the cortex, at least those underlying the alpha-rhythm, the main waves in the standard electroencephalogram.

At times the alpha-rhythm is masked by the presence of the many lesser waves comprising the spontaneous activity of the cortex. The cortical response to flashes of light manifests both an "on" and an "off" component when the flash is long enough and this need only be a fraction of a second. As already indicated the second major component of the cortical response and the alpha-rhythm are related. In fact it seems that a part of it represents the first wave in a train of alpha-waves. A brief but intense flash of light will institute a whole train of alpha-waves in a cortex which at the time is not manifesting prominent alpha-waves spontaneously. This is taken as a demonstration of the fact that sensory stimulation can drive the cortex. This driving effect can also be demonstrated by use of a continued series of light flashes, depending upon the rate at which the flashes are presented. Driving has certain fairly circumscribed upper limits in regard to the flash frequencies involved. If the alpha waves in the cortex are quite pronounced at the time of stimulation, the first few flashes at least will not find themselves equally well able to elicit recordable responses. The sizes of the responses will vary in accordance with where they fall in the activity-rest cycle of the groups of cells responsible for the alpha-waves. Soon however, the result may be one of driving in which fairly regular responses will follow in a train, or else the flash frequency may prove to be so remote from the range in which driving can occur that little detectable result will accrue from the flash series. This does not mean that a rapid series of flashes is ineffective in eliciting what might be called a visual response from the cortex. It only means that whatever activity there is, is more nearly uniformly distributed in space and time so that no groupings of activity are represented by waves in the record.

Response at Other Stations in the Optic Pathway.— Between the eye and the optic cortex there are several way stations such as the lateral geniculate body and the superior colliculus from which recordings can and have been made. Correlations of the events in these stations with the known microanatomical structures involved affords a way of constructing a picture of how the optic pathway operates. Furthermore, such studies have contributed valuable information regarding nervous function in general.

THE NATURE OF VISUAL PERCEPTION

Perception as the Creation of Objects.—The world as the physicist knows it is not composed of the objects we experience, but is made up of molecular and atomic activities which cannot be appreciated in a sensory way at all. They are conceived of only through the effects produced on recording instruments. Were it not for the fact that man cannot think in terms which are devoid of objects, the physicist would probably prefer to rid himself of some of the thinglike characters of his constructs in his own field. One form of this imputed activity is a kind of radiation called light which affects our eyes. The end result is the experience of objects which, although human constructs, are the only "reals" we have. At least, when in doubt, the conflict is resolved by believing something we sense rather than our ideational constructs. It can be said that vision is one of our object-constructing activities. It is by virtue of vision and the other object-constructing processes that me live in a world of obje'cts. All external influences which lead to consciousness at all result in thinglike characteristics.

The minimum of thinglikeness exists in vision when the radiation in the visual field is such as uniformly to stimulate the entire retina. We then say that the visual field is homogeneous. It may be gray, or coloured, but let the least differentiation in radiation reach the eye, as when a black line is drawn on a white card, and immediately one sees a localized thing. The visual field is now differentiated into figure field, and ground field. The visual properties that each possesses are different from the other. One of the simplest illustrations of a figure-ground situation is the perceptual result when two parallel lines are drawn on a blank sheet of paper. (*See* fig. 6.) These may be seen simply as lines in which case each one is a figure on a ground (the blank area), or they may be seen as the edges of a strip of material, the boundaries of a plank or walkway or a vertical pillar. If so, the visual quality of the area they bound is distinctly different from the quality of the area outside the lines. It is said that the area possesses a thinglike quality, whereas the area outside simply gives the impression of extent in space. The area within the figure has a surfacelike property and is localized. The ground is unlocalized and recedes into the remote distance. All visual fields are by no means so simple and what is figure and what is ground becomes more difficult to define. Nevertheless the figure-ground concept has served to emphasize certain basic features of visual perception and has instigated considerable visual research.

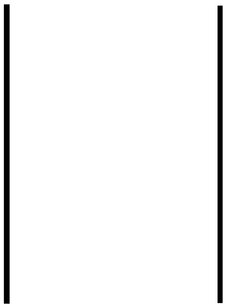

FIG. 6.—A FIGURE-GROUND PATTERN

Segregation and Synthesis.— There remains the problem of why and how certain parts of the visual field are seen as belonging together and others as not. In the case of a single dark line on a white field, the problem is nonexistent, but in the case of complex visual fields, why certain portions are seen as adhering (belonging) together and others not, is a subtle problem. In solving this. there are certain factors that can be imputed to the nature of the visual field itself, and others must be sought in the organization of man himself.

Identity and Localization.— In addition to solving the problem from instant to instant as to what belongs together and thus is one object, and what is to be seen as other objects, the organism must identify and localize the objects it sees.

Temporal Continuity in Vision.—The individual not only supplies the anatomical structures for action but an ongoing functional organism which is often overlooked in analysis. The organism must be looked upon as a continuity so that the investigator's problem is more than a problem of the present. He must see the present in the light of the past and in terms of the future. This is merely to say that organismic activity is directional. Vision partakes of these characteristics and becomes fully understandable only when this is actually recognized in the methods used to analyze it.

Sensation as Prognosis.—Visual perception is prognostic in the sense that what one sees is of one's own construction using the stimulation of the instant in ways which. although perfectly lawful, do not always produce the answer which will tally with some other sense. Vision, taken as a single sense, is generally aided by other senses which help account for its character, but it is possible for these other senses to collide with vision. It is scarcely possible for all of them always to substantiate each other. There are those students of human behaviour who teach that the feeling of certainty is a measure of the many cues which exist at a given moment, and how well they harmonize. Action is not only directional but also purposeful. By purposeful is meant simply that certain conditions are required to bring activity to rest.

SOME FACTORS INVOLVED IN OBJECT PERCEPTION

General.— It was pointed out in the last section that vision is an object-forming activity. The general principles of visual perception were briefly sketched. It is the purpose of the present section to indicate some of the features of the visual processes which provide the basis for separating the various parts of the visual field from each other and thus for the perception of objects. It is only nith an organism which can adapt to levels of illumination, discriminate between the existing levels in the momentarily given field, and appreciate differences involving small spatial dimensions that man can begin to construct a world of sensory objects. His appreciation of temporal features of the stimulus situation is also involved in object perception. For example, the spokes in a wheel may turn so fast that visually the wheel becomes a disk. Out of a series of flashes of light the organism may construct a uniformly illuminated field with surface properties not previously existent.

For the study of the basic functions involved in object-formation, an understanding of what is known as the threshold or limen is necessary.

The Threshold.— The threshold is a concept arising from the fact that sensory changes are not always commensurate with and concomitant with changes in physical conditions. For example, the intensity of illumination upon a surface may change and be accompanied by no shift in the perceived brightness of the surface. A difference is perceived only after the physical change has reached a sufficient magnitude. This amount is spoken of as the threshold. Whereas the shift in illumination may be gradual, the experienced changes may be stepwise if the physical change is slow. Thresholds are defined statistically. If an observer is asked to judge whether two adjacent surfaces are equal in brightness, he will vary from trial to trial in what he sees. If one surface is slightly more luminous than the other, he may see it as brighter than the other in some of the trials. Just what proportion of the trials yields judgments of brighter will depend, among other things, upon the absolute physical intensity differences between the two surfaces. The percentage expressing threshold is arbitrary. In defining threshold, the number of kinds of choices the observer can make is taken into account, for this determines the percentage of times the observer could be correct by guessing. Thresholds have been classified in two groups: (1) absolute and (2) differential. The former are obtained by measuring the required differences in intensity between the target and a homogeneous dark field. The latter are measured by ascertaining differences between two parts of a target in a field, either dark or illuminated, or between an object and its illuminated surrounding field. The determination of thresholds of one sort or another enters into all kinds of experimental investigations of vision.

Adaptation. — If one suddenly enters a dimly lighted room from bright surroundings, he finds himself almost unable to see objects in the room. Shortly, however, the darkness becomes less extreme and the larger or more luminous objects become distinguishable. The brightness level continues to rise from a period of 30 min. to 40 min., or more. This process is known as dark adaptation and is measured by subjection of the individual to complete darkness and determining at a series of successive intervals the threshold for seeing a standard test object. The results show that after dark adaptation an object need be many thousand times less intense in order just to be seen. Thus it may be said that in the fully dark-adapted condition the eye is many thousand times as sensitive as in ordinary daylight. Daylight illuminations, of course, vary over a considerable range and for precise purposes a standard intensity must be chosen for reference and for the preadaptive period. When an individual enters a lighted area from a dark room, the reverse adjustment, namely light adaptation, takes place. This occurs much more rapidly than does dark adaptation. For the most part adaptation is a basic shift in the level of functioning of the photoreceptor cells in the retina. Both the rods and cones adapt. Cone adaptation, of course, occupies the first portion of the dark-adaptation period, and the rods primarily the latter. When thresholds are plotted against time in the dark, the adaptation curve is composed of two segments, the first representing cone adaptation which is complete in the first few minutes and the second representing rod adaptation. Each segment begins with a steep portion and ends by tapering off toward horizontal. Certain other phenomena sometimes included in the category of adaptation take place in the neuroretina and elsewhere in the optic pathway. These phenomena have received much less study than have the receptor processes and are less well known.

Brightness Discrimination. — Brightness discrimination is the broad term which includes all those features of distinguishing one part of the visual field from the other on the basis of relative amounts of radiant flux reaching the different portions of the retina. Discriminations based on differences in wave length are colour discriminations, although amounts of flux cannot be eliminated as factors even here. Colours as well as grays vary in brightness. Brightness discrimination has received much formal investigation. Standard test situations have included: (1) single disks on dark backgrounds, (2) single disks on lighted backgrounds in which cases the intensity levels of the disks were sometimes below that of the backgrounds, (3) bipartite test objects on light or dark backgrounds, in which cases the test objects were either bisected rectangles, or disks, or disk-annulus figures. The detection of the difference between the component surfaces of a bipartite test object is manipulated by the level of the background. The lowest thresholds are obtained when the background is at the mean level of the components. Both the absolute threshold and the differential are dependent upon the area of the test surface.

Visual Resolution and Visual Acuity. — In order that one part of the visual field be distinguished from others, spatial as well as intensity relations must be taken into account. When two portions of the visual field are moderately widely separated, the matter of space is not critical in this distinguishing process. But when two areas are separated by only a narrow area between them, the width of the latter area becomes critical. Two objects not actually touching can become so close that no space between them is discernible. If they are alike in surface brightness they visually become one continuous form. That the separation of two areas can be a finite amount without being discernible makes visual resolution of both practical and theoretical importance. Separations in the visual field are measured by what is known as the visual angle. It is the solid angle subtended at the eye by an object or interspace. The smaller the visual angle at which the separation between any two areas can be perceived, the greater the visual acuity. Visual acuity is generally measured as the reciprocal of the visual angle measured in minutes of arc. Visual acuity is dependent, among other things, upon the resolving power of the retina. This in turn is dependent upon the size and spacing of the retinal elements which make up the grain of the retina. Since the distribution of the light on the retina does not involve gradients as steep as exist at the boundary between the reflecting surfaces in the visual field, a second factor in relation to the mosaic is brought into play; namely, the intensity differential between the total amount of light falling on adjacent retinal elements. If this is of the order of 1%, apparently the end result is the perception of a border. Though retinal cells do not lie in perfectly straight lines, the border that is perceived is nevertheless regular. Visual acuity is measured in a number of standard ways. It is derived either by the use of pairs of bars, gratings, figure C's (Landolt broken circles), or less accurately by lines of letters of predetermined sizes (Snellen charts), etc. The several methods do not yield results of the same order of value. In fact a single dark line on a homogeneous light field has yielded the highest visual acuity of all. A line subtending only 0.5″ of arc in width has been perceived. Visual acuity differs in accordance with the intensity relations between test objects and background. If the bars are dark and on a light ground, the resolvability increases as the intensity level of the ground increases. If bright bars on a dark background are used, the resolvability does not reach so high a maximum as with converse intensity relations between the bars and ground. As the intensity of the bars is increased beyond a certain point, resolvability decreases. Also the width of the bars plays a role in their resolvability. With wide bars visual acuity at first increases rapidly with increase in intensity, and then more slowly. With the same intensity increases in narrow bars, visual acuity reverses in value beyond a certain maximum.

Response to Variable and Intermittent **Illumination.**— Any rapidly varying or rapidly intermittent visual stimulation gives rise to what is known as flicker, an experience occurring in many everyday situations. Intermittent stimulation is important as a means of studying visual response, for by means of a series of flashes not only the lag in response to a single flash, but also the physiological effects remaining from the preceding flash can be studied. An everyday example of the action of an intermittent component of visual stimulation occurs when an individual passes along a high paling fence. In such a situation, a given portion of the retina is subjected to a temporarily alternate series of lights and shadows.

Intermittent stimulation may be so applied to the retina that the members of the series are applied to a succession of different retinal areas. This is the case when a neon lamp is rapidly passed before the eyes. The lamp has an extremely short lag and thus follows the phases of the alternating current with a slight dark interval between glow periods. Each glow period finds the lamp at a different position before the eyes and thus produces an image on a fresh portion of the retina. As a result a row of lamps is seen as the lamp is passed before the eyes. This is one example of stroboscopic effect. Continuously moving objects as a result of a series of stationary picture presentations, as in motion pictures, is another example. A third example' is the stationary appearance derived from a moving object, intermittently illuminated. For example, if a disk with a series of black and white radial bands on it is moved so that one or more of the white bands pass a given point during the dark interval between two flashes of light, the disk will appear to be stationary. If the rate of flashes in the series is known, and the number of bands on the disk is also known, the rate of the revolution of the disk can be calculated. A special application of this exists in the movies when a carriage is seen to pass by the spectators. Very often the spokes of the wheels will be seen to move backward or stand still. This means that the timing of successive frames and the position of the spokes in the frames is inappropriate, except to give the stationary effect or backward motion.

The rate of intermittency of illumination can be made great enough to result in the perception of steady brightness without even a trace of a flicker. The classical formulation with regard to this is Talbot's law. It states that the brightness of subjectively steady light obtained with intermittent illumination is equivalent to the brightness obtained when the same amount of radiation is uniformly distributed in time. For example, if alternate periods of illumination and darkness are of equal length, the brightness level will be one-half of the value resulting from continuous illumination. The point at which all flicker disappears is called the fusion point. The flash rate necessary just to produce fusion is called the critical flicker frequency (c.f.f.). Critical flicker frequency is higher the greater the intensity of the light and the greater the area of the stimulus field. Over a considerable range of intensities this relation describes a straight line when the logarithm of flash intensity is plotted against flash frequency required just to reach the fusion point.

Whereas most of the studies dealing with intermittent stimulation have pertained to critical flicker frequency, some attention has been paid to what happens below that point. The best way to understand some of these phenomena is to know that single isolated flashes produce greater brightness than does continued illumination of the same physical intensity.

However, a finite amount of time is required for a flash to elicit a response, and the brightness of the subjective impression rises to a peak and then declines if the flash is protracted for a considerable period. A very rapid series of flashes, however, simulate uniform stimulation in respect to subjective continuity produced, but not in intensity. Each flash in a series does not elicit the same vigour of response as do isolated flashes. If rates much lower

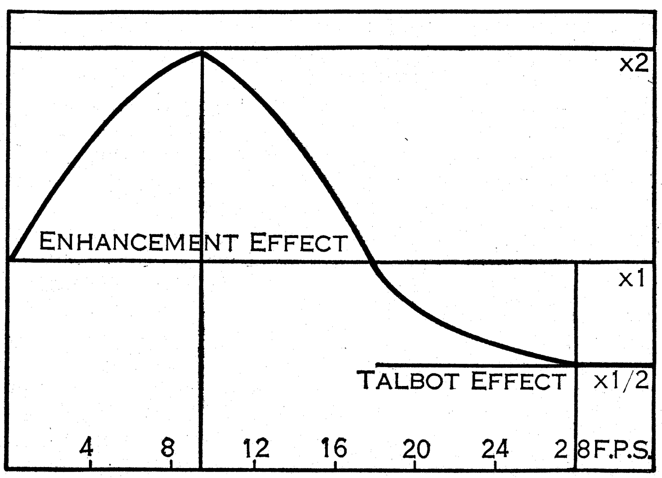

FIG. 7.— THE TALBOT AND ENHANCEMENT EFFECTS

than c.f.f. are used, the net result is greater, however, than that obtained from steady illumination. This is called the enhancement or Bartley effect and reaches a maximum at a flash rate of 8 or 10 per second. Incidentally this rate happens to be of the same order as that of the alpha-rhythm in the cerebral cortex. Certain good reasons are given for attributing the enhancement effect to the same origins as that of the alpha-rhythm. Fig. 7 illustrates both the Talbot effect and the enhancement effect. The horizontal parallel to the abscissa indicates the brightness level of continuous illumination of the same physical intensity as the flashes used. The left end of the curve transcends this and illustrates the enhancement effect. The right end of the curve drops below the horizontal line (brightness of continuous illumination) and illustrates the Talbot effect. The abscissa of the graph indicates the number of flashes per second (f.p.s.). The first perpendicular line is at between 9 f.p.s. and 10 f.p.s. The second one is at c.f.f., in this instance, 28 f.p.s. The light-dark ratio of the cycle used is one-to-one.

Whereas it might be expected that at all flash rates below c.f.f. the subjective pulses would follow the flashes in a one-to-one relation, this is not the case. At times the retinal effects follow at half rate (one retinal discharge burst for every second flash). The subjective rate of the flicker existing just below its final obliteration need not follow the flash rate. If a series of very weak flashes are used, c.f.f. may be found to be as low as 3 or 4 per second. The last vestige of flicker possesses a much higher rate than this. If a series of very intense flashes is used, c.f.f. may be 50 per second. The last vestige of flicker is much below this rate. The actual rate has not been precisely measured, but it is safe to say it is in the region of 20 per second. This discrepancy between flash rate and the last remnant of flicker is taken to be one indication that the intrinsic properties of the ganglion cells themselves play a definitive role in the rate of impulses sent into the optic nerve. Flicker rates tally with this rate rather than flash rate. Under many conditions flash rates and discharge rates coincide; under some they do not.

Contour Formation.— All the factors which pertain to the structurization of objects are not included in dealing with adaptation, visual acuity and brightness discrimination. Another aspect of the matter falls into the category of contour formation. The phenomena pertaining to contour formation include those of brightness contrast and visual field structure. Contour can thus be thought of in two sets of terms, those of gradient and those of shape. Contour is involved in the production of the differential threshold, for one essential feature of distinguishing the intensity level of one area as compared to another is the perception of a boundary between them. Putting the matter the other way around, the matching of two adjacent homogeneous areas is accomplished when conditions are such that the boundary betneen them disappears This is taken advantage of in photometers, instruments designed for measuring light intensities.

It has been found that the presence of other contours in the field of vision influence the level of the differential threshold. In many cases in which it was once thought that only the area of the surrounding field influenced threshold, it has been demonstrated that the existence of other borders in the field played a role. The distance of such borders from the area in question is a factor in their effect.

An example of this is the fact that the threshold of a disk on a slightly darker ground drops as the area of the disk is increased. Some authors attributed this to the inclusion of more and more receptor elements within the retinal area stimulated by the image of the disk. Evidence indicates that the effect is rather to be assigned to the action of border processes. When a disk area is used for measuring threshold. the borders on the opposite sides of the disk tend to interfere with each other, the amount depending on the size of the disk. When the disk is small, the borders of the disk are closer and the threshold is high. In fact some go so far as to state that Fechner's paradox (*q.v.*) is not dependent on the presence or absence of summation, but rather is an example of one of the functions of contour processes. It can be said that whatever reduces or obliterates border formation destroys the appreciation of the brightness a surface would otherwise have. This is illustrated by an experiment in which a dark disk is presented to an observer, and as it is removed a ring whose centre is concentric with the disk is presented. The inner edge of the ring is in the same place as the outer edge of the disk. If the rate of the successive presentations is critically timed, the blackness of the disk disappears. In other words, the area where the dark disk was being shown now becomes white. The disk loses its original value and disappears. If, however. the disk is followed by the presentation of only a half ring, the part of the disk on the ring side is all that will disappear. The processes which are involved in this phenomena may be something as follows: when the disk is presented first, to be soon followed by the ring, the border of the disk may not have had sufficient time to form. Since the border is not completely formed during the only period it could, the ring simply develops as a ring without the disk's ever having been perceivable. At a crucial instant in the existence of the partly formed disk border, the presentation of the ring may be able to utilize it to form or accentuate its own inner border.

Sensations of **Colour.**—Colour is a special sensation excited by the action on the retina of rays of light of a definite wave length. The most likely hypothesis as to the physical nature of light is that colour depends on the rate of vibration of the luminiferous ether, and white light is a compound of all the colours in definite proportion. When a surface reflects solar light into the eye without affecting this proportion, it is white, but if it absorbs all the light and reflects nothing, it appears to be black. If a body held between the eye and the sun transmits light unchanged and is transparent, it is colourless, but if translucent, it is white. If the medium transmits or reflects some rays and absorbs others, it is coloured. Thus, if a body absorbs all the rays of the spectrum but those which cause the sensation of green. we say the body is green in colour; but this green can be perceived only if the rays of light falling on the body contain rays having the special rate of vibration required for this special colour. The part played by the light illuminating the surface and the way in which the colours of mixed pigments are produced are discussed under COLOUR.

Modes of Mixing Colour Sensations.—Various methods have been adopted for studying the effect of mixing colours. They are mixed by:

1. Superimposing parts of two spectra.

2. Method of reflection. Place a red disk near the farther end of a sheet of paper lying on a table and a blue disk on the nearer end. By holding a glass plate vertically, the eye can be so placed as to receive light from the red disk by transmission through the glass, and from the blue disk by reflection. Under such conditions the disk will appear to be purple, and by using disks of different colours, many experiments may be performed.

3. By rotating disks which quickly superpose on the same area of retina the impressions of different wave lengths. Such disks have two or more sectors, each of a different colour. For example, the angles of the sectors originally given by Sir Isaac Newton were:

Red	60° 45.5′	Green	60° 45.5′
Orange	34° 10.5′	Blue	54° 41′
Yellow	54° 41′	Indigo	34° 10.5′
Violet	60° 45.5′		

With sectors of such a size, gray will be produced on rotating the disk rapidly. This method was carried out with great efficiency by the colour top of J. Clerk-Maxwell. This is a flat top, on the surface of which disks of various colours may be placed. Wayne Dancer has added to it a method by which, even while the top is rotating rapidly and the sensation of a mixed colour is strongly perceived, the eye may be able to see the simple colours of which it is composed. This is done by placing on the handle of the top, a short distance above the coloured surface, a thin black disk, perforated by holes of various size and pattern and weighted a little on one side. The disk vibrates to and fro rapidly and breaks the continuity of the colour impression; and thus the constituent colours are readily seen.

Colour Blindness.—The character of colour blindness is studied by ascertaining abilities of individuals to compare narrow bands or single wave lengths of the visible spectrum. The major fact of normal colour vision is that any part of the spectrum may be matched by combining three properly chosen parts of the spectrum. Individuals possessing such vision are trichromats.

Individuals whose colour vision is defective have most frequently been put into three general classes: (1) anomalous trichromats, those who confuse parts of the spectrum, but require three primaries to make a spectral match; (2) the dichromats, the colour-weak persons; (3) the monochromats, the fully colour blind. The dichromats are persons who confuse large sections of the spectrum, matching any part of it with a mixture of two primaries, and matching yellows and blue-greens with white. There are three types of dichromats: (1) protanopes, who confuse green, yellow and red, and match blue-green with white; since their brightness sensitivity is depressed in the red end of the spectrum, they are often called red blind; (2) deuteranopes, who also confuse green, yellow and red, and match a point in the blue-greens with white. but possess brightness perception approaching normal; (3) tritanopes, who are unlike the first two groups since they match a yellow with white. Monochromats confuse various parts of the spectrum with each other, which they match by proper manipulations of intensity. This class includes two types of individuals: (1) those with brightness perception following the visibility curve of the rods; they are the scotopic monochromats; (2) those whose brightness perception simulates cone vision; they are called photopic monochromats. Notwithstanding the impression this classification may give, colour-defective people do not actually fall into distinct classes.

When everyday colour combinations are not discriminated, the individual erroneously sees surfaces juxtaposed, or he mistakes them for a chromatically homogeneous surface. The result is camouflage. In war, camouflage is intended. In everyday affairs, camouflage is incidental and may occur from defective colour vision. For an area to be hidden from the deuteranope or protanope, it is required only that it be neither lighter nor darker and neither yellower nor bluer than the surroundings. Whether it is redder or greener is immaterial.

Two surfaces, although appearing to match in hue, may be different in their reflectances of certain parts of the spectrum. Such surfaces may therefore involve spectral differences undetectable even to the normal eye. Such pairs of colours are termed pseudo matches, or metameric pairs. A metameric pair of coloured surfaces satisfactory to the normal observer will often be a little off-match for an anomalous trichromat.

RELATIONS BETWEEN OBJECT, IMAGE AND VISUAL EXPERIENCE

It is customary to attempt to discover as many fixed relations between object, retinal image and sensation as possible. As far as geometry is concerned, a few generalizations can be made. For example, the relation between the visual angle and the size of the retinal image is fixed. Furthermore there are known relations between the positions of the eyes and certain over-all features of images of two-dimensional objects. There is not a fixed relation between the shapes and sizes and orientations of plane surfaces and the shapes and sizes of the retinal images. Just as long as the outline of an object subtends the same visual angle, it fulfils the same visual function as that of an infinity of other objects which would do likewise. In fig. 8, geometrical patterns 1, 2. 3. 4 and 5 differ in shape, size and in the plane or planes in which they lie. They are not even all plane objects, and their orientation, with reference to the section of the retina on which their image falls, differs in each case. Thus, while there are fixed relations between an object's shape, size, distance and orientation, and the image formed on the retina, these do not differentiate it from some other object of different size, shape, distance and orientation which subtends the same visual angles. The fact that objects subtending the same visual angles are seen as identical can

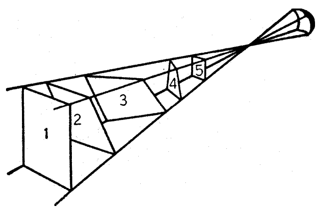

FIG. 8.— GROUP OF FIGURES EACH SUBTENDING THE SAME VISUAL ANGLE

well be illustrated by the following method used by Fritz Heider. Support a small cube by a wire or rod about six inches from a table. At the edge of the table erect a screen bearing a peephole about ten inches from the level of the table. Position the cube so that it presents three vertical edges to view and so that a large white sheet of paper is seen when looking past the cube. While sighting past the visible corners of the cube, place pencil marks to indicate the positions on the paper. Connect the appropriate points by straight lines, and a drawing which is a representation of a distorted three-dimensional figure (when viewed by looking obliquely at it from any ordinary viewing position) will result. However, after removing the cube, view the drawing through the peephole and it will be seen as a cube. This means that both the drawing and the cube itself look like a cube. If the extraneous cubes are eliminated, and the brightness values are equivalent in the fields view, the cube and the drawing will be indistinguishable. The setup is illustrated in fig. 9. A. Ames further exemplified this principle by making three situations equivalent. The original cube is a white wire model, the wire constituting the edges of the cube. This is suspended in space and viewed through a peephole and against a dark background. The second is a white wire plane figure of the proper shape to be equivalent in appearance to the cube when viewed through a properly placed peephole. This also is suspended in space by five invisible wires and viewed against a dark background. The third object which is visually equivalent to the other two is a set of white strings tied to a set of invisible wires which radiate from the peephole viewing position and subtend the proper visual angles. These angles are, of course, those subtended by the corners of the real cube. It does not matter how far away from the eye these strings are attached, or what angles they make with the line of regard; they form the edges of what appears to be a genuine cube. This then is a demonstration of how three very different objects all appear to be the same objects, or perfectly equivalent objects.

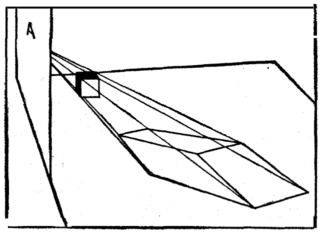

FIG. 9.—VISUAL EQUALITY OF THREE-DIMENSIONAL CUBE AND ITS TWO-DIMENSIONAL REPRESENTATION

Objects of fixed size, shape, distance and orientation, of course, cast a fixed image on the retina so long as the eye does not move. But when the eyes move, the images change location on the two retinas and the relative shapes and sizes of the images change without a resulting change in the perceived object. It remains fixed and retains its original geometrical properties. Objects, on the other hand, appear to change even when practically no change in retinal image occurs. Figures of reversible perspective, such as a cross, etc. (see fig. 10), change from one thing to another under good fixation. Size of retinal image is no sure indicator of the location of the object or of its size. Another factor, called by some known size, must be injected into the situation. The organism does this spontaneously and almost unwittingly in sensation. The fact that there is not a complete set of fixed relations calls for a further consideration of sensation than would be indicated were the fixities to exist. The organism never fails to see something as it is confronted with patterns of light radiation. Since there is no single end result possible, there must be some basis exclusive of the radiation reaching the eye upon which the organism can put some functional reliance. We have already mentioned what, for want of a better name, some have called known size. This may be exemplified in its operation by the use of some familiar object which is presented to the observer alone in a dark field. To do this best, a dark room whose walls have been painted black is used. The object is suspended in mid-air, or supported upon a fine wire post. Light from a small projector is cast upon the object without lighting up the room. Let the familiar object be for example, a playing card, a maple leaf, etc. It subtends an angle dependent upon its distance from the eye; it forms a retinal image whose size is likewise dependent upon the size of the object and its distance from the eye. The observer is able to detect the distance of the object quite well. But let the size of the object be not normal, but considerably greater or smaller than normal. There is no way by which the observer may detect this in the situation we have described. If the specimen is of a giant size, the object will look nearer, the amount depending on the increased visual angle it subtends. If the specimen is miniature, it will seem farther away than if normal, or of giant size.

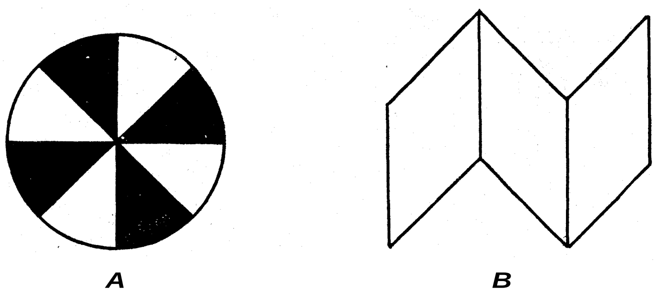

FIG. 10.—REVERSIBLE PERSPECTIVE FIGURES

SPACE PERCEPTION

The perception of objects involves not only their identity, size, shape, brightness and colour, but also their positions relative to each other and to the observer. Space perception is not the perception of space as such, but of objects in their spatial (geometrical) relations to each other and the observer. It is as if sensation were answering the questions "where?" and "what?" in an immediately forthcoming single answer. What an object is seen to be and where it is seen depend upon each other.

A number of factors are involved in producing this outcome. Some of them pertain to organismic function, some to the character of the stimulus (even though dealt with in sensory terms rather than physical) and some to the characteristics of the retinal images.

Monocular Vision.—Most of these factors apply to the use of the single eye as well as in the use of two eyes as in integrated system. Hence monocular vision is all that is necessary for the operation of the factors that are described below. **A** factor of the first type mentioned in the previous paragraph is the organism's use of a reference. An example of this is the operation of known size in the case of familiar objects. This factor in connection with the size of the retinal image largely determines how far away familiar objects are seen to be. Factors of the second type include overlay (super position), brightness, parallax, elevation, colour and distinctness of contours. Overlay is the partial obstruction of the view of some object by another, leading to the impression that the partially obstructed object is farther away than the other one. Brightness is the subjective effect somewhat related to intensity of radiation reaching the eye. It happens that the manipulation of brightness plays a factor in positioning objects and surfaces. The brighter it appears the nearer the object or surface seems. Parallax is the relative change of position of objects with regard to each other. During the individual's motion from place to place, or during the movement of the head only, objects near by tend to move in a direction opposite to that of the observer. This is an aid in discerning the separation of areas in the visual field. That which remains stationary cannot be a part of that which moves, so that areas difficult to segregate are segregated in this way. Elevation is here the name for the fact that an object higher than another is seen to lie farther away. Elevation functions both in actual three-dimensional situations and in two-dimensional representations of three-dimensional situations. Were it not for the fact that elevation functions in this manner, there could be no satisfactory two-dimensional representation of three-dimensional objects.
